16.8 Real Quadratic Fields and Pell's Equation 1349
16.9 Graded Problem Bank 1352

Chapter 1

Introduction to Groups

1.1 Basic Axioms and Examples

The group axioms: identity, inverses, and cancellation

Definition 1.1.1. A *group* is an ordered pair $(G, *)$ where G is a set and $*$ is a binary operation on G (a function $* : G \times G \to G$) satisfying:

(G0) **Closure.** For all $a, b \in G$, $a * b \in G$. (This is built into "$*$ is a binary operation $G \times G \to G$".)

(G1) **Associativity.** For all $a, b, c \in G$, $(a * b) * c = a * (b * c)$.

(G2) **Identity.** There exists $e \in G$ with $e * a = a * e = a$ for all $a \in G$.

(G3) **Inverses.** For each $a \in G$ there exists $a^{-1} \in G$ with $a * a^{-1} = a^{-1} * a = e$.

The group is *abelian* (commutative) if in addition $a * b = b * a$ for all $a, b \in G$. We usually drop $*$ and write ab, and write 1 (or e) for the identity.

Remark 1.1.1. A pair $(S, *)$ that satisfies (G0) and (G1) but not necessarily (G2),(G3) is a *semigroup*; with (G2) added it is a *monoid*. So a group is exactly a monoid in which every element is invertible. The single hardest axiom to verify in practice is associativity (G1); the easiest to *disprove* a group with is the failure of one inverse (G3) or non-closure (G0).

Proposition 1.1.2 (Uniqueness of the identity)**.** *If $(G, *)$ is a group, its identity element is unique.*

Proof. Suppose e and f both satisfy (G2). Then $e = e * f$ (since f is an identity, acting on the right of e) and $e * f = f$ (since e is an identity, acting on the left of f). Hence $e = e * f = f$. □

Proposition 1.1.3 (Uniqueness of inverses)**.** *In a group, each $a \in G$ has a unique inverse.*

Proof. Suppose b and c both invert a, so $a * b = b * a = e$ and $a * c = c * a = e$. Then

$$b = b * e = b * (a * c) = (b * a) * c = e * c = c,$$

using (G2), the inverse property of c, associativity (G1), the inverse property of b, and (G2) again. Hence $b = c$. □

Caution. The proof of Proposition 1.1.3 uses associativity in the crucial middle step. Without (G1) inverses can genuinely fail to be unique, so never quote "inverses are unique" for a structure you have not checked is associative.

Proposition 1.1.4 (Basic inverse identities)**.** *Let G be a group and $a, b \in G$. Then:*

(a) $(a^{-1})^{-1} = a$;

(b) $(ab)^{-1} = b^{-1}a^{-1}$ *(the "socks–shoes" law).*

Proof. (a) By definition a^{-1} is the unique element with $a * a^{-1} = a^{-1} * a = e$. Reading the equations $a^{-1} * a = a * a^{-1} = e$ the other way says precisely that a is an inverse of a^{-1}. By uniqueness (Proposition 1.1.3), $(a^{-1})^{-1} = a$.

(b) Compute directly, using associativity to regroup:

$$(ab)(b^{-1}a^{-1}) = a\big(b\,b^{-1}\big)a^{-1} = a\,e\,a^{-1} = a\,a^{-1} = e,$$

$$(b^{-1}a^{-1})(ab) = b^{-1}\big(a^{-1}a\big)b = b^{-1}\,e\,b = b^{-1}b = e.$$

So $b^{-1}a^{-1}$ is a two-sided inverse of ab; by uniqueness it equals $(ab)^{-1}$. □

Proposition 1.1.5 (Cancellation laws)**.** *Let G be a group and $a, b, c \in G$.*

(a) (Left cancellation) If $ab = ac$ then $b = c$.

(b) (Right cancellation) If $ba = ca$ then $b = c$.

In particular the equations $ax = b$ and $xa = b$ have unique solutions $x = a^{-1}b$ and $x = ba^{-1}$.

Proof. (a) Left-multiply $ab = ac$ by a^{-1}: $a^{-1}(ab) = a^{-1}(ac)$, so $(a^{-1}a)b = (a^{-1}a)c$, i.e. $eb = ec$, i.e. $b = c$. (b) Symmetric: right-multiply $ba = ca$ by a^{-1} to get $b(aa^{-1}) = c(aa^{-1})$, so $b = c$. For $ax = b$, left-multiply by a^{-1} to get $x = a^{-1}b$; this is a solution since $a(a^{-1}b) = (aa^{-1})b = b$, and it is the only one by left cancellation. □

Remark 1.1.2 (Generalized associativity). For $a_1, a_2, \ldots, a_n \in G$ the product $a_1a_2\cdots a_n$ is unambiguous: any way of inserting parentheses to evaluate it gives the same element. So we may drop all parentheses in finite products. The proof is an induction on n reducing every parenthesization to the standard left-nested one $(\cdots((a_1a_2)a_3)\cdots)a_n$ using only (G1).

Method (Is $(S, *)$ a group? A four-step checklist)**.** Check the axioms *in order*, and stop at the first failure.

1. **Closure (G0).** Is $a * b \in S$ for all $a, b \in S$? Look for outputs that escape S (e.g. a quotient leaving $\mathbb{Z}$, a product hitting a forbidden value).
2. **Associativity (G1).** Is $(a * b) * c = a * (b * c)$? Standard ops ($+, \cdot$ on numbers, function composition, matrix product) are associative for free; for an exotic $*$ you must expand both sides symbolically.
3. **Identity (G2).** Solve $e * a = a$ (and $a * e = a$) for a single e that works for *every* a.
4. **Inverses (G3).** For a generic a, solve $a * x = e$ (and $x * a = e$) for $x \in S$. If even one element has no inverse *in* S, it is not a group.

Recognition / how to disprove. To *prove* a group you must verify all four. To *disprove* a group you need exactly one explicit counterexample to one axiom: a single pair leaving S (kills G0), a single bad triple (kills G1), a proof no e exists (kills G2), or a single element with no inverse (kills G3). Always name the witness explicitly.

Worked Example 1.1.6 ($(\mathbb{Z}, +)$ is a group)**.** Show that the integers under ordinary addition form an abelian group.

Recognition. The operation is the standard $+$, so closure, associativity, and commutativity are inherited from arithmetic; only the identity and inverses need a named witness. This is the checklist applied to a "known" operation, where steps 1–2 are immediate.

Solution. Run the four steps. (G0) For $a, b \in \mathbb{Z}$, $a + b \in \mathbb{Z}$: the sum of two integers is an integer. Closed. (G1) Addition of integers is associative: $(a + b) + c = a + (b + c)$ for all a, b, c. (G2) Take $e = 0$: $0 + a = a + 0 = a$ for all $a \in \mathbb{Z}$. Identity exists. (G3) Given $a \in \mathbb{Z}$, take $x = -a \in \mathbb{Z}$: $a + (-a) = (-a) + a = 0$. Inverse exists, and $-a$ is indeed an integer. Commutativity: $a + b = b + a$. So $(\mathbb{Z}, +)$ is an abelian group. *Check.* Solve $5 + x = 2$: by Proposition 1.1.5, $x = (-5) + 2 = -3 \in \mathbb{Z}$, and $5 + (-3) = 2$. Consistent.

Worked Example 1.1.7 ($(\mathbb{Z}/n\mathbb{Z},\cdot)$ is NOT a group)**.** Show that $\mathbb{Z}/n\mathbb{Z}$ (residues mod n, $n \geq 2$) under multiplication of classes is not a group.

Recognition. The candidate identity is $\bar{1}$, and we must check (G3) for *every* class. The trigger: any structure containing an "absorbing" element (here $\bar{0} \cdot \bar{a} = \bar{0}$) cannot have that element invertible, because its products never reach the identity. Disprove via one failing inverse.

Solution. The operation $\bar{a} \cdot \bar{b} = \overline{ab}$ is well defined, closed, associative, and has identity $\bar{1}$ (since $\bar{1} \cdot \bar{a} = \bar{a}$). So $(\mathbb{Z}/n\mathbb{Z},\cdot)$ is a commutative monoid. It fails (G3) at $\bar{0}$: for any $\bar{x} \in \mathbb{Z}/n\mathbb{Z}$, $\bar{0} \cdot \bar{x} = \overline{0 \cdot x} = \bar{0} \neq \bar{1}$ (here $\bar{0} \neq \bar{1}$ because $n \geq 2$). So $\bar{0}$ has no inverse, and $(\mathbb{Z}/n\mathbb{Z},\cdot)$ is *not* a group. *Check (concrete, $n = 6$).* In $\mathbb{Z}/6\mathbb{Z}$: $\bar{0} \cdot \bar{x} = \bar{0}$ for every $\bar{x} \in \{\bar{0}, \ldots, \bar{5}\}$, never $\bar{1}$. Moreover $\bar{2}, \bar{3}, \bar{4}$ also fail: e.g. $\bar{2} \cdot \bar{x}$ runs through $\bar{0}, \bar{2}, \bar{4}, \bar{0}, \bar{2}, \bar{4}$ as $x = 0, \ldots, 5$, never $\bar{1}$ (because $\gcd(2,6) = 2 \nmid 1$). The units are exactly $\bar{1}, \bar{5}$, so deleting non-units gives the genuine group $(\mathbb{Z}/6\mathbb{Z})^\times = \{\bar{1}, \bar{5}\}$.

Worked Example 1.1.8 ($a * b = a + b + ab$ on $\mathbb{R}$: identity 0, but -1 has no inverse)**.** On $\mathbb{R}$ define $a * b = a + b + ab$. Decide whether $(\mathbb{R}, *)$ is a group, and whether $(\mathbb{R} \setminus \{-1\}, *)$ is.

Recognition. The clean trick is the factorization $a * b = (1 + a)(1 + b) - 1$, which turns $*$ into ordinary multiplication after the shift $a \mapsto 1 + a$. Recognition: whenever an exotic operation can be rewritten as $f(a)f(b)$ for a bijection-like f, transport the question to a familiar group/monoid. The forbidden value will be the preimage of 0.

Solution. Set up the shift. Let $u = 1 + a$, $v = 1 + b$. Then

$$a * b = a + b + ab = (1 + a)(1 + b) - 1 = uv - 1, \qquad \text{so } 1 + (a * b) = (1 + a)(1 + b).$$

(G0) Closed on $\mathbb{R}$: $a * b \in \mathbb{R}$. (G1) Associativity: $1 + \big((a * b) * c\big) = (1 + (a * b))(1 + c) = (1 + a)(1 + b)(1 + c)$, symmetric in the grouping, so $(a * b) * c = a * (b * c)$. Associative. (G2) Identity e: need $a + e + ae = a$, i.e. $e(1 + a) = 0$ for all a, forcing $e = 0$. Check: $a * 0 = a + 0 + 0 = a$. Identity is 0. (G3) Inverse of a: need x with $(1 + a)(1 + x) = 1 + 0 = 1$, i.e. $1 + x = \dfrac{1}{1 + a}$, so $x = \dfrac{1}{1 + a} - 1 = \dfrac{-a}{1 + a}$. This requires $1 + a \neq 0$, i.e. $a \neq -1$. At $a = -1$: $(-1) * x = -1 + x - x = -1 \neq 0$ for all x, so -1 has *no* inverse. Hence $(\mathbb{R}, *)$ is **not** a group. On $\mathbb{R} \setminus \{-1\}$ the map $a \mapsto 1 + a$ is a bijection onto $\mathbb{R} \setminus \{0\} = \mathbb{R}^\times$, and it carries $*$ to multiplication. Since $(\mathbb{R}^\times, \cdot)$ is an abelian group, so is $(\mathbb{R} \setminus \{-1\}, *)$: closed (if $a, b \neq -1$ then $(1 + a)(1 + b) \neq 0$ so $a * b \neq -1$), identity 0, inverse $\dfrac{-a}{1 + a}$. *Check.* Take $a = 2$: $x = \dfrac{-2}{3}$, and $2 * (-\frac{2}{3}) = 2 - \frac{2}{3} + 2 \cdot (-\frac{2}{3}) = 2 - \frac{2}{3} - \frac{4}{3} = 2 - 2 = 0$. Correct. The transport of structure is exactly the commuting square

$$\begin{array}{ccc} (\mathbb{R} \setminus \{-1\}) \times (\mathbb{R} \setminus \{-1\}) & \xrightarrow{\ *\ } & \mathbb{R} \setminus \{-1\} \\ \Big\downarrow{\scriptstyle (1+\cdot)\times(1+\cdot)} & & \Big\downarrow{\scriptstyle 1+\cdot} \\ \mathbb{R}^\times \times \mathbb{R}^\times & \xrightarrow[(u,v)\mapsto uv]{} & \mathbb{R}^\times \end{array}$$

Diagram explanation. Objects: Four nodes, all groups. Top-left: the Cartesian product $(\mathbb{R}\setminus\{-1\}) \times (\mathbb{R}\setminus\{-1\})$, where pairs of inputs for the operation $*$ live. Top-right: $\mathbb{R} \setminus \{-1\}$, the group under $*$ whose group structure we are establishing. Bottom-left: $\mathbb{R}^\times \times \mathbb{R}^\times$, pairs of nonzero reals, i.e. inputs for ordinary multiplication. Bottom-right: $\mathbb{R}^\times$, the abelian group of nonzero reals under multiplication. All four are abelian groups (the bottom row is classical; the top row is what we are proving).

Arrows: Top horizontal: the operation $*$, sending (a, b) to $a * b = a + b + ab$. Bottom horizontal: ordinary multiplication $\cdot$, sending (u, v) to uv. Left vertical: the map $(1 + \cdot) \times (1 + \cdot)$, sending (a, b) to $(1 + a, 1 + b)$; it is a bijection $(\mathbb{R} \setminus \{-1\})^2 \to (\mathbb{R}^\times)^2$. Right vertical: the shift $1 + \cdot$, sending a to $1 + a$; it is a bijection $\mathbb{R} \setminus \{-1\} \to \mathbb{R}^\times$.

What commutes: Down-then-right equals right-then-down: $(1 + (a * b)) = (1 + a)(1 + b)$. That is, $(1 + \cdot) \circ * = \cdot \circ ((1 + \cdot) \times (1 + \cdot))$.

Why it commutes: Chase (a, b) along both paths. *Top then right:* first apply $*$ to get $a + b + ab$, then shift to get $1 + (a + b + ab) = 1 + a + b + ab = (1 + a)(1 + b)$. *Left then bottom:* first shift each factor to get $(1 + a, 1 + b)$,

then multiply to get $(1+a)(1+b)$. These are identical by the factorization $1+a+b+ab=(1+a)(1+b)$, which is just the elementary algebraic identity $(1+a)(1+b)=1+a+b+ab$.

Why this matters here: The diagram encodes the algebraic reason why $(\mathbb{R}\setminus\{-1\},*)$ is a group: the shift $a\mapsto 1+a$ is an isomorphism from $(\mathbb{R}\setminus\{-1\},*)$ to $(\mathbb{R}^\times,\cdot)$. Every group axiom for $*$ can be read off from the diagram by transporting it from $\mathbb{R}^\times$ through the bijection. The proof that $(\mathbb{R},*)$ fails to be a group is also recorded: $a=-1$ maps to 0, which is the missing element of $\mathbb{R}^\times$.

Concrete example: Take $a=2$, $b=3$. Top path: $2*3=2+3+6=11$, shift to $1+11=12$. Left-then-bottom: shift to $(3,4)$, multiply to 12. Equal: $12=12$.

Common pitfall: Students sometimes read the right vertical arrow $1+\cdot$ as a group homomorphism in the sense that $1+(a+b)=(1+a)+(1+b)$, which is false. The shift is a homomorphism from $(\mathbb{R}\setminus\{-1\},*)$ to $(\mathbb{R}^\times,\cdot)$, not from $(\mathbb{R},+)$ to $(\mathbb{R}^\times,\cdot)$. The diagram says the shift intertwines $*$ with $\cdot$, not $+$ with $\cdot$.

Takeaway: The point of this diagram is that the exotic operation $*$ is secretly ordinary multiplication in disguise, with the bijection $a\mapsto 1+a$ as the dictionary, so $(\mathbb{R}\setminus\{-1\},*)$ inherits all of $(\mathbb{R}^\times,\cdot)$'s group structure for free.

Worked Example 1.1.9 (Using cancellation to solve $axb=c$ for x)**.** In any group G, solve $a\,x\,b=c$ for x in terms of a,b,c, and prove the solution is unique.

Recognition. This is the equation-solving corollary of cancellation (Proposition 1.1.5): isolate x by peeling off the outer factors with their inverses, respecting the side each sits on. Trigger: an equation with the unknown sandwiched between known group elements; multiply on the matching side and use associativity, never division.

Solution. Start from $axb=c$. Left-multiply by a^{-1}:

$$a^{-1}(axb)=a^{-1}c \implies (a^{-1}a)xb=a^{-1}c \implies xb=a^{-1}c.$$

Now right-multiply by b^{-1}:

$$(xb)b^{-1}=(a^{-1}c)b^{-1} \implies x(bb^{-1})=a^{-1}cb^{-1} \implies x=a^{-1}c\,b^{-1}.$$

Existence: substitute back, $a\,(a^{-1}cb^{-1})\,b=(aa^{-1})c(b^{-1}b)=c$. *Uniqueness:* if $axb=ax'b$ then left-cancel a and right-cancel b to get $x=x'$. So $x=a^{-1}cb^{-1}$ is the unique solution. *Check (in $D_8=\langle r,s\mid r^4=s^2=1,\ sr=r^{-1}s\rangle$).* Solve $r\,x\,s=r^2$. Here $a=r$, $b=s$, $c=r^2$, so $x=a^{-1}c\,b^{-1}=r^{-1}r^2s^{-1}$. Now $r^{-1}=r^3$ and $s^{-1}=s$, hence

$$x=r^3\,r^2\,s=r^5s=r^{5-4}s=r\,s=rs.$$

Verify: $r(rs)s=r^2s^2=r^2$. Correct.

Worked Example 1.1.10 (Socks–shoes in a nonabelian group (S_3 and D_8))**.** Verify $(ab)^{-1}=b^{-1}a^{-1}$ concretely, and show that the "naive" $a^{-1}b^{-1}$ is wrong, in a nonabelian group.

Recognition. Proposition 1.1.4(b) is forced by associativity, but the order reversal only *matters* when $ab\neq ba$. Trigger: any time you invert a product in a noncommutative setting (permutations, matrices, dihedral symmetries), reverse the factors. Test the law against a case where reversing changes the answer.

Solution. In S_3 (compose right-to-left). Let $a=(1\,2\,3)$, $b=(1\,2)$. First ab: apply b then a. $1\xrightarrow{b}2\xrightarrow{a}3$, $2\xrightarrow{b}1\xrightarrow{a}2$, $3\xrightarrow{b}3\xrightarrow{a}1$. So $ab=(1\,3)$, a transposition, hence $(ab)^{-1}=(1\,3)$. Now $b^{-1}a^{-1}$: $b^{-1}=(1\,2)$, $a^{-1}=(1\,3\,2)$. Apply a^{-1} then b^{-1}: $1\xrightarrow{a^{-1}}3\xrightarrow{b^{-1}}3$, $2\xrightarrow{a^{-1}}1\xrightarrow{b^{-1}}2$, $3\xrightarrow{a^{-1}}2\xrightarrow{b^{-1}}1$. So $b^{-1}a^{-1}=(1\,3)=(ab)^{-1}$. Law confirmed. The wrong order $a^{-1}b^{-1}$: apply $b^{-1}=(1\,2)$ then $a^{-1}=(1\,3\,2)$: $1\xrightarrow{b^{-1}}2\xrightarrow{a^{-1}}1$, $2\xrightarrow{b^{-1}}1\xrightarrow{a^{-1}}3$, $3\xrightarrow{b^{-1}}3\xrightarrow{a^{-1}}2$. So $a^{-1}b^{-1}=(2\,3)\neq(1\,3)$. The naive order fails, exactly because S_3 is nonabelian.

In D_8. Let $a=r$, $b=s$, so $ab=rs$. Since $(rs)(rs)=r(sr)s=r(r^{-1}s)s=s^2=1$, the element rs is its own inverse: $(rs)^{-1}=rs$. Socks–shoes gives $b^{-1}a^{-1}=s^{-1}r^{-1}=s\,r^3$. Reduce $sr^3=r^{-3}s=rs$ (using $sr=r^{-1}s$ thrice, equivalently $sr^k=r^{-k}s$). So $b^{-1}a^{-1}=rs=(ab)^{-1}$. Consistent. *Check.* In both groups we recovered $(ab)^{-1}$ on the nose, and in S_3 the reversed and naive orders gave genuinely different permutations $(1\,3)$ vs $(2\,3)$, dramatizing why order reversal is mandatory.

Worked Example 1.1.11 (The square–root subtlety: cancellation does not give $\sqrt{\ }$)**.** In a group, deduce from $x^2 = e$ together with $xy = e$ what y must be, and contrast with trying to "cancel a square."

Recognition. Cancellation removes a *matched* factor from both sides; it does not let you halve an exponent. Trigger: students write $x^2 = y^2 \Rightarrow x = y$ by "cancelling," which is false in general. Use cancellation only as Proposition 1.1.5 licenses it.

Solution. From $xy = e$, no extra multiplication is needed: $xy = e$ already says $y = x^{-1}$ by uniqueness of inverses. If also $x^2 = e$, then $x^{-1} = x$, so $y = x$. Now the contrast: $x^2 = y^2$ does *not* imply $x = y$. In $\mathbb{Z}/8\mathbb{Z}$ under $+$ (so the group operation is addition, and "x^2" means $x + x = 2x$): $2 \cdot \bar{1} = \bar{2}$ and $2 \cdot \bar{5} = \overline{10} = \bar{2}$, so $2\bar{1} = 2\bar{5}$ but $\bar{1} \neq \bar{5}$. The reason: cancelling the 2 would require multiplying by an "inverse of doubling," which is not a group element. Cancellation (Proposition 1.1.5) only cancels the *same* group element a appearing on the *same side*, as in $ab = ac \Rightarrow b = c$; it never cancels a repeated factor that equals the variable. *Check.* In $\mathbb{Z}/8\mathbb{Z}$, $\bar{1} + \bar{1} = \bar{2} = \bar{5} + \bar{5}$ indeed, yet $\bar{1} \neq \bar{5}$: so $2x = 2y$ is consistent with $x \neq y$, and "cancelling the 2" is illegitimate. By contrast, legitimate cancellation cancels a fixed group element on a fixed side: from $\bar{3} + \bar{1} = \bar{3} + \bar{5}$ left cancellation of $\bar{3}$ would give $\bar{1} = \bar{5}$; since $\bar{1} \neq \bar{5}$, the premise must be false, and indeed $\bar{3} + \bar{1} = \bar{4} \neq \bar{0} = \bar{3} + \bar{5}$. No contradiction arises – the legitimate law is never violated.

A 4-element Cayley table and reading axioms off it

For a finite group the entire operation is a multiplication (Cayley) table. Below is the Klein four-group $V_4 = \{e, a, b, c\}$ with $a^2 = b^2 = c^2 = e$ and $ab = c$, $bc = a$, $ca = b$ (all commuting).

$*$	e	a	b	c
e	e	a	b	c
a	a	e	c	b
b	b	c	e	a
c	c	b	a	e

Method (Reading the group axioms off a Cayley table)**.**

1. **Closure (G0):** every entry of the body lies in $\{e, a, b, c\}$ – no new symbols appear.
2. **Identity (G2):** some row equals the column header and its column equals the row header. Here the e-row reads $e\,a\,b\,c$ and the e-column reads $e\,a\,b\,c$, so e is the identity.
3. **Inverses (G3):** the identity e appears in *every* row and *every* column. Here e sits on the diagonal of each, so each element is its own inverse ($x^{-1} = x$).
4. **Latin square (necessary for a group, helps spot errors):** each element appears exactly once per row and once per column (cancellation laws in tabular form). Check: every row and column is a permutation of e, a, b, c.
5. **Associativity (G1):** *not* visible at a glance; must be checked separately (or inherited from a known model). For V_4 it follows from $V_4 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

Recognition. Use a Cayley table whenever $|G|$ is small: it certifies G0, G2, G3 and the cancellation/Latin-square property visually, leaving only associativity to argue.

Worked Example 1.1.12 (Confirming V_4 is an abelian group from its table)**.** Use the table above to verify all axioms except associativity, confirm commutativity, and read off each inverse.

Recognition. Apply the table-reading method: closure (no stray symbols), identity (header-matching row/column), inverses (where e occurs), Latin-square (cancellation), and symmetry across the diagonal (abelian). Associativity is the one axiom the table cannot show, so cite the model $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

Solution. Closure: all 16 body entries are among e, a, b, c. Yes. *Identity:* row e is $e\,a\,b\,c$ and column e is $e\,a\,b\,c$; so $e * x = x * e = x$. Identity $= e$. *Inverses:* e appears at positions $(e, e), (a, a), (b, b), (c, c)$ – once in every row/column – so $e^{-1} = e$, $a^{-1} = a$, $b^{-1} = b$, $c^{-1} = c$. *Latin square:* row a is $a\,e\,c\,b$ (a permutation of e, a, b, c); rows b, c likewise; columns likewise. So left/right cancellation hold. *Abelian:* the table is symmetric across the main diagonal – e.g. entry $(a, b) = c = (b, a)$, $(b, c) = a = (c, b)$, $(a, c) = b = (c, a)$. So $*$ is commutative.

Associativity: inherited from $V_4 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ via $e \mapsto (0,0)$, $a \mapsto (1,0)$, $b \mapsto (0,1)$, $c \mapsto (1,1)$, where the operation is coordinatewise addition mod 2 (associative). *Check.* Test one associativity instance directly against the table: $(a * b) * c = c * c = e$ and $a * (b * c) = a * a = e$. Equal, as the model predicts.

Worked Example 1.1.13 (A defective table: spotting the broken axiom)**.** Decide whether the following table on $\{e, a, b, c\}$ defines a group:

$*$	e	a	b	c
e	e	a	b	c
a	a	b	c	e
b	b	c	e	a
c	c	a	a	b

Recognition. Run the table-reading checklist and stop at the first violated condition. Trigger: a proposed finite operation – always test the Latin-square property first, since a repeated entry in a row or column instantly kills the cancellation laws, which every group satisfies (they follow from (G1)–(G3)).

Solution. Closure: all entries in $\{e, a, b, c\}$. OK. Identity: row/column e match the headers, so e is an identity. OK. Latin square: examine row c: it reads c, a, a, b – the symbol a appears *twice* and e does *not* appear at all. Two failures follow: (i) e is missing from row c, so there is no x with $c * x = e$: element c has *no right inverse*, violating (G3). (ii) The repeat $c * a = a = c * b$ with $a \neq b$ violates left cancellation, which a group must satisfy. Either observation alone shows this is **not** a group. *Check.* In a genuine group every row is a permutation of the elements (rearrangement theorem); row $c = (c, a, a, b)$ is not a permutation, confirming the defect without even testing associativity.

Remark 1.1.3 (Why the table cannot show associativity, and a diagram for cancellation)*.* The Latin-square property is equivalent to both cancellation laws but is *strictly weaker* than being a group: there exist Latin squares ("quasigroups") that are not associative. The cancellation law $ab = ac \Rightarrow b = c$ is exactly the statement that left translation $L_a : x \mapsto ax$ is injective, which on a finite set forces it to be a bijection – this is the rearrangement theorem. As a commuting square, the inverse map intertwines left and right translations:

$$\begin{array}{ccc} G & \xrightarrow{L_a\colon x \mapsto ax} & G \\ {\scriptstyle (\cdot)^{-1}}\downarrow & & \downarrow{\scriptstyle (\cdot)^{-1}} \\ G & \xrightarrow[R_{a^{-1}}\colon y \mapsto ya^{-1}]{} & G \end{array}$$

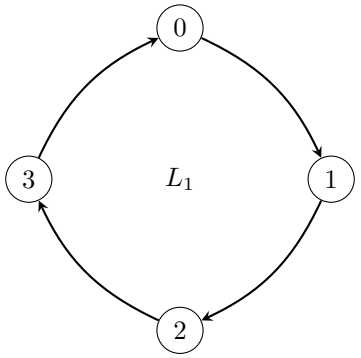
Diagram explanation. Objects: Four copies of the same group G, arranged at the four corners of the square. The top-left and top-right are G viewed as a set of inputs before inversion; the bottom-left and bottom-right are G viewed as the set of outputs after inversion.

Arrows: Top horizontal: left translation L_a, the map $x \mapsto ax$, acting on G from the left by the fixed element a. Bottom horizontal: right translation $R_{a^{-1}}$, the map $y \mapsto ya^{-1}$, acting from the right by a^{-1}. Left vertical: the inversion map $(\cdot)^{-1}$, sending x to x^{-1}. Right vertical: the same inversion map $(\cdot)^{-1}$, sending ax to $(ax)^{-1}$. All four maps are bijections of G to itself.

What commutes: Down-then-right equals right-then-down: $R_{a^{-1}} \circ (\cdot)^{-1} = (\cdot)^{-1} \circ L_a$. Explicitly, for every $x \in G$: $(ax)^{-1} = (x^{-1})a^{-1}$.

Why it commutes: Chase a generic $x \in G$ along both paths. *Right then down:* first apply L_a to get ax, then invert to get $(ax)^{-1} = x^{-1}a^{-1}$ by Proposition 1.1.4(b). *Down then right:* first invert x to get x^{-1}, then apply $R_{a^{-1}}$ to get $x^{-1}a^{-1}$. Both paths yield $x^{-1}a^{-1}$, and they agree because $(ab)^{-1} = b^{-1}a^{-1}$ holds in any group.

Why this matters here: The remark uses this square to explain the rearrangement theorem in a conceptual way: L_a is a bijection because the square writes it as $L_a = (\cdot)^{-1} \circ R_{a^{-1}} \circ (\cdot)^{-1}$, a composite of bijections (inversion is its own inverse and $R_{a^{-1}}$ has inverse R_a), so its inverse as a set-map is $(\cdot)^{-1} \circ R_a \circ (\cdot)^{-1} = L_{a^{-1}}$; i.e. the diagram displays how inversion converts left multiplication into right multiplication. It also shows that the cancellation-law content (L_a injective) is captured by a simple conjugation via the inversion involution.



Concrete example: In $G = S_3$, take $a = (1\,2)$. Then L_a maps $(1\,3)$ to $(1\,2)(1\,3) = (1\,3\,2)$. Inverting: $((1\,2)(1\,3))^{-1} = (1\,3\,2)^{-1} = (1\,2\,3)$. Other path: invert $(1\,3)$ to get $(1\,3)$ (a transposition is its own inverse), then right-multiply by $a^{-1} = (1\,2)$: $(1\,3)(1\,2) = (1\,2\,3)$. Both yield $(1\,2\,3)$.

Common pitfall: Students sometimes expect inversion to intertwine L_a with $L_{a^{-1}}$ (left-multiply by a^{-1}), but the socks-shoes law reverses the side: $(ax)^{-1} = x^{-1}a^{-1}$ is right multiplication by a^{-1}, not left. The diagram makes this reversal of side unavoidable and visible.

Takeaway: The point of this diagram is that inversion in a group converts left multiplication by a into right multiplication by a^{-1}, so the two translations are intertwined by the inversion involution rather than being related by a naive left-to-left substitution.

Commutativity of this square is the identity $(ax)^{-1} = x^{-1}a^{-1}$ from Proposition 1.1.4(b), now read as "inverting turns left multiplication by a into right multiplication by a^{-1}."

Remark 1.1.4 (Geometric picture: left translation permutes a finite group). Concretely, for $G = \mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}$ under addition, left translation $L_1 : x \mapsto x + 1$ is the rotation arrows below. Every vertex has exactly one incoming and one outgoing arrow, so L_1 is a bijection – the geometric content of the rearrangement theorem.

The single 4-cycle $0 \to 1 \to 2 \to 3 \to 0$ shows L_1 has no fixed point and visits every element once, i.e. each row of the $\mathbb{Z}/4\mathbb{Z}$ Cayley table is the cyclic shift of the header.

Further examples: the book's catalogue of groups

The axioms become vivid only against a stock of concrete groups. D&F open Chapter 1 with a standard list; we record it here, separating the abelian number systems from the (non)multiplicative ones and the forward-referenced matrix/permutation groups.

Remark 1.1.5 (Additive number groups). Each of

$$(\mathbb{Z}, +), \quad (\mathbb{Q}, +), \quad (\mathbb{R}, +), \quad (\mathbb{C}, +)$$

is an abelian group: addition is associative and commutative, the identity is 0, and the inverse of x is $-x$. They sit inside one another, $\mathbb{Z} \subset \mathbb{Q} \subset \mathbb{R} \subset \mathbb{C}$, each a subgroup of the next under the same $+$. Note $(\mathbb{Z}, +)$ is the only one of the four in which a single element, namely 1 (or -1), generates the whole group: $\mathbb{Z} = \langle 1 \rangle$.

Remark 1.1.6 (Multiplicative number groups, and what gets deleted). Under multiplication the picture is more delicate because 0 is never invertible. Writing $A^\times = A \setminus \{0\}$ for a field A:

$$(\mathbb{Q}^\times, \cdot), \quad (\mathbb{R}^\times, \cdot), \quad (\mathbb{C}^\times, \cdot)$$

are abelian groups (identity 1, inverse $x^{-1} = 1/x$), but $(\mathbb{Q}, \cdot), (\mathbb{R}, \cdot), (\mathbb{C}, \cdot)$ are *not*, since 0 has no inverse. By contrast $(\mathbb{Z} \setminus \{0\}, \cdot)$ is still not a group: e.g. 2 has no integer inverse (axiom (G3) fails, not merely the deletion of 0). The positive reals and positive rationals form groups under multiplication,

$$(\mathbb{R}^+, \cdot), \qquad (\mathbb{Q}^+, \cdot),$$

because a product of positives is positive (closure) and $1/x > 0$ when $x > 0$ (inverses); these are the multiplicative analogues of the additive groups above, and $x \mapsto \log x$ is a bijection $\mathbb{R}^+ \to \mathbb{R}$ carrying $\cdot$ to $+$.

Remark 1.1.7 (The trivial group and $(\mathbb{Z}/n\mathbb{Z},+)$). The smallest example is the *trivial group* $\{e\}$ with the only possible operation $e*e=e$; it is abelian and $e^{-1}=e$. At the other extreme of "small but interesting" is the additive group of residues

$$(\mathbb{Z}/n\mathbb{Z},+), \qquad \mathbb{Z}/n\mathbb{Z}=\{\bar{0},\bar{1},\dots,\overline{n-1}\}, \quad \bar{a}+\bar{b}=\overline{a+b},$$

which is an abelian group of order n for every $n\geq 1$: identity $\bar{0}$, inverse $-\bar{a}=\overline{n-a}$ (and $-\bar{0}=\bar{0}$). This is genuinely a group even though $(\mathbb{Z}/n\mathbb{Z},\cdot)$ is not (the fragment's worked example); deleting non-units from $\mathbb{Z}/n\mathbb{Z}$ under multiplication leaves the multiplicative group $(\mathbb{Z}/n\mathbb{Z})^\times$ of order $\varphi(n)$, treated later.

Remark 1.1.8 (Forward references: S_n, D_{2n}, GL). Three families that D&F flag here and construct in detail shortly:

(i) the *symmetric group* S_n of all bijections of $\{1,2,\dots,n\}$ to itself under composition, $|S_n|=n!$, nonabelian for $n\geq 3$ (identity id, inverse the inverse permutation);

(ii) the *dihedral group* D_{2n} of the $2n$ symmetries of a regular n-gon, with presentation $r^n=s^2=1$, $sr=r^{-1}s$ (so $|D_{2n}|=2n$), nonabelian for $n\geq 3$;

(iii) the *general linear group* $\mathrm{GL}_n(\mathbb{R})$ (more generally $\mathrm{GL}_n(F)$ over a field F) of invertible $n\times n$ matrices under matrix multiplication, identity the matrix I, inverse the matrix inverse, nonabelian for $n\geq 2$.

In each case associativity is inherited (composition of functions, multiplication of matrices), and the work is identifying the identity and confirming every element is invertible.

Powers of an element and the order of an element

Definition 1.1.14 (Integer powers)**.** Let G be a group, $x\in G$. Define $x^0=1$ (the identity), and for $n\geq 1$

$$x^n=\underbrace{x\,x\cdots x}_{n\text{ factors}}, \qquad x^{-n}=(x^{-1})^n=(x^n)^{-1}.$$

By generalized associativity (Remark 1.1.2) the usual laws of exponents hold for all integers m,n:

$$x^m x^n=x^{m+n}, \qquad (x^m)^n=x^{mn}.$$

In additive notation (e.g. in $(\mathbb{Z}/n\mathbb{Z},+)$ or $(\mathbb{Z},+)$) one writes nx in place of x^n, so "$x^n=1$" reads "$nx=0$".

Remark 1.1.9 ($x^mx^n=x^{m+n}$ but NOT $(xy)^n=x^ny^n$). The single-element laws above need no commutativity. The *two*-element law $(xy)^n=x^ny^n$ does: it holds for all n iff $xy=yx$. For example in D_8, $(rs)^2=rsrs=r(sr)s=r(r^{-1}s)s=s^2=1$, whereas $r^2s^2=r^2\neq 1$. So never distribute a power over a product in a nonabelian group.

Definition 1.1.15 (Order of an element)**.** The *order* of $x\in G$, written $|x|$, is the least positive integer n with $x^n=1$, if such an n exists; otherwise x has *infinite order*, $|x|=\infty$. Equivalently $|x|=\big|\langle x\rangle\big|$, the size of the cyclic subgroup generated by x. The identity is the unique element of order 1.

Proposition 1.1.16 (When $x^k=1$)**.** *Let $x\in G$ have finite order $n=|x|$. For an integer k,*

$$x^k=1 \quad\Longleftrightarrow\quad n\mid k.$$

Consequently $x^a=x^b$ iff $a\equiv b \pmod n$, and the distinct powers of x are exactly $1,x,x^2,\dots,x^{n-1}$.

Proof. ($\Leftarrow$) If $k=qn$ then $x^k=(x^n)^q=1^q=1$. ($\Rightarrow$) Divide: $k=qn+r$ with $0\leq r<n$. Then $1=x^k=(x^n)^qx^r=x^r$, and by minimality of n this forces $r=0$, i.e. $n\mid k$. The last claims follow by applying this to $k=a-b$ and noting $1,x,\dots,x^{n-1}$ are pairwise distinct (a coincidence $x^i=x^j$, $0\leq i<j<n$, would give $x^{j-i}=1$ with $0<j-i<n$). □

Worked Example 1.1.17 (Orders in $\mathbb{Z}$, $\mathbb{R}^\times$, and $\mathbb{C}^\times$)**.** Compute the order of each element in several of the book's standard groups, distinguishing finite from infinite order.

Recognition. Apply Definition 1.1.15 directly: hunt for the least n with $x^n = 1$ (additively $nx = 0$). The trigger is "order of an element"; in the infinite groups below ($\mathbb{Z}$, $\mathbb{R}^\times$, $\mathbb{C}^\times$) most elements have infinite order, and finite order signals a root of unity or a torsion phenomenon.

Solution. In $(\mathbb{Z}, +)$. Here x^n means nx. For $x = 0$, $|0| = 1$. For any $x \neq 0$, $nx = 0$ forces $n = 0$, so no *positive* n works: $|x| = \infty$. Every nonzero integer has infinite order.

In $(\mathbb{R}^\times, \cdot)$. $|1| = 1$ and $|-1| = 2$ (since $(-1)^2 = 1$ and $(-1)^1 = -1 \neq 1$). Any other x ($x \neq \pm 1$) has $|x^n| = |x|^n \neq 1$ unless $|x| = 1$, so $x = \pm 1$ are the only elements of finite order; all others have infinite order, e.g. $|2| = \infty$.

In $(\mathbb{C}^\times, \cdot)$. The element i has powers $i, i^2 = -1, i^3 = -i, i^4 = 1$, so $|i| = 4$. A primitive nth root of unity $\zeta = e^{2\pi i/n}$ has $|\zeta| = n$ exactly (its powers $1, \zeta, \ldots, \zeta^{n-1}$ are distinct). A complex number of modulus $\neq 1$, or of modulus 1 but with irrational angle divided by 2π, has infinite order.

Check. In $\mathbb{C}^\times$, $|i| = 4$ matches Proposition 1.1.16: $i^k = 1 \iff 4 \mid k$, and indeed $i^8 = 1$, $i^6 = i^2 = -1 \neq 1$. The four distinct powers are $1, i, -1, -i$.

Worked Example 1.1.18 (Orders in $(\mathbb{Z}/n\mathbb{Z}, +)$: the formula $|\bar{a}| = n/\gcd(a, n)$)**.** In the additive group $\mathbb{Z}/12\mathbb{Z}$ find the order of $\bar{a}$ for several a, and state the general rule.

Recognition. In $(\mathbb{Z}/n\mathbb{Z}, +)$ the relation $x^k = 1$ is the additive $k\,\bar{a} = \bar{0}$, i.e. $n \mid ka$; the least such $k > 0$ is governed by $\gcd(a, n)$. Trigger: order of an element in a cyclic additive group – reach for the gcd formula rather than listing multiples blindly.

Solution. We seek the least $k \geq 1$ with $k\,\bar{a} = \bar{0}$ in $\mathbb{Z}/12\mathbb{Z}$, i.e. $12 \mid ka$.

- $\bar{1}$: least k with $12 \mid k$ is $k = 12$, so $|\bar{1}| = 12$.
- $\bar{3}$: $12 \mid 3k \iff 4 \mid k$, least is $k = 4$, so $|\bar{3}| = 4$.
- $\bar{4}$: $12 \mid 4k \iff 3 \mid k$, least is $k = 3$, so $|\bar{4}| = 3$.
- $\bar{8}$: $12 \mid 8k \iff 3 \mid 2k \iff 3 \mid k$, least is $k = 3$, so $|\bar{8}| = 3$.
- $\bar{0}$: $|\bar{0}| = 1$.

In general $|\bar{a}| = \dfrac{n}{\gcd(a, n)}$ in $(\mathbb{Z}/n\mathbb{Z}, +)$: since $k\bar{a} = \bar{0} \iff n \mid ka \iff \dfrac{n}{\gcd(a,n)} \mid k$ (dividing $n \mid ka$ through by $\gcd(a, n)$ and using that $\frac{n}{\gcd(a,n)}$ and $\frac{a}{\gcd(a,n)}$ are coprime). *Check.* For $a = 3, n = 12$: $n/\gcd(a, n) = 12/3 = 4$, matching $|\bar{3}| = 4$; and $4\bar{3} = \overline{12} = \bar{0}$ while $1\bar{3}, 2\bar{3}, 3\bar{3} = \bar{3}, \bar{6}, \bar{9} \neq \bar{0}$. The elements of order 12 (the *generators* of $\mathbb{Z}/12\mathbb{Z}$) are exactly the $\bar{a}$ with $\gcd(a, 12) = 1$, namely $\bar{1}, \bar{5}, \bar{7}, \overline{11}$.

Worked Example 1.1.19 (Orders in nonabelian D_8 and S_3)**.** Tabulate the orders of all elements of $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$ and of S_3.

Recognition. Use $|x|$ = least n with $x^n = 1$; for dihedral reflections and transpositions the order is forced to be 2, while rotations and cycles inherit the order of the underlying cyclic shift. Trigger: orders in a small nonabelian group – compute powers directly, exploiting $sr = r^{-1}s$ to reduce.

Solution. In D_8 *(order* 8*).* The rotations: $|1| = 1$; $|r| = 4$ (least k with $r^k = 1$ is 4); $|r^2| = 2$ (since $(r^2)^2 = r^4 = 1$, and $r^2 \neq 1$); $|r^3| = 4$. The reflections s, rs, r^2s, r^3s each square to 1: e.g. $(rs)^2 = rsrs = r(sr)s = r(r^{-1}s)s = rr^{-1}s^2 = 1$, and similarly $(r^k s)^2 = 1$ for every k. None equals 1, so each reflection has order 2. Summary: one element of order 1, five of order 2 (r^2, s, rs, r^2s, r^3s), two of order 4 (r, r^3).

In S_3 *(order* 6*).* The identity has order 1. The three transpositions $(1\,2), (1\,3), (2\,3)$ square to the identity, so each has order 2. The two 3-cycles $(1\,2\,3), (1\,3\,2)$ satisfy $(1\,2\,3)^3 = \mathrm{id}$ with $(1\,2\,3)$ and $(1\,2\,3)^2 = (1\,3\,2)$ both $\neq \mathrm{id}$, so each has order 3. *Check.* The orders tally with the group sizes: in D_8, $1 + 5 + 2 = 8$ elements; in S_3, $1 + 3 + 2 = 6$. Every order divides the group order ($1, 2, 4 \mid 8$ and $1, 2, 3 \mid 6$), as Lagrange's theorem will later guarantee.

Remark 1.1.10 (Order of x versus order of x^{-1}). A fact used constantly: $|x^{-1}| = |x|$, because $x^n = 1 \iff (x^{-1})^n = (x^n)^{-1} = 1$, so x and x^{-1} have exactly the same powers equal to 1. More generally, for any $g \in G$ the element gxg^{-1} has the same order as x, since $(gxg^{-1})^n = gx^ng^{-1}$, which equals 1 exactly when $x^n = 1$. Thus order is unchanged by inversion – the first reason orders organize the structure of a group.

Order of an element; the additive group $\mathbb{Z}/n\mathbb{Z}$ and the unit group $(\mathbb{Z}/n\mathbb{Z})^\times$

Definition 1.1.20. Let G be a group (written multiplicatively, identity 1) and $x \in G$. The *order* of x, written $|x|$, is the least integer $k > 0$ with $x^k = 1$, if such a k exists; otherwise $|x| = \infty$. In an additively written group (identity 0) the same definition reads: $|x|$ is the least $k > 0$ with $kx = 0$, else ∞.

Definition 1.1.21. Fix $n \geq 1$. The set $\mathbb{Z}/n\mathbb{Z} = \{\bar{0}, \bar{1}, \ldots, \overline{n-1}\}$ of residue classes mod n is a group under addition $\bar{a} + \bar{b} = \overline{a+b}$, of order n, with identity $\bar{0}$ and inverse $-\bar{a} = \overline{n-a}$. The *unit group* is

$$(\mathbb{Z}/n\mathbb{Z})^\times = \{\, \bar{a} \in \mathbb{Z}/n\mathbb{Z} \mid \gcd(a, n) = 1 \,\},$$

a group under multiplication $\bar{a} \cdot \bar{b} = \overline{ab}$, of order $\varphi(n)$ (Euler's totient).

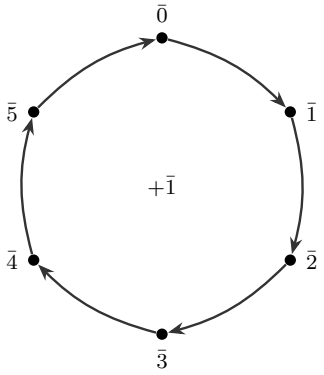
Proposition 1.1.22. *$\bar{a} \in \mathbb{Z}/n\mathbb{Z}$ has a multiplicative inverse mod n if and only if $\gcd(a, n) = 1$. Hence $(\mathbb{Z}/n\mathbb{Z})^\times$ is exactly the set of such classes, and it is a group.*

Proof. ($\Leftarrow$) If $\gcd(a, n) = 1$, Bezout gives integers u, v with $au + nv = 1$, so $\overline{a}\,\overline{u} = \overline{au} = \overline{1 - nv} = \bar{1}$; thus $\bar{u} = \bar{a}^{-1}$. ($\Rightarrow$) If $\bar{a}\,\bar{b} = \bar{1}$ then $ab \equiv 1 \pmod{n}$, i.e. $ab - 1 = nk$ for some $k \in \mathbb{Z}$, so $ab - nk = 1$ and any common divisor of a and n divides 1; hence $\gcd(a, n) = 1$. Closure: $\gcd(a, n) = \gcd(b, n) = 1 \implies \gcd(ab, n) = 1$. Associativity and $\bar{1}$ are inherited from $\mathbb{Z}$, and inverses exist by the equivalence just proved. So $(\mathbb{Z}/n\mathbb{Z})^\times$ is a group of order $\varphi(n) = \#\{1 \leq a \leq n \mid \gcd(a, n) = 1\}$. □

Proposition 1.1.23. *In $(\mathbb{Z}/n\mathbb{Z}, +)$ the order of $\bar{a}$ is $|\bar{a}| = \dfrac{n}{\gcd(a, n)}$. In particular $|\bar{1}| = n$, and $\bar{a}$ generates $\mathbb{Z}/n\mathbb{Z}$ iff $\gcd(a, n) = 1$.*

Proof. $|\bar{a}|$ is the least $k > 0$ with $k\bar{a} = \bar{0}$, i.e. $n \mid ka$. Write $d = \gcd(a, n)$, $a = da'$, $n = dn'$ with $\gcd(a', n') = 1$. Then $n \mid ka \iff dn' \mid kda' \iff n' \mid ka' \iff n' \mid k$ (since $\gcd(a', n') = 1$). The least such $k > 0$ is $n' = n/d$. □

Method (How to compute $|x|$ in any group)**.** Trigger: you are handed a specific element x and asked "what is $|x|$?" or "does x have finite order?"



1. Compute the powers $x^1, x^2, x^3, \ldots$ (additively: $1x, 2x, 3x, \ldots$) one at a time.
2. The order is the FIRST exponent $k > 0$ that returns the identity (1 multiplicatively, 0 additively). Stop there.
3. Shortcut in $(\mathbb{Z}/n\mathbb{Z}, +)$: $|\bar{a}| = n/\gcd(a, n)$ (Prop. 1.1.23); no power-listing needed.
4. Shortcut in $(\mathbb{Z}/n\mathbb{Z})^\times$: $|\bar{a}|$ must divide $\varphi(n)$ (Lagrange), so only test exponents that divide $\varphi(n)$.
5. If no power ever returns the identity (e.g. a nonzero rational under $+$, or a real $\neq \pm 1$ under $\times$), then $|x| = \infty$.

Method (How to identify the units $(\mathbb{Z}/n\mathbb{Z})^\times$)**.** Trigger: you must list $(\mathbb{Z}/n\mathbb{Z})^\times$, or decide whether a given $\bar{a}$ is invertible mod n.

1. List $a = 1, 2, \ldots, n-1$ (and include $a = 1$ always; never include $\bar{0}$ for $n > 1$).
2. Keep exactly those a with $\gcd(a, n) = 1$ (Prop. 1.1.22). Discard any a sharing a prime factor with n.
3. Count: $\#(\mathbb{Z}/n\mathbb{Z})^\times = \varphi(n)$. Sanity-check via $\varphi(p^k) = p^k - p^{k-1}$ and $\varphi(mn) = \varphi(m)\varphi(n)$ for $\gcd(m, n) = 1$.
4. To find an inverse of a unit $\bar{a}$, run the extended Euclidean algorithm on a, n to get $au + nv = 1$; then $\bar{a}^{-1} = \bar{u}$.

Caution. Do not confuse the two groups. In $(\mathbb{Z}/n\mathbb{Z}, +)$ every class is present and the operation is $+$; in $(\mathbb{Z}/n\mathbb{Z})^\times$ only the coprime classes are present and the operation is $\times$. "$|\bar{3}|$ mod 12" is ambiguous until you say which group; additively $|\bar{3}| = 4$, but $\bar{3}$ is not even an element of $(\mathbb{Z}/12\mathbb{Z})^\times$ since $\gcd(3, 12) = 3 \neq 1$.

The additive clock for $(\mathbb{Z}/6\mathbb{Z}, +)$ below shows the single cycle generated by $\bar{1}$; adding $\bar{1}$ steps one notch clockwise, and 6 steps return to $\bar{0}$.

Generators of $(\mathbb{Z}/6\mathbb{Z}, +)$ are exactly the units mod 6: $\bar{1}$ (clockwise step) and $\bar{5} = -\bar{1}$ (counterclockwise step), since $\gcd(1, 6) = \gcd(5, 6) = 1$. The map $\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$, $k \mapsto k\bar{1}$, factors through the quotient, giving the universal picture of a cyclic group:

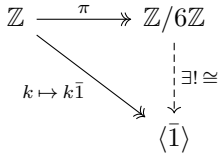


Diagram explanation. Objects: Three groups: $\mathbb{Z}$ (the infinite additive group of integers), $\mathbb{Z}/6\mathbb{Z}$ (the additive quotient group $\mathbb{Z}/6\mathbb{Z}$ of residue classes mod 6, order 6), and $\langle\bar{1}\rangle$ (the cyclic subgroup of $\mathbb{Z}/6\mathbb{Z}$ generated by $\bar{1}$, which equals all of $\mathbb{Z}/6\mathbb{Z}$ since $\bar{1}$ generates).

Arrows: $\pi : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ is the canonical surjection $k \mapsto \bar{k}$, the quotient map that kills the subgroup $6\mathbb{Z}$; the double-head notation records surjectivity. The diagonal $k \mapsto k\bar{1}$ is the evaluation homomorphism sending k to the k-th multiple of $\bar{1}$ in $\mathbb{Z}/6\mathbb{Z}$; it maps onto $\langle\bar{1}\rangle$, so it also carries a double head, and following it with the inclusion $\langle\bar{1}\rangle \hookrightarrow \mathbb{Z}/6\mathbb{Z}$ gives π. The dashed vertical arrow is the unique isomorphism $\mathbb{Z}/6\mathbb{Z} \xrightarrow{\cong} \langle\bar{1}\rangle$ induced by the universal property of the quotient.

What commutes: The triangle commutes: (dashed) $\circ\, \pi = (k \mapsto k\bar{1})$, i.e., applying π then the isomorphism gives the same result as mapping k directly to $k\bar{1}$.

Why it commutes: The diagonal map $k \mapsto k\bar{1}$ kills $6\mathbb{Z}$ (since $6\bar{1} = \bar{0}$), so the universal property of $\mathbb{Z}/6\mathbb{Z} = \mathbb{Z}/6\mathbb{Z}$ provides a unique induced map $\mathbb{Z}/6\mathbb{Z} \to \langle\bar{1}\rangle$ making the triangle commute. Well-definedness: if $k \equiv k' \pmod 6$ then $(k - k')\bar{1} = \bar{0}$, so $k\bar{1} = k'\bar{1}$; the coset representative does not matter.

Why this matters here: This diagram encodes the fact that $(\mathbb{Z}/6\mathbb{Z}, +)$ is cyclic: the single element $\bar{1}$ generates all of $\mathbb{Z}/6\mathbb{Z}$, so the unique induced map is an isomorphism. It is the universal picture the text uses to explain generators of cyclic groups immediately after the clock diagram.

Concrete example: Take $k = 8$. Then $\pi(8) = \bar{2}$ and $8\bar{1} = \bar{8} = \bar{2}$, confirming the triangle for this element. The dashed isomorphism sends $\bar{2} \mapsto 2\bar{1} = \bar{2}$, which is the identity on $\mathbb{Z}/6\mathbb{Z} = \langle\bar{1}\rangle$.

Common pitfall: Students sometimes read the dashed arrow as *defining* $\langle\bar{1}\rangle$ rather than recording the universal property. The isomorphism exists because the kernel of the diagonal map equals $6\mathbb{Z} = \ker\pi$; if the kernel were different, no such induced map would exist.

Takeaway: The point of this diagram is that every cyclic group of order n is a quotient of $\mathbb{Z}$, and the quotient map factors through the group via the unique isomorphism given by the universal property.

Worked examples: computing $|x|$ in $(\mathbb{Z}/n\mathbb{Z}, +)$

Worked Example 1.1.24 (Orders of several elements of $(\mathbb{Z}/12\mathbb{Z}, +)$)**.** Compute $|\bar{a}|$ in $(\mathbb{Z}/12\mathbb{Z}, +)$ for $a = 0, 1, 2, 3, 4, 6, 8, 9$.

Recognition. This is an additive group $\mathbb{Z}/12\mathbb{Z}$, so the shortcut $|\bar{a}| = 12/\gcd(a,12)$ from Prop. 1.1.23 applies directly; the only computation needed is a gcd for each a.

Solution. We tabulate $d = \gcd(a,12)$ and $|\bar{a}| = 12/d$:

a	0	1	2	3	4	6	8	9
$\gcd(a,12)$	12	1	2	3	4	6	4	3
$\lvert\bar{a}\rvert = 12/\gcd$	1	12	6	4	3	2	3	4

Spot-check $a = 8$ by listing additive multiples: $\bar{8},\ \overline{16} = \bar{4},\ \overline{24} = \bar{0}$; that is $1\cdot\bar{8} = \bar{8}$, $2\cdot\bar{8} = \bar{4}$, $3\cdot\bar{8} = \bar{0}$, so $|\bar{8}| = 3$, matching $12/\gcd(8,12) = 12/4 = 3$. Sanity check: every order divides $|\mathbb{Z}/12\mathbb{Z}| = 12$, and indeed $\{1,12,6,4,3,2,3,4\}$ all divide 12. Also $|\bar{0}| = 1$ (the identity), as required.

Worked Example 1.1.25 (An element of order 7 in $\mathbb{Z}/n\mathbb{Z}$)**.** In $(\mathbb{Z}/14\mathbb{Z},+)$, find $|\bar{4}|$ and $|\bar{2}|$.

Recognition. Additive group again, so use $|\bar{a}| = 14/\gcd(a,14)$. The trigger is simply "order in $\mathbb{Z}/n\mathbb{Z}$ under $+$."

Solution. $\gcd(4,14) = 2$, so $|\bar{4}| = 14/2 = 7$. Check: $1\cdot\bar{4} = \bar{4},\ 2\cdot\bar{4} = \bar{8},\ 3\cdot\bar{4} = \overline{12},\ 4\cdot\bar{4} = \overline{16} = \bar{2},\ 5\cdot\bar{4} = \bar{6},\ 6\cdot\bar{4} = \overline{10},\ 7\cdot\bar{4} = \overline{14} = \bar{0}$. First return at $k = 7$. Similarly $\gcd(2,14) = 2$ gives $|\bar{2}| = 7$. Sanity check: $7 \mid 14 = |\mathbb{Z}/14\mathbb{Z}|$. Both $\bar{2}$ and $\bar{4}$ generate the same order-7 subgroup $\{\bar{0},\bar{2},\bar{4},\bar{6},\bar{8},\overline{10},\overline{12}\}$.

Worked Example 1.1.26 (Generators of $\mathbb{Z}/10\mathbb{Z}$)**.** Which classes $\bar{a}$ generate $(\mathbb{Z}/10\mathbb{Z},+)$, i.e. have $|\bar{a}| = 10$?

Recognition. By Prop. 1.1.23, $|\bar{a}| = 10 \iff \gcd(a,10) = 1$. So generators = units mod 10. Trigger: "which elements have full order n."

Solution. Test $a = 1,\dots,9$: gcd with 10 equals 1 exactly for $a \in \{1,3,7,9\}$ (the others share factor 2 or 5). So the generators are $\bar{1},\bar{3},\bar{7},\bar{9}$, and there are $\varphi(10) = \varphi(2)\varphi(5) = 1\cdot 4 = 4$ of them. Check $a = 3$: $\bar{3},\bar{6},\bar{9},\overline{12} = \bar{2},\bar{5},\bar{8},\overline{11} = \bar{1},\bar{4},\bar{7},\overline{10} = \bar{0}$ – exactly 10 distinct classes before returning to $\bar{0}$, so $|\bar{3}| = 10$. Sanity check: number of generators of a cyclic group of order n is $\varphi(n)$, and $\varphi(10) = 4$.

Worked Example 1.1.27 (Reading off an order without the formula)**.** In $(\mathbb{Z}/9\mathbb{Z},+)$ compute $|\bar{6}|$ both by listing and by the gcd formula, and confirm they agree.

Recognition. Additive cyclic group; the point is to verify the shortcut against brute force.

Solution. Listing: $1\cdot\bar{6} = \bar{6},\ 2\cdot\bar{6} = \overline{12} = \bar{3},\ 3\cdot\bar{6} = \overline{18} = \bar{0}$. First return at $k = 3$, so $|\bar{6}| = 3$. Formula: $\gcd(6,9) = 3$, $|\bar{6}| = 9/3 = 3$. They agree. Sanity check: $3 \mid 9 = |\mathbb{Z}/9\mathbb{Z}|$, and the subgroup generated is $\{\bar{0},\bar{3},\bar{6}\}$ of size 3.

Worked examples: the unit group $(\mathbb{Z}/n\mathbb{Z})^\times$

Worked Example 1.1.28 (List $(\mathbb{Z}/15\mathbb{Z})^\times$ and the order of each unit)**.** Write out $(\mathbb{Z}/15\mathbb{Z})^\times$ and compute $|\bar{a}|$ (under multiplication) for every $\bar{a}$ in it.

Recognition. "List $(\mathbb{Z}/n\mathbb{Z})^\times$" triggers the gcd filter (keep a with $\gcd(a,15) = 1$); "order of each" triggers power-listing, restricted to divisors of $\varphi(15)$ by Lagrange.

Solution. $15 = 3\cdot 5$, so $\varphi(15) = \varphi(3)\varphi(5) = 2\cdot 4 = 8$. Discard multiples of 3 $(3,6,9,12)$ and of 5 $(5,10)$. The survivors among $1,\dots,14$ are

$$(\mathbb{Z}/15\mathbb{Z})^\times = \{\bar{1},\bar{2},\bar{4},\bar{7},\bar{8},\overline{11},\overline{13},\overline{14}\}, \qquad \# = 8 = \varphi(15). \ \blacksquare$$

Possible orders divide 8: i.e. $1,2,4,8$. Compute each (all mod 15):

$\bar{a}$	powers until $\bar{1}$	$\lvert\bar{a}\rvert$
$\bar{1}$	$\bar{1}$	1
$\bar{2}$	$\bar{2},\ \bar{4},\ \bar{8},\ \overline{16} = \bar{1}$	4
$\bar{4}$	$\bar{4},\ \overline{16} = \bar{1}$	2
$\bar{7}$	$\bar{7},\ \overline{49} = \bar{4},\ \overline{28} = \overline{13},\ \overline{91} = \bar{1}$	4
$\bar{8}$	$\bar{8},\ \overline{64} = \bar{4},\ \overline{32} = \bar{2},\ \overline{16} = \bar{1}$	4
$\overline{11}$	$\overline{11},\ \overline{121} = \bar{1}$	2
$\overline{13}$	$\overline{13},\ \overline{169} = \bar{4},\ \overline{52} = \bar{7},\ \overline{91} = \bar{1}$	4
$\overline{14}$	$\overline{14},\ \overline{196} = \bar{1}$	2

where e.g. $7^2 = 49 = 45 + 4 \equiv \bar{4}$, $7^3 = 7 \cdot 4 = 28 = 15 + 13 \equiv \overline{13}$, $7^4 = 7 \cdot 13 = 91 = 90 + 1 \equiv \bar{1}$. Sanity check: every order is 1, 2, or 4, each dividing $\varphi(15) = 8$ (Lagrange). ■ Note no element has order 8, so $(\mathbb{Z}/15\mathbb{Z})^\times$ is NOT cyclic; in fact it is $(\mathbb{Z}/15\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$.

Worked Example 1.1.29 (Why $\bar{6}$ is a unit mod 25 but not mod 9)**.** Decide whether $\bar{6} \in (\mathbb{Z}/25\mathbb{Z})^\times$ and whether $\bar{6} \in (\mathbb{Z}/9\mathbb{Z})^\times$, and (where it is a unit) find $|\bar{6}|$ and its inverse.

Recognition. "Is $\bar{a}$ a unit mod n?" triggers the criterion $\gcd(a, n) = 1$ (Prop. 1.1.22). The two moduli differ by their prime factors, which is exactly what the gcd sees.

Solution. Mod 25: $\gcd(6, 25) = 1$ (since $25 = 5^2$ and $5 \nmid 6$), so $\bar{6} \in (\mathbb{Z}/25\mathbb{Z})^\times$. Mod 9: $\gcd(6, 9) = 3 \neq 1$ (both divisible by 3), so $\bar{6} \notin (\mathbb{Z}/9\mathbb{Z})^\times$ – it has no multiplicative inverse. Concretely mod 9 the multiples $6 \cdot 1 = 6$, $6 \cdot 2 = 12 \equiv 3$, $6 \cdot 3 = 18 \equiv 0, \ldots$ never hit $\bar{1}$, confirming non-invertibility. Inverse mod 25 by Euclid: $25 = 4 \cdot 6 + 1$, so $1 = 25 - 4 \cdot 6$, giving $-4 \cdot 6 \equiv 1$, i.e. $\bar{6}^{-1} = \overline{-4} = \overline{21}$. Check $6 \cdot 21 = 126 = 125 + 1 \equiv \bar{1}$ (mod 25). ■ Order of $\bar{6}$ mod 25: $\varphi(25) = 25 - 5 = 20$, so $|\bar{6}| \mid 20$. Compute $6^2 = 36 \equiv \overline{11}$, $6^4 \equiv 11^2 = 121 \equiv \overline{21}$, $6^5 = 6^4 \cdot 6 \equiv 21 \cdot 6 = 126 \equiv \bar{1}$. First return at 5, so $|\bar{6}| = 5$, and $5 \mid 20$. ■

Worked Example 1.1.30 ($|-1| = 2$ in $(\mathbb{Z}/n\mathbb{Z})^\times$ (and the same fact in $\mathbb{R}^\times$))**.** Show $|\overline{-1}| = 2$ in $(\mathbb{Z}/n\mathbb{Z})^\times$ for every $n \geq 3$, and verify it concretely for $n = 8$. Compare with $|-1| = 2$ in $(\mathbb{R}^\times, \cdot)$.

Recognition. "Order of -1" triggers the smallest-power computation: $(-1)^1 = -1 \neq 1$, $(-1)^2 = 1$. The only subtlety is that we need $\overline{-1} \neq \bar{1}$, which forces $n \geq 3$.

Solution. For $n \geq 3$, $\overline{-1} = \overline{n-1} \neq \bar{1}$ (since $n - 1 \geq 2$), so $|\overline{-1}| \neq 1$. And $(\overline{-1})^2 = \bar{1}$, so $|\overline{-1}| = 2$. Note $\gcd(n-1, n) = \gcd(-1, n) = 1$, so $\overline{-1}$ really is a unit. Concretely $n = 8$: $\overline{-1} = \bar{7}$, and $7^2 = 49 = 48 + 1 \equiv \bar{1}$ (mod 8), while $\bar{7} \neq \bar{1}$; hence $|\bar{7}| = 2$. In $\mathbb{R}^\times$: $(-1)^1 = -1 \neq 1$ but $(-1)^2 = 1$, so $|-1| = 2$ there too. Sanity check: in any group an element $x \neq 1$ with $x^2 = 1$ (i.e. $x = x^{-1}$) has order exactly 2; that is precisely the case here. ■

Worked Example 1.1.31 (Order of $\bar{2}$ in three different unit groups)**.** Compute $|\bar{2}|$ in $(\mathbb{Z}/7\mathbb{Z})^\times$, $(\mathbb{Z}/9\mathbb{Z})^\times$, and $(\mathbb{Z}/17\mathbb{Z})^\times$.

Recognition. Each is a unit group; $\bar{2}$ is a unit iff n is odd, which holds for $7, 9, 17$. Use Lagrange to limit candidate orders to divisors of $\varphi(n)$, then list powers of 2.

Solution. **Mod** 7 ($\varphi(7) = 6$, divisors $1, 2, 3, 6$): $2, 4, 8 \equiv 1$. So $|\bar{2}| = 3 \mid 6$. ■ **Mod** 9 ($\varphi(9) = 6$): $2, 4, 8, 16 \equiv 7, 14 \equiv 5, 10 \equiv 1$. Powers $2^1, \ldots, 2^6$ give $2, 4, 8, 7, 5, 1$; first return at 6, so $|\bar{2}| = 6$ – $\bar{2}$ is a generator, $(\mathbb{Z}/9\mathbb{Z})^\times$ is cyclic. ■ **Mod** 17 ($\varphi(17) = 16$, divisors $1, 2, 4, 8, 16$): $2^2 = 4$, $2^4 = 16 \equiv \overline{-1}$, $2^8 \equiv (-1)^2 = 1$. First return at 8 (not at 4, since $2^4 \equiv 16 \neq 1$), so $|\bar{2}| = 8 \mid 16$. ■ Sanity check: in each case the order divides $\varphi(n)$, as Lagrange demands.

Worked examples: infinite order

Worked Example 1.1.32 (An element of infinite order in $(\mathbb{Q}, +)$)**.** Show $\frac{1}{2} \in (\mathbb{Q}, +)$ has infinite order. Contrast with $(\mathbb{Z}/n\mathbb{Z}, +)$ where every order is finite.

Recognition. "Infinite order" triggers: prove NO positive multiple is the identity. Here the identity of $(\mathbb{Q}, +)$ is 0, and we examine $k \cdot \frac{1}{2}$.

Solution. For any integer $k > 0$, $k \cdot \frac{1}{2} = \frac{k}{2}$. This equals the additive identity 0 only if $k = 0$, which is not allowed ($k > 0$). Hence $k \cdot \frac{1}{2} \neq 0$ for all $k > 0$, so $|\frac{1}{2}| = \infty$. The same argument shows every nonzero $q \in \mathbb{Q}$ has infinite additive order: $kq = 0$ with $q \neq 0$ forces $k = 0$. Sanity check: $\mathbb{Q}$ is torsion-free under $+$; the only finite-order element is 0 itself, with $|0| = 1$. This is exactly why $(\mathbb{Q}, +)$ cannot be isomorphic to any finite $\mathbb{Z}/n\mathbb{Z}$.

Worked Example 1.1.33 (An element of infinite order in $(\mathbb{R}^\times, \cdot)$)**.** Show $2 \in (\mathbb{R}^\times, \cdot)$ has infinite order; then show $|-1| = 2$ to highlight the contrast.

Recognition. "Infinite order" in a multiplicative group: prove no positive power equals the identity 1. The trigger is the multiplicative identity 1 versus the powers 2^k.

Solution. For $k > 0$, $2^k \geq 2 > 1$, so $2^k \neq 1$ for every $k > 0$; hence $|2| = \infty$. (Same for any real t with $|t| > 1$, or $0 < |t| < 1$: $|t^k| = |t|^k \neq 1$ for all $k \geq 1$.) By contrast, -1 has $|-1| = 1$ and $(-1)^2 = 1$ with $(-1)^1 = -1 \neq 1$, so $|-1| = 2$. Sanity check: in $(\mathbb{R}^\times, \cdot)$ the only finite-order elements are 1 ($|| = 1$) and -1 ($|| = 2$); these are exactly the real solutions of $x^k = 1$, namely the real roots of unity. ■

Worked Example 1.1.34 (Infinite order via a homomorphism to $\mathbb{Z}$)**.** In $(\mathbb{Q}^\times, \cdot)$ show $|3| = \infty$ by mapping to $(\mathbb{Z}, +)$.

Recognition. When direct power-listing is awkward, look for a homomorphism φ into a torsion-free group: if $\varphi(x)$ has infinite order, so does x. The 3-adic valuation v_3 is such a map.

Solution. Let $v_3 : \mathbb{Q}^\times \to \mathbb{Z}$ send a rational to the exponent of 3 in its prime factorization; it is a homomorphism: $v_3(xy) = v_3(x) + v_3(y)$. The square below commutes (top: multiply two rationals; map down by v_3; bottom: add the valuations):

$$\begin{array}{ccc} \mathbb{Q}^\times \times \mathbb{Q}^\times & \xrightarrow{\ m\ } & \mathbb{Q}^\times \\ \Big\downarrow{\scriptstyle v_3 \times v_3} & & \Big\downarrow{\scriptstyle v_3} \\ \mathbb{Z} \times \mathbb{Z} & \xrightarrow[\ +\ ]{} & \mathbb{Z} \end{array}$$

Diagram explanation. Objects: Four groups: $\mathbb{Q}^\times \times \mathbb{Q}^\times$ (the direct product of the multiplicative group of nonzero rationals with itself), $\mathbb{Q}^\times$ (nonzero rationals under multiplication), $\mathbb{Z} \times \mathbb{Z}$ (the direct product of the integers under addition), and $\mathbb{Z}$ (integers under addition). The top row lives in the multiplicative world; the bottom row in the additive world.

Arrows: $m : \mathbb{Q}^\times \times \mathbb{Q}^\times \to \mathbb{Q}^\times$ is the group multiplication $(x, y) \mapsto xy$. The left vertical $v_3 \times v_3 : (x, y) \mapsto (v_3(x), v_3(y))$ applies the 3-adic valuation componentwise. The right vertical $v_3 : \mathbb{Q}^\times \to \mathbb{Z}$ sends a nonzero rational to the exponent of 3 in its prime factorization (negative for denominator factors). The bottom $+ : \mathbb{Z} \times \mathbb{Z} \to \mathbb{Z}$ is ordinary integer addition $(a, b) \mapsto a + b$.

What commutes: Going right-then-down equals going down-then-right: $v_3(xy) = v_3(x) + v_3(y)$ for all $x, y \in \mathbb{Q}^\times$.

Why it commutes: This is precisely the statement that v_3 is a group homomorphism from $(\mathbb{Q}^\times, \cdot)$ to $(\mathbb{Z}, +)$. For any nonzero rationals $x = 3^a \frac{p}{q}$ and $y = 3^b \frac{r}{s}$ (with $3 \nmid p, q, r, s$), the product $xy = 3^{a+b} \frac{pr}{qs}$ has $v_3(xy) = a + b = v_3(x) + v_3(y)$.

Why this matters here: The diagram is used to prove $|3| = \infty$ in $(\mathbb{Q}^\times, \cdot)$ without listing powers. Since v_3 is a homomorphism into the torsion-free group $(\mathbb{Z}, +)$ and $v_3(3) = 1$ has infinite additive order, 3 itself must have infinite multiplicative order. The commutativity square makes the homomorphism property precise and visible.

Concrete example: Take $x = 6 = 2 \cdot 3$ and $y = \frac{3}{5}$. Then $v_3(x) = 1$, $v_3(y) = 1$, and $xy = \frac{18}{5} = 2 \cdot 3^2 \cdot 5^{-1}$, so $v_3(xy) = 2 = 1 + 1$. The square commutes for this pair.

Common pitfall: Students sometimes think v_3 lands in $\mathbb{Z}_{\geq 0}$; in fact $v_3(\frac{1}{3}) = -1 \in \mathbb{Z}$, so the codomain must be all of $\mathbb{Z}$, not just the nonneg integers.

Takeaway: The point of this diagram is that a homomorphism into a torsion-free group transfers the problem of infinite order from $\mathbb{Q}^\times$ to $\mathbb{Z}$, where it is obvious.

Now $v_3(3^k) = k$. If $3^k = 1$ for some $k > 0$ then $k = v_3(3^k) = v_3(1) = 0$, contradicting $k > 0$. Hence $|3| = \infty$. Sanity check: directly, $3^k \geq 3 > 1$ for $k > 0$, confirming no positive power is 1. ■

One unifying commutative diagram

For a cyclic group the assignment $k \mapsto x^k$ is the universal way orders appear. If $|x| = n < \infty$, the homomorphism $\mathbb{Z} \to G$, $k \mapsto x^k$, has kernel exactly $n\mathbb{Z}$ and factors uniquely through $\mathbb{Z}/n\mathbb{Z}$; if $|x| = \infty$, the map is injective (kernel $\{0\}$), so $\langle x \rangle \cong \mathbb{Z}$:

$$1 \longrightarrow n\mathbb{Z} \hookrightarrow \mathbb{Z} \xrightarrow{k \mapsto x^k} \langle x \rangle \longrightarrow 1$$

Diagram explanation. Objects: Five terms: the trivial group 1, the subgroup $n\mathbb{Z} \leq \mathbb{Z}$ of multiples of n (a normal subgroup of $\mathbb{Z}$), the group $\mathbb{Z}$ of integers, the cyclic subgroup $\langle x \rangle \leq G$ (a group generated by a single element x of order n), and the trivial group 1 again. This is a short exact sequence of groups.

Arrows: The leftmost $1 \to n\mathbb{Z}$ is the unique map from the trivial group. The map $n\mathbb{Z} \hookrightarrow \mathbb{Z}$ is the inclusion (injective), indicated by the hook arrow. The map $\mathbb{Z} \to \langle x \rangle$, $k \mapsto x^k$, is the evaluation homomorphism

(surjective onto $\langle x\rangle$, indicated by the double-head). The rightmost $\langle x\rangle \to 1$ is the unique map to the trivial group.

What commutes: Exactness at $n\mathbb{Z}$: $\mathrm{im}(1 \to n\mathbb{Z}) = \{0\} = \ker(n\mathbb{Z} \hookrightarrow \mathbb{Z})$ since the inclusion is injective. Exactness at $\mathbb{Z}$: $\mathrm{im}(n\mathbb{Z} \hookrightarrow \mathbb{Z}) = n\mathbb{Z} = \ker(k \mapsto x^k)$ because $x^k = 1$ iff $n \mid k$. Exactness at $\langle x\rangle$: $\mathrm{im}(k \mapsto x^k) = \langle x\rangle = \ker(\langle x\rangle \to 1)$ since the map to the trivial group has full kernel.

Why it commutes: The key exactness condition is at $\mathbb{Z}$: the kernel of $k \mapsto x^k$ is $\{k \in \mathbb{Z} : x^k = 1\}$. Since $|x| = n$, an integer k satisfies $x^k = 1$ if and only if $n \mid k$, i.e. $k \in n\mathbb{Z}$. This is exactly the image of the inclusion, establishing exactness.

Why this matters here: This exact sequence packages the fundamental relationship between $|x|$ and the structure of $\langle x\rangle$: it says $\langle x\rangle \cong \mathbb{Z}/n\mathbb{Z}$ (by the first isomorphism theorem) and makes the kernel $n\mathbb{Z}$ explicit. The diagram appears here to set up the factoring triangle below.

Concrete example: Take $G = \mathbb{Z}/12\mathbb{Z}$, $x = \bar{4}$. Then $|\bar{4}| = 3$ and $\langle\bar{4}\rangle = \{\bar{0}, \bar{4}, \bar{8}\}$. The sequence is $1 \to 3\mathbb{Z} \hookrightarrow \mathbb{Z} \xrightarrow{k\mapsto k\bar{4}} \{\bar{0}, \bar{4}, \bar{8}\} \to 1$; check $k\bar{4} = \bar{0}$ iff $12 \mid 4k$ iff $3 \mid k$, so $\ker = 3\mathbb{Z}$. ■

Common pitfall: Students sometimes confuse the subgroup $n\mathbb{Z} \leq \mathbb{Z}$ with the quotient group $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/n\mathbb{Z}$; these are different objects. The sequence records the kernel of the evaluation map as the *subgroup* $n\mathbb{Z}$, not as a quotient.

Takeaway: The point of this diagram is that the order of x is the unique positive integer n for which the kernel of the evaluation map $\mathbb{Z} \to \langle x\rangle$ is exactly $n\mathbb{Z}$, encoding $\langle x\rangle \cong \mathbb{Z}/n\mathbb{Z}$.

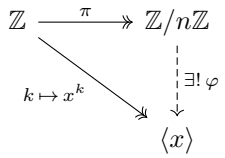

Diagram explanation. Objects: Three groups: $\mathbb{Z}$ (integers under addition), $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/n\mathbb{Z}$ (the quotient group of residue classes mod n, order n), and $\langle x\rangle$ (the cyclic subgroup of G generated by x, where $|x| = n < \infty$).

Arrows: $\pi : \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$, $k \mapsto \bar{k}$, is the canonical surjection (the quotient map killing $n\mathbb{Z}$), shown with a double-head. The diagonal $k \mapsto x^k$ is the evaluation homomorphism, a surjection onto $\langle x\rangle$ with kernel $n\mathbb{Z}$. The dashed vertical $\varphi : \mathbb{Z}/n\mathbb{Z} \to \langle x\rangle$ is the unique induced isomorphism given by the universal property of the quotient; it sends $\bar{k} \mapsto x^k$.

What commutes: The triangle commutes: $\varphi \circ \pi = (k \mapsto x^k)$, i.e., $\varphi(\bar{k}) = x^k$ for all $k \in \mathbb{Z}$.

Why it commutes: Well-definedness of φ: if $\bar{k} = \bar{k'}$ then $k \equiv k' \pmod n$, so $n \mid (k - k')$, so $x^{k-k'} = 1$ (since $|x| = n$), giving $x^k = x^{k'}$. Hence $\varphi(\bar{k}) := x^k$ does not depend on the coset representative, and the universal property of $\mathbb{Z}/n\mathbb{Z}$ produces a unique such φ making the triangle commute. Injectivity: $\varphi(\bar{k}) = 1$ means $x^k = 1$ means $n \mid k$ means $\bar{k} = \bar{0}$.

Why this matters here: This is the universal-property factoring that characterizes all finite cyclic groups: any surjection $\mathbb{Z} \to \langle x\rangle$ with kernel $n\mathbb{Z}$ factors uniquely through $\mathbb{Z}/n\mathbb{Z}$, giving an isomorphism $\mathbb{Z}/n\mathbb{Z} \cong \langle x\rangle$. The diagram unifies the earlier short exact sequence with the explicit structure of $\langle x\rangle$.

Concrete example: Take $G = S_3$ and $x = (1\,2\,3)$. Then $|x| = 3$, $\langle x\rangle = \{e, (1\,2\,3), (1\,3\,2)\}$, and $n = 3$. The induced $\varphi : \mathbb{Z}/3\mathbb{Z} \to \langle x\rangle$ sends $\bar{0} \mapsto e$, $\bar{1} \mapsto (1\,2\,3)$, $\bar{2} \mapsto (1\,3\,2)$, an isomorphism.

Common pitfall: The dashed arrow exists and is unique ONLY because $\ker(k \mapsto x^k) = n\mathbb{Z} = \ker \pi$. If $|x|$ were infinite (kernel $\{0\}$), or a different finite value, the dashed arrow to $\mathbb{Z}/n\mathbb{Z}$ would not be an isomorphism (or might not exist as drawn).

Takeaway: The point of this diagram is that every cyclic group of finite order n is canonically isomorphic to $\mathbb{Z}/n\mathbb{Z}$, with the isomorphism uniquely determined by where a generator x maps under the universal quotient.

Thus $|x|$ is precisely the unique n with $\ker(k \mapsto x^k) = n\mathbb{Z}$ (and $|x| = \infty$ exactly when that kernel is $\{0\}$).

Caution. Lagrange tells you $|\bar{a}|$ divides $\varphi(n)$ in $(\mathbb{Z}/n\mathbb{Z})^\times$, but NOT that it equals $\varphi(n)$. In $(\mathbb{Z}/15\mathbb{Z})^\times$ every element has order $1, 2$, or 4, none equal to $\varphi(15) = 8$, so $(\mathbb{Z}/15\mathbb{Z})^\times$ has no generator. Always test the candidate divisors; do not assume the group is cyclic.

Further examples: small Cayley tables for $\mathbb{Z}/n\mathbb{Z}$ and $(\mathbb{Z}/n\mathbb{Z})^\times$, and orders in other groups

Dummit & Foote introduce $\mathbb{Z}/n\mathbb{Z}$ and $(\mathbb{Z}/n\mathbb{Z})^\times$ very concretely, listing the units mod n by the gcd criterion and computing orders of elements; they also compute orders in the first non-cyclic and infinite groups of the text ($\mathbb{R}^\times$, S_3, the dihedral group D_8 of the square, Q_8, and $\mathrm{GL}_2(\mathbb{R})$). We add the explicit Cayley tables and those element-order computations here.

Remark 1.1.11. D&F write the elements of $\mathbb{Z}/n\mathbb{Z}$ as the bars $\bar{a}$ (or $\overline{a}$), where $\bar{a} = \bar{b}$ exactly when $n \mid (a-b)$. The set $\mathbb{Z}/n\mathbb{Z}$ carries *two* natural operations, $+$ and $\times$, but only $(\mathbb{Z}/n\mathbb{Z}, +)$ is a group for every n; under $\times$ one passes to the units $(\mathbb{Z}/n\mathbb{Z})^\times$ to get a group. The phrase "the integers mod n" refers to the additive group, while "$(\mathbb{Z}/n\mathbb{Z})^\times$" or "the units mod n" refers to the multiplicative group.

Remark 1.1.12. For *every* $n \geq 1$ the additive group $(\mathbb{Z}/n\mathbb{Z}, +)$ is generated by the single element $\bar{1}$, since $\bar{k} = k \cdot \bar{1}$ for all k. Thus $\mathbb{Z}/n\mathbb{Z} = \langle \bar{1} \rangle$ is cyclic of order n. This is the model D&F use whenever they say "the cyclic group of order n."

Remark 1.1.13. D&F denote the dihedral group of symmetries of a regular m-gon by D_{2m}, indexed by its *order* $2m$, not by m. So the symmetry group of the square has order 8 and is written $D_8 = \langle r, s \rangle$ with $r^4 = s^2 = 1$ and $sr = r^{-1}s$ (some texts call this group D_4). We keep D&F's convention throughout.

The additive table of $(\mathbb{Z}/n\mathbb{Z}, +)$

Worked Example 1.1.35 (The complete addition table of $(\mathbb{Z}/6\mathbb{Z}, +)$)**.** Write out the Cayley table for $(\mathbb{Z}/6\mathbb{Z}, +)$ and read off the inverse of each element.

Recognition. This is the defining operation $\bar{a} + \bar{b} = \overline{a+b}$ of Definition 1.1.21 applied to every pair; the table makes the group axioms (closure, identity row/column, a unique $\bar{0}$ in each row giving inverses) visible at a glance.

Solution. Entries are $\overline{a+b}$ mod 6:

$+$	$\bar{0}$	$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$
$\bar{0}$	$\bar{0}$	$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$
$\bar{1}$	$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{0}$
$\bar{2}$	$\bar{2}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{0}$	$\bar{1}$
$\bar{3}$	$\bar{3}$	$\bar{4}$	$\bar{5}$	$\bar{0}$	$\bar{1}$	$\bar{2}$
$\bar{4}$	$\bar{4}$	$\bar{5}$	$\bar{0}$	$\bar{1}$	$\bar{2}$	$\bar{3}$
$\bar{5}$	$\bar{5}$	$\bar{0}$	$\bar{1}$	$\bar{2}$	$\bar{3}$	$\bar{4}$

The $\bar{0}$ entries locate inverses: $-\bar{0} = \bar{0}$, $-\bar{1} = \bar{5}$, $-\bar{2} = \bar{4}$, $-\bar{3} = \bar{3}$, $-\bar{4} = \bar{2}$, $-\bar{5} = \bar{1}$, matching $-\bar{a} = \overline{6-a}$. The table is symmetric across the main diagonal, recording that $(\mathbb{Z}/6\mathbb{Z}, +)$ is abelian. Sanity check: each row is a permutation of the six classes (the Latin-square property every group table has). ■

The multiplication table of $(\mathbb{Z}/n\mathbb{Z})^\times$

Worked Example 1.1.36 (The complete multiplication table of $(\mathbb{Z}/8\mathbb{Z})^\times$)**.** List $(\mathbb{Z}/8\mathbb{Z})^\times$, write out its multiplication table, and find the order of each element.

Recognition. "List $(\mathbb{Z}/n\mathbb{Z})^\times$" invokes the gcd filter (Prop. 1.1.22); the table then exhibits the multiplicative group structure, and orders are read directly from the diagonal of squares.

Solution. $\gcd(a, 8) = 1$ for $a \in \{1, 3, 5, 7\}$, so $(\mathbb{Z}/8\mathbb{Z})^\times = \{\bar{1}, \bar{3}, \bar{5}, \bar{7}\}$ and $\varphi(8) = 4$. Entries $\overline{ab}$ mod 8:

$\times$	$\bar{1}$	$\bar{3}$	$\bar{5}$	$\bar{7}$
$\bar{1}$	$\bar{1}$	$\bar{3}$	$\bar{5}$	$\bar{7}$
$\bar{3}$	$\bar{3}$	$\bar{1}$	$\bar{7}$	$\bar{5}$
$\bar{5}$	$\bar{5}$	$\bar{7}$	$\bar{1}$	$\bar{3}$
$\bar{7}$	$\bar{7}$	$\bar{5}$	$\bar{3}$	$\bar{1}$

Every diagonal square is $\bar{1}$: $3^2 = 9 \equiv \bar{1}$, $5^2 = 25 \equiv \bar{1}$, $7^2 = 49 \equiv \bar{1}$. Hence $|\bar{3}| = |\bar{5}| = |\bar{7}| = 2$ and $|\bar{1}| = 1$. So $(\mathbb{Z}/8\mathbb{Z})^\times$ has no element of order $4 = \varphi(8)$; it is the Klein four-group, $(\mathbb{Z}/8\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, NOT

cyclic. Sanity check: each element is its own inverse, consistent with $x^2 = \bar{1}$ throughout; every order divides $\varphi(8) = 4$. ■

Worked Example 1.1.37 (($\mathbb{Z}/n\mathbb{Z}$)$^\times$ for $n = 5, 7, 9, 10$: which are cyclic)**.** Determine $(\mathbb{Z}/n\mathbb{Z})^\times$ and the order of a small candidate generator for $n = 5, 7, 9, 10$, and state which of these unit groups is cyclic.

Recognition. D&F use small moduli to illustrate that some $(\mathbb{Z}/n\mathbb{Z})^\times$ have a generator (a single power runs through all units) and some do not. Lagrange limits the orders to divisors of $\varphi(n)$.

Solution. $n = 5$: $(\mathbb{Z}/5\mathbb{Z})^\times = \{\bar{1}, \bar{2}, \bar{3}, \bar{4}\}$, $\varphi(5) = 4$. Powers of $\bar{2}$: $2, 4, 3, 1$, so $|\bar{2}| = 4$ and $\bar{2}$ is a generator; $(\mathbb{Z}/5\mathbb{Z})^\times$ is cyclic. $n = 7$: $(\mathbb{Z}/7\mathbb{Z})^\times = \{\bar{1}, \ldots, \bar{6}\}$, $\varphi(7) = 6$. Powers of $\bar{3}$: $3, 2, 6, 4, 5, 1$, so $|\bar{3}| = 6$; $(\mathbb{Z}/7\mathbb{Z})^\times$ is cyclic. $n = 9$: $(\mathbb{Z}/9\mathbb{Z})^\times = \{\bar{1}, \bar{2}, \bar{4}, \bar{5}, \bar{7}, \bar{8}\}$, $\varphi(9) = 6$. Powers of $\bar{2}$: $2, 4, 8, 7, 5, 1$, so $|\bar{2}| = 6$; $(\mathbb{Z}/9\mathbb{Z})^\times$ is cyclic. $n = 10$: $(\mathbb{Z}/10\mathbb{Z})^\times = \{\bar{1}, \bar{3}, \bar{7}, \bar{9}\}$, $\varphi(10) = 4$. Powers of $\bar{3}$: $3, 9, 7, 1$, so $|\bar{3}| = 4$; $(\mathbb{Z}/10\mathbb{Z})^\times$ is cyclic. Sanity check: in each case the listed generator's powers reproduce exactly the $\varphi(n)$ units, and every order divides $\varphi(n)$. (Contrast $(\mathbb{Z}/8\mathbb{Z})^\times$ above and $(\mathbb{Z}/15\mathbb{Z})^\times$ earlier, which are not cyclic.) ■

Orders of elements in the book's first non-cyclic groups

Worked Example 1.1.38 (Orders in S_3)**.** In the symmetric group S_3 (permutations of $\{1, 2, 3\}$, composed right-to-left), compute the order of each element.

Recognition. D&F compute orders in S_3 soon after defining order, to show finite groups can have several different orders. Disjoint-cycle structure determines order: a single k-cycle has order k.

Solution. The six elements are the identity, three transpositions, and two 3-cycles. As cycles:

σ	type	$\lvert\sigma\rvert$
id	identity	1
$(1\,2)$, $(1\,3)$, $(2\,3)$	transposition	2
$(1\,2\,3)$, $(1\,3\,2)$	3-cycle	3

Check a transposition: $(1\,2)^2 = \mathrm{id}$, and $(1\,2) \neq \mathrm{id}$, so order 2. Check a 3-cycle: $(1\,2\,3)^2 = (1\,3\,2) \neq \mathrm{id}$, $(1\,2\,3)^3 = \mathrm{id}$, so order 3. Sanity check: $|S_3| = 6$ and the orders $1, 2, 3$ all divide 6; no element has order 6, so S_3 is not cyclic. ■

Worked Example 1.1.39 (Orders in the dihedral group D_8)**.** In $D_8 = \langle r, s\rangle$ with $r^4 = s^2 = 1$ and $sr = r^{-1}s$, find the order of every element.

Recognition. D&F use the dihedral groups as a standard source of mixed orders: a rotation r^k has order $4/\gcd(k, 4)$, while every reflection sr^k squares to the identity.

Solution. The eight elements are $1, r, r^2, r^3, s, sr, sr^2, sr^3$. Rotations: $|1| = 1$, $|r| = |r^3| = 4$, $|r^2| = 2$. Reflections: each satisfies $(sr^k)^2 = sr^k sr^k = s(r^k s)r^k = s(sr^{-k})r^k = s^2 = 1$, using $r^k s = sr^{-k}$; and $sr^k \neq 1$, so $|sr^k| = 2$ for $k = 0, 1, 2, 3$. Collected:

g	1	r	r^2	r^3	s	sr	sr^2	sr^3
$\lvert g\rvert$	1	4	2	4	2	2	2	2

Sanity check: all orders divide $|D_8| = 8$; there are exactly $\varphi(4) = 2$ elements of order 4 inside the rotation subgroup $\langle r\rangle \cong \mathbb{Z}/4\mathbb{Z}$, namely r and r^3, as the cyclic theory predicts. ■

Worked Example 1.1.40 (Orders in the quaternion group Q_8)**.** In $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$ and $ij = k$, find the order of every element.

Recognition. D&F present Q_8 as a group where, unlike D_8, there is a *unique* element of order 2 and every non-identity element except -1 has order 4. Use $i^2 = j^2 = k^2 = -1$ and $(-1)^2 = 1$.

Solution. $|1| = 1$. Since $(-1)^2 = 1$ and $-1 \neq 1$, $|-1| = 2$. For i: $i^2 = -1$, $i^3 = -i$, $i^4 = (-1)^2 = 1$, so $|i| = 4$; the same computation gives $|-i| = |j| = |-j| = |k| = |-k| = 4$.

g	value	$\lvert g\rvert$
1	1	1
-1	-1	2
$\pm i$, $\pm j$, $\pm k$	square to -1	4

Sanity check: all orders divide $|Q_8| = 8$; there is exactly one element of order 2 (namely -1), in contrast with D_8, which has five (the half-turn r^2 and the four reflections). So D_8 and Q_8 are non-isomorphic groups of the same order. ■

Worked Example 1.1.41 (Infinite order in $\mathrm{GL}_2(\mathbb{R})$)**.** Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \mathrm{GL}_2(\mathbb{R})$. Show $|A| = \infty$, and contrast with $B = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, which has finite order.

Recognition. D&F use GL_n as the standard infinite group in which individual elements may still have finite or infinite order. Compute the powers directly.

Solution. By induction $A^k = \begin{pmatrix} 1 & k \\ 0 & 1 \end{pmatrix}$. For $k > 0$ the top-right entry is $k \neq 0$, so $A^k \neq I$ for every $k \geq 1$; hence $|A| = \infty$. For B: $B^2 = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = -I$, $B^3 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$, $B^4 = I$, so $|B| = 4$ (this B is rotation by $90°$). Sanity check: $\det A = \det B = 1 \neq 0$, so both lie in $\mathrm{GL}_2(\mathbb{R})$; a single group can contain elements of every order, finite and infinite. ■

Remark 1.1.14. The contrast across these examples is the recurring D&F theme. The additive groups $(\mathbb{R}, +)$, $(\mathbb{Q}, +)$, $(\mathbb{Z}, +)$ are *torsion-free*: the identity 0 is the only element of finite order ($|0| = 1$), since $kx = 0$ with $k > 0$ forces $x = 0$. The multiplicative group $(\mathbb{R}^\times, \cdot)$ has just two elements of finite order, $|1| = 1$ and $|-1| = 2$, and $(\mathbb{Q}^\times, \cdot)$ has the same two. By comparison the finite groups $\mathbb{Z}/n\mathbb{Z}$, $(\mathbb{Z}/n\mathbb{Z})^\times$, S_3, D_8, Q_8 realize a whole range of orders. Passing from $+$ to $\times$, or from $\mathbb{Z}$ to $\mathbb{Z}/n\mathbb{Z}$, is exactly what creates nontrivial finite orders.

Exercises (from the text).

1. Determine which of the operations are associative: (a) $a * b = a - b$ on $\mathbb{Z}$; (b) $a * b = a + b + ab$ on $\mathbb{R}$; (c) $a * b = \frac{a+b}{5}$ on $\mathbb{Q}$; (d) $(a, b) * (c, d) = (ad + bc, bd)$ on $\mathbb{Z} \times \mathbb{Z}$; (e) $a * b = \frac{a}{b}$ on $\mathbb{Q} - \{0\}$.
2. Which operations in Exercise 1 are commutative?
3. Prove that addition of residue classes in $\mathbb{Z}/n\mathbb{Z}$ is associative.
4. Prove that multiplication of residue classes in $\mathbb{Z}/n\mathbb{Z}$ is associative.
5. Prove for all $n > 1$ that $\mathbb{Z}/n\mathbb{Z}$ is not a group under multiplication.
6. Which of these are groups under addition? (a) lowest-terms rationals with *odd* denominator; (b) with *even* denominator; (c) $|x| < 1$; (d) $|x| \geq 1$ together with 0; (e) denominators 1 or 2; (f) denominators $1, 2$, or 3.
7. $G = \{x \in \mathbb{R} \mid 0 \leq x < 1\}$ with $x * y =$ fractional part of $x + y$. Show $*$ is a well-defined binary operation and G is abelian.
8. $G = \{z \in \mathbb{C} \mid z^n = 1 \text{ for some } n \in \mathbb{Z}^+\}$ (roots of unity). (a) Group under multiplication; (b) not a group under addition.
9. $G = \{a + b\sqrt{2} \mid a, b \in \mathbb{Q}\}$. (a) Group under addition; (b) nonzero elements form a group under multiplication.
10. Prove a finite group is abelian iff its group table is symmetric.
11. Find the orders of every element of the additive group $\mathbb{Z}/12\mathbb{Z}$.
12. Find the orders of $\bar{1}, \overline{-1}, \bar{5}, \bar{7}, \overline{-7}, \overline{13}$ in $(\mathbb{Z}/12\mathbb{Z})^\times = \{1, 5, 7, 11\}$.
13. Find the orders of $\bar{1}, \bar{2}, \bar{6}, \bar{9}, \overline{10}, \overline{12}, \overline{-1}, \overline{-10}, \overline{-18}$ in $\mathbb{Z}/36\mathbb{Z}$.
14. Find the orders of $\bar{1}, \overline{-1}, \bar{5}, \overline{13}, \overline{-13}, \overline{17}$ in $(\mathbb{Z}/36\mathbb{Z})^\times$.
15. Prove $(a_1 a_2 \cdots a_n)^{-1} = a_n^{-1} a_{n-1}^{-1} \cdots a_1^{-1}$.
16. Prove $x^2 = 1$ iff $|x|$ is 1 or 2.
17. If $|x| = n$, prove $x^{-1} = x^{n-1}$.

18. Prove $xy = yx \iff y^{-1}xy = x \iff x^{-1}y^{-1}xy = 1$.
19. For $x \in G$, $a, b \in \mathbb{Z}^+$: (a) $x^{a+b} = x^a x^b$, $(x^a)^b = x^{ab}$; (b) $(x^a)^{-1} = x^{-a}$; (c) extend (a) to all integers.
20. Show that x and x^{-1} have the same order.
21. G finite, $|x| = n$ odd. Prove $x = (x^2)^k$ for some k.
22. Prove $|x| = |g^{-1}xg|$, and deduce $|ab| = |ba|$.
23. $|x| = n < \infty$, $n = st$. Prove $|x^s| = t$.
24. If a, b commute, prove $(ab)^n = a^n b^n$ for all $n \in \mathbb{Z}$.
25. Prove that if $x^2 = 1$ for all $x \in G$, then G is abelian.
26. If $\varnothing \neq H \subseteq G$ is closed under the operation and inverses, prove H is a **subgroup**.
27. Prove $\{x^n \mid n \in \mathbb{Z}\}$ is a subgroup (the cyclic subgroup $\langle x \rangle$).
28. Verify the group axioms for $A \times B$.
29. Prove $A \times B$ is abelian iff both A and B are.
30. Show $(a, 1), (1, b)$ commute and $|(a, b)| = \operatorname{lcm}(|a|, |b|)$.
31. Prove a finite group of even order contains an element of order 2.
32. If $|x| = n$, prove $1, x, \ldots, x^{n-1}$ are distinct, and $|x| \leq |G|$.
33. $|x| = n$. (a) n odd $\Rightarrow x^i \neq x^{-i}$ $(1 \leq i \leq n-1)$; (b) $n = 2k \Rightarrow x^i = x^{-i}$ iff $i = k$ $(1 \leq i \leq n-1)$.
34. If x has infinite order, prove the powers x^n are distinct.
35. If $|x| = n$, show every power of x lies in $\{1, x, \ldots, x^{n-1}\}$.
36. $G = \{1, a, b, c\}$, order 4, no element of order 4. Show the table is unique and G abelian.

Additional exercises.

1. Let $*$ be the binary operation on $\mathbb{Z}$ defined by $a * b = a + b - ab$. (a) Compute $2 * 3$, $(2 * 3) * 4$, and $2 * (3 * 4)$. (b) Determine whether $*$ is commutative and whether it is associative. (c) Show that 0 is an identity for $*$, and find every $a \in \mathbb{Z}$ that has a two-sided $*$-inverse in $\mathbb{Z}$.
2. On the set $S = \mathbb{R} \setminus \{0\}$ define $a \star b = |a|\, b$. (a) Verify that $\star$ is a well-defined binary operation on S (i.e. $a \star b \neq 0$ whenever $a, b \neq 0$). (b) Is $\star$ associative? Is it commutative? Justify each answer with an explicit computation or counterexample. (c) Does $\star$ have a (two-sided) identity element? Prove your claim.
3. Let G be a group and let $a, b, c \in G$. Solve each of the following equations for x in terms of a, b, c, using only the group axioms (give the unique solution in (a) and (c), and name the axiom used at each step): (a) $axb = c$; (b) $xax = a$ given that $x = x^{-1}$ (show that the solutions are exactly the x with $x^2 = 1$ and $xa = ax$, so $x = 1$ always works but need not be the only solution); (c) $axa^{-1} = b$.
4. Recall $(\mathbb{Z}/n\mathbb{Z})^\times$ is the set of residues $\overline{a}$ with $\gcd(a, n) = 1$ under multiplication mod n. (a) List the elements of $(\mathbb{Z}/15\mathbb{Z})^\times$, and compute $\overline{2} \cdot \overline{8}$, $\overline{4} \cdot \overline{4}$, and $\overline{7} \cdot \overline{13}$ in $(\mathbb{Z}/15\mathbb{Z})^\times$. (b) Find $\overline{7}^{-1}$ in $(\mathbb{Z}/15\mathbb{Z})^\times$ by exhibiting an integer x with $7x \equiv 1 \pmod{15}$. (c) Explain why $\overline{6}$ is NOT an element of $(\mathbb{Z}/15\mathbb{Z})^\times$, and why this is exactly what is needed for $((\mathbb{Z}/n\mathbb{Z})^\times, \cdot\,)$ to be a group.
5. In a group G, prove the "socks and shoes" rule: for all $a, b \in G$, $(ab)^{-1} = b^{-1}a^{-1}$. Then prove by induction that $(a_1 a_2 \cdots a_k)^{-1} = a_k^{-1} \cdots a_2^{-1} a_1^{-1}$ for all $k \geq 1$.
6. Let G be a group in which $x^2 = 1$ for every $x \in G$. (a) Show that $x = x^{-1}$ for all $x \in G$. (b) Using (a), show that G is abelian. (Hint: expand $(ab)^2 = 1$.) (c) Give an explicit example of such a group with exactly 4 elements.
7. Let G be a finite group and fix $a \in G$. Define $L_a \colon G \to G$ by $L_a(x) = ax$. (a) Prove L_a is a bijection of the set G (find its inverse map explicitly). (b) Conclude that each element of G appears exactly once in every row of the group's multiplication (Cayley) table.

Commutative-diagram exercises.

1. Let $\pi\colon \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ be the reduction-mod-n map $\pi(a) = \overline{a}$, and recall it satisfies $\pi(a+b) = \pi(a) + \pi(b)$. (a) Show that the addition on $\mathbb{Z}/n\mathbb{Z}$ is the unique operation making the square

$$\begin{array}{ccc} \mathbb{Z} \times \mathbb{Z} & \xrightarrow{\;+\;} & \mathbb{Z} \\ {\scriptstyle \pi\times\pi}\downarrow & & \downarrow{\scriptstyle \pi} \\ \mathbb{Z}/n\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} & \xrightarrow[\;\oplus\;]{} & \mathbb{Z}/n\mathbb{Z} \end{array}$$

   commute (i.e. $\pi(a) \oplus \pi(b) = \pi(a+b)$ for all a, b); this is what "well-defined mod n" means. (b) State and verify the analogous commuting square for multiplication, replacing $+$ by $\cdot$ and $\oplus$ by the product on $\mathbb{Z}/n\mathbb{Z}$.

2. Consider the two compositions $\mathbb{Z} \xrightarrow{f} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/6\mathbb{Z}$, where π is reduction mod 6 and $f(a) = 3a$. (a) Compute the image of the composite $\pi \circ f\colon \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ by listing $(\pi \circ f)(a)$ for $a = 0, 1, 2, 3$. (b) Identify the set of $a \in \mathbb{Z}$ with $(\pi \circ f)(a) = \overline{0}$, and describe it as $m\mathbb{Z}$ for the appropriate integer m. (c) Draw the diagram exhibiting $\pi \circ f$ as a single arrow $\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ and label that arrow with the rule $a \mapsto \overline{3a}$.

3. For a binary operation $*$ on a set A, the operation is a map $m\colon A \times A \to A$, $m(a, b) = a * b$. The operation is commutative exactly when the triangle built from the swap map $\tau\colon A \times A \to A \times A$, $\tau(a, b) = (b, a)$, commutes:

$$\begin{array}{ccc} A \times A & \xrightarrow{\;\tau\;} & A \times A \\ & {\scriptstyle m}\searrow & \downarrow{\scriptstyle m} \\ & & A \end{array}$$

   (a) Explain in words what the commutativity of this diagram says about $*$. (b) For $A = \mathbb{Z}$ and $a * b = a - b$, exhibit a specific pair (a, b) for which the diagram fails to commute, thereby proving subtraction is not commutative.

4. Let $\varphi\colon \mathbb{Z} \to \mathbb{Z}/12\mathbb{Z}$ be reduction mod 12, a surjection of additive groups. Define its kernel $K = \{\, a \in \mathbb{Z} \mid \varphi(a) = \overline{0} \,\}$. (a) Show $K = 12\mathbb{Z}$, and complete the labels in the sequence

$$0 \longrightarrow K \xhookrightarrow{\;\iota\;} \mathbb{Z} \xrightarrow{\;\varphi\;} \mathbb{Z}/12\mathbb{Z} \longrightarrow 0$$

   by giving the inclusion ι explicitly. (b) For the element $\overline{8} \in \mathbb{Z}/12\mathbb{Z}$, list three different integers a with $\varphi(a) = \overline{8}$, and explain how any two of them differ by an element of K.

5. (Intro pullback / fiber product.) Let $\mu\colon \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ be reduction mod 2, $\mu(a) = \overline{a}$. Form the set

$$P = \{\, (a, b) \in \mathbb{Z} \times \mathbb{Z} \mid a \equiv b \pmod 2 \,\} = \{\, (a, b) \in \mathbb{Z} \times \mathbb{Z} \mid \mu(a) = \mu(b) \,\},$$

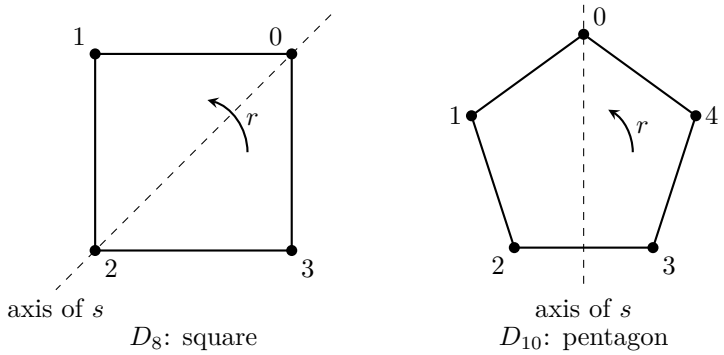
   the pullback (fiber product) of μ with itself, fitting into the square

$$\begin{array}{ccc} P & \xrightarrow{\;p_2\;} & \mathbb{Z} \\ {\scriptstyle p_1}\downarrow & & \downarrow{\scriptstyle \mu} \\ \mathbb{Z} & \xrightarrow[\;\mu\;]{} & \mathbb{Z}/2\mathbb{Z} \end{array}$$

   where $p_1(a, b) = a$ and $p_2(a, b) = b$ are the two coordinate projections. (a) Verify that this square commutes: show $\mu(a) = \mu(b)$ for every $(a, b) \in P$. (b) Show P is closed under coordinatewise addition, so $(P, +)$ is a group; exhibit its identity and the inverse of a typical element (a, b). (c) Exhibit one element of P and one element of $\mathbb{Z} \times \mathbb{Z}$ that is NOT in P, justifying each membership decision by the mod-2 condition.

1.2 Dihedral Groups

The dihedral group D_{2n}: symmetries of a regular n-gon



Definition 1.2.1 (Dihedral group)**.** Fix $n \geq 3$. Label the vertices of a regular n-gon $0, 1, \ldots, n-1$ counterclockwise. The *dihedral group* D_{2n} is the group of all rigid symmetries (rotations and reflections) of this polygon under composition. It is generated by

$$r = \text{rotation counterclockwise by } 2\pi/n, \qquad s = \text{reflection across the axis through vertex } 0,$$

subject to the relations

$$r^n = 1, \qquad s^2 = 1, \qquad srs = r^{-1} \quad (\text{equivalently } sr = r^{-1}s, \;\; r^k s = sr^{-k}).$$

Here is the square (D_8, $n = 4$) with the rotation r and the reflection axis fixed by s (for even n the axis through vertex 0 is a diagonal, passing through the opposite vertex $n/2$, here vertex 2), and the pentagon (D_{10}, $n = 5$) with r and the axis of s (for odd n the axis through vertex 0 passes through the midpoint of the opposite edge):

D_8: square $\qquad$ D_{10}: pentagon

Proposition 1.2.2 (Order and normal form)**.** $|D_{2n}| = 2n$*, and every element of* D_{2n} *can be written* uniquely *in one of the two normal forms*

$$r^i \quad (\textit{a rotation}), \qquad sr^i \quad (\textit{a reflection}), \qquad 0 \leq i < n.$$

Thus $D_{2n} = \{1, r, \ldots, r^{n-1}, s, sr, \ldots, sr^{n-1}\}$*, a disjoint union of* n *rotations and* n *reflections.*

Proof. Since $r^n = 1$, the rotations are exactly $\{r^i : 0 \leq i < n\}$, n in number. The relation $sr = r^{-1}s$ lets us move every s to the *left* of every r: any word in r, s collapses to $s^a r^i$ with $a \in \{0, 1\}$ (using $s^2 = 1$) and $0 \leq i < n$ (using $r^n = 1$). Hence every element is r^i or sr^i, giving at most $2n$ elements. Geometrically r has order n (a rotation by $2\pi/n$) and $s \neq r^i$ for any i (a reflection reverses orientation; rotations preserve it), so the two families are disjoint and the $2n$ listed symmetries are distinct. The polygon has exactly $2n$ symmetries (a vertex 0 can go to any of n positions, then orientation can be preserved or reversed: $n \cdot 2 = 2n$), so $|D_{2n}| = 2n$ and the listing is complete; uniqueness of r^i vs. sr^i and of the exponent i follows from $|D_{2n}| = 2n$. □

Proposition 1.2.3 (Orders of elements)**.** *In* D_{2n}*:*

$$|r^k| = \frac{n}{\gcd(n, k)}, \qquad |sr^i| = 2 \;\; \textit{for every } i.$$

In particular r *has order* n*, and all* n *reflections are involutions.*

Proof. Inside the cyclic subgroup $\langle r \rangle \cong \mathbb{Z}/n\mathbb{Z}$ the order of r^k is $n/\gcd(n, k)$ (standard cyclic-group fact). For a reflection,

$$(sr^i)^2 = sr^i \, sr^i = s(r^i s)r^i = s(sr^{-i})r^i = s^2 r^{-i+i} = 1,$$

using $r^i s = sr^{-i}$. Since $sr^i \neq 1$ (it is a reflection, not the identity), $|sr^i| = 2$. □

Method (How to simplify a word and read off the order in D_{2n})**.** *Trigger.* Any product of r's and s's in D_{2n}, e.g. $(sr^a)(sr^b)$, $r^k s r^{-k}$, or $(sr^i)^m$.

1. **Push every s left.** Repeatedly apply $r^k s = sr^{-k}$ to slide each s past any r on its left, flipping that r's exponent sign.
2. **Cancel adjacent s's** via $s^2 = 1$. You end with $s^a r^m$, $a \in \{0, 1\}$.
3. **Reduce the exponent** m modulo n (since $r^n = 1$) to land in $0 \le m < n$.
4. **Read the answer:** r^m is a rotation with $|r^m| = n/\gcd(n, m)$; sr^m is a reflection with order 2.

Mnemonic: "s flips the sign of every r it jumps over." An *even* number of s's gives a rotation; an *odd* number gives a reflection.

Caution. D_{2n} is *non-abelian* for $n \ge 3$: $sr = r^{-1}s \ne rs$ unless $r = r^{-1}$. Never silently commute r past s; you must use $rs = sr^{-1}$ (sign flip), not $rs = sr$.

Worked Example 1.2.4 (Multiply two reflections: $(sr^3)(sr^5)$ in D_{12})**.** In D_{12} (so $n = 6$), compute $(sr^3)(sr^5)$ and put it in normal form. Is the result a rotation or a reflection?

Recognition. This is a product of two reflections (two factors each containing one s): an *even* number of s's, so the answer must be a rotation r^m. Use the method: push the inner s left past r^3.

Solution.

$$(sr^3)(sr^5) = s\,(r^3 s)\,r^5 = s\,(sr^{-3})\,r^5 = s^2 r^{-3} r^5 = r^2.$$

Here $r^3 s = sr^{-3}$ (sign flip), then $s^2 = 1$, then add exponents $-3 + 5 = 2$. Reduce mod $n = 6$: 2 is already in $\{0, \ldots, 5\}$, so the normal form is $\boxed{r^2}$, a rotation. *Check.* $|r^2| = 6/\gcd(6, 2) = 3$. Two reflections compose to a rotation (orientation-reversing twice = orientation-preserving), consistent with getting r^2.

Worked Example 1.2.5 (The conjugate $r^k s r^{-k}$)**.** In D_{2n}, simplify $r^k s r^{-k}$ to normal form. Interpret the result.

Recognition. One s in the middle: odd number of s's, so expect a reflection sr^m. Slide the s to the far left by pushing it past r^k on its left (or equivalently push r^k to the right of s).

Solution. Use $r^k s = sr^{-k}$ on the leftmost pair:

$$r^k s r^{-k} = (r^k s) r^{-k} = (sr^{-k}) r^{-k} = s r^{-k-k} = s r^{-2k}.$$

Reduce the exponent mod n: $sr^{-2k} = sr^{\,n-2k \bmod n}$. Normal form $\boxed{sr^{-2k}}$ (a reflection). *Check.* As a reflection it should square to 1: $(sr^{-2k})^2 = 1$ by Proposition 1.2.3. Geometrically, conjugating the axis of s by the rotation r^k rotates that axis through the angle $2\pi k/n$ (onto the axis through vertex k), i.e. by $2k$ steps of π/n (the angle between neighboring reflection axes), matching the index $-2k$.

Worked Example 1.2.6 (All elements of order 2 in D_8)**.** List every element of D_8 ($n = 4$) of order exactly 2.

Recognition. Order-2 elements are the self-inverse non-identity elements. Split into rotations r^k (use $|r^k| = 4/\gcd(4, k)$) and reflections sr^i (all have order 2).

Solution. Rotations. $|r^0| = 1$; $|r| = 4/\gcd(4, 1) = 4$; $|r^2| = 4/\gcd(4, 2) = 2$; $|r^3| = 4/\gcd(4, 3) = 4$. So the only rotation of order 2 is r^2. *Reflections.* By Proposition 1.2.3, s, sr, sr^2, sr^3 each have order 2. Thus the order-2 elements are

$$\boxed{r^2,\ s,\ sr,\ sr^2,\ sr^3} \qquad (5 \text{ elements}).$$

Check. $|D_8| = 8$; removing 1 (order 1) and r, r^3 (order 4) leaves exactly these 5, all of order 2. $(r^2)^2 = r^4 = 1$ confirms r^2; e.g. $(sr)^2 = sr\,sr = s(rs)r = s(sr^{-1})r = s^2 r^0 = 1$.

Worked Example 1.2.7 (Every reflection is an involution)**.** Show directly that $|sr^i| = 2$ for all i, working in D_{10} ($n = 5$) with $i = 3$ as a concrete instance, then in general.

Recognition. The element sr^i contains one s. Squaring it puts two s's adjacent after one sign-flip; cancel them.

Solution. Concrete (D_{10}, $i = 3$):

$$(sr^3)^2 = sr^3\, sr^3 = s(r^3 s)r^3 = s(sr^{-3})r^3 = s^2 r^0 = 1,$$

and $sr^3 \neq 1$, so $|sr^3| = 2$. *General:* $(sr^i)^2 = s(r^i s)r^i = s(sr^{-i})r^i = s^2 r^{-i+i} = 1$ and $sr^i \neq 1$, hence $|sr^i| = 2$. *Check.* The key step is the single sign flip $r^i s = sr^{-i}$; the two s's then meet and cancel, leaving $r^{-i+i} = r^0 = 1$. Valid for every i and every n.

Worked Example 1.2.8 (Product of two reflections is a rotation; build any rotation)**.** In D_{2n}, show $(sr^a)(sr^b) = r^{\,b-a}$. Use it in D_{10} to write the rotation r^2 as a product of two reflections.

Recognition. Two reflections = even number of s's $\Rightarrow$ a rotation. Push the inner s left past r^a.

Solution. General formula:

$$(sr^a)(sr^b) = s(r^a s)r^b = s(sr^{-a})r^b = s^2 r^{-a+b} = r^{\,b-a}.$$

Application in D_{10} ($n = 5$): to get r^2 we need $b - a \equiv 2 \pmod 5$. Pick $a = 0, b = 2$:

$$(sr^0)(sr^2) = s \cdot sr^2 = r^2. \qquad \text{(Check: } b - a = 2.\text{)}$$

Another choice $a = 1, b = 3$: $(sr)(sr^3) = r^{3-1} = r^2$, same rotation. *Check.* $(s)(sr^2) = s^2 r^2 = r^2$ directly; and any r^m arises since $b - a$ ranges over all residues mod n. This shows the n reflections generate $\langle r \rangle$, hence all of D_{2n}.

Worked Example 1.2.9 (A longer word: $r^2 sr^3 sr$ in D_{14})**.** Simplify $r^2 sr^3 sr$ in D_{14} ($n = 7$) to normal form and give its order.

Recognition. Two s's (even) $\Rightarrow$ rotation. Push each s leftward; each jump over a power of r flips that power's sign.

Solution. Start by sliding the left s past r^3, then the resulting s's cancel:

$$r^2 sr^3 sr = r^2(sr^3)sr = r^2(r^{-3}s)sr = r^{2-3}s^2 r = r^{-1}r = r^0 = 1.$$

(I used $sr^3 = r^{-3}s$, i.e. $sr^k = r^{-k}s$ for all k.) Normal form: $\boxed{1}$. *Check (push both s's the other way).* $r^2 sr^3 sr$; pair the inner block $sr^3 s = (sr^3)s = (r^{-3}s)s = r^{-3}$, so the word is $r^2 \cdot r^{-3} \cdot r = r^{2-3+1} = r^0 = 1$. Same answer, $|1| = 1$.

Worked Example 1.2.10 (Solve for x: $r^3 x = sr$ in D_8)**.** In D_8 ($n = 4$) find the unique x with $r^3 x = sr$, in normal form.

Recognition. Left-multiply by $(r^3)^{-1} = r^{-3} = r^1$ (since $r^4 = 1$). The right side is a reflection, so x will be a reflection.

Solution.

$$x = r^{-3}(sr) = r^1(sr) = (rs)r = (sr^{-1})r = sr^0 = s.$$

Here $rs = sr^{-1}$ (one sign flip). So $\boxed{x = s}$. *Check.* $r^3 x = r^3 s$. And $r^3 s = sr^{-3} = sr^1 = sr$ (since $-3 \equiv 1 \bmod 4$). Indeed $r^3 s = sr$, matching the right-hand side.

The relation $srs = r^{-1}$ says exactly that conjugation by s inverts r; equivalently the map $r \mapsto r^{-1}$, $s \mapsto s$ extends to an automorphism. This is encoded by the commuting square (left) and the fact that s conjugates $\langle r \rangle$ by inversion (right):

$$\begin{array}{ccc} \langle r \rangle & \xrightarrow{\;x \mapsto sxs\;} & \langle r \rangle \\ {\scriptstyle \iota}\big\downarrow & & \big\downarrow{\scriptstyle \iota} \\ D_{2n} & \xrightarrow[\;x \mapsto sxs\;]{} & D_{2n} \end{array} \qquad\qquad r \xmapsto{\text{conj. by } s} r^{-1}$$

Diagram explanation. Objects: The square uses two copies each of two groups: the cyclic rotation subgroup $\langle r\rangle \cong \mathbb{Z}/n\mathbb{Z}$ (upper row) and the full dihedral group D_{2n} (lower row), each appearing twice (once as domain, once as codomain). The right diagram has a single element-level arrow tracking what conjugation does to the generator r.

Arrows: The top horizontal arrow is the map $\langle r\rangle \to \langle r\rangle$, $x \mapsto sxs$ (conjugation by s, restricted to $\langle r\rangle$). The bottom horizontal arrow is the same conjugation formula on all of D_{2n}. The two vertical arrows are the inclusion $\iota\colon \langle r\rangle \hookrightarrow D_{2n}$ (the canonical inclusion homomorphism). The right mini-diagram records the single value $r \mapsto r^{-1}$, confirming that conjugation by s inverts the generator.

What commutes: The square says that inclusion then conjugation equals conjugation then inclusion: for every $x \in \langle r\rangle$, applying the top map and then the right inclusion gives $sxs \in D_{2n}$; applying the left inclusion first and then the bottom map also gives $sxs \in D_{2n}$. These are the same element, so the square commutes: $\iota \circ (x \mapsto sxs) = (x \mapsto sxs) \circ \iota$, where $\iota : \langle r\rangle \hookrightarrow D_{2n}$.

Why it commutes: Chase $x \in \langle r\rangle$, say $x = r^k$. Top then right: $r^k \mapsto sr^k s \mapsto sr^k s \in D_{2n}$. Left then bottom: $r^k \mapsto r^k \in D_{2n} \mapsto sr^k s$. Both give $sr^k s$. The two paths agree because both just compute sxs and include the result; the square is recording compatibility of a formula with an inclusion, not a non-trivial constraint.

Why this matters here: The prose just established $srs = r^{-1}$, which says conjugation by s is not merely a set-map but an automorphism of $\langle r\rangle$ that happens to extend to all of D_{2n}. The square makes that extension visible: the automorphism of $\langle r\rangle$ is the restriction of the conjugation automorphism of D_{2n}. This is the structural content behind the relation $srs = r^{-1}$ and it will recur when proving $\langle r\rangle \trianglelefteq D_{2n}$.

Concrete example: In D_8 ($n = 4$), take $x = r^2 \in \langle r\rangle$. Top path: $r^2 \mapsto sr^2 s = r^{-2} = r^2$. Bottom path: include $r^2 \in D_8$, then $r^2 \mapsto sr^2 s = r^2$. The element-level diagram gives $r \mapsto r^{-1} = r^3$, so conjugation inverts: $sr^2 s = (r^{-1})^2 = r^2$ (consistent since $r^2 = r^{-2}$ in $\mathbb{Z}/4\mathbb{Z}$).

Common pitfall: Students sometimes read the commuting square as saying the two horizontal maps are the *same* arrow or that the inclusions are isomorphisms. They are not: the inclusions are proper embeddings ($\langle r\rangle \subsetneq D_{2n}$ for $n \geq 3$), and the commutativity just records that the conjugation formula $x \mapsto sxs$ is consistent across the two group levels.

Takeaway: The point of this diagram is that the relation $srs = r^{-1}$ is not merely an algebraic identity but says that conjugation by s is an automorphism of $\langle r\rangle$ that extends compatibly to all of D_{2n}, making $\langle r\rangle$ a normal subgroup.

The universal property of D_{2n} (it is the largest group on generators a, b with $a^n = b^2 = 1$, $bab = a^{-1}$) gives, for any group G containing elements ρ, σ with $\rho^n = \sigma^2 = 1$ and $\sigma\rho\sigma = \rho^{-1}$, a unique homomorphism filling the dashed arrow:

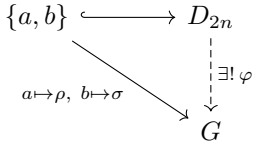


Diagram explanation. Objects: Three objects appear. The generating set $\{a, b\}$ is not a group but the source data: two abstract symbols satisfying $a^n = b^2 = 1$ and $bab = a^{-1}$. The group D_{2n} is the dihedral group presented by those generators and relations. The group G is any group containing elements ρ, σ with $\rho^n = \sigma^2 = 1$ and $\sigma\rho\sigma = \rho^{-1}$.

Arrows: The top horizontal arrow $\{a, b\} \hookrightarrow D_{2n}$ is the inclusion of the generators into D_{2n} (the canonical embedding sending $a \mapsto r$, $b \mapsto s$). The diagonal arrow $\{a, b\} \to G$ is the assignment $a \mapsto \rho$, $b \mapsto \sigma$, recording the hypothesized relations in G. The dashed vertical arrow $\varphi : D_{2n} \to G$ is the unique group homomorphism extending the diagonal assignment; it is dashed because its existence and uniqueness are what the diagram asserts.

What commutes: The triangle commutes: the composition $\{a, b\} \hookrightarrow D_{2n} \xrightarrow{\varphi} G$ equals the direct assignment $a \mapsto \rho$, $b \mapsto \sigma$. Concretely: $\varphi(r) = \rho$ and $\varphi(s) = \sigma$, and for every word r^i or sr^i in D_{2n}, $\varphi(r^i) = \rho^i$ and $\varphi(sr^i) = \sigma\rho^i$.

Why it commutes: Well-definedness is the key point. Every element of D_{2n} has a unique normal form r^i or sr^i, so defining $\varphi(r^i) = \rho^i$ and $\varphi(sr^i) = \sigma\rho^i$ is unambiguous. The relations $\rho^n = 1$, $\sigma^2 = 1$, $\sigma\rho\sigma = \rho^{-1}$ in

G guarantee that φ respects the group operation: e.g. $\varphi(sr \cdot r^i) = \sigma\rho^{i+1} = \varphi(sr)\varphi(r^i)$. The assignment on $\{a, b\}$ forced φ uniquely because a, b generate D_{2n}.

Why this matters here: This is the universal property of D_{2n} as a group presented by generators and relations. It converts the geometric fact "D_{2n} is the symmetry group" into the algebraic fact "any group satisfying those relations receives a homomorphism from D_{2n}." Every time one constructs a homomorphism out of D_{2n} in the chapter, this triangle is the silent justification: just verify $\rho^n = \sigma^2 = 1$ and $\sigma\rho\sigma = \rho^{-1}$ in the target.

Concrete example: Take $G = \mathbb{Z}/2\mathbb{Z}$ (written additively, so ρ^n means $n\rho$), $\rho = \overline{0}$, $\sigma = \overline{1}$. Then $\rho^n = \overline{0}$, $\sigma^2 = \overline{1} + \overline{1} = \overline{0}$, and $\sigma\rho\sigma = \overline{1} + \overline{0} + \overline{1} = \overline{0} = -\rho = \rho^{-1}$, so φ exists: it sends every rotation r^i to $\overline{0}$ and every reflection sr^i to $\overline{1}$. (By contrast, $G = \mathbb{Z}/n\mathbb{Z}$ with $\rho = \overline{1}$, $\sigma = \overline{0}$ does not work for $n \geq 3$: there $\sigma\rho\sigma = \overline{1} \neq \overline{n-1} = \rho^{-1}$.) Another example: $G = D_{2n}$ itself, $\rho = r$, $\sigma = s$; then $\varphi = \mathrm{id}_{D_{2n}}$ fills the dashed arrow, confirming that D_{2n} maps to itself via the identity.

Common pitfall: Students sometimes think the dashed arrow exists for any $\rho, \sigma \in G$. It does not: the three relations $\rho^n = 1$, $\sigma^2 = 1$, $\sigma\rho\sigma = \rho^{-1}$ must hold in G first. Without them, there is no well-defined φ: for instance srs and r^{-1} are the same element of D_{2n}, so φ would have to send it both to $\sigma\rho\sigma$ and to ρ^{-1}, which is impossible if $\sigma\rho\sigma \neq \rho^{-1}$. The relations are the kernel condition that makes the induced map well-defined.

Takeaway: The point of this diagram is that D_{2n} is the universal group on two generators satisfying the dihedral relations, meaning any concrete realization of those relations in a group G yields a unique homomorphism $D_{2n} \to G$ extending the generator assignment.

Remark 1.2.1. The rotation subgroup $\langle r \rangle = \{1, r, \ldots, r^{n-1}\} \cong \mathbb{Z}/n\mathbb{Z}$ is normal in D_{2n} (index 2), and $D_{2n}/\langle r \rangle \cong \mathbb{Z}/2\mathbb{Z}$ records the rotation/reflection parity (s flips parity). This is why an even number of s's in any word yields a rotation and an odd number yields a reflection, the recognition shortcut used throughout.

Caution. When reducing exponents, do it *modulo* n, not arbitrarily: in D_8, $r^{-3} = r^1$ because $-3 \equiv 1 \pmod 4$, but in D_{14}, $r^{-3} = r^4$. Mixing up n is the most common arithmetic slip.

Further examples

The book builds D_{2n} by hand from the geometry before any relation is asserted, fixes a working notation for elements, and pins down the small cases by listing every symmetry explicitly. The material below records that concrete construction and those examples; throughout this subsection the vertices are relabelled $1, 2, \ldots, n$ (so vertex 1 plays the role of vertex 0 in Definition 1.2.1), to match the permutation bookkeeping D&F uses in the small cases.

Definition 1.2.11 (Symmetry of a polygon, as in D&F)**.** A *symmetry* of the regular n-gon ($n \geq 3$) is a rigid motion of the plane that carries the polygon onto itself. Concretely, label the vertices $1, 2, \ldots, n$ consecutively, and record each symmetry by what it does to the vertices: it is a permutation σ of $\{1, 2, \ldots, n\}$ that sends adjacent vertices to adjacent vertices. The set of all such symmetries, under composition of motions, is the dihedral group D_{2n}. (D&F write the subscript $2n$ to display the order; some texts write D_n. Here D_{2n} always has $2n$ elements.)

Proposition 1.2.12 (D&F's adjacency count: there are exactly $2n$ symmetries)**.** *A symmetry of the regular n-gon is determined by where it sends vertex* 1 *and where it sends the adjacent vertex* 2*. Vertex* 1 *may go to any of the n vertices; once its image is fixed, the adjacent vertex* 2 *must land on one of the two vertices adjacent to the image of* 1*. Hence there are at most $n \cdot 2 = 2n$ symmetries, and since the n rotations together with the n reflections are all distinct symmetries, there are exactly $2n$.*

Proof. Let σ be a symmetry. Choose the image $\sigma(1)$: there are n choices. Because σ preserves adjacency and distances, $\sigma(2)$ must be one of the two neighbors of $\sigma(1)$, giving 2 choices. Now $\sigma(1)$ and $\sigma(2)$ already determine σ on every remaining vertex: vertex 3 is the neighbor of 2 other than 1, so $\sigma(3)$ is forced to be the neighbor of $\sigma(2)$ other than $\sigma(1)$, and so on around the polygon. Thus σ is determined by the pair $(\sigma(1), \sigma(2))$, so there are at most $2n$ symmetries. Exhibiting $2n$ distinct ones (the rotations r^i and reflections sr^i, $0 \leq i < n$) shows the bound is met. □

Remark 1.2.2 (How D&F fixes notation). Once the count is known, D&F names two specific symmetries and uses them as a working alphabet. Let r be the rotation through $2\pi/n$ (one vertex step, in the direction of

increasing labels) and let s be the reflection fixing vertex 1. The text then verifies, directly from the geometry, that

$$1, r, r^2, \ldots, r^{n-1} \text{ are distinct with } r^n = 1; \qquad s^2 = 1; \qquad s \neq r^i \text{ for any } i,$$

and the single mixing relation, obtained by tracking what each side does to the vertices,

$$rs = sr^{-1} \qquad (\text{equivalently } srs^{-1} = r^{-1}, \;\; s^{-1}rs = r^{-1}).$$

Every element is then named in the form r^i or sr^i with $0 \leq i < n$; this naming, not an abstract presentation, is what the book computes with.

Worked Example 1.2.13 (The smallest case: D_6, symmetries of the triangle)**.** Take the equilateral triangle with vertices $1, 2, 3$. List all $6 = 2 \cdot 3$ symmetries of D_6 both as words in r, s and as permutations of $\{1, 2, 3\}$, where r rotates $1 \to 2 \to 3 \to 1$ and s fixes vertex 1.

Recognition. Proposition 1.2.12 guarantees exactly $2n = 6$ symmetries. List the three rotations $1, r, r^2$ and the three reflections s, sr, sr^2, then read off each one's action on the vertices to confirm they are distinct.

Solution. The rotation r sends $1 \mapsto 2,\ 2 \mapsto 3,\ 3 \mapsto 1$, i.e. the 3-cycle $(1\,2\,3)$; the reflection s fixes vertex 1 and swaps the other two, i.e. $(2\,3)$. Compute the rest (permutations compose right-to-left):

1	$=$	identity	fixes $1, 2, 3$,
r	$=$	$(1\,2\,3)$	$1 \mapsto 2 \mapsto 3 \mapsto 1$,
r^2	$=$	$(1\,3\,2)$	$1 \mapsto 3 \mapsto 2 \mapsto 1$,
s	$=$	$(2\,3)$	fixes 1,
sr	$=$	$(2\,3)(1\,2\,3) = (1\,3)$	fixes 2,
sr^2	$=$	$(2\,3)(1\,3\,2) = (1\,2)$	fixes 3.

So $D_6 = \{1, r, r^2, s, sr, sr^2\}$, and as permutations these are exactly the six elements of $\mathrm{Sym}\{1, 2, 3\}$. *Check.* The three reflections $s = (2\,3)$, $sr = (1\,3)$, $sr^2 = (1\,2)$ are the three transpositions, each fixing one vertex; the three rotations are the identity and the two 3-cycles. All six permutations are distinct, confirming $|D_6| = 6$. Here $D_6 \cong \mathrm{Sym}\{1, 2, 3\}$ because both have order 6 and every permutation of the three vertices is a symmetry of the triangle.

Worked Example 1.2.14 (D_8 as permutations of the square's vertices)**.** For the square with vertices $1, 2, 3, 4$ in cyclic order, write each of the 8 elements of D_8 as a permutation of $\{1, 2, 3, 4\}$, with $r = (1\,2\,3\,4)$ and s the reflection fixing vertices 1 and 3 (the diagonal axis).

Recognition. There are $2n = 8$ symmetries by Proposition 1.2.12. The four rotations are powers of $r = (1\,2\,3\,4)$; the four reflections are s, sr, sr^2, sr^3. Multiply out each reflection as a permutation, composing right-to-left.

Solution. The reflection across the diagonal through vertices 1 and 3 fixes those and swaps $2, 4$, so $s = (2\,4)$. Composing right-to-left (sr means "apply r, then s"):

$$\begin{array}{ll} 1 = \mathrm{id}, & s = (2\,4), \\ r = (1\,2\,3\,4), & sr = (2\,4)(1\,2\,3\,4) = (1\,4)(2\,3), \\ r^2 = (1\,3)(2\,4), & sr^2 = (2\,4)(1\,3)(2\,4) = (1\,3), \\ r^3 = (1\,4\,3\,2), & sr^3 = (2\,4)(1\,4\,3\,2) = (1\,2)(3\,4). \end{array}$$

Check. The reflections split into the two diagonal flips $s = (2\,4)$, $sr^2 = (1\,3)$ (each fixing two opposite vertices) and the two edge-midpoint flips $sr = (1\,4)(2\,3)$, $sr^3 = (1\,2)(3\,4)$ (fixing no vertex), as expected for even n. Each squares to the identity, e.g. $(1\,4)(2\,3)$ has order 2, matching $|sr^i| = 2$. The eight permutations are distinct, so $|D_8| = 8$, and D_8 sits as a subgroup of $\mathrm{Sym}\{1, 2, 3, 4\}$ of index 3 (since $|\mathrm{Sym}\{1, 2, 3, 4\}| = 24$).

Worked Example 1.2.15 (Verifying the relation $rs = sr^{-1}$ on vertices)**.** Confirm D&F's mixing relation $rs = sr^{-1}$ directly on the square ($n = 4$) by evaluating both sides on every vertex, using $r = (1\,2\,3\,4)$ and $s = (2\,4)$.

Recognition. The relation $rs = sr^{-1}$ is the one non-obvious defining fact; D&F establishes it geometrically. To verify it concretely, compute the permutation on each side and compare images vertex by vertex (right-to-left composition).

Solution. Left side rs: apply $s = (2\,4)$ first, then $r = (1\,2\,3\,4)$.

$$1 \xrightarrow{s} 1 \xrightarrow{r} 2, \quad 2 \xrightarrow{s} 4 \xrightarrow{r} 1, \quad 3 \xrightarrow{s} 3 \xrightarrow{r} 4, \quad 4 \xrightarrow{s} 2 \xrightarrow{r} 3,$$

so $rs = (1\,2)(3\,4)$. Right side sr^{-1} with $r^{-1} = r^3 = (1\,4\,3\,2)$: apply r^{-1} first, then s.

$$1 \xrightarrow{r^{-1}} 4 \xrightarrow{s} 2, \quad 2 \xrightarrow{r^{-1}} 1 \xrightarrow{s} 1, \quad 3 \xrightarrow{r^{-1}} 2 \xrightarrow{s} 4, \quad 4 \xrightarrow{r^{-1}} 3 \xrightarrow{s} 3,$$

so $sr^{-1} = (1\,2)(3\,4)$. The two permutations agree, so $rs = sr^{-1}$ holds. *Check.* Both sides equal $sr^3 = (1\,2)(3\,4)$ from the previous example, as they must, since $rs = sr^{-1}$ and $r^{-1} = r^3$ give $sr^{-1} = sr^3$; but here we verified $rs = sr^{-1}$ as permutations without assuming the relation. This is the geometric content D&F extracts: reflecting, then rotating, equals rotating backward, then reflecting.

Remark 1.2.3 (Why D&F insists $n \geq 3$ for the polygon picture). The geometric construction names r as a rotation by $2\pi/n$ and s as a reflection, which requires an honest regular n-gon, so $n \geq 3$. The same relations $r^n = s^2 = 1,\ rs = sr^{-1}$ make sense as an abstract presentation for $n = 1, 2$ as well, giving $D_2 \cong \mathbb{Z}/2\mathbb{Z}$ and $D_4 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ (the Klein four-group, since $r^2 = 1$ forces $r = r^{-1}$, hence $rs = sr^{-1} = sr$ and the group is abelian); these degenerate cases are consistent but lie outside the polygon-symmetry picture that motivates the definition.

Exercises (from the text).

1. Compute the order of each element of (a) D_6, (b) D_8, (c) D_{10}.
2. Show that if $x \in D_{2n}$ is not a power of r, then $rx = xr^{-1}$.
3. Show every non-rotation has order 2; deduce $D_{2n} = \langle s, sr \rangle$.
4. If $n = 2k \geq 4$, show $z = r^k$ has order 2 and is central — the only such nonidentity element.
5. If $n \geq 3$ is odd, show only the identity commutes with all of D_{2n}.
6. Let x, y have order 2 and $t = xy$. Prove $tx = xt^{-1}$.
7. Show $\langle a, b \mid a^2 = b^2 = (ab)^n = 1 \rangle$ presents D_{2n}, via $a = s$, $b = sr$.
8. Find the order of the cyclic subgroup $\langle r \rangle \leq D_{2n}$.
9. Rigid motions of a **tetrahedron**: show the order is 12.
10. Rigid motions of a **cube**: order 24.
11. Rigid motions of an **octahedron**: order 24.
12. Rigid motions of a **dodecahedron**: order 60.
13. Rigid motions of an **icosahedron**: order 60.
14. Find a set of generators for $\mathbb{Z}$.
15. Find generators and relations for $\mathbb{Z}/n\mathbb{Z}$.
16. Show $\langle x_1, y_1 \mid x_1^2 = y_1^2 = (x_1 y_1)^2 = 1 \rangle$ is the dihedral group D_4.
17. $X_{2n} = \langle x, y \mid x^n = y^2 = 1,\ xy = yx^2 \rangle$: find the order for $n = 3k$ and for $\gcd(3, n) = 1$.
18. $Y = \langle u, v \mid u^4 = v^3 = 1,\ uv = v^2u^2 \rangle$ collapses. Show $Y = 1$.

Additional exercises.

1. In D_{2n} with $r^n = s^2 = 1$ and $sr = r^{-1}s$, prove the general commutation rule $sr^k = r^{-k}s$ for every integer k. Then use it to simplify r^3sr^2sr inside D_{16} (so $n = 8$) to the standard form $r^a s^b$ with $0 \leq a \leq 7$ and $0 \leq b \leq 1$.
2. Work in D_{12} (so $n = 6$, $r^6 = s^2 = 1$). Compute the order of each of the following elements, showing the computation: (a) r^4; (b) sr^3; (c) r^2s; (d) $(sr)^2$. (Recall every element of the form $r^k s$ is a reflection.)

3. Show that in D_{2n} every element can be written uniquely as $r^a s^b$ with $0 \le a \le n-1$ and $0 \le b \le 1$, and conclude $|D_{2n}| = 2n$. Then list all elements of D_{10} in this normal form.

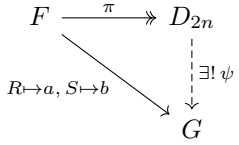
4. Determine the order of r^k in D_{2n} as a function of k and n, and prove your formula. Use it to find every k with $0 \le k \le 11$ for which r^k generates $\langle r \rangle$ inside D_{24} (so $n = 12$).

5. Let $x = sr$ and $y = sr^2$ in D_{16} (so $n = 8$). Show that x and y are each reflections (order 2), compute the order of the rotation xy, and deduce that $\langle x, y \rangle$ contains a rotation of order 4. Identify $\langle x, y \rangle$ explicitly as a subset of D_{16}.

6. Find all elements of order 2 in D_{2n}, treating the cases n odd and n even separately. (Hint: a rotation r^k has order 2 iff $2k \equiv 0 \pmod{n}$ with $r^k \neq 1$; every reflection $r^k s$ has order 2.) Apply your count to D_8 and to D_{10}.

7. Prove that $Z(D_{2n}) = \{1\}$ when n is odd and $Z(D_{2n}) = \{1, r^{n/2}\}$ when n is even. (An element g is central iff $gs = sg$ and $gr = rg$; use the normal form $r^a s^b$.)

Commutative-diagram exercises.



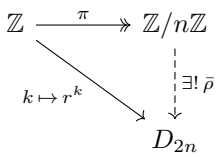
1. Label the vertices of a regular n-gon $1, 2, \ldots, n$ counterclockwise. Define $\varphi : D_{2n} \to \mathrm{Sym}(n)$ by sending each symmetry to its induced permutation of the vertices, with $r \mapsto (1\,2\,\cdots\,n)$ and s the reflection fixing vertex 1. For $n = 4$ write $\varphi(r)$ and $\varphi(s)$ as explicit permutations in Sym(4), verify $\varphi(s)\varphi(r) = \varphi(r)^{-1}\varphi(s)$ in Sym(4), and conclude that φ is a homomorphism. Compute $\ker \varphi$.

2. With φ as above, show φ is injective by computing $\ker \varphi$, so the sequence

$$1 \longrightarrow \ker \varphi \hookrightarrow D_{2n} \xrightarrow{\varphi} \mathrm{Sym}(n)$$

realizes D_{2n} as a subgroup of $\mathrm{Sym}(n)$. For $n = 3$ show φ is moreover surjective onto Sym(3), hence $D_6 \cong \mathrm{Sym}(3)$, and exhibit the matching bijection element by element.

3. Let F be the free group on two symbols R, S and let $\pi : F \to D_{2n}$ be the homomorphism with $R \mapsto r$, $S \mapsto s$. The relations R^n, S^2, $SRSR$ lie in $\ker \pi$. Given any group G with elements a, b satisfying $a^n = b^2 = 1$ and $ba = a^{-1}b$, show there is a unique homomorphism $\psi : D_{2n} \to G$ with $r \mapsto a$, $s \mapsto b$, making



commute. (This is the universal/presentation property of $D_{2n} = \langle r, s \mid r^n = s^2 = 1,\ sr = r^{-1}s \rangle$.)

4. Use the universal property of the previous problem to construct an explicit surjective homomorphism $D_{2n} \to \mathbb{Z}/2\mathbb{Z}$ that sends every rotation to 0 and every reflection to 1. (Take $G = \mathbb{Z}/2\mathbb{Z}$ and choose a, b satisfying the dihedral relations.) Verify the defining relations hold for your chosen a, b, identify the kernel, and draw the resulting short exact sequence

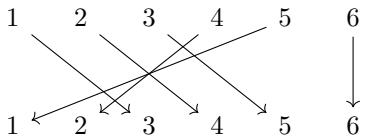
$$1 \longrightarrow \langle r \rangle \hookrightarrow D_{2n} \twoheadrightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 1.$$

5. Let $\rho : \mathbb{Z} \to D_{2n}$ be the unique homomorphism with $1 \mapsto r$ (existence by the universal property of $\mathbb{Z}$). Show ρ factors through $\mathbb{Z}/n\mathbb{Z}$, giving the commutative triangle

Identify $\ker \rho$, prove $\bar{\rho}$ is injective, and describe its image inside D_{2n}. Conjugate the image by s and verify the relation $s\, r^k\, s^{-1} = r^{-k}$ holds for all k, exhibiting $\langle r \rangle$ as a normal subgroup.

1.3 Symmetric Groups

The symmetric group S_n: cycle notation, products, and inverses



Definition 1.3.1 (Symmetric group)**.** For $n \geq 1$, $S_n = \mathrm{Sym}(\{1, 2, \ldots, n\})$ is the group of all bijections $\{1, \ldots, n\} \to \{1, \ldots, n\}$ under composition. Its identity is id (every point fixed), and we compose *right-to-left*: $(\sigma\tau)(x) = \sigma\big(\tau(x)\big)$, so τ acts first.

Theorem 1.3.2 (Order of S_n)**.** $|S_n| = n!$.

Proof. A bijection f is determined by choosing $f(1), f(2), \ldots, f(n)$ in turn. There are n choices for $f(1)$; once chosen, $n-1$ remaining values for $f(2)$ (it must differ from $f(1)$); then $n-2$ for $f(3)$, and so on down to 1 choice for $f(n)$. By the multiplication principle the count is $n(n-1)\cdots 2 \cdot 1 = n!$, and every such choice gives a genuine bijection. □

Definition 1.3.3 (Cycle notation)**.** A *k-cycle* $(a_1\, a_2\, \cdots\, a_k)$ is the permutation sending $a_1 \mapsto a_2 \mapsto \cdots \mapsto a_k \mapsto a_1$ and fixing every other point. Two cycles are *disjoint* if they move no common point. A *transposition* is a 2-cycle.

A single permutation pictured as a two-row map; the arrows are exactly the rule $\sigma = (1\,3\,5)(2\,4)$ on $\{1, \ldots, 6\}$ (so 6 is fixed):

Reading the targets off the bottom row: $1 \mapsto 3,\ 2 \mapsto 4,\ 3 \mapsto 5,\ 4 \mapsto 2,\ 5 \mapsto 1,\ 6 \mapsto 6$.

Diagram explanation. Objects: Two copies of the set $\{1, 2, 3, 4, 5, 6\}$: the top row is the *domain* and the bottom row is the *codomain*, both just the same finite set viewed as inputs vs. outputs of the bijection $\sigma = (1\,3\,5)(2\,4)$.

Arrows: Each arrow runs from a point i in the top row to the point $\sigma(i)$ in the bottom row. Specifically: $1 \to 3$ (start of the 3-cycle), $3 \to 5$ (second step), $5 \to 1$ (closing the 3-cycle), $2 \to 4$ (start of the transposition), $4 \to 2$ (closing it), and $6 \to 6$ (a vertical arrow, indicating 6 is a fixed point). Every arrow is the application of the permutation to one element; no arrow is a group homomorphism.

What commutes: This is a function diagram, not a square or triangle, so there is no composition identity to verify. The single constraint is that the arrow out of each top-row node lands on exactly one bottom-row node and every bottom-row node is hit exactly once – i.e. the arrows encode a bijection, which the cycle structure guarantees.

Why it commutes: Because σ is a well-defined function: each of the six inputs has a unique output determined by the cycles $(1\,3\,5)$ and $(2\,4)$, and the outputs are all distinct (no two arrows share a target), confirming σ is a bijection.

Why this matters here: This picture sits immediately after the formal definition of a k-cycle and is the *transition bridge* from the abstract cycle notation to the concrete function-values picture. It makes the definition checkable at a glance: every orbit forms a path of arrows, and a fixed point is the special case of a trivial self-loop. It also anticipates the two-row (matrix) notation introduced later.

Concrete example: For $\sigma = (1\,2)$ in S_3, the diagram has $1 \to 2$, $2 \to 1$ (the transposition), and $3 \to 3$ (fixed point vertical arrow), illustrating the same pattern with the simplest nontrivial case.

Common pitfall: Students sometimes read a multi-step path (e.g. $1 \to 3 \to 5 \to 1$) as a single arrow labelled by the composition σ^3, but each arrow in the diagram represents *one application* of σ. Reading the path as composition conflates the picture with the orbit diagram, which is a different object.

Takeaway: The point of this diagram is that cycle notation is just a compressed description of the arrow-map: each cycle lists one closed path of arrows, and fixed points are the trivial vertical arrows.

Theorem 1.3.4 (Disjoint-cycle decomposition)**.** *Every $\sigma \in S_n$ is a product of disjoint cycles. This decomposition is unique up to the order of the factors and up to cyclic rotation within each cycle (fixed points are customarily omitted).*

Proof. Define a relation on $\{1, \dots, n\}$ by $x \sim y$ iff $y = \sigma^m(x)$ for some $m \in \mathbb{Z}$. This is an equivalence relation (reflexive via $m = 0$, symmetric via $-m$, transitive by adding exponents), so $\{1, \dots, n\}$ splits into disjoint orbits. On the orbit of x, the points $x, \sigma(x), \sigma^2(x), \dots$ recur with least period k (finiteness forces $\sigma^k(x) = x$ for some least $k \geq 1$), giving the cycle $(x\, \sigma(x) \cdots \sigma^{k-1}(x))$. Distinct orbits are disjoint, and σ agrees with the product of these cycles on every point, hence equals it. Uniqueness: the orbits are intrinsic to σ, and within an orbit the cyclic order $x \to \sigma(x) \to \cdots$ is forced, so the only freedom is the listing order of the cycles and the starting point of each. □

Proposition 1.3.5 (Disjoint cycles commute)**.** *If cycles α, β are disjoint then $\alpha\beta = \beta\alpha$.*

Proof. Let x be arbitrary. If α moves x then β fixes x and also fixes $\alpha(x)$ (both lie in α's support, which β avoids), so $(\alpha\beta)(x) = \alpha(x) = (\beta\alpha)(x)$. Symmetrically if β moves x. If both fix x, both sides give x. Thus $\alpha\beta$ and $\beta\alpha$ agree everywhere. □

Proposition 1.3.6 (Inverse reverses each cycle)**.** $(a_1\, a_2 \cdots a_k)^{-1} = (a_k\, a_{k-1} \cdots a_1)$*, and for a product of disjoint cycles $\sigma = \gamma_1 \cdots \gamma_r$ we have $\sigma^{-1} = \gamma_1^{-1} \cdots \gamma_r^{-1}$ (order is irrelevant since disjoint cycles commute).*

Proof. A k-cycle sends $a_i \mapsto a_{i+1}$ (indices mod k); its inverse must send $a_{i+1} \mapsto a_i$, i.e. run the same wheel backwards, which is precisely $(a_k \cdots a_1)$. For a product, $(\gamma_1 \cdots \gamma_r)^{-1} = \gamma_r^{-1} \cdots \gamma_1^{-1}$ in general; disjointness lets us reorder the factors freely by Proposition 1.3.5. □

Method (How to multiply two permutations $\sigma\tau$)**.** Trigger: you must compose two permutations (given in cycle form or two-row form), and you want the answer back in disjoint cycles.

1. Fix the convention: $(\sigma\tau)(x) = \sigma(\tau(x))$ – apply the *right* factor τ first, then feed the result to σ.
2. Start at 1. Track it through the cycles *right to left*: find where the rightmost cycle sends it, carry that number leftward through each remaining cycle.
3. Write $1 \mapsto$ (final image). Continue from that image; when you return to 1, close the cycle.
4. Pick the smallest unused point and repeat until all of $\{1, \dots, n\}$ is placed. Drop fixed points.

Caution. Do not read cycles left-to-right. D&F applies the *rightmost* factor first, so $\sigma\tau$ means "τ then σ." Reading the other way computes $\tau\sigma$, which is usually a different permutation.

Worked Example 1.3.7 (Multiply two permutations of $\{1, \dots, 6\}$)**.** Let $\sigma = (1\,3\,5)(2\,4)$ and $\tau = (1\,2\,6)(3\,5)$ in S_6. Compute $\sigma\tau$.

Recognition. Two permutations, product wanted: this is the multiply-method. The trigger is the juxtaposition $\sigma\tau$; resolve it by tracking each point with τ first (rightmost), then σ.

Solution. First record both maps. From $\sigma = (1\,3\,5)(2\,4)$: $1 \mapsto 3$, $2 \mapsto 4$, $3 \mapsto 5$, $4 \mapsto 2$, $5 \mapsto 1$, $6 \mapsto 6$. From $\tau = (1\,2\,6)(3\,5)$: $1 \mapsto 2$, $2 \mapsto 6$, $3 \mapsto 5$, $4 \mapsto 4$, $5 \mapsto 3$, $6 \mapsto 1$. Now $(\sigma\tau)(x) = \sigma(\tau(x))$:

$$1 \xrightarrow{\tau} 2 \xrightarrow{\sigma} 4, \quad 2 \xrightarrow{\tau} 6 \xrightarrow{\sigma} 6, \quad 3 \xrightarrow{\tau} 5 \xrightarrow{\sigma} 1,$$
$$4 \xrightarrow{\tau} 4 \xrightarrow{\sigma} 2, \quad 5 \xrightarrow{\tau} 3 \xrightarrow{\sigma} 5, \quad 6 \xrightarrow{\tau} 1 \xrightarrow{\sigma} 3.$$

So $1 \mapsto 4 \mapsto 2 \mapsto 6 \mapsto 3 \mapsto 1$ (closing), and $5 \mapsto 5$ is fixed. Hence

$$\sigma\tau = (1\,4\,2\,6\,3).$$

Check: a 5-cycle moves exactly $\{1, 2, 3, 4, 6\}$ and fixes 5, matching the table; and 5 is the unique fixed point, consistent with $\tau(5) = 3,\ \sigma(3) = 5$.

Worked Example 1.3.8 (Order matters: same factors, other product)**.** With σ, τ as above, compute $\tau\sigma$ and compare with $\sigma\tau$.

Recognition. Same two permutations but the product is reversed. The recognition cue is that we swapped the order, so now apply σ first, then τ. Expect a different answer because S_6 is nonabelian.

Solution. $(\tau\sigma)(x) = \tau(\sigma(x))$:

$$1 \xrightarrow{\sigma} 3 \xrightarrow{\tau} 5, \quad 2 \xrightarrow{\sigma} 4 \xrightarrow{\tau} 4, \quad 3 \xrightarrow{\sigma} 5 \xrightarrow{\tau} 3,$$
$$4 \xrightarrow{\sigma} 2 \xrightarrow{\tau} 6, \quad 5 \xrightarrow{\sigma} 1 \xrightarrow{\tau} 2, \quad 6 \xrightarrow{\sigma} 6 \xrightarrow{\tau} 1.$$

Following $1 \mapsto 5 \mapsto 2 \mapsto 4 \mapsto 6 \mapsto 1$ and $3 \mapsto 3$ fixed:

$$\tau\sigma = (1\,5\,2\,4\,6) \neq (1\,4\,2\,6\,3) = \sigma\tau.$$

Check: both are 5-cycles (same cycle type, as they must be since $\tau\sigma$ and $\sigma\tau$ are conjugate via $\tau\sigma = \tau(\sigma\tau)\tau^{-1}$), but they fix different points (3 versus 5), confirming $\sigma\tau \neq \tau\sigma$.

Worked Example 1.3.9 (A product of two overlapping cycles)**.** In S_5 compute $(1\,2\,4\,3)(1\,3\,5)$.

Recognition. Two cycles sharing the points 1 and 3: overlapping, so we cannot just juxtapose – we must track points, rightmost cycle first.

Solution. Right factor $(1\,3\,5)$: $1 \mapsto 3$, $3 \mapsto 5$, $5 \mapsto 1$, others fixed. Left factor $(1\,2\,4\,3)$: $1 \mapsto 2$, $2 \mapsto 4$, $4 \mapsto 3$, $3 \mapsto 1$, with 5 fixed. Compose $x \mapsto \text{left}(\text{right}(x))$:

$$1 \to 3 \to 1, \quad 2 \to 2 \to 4, \quad 3 \to 5 \to 5,$$
$$4 \to 4 \to 3, \quad 5 \to 1 \to 2.$$

So $1 \mapsto 1$ (fixed); then $2 \mapsto 4 \mapsto 3 \mapsto 5 \mapsto 2$ closes:

$$(1\,2\,4\,3)(1\,3\,5) = (2\,4\,3\,5).$$

Check: 1 is fixed, and the other four points form one 4-cycle moving $\{2, 3, 4, 5\}$; total support size 4 matches the four nonfixed images.

Worked Example 1.3.10 (Multiply three factors of $\{1, \ldots, 6\}$)**.** Compute $(1\,2)(3\,4\,5)(2\,3\,6)$ in S_6.

Recognition. Three factors; the method extends unchanged – push each point right-to-left through all three cycles in succession.

Solution. Maps: rightmost $(2\,3\,6)$: $2 \to 3, 3 \to 6, 6 \to 2$. Middle $(3\,4\,5)$: $3 \to 4, 4 \to 5, 5 \to 3$. Left $(1\,2)$: $1 \to 2, 2 \to 1$. Now carry each x through right→middle→left:

$$1 \to 1 \to 1 \to 2, \quad 2 \to 3 \to 4 \to 4, \quad 3 \to 6 \to 6 \to 6,$$
$$4 \to 4 \to 5 \to 5, \quad 5 \to 5 \to 3 \to 3, \quad 6 \to 2 \to 2 \to 1.$$

Thread the images $1 \mapsto 2, 2 \mapsto 4, 4 \mapsto 5, 5 \mapsto 3, 3 \mapsto 6, 6 \mapsto 1$: $1 \mapsto 2 \mapsto 4 \mapsto 5 \mapsto 3 \mapsto 6 \mapsto 1$, a single 6-cycle:

$$(1\,2)(3\,4\,5)(2\,3\,6) = (1\,2\,4\,5\,3\,6).$$

Check: the result moves all six points and is a 6-cycle, so it has order 6; as a sanity test $1 \mapsto 2$ agrees with the last column reading $(1 \to 1 \to 1 \to 2)$.

Method (How to decompose a messy product into disjoint cycles)**.** Trigger: you are handed a product of several (possibly overlapping) cycles and asked for its disjoint-cycle form, or you must compute an orbit structure / order.

1. Apply the multiply-method to get the single map $x \mapsto \sigma(x)$ for all x.
2. "Follow the orbits": start at the smallest point, write $a \mapsto \sigma(a) \mapsto \sigma^2(a) \mapsto \cdots$ until you return; that closes one cycle.
3. Jump to the smallest unused point; repeat. Omit fixed points.

4. Sanity: the cycle lengths must sum to n minus the number of fixed points; the order of σ is the lcm of the cycle lengths.

Worked Example 1.3.11 (Decompose a four-factor mess)**.** Write $(1\,2\,3)(2\,4)(1\,5\,3)(4\,2)$ as a product of disjoint cycles in S_5.

Recognition. A long chain of overlapping cycles: pure decomposition. Build the full map by the multiply-method, then read orbits.

Solution. Maps (rightmost first): $(4\,2)$ swaps $2, 4$; $(1\,5\,3)$: $1 \to 5, 5 \to 3, 3 \to 1$; $(2\,4)$ swaps $2, 4$; $(1\,2\,3)$: $1 \to 2, 2 \to 3, 3 \to 1$. Carry each x through all four, right to left:

$$\begin{aligned}
1 &\xrightarrow{(42)} 1 \xrightarrow{(153)} 5 \xrightarrow{(24)} 5 \xrightarrow{(123)} 5,\\
2 &\xrightarrow{(42)} 4 \xrightarrow{(153)} 4 \xrightarrow{(24)} 2 \xrightarrow{(123)} 3,\\
3 &\xrightarrow{(42)} 3 \xrightarrow{(153)} 1 \xrightarrow{(24)} 1 \xrightarrow{(123)} 2,\\
4 &\xrightarrow{(42)} 2 \xrightarrow{(153)} 2 \xrightarrow{(24)} 4 \xrightarrow{(123)} 4,\\
5 &\xrightarrow{(42)} 5 \xrightarrow{(153)} 3 \xrightarrow{(24)} 3 \xrightarrow{(123)} 1.
\end{aligned}$$

So the net map is $1 \mapsto 5$, $2 \mapsto 3$, $3 \mapsto 2$, $4 \mapsto 4$, $5 \mapsto 1$. Follow orbits: $1 \mapsto 5 \mapsto 1$ gives $(1\,5)$; $2 \mapsto 3 \mapsto 2$ gives $(2\,3)$; 4 fixed.

$$(1\,2\,3)(2\,4)(1\,5\,3)(4\,2) = (1\,5)(2\,3).$$

Check: cycle lengths $2 + 2 = 4 = 5 - 1$ (one fixed point 4), consistent; and the order is $\mathrm{lcm}(2, 2) = 2$, so squaring should give id, which it does since each factor is its own inverse.

Worked Example 1.3.12 (Decompose and read off the order)**.** In S_7 simplify $(1\,4\,7)(2\,5)(1\,2\,3\,4)$ and state its order.

Recognition. Overlapping product; decompose, then the order is lcm of resulting cycle lengths.

Solution. Rightmost $(1\,2\,3\,4)$: $1 \to 2, 2 \to 3, 3 \to 4, 4 \to 1$. Middle $(2\,5)$: swaps $2, 5$. Left $(1\,4\,7)$: $1 \to 4, 4 \to 7, 7 \to 1$. Carry right→left:

$$\begin{aligned}
&1 \to 2 \to 5 \to 5, \quad 2 \to 3 \to 3 \to 3, \quad 3 \to 4 \to 4 \to 7,\\
&4 \to 1 \to 1 \to 4, \quad 5 \to 5 \to 2 \to 2, \quad 6 \to 6, \qquad\qquad 7 \to 7 \to 7 \to 1.
\end{aligned}$$

Net: $1 \mapsto 5, 5 \mapsto 2, 2 \mapsto 3, 3 \mapsto 7, 7 \mapsto 1$ and $4 \mapsto 4, 6 \mapsto 6$ fixed. Orbit of 1: $1 \mapsto 5 \mapsto 2 \mapsto 3 \mapsto 7 \mapsto 1$:

$$(1\,4\,7)(2\,5)(1\,2\,3\,4) = (1\,5\,2\,3\,7), \qquad \text{order } = \mathrm{lcm}(5) = 5.$$

Check: a single 5-cycle moving $\{1, 2, 3, 5, 7\}$, fixing $4, 6$; lengths sum $5 = 7 - 2$.

Method (How to invert a permutation)**.** Trigger: you need σ^{-1}, or to solve $\sigma x = \tau$ (then $x = \sigma^{-1}\tau$).

1. Put σ in disjoint-cycle form.
2. Reverse the entries of each cycle: $(a_1\, a_2\, \cdots\, a_k) \mapsto (a_k\, \cdots\, a_2\, a_1)$. Equivalently keep a_1 first and reverse the rest: $(a_1\, a_k\, a_{k-1}\, \cdots\, a_2)$.
3. Leave fixed points fixed. The reversed cycles are still disjoint.
4. Check: $\sigma\sigma^{-1} = \mathrm{id}$, i.e. composing should fix every point.

Caution. Reverse each cycle *individually*; do not reverse the whole written string across cycle boundaries. And a transposition is its own inverse: $(a\,b)^{-1} = (a\,b)$.

Worked Example 1.3.13 (Inverse by reversing cycles)**.** Find σ^{-1} for $\sigma = (1\,5\,2\,6\,3)(4\,7)$ in S_7.

Recognition. Inverse requested and σ is already in disjoint cycles: apply the reverse-each- cycle rule directly.

Solution. Reverse the 5-cycle: $(1\,5\,2\,6\,3)^{-1} = (3\,6\,2\,5\,1) = (1\,3\,6\,2\,5)$ (rotated to start at 1). The transposition is self-inverse: $(4\,7)^{-1} = (4\,7)$. Hence

$$\sigma^{-1} = (1\,3\,6\,2\,5)(4\,7).$$

Check: σ sends $1 \mapsto 5$, so σ^{-1} must send $5 \mapsto 1$ – indeed $(1\,3\,6\,2\,5)$ ends $5 \mapsto 1$. And $\sigma : 6 \mapsto 3$, $\sigma^{-1} : 3 \mapsto 6$, consistent. Composing $\sigma\sigma^{-1}$ fixes all of $\{1, \ldots, 7\}$.

Worked Example 1.3.14 (Inverse of a product, two ways)**.** Let $\alpha = (1\,2\,3)$ and $\beta = (1\,4)$ in S_4. Compute $(\alpha\beta)^{-1}$ directly, and confirm via $\beta^{-1}\alpha^{-1}$.

Recognition. Inverse of a product: recall $(\alpha\beta)^{-1} = \beta^{-1}\alpha^{-1}$ (order flips), and here α, β overlap at 1, so we cannot drop the flip.

Solution. First $\alpha\beta$: rightmost $\beta = (1\,4)$: $1 \to 4, 4 \to 1$; left $\alpha = (1\,2\,3)$. $1 \to 4 \to 4,\ 2 \to 2 \to 3,\ 3 \to 3 \to 1,\ 4 \to 1 \to 2$. Net $1 \mapsto 4, 4 \mapsto 2, 2 \mapsto 3, 3 \mapsto 1$, i.e. $\alpha\beta = (1\,4\,2\,3)$. Reverse: $(\alpha\beta)^{-1} = (1\,3\,2\,4)$. Cross-check: $\beta^{-1}\alpha^{-1} = (1\,4)(1\,3\,2)$. Rightmost $(1\,3\,2)$:$1 \to 3, 3 \to 2, 2 \to 1$; left $(1\,4)$. $1 \to 3 \to 3,\ 2 \to 1 \to 4,\ 3 \to 2 \to 2,\ 4 \to 4 \to 1$: net $1 \mapsto 3, 3 \mapsto 2, 2 \mapsto 4, 4 \mapsto 1 = (1\,3\,2\,4)$. The two agree. Check: $(\alpha\beta)(\alpha\beta)^{-1}$ should be id; e.g. $1 \xrightarrow{(\alpha\beta)^{-1}} 3 \xrightarrow{\alpha\beta} 1$, good.

Method (How to compute a power σ^m)**.** Trigger: you want σ^m or the order $|\sigma|$.

1. If σ is a single k-cycle, σ^m advances each point by m steps around the wheel. When $\gcd(m, k) = 1$, σ^m is again a single k-cycle; in general σ^m splits into $\gcd(m, k)$ cycles each of length $k/\gcd(m, k)$.
2. If $\sigma = \gamma_1 \cdots \gamma_r$ disjoint, then $\sigma^m = \gamma_1^m \cdots \gamma_r^m$ (disjoint cycles commute), so power each factor separately.
3. $|\sigma| =$ lcm of the cycle lengths.

Worked Example 1.3.15 (Cube of a single cycle)**.** Compute $(1\,2\,3\,4\,5\,6\,7)^3$ in S_7.

Recognition. A power of one k-cycle: advance each point 3 steps. Here $k = 7$, $\gcd(3, 7) = 1$, so expect a single 7-cycle.

Solution. Stepping +3 around $(1\,2\,3\,4\,5\,6\,7)$: $1 \to 4$, $4 \to 7$, $7 \to 3$, $3 \to 6$, $6 \to 2$, $2 \to 5$, $5 \to 1$. Threading from 1:

$$(1\,2\,3\,4\,5\,6\,7)^3 = (1\,4\,7\,3\,6\,2\,5).$$

Check: $\gcd(3, 7) = 1$ predicts one 7-cycle, as found. Order of the result is 7, matching $|\sigma| = 7$.

Worked Example 1.3.16 (Powers that split a cycle)**.** In S_6 compute $(1\,2\,3\,4\,5\,6)^3$ and verify the splitting rule.

Recognition. Power of a 6-cycle by $m = 3$; since $\gcd(3, 6) = 3$ the rule predicts 3 cycles of length $6/3 = 2$ – so a product of transpositions, not a single cycle.

Solution. Step +3: $1 \to 4, 4 \to 1$; $2 \to 5, 5 \to 2$; $3 \to 6, 6 \to 3$. Hence

$$(1\,2\,3\,4\,5\,6)^3 = (1\,4)(2\,5)(3\,6).$$

Check: $\gcd(3, 6) = 3$ cycles, each length 2, total support 6. Order $\mathrm{lcm}(2, 2, 2) = 2$, consistent with σ^3 where $|\sigma| = 6$ and $6/\gcd(6, 3) = 2$.

Worked Example 1.3.17 (Power of a multi-cycle permutation)**.** Let $\sigma = (1\,2\,3\,4)(5\,6\,7\,8)$ in S_8. Compute σ^2 and σ^3.

Recognition. Disjoint product, so power each 4-cycle separately. For $m = 2$, $\gcd(2, 4) = 2$ splits each into two transpositions; for $m = 3$, $\gcd(3, 4) = 1$ keeps each a 4-cycle (the reverse, since $3 \equiv -1 \bmod 4$).

Solution. σ^2: each 4-cycle steps +2. $(1\,2\,3\,4)^2 = (1\,3)(2\,4)$ and $(5\,6\,7\,8)^2 = (5\,7)(6\,8)$, so

$$\sigma^2 = (1\,3)(2\,4)(5\,7)(6\,8).$$

σ^3: step $+3 \equiv -1$, i.e. reverse each cycle. $(1\,2\,3\,4)^3 = (1\,4\,3\,2)$ and $(5\,6\,7\,8)^3 = (5\,8\,7\,6)$, so

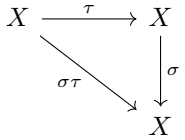
$$\sigma^3 = (1\,4\,3\,2)(5\,8\,7\,6) = \sigma^{-1}.$$

Check: $|\sigma| = \operatorname{lcm}(4,4) = 4$, so $\sigma^3 = \sigma^{-1}$ exactly as found; and σ^2 has order $\operatorname{lcm}(2,2,2,2) = 2$, while $(\sigma^2)^2 = \sigma^4 = \mathrm{id}$, consistent.

Worked Example 1.3.18 (Disjoint cycles commute; overlapping ones need not)**.** In S_5 verify $(1\,2\,3)(4\,5) = (4\,5)(1\,2\,3)$ but $(1\,2)(1\,3) \neq (1\,3)(1\,2)$.

Recognition. Commutativity question: the deciding feature is disjointness. Disjoint supports $\{1,2,3\}$ vs $\{4,5\}$ predict commuting (Proposition 1.3.5); shared point 1 predicts possible failure.

Solution. Disjoint case: $(1\,2\,3)$ fixes $4,5$ and $(4\,5)$ fixes $1,2,3$, so in either order $1 \mapsto 2, 2 \mapsto 3, 3 \mapsto 1, 4 \mapsto 5, 5 \mapsto 4$; both products equal the same disjoint form:



$$(1\,2\,3)(4\,5) = (4\,5)(1\,2\,3).$$

Overlapping case: compute $(1\,2)(1\,3)$, rightmost $(1\,3)$ first: $1 \to 3 \to 3$, $3 \to 1 \to 2$, $2 \to 2 \to 1$, giving $(1\,3\,2)$. Now $(1\,3)(1\,2)$, rightmost $(1\,2)$ first: $1 \to 2 \to 2$, $2 \to 1 \to 3$, $3 \to 3 \to 1$, giving $(1\,2\,3)$. Thus

$$(1\,2)(1\,3) = (1\,3\,2) \neq (1\,2\,3) = (1\,3)(1\,2).$$

Check: the two answers are inverses of each other (reversing $(1\,3\,2)$ gives $(1\,2\,3)$), exactly the expected $\beta\alpha = (\alpha\beta)^{-1}$ relation for two transpositions, confirming noncommutativity.

Remark 1.3.1 (Why the multiply-method is just composition of functions). The whole machinery above is one commutative triangle: tracking a point x through τ then σ *is* evaluating the composite arrow. With $X = \{1, \ldots, n\}$,

The diagonal $\sigma\tau$ commutes with the path "τ then σ" by definition, which is why every worked example reads "$x \xrightarrow{\tau} \tau(x) \xrightarrow{\sigma} \sigma(\tau(x))$." Inversion is the same triangle read backwards: σ^{-1} is the unique arrow making $\sigma^{-1} \circ \sigma = \mathrm{id}_X = \sigma \circ \sigma^{-1}$.

Diagram explanation. Objects: Three copies of $X = \{1, \ldots, n\}$, arranged as vertices of a triangle. The upper-left and upper-right copies are the domain and intermediate set; the bottom copy is the codomain. All three are the same set, viewed at different stages of the two-step composition.

Arrows: The horizontal arrow $\tau\colon X \to X$ sends each x to $\tau(x)$. The vertical arrow $\sigma\colon X \to X$ sends each y to $\sigma(y)$. The diagonal arrow $\sigma\tau\colon X \to X$ is the composite, sending x directly to $\sigma(\tau(x))$. All three arrows are bijections (permutations).

What commutes: The triangle commutes: going right then down equals going diagonally, i.e. $\sigma \circ \tau = \sigma\tau$ as functions on X. In element terms, for every $x \in X$: $x \xrightarrow{\tau} \tau(x) \xrightarrow{\sigma} \sigma(\tau(x))$ equals $x \xrightarrow{\sigma\tau} \sigma(\tau(x))$. These are two notations for the same value.

Why it commutes: The diagonal is *defined* to be the composite: the notation $\sigma\tau$ means "apply τ first, then σ." There is no independent condition to verify; commutativity here is a tautology that unpacks the definition of function composition. The diagram is not asserting a nontrivial identity – it is displaying the definition visually.

Why this matters here: This triangle appears in the remark explaining why the right-to-left reading convention is unavoidable. Every worked example in the section tracks a point x along the top-right path (τ first, then σ), but students who read left-to-right instinctively want to apply σ first. The triangle makes the convention concrete: the diagonal is the composite, and the two-step path on the outside is how one *computes* it.

Concrete example: Take $\tau = (1\,2)$ and $\sigma = (2\,3)$ in S_3. Then $\sigma\tau$ sends $1 \xrightarrow{\tau} 2 \xrightarrow{\sigma} 3$, so $1 \mapsto 3$. The diagonal arrow confirms this without redundancy: $(\sigma\tau)(1) = \sigma(\tau(1)) = \sigma(2) = 3$.

Common pitfall: Students often read the horizontal arrow as applying τ "on the right" and conclude that $\sigma\tau$ means "σ acts first." The diagram corrects this: the horizontal arrow τ is applied *first* (upper-left to upper-right), and only then does σ act (upper-right to bottom).

Takeaway: The point of this diagram is that the notation $\sigma\tau$ is shorthand for the two-step outer path of the triangle, making the right-to-left composition convention a visual fact rather than a memory rule.

Further examples and conventions in S_n

Definition 1.3.19 (S_Ω on an arbitrary finite set)**.** For any nonempty set Ω, the *symmetric group on* Ω, written S_Ω, is the group of all bijections $\Omega \to \Omega$ under function composition. The case $\Omega = \{1, 2, \ldots, n\}$ gives the S_n of Definition 1.3.1; in general one writes S_n in place of S_Ω whenever Ω has been identified with $\{1, \ldots, n\}$. The group structure depends only on the cardinality $|\Omega|$, not on the names of the elements: if $|\Omega| = n$ then $S_\Omega \cong S_n$, so up to relabeling there is just one symmetric group on n symbols.

Remark 1.3.2 (The two-row (function) notation). Underlying cycle notation is the raw data of a permutation $\sigma \in S_n$: the list of images $\sigma(1), \sigma(2), \ldots, \sigma(n)$. A compact display writes the inputs in a top row and the outputs beneath:

$$\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix} \quad \text{means} \quad \sigma(1) = 3,\ \sigma(2) = 5,\ \sigma(3) = 4,\ \sigma(4) = 1,\ \sigma(5) = 2.$$

A permutation is exactly such a table whose bottom row is a rearrangement of the top row. Cycle notation just repackages this table; the one above is the cycle $(1\,3\,4)(2\,5)$.

Remark 1.3.3 (Conventions for writing cycles). Three bookkeeping conventions are standard; D&F adopts the first two explicitly and remarks on the third.

1. (1-cycles omitted.) Fixed points are not written. To pin down a canonical display one may further agree to begin each cycle with the smallest number it moves and to list the cycles in increasing order of those leading entries; with that agreement the disjoint-cycle form becomes a unique string for reading off and comparing permutations.

2. (Identity.) The identity moves no point, so the omit-fixed-points rule would leave an empty string; D&F therefore writes the identity simply as the symbol 1.

3. (Ambient group.) The integer n being permuted is not recoverable from the written cycles alone: $(1\,2)$ names a different group element in each of $S_2, S_3, S_{10}, \ldots$ (in every case the transposition fixing all other points). The ambient S_n must be stated.

Worked Example 1.3.20 (Reading a two-row table as disjoint cycles)**.** Convert $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 3 & 5 & 6 & 1 & 2 & 4 \end{pmatrix} \in S_6$ to disjoint-cycle form.

Recognition. A permutation handed to us in the explicit image table (Remark 1.3.2); to read its structure we follow orbits, the standard table-to-cycles conversion.

Solution. Read images straight off the bottom row: $\sigma(1) = 3,\ \sigma(2) = 5,\ \sigma(3) = 6,\ \sigma(4) = 1,\ \sigma(5) = 2,\ \sigma(6) = 4$. Start at the smallest point and follow the orbit until it closes:

$$1 \mapsto 3 \mapsto 6 \mapsto 4 \mapsto 1, \qquad 2 \mapsto 5 \mapsto 2.$$

The first orbit is the 4-cycle $(1\,3\,6\,4)$; the second is the transposition $(2\,5)$; no point is fixed. Listing cycles by least entry (Remark 1.3.3):

$$\sigma = (1\,3\,6\,4)(2\,5).$$

Check: lengths $4 + 2 = 6$ account for all six points (no fixed points), and the bottom row $3, 5, 6, 1, 2, 4$ is a permutation of $1, \ldots, 6$, so the table was a genuine bijection.

Worked Example 1.3.21 (A product computed straight from the function values)**.** In S_5 let $\sigma = (1\,2\,3\,4\,5)$ and $\tau = (1\,3\,5)$. Compute the products $\sigma\tau$ and $\tau\sigma$, working directly from σ, τ as functions.

Recognition. Two cycles overlapping on $\{1, 3, 5\}$; the products are evaluated by the rightmost-first composition rule, and comparing the two orders gives a second nonabelian witness in a smaller group than before.

Solution. Image lists: $\sigma:\ 1 \mapsto 2, 2 \mapsto 3, 3 \mapsto 4, 4 \mapsto 5, 5 \mapsto 1$; $\quad \tau:\ 1 \mapsto 3, 3 \mapsto 5, 5 \mapsto 1$ with $2, 4$ fixed.

For $\sigma\tau$, apply τ then σ, i.e. $x \mapsto \sigma(\tau(x))$:

$$1 \mapsto \sigma(3) = 4, \quad 2 \mapsto \sigma(2) = 3, \quad 3 \mapsto \sigma(5) = 1, \quad 4 \mapsto \sigma(4) = 5, \quad 5 \mapsto \sigma(1) = 2.$$

Threading $1 \mapsto 4 \mapsto 5 \mapsto 2 \mapsto 3 \mapsto 1$ gives $\sigma\tau = (1\,4\,5\,2\,3)$.

For $\tau\sigma$, apply σ then τ, i.e. $x \mapsto \tau(\sigma(x))$:

$$1 \mapsto \tau(2) = 2, \quad 2 \mapsto \tau(3) = 5, \quad 3 \mapsto \tau(4) = 4, \quad 4 \mapsto \tau(5) = 1, \quad 5 \mapsto \tau(1) = 3.$$

Threading $1 \mapsto 2 \mapsto 5 \mapsto 3 \mapsto 4 \mapsto 1$ gives $\tau\sigma = (1\,2\,5\,3\,4)$. Hence

$$\sigma\tau = (1\,4\,5\,2\,3) \neq (1\,2\,5\,3\,4) = \tau\sigma,$$

so these two elements do not commute. Check: both products are 5-cycles (every point moves), as forced by $\tau\sigma$ and $\sigma\tau$ always being conjugate; they disagree because $\sigma\tau$ sends $1 \mapsto 4$ while $\tau\sigma$ sends $1 \mapsto 2$.

Worked Example 1.3.22 (A product whose factors are not all disjoint)**.** In S_6 compute the product $(1\,5)(2\,4\,6)(3\,5)$ and put it in disjoint-cycle form.

Recognition. Three factors with $(1\,5)$ and $(3\,5)$ sharing the point 5: not pairwise disjoint, so juxtaposition is invalid and we must track points right-to-left.

Solution. Image lists, rightmost first. $(3\,5):\ 3 \mapsto 5, 5 \mapsto 3$. $(2\,4\,6):\ 2 \mapsto 4, 4 \mapsto 6, 6 \mapsto 2$. $(1\,5):\ 1 \mapsto 5, 5 \mapsto 1$. Carry each x through right→middle→left:

$$1 \xrightarrow{(35)} 1 \xrightarrow{(246)} 1 \xrightarrow{(15)} 5, \quad 2 \xrightarrow{(35)} 2 \xrightarrow{(246)} 4 \xrightarrow{(15)} 4,$$
$$3 \xrightarrow{(35)} 5 \xrightarrow{(246)} 5 \xrightarrow{(15)} 1, \quad 4 \xrightarrow{(35)} 4 \xrightarrow{(246)} 6 \xrightarrow{(15)} 6,$$
$$5 \xrightarrow{(35)} 3 \xrightarrow{(246)} 3 \xrightarrow{(15)} 3, \quad 6 \xrightarrow{(35)} 6 \xrightarrow{(246)} 2 \xrightarrow{(15)} 2.$$

Net map: $1 \mapsto 5$, $2 \mapsto 4$, $3 \mapsto 1$, $4 \mapsto 6$, $5 \mapsto 3$, $6 \mapsto 2$. Follow orbits from the smallest point: $1 \mapsto 5 \mapsto 3 \mapsto 1$ and $2 \mapsto 4 \mapsto 6 \mapsto 2$:

$$(1\,5)(2\,4\,6)(3\,5) = (1\,5\,3)(2\,4\,6).$$

Check: two 3-cycles, support $3 + 3 = 6$, no fixed points; order $\mathrm{lcm}(3, 3) = 3$.

Worked Example 1.3.23 (Identity written as the symbol 1)**.** Simplify $(1\,3)(2\,4)(1\,3)(2\,4)$ in S_4 and write the result using the convention of Remark 1.3.3.

Recognition. A product of commuting transpositions repeated; recognizing each transposition is its own inverse, the whole product should collapse to the identity.

Solution. The two transpositions $(1\,3)$ and $(2\,4)$ are disjoint, hence commute, so

$$(1\,3)(2\,4)(1\,3)(2\,4) = (1\,3)(1\,3)\,(2\,4)(2\,4) = \mathrm{id}\,.$$

Directly: $(1\,3)^2 = \mathrm{id}$ and $(2\,4)^2 = \mathrm{id}$. By the omit-fixed-points convention every 1-cycle would be dropped, leaving an empty string; the agreed notation for this element is therefore the single symbol

$$(1\,3)(2\,4)(1\,3)(2\,4) = 1.$$

Check: a transposition has order 2, so each squared factor is id; the result fixes all of $\{1, 2, 3, 4\}$, consistent with writing it as 1.

Remark 1.3.4 (A permutation and its inverse from the table). In two-row form, σ^{-1} is obtained by swapping the two rows and then reordering the columns so the top row reads $1, 2, \ldots, n$ again. For $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 4 & 1 & 2 \end{pmatrix}$, swapping rows gives the pairing $3 \mapsto 1, 5 \mapsto 2, 4 \mapsto 3, 1 \mapsto 4, 2 \mapsto 5$, i.e.

$$\sigma^{-1} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 4 & 5 & 1 & 3 & 2 \end{pmatrix} = (1\,4\,3)(2\,5),$$

which is the cycle $(1\,3\,4)(2\,5)$ run backwards, agreeing with the reverse-each-cycle rule (Proposition 1.3.6).

Remark 1.3.5 (Sizes one can compute by hand). The factorial growth of Theorem 1.3.2 is steep: $|S_1| = 1$, $|S_2| = 2$, $|S_3| = 6$, $|S_4| = 24$, $|S_5| = 120$, $|S_6| = 720$. Already S_3 is the smallest nonabelian group, and S_4 has 24 elements – the same order as D_{24} but a genuinely different group. This is why concrete permutation computations are nearly always done in cycle notation rather than by listing the full multiplication table.

The order of a permutation: lcm of disjoint cycle lengths, cycle type, and counting

Throughout, permutations act on $\{1, 2, \ldots, n\}$ and compose RIGHT-TO-LEFT (apply the rightmost factor first), the D&F convention. We write a permutation in disjoint cycle notation; fixed points may be omitted.

Definition 1.3.24 (Disjoint cycles, cycle type)**.** Two cycles are *disjoint* if no integer is moved by both. Every $\sigma \in S_n$ factors as a product of disjoint cycles, unique up to the order of the factors. Listing the lengths of those cycles (including the 1-cycles, i.e. the fixed points) as a partition of n gives the *cycle type* of σ. For example $\sigma = (1\,2\,3)(4\,5) \in S_5$ has cycle type $3 + 2$; the identity of S_5 has cycle type $1 + 1 + 1 + 1 + 1$.

Lemma 1.3.25 (Order of a single cycle)**.** *A k-cycle $\tau = (a_1\, a_2\, \cdots\, a_k)$ has order exactly k.*

Proof. The cycle sends $a_i \mapsto a_{i+1}$ (indices mod k), so τ^m sends $a_i \mapsto a_{i+m}$. Thus $\tau^m = \mathrm{id}$ iff $a_{i+m} = a_i$ for all i iff $m \equiv 0 \pmod{k}$, i.e. iff $k \mid m$. The least positive such m is k, so $|\tau| = k$. □

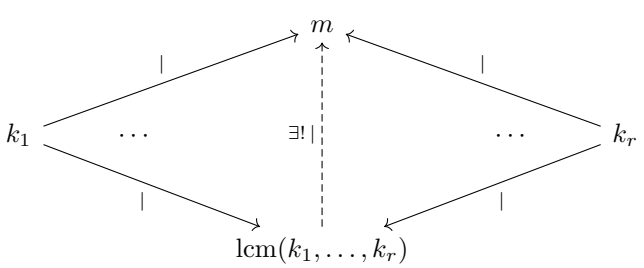
Theorem 1.3.26 (Order = lcm of disjoint cycle lengths)**.** *If $\sigma = \tau_1\tau_2\cdots\tau_r$ is a product of* disjoint *cycles of lengths $k_1, k_2, \ldots, k_r$, then*

$$|\sigma| = \mathrm{lcm}(k_1, k_2, \ldots, k_r).$$

Proof. Disjoint cycles commute, since they move disjoint sets of points. Hence for every integer m,

$$\sigma^m = \tau_1^m \tau_2^m \cdots \tau_r^m.$$

The cycle τ_j^m acts only on the points moved by τ_j, and these point-sets are pairwise disjoint. Therefore $\sigma^m = \mathrm{id}$ iff each factor acts as the identity on its own set, i.e. iff $\tau_j^m = \mathrm{id}$ for every j. By Lemma 1.3.25, $\tau_j^m = \mathrm{id}$ iff $k_j \mid m$. So



$$\sigma^m = \mathrm{id} \quad \Longleftrightarrow \quad k_j \mid m \text{ for all } j \quad \Longleftrightarrow \quad \mathrm{lcm}(k_1, \ldots, k_r) \mid m,$$

the last equivalence being the defining property of the least common multiple. The least positive m with this property is $\mathrm{lcm}(k_1, \ldots, k_r)$, which is therefore $|\sigma|$. □

Caution. The cycles must be *disjoint* before you read off lengths. $(1\,2\,3)(2\,4)$ is NOT type $3 + 2$ of order 6; the cycles share the point 2, so you must first multiply them out: $(1\,2\,3)(2\,4) = (1\,2\,4\,3)$, a 4-cycle of order 4.

Caution. Use lcm, never the product. $|(1\,2\,3)(4\,5\,6)| = \mathrm{lcm}(3, 3) = 3$, not 9.

The equivalence chain in the proof is exactly a divisibility ladder: every multiple of σ's order is a common multiple of the cycle lengths, and conversely. The universal property of lcm is the same as a coproduct/least-upper-bound condition in the divisibility poset:

Reading the bottom node: lcm divides every common multiple m (dashed unique arrow), and that is precisely the statement "$\sigma^m = \mathrm{id} \iff \mathrm{lcm} \mid m$."

Diagram explanation. Objects: Four nodes live in the divisibility poset (integers ordered by divisibility, where $a \to b$ means $a \mid b$). The bottom node is $\mathrm{lcm}(k_1, \ldots, k_r)$, the least common multiple of the cycle lengths. The top node is m, an arbitrary common multiple of all cycle lengths. The two nodes k_1 and k_r (with implicit intermediates $k_2, \ldots, k_{r-1}$) are the individual cycle lengths; in the poset they lie *below* both lcm and m (each k_j divides both), even though the picture draws lcm at the bottom.

Arrows: Each solid arrow $k_j \mid m$ asserts that k_j divides m (i.e. m is a common multiple of all k_j). Each solid arrow $k_j \mid \mathrm{lcm}$ (running down from k_1 and k_r to the bottom node) asserts that k_j divides lcm, since lcm is a multiple of each k_j. The dashed arrow $\mathrm{lcm} \xrightarrow{\exists! \mid} m$ is the unique factorization arrow: if m is any common multiple of the k_j, then $\mathrm{lcm} \mid m$. This is the defining universal property of the least common multiple in the divisibility poset: lcm is the unique smallest common multiple.

What commutes: The diagram commutes in the sense that, for each j, both paths from k_j to m agree: the path $k_j \mid \mathrm{lcm} \mid m$ (down to lcm, then along the dashed arrow) and the direct solid arrow $k_j \mid m$ yield the same divisibility conclusion. Formally, $k_j \mid \mathrm{lcm}$ and $\mathrm{lcm} \mid m$ imply $k_j \mid m$ by transitivity; in a poset any two parallel arrows are equal, so commutativity is automatic.

Why it commutes: Commutativity is automatic (divisibility is transitive); the real content is that the dashed arrow exists. The universal property says: the integer lcm is characterized by (1) $k_j \mid \mathrm{lcm}$ for all j, and (2) if $k_j \mid m$ for all j then $\mathrm{lcm} \mid m$—exactly the dashed arrow's content.

Why this matters here: The theorem just proved says $\sigma^m = \mathrm{id}$ iff $k_j \mid m$ for all j iff $\mathrm{lcm}(k_1, \ldots, k_r) \mid m$. The diagram visualizes the equivalence of these two conditions: the dashed arrow IS the step "common multiple $\Rightarrow$ divisible by lcm," which is what makes the proof work. Without this universal property, one could only say $\sigma^{\mathrm{product}} = \mathrm{id}$, giving a weaker bound.

Concrete example: Take $\sigma = (1\,2\,3)(4\,5) \in S_5$, so $k_1 = 3$, $k_2 = 2$. Then lcm $= 6$. The diagram with $m = 12$: both $3 \mid 12$ and $2 \mid 12$ (solid arrows), and the dashed arrow says $6 \mid 12$. With $m = 4$: $3 \nmid 4$, so 4 is not a common multiple, and the dashed arrow does not apply—confirming $\sigma^4 \neq \mathrm{id}$.

Common pitfall: Students often read the arrows as $\mathrm{lcm} \mid k_j$ (the lcm divides each k_j), reversing the direction. In fact $k_j \mid \mathrm{lcm}$: each individual cycle length divides the least common multiple, not the other way around. The dashed arrow points *up* from lcm to m because lcm is smaller (in the divisibility order, "smaller" means "divides").

Takeaway: The point of this diagram is that the lcm plays the role of a coproduct in the divisibility poset—it is the unique common multiple that divides every common multiple, so $\sigma^m = \mathrm{id}$ is equivalent to the single divisibility condition $\mathrm{lcm}(k_1, \ldots, k_r) \mid m$.

Method (How to compute $|\sigma|$ for $\sigma \in S_n$)**.**

1. Write σ in disjoint cycle notation. If a product is given with overlapping cycles, multiply it out first (right-to-left) until the cycles are disjoint.
2. Record the length of each disjoint cycle: $k_1, k_2, \ldots, k_r$.
3. Output $|\sigma| = \mathrm{lcm}(k_1, \ldots, k_r)$.
4. Sanity check: $|\sigma| \mid n!$ always holds, but $|\sigma| \leq n$ *is false in general* (e.g. $|(1\,2\,3)(4\,5)| = 6 > 5$); what does hold is $k_j \leq n$ for each j and $\sum k_j \leq n$. Verify by computing $\sigma^{|\sigma|}$ on one moved point *of every cycle* (it must fix each of them); a single moved point is not enough.

Trigger. Use this *whenever* a problem asks for the order of an explicit permutation, or the order of an element of S_n, A_n, or any group of permutations.

Worked Example 1.3.27 (Order of a $3 + 2$ permutation)**.** Compute $|(1\,2\,3)(4\,5)|$ in S_5.

Recognition. The element is already a product of disjoint cycles (no shared points: $\{1, 2, 3\} \cap \{4, 5\} = \varnothing$). Theorem 1.3.26 applies directly: take lcm of the lengths.

Solution. Lengths are 3 and 2. So

$$|(1\,2\,3)(4\,5)| = \mathrm{lcm}(3, 2) = 6.$$

Check by raising to the power 6. Since the cycles commute, $\big((1\,2\,3)(4\,5)\big)^6 = (1\,2\,3)^6(4\,5)^6$. Now $(1\,2\,3)^6 = (1\,2\,3)^{3\cdot 2} = \mathrm{id}$ and $(4\,5)^6 = (4\,5)^{2\cdot 3} = \mathrm{id}$, so the sixth power is id. And no smaller exponent works: at exponent 2 the 3-cycle survives ($(1\,2\,3)^2 = (1\,3\,2) \neq \mathrm{id}$); at exponent 3 the transposition survives ($(4\,5)^3 = (4\,5) \neq \mathrm{id}$). Hence the order is exactly 6.

Worked Example 1.3.28 (Order of a $4+3+2$ permutation in S_9)**.** Compute $|(1\,2\,3\,4)(5\,6\,7)(8\,9)|$.

Recognition. Three pairwise-disjoint cycles ($\{1,2,3,4\}$, $\{5,6,7\}$, $\{8,9\}$ are disjoint). Apply Theorem 1.3.26.

Solution. Lengths $4, 3, 2$. We have $\mathrm{lcm}(4,3,2)$: factor $4 = 2^2$, $3 = 3$, $2 = 2$, so $\mathrm{lcm} = 2^2 \cdot 3 = 12$. Thus

$$|(1\,2\,3\,4)(5\,6\,7)(8\,9)| = \mathrm{lcm}(4,3,2) = 12.$$

Check: σ^{12} raises each cycle to a multiple of its length ($12 = 4\cdot 3 = 3\cdot 4 = 2\cdot 6$), so $\sigma^{12} = \mathrm{id}$. A proper divisor must miss at least one cycle: σ^6 gives $(1\,2\,3\,4)^6 = (1\,2\,3\,4)^2 = (1\,3)(2\,4) \neq \mathrm{id}$; σ^4 gives $(5\,6\,7)^4 = (5\,6\,7) \neq \mathrm{id}$. So 12 is minimal.

Worked Example 1.3.29 (Overlapping cycles: multiply first)**.** Compute $|(1\,2\,3)(2\,4)|$ in S_4.

Recognition. The two cycles share the point 2, so they are NOT disjoint. Do not read off $\mathrm{lcm}(3,2)$. First multiply right-to-left to get the disjoint form, then apply Theorem 1.3.26.

Solution. Compute $\sigma = (1\,2\,3)(2\,4)$ by tracking each point, applying $(2\,4)$ first then $(1\,2\,3)$:

$$1 \overset{(2\,4)}{\mapsto} 1 \overset{(1\,2\,3)}{\mapsto} 2, \quad 2 \overset{(2\,4)}{\mapsto} 4 \overset{(1\,2\,3)}{\mapsto} 4, \quad 4 \overset{(2\,4)}{\mapsto} 2 \overset{(1\,2\,3)}{\mapsto} 3, \quad 3 \overset{(2\,4)}{\mapsto} 3 \overset{(1\,2\,3)}{\mapsto} 1.$$

So $1 \mapsto 2 \mapsto 4 \mapsto 3 \mapsto 1$, giving $\sigma = (1\,2\,4\,3)$, a single 4-cycle. Therefore

$$|\sigma| = \mathrm{lcm}(4) = 4.$$

Check: $\sigma^2 = (1\,4)(2\,3) \neq \mathrm{id}$, $\sigma^4 = \mathrm{id}$. Order 4, confirming the overlap warning.

Worked Example 1.3.30 (Order in A_8, a $5+3$ element)**.** Compute $|(1\,2\,3\,4\,5)(6\,7\,8)|$ and confirm the element lies in A_8.

Recognition. Disjoint 5-cycle and 3-cycle. Order by Theorem 1.3.26; parity by counting transpositions.

Solution. $\mathrm{lcm}(5,3) = 15$ since $\gcd(5,3) = 1$ forces $\mathrm{lcm} = 5\cdot 3$. So $|\sigma| = 15$. Parity: a 5-cycle is a product of 4 transpositions (even), a 3-cycle is a product of 2 transpositions (even); total 6 transpositions, so $\mathrm{sgn}(\sigma) = (+1)$ and $\sigma \in A_8$. Check: $\sigma^{15} = \mathrm{id}$ ($5 \mid 15$, $3 \mid 15$); σ^5 leaves $(6\,7\,8)^5 = (6\,7\,8)^2 = (6\,8\,7) \neq \mathrm{id}$; σ^3 leaves $(1\,2\,3\,4\,5)^3 \neq \mathrm{id}$. Minimal exponent 15.

Worked Example 1.3.31 (Largest order of an element of S_7 (Landau's problem))**.** Find $g(7) = \max\{|\sigma| : \sigma \in S_7\}$.

Recognition. Order = lcm of cycle lengths, and the lengths form a partition of (at most) 7. So maximize lcm of a partition of 7. This is Landau's function $g(7)$; just search all partitions.

Solution. List partitions of 7 and their lcm (fixed points contribute length 1 and do not change lcm, so we only need partitions whose parts sum to at most 7; using all 7 points is never worse):

7	$\mathrm{lcm} = 7$
$6+1$	6
$5+2$	$\mathrm{lcm}(5,2) = 10$
$4+3$	$\mathrm{lcm}(4,3) = 12$
$5+1+1$	5
$4+2+1$	4
$3+2+2$	$\mathrm{lcm}(3,2,2) = 6$
$3+3+1$	3
$2+2+2+1$	2

The maximum is 12, attained by cycle type $4+3$, e.g. $\sigma = (1\,2\,3\,4)(5\,6\,7)$. Hence

$$g(7) = 12.$$

Check: any partition using a part ≥ 5 pairs with at most 2 remaining points, capping lcm at $\mathrm{lcm}(5,2) = 10 < 12$; a part of 7 alone gives only 7. So $4+3$ wins. (Note $12 > 7$: the maximal order can exceed n.)

Worked Example 1.3.32 (Why an n-cycle has order n)**.** Show directly that $\sigma = (1\,2\,3\,\cdots\,n) \in S_n$ has $|\sigma| = n$.

Recognition. Single cycle of length n. This is the base case Lemma 1.3.25; Theorem 1.3.26 then reads $\operatorname{lcm}(n) = n$. We re-derive it concretely.

Solution. Here $\sigma(i) = i + 1$ for $i < n$ and $\sigma(n) = 1$; equivalently $\sigma(i) \equiv i + 1 \pmod{n}$ on residues $\{1, \ldots, n\}$. By induction $\sigma^m(i) \equiv i + m \pmod{n}$. Then $\sigma^m = \mathrm{id}$ iff $i + m \equiv i \pmod{n}$ for all i iff $m \equiv 0 \pmod{n}$ iff $n \mid m$. Least positive: $m = n$. So $|\sigma| = n = \operatorname{lcm}(n)$. We can picture σ as rotation of a labeled n-clock (here $n = 6$): each application advances every label by one position, so it takes exactly 6 steps to return.

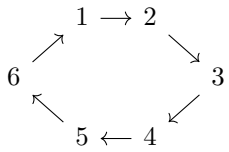


Diagram explanation. Objects: The six nodes $1, 2, 3, 4, 5, 6$ are the elements of the set $\{1, \ldots, 6\}$ on which the 6-cycle $\sigma = (1\,2\,3\,4\,5\,6)$ acts. They are arranged in a hexagonal pattern to mirror the rotational symmetry of the cycle.

Arrows: Each arrow $i \to i + 1$ (with $6 \to 1$ wrapping around) encodes the action of σ: the permutation sends each element to the next one in the cycle. Every arrow is an instance of the map $\sigma : \{1, \ldots, 6\} \to \{1, \ldots, 6\}$, the single permutation applied once.

What commutes: There is one closed loop: following all six arrows returns to the starting point, expressing $\sigma^6 = \mathrm{id}$. More precisely, the composition of the six arrows $1 \to 2 \to 3 \to 4 \to 5 \to 6 \to 1$ is the identity map on $\{1, \ldots, 6\}$. No proper sub-loop (of length $1, 2, 3$) returns to its start, witnessing that no proper divisor of 6 is the order of σ.

Why it commutes: Starting at any node i, applying σ six times sends $i \mapsto i + 1 \mapsto \cdots \mapsto i + 6 \equiv i \pmod{6}$, returning to i. In general $\sigma^m(i) = i + m \pmod{6}$, which equals i iff $6 \mid m$. The diagram makes this visible: going around the full hexagon ($m = 6$ steps) closes the loop; going halfway ($m = 3$) lands at the antipodal node, not the start.

Why this matters here: This diagram serves as a concrete, pictorial proof of Lemma 1.3.25 for $n = 6$: the order of a 6-cycle is 6. It replaces the algebraic argument "$\sigma^m = \mathrm{id}$ iff $6 \mid m$" with the visual fact that you must traverse the full hexagon to return home. It also motivates thinking of a k-cycle as a rotation of a labeled k-gon, an intuition that generalizes Lemma 1.3.25 to arbitrary k.

Concrete example: Take $n = 4$ and $\sigma = (1\,2\,3\,4)$. The square $1 \to 2 \to 3 \to 4 \to 1$ closes after 4 steps, confirming $|\sigma| = 4$. After 2 steps, $\sigma^2 = (1\,3)(2\,4)$, which swaps opposite corners—not the identity—showing that the order is not 2 (although 2 divides it): a partial traversal does not return home.

Common pitfall: Students sometimes count the number of nodes (here 6) and confuse it with the number of arrows or think the order could be less than 6 because the diagram looks "symmetric." The symmetry is rotational, not reflective: there is no sub-loop of length 2 or 3 that closes, even though 2 and 3 divide 6.

Takeaway: The point of this diagram is that a k-cycle acts as a rotation of a labeled k-gon, so it takes exactly k applications to return every element to its starting position, proving the order is exactly k.

Check ($n = 6$): $\sigma = (1\,2\,3\,4\,5\,6)$, $\sigma^3 = (1\,4)(2\,5)(3\,6) \neq \mathrm{id}$, $\sigma^6 = \mathrm{id}$. Order 6.

Method (How to count permutations of a given cycle type in S_n)**.** To count elements of cycle type with m_k cycles of length k (so $\sum_k k\, m_k = n$, counting fixed points as 1-cycles), use the formula

$$\#\{\text{type}\} = \frac{n!}{\displaystyle\prod_{k \geq 1} k^{m_k}\, m_k!}.$$

Why: fill the n slots of the cycle skeleton in $n!$ ways; divide by k^{m_k} because each k-cycle can be cyclically rotated k ways to the same cycle, and by $m_k!$ because the m_k cycles of equal length k can be permuted among themselves. *Recipe / trigger.* Use this *whenever* you must count permutations of a specified cycle

type, count k-cycles, count elements of a given order, or count elements of fixed parity. To count elements of a given *order* d, sum the counts over all cycle types whose lengths have lcm $= d$.

Worked Example 1.3.33 (Count the 3-cycles in S_5)**.** How many elements of S_5 are 3-cycles?

Recognition. "3-cycle in S_5" is cycle type $3+1+1$: one 3-cycle, two fixed points. Use the counting formula with $m_3 = 1,\ m_1 = 2$.

Solution. Direct count: choose and arrange the 3 moved points. Choose which 3 of 5 points: $\binom{5}{3} = 10$. Each set of 3 points forms $(3-1)! = 2$ distinct 3-cycles (a k-set yields $(k-1)!$ cycles). So $10 \cdot 2 = 20$. By the formula with $n = 5$, $m_3 = 1$, $m_1 = 2$:

$$\frac{5!}{3^1 \cdot 1! \cdot 1^2 \cdot 2!} = \frac{120}{3 \cdot 1 \cdot 1 \cdot 2} = \frac{120}{6} = 20.$$

Check: both methods give 20. (All 3-cycles are even, so these 20 lie in A_5.)

Worked Example 1.3.34 (Count elements of order 2 in S_4)**.** How many $\sigma \in S_4$ satisfy $|\sigma| = 2$?

Recognition. Order 2 means lcm of cycle lengths $= 2$, so every cycle has length 1 or 2 and at least one length is 2. The two cycle types are $2+1+1$ (a transposition) and $2+2$ (a double transposition). Count each, then add.

Solution. Transpositions ($2+1+1$, $m_2 = 1, m_1 = 2$): $\binom{4}{2} = 6$. Via formula: $4!/(2^1\,1!\,1^2\,2!) = 24/(2 \cdot 2) = 6$.
Double transpositions ($2+2$, $m_2 = 2$): formula gives $4!/(2^2\,2!) = 24/(4 \cdot 2) = 24/8 = 3$. Listing them confirms: $(1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)$, exactly 3.
Total order-2 elements: $6 + 3 = 9$. Check: these are all non-identity involutions; together with id they are the 10 self-inverse elements. (The three double transpositions plus id form V_4.)

Worked Example 1.3.35 (Count the 4-cycles in S_4 and read off their order)**.** How many 4-cycles does S_4 have, and what is their order?

Recognition. Cycle type 4 (one 4-cycle, no fixed points): $m_4 = 1$. Order is $\mathrm{lcm}(4) = 4$ by Theorem 1.3.26.

Solution. Count: a 4-set yields $(4-1)! = 3! = 6$ distinct 4-cycles, and there is only one way to choose all 4 of the 4 points. So 6. Via formula: $4!/(4^1 \cdot 1!) = 24/4 = 6$. Each has order $\mathrm{lcm}(4) = 4$. Check: S_4 has 24 elements; partitioning $24 = 1(\text{id}) + 6(\text{type } 2) + 3(\text{type } 2{+}2) + 8(\text{type } 3{+}1) + 6(\text{type } 4) = 24$, the 4-cycle count 6 fits.

Worked Example 1.3.36 (Count elements of order 6 in S_5)**.** How many $\sigma \in S_5$ have $|\sigma| = 6$?

Recognition. Order 6 = lcm of cycle lengths forces lengths whose lcm is 6; with parts summing to ≤ 5 the only option is $3+2$ (since $6 = \mathrm{lcm}(3,2)$, and 6 alone needs a 6-cycle, impossible in S_5). Count cycle type $3+2$.

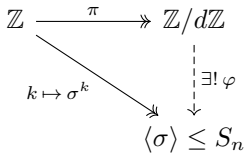
Solution. Cycle type $3+2$ uses all 5 points: $m_3 = 1, m_2 = 1$. Formula:

$$\frac{5!}{3^1 \cdot 1! \cdot 2^1 \cdot 1!} = \frac{120}{3 \cdot 2} = \frac{120}{6} = 20.$$

Cross-check constructively: choose the 3-cycle's points $\binom{5}{3} = 10$, arrange them as a cycle $(3-1)! = 2$ ways, and the remaining 2 points form a unique 2-cycle. So $10 \cdot 2 \cdot 1 = 20$. Each such σ has order $\mathrm{lcm}(3,2) = 6$. Answer: 20.

Worked Example 1.3.37 (Count elements of order 3 in A_4)**.** How many elements of order 3 lie in A_4?

Recognition. Order 3 means lcm of lengths $= 3$; in S_4 the only possibility is type $3+1$ (a 3-cycle). All 3-cycles are even, so they all lie in A_4. Count 3-cycles in S_4.



Solution. Type $3+1$ in S_4: $m_3 = 1, m_1 = 1$. Formula: $4!/(3^1 \cdot 1! \cdot 1^1 \cdot 1!) = 24/3 = 8$. Constructive check: $\binom{4}{3} = 4$ choices of moved points, each giving $(3-1)! = 2$ cycles, total $4 \cdot 2 = 8$. Since every 3-cycle is even, all 8 lie in A_4. As $|A_4| = 12$, the order-3 elements (8) plus the identity (1) plus the three double transpositions (3) give $8 + 1 + 3 = 12$, confirming the count.

The full census of S_4 by cycle type ties everything together. Each row's order is lcm of the parts; each count is the formula $n!/\prod_k k^{m_k} m_k!$ with $n = 4$.

Cycle type	Order = lcm	Count	Parity
$1+1+1+1$ (id)	1	1	even
$2+1+1$	2	6	odd
$2+2$	2	3	even
$3+1$	3	8	even
4	4	6	odd
Total	—	24	—

Reading the table: even elements $1+3+8=12=|A_4|$; odd elements $6+6=12$; orders occurring are $\{1,2,3,4\}$, and indeed lcm never exceeds $g(4)=4$ here (max over partitions of 4: $\operatorname{lcm}(4)=4$, $\operatorname{lcm}(3,1)=3$, $\operatorname{lcm}(2,2)=2$, so $g(4)=4$).

Remark 1.3.6. The counting and order facts package neatly: for σ of order d, the cyclic subgroup $\langle\sigma\rangle \cong \mathbb{Z}/d\mathbb{Z}$, and the surjection $\mathbb{Z} \to \langle\sigma\rangle$ factors uniquely through $\mathbb{Z}/d\mathbb{Z}$. This is the universal property of the quotient applied to the element σ:

Here $d=|\sigma|=\operatorname{lcm}$ of the cycle lengths is exactly the integer for which $\pi:\mathbb{Z}\to\mathbb{Z}/d\mathbb{Z}$ has $\ker\pi = d\mathbb{Z} = \{m : \sigma^m = \mathrm{id}\}$, recovering Theorem 1.3.26's kernel description $\{m : \operatorname{lcm} \mid m\}$.

Diagram explanation. Objects: Three groups appear. $\mathbb{Z}$ is the additive group of integers—the universal source of cyclic behavior. $\mathbb{Z}/d\mathbb{Z} = \mathbb{Z}/d\mathbb{Z}$ is the cyclic group of order $d=|\sigma|=\operatorname{lcm}(k_1,\dots,k_r)$, the abstract cyclic group of the same order as $\langle\sigma\rangle$. $\langle\sigma\rangle \leq S_n$ is the cyclic subgroup generated by σ, a concrete group of permutations.

Arrows: The horizontal arrow $\pi:\mathbb{Z}\twoheadrightarrow\mathbb{Z}/d\mathbb{Z}$ is the canonical surjective quotient map $k\mapsto\bar{k}=k+d\mathbb{Z}$; it kills the subgroup $d\mathbb{Z}=\ker\pi$. The diagonal arrow $\mathbb{Z}\to\langle\sigma\rangle$ is the power map $k\mapsto\sigma^k$, the group homomorphism sending $1\in\mathbb{Z}$ to the generator σ. The dashed vertical arrow $\varphi:\mathbb{Z}/d\mathbb{Z}\to\langle\sigma\rangle$ is the unique induced isomorphism $\bar{k}\mapsto\sigma^k$, which exists because $\ker(\text{power map}) = d\mathbb{Z} = \ker\pi$.

What commutes: The triangle commutes: $\varphi\circ\pi = (\text{power map})$. In formulas, for every $k\in\mathbb{Z}$, $\varphi(\pi(k)) = \varphi(\bar{k}) = \sigma^k$, which equals the diagonal arrow evaluated at k. The commutativity asserts that the two paths from $\mathbb{Z}$ to $\langle\sigma\rangle$—going first to $\mathbb{Z}/d\mathbb{Z}$ then applying φ, or going directly via $k\mapsto\sigma^k$—give the same result.

Why it commutes: Well-definedness is the key check. The induced map φ is defined on cosets: $\varphi(k+d\mathbb{Z})=\sigma^k$. For this to be well-defined, two representatives of the same coset must yield the same image: if $k\equiv k' \pmod d$, then $k'-k\in d\mathbb{Z}$, so $\sigma^{k'-k}=\mathrm{id}$ (since $|\sigma|=d$ means $d\mathbb{Z}=\ker(\text{power map})$), and thus $\sigma^{k'}=\sigma^k$. The commutativity $\varphi\circ\pi=$ power map follows: $\varphi(\pi(k))=\varphi(\bar{k})=\sigma^k$, the same as the diagonal.

Why this matters here: Theorem 1.3.26 computed $|\sigma|=d=\operatorname{lcm}(k_1,\dots,k_r)$ by identifying $\ker(\text{power map}) = d\mathbb{Z}$. This diagram packages that result as an isomorphism: φ is injective (trivial kernel on $\mathbb{Z}/d\mathbb{Z}$) and surjective (every power σ^k is hit), so $\langle\sigma\rangle\cong\mathbb{Z}/d\mathbb{Z}$. The diagram summarizes the entire structure of the cyclic group generated by σ in one picture.

Concrete example: Take $\sigma=(1\,2\,3)\in S_3$, so $d=3$. The power map $\mathbb{Z}\to\langle\sigma\rangle$ sends $0\mapsto\mathrm{id}$, $1\mapsto(1\,2\,3)$, $2\mapsto(1\,3\,2)$, $3\mapsto\mathrm{id}$, and has kernel $3\mathbb{Z}$. The quotient $\pi:\mathbb{Z}\to\mathbb{Z}/3\mathbb{Z}$ has the same kernel. The induced $\varphi:\mathbb{Z}/3\mathbb{Z}\to\langle(1\,2\,3)\rangle$ sending $\bar{0}\mapsto\mathrm{id}$, $\bar{1}\mapsto(1\,2\,3)$, $\bar{2}\mapsto(1\,3\,2)$ is an isomorphism, confirming $\langle(1\,2\,3)\rangle\cong\mathbb{Z}/3\mathbb{Z}$.

Common pitfall: The dashed arrow φ is an isomorphism only because the kernel of the power map equals $d\mathbb{Z}$ exactly. If one mistakenly used a different modulus $d'\neq d$, the induced map would fail to be well-defined or would not be injective. One must first establish $|\sigma|=d$ before invoking the universal property; the diagram does not itself prove $|\sigma|=d$.

Takeaway: The point of this diagram is that the universal property of $\mathbb{Z}/d\mathbb{Z}$ as the quotient of $\mathbb{Z}$ by its index-d subgroup $d\mathbb{Z}$ upgrades Theorem 1.3.26's order formula into a structural isomorphism $\langle\sigma\rangle\cong\mathbb{Z}/\operatorname{lcm}(k_1,\dots,k_r)\mathbb{Z}$.

Cycle notation: conventions, products, inverses, and powers

Definition 1.3.38 (Cycle, 1-cycles, and the standing notational conventions)**.** A *cycle* is a string of integers $(a_1\, a_2\, \cdots\, a_m)$ representing the permutation that sends $a_i \mapsto a_{i+1}$ for $1 \le i < m$, sends $a_m \mapsto a_1$, and fixes every integer not appearing in the string. The number m of entries is the *length* of the cycle, and such a cycle is called an *m-cycle*. Two conventions are used throughout:

1. Numbers fixed by a permutation are *not* written; in particular a 1-cycle is the identity. Written on its own, a single 1-cycle (a_1) *is* the identity permutation.
2. The same cycle may be written starting at any of its entries: $(a_1\, a_2\, \cdots\, a_m) = (a_2\, a_3\, \cdots\, a_m\, a_1)$, and so on. Thus a cycle has m equally valid notations.

Remark 1.3.7. In a product of cycles a number *may* appear in more than one cycle; the product is still a well-defined permutation, computed right-to-left, but it is not yet in the standard "product of disjoint cycles" form. One must multiply such an expression out before reading off cycle lengths. This is the situation flagged in the first Caution after Theorem 1.3.26, and the worked example "Overlapping cycles: multiply first" carries out the multiplication.

Worked Example 1.3.39 (The book's S_{13} permutation in cycle notation)**.** Take the permutation σ of $\{1, 2, \ldots, 13\}$ defined by the value list

$$\sigma : 1 \mapsto 12,\ 2 \mapsto 13,\ 3 \mapsto 3,\ 4 \mapsto 1,\ 5 \mapsto 11,\ 6 \mapsto 9,\ 7 \mapsto 5,$$
$$8 \mapsto 10,\ 9 \mapsto 6,\ 10 \mapsto 4,\ 11 \mapsto 7,\ 12 \mapsto 8,\ 13 \mapsto 2.$$

Write σ in cycle notation and find $|\sigma|$.

Recognition. This is the book's basic procedure: build each cycle by following an element forward under σ until it returns, start a new cycle from any number not yet used, and stop when every number is placed. Then the order is the lcm of the resulting cycle lengths (Theorem 1.3.26).

Solution. Start at 1 and follow σ repeatedly:

$$1 \mapsto 12 \mapsto 8 \mapsto 10 \mapsto 4 \mapsto 1,$$

closing the cycle $(1\,12\,8\,10\,4)$, a 5-cycle. The smallest unused number is 2:

$$2 \mapsto 13 \mapsto 2,$$

giving the 2-cycle $(2\,13)$. Next unused is 3, and $3 \mapsto 3$, a fixed point (a 1-cycle, omitted). Next is 5:

$$5 \mapsto 11 \mapsto 7 \mapsto 5,$$

the 3-cycle $(5\,11\,7)$. Next unused is 6:

$$6 \mapsto 9 \mapsto 6,$$

the 2-cycle $(6\,9)$. Every number is now placed. Hence

$$\sigma = (1\,12\,8\,10\,4)(2\,13)(5\,11\,7)(6\,9),$$

a product of disjoint cycles of lengths $5, 2, 3, 2$ (and one omitted fixed point 3). Therefore

$$|\sigma| = \operatorname{lcm}(5, 2, 3, 2) = \operatorname{lcm}(5, 3, 2) = 30.$$

Check: the lengths sum to $5 + 2 + 3 + 2 + 1 = 13$, accounting for all 13 points; and 30 is divisible by each of $5, 3, 2$ while no proper divisor of 30 is divisible by all three (e.g. 15 is odd, so misses the 2-cycles; 10 misses the 3-cycle; 6 misses the 5-cycle).

Worked Example 1.3.40 (Composing two permutations and re-reading the cycle type)**.** With $\sigma = (1\,12\,8\,10\,4)(2\,13)(5\,11\,7)(6\,9)$ as above and

$$\tau = (1\,3\,5\,7\,9\,11\,13)(2\,4\,6\,8\,10\,12),$$

compute the product $\sigma\tau$ (apply τ first) on a few points, illustrating the book's right-to-left composition.

Recognition. This is the text's emphasis that permutation products are read right-to-left and that the cycle structure of a product is generally unrelated to that of the factors; one simply tracks images. We need only the images of a few points to display the mechanics.

Solution. Apply τ then σ. For the point 1:

$$1 \overset{\tau}{\mapsto} 3 \overset{\sigma}{\mapsto} 3, \qquad \text{so } (\sigma\tau)(1) = 3.$$

For the point 2:

$$2 \overset{\tau}{\mapsto} 4 \overset{\sigma}{\mapsto} 1, \qquad \text{so } (\sigma\tau)(2) = 1.$$

For the point 4:

$$4 \overset{\tau}{\mapsto} 6 \overset{\sigma}{\mapsto} 9, \qquad \text{so } (\sigma\tau)(4) = 9.$$

Thus the cycle of $\sigma\tau$ through 2 begins $2 \mapsto 1 \mapsto 3 \mapsto \cdots$, already different from any cycle of σ or of τ. The point of the example is the procedure, not a memorized rule: do *not* expect $\sigma\tau$ to inherit the cycle type of σ or τ.

Remark 1.3.8 (Inverse of a permutation in cycle notation)*.* The inverse of a cycle is obtained by reversing it:

$$(a_1\, a_2\, \cdots\, a_m)^{-1} = (a_m\, a_{m-1}\, \cdots\, a_1).$$

Since disjoint cycles commute, the inverse of a product of disjoint cycles is the product of the reversed cycles (in any order). For instance

$$\big((1\,12\,8\,10\,4)(2\,13)(5\,11\,7)(6\,9)\big)^{-1} = (1\,4\,10\,8\,12)(2\,13)(5\,7\,11)(6\,9).$$

A permutation and its inverse always have the same cycle type, hence the same order; a 2-cycle is its own inverse.

Proposition 1.3.41 (Powers of a single cycle)**.** *Let $\tau = (a_1\, a_2\, \cdots\, a_m)$ be an m-cycle. Then τ^t has order $m/\gcd(m,t)$, and τ^t is itself a single m-cycle if and only if $\gcd(m,t) = 1$. In general τ^t splits into $\gcd(m,t)$ disjoint cycles, each of length $m/\gcd(m,t)$.*

Proof. Write $d = \gcd(m,t)$. The element a_i moves under τ^t to a_{i+t} (indices mod m), so the orbit of a_1 under τ^t is $\{a_1, a_{1+t}, a_{1+2t}, \dots\}$, whose size equals the additive order of t in $\mathbb{Z}/m\mathbb{Z}$, namely m/d. The m points thus partition into orbits all of this common size m/d, and there are $m/(m/d) = d$ of them. Hence τ^t is a product of d disjoint (m/d)-cycles, of order $\operatorname{lcm}(m/d, \dots, m/d) = m/d$ by Theorem 1.3.26. It is a single m-cycle exactly when $d = 1$. □

Worked Example 1.3.42 (Splitting a power of a 6-cycle)**.** Let $\tau = (1\,2\,3\,4\,5\,6)$. Find τ^2, τ^3, and their orders, and reconcile with Proposition 1.3.41.

Recognition. τ is a 6-cycle, so τ^t is governed by $\gcd(6,t)$: the power splits into $\gcd(6,t)$ cycles of length $6/\gcd(6,t)$.

Solution. For $t = 2$: $\gcd(6,2) = 2$, so τ^2 is 2 disjoint 3-cycles. Tracking, $1 \mapsto 3 \mapsto 5 \mapsto 1$ and $2 \mapsto 4 \mapsto 6 \mapsto 2$, hence

$$\tau^2 = (1\,3\,5)(2\,4\,6), \qquad |\tau^2| = 6/\gcd(6,2) = 3.$$

For $t = 3$: $\gcd(6,3) = 3$, so τ^3 is 3 disjoint 2-cycles. Tracking, $1 \mapsto 4$, $2 \mapsto 5$, $3 \mapsto 6$, hence

$$\tau^3 = (1\,4)(2\,5)(3\,6), \qquad |\tau^3| = 6/\gcd(6,3) = 2.$$

Check: $|\tau^2| = 3$ and $|\tau^3| = 2$ agree with the general fact $|\tau^t| = |\tau|/\gcd(|\tau|, t)$ for $|\tau| = 6$, and the cycle splittings match the predicted counts (2 cycles of length 3, then 3 cycles of length 2).

Exercises (from the text).

1. Let $\sigma : 1\to 3, 2\to 4, 3\to 5, 4\to 2, 5\to 1$ and $\tau : 1\to 5, 2\to 3, 3\to 2, 4\to 4, 5\to 1$. Find the cycle decompositions of $\sigma, \tau, \sigma^2, \sigma\tau, \tau\sigma, \tau^2\sigma$.
2. For the permutations σ, τ of $\{1, \dots, 15\}$ in the text, find $\sigma, \tau, \sigma^2, \sigma\tau, \tau\sigma, \tau^2\sigma$.
3. Compute the order of each permutation in Exercises 1 and 2.
4. Compute the order of each element in (a) S_3, (b) S_4.
5. Find the order of $(1\,12\,8\,10\,4)(2\,13)(5\,11\,7)(6\,9)$.
6. Cycle decomposition of each order-4 element of S_4.
7. Cycle decomposition of each order-2 element of S_4.
8. Prove that if $\Omega = \{1, 2, 3, \dots\}$ then S_Ω is infinite.
9. For which i is the ith power of a (a) 12-, (b) 8-, (c) 14-cycle again a full cycle?
10. If $\sigma = (a_1 \cdots a_m)$, show $\sigma^i(a_k) = a_{k+i}$ and $|\sigma| = m$.
11. Show σ^i (for an m-cycle) is an m-cycle iff $\gcd(i, m) = 1$.
12. (a) Is $(1\,2)(3\,4)(5\,6)(7\,8)(9\,10)$ a power of an n-cycle ($n \geq 10$)? (b) $(1\,2)(3\,4\,5)$, $n \geq 5$?
13. Order 2 in S_n iff the cycle type is disjoint 2-cycles.
14. p prime: order p iff disjoint p-cycles. Counterexample for composite.
15. Prove the order equals the lcm of the cycle lengths.
16. Number of m-cycles in S_n ($n \geq m$).
17. Number of products of two disjoint 2-cycles ($n \geq 4$).
18. All n with an order-n element in S_5.
19. All n with an order-n element in S_7.
20. Generators and relations for S_3.

Additional exercises.

1. Let $\sigma = (1\ 3\ 5\ 2)(4\ 6)$ and $\tau = (1\ 2\ 6)(3\ 4)$ in S_6. Compute the products $\sigma\tau$ and $\tau\sigma$ (composing right-to-left, D&F convention), and express each as a product of disjoint cycles. Are $\sigma\tau$ and $\tau\sigma$ equal?
2. For the permutation $\sigma = (1\ 12\ 8\ 10\ 4)(2\ 13)(5\ 11\ 7)(6\ 9)$ in S_{13}, find $|\sigma|$, compute σ^{-1} as a product of disjoint cycles, and determine σ^{100} as a product of disjoint cycles.
3. Find ALL the distinct cycle types of elements of S_5. For each cycle type, list its order and the number of elements of S_5 of that type. Verify that the counts sum to 120.
4. Let $\sigma = (1\ 2\ 3\ 4\ 5\ 6\ 7) \in S_7$. Determine every integer k with $0 \leq k \leq 6$ for which σ^k is a single 7-cycle, and every k for which σ^k is NOT a single 7-cycle, explaining the difference using $\gcd(k, 7)$.
5. Prove that for any $\sigma \in S_n$ and any cycle $(a_1\ a_2\ \cdots\ a_k)$, one has

$$\sigma\,(a_1\ a_2\ \cdots\ a_k)\,\sigma^{-1} = (\sigma(a_1)\ \sigma(a_2)\ \cdots\ \sigma(a_k)).$$

   Then use this to find an explicit $\sigma \in S_5$ with $\sigma\,(1\ 2\ 3)(4\ 5)\,\sigma^{-1} = (2\ 5\ 4)(1\ 3)$, or prove none exists.
6. Determine the largest possible order of an element of S_7, and exhibit one permutation in S_7 achieving that order written as a product of disjoint cycles. Justify why no element of S_7 has larger order.
7. Let $n \geq 2$. Show that every element of S_n can be written as a product of the 2-cycles (transpositions) $(1\ 2), (1\ 3), \dots, (1\ n)$. Illustrate by writing $(2\ 4\ 5)(1\ 3) \in S_5$ as such a product.

Commutative-diagram exercises.

1. View each $\sigma \in S_n$ as a bijective map $\sigma\colon \{1,2,\dots,n\} \to \{1,2,\dots,n\}$. For $\sigma = (1\ 3\ 2)$ and $\tau = (2\ 3)$ in S_3, verify by checking on each of $1, 2, 3$ that the diagram

$$\begin{array}{ccc} \{1,2,3\} & \xrightarrow{\ \tau\ } & \{1,2,3\} \\ & \searrow^{\sigma\tau} & \downarrow{\scriptstyle \sigma} \\ & & \{1,2,3\} \end{array}$$

   commutes, where $\sigma\tau$ denotes the composite $\sigma \circ \tau$ (apply τ first). Then state, for general $\sigma, \tau \in S_n$, why the analogous triangle always commutes.

2. Fix $\sigma \in S_n$, let $a \in \{1,\dots,n\}$, and let $\mathrm{ev}_a\colon S_n \to \{1,\dots,n\}$ be the evaluation map $\tau \mapsto \tau(a)$. Show the square

$$\begin{array}{ccc} S_n & \xrightarrow{\ \tau \mapsto \sigma\tau\ } & S_n \\ {\scriptstyle \mathrm{ev}_a}\downarrow & & \downarrow{\scriptstyle \mathrm{ev}_a} \\ \{1,\dots,n\} & \xrightarrow[x \mapsto \sigma(x)]{} & \{1,\dots,n\} \end{array}$$

   makes sense and commutes; that is, prove $\mathrm{ev}_a(\sigma\tau) = \sigma(\mathrm{ev}_a(\tau))$ for every $\tau \in S_n$. Interpret this as "S_n acts on $\{1,\dots,n\}$."

3. The symmetric group S_n acts on $X = \{1,\dots,n\}$ by $\sigma \cdot x = \sigma(x)$. The action axioms say the following two diagrams commute, where $m\colon S_n \times S_n \to S_n$ is multiplication and $\rho\colon S_n \times X \to X$ is $(\sigma, x) \mapsto \sigma(x)$:

$$\begin{array}{ccc} S_n \times S_n \times X & \xrightarrow{\mathrm{id} \times \rho} & S_n \times X \\ {\scriptstyle m \times \mathrm{id}}\downarrow & & \downarrow{\scriptstyle \rho} \\ S_n \times X & \xrightarrow[\rho]{} & X \end{array} \qquad \begin{array}{ccc} \{1\} \times X & \xrightarrow{\ ? \times \mathrm{id}\ } & S_n \times X \\ & \searrow^{\cong} & \downarrow{\scriptstyle \rho} \\ & & X \end{array}$$

   Identify the map labelled ? in the right-hand triangle, and prove both diagrams commute using only that $\sigma\tau$ means "apply τ then σ" and that the identity permutation fixes every point.

4. For $n = 4$ let $X = \{1,2,3,4\}$ and consider the assignment $P\colon S_4 \to \mathrm{Sym}(X)$ sending each σ to itself as a bijection. Letting μ denote multiplication in each group, draw and verify (on the generators $\sigma = (1\ 2\ 3\ 4)$ and $\tau = (1\ 2)$) that

$$\begin{array}{ccc} S_4 \times S_4 & \xrightarrow{\ \mu\ } & S_4 \\ {\scriptstyle P \times P}\downarrow & & \downarrow{\scriptstyle P} \\ \mathrm{Sym}(X) \times \mathrm{Sym}(X) & \xrightarrow[\mu]{} & \mathrm{Sym}(X) \end{array}$$

   commutes, i.e. P respects composition. Explain why the existence of this commuting square is exactly the statement that the natural permutation representation is a homomorphism.

5. Let $\sigma = (1\ 2\ 3\ 4\ 5) \in S_5$ and let $\varphi\colon \mathbb{Z} \to S_5$ be the unique homomorphism with $\varphi(k) = \sigma^k$. Identify $\ker\varphi$, and using the factorization

$$\begin{array}{ccc} \mathbb{Z} & \xrightarrow{\ \pi\ } & \mathbb{Z}/\ker\varphi \\ & \searrow^{k \mapsto \sigma^k} & \downarrow{\scriptstyle \exists!\, \overline{\varphi}} \\ & & S_5 \end{array}$$

   determine the image $\overline{\varphi}(\mathbb{Z}/\ker\varphi)$ explicitly as a subgroup of S_5 (list its elements as cycles) and state its order.

1.4 Matrix Groups

The general and special linear groups $\mathrm{GL}_n(F)$ and $\mathrm{SL}_n(F)$

Fix a field F. Throughout, $F^\times = F \setminus \{0\}$ is the multiplicative group of nonzero elements. We will care most about the finite fields $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ for p prime, where $\mathbb{F}_p^\times$ is cyclic of order $p-1$.

Definition 1.4.1. $\mathrm{GL}_n(F)$ is the set of invertible $n \times n$ matrices with entries in F, under matrix multiplication. $\mathrm{SL}_n(F) = \{A \in \mathrm{GL}_n(F) \mid \det A = 1\}$ is the *special linear group.*

Proposition 1.4.2. $\mathrm{GL}_n(F)$ *is a group, and* $A \in M_n(F)$ *lies in* $\mathrm{GL}_n(F)$ *if and only if* $\det A \neq 0$ *(equivalently* $\det A \in F^\times$*).*

Proof. Matrix multiplication is associative and the identity matrix I is a two-sided identity, so we need only closure and inverses. A square matrix A over a field has a two-sided inverse iff $\det A \neq 0$; in that case $\det(A^{-1}) = (\det A)^{-1} \neq 0$, so $A^{-1} \in \mathrm{GL}_n(F)$. For closure, if $\det A \neq 0$ and $\det B \neq 0$ then $\det(AB) = \det A \det B \neq 0$ (a field has no zero divisors), so $AB \in \mathrm{GL}_n(F)$. Hence $\mathrm{GL}_n(F)$ is closed and contains inverses, so it is a group. □

Proposition 1.4.3. *The map* $\det : \mathrm{GL}_n(F) \to F^\times$ *is a surjective group homomorphism with kernel* $\mathrm{SL}_n(F)$*. Consequently* $\mathrm{SL}_n(F) \trianglelefteq \mathrm{GL}_n(F)$ *and* $\mathrm{GL}_n(F)/\mathrm{SL}_n(F) \cong F^\times$*.*

Proof. Homomorphism: $\det(AB) = \det A \det B$ is the multiplicativity of the determinant, and the target operation on $F^\times$ is multiplication, so det is a homomorphism into $F^\times$ (the image is in $F^\times$ by Proposition 1.4.2). *Surjective:* for $a \in F^\times$ the matrix $\mathrm{diag}(a, 1, \ldots, 1)$ has determinant a, so every value is hit. *Kernel:* $\det A = 1$ is exactly the defining condition of $\mathrm{SL}_n(F)$, so $\ker(\det) = \mathrm{SL}_n(F)$. The kernel of a homomorphism is normal, and the First Isomorphism Theorem gives $\mathrm{GL}_n(F)/\mathrm{SL}_n(F) \cong \det(\mathrm{GL}_n(F)) = F^\times$. □

The content of Proposition 1.4.3 is the *short exact sequence*

$$1 \longrightarrow \mathrm{SL}_n(F) \xhookrightarrow{\iota} \mathrm{GL}_n(F) \xrightarrow{\det} F^\times \longrightarrow 1.$$

Diagram explanation. Objects: Five nodes: the trivial group 1 (appearing twice, at both ends), the special linear group $\mathrm{SL}_n(F)$ (the normal subgroup of matrices with determinant 1), the general linear group $\mathrm{GL}_n(F)$ (invertible $n \times n$ matrices over F), and the multiplicative group $F^\times = F \setminus \{0\}$ (the group of units of the field, under multiplication).

Arrows: The left $1 \to \mathrm{SL}_n(F)$ is the unique map sending $1 \mapsto I$ (the identity matrix). The hooked arrow $\iota : \mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F)$ is the inclusion map, injective by definition. The double-headed arrow $\det : \mathrm{GL}_n(F) \twoheadrightarrow F^\times$ sends a matrix to its determinant; it is surjective (for any $a \in F^\times$, $\mathrm{diag}(a, 1, \ldots, 1)$ achieves it). The right $F^\times \to 1$ sends everything to 1.

What commutes: This is an exact sequence, so the condition is im = ker at each interior node. At $\mathrm{SL}_n(F)$: $\mathrm{im}(1 \to \mathrm{SL}_n(F)) = \{I\} = \ker \iota$ (since ι is injective). At $\mathrm{GL}_n(F)$: $\mathrm{im}\ \iota = \mathrm{SL}_n(F)$ and $\ker \det = \mathrm{SL}_n(F)$, so $\mathrm{im}\ \iota = \ker \det$. At $F^\times$: $\mathrm{im} \det = F^\times = \ker(F^\times \to 1)$.

Why it commutes: The key exactness is at $\mathrm{GL}_n(F)$. A matrix A lies in $\mathrm{im}\ \iota$ iff $A \in \mathrm{SL}_n(F)$, i.e. $\det A = 1$, which is exactly the condition $A \in \ker \det$. The two sets coincide by definition of $\mathrm{SL}_n(F)$.

Why this matters here: This diagram is a clean summary of Proposition 1.4.3: the determinant map is a surjective homomorphism with kernel exactly $\mathrm{SL}_n(F)$. The short exact sequence packages injectivity of ι, surjectivity of det, and the kernel condition into one picture, setting up the First Isomorphism Theorem.

Concrete example: For $n = 2$, $F = \mathbb{F}_3$: the sequence is $1 \to \mathrm{SL}_2(\mathbb{F}_3) \hookrightarrow \mathrm{GL}_2(\mathbb{F}_3) \xrightarrow{\det} \mathbb{F}_3^\times \to 1$, with $|\mathrm{SL}_2(\mathbb{F}_3)| = 24$, $|\mathrm{GL}_2(\mathbb{F}_3)| = 48$, $|\mathbb{F}_3^\times| = 2$, and $48 = 24 \cdot 2$.

Common pitfall: Students sometimes confuse "short exact sequence" with "the two groups are equal." Here $\mathrm{SL}_n(F)$ embeds into $\mathrm{GL}_n(F)$ as a proper subgroup (when $|F^\times| > 1$); it is not all of $\mathrm{GL}_n(F)$. The sequence shows how $\mathrm{GL}_n(F)$ is an extension of $F^\times$ by $\mathrm{SL}_n(F)$, not that the three groups coincide.

Takeaway: The point of this diagram is that det witnesses an exact decomposition: $\mathrm{GL}_n(F)$ sits between $\mathrm{SL}_n(F)$ and $F^\times$ in a way that makes $\mathrm{SL}_n(F)$ the kernel and $F^\times$ the quotient.

Here ι is the inclusion (injective, so "hook"), det is surjective (so "two heads"), exactness at $\mathrm{GL}_n(F)$ says $\operatorname{im}\iota = \ker\det$, i.e. $\mathrm{SL}_n(F) = \ker\det$. The quotient map fits the First Isomorphism Theorem triangle:

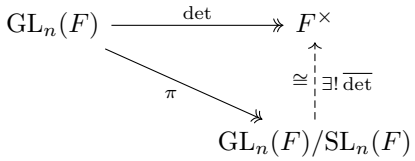


Diagram explanation. Objects: Three nodes: $\mathrm{GL}_n(F)$ (the group being quotiented), $F^\times$ (the target of the determinant), and $\mathrm{GL}_n(F)/\mathrm{SL}_n(F)$ (the quotient group whose elements are cosets $A \cdot \mathrm{SL}_n(F)$).

Arrows: $\det : \mathrm{GL}_n(F) \twoheadrightarrow F^\times$ is the surjective determinant homomorphism. $\pi : \mathrm{GL}_n(F) \twoheadrightarrow \mathrm{GL}_n(F)/\mathrm{SL}_n(F)$ is the canonical quotient map sending $A \mapsto A \cdot \mathrm{SL}_n(F)$. The dashed arrow $\overline{\det} : \mathrm{GL}_n(F)/\mathrm{SL}_n(F) \xrightarrow{\sim} F^\times$ is the unique induced isomorphism, sending the coset $A \cdot \mathrm{SL}_n(F) \mapsto \det A$; it is well-defined because any two representatives of the same coset differ by an element of $\mathrm{SL}_n(F)$, which has determinant 1, so they have equal determinants.

What commutes: The triangle commutes: $\overline{\det} \circ \pi = \det$. That is, applying the quotient map first and then the induced isomorphism gives the same result as applying det directly.

Why it commutes: Chase $A \in \mathrm{GL}_n(F)$: along det it goes to $\det A$. Along π it goes to the coset $A \cdot \mathrm{SL}_n(F)$, and then $\overline{\det}$ sends that coset to $\det A$ (by definition of $\overline{\det}$). Both paths yield $\det A$.

Why this matters here: This is the First Isomorphism Theorem applied to det. It says the quotient $\mathrm{GL}_n(F)/\mathrm{SL}_n(F)$ is not merely abstractly isomorphic to $F^\times$ but is isomorphic via the uniquely determined map $\overline{\det}$. The dashed arrow signals existence and uniqueness of the induced map.

Concrete example: For $n = 2$, $F = \mathbb{F}_5$: $\overline{\det} : \mathrm{GL}_2(\mathbb{F}_5)/\mathrm{SL}_2(\mathbb{F}_5) \to \mathbb{F}_5^\times$ sends the coset $\operatorname{diag}(2,1) \cdot \mathrm{SL}_2(\mathbb{F}_5)$ to $\det\operatorname{diag}(2,1) = 2 \in \mathbb{F}_5^\times$, establishing a bijection between the 4 cosets and the 4 elements of $\mathbb{F}_5^\times = \{1,2,3,4\}$.

Common pitfall: The dashed arrow $\overline{\det}$ exists only because $\mathrm{SL}_n(F) = \ker\det$. If one tried to induce a map from a quotient by a normal subgroup N that is not contained in $\ker\det$, well-definedness fails: two representatives of the same N-coset could have different determinants. The kernel containment condition $N \leq \ker\det$ is the *prerequisite*, not a consequence.

Takeaway: The point of this diagram is that the First Isomorphism Theorem factors det through the canonical quotient, proving $\mathrm{GL}_n(F)/\mathrm{SL}_n(F) \cong F^\times$ via the unique well-defined map $\overline{\det}$.

Method (Recognize and invert/multiply in $\mathrm{GL}_2(F)$)**.** Use this whenever you must decide if a 2×2 matrix is invertible, or multiply/invert one, over a field (especially $\mathbb{F}_p$).

1. **Invertibility test:** for $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ compute $\det A = ad - bc$ *in* F. Over $\mathbb{F}_p$, reduce $ad - bc \bmod p$. Then $A \in \mathrm{GL}_2(\mathbb{F}_p) \iff ad - bc \not\equiv 0 \pmod p$.
2. **Inverse formula:** if $\det A = \Delta \neq 0$, then $A^{-1} = \Delta^{-1}\left(\begin{smallmatrix} d & -b \\ -c & a \end{smallmatrix}\right)$, where Δ^{-1} is the multiplicative inverse of Δ in $F^\times$. Over $\mathbb{F}_p$, find Δ^{-1} by solving $\Delta\, x \equiv 1 \pmod p$.
3. **Product:** multiply rows-into-columns, then reduce each entry mod p.

Trigger: "invertible over $\mathbb{F}_p$," "inverse mod p," or "$\mathrm{GL}_2/\mathrm{SL}_2$."

Caution. Over $\mathbb{F}_p$ a nonzero determinant is enough — you do *not* need $\det = \pm 1$. E.g. $\det = 2$ over $\mathbb{F}_5$ is invertible because $2 \not\equiv 0 \pmod 5$ (indeed $2^{-1} \equiv 3$), although $2 \not\equiv \pm 1 \pmod 5$. The "$\det = \pm 1$" instinct is from $\mathrm{GL}_n(\mathbb{Z})$, a different group.

Worked Example 1.4.4 (Invertibility test over $\mathbb{F}_5$ and over $\mathbb{F}_3$)**.** Is $A = \left(\begin{smallmatrix} 2 & 4 \\ 3 & 1 \end{smallmatrix}\right)$ invertible over $\mathbb{F}_5$? Over $\mathbb{F}_3$?

Recognition. Invertibility over a field is governed by one number, $\det A$ (Proposition 1.4.2). Compute det and reduce modulo the prime; nonzero means yes.

Solution. Over the integers $\det A = 2 \cdot 1 - 4 \cdot 3 = 2 - 12 = -10$. Over $\mathbb{F}_5$: $-10 \equiv 0 \pmod 5$, so $A \notin \mathrm{GL}_2(\mathbb{F}_5)$ (not invertible). Over $\mathbb{F}_3$: $-10 \equiv -10 + 12 = 2 \pmod 3$, and $2 \neq 0$, so $A \in \mathrm{GL}_2(\mathbb{F}_3)$. *Check.* Same integer entries, different prime gives different answers — exactly because invertibility is a statement about $\det A$ *in* F, not in $\mathbb{Z}$. Over $\mathbb{F}_5$ the rows $(2,4)$ and $(3,1)$ satisfy $(3,1) = 4 \cdot (2,4)$ since $4 \cdot 2 = 8 \equiv 3$ and $4 \cdot 4 = 16 \equiv 1 \pmod 5$, so they are dependent — consistent with $\det \equiv 0$.

Worked Example 1.4.5 (Multiply and invert a specific matrix over $\mathbb{F}_3$)**.** Let $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 1 \end{smallmatrix}\right)$ over $\mathbb{F}_3$. Compute $\det A$, $\det B$, AB, and A^{-1}.

Recognition. Two 2×2 matrices over $\mathbb{F}_3$: use the Method box. Determinant first (to confirm membership and to get Δ^{-1} for the inverse), then the row-into-column product, then the adjugate formula.

Solution. **Determinants:** $\det A = 2 \cdot 1 - 1 \cdot 1 = 1 \equiv 1 \pmod 3$, so $A \in \mathrm{SL}_2(\mathbb{F}_3)$. $\det B = 0 \cdot 1 - 2 \cdot 1 = -2 \equiv 1 \pmod 3$, so $B \in \mathrm{SL}_2(\mathbb{F}_3)$ too.

Product AB:

$$AB = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 0 & 2 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 2\cdot 0 + 1 \cdot 1 & 2 \cdot 2 + 1 \cdot 1 \\ 1 \cdot 0 + 1 \cdot 1 & 1 \cdot 2 + 1 \cdot 1 \end{pmatrix} = \begin{pmatrix} 1 & 5 \\ 1 & 3 \end{pmatrix} \equiv \begin{pmatrix} 1 & 2 \\ 1 & 0 \end{pmatrix} \pmod 3.$$

(Check $\det(AB) \equiv 1 \cdot 0 - 2 \cdot 1 = -2 \equiv 1$, matching $\det A \det B = 1 \cdot 1$.)

Inverse A^{-1}: here $\Delta = \det A = 1$, so $\Delta^{-1} = 1$, and

$$A^{-1} = 1 \cdot \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix} \equiv \begin{pmatrix} 1 & 2 \\ 2 & 2 \end{pmatrix} \pmod 3.$$

Check. $A\,A^{-1} = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 2 \\ 2 & 2 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 2\cdot 1 + 1 \cdot 2 & 2 \cdot 2 + 1 \cdot 2 \\ 1 \cdot 1 + 1 \cdot 2 & 1 \cdot 2 + 1 \cdot 2 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 4 & 6 \\ 3 & 4 \end{smallmatrix}\right) \equiv \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) \pmod 3$. Correct.

Worked Example 1.4.6 (Inverse when $\det \neq 1$: a matrix over $\mathbb{F}_7$)**.** Invert $A = \left(\begin{smallmatrix} 3 & 1 \\ 2 & 4 \end{smallmatrix}\right)$ over $\mathbb{F}_7$.

Recognition. The adjugate formula needs Δ^{-1} in $F^\times$. Here $\Delta \neq 1$, so the real work is computing the modular inverse of Δ in $\mathbb{F}_7$. This is the case students mishandle by forgetting the scalar Δ^{-1}.

Solution. $\Delta = \det A = 3 \cdot 4 - 1 \cdot 2 = 12 - 2 = 10 \equiv 3 \pmod 7$, nonzero, so $A \in \mathrm{GL}_2(\mathbb{F}_7)$. Find 3^{-1} in $\mathbb{F}_7$: $3 \cdot 5 = 15 \equiv 1$, so $3^{-1} \equiv 5$. Then

$$A^{-1} = 3^{-1}\begin{pmatrix} 4 & -1 \\ -2 & 3 \end{pmatrix} = 5\begin{pmatrix} 4 & -1 \\ -2 & 3 \end{pmatrix} = \begin{pmatrix} 20 & -5 \\ -10 & 15 \end{pmatrix} \equiv \begin{pmatrix} 6 & 2 \\ 4 & 1 \end{pmatrix} \pmod 7,$$

using $20 \equiv 6$, $-5 \equiv 2$, $-10 \equiv 4$, $15 \equiv 1 \pmod 7$. *Check.* $A\,A^{-1} = \left(\begin{smallmatrix} 3 & 1 \\ 2 & 4 \end{smallmatrix}\right)\left(\begin{smallmatrix} 6 & 2 \\ 4 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 18+4 & 6+1 \\ 12+16 & 4+4 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 22 & 7 \\ 28 & 8 \end{smallmatrix}\right) \equiv \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) \pmod 7$. Correct.

Worked Example 1.4.7 (Noncommutativity is real)**.** With $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 1 \end{smallmatrix}\right)$ over $\mathbb{F}_3$ as above, show $AB \neq BA$.

Recognition. $\mathrm{GL}_n(F)$ is nonabelian for $n \geq 2$; to *prove* it for specific matrices, just compute both products and exhibit one differing entry.

Solution. We found $AB \equiv \left(\begin{smallmatrix} 1 & 2 \\ 1 & 0 \end{smallmatrix}\right)$. Now

$$BA = \begin{pmatrix} 0 & 2 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 0+2 & 0+2 \\ 2+1 & 1+1 \end{pmatrix} = \begin{pmatrix} 2 & 2 \\ 3 & 2 \end{pmatrix} \equiv \begin{pmatrix} 2 & 2 \\ 0 & 2 \end{pmatrix} \pmod 3.$$

The $(1,1)$ entries differ (1 vs 2), so $AB \neq BA$. *Check.* Both have determinant $1 \cdot 0 - 2 \cdot 1 = -2 \equiv 1$ and $2 \cdot 2 - 2 \cdot 0 = 4 \equiv 1$, as forced by $\det(AB) = \det(BA) = \det A \det B$; equal determinants but unequal matrices is exactly how noncommutativity shows up here.

Method (Compute the order of an element of $\mathrm{GL}_2(\mathbb{F}_p)$)**.** Use this when asked for $|A|$, $A \in \mathrm{GL}_2(\mathbb{F}_p)$.

1. By Lagrange, $|A|$ divides $|\mathrm{GL}_2(\mathbb{F}_p)| = (p^2 - 1)(p^2 - p)$; this bounds the search.
2. Compute $A^2, A^3, \ldots$ reducing mod p each step until you reach I. The first k with $A^k = I$ is $|A|$.
3. Shortcuts: a diagonal matrix $\mathrm{diag}(\lambda, \mu)$ has order $\mathrm{lcm}(|\lambda|, |\mu|)$ in $F^\times$; a transvection $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ has order p since $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)^k = \left(\begin{smallmatrix} 1 & k \\ 0 & 1 \end{smallmatrix}\right)$.

Trigger: "order of this matrix," "smallest k with $A^k = I$."

Worked Example 1.4.8 (Order of a rotation-type element over $\mathbb{F}_3$)**.** Find $|R|$ for $R = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ over $\mathbb{F}_3$, i.e. $R = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$.

Recognition. Order question in $\mathrm{GL}_2(\mathbb{F}_3)$: apply the Method box. R looks like a 90° rotation, so expect a small order; just power it.

Solution. $R = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ (since $-1 \equiv 2 \pmod 3$). Then

$$R^2 = \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}^2 = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}, \qquad R^4 = (R^2)^2 = \begin{pmatrix} 4 & 0 \\ 0 & 4 \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \pmod 3.$$

Since $R^2 = 2I \neq I$ but $R^4 = I$, we get $|R| = 4$. *Check.* $4 \mid |\mathrm{GL}_2(\mathbb{F}_3)| = 48$ (Lagrange), and $\det R = 0 \cdot 0 - 2 \cdot 1 = -2 \equiv 1$, so $R \in \mathrm{SL}_2(\mathbb{F}_3)$; $|R| = 4$ divides $|\mathrm{SL}_2(\mathbb{F}_3)| = 24$. Consistent.

Worked Example 1.4.9 (A transvection has order p)**.** Compute $|T|$ for $T = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ in $\mathrm{GL}_2(\mathbb{F}_3)$ and in $\mathrm{GL}_2(\mathbb{F}_5)$.

Recognition. Upper-triangular unipotent matrix: use the transvection shortcut $T^k = \left(\begin{smallmatrix} 1 & k \\ 0 & 1 \end{smallmatrix}\right)$ and find the smallest k with $k \equiv 0$ in F.

Solution. By induction $T^k = \left(\begin{smallmatrix} 1 & k \\ 0 & 1 \end{smallmatrix}\right)$ (each multiplication adds 1 to the top-right). We need $k \equiv 0 \pmod p$: over $\mathbb{F}_3$, smallest such k is 3, so $|T| = 3$ (indeed $T^3 = \left(\begin{smallmatrix} 1 & 3 \\ 0 & 1 \end{smallmatrix}\right) \equiv I$); over $\mathbb{F}_5$, smallest is 5, so $|T| = 5$. *Check.* $3 \mid 48$ and $5 \mid |\mathrm{GL}_2(\mathbb{F}_5)| = (25-1)(25-5) = 24 \cdot 20 = 480$. The element order equals the characteristic p — a hallmark of nonidentity unipotent elements of $\mathrm{GL}_2(\mathbb{F}_p)$.

Worked Example 1.4.10 (Order of a diagonal matrix via lcm)**.** Find $|D|$ for $D = \mathrm{diag}(2, 1)$ in $\mathrm{GL}_2(\mathbb{F}_3)$, and for $D' = \mathrm{diag}(2, 3)$ in $\mathrm{GL}_2(\mathbb{F}_5)$.

Recognition. Diagonal matrix: powers act entrywise, $D^k = \mathrm{diag}(\lambda^k, \mu^k)$, so $|D| = \mathrm{lcm}(|\lambda|, |\mu|)$ in $F^\times$. Reduce to orders of scalars.

Solution. Over $\mathbb{F}_3$: $|2|$ in $\mathbb{F}_3^\times$ is 2 (since $2^2 = 4 \equiv 1$), $|1| = 1$. So $|D| = \mathrm{lcm}(2, 1) = 2$. Direct check: $D^2 = \mathrm{diag}(4, 1) \equiv \mathrm{diag}(1, 1) = I$. Over $\mathbb{F}_5$: $\mathbb{F}_5^\times$ is cyclic of order 4. $|2|$: $2^1 = 2, 2^2 = 4, 2^3 = 8 \equiv 3, 2^4 = 16 \equiv 1$, so $|2| = 4$. $|3|$: $3^2 = 9 \equiv 4, 3^4 \equiv 1$, and $3^2 \not\equiv 1$, so $|3| = 4$. Thus $|D'| = \mathrm{lcm}(4, 4) = 4$. *Check.* $\det D = 2 \equiv 2$, an order-2 element of $\mathbb{F}_3^\times$; under $\det : \mathrm{GL}_2 \to \mathbb{F}_3^\times$ the image of D has order 2, and $|\det D| \mid |D| = 2$. For D', $\det D' = 2 \cdot 3 = 6 \equiv 1$, so $D' \in \mathrm{SL}_2(\mathbb{F}_5)$ with $|D'| = 4 \mid |\mathrm{SL}_2(\mathbb{F}_5)| = 480/4 = 120$. Consistent.

Worked Example 1.4.11 (An element whose order needs Lagrange to guess)**.** Find $|A|$ for $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 2 \end{smallmatrix}\right)$ in $\mathrm{GL}_2(\mathbb{F}_3)$.

Recognition. No obvious shortcut (not diagonal, not unipotent). Use Lagrange to limit candidates, then power A.

Solution. $\det A = 1 \cdot 2 - 1 \cdot 1 = 1$, so $A \in \mathrm{SL}_2(\mathbb{F}_3)$, hence $|A| \mid 24$. Power it:

$$A^2 = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}^2 = \begin{pmatrix} 1+1 & 1+2 \\ 1+2 & 1+4 \end{pmatrix} = \begin{pmatrix} 2 & 3 \\ 3 & 5 \end{pmatrix} \equiv \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} \pmod 3.$$

So $A^2 = 2I$, hence $A^4 = (2I)^2 = 4I \equiv I \pmod 3$. Since $A^2 = 2I \neq I$, $|A| = 4$. *Check.* $4 \mid 24$, consistent with Lagrange. Also $A^2 = 2I$ means A is a square root of $2I$ in $\mathrm{SL}_2(\mathbb{F}_3)$; squaring once more lands on I, confirming order 4.

Counting $\mathrm{GL}_2(\mathbb{F}_p)$ by counting bases

Theorem 1.4.12. *For a prime p,*

$$|\mathrm{GL}_2(\mathbb{F}_p)| = (p^2-1)(p^2-p), \qquad |\mathrm{SL}_2(\mathbb{F}_p)| = \frac{(p^2-1)(p^2-p)}{p-1}.$$

More generally $|\mathrm{GL}_n(\mathbb{F}_p)| = \prod_{k=0}^{n-1}(p^n - p^k)$.

Proof. An $n \times n$ matrix is invertible iff its columns form a basis of $F^n = \mathbb{F}_p^n$, equivalently an ordered linearly independent list of n vectors. Build the columns one at a time. The first column v_1 can be any nonzero vector: $p^n - 1$ choices (p^n vectors, minus the zero vector). Having chosen independent $v_1, \ldots, v_k$, the next column v_{k+1} must avoid their span, which has p^k vectors; so there are $p^n - p^k$ choices. Multiplying, $|\mathrm{GL}_n(\mathbb{F}_p)| = \prod_{k=0}^{n-1}(p^n - p^k)$.

For $n = 2$ this is $(p^2 - 1)(p^2 - p)$. Finally $\det : \mathrm{GL}_2(\mathbb{F}_p) \twoheadrightarrow \mathbb{F}_p^\times$ has $|\mathbb{F}_p^\times| = p - 1$, and by Proposition 1.4.3 all fibers of a surjective homomorphism have equal size $|\mathrm{SL}_2(\mathbb{F}_p)|$; since the fibers are the cosets of $\ker \det = \mathrm{SL}_2(\mathbb{F}_p)$, Lagrange gives $|\mathrm{SL}_2(\mathbb{F}_p)| = |\mathrm{GL}_2(\mathbb{F}_p)|/(p-1)$. □

The fiber/coset picture of the last step:

$$\det^{-1}(1) = \mathrm{SL}_2(\mathbb{F}_p) \xmapsto{\det} 1$$

$$\det^{-1}(a) \xmapsto{\det} a$$

$$\det^{-1}(b) \xmapsto{\det} b$$

Diagram explanation. Objects: On the left, three cosets (fibers) of $\mathrm{SL}_2(\mathbb{F}_p)$ inside $\mathrm{GL}_2(\mathbb{F}_p)$: $\det^{-1}(1) = \mathrm{SL}_2(\mathbb{F}_p)$ (the identity coset, i.e. the kernel), and two generic fibers $\det^{-1}(a)$ and $\det^{-1}(b)$ for $a, b \in \mathbb{F}_p^\times$ with $a \neq b$. On the right, the corresponding elements $1, a, b$ of $F^\times = \mathbb{F}_p^\times$.

Arrows: Each horizontal mapsto arrow $\det^{-1}(c) \mapsto c$ represents the action of det on an entire fiber: every matrix in $\det^{-1}(c)$ is sent to the single value $c \in \mathbb{F}_p^\times$. These are not maps between groups but rather set-valued fibers of the surjective homomorphism det.

What commutes: There is no composition to check; the diagram is a schematic, not a square. The key equality is that $|\det^{-1}(a)| = |\mathrm{SL}_2(\mathbb{F}_p)|$ for every $a \in \mathbb{F}_p^\times$: all $p - 1$ fibers have equal size because left multiplication by any g with $\det g = a$ is a bijection $\mathrm{SL}_2(\mathbb{F}_p) \to \det^{-1}(a)$, sending $S \mapsto gS$.

Why it commutes: For any $a \in \mathbb{F}_p^\times$, pick $g \in \mathrm{GL}_2(\mathbb{F}_p)$ with $\det g = a$. Then $\det^{-1}(a) = g \cdot \mathrm{SL}_2(\mathbb{F}_p)$ (the left coset), since $\det(gS) = \det g \cdot \det S = a \cdot 1 = a$ for all $S \in \mathrm{SL}_2(\mathbb{F}_p)$. Hence the fiber is a left coset of $\mathrm{SL}_2(\mathbb{F}_p)$, and all cosets have equal size $|\mathrm{SL}_2(\mathbb{F}_p)|$ by Lagrange.

Why this matters here: This picture explains why $|\mathrm{GL}_2(\mathbb{F}_p)| = |\mathrm{SL}_2(\mathbb{F}_p)| \cdot (p - 1)$: the group partitions into exactly $p - 1$ fibers of equal size $|\mathrm{SL}_2(\mathbb{F}_p)|$. It is the coset-counting step at the end of the proof of Theorem 1.4.12.

Concrete example: For $p = 3$: $\mathbb{F}_3^\times = \{1, 2\}$, so there are two fibers: $\det^{-1}(1) = \mathrm{SL}_2(\mathbb{F}_3)$ of size 24, and $\det^{-1}(2)$ also of size 24. Together they account for all 48 elements of $\mathrm{GL}_2(\mathbb{F}_3)$.

Common pitfall: The fibers are *cosets* of $\mathrm{SL}_2(\mathbb{F}_p)$ in $\mathrm{GL}_2(\mathbb{F}_p)$, not subgroups. Only $\det^{-1}(1) = \mathrm{SL}_2(\mathbb{F}_p)$ is a subgroup; the others ($\det^{-1}(a)$ for $a \neq 1$) do not contain the identity I and are not subgroups.

Takeaway: The point of this diagram is that the $p - 1$ fibers of det are exactly the cosets of $\mathrm{SL}_2(\mathbb{F}_p)$, all of equal size, which forces $|\mathrm{GL}_2(\mathbb{F}_p)| = (p - 1) \cdot |\mathrm{SL}_2(\mathbb{F}_p)|$.

Each fiber $\det^{-1}(a)$ is a coset $g\mathrm{SL}_2(\mathbb{F}_p)$ (any g with $\det g = a$), so all $p - 1$ fibers have the same size $|\mathrm{SL}_2(\mathbb{F}_p)|$, and they partition $\mathrm{GL}_2(\mathbb{F}_p)$.

Method (Count $|\mathrm{GL}_2(\mathbb{F}_p)|$ and $|\mathrm{SL}_2(\mathbb{F}_p)|$)**.** Use this whenever a group order over $\mathbb{F}_p$ is requested.

1. Columns-as-basis count: first column $p^2 - 1$ ways (any nonzero vector), second column $p^2 - p$ ways (any vector outside the line spanned by the first). Multiply: $|\mathrm{GL}_2(\mathbb{F}_p)| = (p^2 - 1)(p^2 - p)$.
2. Divide by $|F^\times| = p - 1$ to get $|\mathrm{SL}_2(\mathbb{F}_p)|$ (kernel of det).

Trigger: "how many invertible matrices," "order of $\mathrm{GL}_2(\mathbb{F}_p)$ or SL_2."

Worked Example 1.4.13 ($\mathrm{GL}_2(\mathbb{F}_2)$ has order 6 and is $\cong S_3$)**.** Show $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$ and prove $\mathrm{GL}_2(\mathbb{F}_2) \cong S_3$.

Recognition. "Order 6" is the counting formula at $p = 2$. "$\cong S_3$" is a trigger for a *group action*: $\mathrm{GL}_2(\mathbb{F}_2)$ permutes the nonzero vectors of $\mathbb{F}_2^2$, and there are exactly 3 of them. Build the homomorphism $\mathrm{GL}_2(\mathbb{F}_2) \to S_3$ and show it is an isomorphism.

Solution. **Order:** $|\mathrm{GL}_2(\mathbb{F}_2)| = (2^2-1)(2^2-2) = 3\cdot 2 = 6$.

The action. $\mathbb{F}_2^2$ has $2^2-1 = 3$ nonzero vectors; label them

$$e_1 = \tbinom{1}{0}\ (\text{“1”}), \quad e_2 = \tbinom{0}{1}\ (\text{“2”}), \quad e_1+e_2 = \tbinom{1}{1}\ (\text{“3”}).$$

Every $A \in \mathrm{GL}_2(\mathbb{F}_2)$ permutes these three (it is a bijection of $\mathbb{F}_2^2$ fixing 0), giving a homomorphism $\Phi : \mathrm{GL}_2(\mathbb{F}_2) \to S_3 = \mathrm{Sym}(\{1,2,3\})$.

Injective. If $\Phi(A) = \mathrm{id}$ then A fixes e_1 and e_2, so $A = I$ (its columns are Ae_1, Ae_2). Thus $\ker\Phi = \{I\}$.

Surjective / iso. An injective map between finite sets of equal size 6 is a bijection, so Φ is an isomorphism, $\mathrm{GL}_2(\mathbb{F}_2) \cong S_3$.

Sample correspondences (verified).

$$\begin{pmatrix}1&1\\0&1\end{pmatrix} :\ 1\mapsto 1,\ 2\mapsto 3,\ 3\mapsto 2\ =\ (2\,3), \qquad \begin{pmatrix}0&1\\1&0\end{pmatrix} :\ 1\mapsto 2,\ 2\mapsto 1,\ 3\mapsto 3\ =\ (1\,2).$$

(For the first: $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)e_2 = \binom{1}{1} = 3$ and it sends $3 = \binom{1}{1} \mapsto \binom{0}{1} = 2$.)

Check via orders. Computing every element's order gives the multiset $\{1,2,2,2,3,3,3\}$: one identity, three involutions, two 3-cycles — exactly the order profile of S_3 (three transpositions, two 3-cycles). Also note $\mathbb{F}_2^\times = \{1\}$ is trivial, so det is trivial and $\mathrm{SL}_2(\mathbb{F}_2) = \mathrm{GL}_2(\mathbb{F}_2)$ has order $6/1 = 6$, matching $|S_3| = |A_3|\cdot 2$ structurally.

Worked Example 1.4.14 ($|\mathrm{GL}_2(\mathbb{F}_3)| = 48$ and $|\mathrm{SL}_2(\mathbb{F}_3)| = 24$)**.** Compute both orders directly from the formula.

Recognition. Pure plug-in to the counting Method at $p = 3$, then divide by $|\mathbb{F}_3^\times| = 2$.

Solution. $|\mathrm{GL}_2(\mathbb{F}_3)| = (3^2-1)(3^2-3) = (9-1)(9-3) = 8\cdot 6 = 48$. Then $|\mathrm{SL}_2(\mathbb{F}_3)| = 48/(3-1) = 48/2 = 24$.
Check (recount the columns). First column any of $3^2-1 = 8$ nonzero vectors; second column any of $3^2-3 = 6$ vectors off the chosen line (the line through v_1 has 3 vectors, leaving $9-3=6$). $8\cdot 6 = 48$. And $48 = |\mathrm{SL}_2(\mathbb{F}_3)|\cdot|\mathbb{F}_3^\times| = 24\cdot 2$. Consistent.

Worked Example 1.4.15 ($|\mathrm{GL}_2(\mathbb{F}_5)|$ and $|\mathrm{SL}_2(\mathbb{F}_5)|$)**.** Compute $|\mathrm{GL}_2(\mathbb{F}_5)|$ and $|\mathrm{SL}_2(\mathbb{F}_5)|$.

Recognition. Same Method at $p = 5$; the only new wrinkle is $|\mathbb{F}_5^\times| = 4$.

Solution. $|\mathrm{GL}_2(\mathbb{F}_5)| = (5^2-1)(5^2-5) = (25-1)(25-5) = 24\cdot 20 = 480$. $|\mathrm{SL}_2(\mathbb{F}_5)| = 480/(5-1) = 480/4 = 120$.
Check. $120\cdot 4 = 480$. Also $|\mathrm{SL}_2(\mathbb{F}_5)| = 120 = |S_5|$ — in fact $\mathrm{SL}_2(\mathbb{F}_5)$ has order 120 but is *not* $\cong S_5$ (it is the binary icosahedral group); equal order does not force isomorphism. The arithmetic check $480/4 = 120$ is what we needed.

Worked Example 1.4.16 (SL as the kernel: locating a matrix's coset)**.** Over $\mathbb{F}_5$, the matrix $A = \left(\begin{smallmatrix}2&0\\0&1\end{smallmatrix}\right)$ has $\det A = 2$. To which coset of $\mathrm{SL}_2(\mathbb{F}_5)$ does it belong, and what is $|A\,\mathrm{SL}_2(\mathbb{F}_5)|$ in the quotient?

Recognition. “Kernel of det” plus “coset” triggers the First Isomorphism Theorem: $\mathrm{GL}_2(\mathbb{F}_5)/\mathrm{SL}_2(\mathbb{F}_5) \cong \mathbb{F}_5^\times$ via $A\,\mathrm{SL}_2 \mapsto \det A$. The coset is determined entirely by $\det A$, and the order of the coset equals $|\det A|$ in $\mathbb{F}_5^\times$.

Solution. Under the isomorphism $\overline{\det} : \mathrm{GL}_2(\mathbb{F}_5)/\mathrm{SL}_2(\mathbb{F}_5) \to \mathbb{F}_5^\times$, the coset $A\,\mathrm{SL}_2(\mathbb{F}_5)$ maps to $\det A = 2$. So A lies in the coset $\overline{\det}^{-1}(2) = \{B \mid \det B = 2\}$, which is *not* SL_2 (that is the identity coset, det = 1). Its order in the quotient equals $|2|$ in $\mathbb{F}_5^\times$: as computed earlier $|2| = 4$. So $A\,\mathrm{SL}_2(\mathbb{F}_5)$ has order 4 in $\mathrm{GL}_2(\mathbb{F}_5)/\mathrm{SL}_2(\mathbb{F}_5)$.
Check. This matches the diagram

$$\begin{array}{ccc} \mathrm{GL}_2(\mathbb{F}_5) & \xrightarrow{\ \det\ } & \mathbb{F}_5^\times \\ \\ A & \longmapsto & 2 \end{array}$$

Diagram explanation. Objects: Four nodes arranged as a 2×2 grid: $\mathrm{GL}_2(\mathbb{F}_5)$ (the group of invertible 2×2 matrices over $\mathbb{F}_5$) in the upper left, $\mathbb{F}_5^\times$ (the group of nonzero elements of $\mathbb{F}_5$ under multiplication) in the upper right, the specific matrix $A = \mathrm{diag}(2,1)$ (an element of $\mathrm{GL}_2(\mathbb{F}_5)$) in the lower left, and the scalar $2 \in \mathbb{F}_5^\times$ in the lower right.

Arrows: The top arrow $\det : \mathrm{GL}_2(\mathbb{F}_5) \twoheadrightarrow \mathbb{F}_5^\times$ is the surjective determinant homomorphism. The bottom arrow $A \mapsto 2$ records the value $\det A = \det \mathrm{diag}(2,1) = 2$ for the specific matrix A; it is not a separate map but a witness that A lies in the fiber $\det^{-1}(2)$.

What commutes: There is no square to check: the bottom row is the top row evaluated at the element $A \in \mathrm{GL}_2(\mathbb{F}_5)$, which det sends to $2 \in \mathbb{F}_5^\times$. Written: $\det(A) = 2$.

Why it commutes: $A = \mathrm{diag}(2,1)$ has $\det A = 2 \cdot 1 = 2$ in $\mathbb{F}_5$, and $2 \neq 0$, so $A \in \mathrm{GL}_2(\mathbb{F}_5)$ and $\det A = 2$.

Why this matters here: This diagram serves as a verification step: after the First Isomorphism Theorem identifies the coset $A \cdot \mathrm{SL}_2(\mathbb{F}_5)$ with $\det A = 2 \in \mathbb{F}_5^\times$, the picture makes the correspondence explicit. It confirms that A lies outside $\mathrm{SL}_2(\mathbb{F}_5)$ (which corresponds to 1) and in the coset labeled by 2.

Concrete example: For $A = \mathrm{diag}(3,1) \in \mathrm{GL}_2(\mathbb{F}_5)$: $\det A = 3$, so A lies in the coset $\det^{-1}(3)$, and the order of this coset in $\mathrm{GL}_2(\mathbb{F}_5)/\mathrm{SL}_2(\mathbb{F}_5)$ equals $|3|$ in $\mathbb{F}_5^\times$, which is 4.

Common pitfall: The lower row looks like a map between groups, but A is a single element, not a group. Students sometimes read this as a group homomorphism $\{A\} \to \{2\}$; it is simply recording where the determinant sends the specific matrix A, as evidence that the isomorphism $\overline{\det}$ works on a concrete element.

Takeaway: The point of this diagram is that $\det A = 2$ places A exactly in the non-identity coset of $\mathrm{SL}_2(\mathbb{F}_5)$ labeled 2, making the abstract First Isomorphism Theorem visible on a single matrix.

and indeed $A^4 = \mathrm{diag}(2^4, 1) = \mathrm{diag}(16,1) \equiv \mathrm{diag}(1,1) = I \pmod 5$, while $A^2 = \mathrm{diag}(4,1) \neq I$, so even *in* GL_2 we have $|A| = 4$, consistent with the coset order dividing it.

Caution. $\mathrm{GL}_2(\mathbb{F}_5)/\mathrm{SL}_2(\mathbb{F}_5) \cong \mathbb{F}_5^\times$ is cyclic of order 4, but $\mathrm{GL}_2(\mathbb{F}_5)$ itself is far from abelian. Do not confuse the quotient (which only remembers determinants) with the whole group. Two matrices in the same coset can fail to commute; they merely have the same determinant.

Worked Example 1.4.17 (Why det being a homomorphism is exactly multiplicativity)**.** Verify the homomorphism square for $\det : \mathrm{GL}_2(\mathbb{F}_3) \to \mathbb{F}_3^\times$ on $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 2 \end{smallmatrix}\right)$.

Recognition. "det is a homomorphism" is encoded in a commuting square: multiply-then-det equals det-then-multiply. To verify on specific inputs, compute both paths around the square.

Solution. $\det A = 2 \cdot 1 - 1 \cdot 1 = 1$ and $\det B = 1 \cdot 2 - 1 \cdot 0 = 2$, so $\det A \cdot \det B = 1 \cdot 2 = 2$ in $\mathbb{F}_3^\times$. Now

$$AB = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 2 & 2+2 \\ 1 & 1+2 \end{pmatrix} = \begin{pmatrix} 2 & 4 \\ 1 & 3 \end{pmatrix} \equiv \begin{pmatrix} 2 & 1 \\ 1 & 0 \end{pmatrix} \pmod 3,$$

and $\det(AB) \equiv 2 \cdot 0 - 1 \cdot 1 = -1 \equiv 2 \pmod 3$. Both paths give 2. The square

$$\begin{array}{ccc} \mathrm{GL}_2(\mathbb{F}_3) \times \mathrm{GL}_2(\mathbb{F}_3) & \xrightarrow{\text{multiply}} & \mathrm{GL}_2(\mathbb{F}_3) \\ \downarrow{\scriptstyle \det \times \det} & & \downarrow{\scriptstyle \det} \\ \mathbb{F}_3^\times \times \mathbb{F}_3^\times & \xrightarrow[\text{multiply}]{} & \mathbb{F}_3^\times \end{array}$$

Diagram explanation. Objects: Four nodes: $\mathrm{GL}_2(\mathbb{F}_3) \times \mathrm{GL}_2(\mathbb{F}_3)$ (upper left; pairs of invertible 2×2 matrices over $\mathbb{F}_3$), $\mathrm{GL}_2(\mathbb{F}_3)$ (upper right; a single invertible matrix), $\mathbb{F}_3^\times \times \mathbb{F}_3^\times$ (lower left; pairs of nonzero scalars in $\mathbb{F}_3$), and $\mathbb{F}_3^\times$ (lower right; a single nonzero scalar in $\mathbb{F}_3$).

Arrows: The top arrow "multiply" sends $(A, B) \mapsto AB$ (matrix multiplication in $\mathrm{GL}_2(\mathbb{F}_3)$). The left arrow $\det \times \det$ sends $(A, B) \mapsto (\det A, \det B)$ (applying det to each component). The bottom arrow "multiply" sends $(x, y) \mapsto xy$ (multiplication in $\mathbb{F}_3^\times$). The right arrow det sends $C \mapsto \det C$.

What commutes: The square commutes: (right-then-down) $=$ det $\circ$multiply $: (A, B) \mapsto \det(AB)$, and (down-then-right) $=$ multiply $\circ (\det \times \det) : (A, B) \mapsto \det A \cdot \det B$. These are equal: $\det(AB) = \det A \cdot \det B$.

Why it commutes: This is exactly the multiplicativity of the determinant, the foundational property $\det(AB) = \det A \det B$ that holds over any field. Chase the pair (A, B): right-then-down gives $\det(AB)$; down-then-right gives $(\det A, \det B)$ then $\det A \cdot \det B$. These agree because det is multiplicative, i.e. a homomorphism of multiplicative monoids $M_n(F) \to F$ (it is not additive, so it is not a ring homomorphism).

Why this matters here: The diagram encodes the definition of a group homomorphism in categorical language. Saying "det is a group homomorphism" is exactly saying this square commutes: the multiplication operations in $\mathrm{GL}_2(\mathbb{F}_3)$ and $\mathbb{F}_3^\times$ are compatible via det. The worked example on A and B verifies it on a specific pair as a sanity check.

Concrete example: With $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 2 \end{smallmatrix}\right)$ over $\mathbb{F}_3$: $\det A = 1$, $\det B = 2$, $\det A \cdot \det B = 2$, and $\det(AB) = 2$ (computed directly from AB). Both routes give 2, confirming commutativity.

Common pitfall: Students sometimes think the square commutes only for specific (A, B) and needs to be checked case by case. In fact, $\det(AB) = \det A \cdot \det B$ is an identity of polynomial functions in the entries of A and B; commutativity of this square is a universal algebraic fact, not a lucky coincidence for particular matrices.

Takeaway: The point of this diagram is that the multiplicativity identity $\det(AB) = \det A \det B$ is exactly the commutativity of a categorical square, expressing that det is a group homomorphism.

commutes on (A, B): down-then-right gives $\det A \cdot \det B = 2$; right-then-down gives $\det(AB) = 2$. *Check.* Agreement of the two routes is precisely the identity $\det(AB) = \det A \det B$, which is what makes det a group homomorphism (Proposition 1.4.3).

Further examples: the definition unwound and the smallest case in full

The fragment above develops $\mathrm{GL}_n(F)$ and $\mathrm{SL}_n(F)$ structurally. Here we record the book's own concrete starting point: the explicit field axioms behind the symbol F, the element-by-element description of the smallest interesting case $\mathrm{GL}_2(\mathbb{F}_2)$, and the bookkeeping that decides exactly when $\mathrm{GL}_n(F)$ is finite or nonabelian.

Definition 1.4.18. A *field* is a set F with two operations $+$ and $\cdot$ such that $(F, +)$ is an abelian group with identity 0, $F^\times = F \setminus \{0\}$ is an abelian group under $\cdot$ with identity 1, and the distributive law $a \cdot (b+c) = a \cdot b + a \cdot c$ holds. The fields used below are $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, and the finite fields $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ for p prime, where entries of a matrix are reduced mod p and $\mathrm{GL}_n(\mathbb{F}_p)$ is a finite group.

Remark 1.4.1. The point the book stresses about the invertibility criterion $\det A \neq 0$ (Proposition 1.4.2) is that "invertible" is relative to the field: the *same* integer matrix can be invertible over one $\mathbb{F}_p$ and singular over another, because $\det A$ is computed in $\mathbb{Z}$ but tested in F. The fragment's first worked example shows exactly this for $\left(\begin{smallmatrix} 2 & 4 \\ 3 & 1 \end{smallmatrix}\right)$ over $\mathbb{F}_5$ versus $\mathbb{F}_3$.

Proposition 1.4.19. *$\mathrm{GL}_n(F)$ is a finite group if and only if F is a finite field. If $|F| = q$, then*

$$|\mathrm{GL}_n(F)| = \prod_{k=0}^{n-1} \left(q^n - q^k\right) = (q^n - 1)(q^n - q) \cdots (q^n - q^{n-1}).$$

In particular $\mathrm{GL}_n(\mathbb{Q})$, $\mathrm{GL}_n(\mathbb{R})$, $\mathrm{GL}_n(\mathbb{C})$ are infinite for every $n \geq 1$, while $\mathrm{GL}_n(\mathbb{F}_p)$ is finite.

Proof. If F is infinite, the scalar matrices aI for $a \in F^\times$ already give infinitely many distinct elements of $\mathrm{GL}_n(F)$, so the group is infinite. If $|F| = q < \infty$, the columns-as-basis count of the fragment's Theorem 1.4.12 applies verbatim with p replaced by q: the first column is any nonzero vector ($q^n - 1$ choices) and, having chosen independent columns $v_1, \ldots, v_k$, the next must avoid their span of size q^k ($q^n - q^k$ choices). The product is finite, so $\mathrm{GL}_n(F)$ is finite. □

Worked Example 1.4.20 (The six elements of $\mathrm{GL}_2(\mathbb{F}_2)$, listed)**.** Write down every matrix in $\mathrm{GL}_2(\mathbb{F}_2)$ explicitly, and confirm there are 6 of them.

Recognition. Over $\mathbb{F}_2$ each entry is 0 or 1, so there are only $2^4 = 16$ matrices in $M_2(\mathbb{F}_2)$ to screen. By Proposition 1.4.2 keep exactly those with $\det \equiv 1 \pmod 2$ (the only nonzero value in $\mathbb{F}_2$). This makes the abstract count $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$ completely concrete.

Solution. For $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ over $\mathbb{F}_2$, $\det A = ad - bc \equiv ad + bc \pmod 2$ (since $-1 \equiv 1$). We need $ad + bc \equiv 1$, i.e. exactly one of the products ad, bc equals 1. Listing all 16 and keeping those:

$$I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}.$$

That is exactly 6 matrices, so $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$, matching $(2^2-1)(2^2-2) = 3 \cdot 2 = 6$. *Check.* The remaining ten matrices in $M_2(\mathbb{F}_2)$ all have $\det \equiv 0$: the zero matrix, the all-ones matrix $\left(\begin{smallmatrix}1&1\\1&1\end{smallmatrix}\right)$, and rank-1 matrices with a zero or repeated row/column such as $\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}0&0\\0&1\end{smallmatrix}\right)$. Since $\mathbb{F}_2^\times = \{1\}$, det is the trivial homomorphism, so $\mathrm{SL}_2(\mathbb{F}_2) = \mathrm{GL}_2(\mathbb{F}_2)$: the six listed matrices are simultaneously all of $\mathrm{SL}_2(\mathbb{F}_2)$.

Worked Example 1.4.21 (A concrete product and inverse inside the list)**.** Inside $\mathrm{GL}_2(\mathbb{F}_2)$, multiply $A = \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ by $B = \left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$ both ways, and find A^{-1}.

Recognition. Two members of the explicit list above: carry out the row-into-column products mod 2 and read the results off the same six matrices. The inverse uses the $\mathbb{F}_2$ adjugate formula with $\Delta^{-1} = 1$.

Solution. **Products.**

$$AB = \begin{pmatrix}1&1\\0&1\end{pmatrix}\begin{pmatrix}0&1\\1&0\end{pmatrix} = \begin{pmatrix}0+1&1+0\\0+1&0+0\end{pmatrix} = \begin{pmatrix}1&1\\1&0\end{pmatrix},$$

$$BA = \begin{pmatrix}0&1\\1&0\end{pmatrix}\begin{pmatrix}1&1\\0&1\end{pmatrix} = \begin{pmatrix}0+0&0+1\\1+0&1+0\end{pmatrix} = \begin{pmatrix}0&1\\1&1\end{pmatrix}.$$

Both lie in the six-element list, and $AB \neq BA$, so $\mathrm{GL}_2(\mathbb{F}_2)$ is nonabelian even though it has only 6 elements. **Inverse.** $\det A = 1 \cdot 1 - 1 \cdot 0 = 1$, so $\Delta^{-1} = 1$ and $A^{-1} = \left(\begin{smallmatrix}d&-b\\-c&a\end{smallmatrix}\right) = \left(\begin{smallmatrix}1&-1\\0&1\end{smallmatrix}\right) \equiv \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right) \pmod 2$. Thus A is its own inverse. *Check.* $A^2 = \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right) = \left(\begin{smallmatrix}1&2\\0&1\end{smallmatrix}\right) \equiv \left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right) = I \pmod 2$, confirming $A^{-1} = A$ and $|A| = 2$. This is the transvection shortcut $T^k = \left(\begin{smallmatrix}1&k\\0&1\end{smallmatrix}\right)$ at $p = 2$.

Proposition 1.4.22. *For every field F and every $n \geq 2$, $\mathrm{GL}_n(F)$ is nonabelian. For $n = 1$, $\mathrm{GL}_1(F) \cong F^\times$ is abelian.*

Proof. For $n = 1$ a 1×1 matrix (a) is invertible iff $a \neq 0$, and matrix multiplication is multiplication in F, so $\mathrm{GL}_1(F) \cong F^\times$, which is abelian. For $n = 2$, the two matrices

$$E = \begin{pmatrix}1&1\\0&1\end{pmatrix}, \qquad E' = \begin{pmatrix}1&0\\1&1\end{pmatrix}$$

both have determinant 1, hence lie in $\mathrm{GL}_2(F)$, and

$$EE' = \begin{pmatrix}2&1\\1&1\end{pmatrix}, \qquad E'E = \begin{pmatrix}1&1\\1&2\end{pmatrix},$$

which differ in the $(1,1)$ entry: these entries are $1+1$ and 1, and $1+1=1$ would force $1=0$, impossible in a field. (This holds even in characteristic 2, where the entries are 0 and 1.) For general $n \geq 2$, embed E and E' in the top-left 2×2 block and the identity elsewhere; the same two blocks fail to commute. Hence $\mathrm{GL}_n(F)$ is nonabelian. □

Remark 1.4.2. The witnesses E, E' above both have determinant 1, so they lie in $\mathrm{SL}_n(F)$; hence $\mathrm{SL}_n(F)$ is also nonabelian for every $n \geq 2$. The same pair witnesses noncommutativity over every field at once, which is why a single computation settles the claim for $\mathbb{Q}, \mathbb{R}, \mathbb{C}$ and all $\mathbb{F}_p$ simultaneously.

Worked Example 1.4.23 (Orders of $\mathrm{GL}_2(\mathbb{F}_p)$ assembled from Proposition 1.4.19)**.** Tabulate $|\mathrm{GL}_2(\mathbb{F}_p)|$ for $p = 2, 3, 5, 7$ and confirm each is divisible by p and by $p-1$.

Recognition. Direct substitution into $|\mathrm{GL}_2(\mathbb{F}_p)| = (p^2-1)(p^2-p) = p(p-1)(p+1)(p-1) = p(p-1)^2(p+1)$. The factored form makes two divisibilities visible at once: a transvection of order p forces $p \mid |\mathrm{GL}_2(\mathbb{F}_p)|$, and the determinant image $\mathbb{F}_p^\times$ of order $p-1$ forces $(p-1) \mid |\mathrm{GL}_2(\mathbb{F}_p)|$.

Solution. Using $|\mathrm{GL}_2(\mathbb{F}_p)| = p(p-1)^2(p+1)$, grouped as $p \cdot (p-1)^2 \cdot (p+1)$:

p	$p \cdot (p-1)^2 \cdot (p+1)$	$\lvert\mathrm{GL}_2(\mathbb{F}_p)\rvert$
2	$2 \cdot 1 \cdot 3$	6
3	$3 \cdot 4 \cdot 4$	48
5	$5 \cdot 16 \cdot 6$	480
7	$7 \cdot 36 \cdot 8$	2016

Each row is divisible by p (the transvection $\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ has order p) and by $p-1$ (the diagonal entries from $\mathbb{F}_p^\times$). *Check.* The values for $p = 2, 3, 5$ agree with the fragment's 6, 48, 480; for $p = 7$, $(49-1)(49-7) = 48 \cdot 42 = 2016 = 7 \cdot 36 \cdot 8$. Dividing each by $p - 1 = |\mathbb{F}_p^\times|$ recovers $|\mathrm{SL}_2(\mathbb{F}_p)|$: $6, 24, 120, 336$ respectively.

Caution. The factorization $|\mathrm{GL}_2(\mathbb{F}_p)| = p(p-1)^2(p+1)$ counts the group; it does *not* by itself name a cyclic subgroup of each size. In particular, divisibility by $(p-1)^2$ reflects the diagonal matrices $\mathrm{diag}(a,b)$ with $a,b \in \mathbb{F}_p^\times$, which form an abelian subgroup of order $(p-1)^2$ that is *not* cyclic when $p-1>1$ (it is a product of two copies of $\mathbb{F}_p^\times$). So do not read element orders off the factors of the count.

Exercises (from the text).

1. Prove $|GL_2(\mathbb{F}_2)| = 6$.
2. List all elements of $GL_2(\mathbb{F}_2)$ and their orders.
3. Show $GL_2(\mathbb{F}_2)$ is non-abelian.
4. Show $\mathbb{Z}/n\mathbb{Z}$ is not a field when n is composite.
5. Show $GL_n(F)$ is finite iff F is finite.
6. If $|F| = q$, prove $|GL_n(F)| < q^{n^2}$.
7. p prime: prove $|GL_2(\mathbb{F}_p)| = p^4 - p^3 - p^2 + p$.
8. Show $GL_n(F)$ is non-abelian for all $n \geq 2$.
9. Prove 2×2 real matrix multiplication is associative.
10. $G = \left\{ \left(\begin{smallmatrix} a & b \\ 0 & c \end{smallmatrix}\right) : a, c \neq 0 \right\}$: show closure, find inverses, deduce $G \leq GL_2(\mathbb{R})$.
11. Heisenberg group $H(F)$: compute XY, find X^{-1}, show $|H(F)| = |F|^3$.

Additional exercises.

1. Let F be a field. Recall $\mathrm{GL}_n(F) = \{A \mid A \text{ is } n \times n \text{ over } F \text{ with } \det A \neq 0\}$.
   (a) Verify directly from the axioms that $\mathrm{GL}_2(\mathbb{F}_2)$ is a group of order 6 by listing all six matrices.
   (b) Exhibit two elements of $\mathrm{GL}_2(\mathbb{F}_2)$ that do not commute, and conclude $\mathrm{GL}_2(\mathbb{F}_2)$ is nonabelian.
   (c) Find an element of $\mathrm{GL}_2(\mathbb{F}_2)$ of order 3 and an element of order 2.
2. Let $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \in \mathrm{GL}_2(\mathbb{R})$.
   (a) Compute A^n for $n \in \mathbb{Z}$ and prove your formula by induction.
   (b) Deduce $|A| = \infty$ in $\mathrm{GL}_2(\mathbb{R})$.
   (c) Now regard A as an element of $\mathrm{GL}_2(\mathbb{Z}/3\mathbb{Z})$ (reduce entries mod 3). Compute $|A|$ there.
3. Let p be a prime. Show that $|\mathrm{GL}_2(\mathbb{F}_p)| = (p^2-1)(p^2-p)$ by counting ordered pairs of linearly independent columns: the first column may be any nonzero vector and the second any vector not in the span of the first. Use this to compute $|\mathrm{GL}_2(\mathbb{F}_3)|$ and $|\mathrm{GL}_2(\mathbb{F}_5)|$.
4. Let $B = \left\{ \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \mid a, d \in F^\times,\ b \in F \right\}$, the upper-triangular invertible 2×2 matrices over a field F.
   (a) Prove $B \leq \mathrm{GL}_2(F)$.
   (b) When $F = \mathbb{F}_p$, compute $|B|$ in terms of p.
   (c) Show B is nonabelian for every field F with more than two elements by exhibiting two noncommuting elements.
5. Let F be a field and let $Z = \{cI \mid c \in F^\times\} \leq \mathrm{GL}_n(F)$ be the scalar matrices.
   (a) Prove every element of Z commutes with every element of $\mathrm{GL}_n(F)$.
   (b) Conversely, prove that if $M \in \mathrm{GL}_2(F)$ commutes with $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and with $\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, then M is a scalar matrix.

6. Let $O = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ and $T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ in $\mathrm{SL}_2(\mathbb{Z})$.

   (a) Compute $|O|$ in $\mathrm{SL}_2(\mathbb{Z})$.

   (b) Let $S = OT$. Compute S^2, S^3, and find $|S|$.

   (c) Conclude that $\mathrm{SL}_2(\mathbb{Z})$ contains elements of finite order 4 and 6 but is itself infinite.

7. Over $F = \mathbb{R}$, decide which of the following are subgroups of $\mathrm{GL}_2(\mathbb{R})$; for each, prove it is a subgroup or exhibit the failed axiom.

   (a) $\{A \mid \det A = 1\}$;

   (b) $\{A \mid \det A \in \{1, -1\}\}$;

   (c) $\{A \mid \det A > 0\}$;

   (d) $\{A \mid A \text{ is diagonal}\}$ intersected with $\mathrm{GL}_2(\mathbb{R})$;

   (e) $\{A \mid \det A \text{ is a positive integer}\}$.

Commutative-diagram exercises.

1. Let F be a field. The determinant gives a map $\det\colon \mathrm{GL}_n(F) \to F^\times$.

   (a) State precisely why det is a homomorphism, i.e. fill in the labels making the square commute:

$$\begin{array}{ccc} \mathrm{GL}_n(F) \times \mathrm{GL}_n(F) & \xrightarrow{\ m\ } & \mathrm{GL}_n(F) \\ \Big\downarrow{\scriptstyle \det \times \det} & & \Big\downarrow{\scriptstyle \det} \\ F^\times \times F^\times & \xrightarrow[(a,b)\mapsto ab]{} & F^\times \end{array}$$

   (b) Show det is surjective by exhibiting, for each $c \in F^\times$, a matrix in $\mathrm{GL}_n(F)$ with determinant c.

   (c) Identify $\ker(\det)$ explicitly and name the standard symbol for it.

2. Recall $\mathrm{SL}_n(F) = \ker(\det)$. Verify that

$$1 \longrightarrow \mathrm{SL}_n(F) \xhookrightarrow{\ \iota\ } \mathrm{GL}_n(F) \xrightarrow{\ \det\ } F^\times \longrightarrow 1$$

   is a short exact sequence: prove (i) ι is injective, (ii) det is surjective, and (iii) $\mathrm{im}(\iota) = \ker(\det)$. Then for $F = \mathbb{F}_p$ deduce $|\mathrm{SL}_n(\mathbb{F}_p)| = |\mathrm{GL}_n(\mathbb{F}_p)|/(p-1)$, and compute $|\mathrm{SL}_2(\mathbb{F}_3)|$.

3. Let $\varphi\colon \mathrm{GL}_2(\mathbb{R}) \to \mathrm{GL}_2(\mathbb{R})$ be a fixed conjugation $\varphi(A) = PAP^{-1}$ for some fixed $P \in \mathrm{GL}_2(\mathbb{R})$. Show φ is a homomorphism by checking the square

$$\begin{array}{ccc} \mathrm{GL}_2(\mathbb{R}) \times \mathrm{GL}_2(\mathbb{R}) & \xrightarrow{\ m\ } & \mathrm{GL}_2(\mathbb{R}) \\ \Big\downarrow{\scriptstyle \varphi\times\varphi} & & \Big\downarrow{\scriptstyle \varphi} \\ \mathrm{GL}_2(\mathbb{R}) \times \mathrm{GL}_2(\mathbb{R}) & \xrightarrow[\ m\ ]{} & \mathrm{GL}_2(\mathbb{R}) \end{array}$$

   commutes, and prove that $\det \circ \varphi = \det$ (so conjugation preserves determinant). Interpret this last fact as commutativity of a triangle over $\mathbb{R}^\times$.

4. The reduction-mod-n map on entries induces $\rho\colon \mathrm{GL}_2(\mathbb{Z}) \to \mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})$.

   (a) Explain why ρ is well defined: show that if $A \in \mathrm{GL}_2(\mathbb{Z})$ (so $\det A = \pm 1$) then its reduction lies in $\mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})$.

(b) Show the square

$$\begin{array}{ccc} \mathrm{GL}_2(\mathbb{Z}) & \xrightarrow{\ \rho\ } & \mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z}) \\ {\scriptstyle \det}\downarrow & & \downarrow{\scriptstyle \det} \\ \{\pm 1\} & \xrightarrow[\ \pi\ ]{} & (\mathbb{Z}/n\mathbb{Z})^\times \end{array}$$

commutes, where π is reduction mod n.

(c) For $n = 2$, describe $\mathrm{im}(\rho)$ as a subset of $\mathrm{GL}_2(\mathbb{F}_2)$ and decide whether ρ is surjective onto $\mathrm{GL}_2(\mathbb{F}_2)$.

5. Let $G = \mathrm{GL}_2(\mathbb{F}_2)$ act on the set $X = \mathbb{F}_2^2 \setminus \{0\}$ of three nonzero column vectors by $A \cdot v = Av$.

(a) Check this is a well-defined action: $Av \in X$ for $A \in G$, $I \cdot v = v$, and $(AB) \cdot v = A \cdot (B \cdot v)$.

(b) This gives a permutation representation $\Phi\colon \mathrm{GL}_2(\mathbb{F}_2) \to \mathrm{Sym}(X) \cong S_3$. Compute Φ on the two generators $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ as explicit permutations of the three vectors.

(c) Using the counts $|\mathrm{GL}_2(\mathbb{F}_2)| = 6 = |S_3|$, prove Φ is an isomorphism by showing $\ker \Phi = 1$ and counting; display $\ker \Phi$ as the leftmost term of

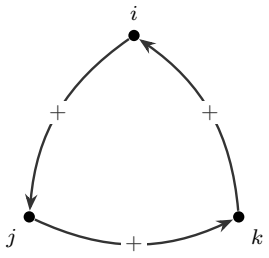
$$1 \longrightarrow \ker \Phi \hookrightarrow \mathrm{GL}_2(\mathbb{F}_2) \xrightarrow{\ \Phi\ } \mathrm{Sym}(X)$$

1.5 The Quaternion Group

The quaternion group Q_8: multiplication, orders, center, subgroups

Definition 1.5.1 (The quaternion group)**.** The *quaternion group* is the set

$$Q_8 = \{\, 1,\, -1,\, i,\, -i,\, j,\, -j,\, k,\, -k \,\}$$



of eight elements, with multiplication generated by the relations

$$i^2 = j^2 = k^2 = -1, \qquad ij = k, \quad jk = i, \quad ki = j,$$

$$ji = -k, \quad kj = -i, \quad ik = -j,$$

together with the rule that -1 multiplies as an ordinary sign ($(-1)^2 = 1$, $(-1)x = x(-1) = -x$ for all x).

The relations are NOT symmetric: $ij = k$ but $ji = -k$. The entire multiplication is encoded in one picture and three sign rules.

Forward arrows in the cyclic order $i \to j \to k \to i$ give a $+$
($ij = k$, $jk = i$, $ki = j$); going backward flips the sign to $-$.

Reading the cycle $i \to j \to k \to i$: *the product of two consecutive letters, in cyclic order, is the next letter with a + sign*; reversing the two factors flips the sign. Squaring any of i, j, k gives -1.

Method (How to multiply two quaternions $\pm a$ and $\pm b$)**.** To compute $(\varepsilon_1 a)(\varepsilon_2 b)$ where $\varepsilon_1, \varepsilon_2 \in \{+1, -1\}$ and $a, b \in \{1, i, j, k\}$:

1. **Pull out the signs.** The total sign is $\varepsilon_1\varepsilon_2$; set it aside and multiply $a \cdot b$.
2. **If either factor is** 1**:** the product is the other factor.
3. **If** $a = b$ **(same letter, both in** $\{i, j, k\}$**):** the product is -1.
4. **If** $a \neq b$ **are distinct letters in** $\{i, j, k\}$**:** read the cyclic order $i \to j \to k \to i$. If $a \to b$ is a *forward* step (one of ij, jk, ki), the product is the third letter with sign $+$. If $a \to b$ is *backward* (one of ji, kj, ik), the product is the third letter with sign $-$.
5. **Reattach the sign** $\varepsilon_1\varepsilon_2$ from step 1.

Recognition trigger. Use this whenever you see a product of two of the eight symbols $\pm 1, \pm i, \pm j, \pm k$. The hard part is always one of the six products ij, jk, ki, ji, kj, ik; everything else is sign bookkeeping. Remember Q_8 is non-abelian, so *order matters*: never assume $ab = ba$.

Caution. Do not import the rule $ab = ba$ from $\mathbb{Z}$ or from cyclic groups. In Q_8, $ij = k$ but $ji = -k \neq k$. Writing $ij = ji$ corrupts every later computation.

Worked Example 1.5.2 (The six core products)**.** Compute ij, ji, jk, ki, and k^2.

Recognition. Each is a product of two of i, j, k, so step 4 (or step 3 for k^2) of the method applies. I just need to decide forward vs. backward in the cycle $i \to j \to k \to i$.

Solution.

- ij: step $i \to j$ is *forward* (it is the listed relation $ij = k$). Third letter is k, sign $+$. So $ij = k$.
- ji: step $j \to i$ is *backward* (reverse of ij). Third letter k, sign $-$. So $ji = -k$.
- jk: step $j \to k$ is *forward* ($jk = i$). So $jk = i$.
- ki: step $k \to i$ is *forward* ($ki = j$). So $ki = j$.
- k^2: same letter twice, step 3 gives $k^2 = -1$.

Check. $ij = k$ and $ji = -k$ are negatives of each other, confirming non-commutativity. Also $ij \cdot ji = k \cdot (-k) = -k^2 = -(-1) = 1$, consistent with $(ij)(ji) = i(jj)i = i(-1)i = -i^2 = -(-1) = 1$. Both routes give 1. ■

Worked Example 1.5.3 (A length-three product with a sign)**.** Compute $(-i)\,(jk)$ and then $i\,j\,k$.

Recognition. There are two factors $(-i)$ and (jk); I evaluate the inner product first, then apply the method. For ijk I associate as $(ij)k$ (the group is associative, so grouping is free) and reduce.

Solution. First $jk = i$ (forward step). Then

$$(-i)(jk) = (-i)(i) = -(i^2) = -(-1) = 1.$$

For ijk: $ij = k$, so $ijk = (ij)k = k \cdot k = k^2 = -1$. *Check.* Associate the other way: $i(jk) = i \cdot i = i^2 = -1$. Same answer, as associativity demands. ■Note $ijk = -1$ is the famous Hamilton relation (carved into Broom Bridge).

Worked Example 1.5.4 (Products with negatives on both sides)**.** Compute $(-j)(-k)$ and $(-k)(j)$ in Q_8.

Recognition. Both are products of signed letters; step 1 isolates the signs, then step 4 handles the letters.

Solution. For $(-j)(-k)$: signs multiply to $(-1)(-1) = +1$; letters $jk = i$ (forward). So $(-j)(-k) = +i = i$. For $(-k)(j)$: sign is $(-1)(+1) = -1$; letters kj is the *backward* step of jk, so $kj = -i$. Reattaching the leading sign: $(-k)(j) = (-1)(kj) = (-1)(-i) = i$. *Check.* Compute $(-k)j$ directly as a single signed product: total sign -1 times $kj = -i$ gives $(-1)(-i) = i$. Agrees. ■

Worked Example 1.5.5 (A conjugation computation)**.** Compute $j\,i\,j^{-1}$ in Q_8. (Here j^{-1} is the inverse of j.)

Recognition. This is a conjugate gxg^{-1} with $g = j$, $x = i$. I first need j^{-1}. Since $|j| = 4$, $j^{-1} = j^3 = -j$ (because $j^2 = -1 \implies j^3 = j^2 j = -j$). Then multiply left to right.

Solution. We have $j^{-1} = -j$. So

$$j\,i\,j^{-1} = j\,i\,(-j) = -\,(ji)\,j = -(-k)\,j = k\,j.$$

Now kj is the backward step of jk, so $kj = -i$. Hence

$$j\,i\,j^{-1} = -i.$$

Check. A conjugate must have the same order as i, and indeed $|-i| = 4 = |i|$. Moreover $jij^{-1} = -i = i^{-1}$, so conjugation by j inverts i — exactly the dihedral-style relation that lives inside Q_8. ■

Worked Example 1.5.6 (Reading off the table to solve $xi = j$)**.** Find all $x \in Q_8$ with $xi = j$.

Recognition. This is a linear equation in the group: right-multiply both sides by i^{-1}. Since $|i| = 4$, $i^{-1} = i^3 = -i$. Uniqueness of solutions in a group guarantees exactly one x.

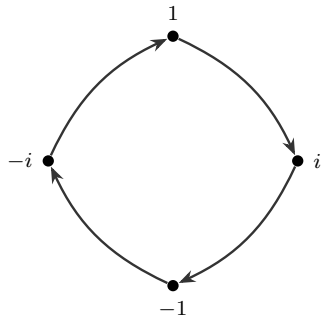
Solution. Right-multiply $xi = j$ by $i^{-1} = -i$:

$$x = j\,i^{-1} = j(-i) = -(ji) = -(-k) = k.$$

So $x = k$ is the unique solution. *Check.* Verify $ki = j$ (forward step) — yes, that is a defining relation. ■

Orders of the eight elements

Proposition 1.5.7 (Element orders in Q_8)**.** *In Q_8: $|1| = 1$, $|-1| = 2$, and $|i| = |-i| = |j| = |-j| = |k| = |-k| = 4$.*



Proof. 1 is the identity, so $|1| = 1$. For -1: $(-1)^1 = -1 \neq 1$ and $(-1)^2 = 1$, so $|-1| = 2$. For i: $i^1 = i$, $i^2 = -1$, $i^3 = i^2 i = -i$, $i^4 = (i^2)^2 = (-1)^2 = 1$, and none of i, i^2, i^3 is 1; hence $|i| = 4$. The same computation, replacing i by any of $\pm i, \pm j, \pm k$, gives square $= -1$, fourth power $= 1$: e.g. $(-i)^2 = i^2 = -1$, $(-i)^4 = 1$. So each of the six has order 4. □

Method (How to compute $|x|$ in Q_8)**.**

1. Compute x^2.
2. If $x^2 = 1$: then $|x| \in \{1, 2\}$; it is 1 only when $x = 1$, else 2. (Only -1 has order 2.)
3. If $x^2 = -1$: then $x^4 = (x^2)^2 = (-1)^2 = 1$ and $x^2 \neq 1$, so $|x| = 4$.

Recognition trigger. Every element of Q_8 squares to 1 or -1. So the order is forced after a single squaring. There is NO element of order $3, 6, 8$ — the only orders that occur are $1, 2, 4$, and 1 and 2 occur exactly once each.

We can picture the cyclic subgroup $\langle i \rangle = \{1, i, -1, -i\}$ as a clock with the rotation $x \mapsto ix$:

multiply by i: $1 \to i \to -1 \to -i \to 1$ (order 4)

Diagram explanation. Objects: Four nodes arranged clockwise at the cardinal points of a circle: 1 (top), i (right), -1 (bottom), $-i$ (left). Each node is an element of the cyclic subgroup $\langle i\rangle = \{1, i, -1, -i\} \leq Q_8$, which is a cyclic group of order 4.

Arrows: Each curved arrow from node x to node ix represents the left-multiplication map $L_i \colon x \mapsto ix$ restricted to $\langle i\rangle$. Specifically: $1 \to i$ (since $i \cdot 1 = i$), $i \to -1$ (since $i \cdot i = -1$), $-1 \to -i$ (since $i \cdot (-1) = -i$), $-i \to 1$ (since $i \cdot (-i) = -(i \cdot i) = 1$). The arrows form a single directed 4-cycle.

What commutes: The diagram encodes one cyclic path: applying L_i four times returns to the start, so $L_i^4 = \mathrm{id}$. The composed path $1 \xrightarrow{L_i} i \xrightarrow{L_i} -1 \xrightarrow{L_i} -i \xrightarrow{L_i} 1$ is the group relation $i^4 = 1$.

Why it commutes: Chase 1 around: $i^1 = i$, $i^2 = -1$, $i^3 = -i$, $i^4 = 1$. The fourth power returns to the identity because $i^2 = -1$ and $(-1)^2 = 1$ in Q_8, so $i^4 = (i^2)^2 = (-1)^2 = 1$. No shorter power returns to 1 (each intermediate value is distinct), confirming $\mathrm{ord}(i) = 4$.

Why this matters here: This picture appears immediately after the proposition asserting $\mathrm{ord}(i) = 4$. It gives a geometric reason: the orbit of 1 under repeated left-multiplication by i visits exactly 4 distinct elements before cycling, so the period is 4, not 1 or 2. It also makes visible why -1 is "halfway around," matching $i^2 = -1$.

Concrete example: In $\mathbb{Z}/4\mathbb{Z}$ under addition, the map $x \mapsto x + 1$ gives the same 4-cycle: $0 \to 1 \to 2 \to 3 \to 0$. The identification $0 \leftrightarrow 1$, $1 \leftrightarrow i$, $2 \leftrightarrow -1$, $3 \leftrightarrow -i$ gives an explicit isomorphism $\langle i\rangle \cong \mathbb{Z}/4\mathbb{Z}$.

Common pitfall: Students sometimes read the arrows as right-multiplication ($x \mapsto xi$) rather than left-multiplication ($x \mapsto ix$). In an abelian group these coincide, but in Q_8 they can differ for other choices of acting element. Here, however, every node lies in the cyclic (hence abelian) subgroup $\langle i\rangle$, so $ix = xi$ for each node and the two readings give the same arrows; the distinction matters only for $x \notin \langle i\rangle$, e.g. $ij = k$ but $ji = -k$.

Takeaway: The point of this diagram is that the four elements $1, i, -1, -i$ form a single closed orbit under left-multiplication by i, giving a visual proof that $\mathrm{ord}(i) = 4$ and that $\langle i\rangle$ is cyclic of order 4.

Worked Example 1.5.8 (Order of -1 vs. order of i)**.** Determine $|-1|$ and $|i|$ and explain why they differ even though both are "minus-ish" looking.

Recognition. Apply the squaring method. The key difference: $(-1)^2 = 1$ but $i^2 = -1 \neq 1$.

Solution. $(-1)^2 = 1$, and $-1 \neq 1$, so $|-1| = 2$. For i: $i^2 = -1 \neq 1$, so by step 3, $|i| = 4$. *Check.* $i^2 = -1$ means i is a square root of -1, so i cannot have order 2 (an order-2 element squares to 1). Consistent. ■

Worked Example 1.5.9 (Order of $-k$)**.** Compute $|-k|$.

Recognition. Single squaring. Watch the sign: $(-k)^2 = (-1)^2 k^2$.

Solution. $(-k)^2 = (-1)^2 k^2 = (+1)(-1) = -1 \neq 1$. By step 3, $(-k)^4 = 1$ and order is 4. So $|-k| = 4$. *Check.* List the powers: $(-k)^1 = -k$, $(-k)^2 = -1$, $(-k)^3 = (-k)^2(-k) = (-1)(-k) = k$, $(-k)^4 = k(-k) = -k^2 = 1$. First return to 1 at exponent 4. ■

Worked Example 1.5.10 (How many elements of each order?)**.** Count the elements of Q_8 of order 1, 2, and 4.

Recognition. Use Proposition 1.5.7: tabulate.

Solution. Order 1: only $\{1\}$ — that is 1 element. Order 2: only $\{-1\}$ — that is 1 element. Order 4: the remaining $\{\pm i, \pm j, \pm k\}$ — that is 6 elements. *Check.* $1 + 1 + 6 = 8 = |Q_8|$ counts every element exactly once. ■This single-element-of-order-2 fact is the fingerprint we use later to distinguish Q_8 from D_8.

Worked Example 1.5.11 (Is there an element of order 8?)**.** Decide whether Q_8 is cyclic.

Recognition. A group of order 8 is cyclic iff it has an element of order 8. Check the maximal element order.

Solution. By Proposition 1.5.7 the largest order occurring is $4 < 8$. So no element generates Q_8; Q_8 is *not* cyclic. *Check.* Also Q_8 is non-abelian ($ij \neq ji$), and every cyclic group is abelian, so it cannot be cyclic. Two independent reasons agree. ■

Worked Example 1.5.12 (Square roots of -1)**.** Find every $x \in Q_8$ with $x^2 = -1$.

Recognition. "$x^2 = -1$" is exactly the step-3 condition, which characterizes the order-4 elements.

Solution. An element satisfies $x^2 = -1$ iff $|x| = 4$ (since $|x| = 1$ gives $x^2 = 1$ and $|x| = 2$ gives $x^2 = 1$). The order-4 elements are $\pm i, \pm j, \pm k$. So there are *six* square roots of -1. *Check.* Verify two of them: $(-j)^2 = j^2 = -1$ and $i^2 = -1$. ■Contrast with $\mathbb{C}$, where -1 has only two square roots; the non-commutativity of Q_8 allows six.

The center $Z(Q_8)$

Definition 1.5.13 (Center)**.** The *center* of a group G is $Z(G) = \{z \in G \mid zx = xz \text{ for all } x \in G\}$.

Proposition 1.5.14 (Center of Q_8)**.** $Z(Q_8) = \{1, -1\}$.

Proof. Certainly 1 and -1 commute with everything (1 is the identity, and -1 acts as a scalar sign: $(-1)x = -x = x(-1)$). So $\{1, -1\} \leq Z(Q_8)$. Conversely, no order-4 element is central: from the Worked Example on conjugation, $jij^{-1} = -i \neq i$, so $ji \neq ij$ and $i \notin Z(Q_8)$. By symmetry of the relations under the cyclic permutation $i \to j \to k \to i$, also $j, k \notin Z(Q_8)$, and likewise $-i, -j, -k \notin Z(Q_8)$ (if z is non-central so is $-z$, since $(-z)x = -zx$ and $x(-z) = -xz$ differ exactly when $zx \neq xz$). Hence $Z(Q_8) = \{1, -1\}$. □

Method (How to find the center of a small group)**.**

1. The identity is always central; in Q_8 test the candidate -1 too (it is a scalar, hence central).
2. For each remaining x, exhibit ONE witness y with $xy \neq yx$ to eliminate x.
3. For Q_8, the witnesses come free from the cycle: i fails against j ($ij = k \neq -k = ji$); j fails against k; k fails against i.
4. Collect the survivors. The center is always a subgroup, so its size must divide $|Q_8|$ — a useful sanity check.

Recognition trigger. Use this whenever asked for $Z(G)$, the set of elements commuting with h, or whether $G/Z(G)$ has a given order. In Q_8 the answer is always $\{1, -1\}$, so $|Q_8/Z(Q_8)| = 4$.

Caution. A single product $xy = yx$ does NOT put x in the center; x must commute with *every* element. For instance i commutes with $-i$ and with ± 1, yet $i \notin Z(Q_8)$ because i fails to commute with j.

The quotient $Q_8/Z(Q_8)$ sits in the exact sequence below; it has order $8/2 = 4$ and is isomorphic to V_4 (every nonidentity coset squares to the identity coset, since $i^2 = j^2 = k^2 = -1 \in Z$).

$$1 \longrightarrow \{1, -1\} \hookrightarrow Q_8 \xrightarrow{\pi} Q_8/\{1, -1\} \cong V_4 \longrightarrow 1$$

Diagram explanation. Objects: Five nodes forming a short exact sequence. The terminal objects 1 (far left) and 1 (far right) are the trivial group. The node $\{1, -1\}$ is the center $Z(Q_8)$, a normal subgroup of order 2. The middle node Q_8 is the full quaternion group of order 8. The rightmost nontrivial node $Q_8/\{1, -1\} \cong V_4$ is the quotient group of order 4, the Klein four-group.

Arrows: The left $1 \to \{1, -1\}$ is the unique map from the trivial group (sending the identity to $1 \in Q_8$). The hooked arrow $\{1, -1\} \hookrightarrow Q_8$ is the inclusion map ι, injecting $\{1, -1\}$ as a subgroup. The arrow $\pi\colon Q_8 \to Q_8/\{1, -1\}$ is the canonical quotient projection, sending $g \mapsto g\{1, -1\}$. The rightmost arrow $Q_8/\{1, -1\} \to 1$ is the unique map to the trivial group (kills everything). Well-definedness of π: the coset $g\{1, -1\}$ depends only on the coset of g, and since $\{1, -1\} \trianglelefteq Q_8$ (it equals $Z(Q_8)$), left and right cosets agree, so π is a well-defined group homomorphism.

What commutes: Exactness at $\{1, -1\}$: $\mathrm{im}(\iota_{\text{trivial}}) = \{1\} = \ker(\iota)$, i.e. ι is injective. Exactness at Q_8: $\ker(\pi) = \{1, -1\} = \mathrm{im}(\iota)$, meaning exactly the elements of $\{1, -1\}$ map to the identity coset under π. Exactness at $Q_8/\{1, -1\}$: π is surjective, so $\mathrm{im}(\pi) = Q_8/\{1, -1\} = \ker(\text{terminal map})$.

Why it commutes: The kernel condition $\ker(\pi) = \{1, -1\}$ holds by definition of the quotient map: $\pi(g) = \{1, -1\}$ (the identity coset) if and only if $g \in \{1, -1\}$. Injectivity of ι is automatic since an inclusion map

sends distinct elements to distinct elements. Surjectivity of π holds because every coset $g\{1,-1\}$ is in the image of π.

Why this matters here: This sequence appears immediately after the proof that $Z(Q_8) = \{1,-1\}$ and the observation that $Q_8/Z(Q_8)$ has order 4 and is isomorphic to V_4. It packages the relationship between Q_8, its center, and the quotient into one diagram, making precise the claim that Q_8 is a nontrivial central extension of V_4 by $\mathbb{Z}/2\mathbb{Z}$.

Concrete example: The same pattern occurs for $\mathbb{Z}/4\mathbb{Z}$: the sequence $1 \to \{0,2\} \hookrightarrow \mathbb{Z}/4\mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \to 1$ (where $\pi(n) = n \bmod 2$) is exact. Here $\{0,2\}$ plays the role of the central subgroup of order 2.

Common pitfall: Students sometimes confuse the hooked inclusion $\{1,-1\} \hookrightarrow Q_8$ with an isomorphism. The hook on the arrow signals injectivity only, not surjectivity. The inclusion is a proper embedding: $|\{1,-1\}| = 2$ while $|Q_8| = 8$, so this map is far from an isomorphism.

Takeaway: The point of this diagram is that Q_8 sits as a central extension between its order-2 center $\{1,-1\}$ and its order-4 quotient V_4, making the exact sequence the cleanest summary of how the center fits into the group's structure.

Worked Example 1.5.15 (Verify $-1 \in Z(Q_8)$ directly)**.** Show -1 commutes with j.

Recognition. Apply the scalar rule: -1 behaves as a sign in front of any element.

Solution. $(-1)j = -j$ and $j(-1) = -j$. Equal, so -1 and j commute. *Check.* The same scalar argument works against $i, k, \pm 1$, so -1 commutes with all eight elements: $-1 \in Z(Q_8)$. ■

Worked Example 1.5.16 (Eliminate k from the center)**.** Show $k \notin Z(Q_8)$ by producing a witness.

Recognition. Need ONE element y with $ky \neq yk$. The cycle says $ki = j$ but $ik = -j$.

Solution. Take $y = i$. Then $ki = j$ (forward) while $ik = -j$ (backward). Since $j \neq -j$, $ki \neq ik$, so $k \notin Z(Q_8)$. *Check.* $j \neq -j$ because j and $-j$ are listed as distinct elements of Q_8 (if $j = -j$ held, then $2j = 0$ in additive language, but Q_8 has no such collapse: j and $-j$ have distinct images in the multiplication table). ■

Worked Example 1.5.17 (Centralizer of i)**.** Compute $C_{Q_8}(i) = \{x \mid xi = ix\}$.

Recognition. An element commutes with i iff it lies in $\langle i \rangle = \{1, i, -1, -i\}$; test each of the eight.

Solution. Powers of i always commute with i: $1, i, -1, -i$ all commute with i (a cyclic subgroup is abelian). For j: $ij = k$, $ji = -k$, unequal — j excluded; similarly $-j, k, -k$ excluded by sign symmetry. So

$$C_{Q_8}(i) = \{1, -1, i, -i\} = \langle i \rangle.$$

Check. $|C_{Q_8}(i)| = 4$ divides 8 ■, and $Z(Q_8) = \{1,-1\} \leq C_{Q_8}(i)$ as it must (the center lies in every centralizer). ■

Worked Example 1.5.18 (Size of a conjugacy class)**.** The conjugacy class of i has size $[Q_8 : C_{Q_8}(i)]$. Compute it and list the class.

Recognition. Orbit–stabilizer: the class size equals the index of the centralizer found above.

Solution. $[Q_8 : C_{Q_8}(i)] = 8/4 = 2$. So the class of i has 2 elements. Computing conjugates: $jij^{-1} = -i$ (done earlier), and $1 \cdot i \cdot 1 = i$. So the class is $\{i, -i\}$. *Check.* Class sizes must sum to 8. The classes are $\{1\}$, $\{-1\}$ (both central, size 1), and $\{i,-i\}, \{j,-j\}, \{k,-k\}$ (size 2 each): $1 + 1 + 2 + 2 + 2 = 8$. ■

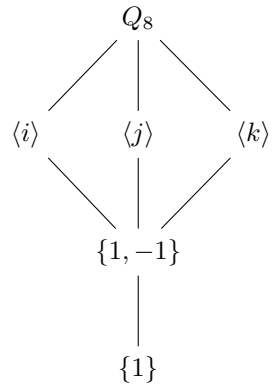
Worked Example 1.5.19 (Order of the quotient $Q_8/Z(Q_8)$)**.** Compute $|Q_8/Z(Q_8)|$ and decide whether it is cyclic.

Recognition. Use Lagrange: $|G/N| = |G|/|N|$. Then check whether the quotient could be cyclic.

Solution. $|Q_8/Z(Q_8)| = 8/2 = 4$. If it were cyclic of order 4, then $Q_8/Z(Q_8)$ cyclic would force Q_8 abelian (a standard fact: $G/Z(G)$ cyclic $\implies$ G abelian). But Q_8 is non-abelian, contradiction. So $Q_8/Z(Q_8) \cong V_4$ (the only non-cyclic group of order 4). *Check.* In the quotient, $\bar{i}^2 = \overline{i^2} = \overline{-1} = \bar{1}$, and likewise $\bar{j}^2 = \bar{k}^2 = \bar{1}$; every nonidentity element has order 2, the signature of V_4. ■

The subgroups of Q_8 — all normal

Proposition 1.5.20 (Subgroup lattice of Q_8)**.** *Q_8 has exactly six subgroups:*



$$\{1\}, \quad \{1,-1\}, \quad \langle i\rangle, \quad \langle j\rangle, \quad \langle k\rangle, \quad Q_8,$$

of orders $1,2,4,4,4,8$ respectively, where $\langle i\rangle = \{1,i,-1,-i\}$, $\langle j\rangle = \{1,j,-1,-j\}$, $\langle k\rangle = \{1,k,-1,-k\}$. Every one of these subgroups is normal in Q_8.

Proof. Order 1 and 8: $\{1\}$ and Q_8 always occur. *Order 2:* a subgroup of order 2 is $\{1,x\}$ with $|x| = 2$; the only order-2 element is -1, giving $\{1,-1\}$ as the unique order-2 subgroup. *Order 4:* by Lagrange the index is 2. Any order-4 subgroup must contain an element of order 4 (a group of order 4 with no order-4 element is V_4, but V_4 would need three elements of order 2, and Q_8 has only one). Such a subgroup is then cyclic, $\langle x\rangle$ with $|x| = 4$. Now $\langle i\rangle = \langle -i\rangle = \{1,i,-1,-i\}$, $\langle j\rangle = \langle -j\rangle$, $\langle k\rangle = \langle -k\rangle$ — three distinct cyclic subgroups, and these exhaust the order-4 subgroups since the six order-4 elements pair off into these three. *Normality:* subgroups of index 2 are automatically normal, so $\langle i\rangle, \langle j\rangle, \langle k\rangle$ are normal; $\{1\}$ and Q_8 are trivially normal. For $\{1,-1\} = Z(Q_8)$, the center is always normal (indeed $g(-1)g^{-1} = -1$ for all g). Hence all six are normal. □

A group, like Q_8, in which every subgroup is normal but which is itself non-abelian is called a *Hamiltonian group*; Q_8 is the smallest one.

The lattice (lines mean "is contained in"; all six nodes are normal subgroups):

Method (How to check a subgroup $H \trianglelefteq G$ in Q_8)**.**

1. **Index 2 shortcut:** if $[G:H] = 2$, then $H \trianglelefteq G$ automatically (left cosets = right cosets). In Q_8 this instantly handles $\langle i\rangle, \langle j\rangle, \langle k\rangle$.
2. **Center shortcut:** $Z(G) \trianglelefteq G$ always; this handles $\{1,-1\}$.
3. **Trivial cases:** $\{1\} \trianglelefteq G$ and $G \trianglelefteq G$.
4. **General test** (if needed): verify $gHg^{-1} \subseteq H$ for g ranging over a generating set of G.

Recognition trigger. Use the index-2 shortcut whenever $|H| = \frac{1}{2}|G|$ — it is the fastest normality proof in Q_8. Because Q_8 has only the six subgroups above, and each is caught by step 1, 2, or 3, EVERY subgroup of Q_8 is normal.

Caution. "All subgroups normal" does NOT mean "abelian." Q_8 is non-abelian yet every subgroup is normal. The implication only runs one way: abelian $\implies$ all subgroups normal, not conversely.

Worked Example 1.5.21 ($\langle j\rangle$ is normal)**.** Show $\langle j\rangle = \{1,j,-1,-j\} \trianglelefteq Q_8$.

Recognition. $\langle j\rangle$ has order 4, index $8/4 = 2$ — the index-2 shortcut applies. As an explicit check I also conjugate the generator j by i.

Solution. Since $[Q_8 : \langle j\rangle] = 2$, $\langle j\rangle$ is normal. Explicit check via conjugation by i (using $i^{-1} = -i$):

$$iji^{-1} = ij(-i) = -(ij)i = -(k)(i) = -(ki) = -j \in \langle j\rangle.$$

Check. $-j \in \langle j\rangle$, so conjugation by i maps the generator j back into $\langle j\rangle$; combined with the index-2 fact, $\langle j\rangle \trianglelefteq Q_8$. ■

Worked Example 1.5.22 (The order-2 subgroup is unique and normal)**.** Show $\{1, -1\}$ is the only subgroup of order 2 and that it is normal.

Recognition. A subgroup of order 2 is determined by its unique order-2 element; Q_8 has exactly one such element. Normality follows from it being the center.

Solution. The only element of order 2 is -1 (Worked Example counting orders). So $\{1, -1\}$ is the unique order-2 subgroup. It equals $Z(Q_8)$, and the center is normal: for any g, $g(-1)g^{-1} = (-1)gg^{-1} = -1 \in \{1, -1\}$. *Check.* $g(-1)g^{-1} = -1$ uses that -1 is central (scalar). ■

Worked Example 1.5.23 (Intersection of two order-4 subgroups)**.** Compute $\langle i\rangle \cap \langle j\rangle$.

Recognition. An intersection of subgroups is a subgroup; list elements and keep the common ones.

Solution. $\langle i\rangle = \{1, i, -1, -i\}$ and $\langle j\rangle = \{1, j, -1, -j\}$. The common elements are 1 and -1. So $\langle i\rangle \cap \langle j\rangle = \{1, -1\} = Z(Q_8)$. *Check.* $|\langle i\rangle \cap \langle j\rangle| = 2$ divides both $|\langle i\rangle| = 4$ and $|\langle j\rangle| = 4$ ■. Geometrically, every pair of distinct order-4 subgroups meets exactly in the center — that is why $\{1, -1\}$ sits at the unique node below all three in the lattice. ■

Worked Example 1.5.24 (Counting subgroups confirms the lattice)**.** Verify the total number of subgroups is 6 by tallying by order.

Recognition. Use Proposition 1.5.20 and Lagrange: possible orders divide 8, i.e. $1, 2, 4, 8$.

Solution. Order 1: $\{1\}$ — 1 subgroup. Order 8: Q_8 — 1. Order 2: only $\{1, -1\}$ — 1. Order 4: $\langle i\rangle, \langle j\rangle, \langle k\rangle$ — 3. Total $1 + 1 + 1 + 3 = 6$. *Check.* No order can be skipped that Lagrange forbids; $1, 2, 4, 8$ are exactly the divisors of 8, and we found at least one subgroup of each. ■

Worked Example 1.5.25 (Every subgroup normal, fast)**.** Without case-checking each conjugate, argue that all six subgroups of Q_8 are normal.

Recognition. Match each subgroup to a shortcut from the method box.

Solution. $\{1\}$ and Q_8: trivially normal. $\{1, -1\} = Z(Q_8)$: center, normal. $\langle i\rangle, \langle j\rangle, \langle k\rangle$: each has index 2, hence normal. That covers all six. *Check.* The shortcuts are independent of any specific conjugation computation, yet they agree with the brute-force verification that $gHg^{-1} = H$ for every g and every H. ■

Q_8 versus D_8: same order, NOT isomorphic

Recall $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s\rangle$ is the symmetry group of the square, also of order 8 and also non-abelian. A natural question: are Q_8 and D_8 "the same group in disguise"? The square-counting below shows they are not.

Proposition 1.5.26 ($Q_8 \ncong D_8$)**.** *Q_8 and D_8 are non-isomorphic groups of order 8.*

Proof. The number of elements of order 2 is an isomorphism invariant (an isomorphism φ satisfies $|\varphi(x)| = |x|$, so it bijects order-2 elements to order-2 elements). In Q_8 there is exactly *one* element of order 2, namely -1 (Worked Example on counting orders). In D_8 the elements of order 2 are r^2 and the four reflections s, rs, r^2s, r^3s — that is *five* elements of order 2 (each reflection squares to 1, and r^2 is the half-turn). Since $1 \neq 5$, no isomorphism $Q_8 \to D_8$ can exist. □

Method (How to prove two finite groups are NOT isomorphic)**.**

1. Compute a numerical invariant for both: most often *the multiset of element orders* (equivalently, "how many elements of each order").
2. Other invariants if the orders match: abelian?, size of the center, number of subgroups of a given order, is it cyclic?, exponent.
3. If ANY invariant differs, the groups are not isomorphic. (If all your invariants match, you have NOT proved isomorphism — you must then exhibit an explicit isomorphism.)

Recognition trigger. Use this whenever asked "is $G \cong H$?" for two concrete groups. For two non-abelian groups of order 8, the order-2 count is the cleanest separator: Q_8 has 1, D_8 has 5.

Caution. Matching orders ($|Q_8| = |D_8| = 8$) and "both non-abelian" is NOT enough to conclude $Q_8 \cong D_8$. Equal order and equal abelian-ness are necessary, not sufficient. You must compare finer invariants — here, the count of order-2 elements differs.

The contrast at a glance:

Invariant	Q_8	D_8
order of group	8	8
abelian?	no	no
elements of order 1	1	1
elements of order 2	**1**	**5**
elements of order 4	6	2
center	$\{1, -1\}$, size 2	$\{1, r^2\}$, size 2
# subgroups of order 4	3 (all cyclic)	3 (one cyclic $\langle r \rangle$, two $\cong V_4$)
every subgroup normal?	yes	no ($\langle s \rangle$ is not normal)

Worked Example 1.5.27 (Order-2 count in D_8)**.** List all elements of D_8 of order 2 and count them.

Recognition. Use the normal form $r^a s^b$ with $0 \le a \le 3$, $b \in \{0, 1\}$. Rotations r^a have order $4/\gcd(a, 4)$; reflections $r^a s$ all have order 2.

Solution. Rotations: $r^0 = 1$ (order 1), r^1 (order 4), r^2 (order 2), r^3 (order 4). Reflections: s, rs, r^2s, r^3s each satisfy $(r^a s)^2 = r^a s r^a s = r^a (s r^a) s = r^a r^{-a} s^2 = 1$ using $sr^a = r^{-a}s$ and $s^2 = 1$, so each has order 2. Order-2 elements: $\{r^2, s, rs, r^2s, r^3s\}$ — five of them. *Check.* Total elements 1(id)+1(order-2 rotation)+2(order 4)+4(reflections)= $8 = |D_8|$, and $1 + 4 = 5$ have order 2. ■

Worked Example 1.5.28 (Order-2 count in Q_8)**.** Confirm Q_8 has exactly one element of order 2.

Recognition. From Proposition 1.5.7, an element has order 2 iff it squares to 1 but is not 1.

Solution. Squaring each: $i^2 = j^2 = k^2 = (-i)^2 = (-j)^2 = (-k)^2 = -1 \neq 1$, $1^2 = 1$, $(-1)^2 = 1$. Only -1 squares to 1 while being $\neq 1$. So exactly one element, -1, has order 2. *Check.* Matches the $1 + 1 + 6$ tally from before. ■

Worked Example 1.5.29 (The decisive comparison)**.** Use the order-2 counts to conclude $Q_8 \ncong D_8$.

Recognition. Apply the non-isomorphism method: the order-2 count is an isomorphism invariant.

Solution. Q_8 has 1 element of order 2; D_8 has 5. An isomorphism preserves element orders, hence preserves these counts. Since $1 \neq 5$, $Q_8 \ncong D_8$. *Check.* A second invariant agrees — "every subgroup normal" holds in Q_8 but fails in D_8 (the reflection subgroup $\langle s \rangle$ is not normal: $rsr^{-1} = r^2 s \notin \langle s \rangle = \{1, s\}$). Two invariants, same verdict. ■

Worked Example 1.5.30 (Both share a V_4 quotient — why that does not save the isomorphism)**.** Show $Q_8/Z(Q_8) \cong V_4 \cong D_8/Z(D_8)$, and explain why this does not imply $Q_8 \cong D_8$.

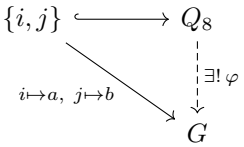
Recognition. Compute each central quotient; both have order $8/2 = 4$ and are non-cyclic, hence $\cong V_4$. But isomorphic quotients by isomorphic centers do not force the groups isomorphic.

Solution. $Q_8/Z(Q_8)$: order 4, non-cyclic (shown earlier), so $\cong V_4$. $D_8/Z(D_8)$: $Z(D_8) = \{1, r^2\}$, quotient order 4; the images of r and s each square to the identity coset ($r^2 \in Z$, $s^2 = 1$), so it is $\cong V_4$. Thus both central quotients are V_4. Yet the groups differ: the extension $1 \to Z \to G \to V_4 \to 1$ can be "twisted" differently — in Q_8 every preimage of a nonidentity coset has order 4, while in D_8 the reflection preimages have order 2. So equal quotients do not lift to an isomorphism of G. *Check.* The order-2 count (1 vs. 5) already proved non-isomorphism; this example shows where the naive "same quotient" argument breaks. ■

Worked Example 1.5.31 (An invariant that does NOT distinguish them)**.** Show that "size of the center" fails to separate Q_8 and D_8, and identify an invariant that succeeds.

Recognition. Some invariants coincide for non-isomorphic groups; you need one that differs.

Solution. $|Z(Q_8)| = |\{1, -1\}| = 2$ and $|Z(D_8)| = |\{1, r^2\}| = 2$. Equal — so the center's size cannot distinguish them. A separating invariant: the number of order-2 elements (1 for Q_8, 5 for D_8), or equivalently the number of order-4 elements (6 vs. 2). *Check.* Indeed Q_8 has 6 order-4 elements ($\pm i, \pm j, \pm k$) and D_8 only 2 (r, r^3). The discrepancy is the same fact viewed through order-4 instead of order-2. ■



Master reference: the 8×8 multiplication table of Q_8

Entry in row g, column h is the product gh (row element first). Read off, for example, row i, column j: $ij = k$; row j, column i: $ji = -k$.

$\cdot$	1	-1	i	$-i$	j	$-j$	k	$-k$
1	1	-1	i	$-i$	j	$-j$	k	$-k$
-1	-1	1	$-i$	i	$-j$	j	$-k$	k
i	i	$-i$	-1	1	k	$-k$	$-j$	j
$-i$	$-i$	i	1	-1	$-k$	k	j	$-j$
j	j	$-j$	$-k$	k	-1	1	i	$-i$
$-j$	$-j$	j	k	$-k$	1	-1	$-i$	i
k	k	$-k$	j	$-j$	$-i$	i	-1	1
$-k$	$-k$	k	$-j$	j	i	$-i$	1	-1

Remark 1.5.1. Sanity checks on the table: (1) each row and each column is a permutation of all eight elements (the Latin-square property forced by group axioms). (2) The diagonal entries (squares) are $1, 1, -1, -1, -1, -1, -1, -1$: exactly one 1 off the identity row (namely $(-1)^2 = 1$) and six -1's, matching "one element of order 2, six of order 4." (3) The block for $\{1, -1\}$ (top-left 2×2) is closed — it is the central subgroup. (4) Asymmetry across the diagonal (e.g. row i col j is k but row j col i is $-k$) visibly certifies non-commutativity.

Finally, the universal property that makes the table legitimate: Q_8 is the group *presented* by $\langle i, j \mid i^4 = 1,\ i^2 = j^2,\ jij^{-1} = i^{-1} \rangle$ (with $k := ij$, $-1 := i^2$). Any map of i, j into a group G respecting these relations extends uniquely:

provided $a, b \in G$ satisfy $a^4 = 1$, $a^2 = b^2$, $bab^{-1} = a^{-1}$. This is the precise sense in which "Q_8 is generated by i, j subject to those relations," and it is what guarantees the multiplication table above is the unique one consistent with Definition 1.5.1.

Diagram explanation. Objects: Three nodes. The set $\{i, j\}$ (upper-left) is just the two-element generating set of Q_8, not a group. The group Q_8 (upper-right) is the quaternion group of order 8, presented by generators i, j subject to $i^4 = 1$, $i^2 = j^2$, $jij^{-1} = i^{-1}$. The group G (lower-right) is any group containing elements $a = \varphi(i)$ and $b = \varphi(j)$ satisfying those same three relations.

Arrows: The hooked arrow $\{i, j\} \hookrightarrow Q_8$ is the inclusion of the generating set into Q_8. The diagonal arrow $\{i, j\} \to G$ labelled $i \mapsto a$, $j \mapsto b$ is the prescribed assignment of generators to elements of G (not yet a group homomorphism, merely a function on the generating set). The dashed vertical arrow $\varphi\colon Q_8 \to G$ is the unique group homomorphism whose existence and uniqueness are asserted by the universal property of the presentation; it is the induced map extending the assignment $i \mapsto a$, $j \mapsto b$ to all of Q_8.

What commutes: The triangle commutes: the composite $\{i, j\} \hookrightarrow Q_8 \xrightarrow{\varphi} G$ equals the direct assignment $\{i, j\} \to G$. In formulas: $\varphi(i) = a$ and $\varphi(j) = b$.

Why it commutes: Well-definedness of φ: every element of Q_8 is a product of powers of i and j, and φ is defined by $\varphi(i^{e_1} j^{e_2} \cdots) = a^{e_1} b^{e_2} \cdots$. This is well-defined because any relation holding among i, j in Q_8 (such as $i^4 = 1$ or $ij \cdot (ij)^{-1} = 1$) also holds for a, b in G by hypothesis, so different words representing the same element of Q_8 map to the same element of G. Uniqueness: any homomorphism $Q_8 \to G$ with $\varphi(i) = a$, $\varphi(j) = b$ is forced on all of Q_8 since i, j generate Q_8.

Why this matters here: This diagram appears at the conclusion of the section as the rigorous justification that the multiplication table is uniquely determined. Without the universal property, one could worry that

defining Q_8 by generators and relations might be inconsistent or ambiguous. The diagram says: any group G containing elements obeying those relations automatically receives a unique map from Q_8, confirming that Q_8 is the "most efficient" or "freest" such group, and in particular that the table has exactly one consistent completion.

Concrete example: Take $G = \langle i \rangle \cong \mathbb{Z}/4\mathbb{Z} \leq Q_8$ and the assignment $i \mapsto i$, $j \mapsto i$. Then $a = b = i$ satisfies $a^4 = 1$ and $a^2 = b^2$, but $bab^{-1} = iai^{-1} = a \neq a^{-1} = -i$ (since $i \neq -i$), so the third relation fails and no homomorphism $Q_8 \to G$ with this assignment exists. This shows the relation conditions are essential: the diagram produces φ only when all three are satisfied.

Common pitfall: The dashed arrow is labelled $\exists!\,\varphi$, meaning it exists AND is unique. Students sometimes read this as merely an existence claim and forget uniqueness, or conversely assume every assignment $i \mapsto a$, $j \mapsto b$ produces some homomorphism. The dashed arrow exists only when a, b satisfy all three relations; if even one fails, the diagram does not commute and φ does not exist.

Takeaway: The point of this diagram is that the universal property of the presentation of Q_8 guarantees that any group containing elements satisfying the three quaternion relations receives a unique homomorphism from Q_8, which is precisely what makes the generator-relation definition consistent and the multiplication table uniquely determined.

Further examples: the quaternion group as listed in the text

D&F introduce Q_8 by *listing* its eight elements and then specifying the products directly; from those products every one of the 64 entries of the multiplication table is determined. Writing the table out is left to the reader (Exercise 2 below). The book does not verify associativity here: it calls the check tedious and says it will be proved later by less computational means (one triple is checked by hand below). We record the book's listing form of the definition and the immediate facts it draws from it; the relation form, the picture, and the 8×8 table appear above and are not repeated here.

Definition 1.5.32 (Quaternion group, listing form)**.** The *quaternion group* Q_8 is the set

$$Q_8 = \{\, 1,\ -1,\ i,\ -i,\ j,\ -j,\ k,\ -k \,\}$$

with an associative product $\cdot$ given by the complete list of rules

$$1 \cdot a = a \cdot 1 = a \quad \text{for all } a \in Q_8,$$

$$(-1) \cdot (-1) = 1, \qquad (-1) \cdot a = a \cdot (-1) = -a \quad \text{for all } a \in Q_8,$$

$$i \cdot i = j \cdot j = k \cdot k = -1,$$

$$i \cdot j = k, \quad j \cdot i = -k, \qquad j \cdot k = i, \quad k \cdot j = -i, \qquad k \cdot i = j, \quad i \cdot k = -j.$$

Here 1 is the identity and -1 commutes with every element. Together with associativity, these rules determine $g \cdot h$ for all $g, h \in Q_8$ (for instance $(-i) \cdot (-j) = (-1) \cdot (-1) \cdot i \cdot j = i \cdot j = k$).

The symbol "$-$" here is purely notational: $-a$ denotes the single element $(-1) \cdot a$, not a separately defined operation, and the eight symbols are pairwise distinct. This listing form is the book's own; it agrees element-for-element with the relation form in Definition 1.5.1.

Remark 1.5.2. Three facts the text reads directly off the list in Definition 1.5.32:

1. Q_8 has *order* 8 (eight distinct elements), with identity 1 and with -1 playing the role of a central sign.
2. Q_8 is *nonabelian*: $i \cdot j = k$ but $j \cdot i = -k$, and $k \neq -k$.
3. Each element has its inverse on the list: 1 and -1 are self-inverse, and the inverse of any of $\pm i, \pm j, \pm k$ is its negative, since $i \cdot (-i) = -(i \cdot i) = -(-1) = 1$ and likewise for j, k.

Worked Example 1.5.33 (Associativity on a sample triple)**.** The definition *assumes* associativity. As a self-consistency check, verify $(i \cdot j) \cdot k = i \cdot (j \cdot k)$ using only the listed products.

Recognition. Associativity is part of the definition, not something derived from the relations elsewhere; verifying one triple by hand shows the listed rules do not contradict it.

Solution. Left grouping: $i \cdot j = k$, so $(i \cdot j) \cdot k = k \cdot k = -1$. Right grouping: $j \cdot k = i$, so $i \cdot (j \cdot k) = i \cdot i = -1$. Both equal -1, so $(i \cdot j) \cdot k = i \cdot (j \cdot k)$. *Check.* The common value -1 is the relation $i \cdot j \cdot k = -1$; the two groupings agreeing is exactly what associativity asserts on this triple. ■

Worked Example 1.5.34 (Reducing a fully signed product from the raw list)**.** Using only the rules in Definition 1.5.32, compute $(-i) \cdot (-j)$ and $(-j) \cdot (-i)$, and contrast the two.

Recognition. Each is a product of two signed letters. The rule $(-1) \cdot a = -a$ lets me collect both signs onto a single leading $+1$, then apply one of the six listed letter-products.

Solution. For $(-i) \cdot (-j)$: the two signs give $(-1) \cdot (-1) = 1$, and $i \cdot j = k$, so $(-i) \cdot (-j) = k$. For $(-j) \cdot (-i)$: again the signs give $+1$, and $j \cdot i = -k$, so $(-j) \cdot (-i) = -k$. *Check.* The signs cancel in both, yet the results k and $-k$ differ, because the underlying letter-products $i \cdot j$ and $j \cdot i$ already differ in sign. Removing the negatives does not remove the noncommutativity. ■

Worked Example 1.5.35 (Inverses straight from the listing)**.** Using Remark 1.5.2(3), write down i^{-1}, $(-j)^{-1}$, and $(-1)^{-1}$ directly from the listed products, without computing any orders.

Recognition. The listing pairs each letter with its negative (for $\pm i, \pm j, \pm k$) or with itself (for ± 1) to produce 1, which is exactly the defining property of an inverse.

Solution. $i \cdot (-i) = -(i \cdot i) = -(-1) = 1$, so $i^{-1} = -i$. Next $(-j) \cdot j = -(j \cdot j) = 1$, so $(-j)^{-1} = j$. And $(-1) \cdot (-1) = 1$, so $(-1)^{-1} = -1$. *Check.* This recovers the inverses from the raw list alone; it matches the order computation $|i| = |j| = 4$, which forces $i^{-1} = i^3 = -i$ and $j^{-1} = j^3 = -j$. ■

Exercises (from the text).

1. Compute the order of each element of Q_8.
2. Write out the group tables for S_3, D_8, and Q_8.
3. Find a set of generators and relations for Q_8.

Additional exercises.

1. Using only the defining relations $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$ of $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, compute each of the following products and express the answer as one of the eight elements: (a) ji; (b) kj; (c) ik; (d) $(ij)k$; (e) $i(jk)$; (f) $(-i)(-j)$. In particular verify $ji = -ij$, so Q_8 is nonabelian.
2. Determine the order $|x|$ of every element $x \in Q_8$. List which elements have order 1, which have order 2, and which have order 4. Conclude that Q_8 has a unique element of order 2, and identify it.
3. Find every subgroup of Q_8. For each one give a set of generators and its order, and verify your list against Lagrange's theorem (every subgroup order divides 8). Show that $\langle i \rangle$, $\langle j \rangle$, $\langle k \rangle$ are exactly the three subgroups of order 4.
4. Prove that every subgroup of Q_8 is normal. (Suggestion: $\langle -1 \rangle$ is central, and each subgroup of order 4 has index 2.) A nonabelian group all of whose subgroups are normal is called Hamiltonian; conclude Q_8 is the smallest such group.
5. Show that Q_8 and D_8 are not isomorphic, even though both are nonabelian of order 8. (Hint: count elements of order 2 in each. Recall D_8 has $r^4 = s^2 = 1$, $sr = r^{-1}s$.)
6. The center of a group is $Z(G) = \{z \in G \mid zx = xz \text{ for all } x \in G\}$. Prove $Z(Q_8) = \{\pm 1\} = \langle -1 \rangle$, and show that -1 is the unique element x with $x^2 = 1$ and $x \neq 1$.
7. Define a map $\varphi\colon Q_8 \to \mathrm{GL}_2(\mathbb{C})$ by $\varphi(i) = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}$, $\varphi(j) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$, and extend so that $\varphi(k) = \varphi(i)\varphi(j)$ and $\varphi(-1) = -I$. Verify that $\varphi(i)^2 = \varphi(j)^2 = \varphi(k)^2 = -I$ and $\varphi(i)\varphi(j) = \varphi(k)$, so these matrices satisfy the quaternion relations.

Commutative-diagram exercises.

1. Let $N = \{\pm 1\} = \langle -1 \rangle \trianglelefteq Q_8$ and let $V = Q_8/N$. Show $|V| = 4$ and that every nonidentity element of V has order 2, so $V \cong V_4$, the Klein four-group. Writing $\pi\colon Q_8 \to V$ for the quotient map, fill in the cosets so that the sequence

$$1 \longrightarrow \langle -1 \rangle \hookrightarrow Q_8 \xrightarrow{\pi} V_4 \longrightarrow 1$$

is exact (i.e. $\ker \pi = \langle -1 \rangle$ and π is onto), and list $\pi(i), \pi(j), \pi(k)$ as elements of V_4.

2. With $\pi\colon Q_8 \to V_4$ as above, prove that multiplication on the quotient is the unique map $\bar{m}$ making the diagram

$$\begin{array}{ccc} Q_8 \times Q_8 & \xrightarrow{m} & Q_8 \\ {\scriptstyle \pi\times\pi}\downarrow & & \downarrow{\scriptstyle \pi} \\ V_4 \times V_4 & \xrightarrow[\exists!\, \bar{m}]{} & V_4 \end{array}$$

commute, where m is the product in Q_8. Identify $\bar{m}$ explicitly with the group law of V_4, and explain why well-definedness of $\bar{m}$ is exactly the normality of $\langle -1 \rangle$.

3. Recall the universal property of $\mathbb{Z}$: a homomorphism $\mathbb{Z} \to G$ is determined by where 1 goes. Use this to describe all homomorphisms $\mathbb{Z} \to Q_8$, and show that each factors uniquely through some $\mathbb{Z}/n\mathbb{Z}$:

$$\begin{array}{ccc} \mathbb{Z} & \xrightarrow{\pi} & \mathbb{Z}/n\mathbb{Z} \\ & {\scriptstyle 1 \mapsto x}\searrow & \downarrow{\scriptstyle \exists!\, \varphi} \\ & & Q_8 \end{array}$$

For each $x \in Q_8$ state the value of $n = |x|$ that makes the diagram commute.

4. Let $\varphi\colon Q_8 \to \mathrm{GL}_2(\mathbb{C})$ be the homomorphism from Additional Exercise 7. Compute $\ker \varphi$ and verify the exact sequence

$$1 \longrightarrow \ker \varphi \hookrightarrow Q_8 \xrightarrow{\varphi} \mathrm{GL}_2(\mathbb{C})$$

makes φ injective. Conclude Q_8 is isomorphic to its image, a subgroup of $\mathrm{GL}_2(\mathbb{C})$ of order 8.

5. Both D_8 and Q_8 surject onto V_4 with kernel of order 2:

$$\begin{array}{ccccccccc} 1 & \longrightarrow & \langle -1 \rangle & \hookrightarrow & Q_8 & \xrightarrow{\pi} & V_4 & \longrightarrow & 1 \\ & & & & {\scriptstyle \psi}\downarrow & & \| & & \\ 1 & \longrightarrow & \langle r^2 \rangle & \hookrightarrow & D_8 & \longrightarrow & V_4 & \longrightarrow & 1 \end{array}$$

Show that there is no isomorphism $\psi\colon Q_8 \to D_8$ commuting with the two surjections onto V_4 (indeed none at all, by Additional Exercise 5). Explain which structural invariant – the number of order-2 elements lying in the kernel versus outside it – obstructs such a ψ.

1.6 Homomorphisms and Isomorphisms

Homomorphisms and isomorphisms: kernel, image, and order divisibility

Definition 1.6.1 (Homomorphism)**.** Let $(G, \cdot)$ and $(H, *)$ be groups. A map $\varphi : G \to H$ is a *homomorphism* if

$$\varphi(xy) = \varphi(x) * \varphi(y) \qquad \text{for all } x, y \in G.$$

We almost always suppress the operation symbols and just write $\varphi(xy) = \varphi(x)\varphi(y)$, the product on the left taken in G and the product on the right taken in H. The single defining equation says exactly: "multiply-then-map equals map-then-multiply." Diagrammatically, the multiplication square

$$\begin{array}{ccc} G \times G & \xrightarrow{m_G} & G \\ {\scriptstyle \varphi\times\varphi}\downarrow & & \downarrow{\scriptstyle \varphi} \\ H \times H & \xrightarrow[m_H]{} & H \end{array}$$

Diagram explanation. Objects: The four nodes are: $G \times G$ (the set of ordered pairs of elements of G, which is itself a group under coordinatewise multiplication), G (the source group), $H \times H$ (ordered pairs from H), and H (the target group). All four are groups.

Arrows: $m_G : G \times G \to G$ is the multiplication map of G, $m_G(x, y) = xy$. $m_H : H \times H \to H$ is the multiplication map of H, $m_H(a, b) = ab$. The right vertical arrow $\varphi : G \to H$ is the proposed homomorphism. The left vertical arrow $\varphi \times \varphi : G \times G \to H \times H$ is its coordinatewise extension, $(\varphi \times \varphi)(x, y) = (\varphi(x), \varphi(y))$.

What commutes: Right-then-down equals down-then-right: $\varphi \circ m_G = m_H \circ (\varphi \times \varphi)$. Concretely: $\varphi(m_G(x, y)) = m_H(\varphi(x), \varphi(y))$, i.e. $\varphi(xy) = \varphi(x)\varphi(y)$.

Why it commutes: Take $(x, y) \in G \times G$. Along the top-then-right path: first m_G multiplies to give $xy \in G$, then φ maps to $\varphi(xy) \in H$. Along the left-then-bottom path: first $\varphi \times \varphi$ gives $(\varphi(x), \varphi(y)) \in H \times H$, then m_H multiplies to give $\varphi(x)\varphi(y) \in H$. The two outputs agree if and only if $\varphi(xy) = \varphi(x)\varphi(y)$, which is *exactly* the homomorphism condition. The diagram does not prove commutativity; it encodes it as the defining requirement.

Why this matters here: This square is the definition of homomorphism stated in purely categorical language. It makes visible that "respecting the operation" means the map φ and the two multiplication maps together form a consistent diagram, without privileging any particular formula. Every theorem about homomorphisms (kernel, order divisibility, composition) ultimately follows from this one square commuting.

Concrete example: Let $G = H = (\mathbb{Z}, +)$ and $\varphi(x) = 2x$. Then $m_G(x, y) = x + y$, $m_H = +$, and $\varphi(x + y) = 2(x + y) = 2x + 2y = \varphi(x) + \varphi(y)$, so the square commutes and φ is a homomorphism.

Common pitfall: Students sometimes read the square as saying "φ commutes with itself." It says φ commutes with the *multiplication maps* m_G and m_H – two entirely different arrows. The commutativity is between φ and the group operations, not between φ and $\varphi \times \varphi$.

Takeaway: The point of this diagram is that the homomorphism condition $\varphi(xy) = \varphi(x)\varphi(y)$ is exactly the commutativity of the multiplication square, making the definition coordinate-free and composable.

commutes, where $m_G(x, y) = xy$, $m_H(a, b) = ab$, and $(\varphi \times \varphi)(x, y) = (\varphi(x), \varphi(y))$. Going right-then-down sends $(x, y) \mapsto xy \mapsto \varphi(xy)$; going down-then-right sends $(x, y) \mapsto (\varphi(x), \varphi(y)) \mapsto \varphi(x)\varphi(y)$. Equality of these two paths *is* the homomorphism law.

Definition 1.6.2 (Isomorphism)**.** A homomorphism $\varphi : G \to H$ is an *isomorphism* if it is a bijection. If such a φ exists we write $G \cong H$ and say G and H are isomorphic. The inverse map $\varphi^{-1} : H \to G$ is then automatically a homomorphism (see Proposition 1.6.5), so $\cong$ is an equivalence relation.

Definition 1.6.3 (Kernel and image)**.** Let $\varphi : G \to H$ be a homomorphism with identities $1_G \in G$, $1_H \in H$. The *kernel* and *image* are

$$\ker \varphi = \{\, g \in G \mid \varphi(g) = 1_H \,\} \subseteq G, \qquad \varphi(G) = \{\, \varphi(g) \mid g \in G \,\} \subseteq H.$$

The kernel measures how far φ is from injective; the image measures how far φ is from surjective. The cleanest packaging is the exact-sequence diagram

$$1 \longrightarrow \ker \varphi \xhookrightarrow{\iota} G \xrightarrow{\varphi} H$$

Diagram explanation. Objects: 1 is the trivial group containing only the identity 1_H; $\ker \varphi$ is the kernel subgroup of G (all elements that φ kills); G is the source group; H is the target group.

Arrows: The arrow $1 \to \ker\varphi$ is the unique map from the trivial group, inserting 1_G into the kernel (it records that the kernel is nonempty). The hooked arrow $\iota : \ker\varphi \hookrightarrow G$ is the subgroup inclusion (a homomorphism, injective by definition). The arrow $\varphi : G \to H$ is the homomorphism being studied.

What commutes: This is a *left-exact sequence*: exactness at $\ker\varphi$ means $\mathrm{im}(1 \to \ker\varphi) = \{1_G\} = \ker(\iota)$, which is trivially true since ι is injective. Exactness at G means $\mathrm{im}(\iota) = \ker(\varphi)$, i.e. the subgroup entering G from the left is precisely the set of elements killed by φ.

Why it commutes: By definition $\ker\varphi = \{g \in G : \varphi(g) = 1_H\}$, so an element is in $\mathrm{im}(\iota)$ if and only if it maps to 1_H under φ, which is exactly $\ker(\varphi)$. No deeper check is needed: the diagram packages the definition.

Why this matters here: The sequence compresses the two-line prose "$\ker\varphi$ consists of elements sent to 1_H; ι just includes them back into G" into a single readable picture. It primes the First Isomorphism Theorem, where this sequence will be extended on the right by a quotient arrow.

Concrete example: For $\varphi = \det : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$, the sequence reads $1 \to \mathrm{SL}_2(\mathbb{R}) \hookrightarrow \mathrm{GL}_2(\mathbb{R}) \xrightarrow{\det} \mathbb{R}^\times$: matrices of determinant 1 inject into all invertible matrices, and exactly those die under det.

Common pitfall: The sequence stops at H; there is no arrow saying φ is surjective. Students sometimes read a four-term sequence ending at H as implying $\varphi(G) = H$ – that would require a $\to 1$ on the right. Here φ might not be surjective.

Takeaway: The point of this diagram is that the kernel-inclusion sequence encodes injectivity at $\ker\varphi$ and the defining property of $\ker\varphi$ at G in a single left-exact picture, making both visible at a glance.

read as: "the kernel injects into G, and exactly the kernel dies under φ."

Proposition 1.6.4 (Basic identities)**.** *Let $\varphi : G \to H$ be a homomorphism. Then*

(1) $\varphi(1_G) = 1_H$;

(2) $\varphi(x^{-1}) = \varphi(x)^{-1}$ for all $x \in G$;

(3) $\varphi(x^n) = \varphi(x)^n$ for all $x \in G$ and all $n \in \mathbb{Z}$.

Proof. (1) Since $1_G = 1_G \cdot 1_G$, applying φ gives $\varphi(1_G) = \varphi(1_G)\varphi(1_G)$. Left-multiply both sides by $\varphi(1_G)^{-1}$ in H:

$$\varphi(1_G)^{-1}\varphi(1_G) = \varphi(1_G)^{-1}\varphi(1_G)\varphi(1_G) \implies 1_H = \varphi(1_G).$$

(2) Fix $x \in G$. Then $\varphi(x)\varphi(x^{-1}) = \varphi(xx^{-1}) = \varphi(1_G) = 1_H$ by (1), and likewise $\varphi(x^{-1})\varphi(x) = \varphi(x^{-1}x) = \varphi(1_G) = 1_H$. So $\varphi(x^{-1})$ is a two-sided inverse of $\varphi(x)$ in H; by uniqueness of inverses, $\varphi(x^{-1}) = \varphi(x)^{-1}$.

(3) For $n \geq 0$ induct: $n = 0$ is (1) ($\varphi(x^0) = \varphi(1_G) = 1_H = \varphi(x)^0$), and if $\varphi(x^n) = \varphi(x)^n$ then $\varphi(x^{n+1}) = \varphi(x^n x) = \varphi(x^n)\varphi(x) = \varphi(x)^n\varphi(x) = \varphi(x)^{n+1}$. For $n < 0$ write $n = -m$ with $m > 0$: using (2), $\varphi(x^{-m}) = \varphi((x^m)^{-1}) = \varphi(x^m)^{-1} = (\varphi(x)^m)^{-1} = \varphi(x)^{-m}$. □

Proposition 1.6.5 (Inverse of an isomorphism is a homomorphism)**.** *If $\varphi : G \to H$ is an isomorphism, then $\varphi^{-1} : H \to G$ is a homomorphism.*

Proof. Let $a, b \in H$ and set $x = \varphi^{-1}(a)$, $y = \varphi^{-1}(b)$, so $\varphi(x) = a$, $\varphi(y) = b$. Then $\varphi(xy) = \varphi(x)\varphi(y) = ab$, hence applying the bijection φ^{-1} gives $\varphi^{-1}(ab) = xy = \varphi^{-1}(a)\varphi^{-1}(b)$. □

Proposition 1.6.6 (Kernel and image are subgroups)**.** *Let $\varphi : G \to H$ be a homomorphism. Then $\ker\varphi \leq G$ and $\varphi(G) \leq H$.*

Proof. We use the one-step subgroup test (nonempty, closed under xy^{-1}).

Kernel. $1_G \in \ker\varphi$ by Proposition 1.6.4(1), so $\ker\varphi \neq \varnothing$. If $x, y \in \ker\varphi$ then $\varphi(xy^{-1}) = \varphi(x)\varphi(y)^{-1} = 1_H \cdot 1_H^{-1} = 1_H$, so $xy^{-1} \in \ker\varphi$.

Image. $1_H = \varphi(1_G) \in \varphi(G)$, so $\varphi(G) \neq \varnothing$. If $a, b \in \varphi(G)$, write $a = \varphi(x)$, $b = \varphi(y)$; then $ab^{-1} = \varphi(x)\varphi(y)^{-1} = \varphi(x)\varphi(y^{-1}) = \varphi(xy^{-1}) \in \varphi(G)$. □

Proposition 1.6.7 (Order divisibility)**.** *Let $\varphi : G \to H$ be a homomorphism and $x \in G$.*

(1) If $|x| = n < \infty$, then $|\varphi(x)|$ divides n. In particular $|\varphi(x)|$ is finite.

(2) If φ is injective, then $|\varphi(x)| = |x|$ (equality, allowing $\infty = \infty$).

Proof. (1) Let $n = |x|$, so $x^n = 1_G$. Then $\varphi(x)^n = \varphi(x^n) = \varphi(1_G) = 1_H$ by Proposition 1.6.4(3). Let $m = |\varphi(x)|$. The set $\{k \in \mathbb{Z} \mid \varphi(x)^k = 1_H\}$ equals $m\mathbb{Z}$ (the standard fact that the order generates the relations), and we have just shown n lies in this set; hence $m \mid n$.

(2) Let $n = |x|$ and $m = |\varphi(x)|$. By (1), $m \mid n$ when n is finite. Conversely $\varphi(x^m) = \varphi(x)^m = 1_H = \varphi(1_G)$, and injectivity forces $x^m = 1_G$, so $n \mid m$ (by the same generating-relation fact). Thus $m \mid n$ and $n \mid m$ give $m = n$. If $n = \infty$ then $x^k \neq 1_G$ for all $k \geq 1$, and injectivity makes $\varphi(x)^k = \varphi(x^k) \neq \varphi(1_G) = 1_H$, so $m = \infty$ too. □

Remark 1.6.1 (Image factorization). Every homomorphism factors through its image as a surjection followed by an inclusion:

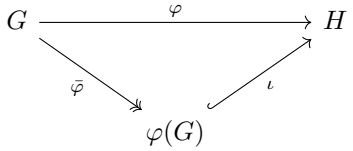


Diagram explanation. Objects: G is the source group; $\varphi(G)$ is the image of φ, a subgroup of H (by Proposition 1.6.6); H is the target group.

Arrows: The top horizontal arrow $\varphi : G \to H$ is the original homomorphism. The left diagonal arrow $\bar{\varphi} : G \twoheadrightarrow \varphi(G)$ is the corestriction of φ to its image: $\bar{\varphi}(g) = \varphi(g)$, with codomain shrunk to $\varphi(G)$; it is surjective by construction (every element of $\varphi(G)$ is hit). The right diagonal arrow $\iota : \varphi(G) \hookrightarrow H$ is the subgroup inclusion; it is injective.

What commutes: The triangle commutes: $\iota \circ \bar{\varphi} = \varphi$. That is, going along the bottom two arrows gives the same map as going along the top single arrow: both send $g \in G$ to $\varphi(g) \in H$.

Why it commutes: Chase $g \in G$. The direct path φ sends $g \mapsto \varphi(g) \in H$. The two-step path sends $g \overset{\bar{\varphi}}{\mapsto} \varphi(g) \in \varphi(G) \overset{\iota}{\mapsto} \varphi(g) \in H$. The outputs are identical; commutativity is definitional.

Why this matters here: This remark establishes the canonical *epi-mono factorization*: every homomorphism decomposes as a surjection followed by an injection. The decomposition is unique up to isomorphism and is the precursor to the First Isomorphism Theorem, which further identifies the kernel of $\bar{\varphi}$ and gives $G/\ker\varphi \cong \varphi(G)$.

Concrete example: For $\det : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$, the corestriction $\overline{\det} : \mathrm{GL}_2(\mathbb{R}) \twoheadrightarrow \mathbb{R}^\times$ is already surjective (every nonzero real is a determinant), so $\varphi(G) = \mathbb{R}^\times$ and the inclusion ι is the identity; the triangle collapses to a tautology in this case.

Common pitfall: Students sometimes think $\bar{\varphi}$ is a *new* or *different* map from φ; it has the same formula but a smaller codomain. In particular $\bar{\varphi}$ is surjective while φ is generally not – the difference is entirely in which set you declare as the codomain.

Takeaway: The point of this diagram is that every homomorphism splits canonically into a surjection onto its image followed by the subgroup inclusion, separating the "what gets hit" part from the "where it sits" part.

Here $\bar{\varphi}(g) = \varphi(g)$ viewed as an element of $\varphi(G)$ (surjective by construction), and ι is the subgroup inclusion $\varphi(G) \hookrightarrow H$. The triangle commutes because both routes send $g \mapsto \varphi(g)$. This is the universal picture behind "a hom is determined by what it surjects onto, sitting inside H."

Method (Verify a map is a homomorphism)**.** Trigger: you are handed a map $\varphi : G \to H$ between two specified groups and asked whether it "respects the operation," or you want to use any hom theorem (kernel, order divisibility) and must first earn the right.

1. Identify the operations: what is the product in G, what is the product in H? (Common traps: $H = \mathbb{R}^\times$ uses multiplication; $H = (\mathbb{R}, +)$ uses addition.)
2. Take *generic* $x, y \in G$ (not specific numbers).
3. Compute $\varphi(xy)$ using the G-product inside, then simplify in H.

4. Separately compute $\varphi(x)\varphi(y)$ using the H-product.

5. If the two expressions are equal for all x, y, it is a homomorphism. If they differ, you must exhibit one explicit pair (x, y) making them unequal – that single counterexample is a complete disproof.

Sanity bonus: a genuine homomorphism must send $1_G \mapsto 1_H$. If $\varphi(1_G) \neq 1_H$, stop – it is not a homomorphism.

Method (Compute the kernel and the image)**.** Trigger: a homomorphism is given and you want $\ker\varphi$ (the "collapse") or $\varphi(G)$ (the "reach"), e.g. to test injectivity/surjectivity.

1. **Kernel.** Solve the equation $\varphi(g) = 1_H$ for g. The solution set *is* $\ker\varphi$. Then φ is injective $\iff$ $\ker\varphi = \{1_G\}$.

2. **Image.** Determine which $h \in H$ are hit: for each candidate h, decide whether $\varphi(g) = h$ has a solution $g \in G$. The set of solvable h is $\varphi(G)$. Then φ is surjective $\iff$ $\varphi(G) = H$.

3. Both are subgroups (Proposition 1.6.6); use that as a check – e.g. your kernel must contain 1_G and be closed under inverses.

Method (Use order divisibility to rule maps out)**.** Trigger: you must decide whether *any* homomorphism $\varphi : G \to H$ can send a given element x to a given target y, or whether a nontrivial hom can exist at all.

1. Compute $|x|$ in G.

2. For a proposed value $\varphi(x) = y$, compute $|y|$ in H.

3. If $|y| \nmid |x|$, then $\varphi(x) = y$ is *impossible* for a homomorphism, by Proposition 1.6.7(1).

4. To kill all nontrivial homs from a cyclic $G = \langle x\rangle$: a hom is determined by $\varphi(x)$, and $|\varphi(x)| \mid |x|$. If the only element of H whose order divides $|x|$ is 1_H, then $\varphi(x) = 1_H$, forcing $\varphi \equiv 1_H$ (trivial).

Caution. $\ker\varphi$ lives in G and always contains 1_G; never write "$\ker\varphi = \varnothing$." A trivial kernel is $\ker\varphi = \{1_G\}$, not the empty set. The empty set is not a subgroup.

Caution. The direction of divisibility is fixed: $|\varphi(x)| \mid |x|$, never the reverse. A homomorphism can shrink an order ($|x| = 6 \to |\varphi(x)| = 2$) but can never grow it.

Worked Example 1.6.8 (The determinant $\det : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$)**.** Show $\det : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$, $A \mapsto \det A$, is a homomorphism, and find its kernel and image.

Recognition. This is a "verify the map" problem: source is the group of invertible 2×2 real matrices under multiplication, target is $\mathbb{R} \setminus \{0\}$ under multiplication. The trigger word is the multiplicativity of determinant, $\det(AB) = \det A \det B$ – that single classical identity *is* the homomorphism law, so this is the cleanest possible case of the Method "Verify a map is a homomorphism."

Solution. Take generic $A, B \in \mathrm{GL}_2(\mathbb{R})$. The G-product is matrix multiplication, the H-product is multiplication of nonzero reals.

$$\det(AB) = \det A \det B = \det(A) \cdot \det(B),$$

which is precisely $\varphi(AB) = \varphi(A)\varphi(B)$. (Both A, B invertible means $\det A, \det B \neq 0$, so the output truly lands in $\mathbb{R}^\times$.) Hence det is a homomorphism.

Kernel. Solve $\det A = 1$: $\ker\det = \{A \in \mathrm{GL}_2(\mathbb{R}) \mid \det A = 1\} = \mathrm{SL}_2(\mathbb{R})$, the special linear group.

Image. For any $t \in \mathbb{R}^\times$ the matrix $\mathrm{diag}(t, 1) = \left(\begin{smallmatrix} t & 0 \\ 0 & 1 \end{smallmatrix}\right)$ has determinant t, so every nonzero real is hit: $\varphi(\mathrm{GL}_2(\mathbb{R})) = \mathbb{R}^\times$. Thus det is surjective but far from injective.

Check: $\varphi(1_G) = \det I_2 = 1 = 1_H$. And $\ker = \mathrm{SL}_2(\mathbb{R})$ is closed under inverses since $\det(A^{-1}) = (\det A)^{-1} = 1$. Consistent.

$$1 \longrightarrow \mathrm{SL}_2(\mathbb{R}) \hookrightarrow \mathrm{GL}_2(\mathbb{R}) \xrightarrow{\det} \mathbb{R}^\times$$

Diagram explanation. Objects: 1 is the trivial group; $\mathrm{SL}_2(\mathbb{R}) = \{A \in \mathrm{GL}_2(\mathbb{R}) : \det A = 1\}$ is the special linear group, the kernel of det; $\mathrm{GL}_2(\mathbb{R})$ is the general linear group of invertible real 2×2 matrices; $\mathbb{R}^\times = \mathbb{R} \setminus \{0\}$ is the multiplicative group of nonzero reals.

Arrows: $1 \to \mathrm{SL}_2(\mathbb{R})$ inserts the identity matrix. The hooked arrow $\mathrm{SL}_2(\mathbb{R}) \hookrightarrow \mathrm{GL}_2(\mathbb{R})$ is the subgroup inclusion (every matrix of determinant 1 is in particular invertible). The double-headed arrow $\det : \mathrm{GL}_2(\mathbb{R}) \twoheadrightarrow \mathbb{R}^\times$ is the determinant homomorphism, surjective because $\mathrm{diag}(t, 1)$ has determinant t for any $t \neq 0$.

What commutes: Exactness at $\mathrm{SL}_2(\mathbb{R})$: $\mathrm{im}(1 \to \mathrm{SL}_2(\mathbb{R})) = \{I_2\} = \ker(\hookrightarrow)$ — trivially true since the inclusion is injective. Exactness at $\mathrm{GL}_2(\mathbb{R})$: $\mathrm{im}(\hookrightarrow) = \mathrm{SL}_2(\mathbb{R}) = \ker(\det)$ — true by definition of $\mathrm{SL}_2(\mathbb{R})$. Together: the sequence is exact, and the surjection on the right records that every nonzero real is a determinant.

Why it commutes: An element in $\mathrm{SL}_2(\mathbb{R})$ has $\det = 1$, so it is in $\ker(\det)$; and every element of $\ker(\det)$ lies in $\mathrm{SL}_2(\mathbb{R})$ by definition. The inclusion and the arrow from 1 are both trivially compatible. The surjectivity follows from the explicit section $t \mapsto \mathrm{diag}(t, 1)$.

Why this matters here: This sequence is the payoff of the whole computation: it organizes the three facts — kernel is $\mathrm{SL}_2(\mathbb{R})$, the map is a surjection, and the kernel includes into $\mathrm{GL}_2(\mathbb{R})$ — into a single compact picture that a reader can scan in one glance. It is also a prototype exact sequence for all later examples.

Concrete example: Restrict to 2×2 matrices over $\mathbb{F}_p$. The sequence becomes $1 \to \mathrm{SL}_2(\mathbb{F}_p) \hookrightarrow \mathrm{GL}_2(\mathbb{F}_p) \xrightarrow{\det} \mathbb{F}_p^\times \to 1$, which is exact and shows $|\mathrm{GL}_2(\mathbb{F}_p)| = |\mathrm{SL}_2(\mathbb{F}_p)| \cdot (p - 1)$.

Common pitfall: The two-headed arrowhead on det is not decoration; it means the map is surjective onto $\mathbb{R}^\times$. Without it the sequence would record nothing about surjectivity. The equivalent convention is to append "$\to 1$" at the right: exactness at $\mathbb{R}^\times$ then says exactly that det is surjective, i.e. the sequence is short exact.

Takeaway: The point of this diagram is that it records in one line all three structural facts about det: the kernel is $\mathrm{SL}_2(\mathbb{R})$, it includes into $\mathrm{GL}_2(\mathbb{R})$, and the quotient maps surjectively onto $\mathbb{R}^\times$.

Worked Example 1.6.9 (Reduction mod n, $\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$)**.** Show $\pi : \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$, $a \mapsto \bar{a} = a \bmod n$, is a homomorphism of additive groups, and compute $\ker \pi$ and $\pi(\mathbb{Z})$.

Recognition. "Verify a map" again, but now *both* groups are additive: the law to check is $\pi(a+b) = \pi(a)+\pi(b)$, i.e. "the class of a sum is the sum of the classes." The trigger is that addition of residue classes is *defined* by representatives, which is exactly this equation.

Solution. Generic $a, b \in \mathbb{Z}$. The G-product is $+$ in $\mathbb{Z}$; the H-product is $+$ in $\mathbb{Z}/n\mathbb{Z}$, where by definition $\bar{a} + \bar{b} = \overline{a + b}$. Then

$$\pi(a + b) = \overline{a + b} = \bar{a} + \bar{b} = \pi(a) + \pi(b).$$

So π is a homomorphism.

Kernel. Solve $\pi(a) = \bar{0}$, i.e. $a \equiv 0 \pmod{n}$: $\ker \pi = n\mathbb{Z}$.

Image. Every class $\bar{r}$ for $r \in \{0, 1, \ldots, n-1\}$ equals $\pi(r)$, so $\pi(\mathbb{Z}) = \mathbb{Z}/n\mathbb{Z}$; π is surjective.

Check: $\pi(0) = \bar{0} = 1_H$. Order divisibility in action: $|1| = \infty$ in $\mathbb{Z}$ while $|\pi(1)| = |\bar{1}| = n$ in $\mathbb{Z}/n\mathbb{Z}$ – consistent, since there is no divisibility constraint when $|x| = \infty$. The universal picture:

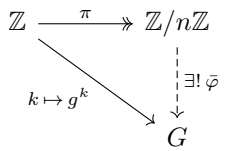

Diagram explanation. Objects: $\mathbb{Z}$ is the additive group of integers; $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/n\mathbb{Z}$ is the additive group of integers mod n; G is any group containing an element g with $g^n = 1_G$.

Arrows: $\pi : \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$, $k \mapsto \bar{k}$, is the surjective reduction-mod-n homomorphism (proven earlier in the worked example). The diagonal arrow $k \mapsto g^k : \mathbb{Z} \to G$ is a homomorphism because $g^{k+\ell} = g^k g^\ell$. The dashed vertical arrow $\bar{\varphi} : \mathbb{Z}/n\mathbb{Z} \to G$, $\bar{k} \mapsto g^k$, is the unique induced map; it exists because $\ker \pi = n\mathbb{Z} \subseteq \ker(k \mapsto g^k)$ (since $g^n = 1_G$ implies $g^{nq} = 1_G$ for all q).

What commutes: The triangle commutes: $\bar{\varphi} \circ \pi = k \mapsto g^k$. That is, $\bar{\varphi}(\bar{k}) = g^k$ for all k. The two paths from $\mathbb{Z}$ to G give the same result.

Why it commutes: Well-definedness of $\bar{\varphi}$: if $\bar{k} = \bar{\ell}$ then $n \mid (k - \ell)$, so $k - \ell = nq$ for some $q \in \mathbb{Z}$, and $g^k = g^{\ell+nq} = g^\ell (g^n)^q = g^\ell \cdot 1_G = g^\ell$. Hence the formula $\bar{\varphi}(\bar{k}) = g^k$ is independent of the representative chosen for the coset $\bar{k}$. The homomorphism property of $\bar{\varphi}$ follows from that of $k \mapsto g^k$.

Why this matters here: This is the universal property of $\mathbb{Z}/n\mathbb{Z}$: any homomorphism $\mathbb{Z} \to G$ that kills $n\mathbb{Z}$ factors uniquely through π. It is why $\mathbb{Z}/n\mathbb{Z}$ can be used as a "template" for any group with an element of order dividing n, and is the diagram-theoretic content behind $\mathbb{Z}/n\mathbb{Z} \cong \langle g \rangle$ when $|g| = n$.

Concrete example: Take $G = S_3$ and $g = (1\,2\,3)$, which has order 3, so $n = 3$. The map $\bar{\varphi} : \mathbb{Z}/3\mathbb{Z} \to \langle (1\,2\,3) \rangle$, $\bar{k} \mapsto (1\,2\,3)^k$, is the unique induced isomorphism; it is well defined because $g^3 = \mathrm{id}$.

Common pitfall: Well-definedness is not free; it requires $g^n = 1_G$. If g has order $d \mid n$ but $d < n$, the map $\bar{\varphi}$ still exists (since $d \mid n$ gives $g^n = 1$), but it is no longer injective. Students must check $g^n = 1$ before claiming $\bar{\varphi}$ is well defined.

Takeaway: The point of this diagram is that $\mathbb{Z}/n\mathbb{Z}$ is the universal group generated by one element of order dividing n: any homomorphism from $\mathbb{Z}$ that annihilates $n\mathbb{Z}$ factors uniquely through $\mathbb{Z}/n\mathbb{Z}$.

(For any $g \in G$ with $g^n = 1$, $k \mapsto g^k$ factors uniquely through π – the source of $\mathbb{Z}/n\mathbb{Z} \cong \langle g \rangle$ when $|g| = n$.)

Worked Example 1.6.10 (The exponential $\exp : (\mathbb{R}, +) \to (\mathbb{R}^\times, \cdot)$)**.** Show $\exp : (\mathbb{R}, +) \to (\mathbb{R}^\times, \cdot)$, $x \mapsto e^x$, is a homomorphism with trivial kernel and image $\mathbb{R}^{>0}$, hence an isomorphism onto $\mathbb{R}^{>0}$.

Recognition. "Verify a map" where the operations *differ on the two sides*: source addition, target multiplication. The trigger is the law of exponents $e^{x+y} = e^x e^y$, which is the homomorphism equation $\varphi(x + y) = \varphi(x)\varphi(y)$ verbatim.

Solution. Generic $x, y \in \mathbb{R}$. Source product is $+$, target product is $\cdot$:

$$\exp(x + y) = e^{x+y} = e^x e^y = \exp(x) \exp(y).$$

So exp is a homomorphism.

Kernel. Solve $e^x = 1$ (the identity of $\mathbb{R}^\times$ is 1): the only real solution is $x = 0$, so $\ker \exp = \{0\} = \{1_G\}$. Hence exp is injective (trivial kernel $\implies$ injective, by the criterion in the Method "Compute the kernel and the image").

Image. $e^x > 0$ for all x, and every positive real t has $t = e^{\ln t}$, so the image is exactly $\mathbb{R}^{>0} = \{t \in \mathbb{R} \mid t > 0\}$, the subgroup of positive reals under multiplication. Negative reals are *not* hit, so exp is not onto $\mathbb{R}^\times$.

Therefore $\exp : (\mathbb{R}, +) \to (\mathbb{R}^{>0}, \cdot)$ is a bijective homomorphism, an isomorphism; $(\mathbb{R}, +) \cong (\mathbb{R}^{>0}, \cdot)$ with inverse ln.

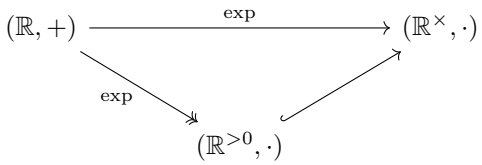

Diagram explanation. Objects: $(\mathbb{R}, +)$ is the additive group of real numbers; $(\mathbb{R}^{>0}, \cdot)$ is the multiplicative group of positive reals, which is the image of exp; $(\mathbb{R}^\times, \cdot)$ is the multiplicative group of all nonzero reals, in which $\mathbb{R}^{>0}$ sits as a proper subgroup.

Arrows: The top horizontal arrow $\exp : (\mathbb{R}, +) \to (\mathbb{R}^\times, \cdot)$ is the original exponential homomorphism $x \mapsto e^x$. The left diagonal arrow $\exp : (\mathbb{R}, +) \twoheadrightarrow (\mathbb{R}^{>0}, \cdot)$ is the corestriction of exp to its image; it is surjective because every $t > 0$ satisfies $t = e^{\ln t}$. The right diagonal arrow $\iota : (\mathbb{R}^{>0}, \cdot) \hookrightarrow (\mathbb{R}^\times, \cdot)$ is the subgroup inclusion of positive reals into all nonzero reals; it is injective.

What commutes: $\iota \circ \exp_{\twoheadrightarrow} = \exp$: both paths from $(\mathbb{R}, +)$ to $(\mathbb{R}^\times, \cdot)$ send $x \mapsto e^x$.

Why it commutes: The corestriction assigns $x \mapsto e^x \in \mathbb{R}^{>0}$, then the inclusion re-embeds that positive real back into $\mathbb{R}^\times$; the composite is $x \mapsto e^x \in \mathbb{R}^\times$, which is exactly exp. This is an instance of the epi-mono factorization from Remark 1.6.1.

Why this matters here: The triangle makes explicit why exp is an isomorphism onto $\mathbb{R}^{>0}$ but *not* onto $\mathbb{R}^\times$: the corestriction is a bijective homomorphism $(\mathbb{R}, +) \cong (\mathbb{R}^{>0}, \cdot)$, while the inclusion witnesses that $\mathbb{R}^{>0}$ is only a proper subgroup of $\mathbb{R}^\times$ (the negative reals are missing from the image).

Concrete example: The inverse isomorphism $\ln : (\mathbb{R}^{>0}, \cdot) \to (\mathbb{R}, +)$ reverses the corestriction: $\ln(e^x) = x$ and $e^{\ln t} = t$, confirming $(\mathbb{R}, +) \cong (\mathbb{R}^{>0}, \cdot)$ with ln as the inverse dictionary.

Common pitfall: Both arrows labelled exp look the same but have different codomains. The surjective corestriction has codomain $\mathbb{R}^{>0}$; the top arrow has codomain $\mathbb{R}^\times$. Treating them as identical ignores the key point: surjectivity depends on the declared codomain.

Takeaway: The point of this diagram is that exp factors through the epi-mono decomposition, proving it is an isomorphism onto $\mathbb{R}^{>0}$ and simultaneously showing why it falls short of surjectivity onto all of $\mathbb{R}^\times$.

Check: $\exp(0) = 1 = 1_H$, and $\exp(-x) = e^{-x} = (e^x)^{-1} = \exp(x)^{-1}$, matching Proposition 1.6.4(2).

Worked Example 1.6.11 (Squaring on $(\mathbb{Z}/8\mathbb{Z})^\times$ is a homomorphism (abelian target))**.** Let $G = (\mathbb{Z}/8\mathbb{Z})^\times = \{\bar{1}, \bar{3}, \bar{5}, \bar{7}\}$ under multiplication mod 8. Show $\varphi : G \to G$, $\varphi(x) = x^2$, is a homomorphism and compute kernel and image.

Recognition. "Verify a map": squaring is a homomorphism precisely when the group is abelian, since $\varphi(xy) = (xy)^2 = xyxy$ collapses to x^2y^2 iff $xy = yx$. $(\mathbb{Z}/8\mathbb{Z})^\times$ is abelian, so the trigger "abelian $\implies$ $x \mapsto x^2$ is a hom" fires.

Solution. Generic $x, y \in G$; G is abelian, so

$$\varphi(xy) = (xy)^2 = xyxy = x(yx)y = x(xy)y = x^2y^2 = \varphi(x)\varphi(y).$$

Homomorphism confirmed.

Compute values (mod 8): $\bar{1}^2 = \bar{1}$, $\bar{3}^2 = \bar{9} = \bar{1}$, $\bar{5}^2 = \overline{25} = \bar{1}$, $\bar{7}^2 = \overline{49} = \bar{1}$. Every element squares to $\bar{1}$ (indeed $(\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$, exponent 2).

Kernel. Solve $\varphi(x) = \bar{1}$, i.e. $x^2 = \bar{1}$: all four elements qualify, so $\ker\varphi = G = (\mathbb{Z}/8\mathbb{Z})^\times$.

Image. $\varphi(G) = \{\bar{1}\}$, the trivial subgroup.

Check: $\varphi(\bar{1}) = \bar{1} = 1_H$; kernel is all of G and image is trivial, consistent with $|\ker\varphi| \cdot |\varphi(G)| = 4 \cdot 1 = 4 = |G|$ (a preview of the First Isomorphism Theorem's counting). Order check: $|\bar{3}| = 2$ and $|\varphi(\bar{3})| = |\bar{1}| = 1$, and $1 \mid 2$. Good.

Worked Example 1.6.12 (A sign-type homomorphism $\mathrm{sgn} : S_3 \to \{\pm 1\}$)**.** Show the sign map $\mathrm{sgn} : S_3 \to \langle -1 \rangle = \{1, -1\}$ (under multiplication) is a homomorphism, and find its kernel and image.

Recognition. "Verify a map" onto a 2-element group. The recognition: sgn multiplies under composition, $\mathrm{sgn}(\sigma\tau) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau)$, because parities add and $(-1)^{a+b} = (-1)^a(-1)^b$. That identity is the homomorphism law into $\{\pm 1\}$.

Solution. Generic $\sigma, \tau \in S_3$. Writing each as a product of transpositions, the number of transpositions of $\sigma\tau$ has the same parity as (count for σ) + (count for τ). With $\mathrm{sgn}(\rho) = (-1)^{(\#\text{transpositions of } \rho)}$,

$$\mathrm{sgn}(\sigma\tau) = (-1)^{a+b} = (-1)^a(-1)^b = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau),$$

so sgn is a homomorphism.

Kernel. $\mathrm{sgn}(\rho) = 1$ exactly for even permutations. In S_3 the even ones are $\{\mathrm{id}, (1\,2\,3), (1\,3\,2)\} = A_3$. So $\ker\mathrm{sgn} = A_3$, the cyclic group of order 3.

Image. A single transposition, e.g. $(1\,2)$, has sgn $= -1$, and id has sgn $= 1$, so both ± 1 are hit: $\mathrm{sgn}(S_3) = \{\pm 1\}$, surjective.

Check: $\mathrm{sgn}(\mathrm{id}) = 1 = 1_H$. Counting: $|\ker| \cdot |\mathrm{im}| = 3 \cdot 2 = 6 = |S_3|$. Order check: $|(1\,2)| = 2$ in S_3 and $|\mathrm{sgn}(1\,2)| = |-1| = 2$, with $2 \mid 2$.

$$1 \longrightarrow A_3 \hookrightarrow S_3 \xrightarrow{\mathrm{sgn}} \{\pm 1\}$$

Diagram explanation. Objects: 1 is the trivial group; $A_3 = \{\mathrm{id}, (1\,2\,3), (1\,3\,2)\} \leq S_3$ is the alternating group on three letters, the kernel of sgn (even permutations of S_3); S_3 is the symmetric group on three letters; $\{\pm 1\} = \langle -1 \rangle$ is the two-element multiplicative group.

Arrows: $1 \to A_3$ inserts the identity. The hooked arrow $A_3 \hookrightarrow S_3$ is the subgroup inclusion. The double-headed arrow $\mathrm{sgn} : S_3 \twoheadrightarrow \{\pm 1\}$ is the sign homomorphism, surjective because, for example, $\mathrm{sgn}(\mathrm{id}) = 1$ and $\mathrm{sgn}((1\,2)) = -1$.

What commutes: Exactness at A_3: the inclusion is injective, so $\ker(\hookrightarrow) = \{1_G\} = \mathrm{im}(1 \to A_3)$. Exactness at S_3: $\mathrm{im}(\hookrightarrow) = A_3 = \ker(\mathrm{sgn})$, i.e. a permutation is even if and only if it lies in the image of the inclusion.

Why it commutes: A permutation σ is in A_3 iff $\mathrm{sgn}(\sigma) = 1$, so $A_3 = \ker(\mathrm{sgn})$ by definition. The inclusion just places those permutations back inside S_3; exactness at S_3 is a direct restatement of "the even permutations are exactly those that sgn sends to 1."

Why this matters here: This is the compact summary of the entire computation: kernel A_3, inclusion, surjective sign map. It also illustrates the general principle that a surjective homomorphism onto a group of order 2 always has kernel equal to the "even" elements, and its kernel is normal of index 2.

Concrete example: The analogous sequence for S_n is $1 \to A_n \hookrightarrow S_n \xrightarrow{\mathrm{sgn}} \{\pm 1\} \to 1$, a short exact sequence whose existence for all $n \geq 2$ is one of the first structural theorems about symmetric groups.

Common pitfall: A_3 has order 3, not 2. Students occasionally confuse the kernel of a map to $\{\pm 1\}$ with a group of order 2; the kernel has order $|S_3|/|\{\pm 1\}| = 3$ here. The surjection to a group of order 2 means the kernel has index 2, but its order depends on $|S_3|$.

Takeaway: The point of this diagram is that the sign map yields a short exact sequence that cleanly encodes the even/odd splitting of S_3 into a single four-node picture, which generalizes immediately to S_n for all $n \geq 2$.

Worked Example 1.6.13 (A map that FAILS to be a homomorphism)**.** Decide whether $\varphi : (\mathbb{R}, +) \to (\mathbb{R}, +)$, $\varphi(x) = x + 1$, is a homomorphism.

Recognition. "Verify a map." First sanity reflex from the Method: a homomorphism must fix the identity, $\varphi(0) = 0$. Here $\varphi(0) = 0 + 1 = 1 \neq 0$, which already smells fatal. We confirm with an explicit pair, as the Method demands for a disproof.

Solution. Compute both sides on generic x, y:

$$\varphi(x + y) = (x + y) + 1, \qquad \varphi(x) + \varphi(y) = (x + 1) + (y + 1) = x + y + 2.$$

These are equal iff $x + y + 1 = x + y + 2$, i.e. $1 = 2$, which is false. Concretely take $x = y = 0$:

$$\varphi(0 + 0) = \varphi(0) = 1, \qquad \varphi(0) + \varphi(0) = 1 + 1 = 2, \qquad 1 \neq 2.$$

So $\varphi(x + y) \neq \varphi(x) + \varphi(y)$ for this single pair, and φ is *not* a homomorphism. (The underlying reason: $x \mapsto x + 1$ is a *translation*, an affine map with nonzero shift; among the affine maps $x \mapsto cx + d$, only those with zero shift ($d = 0$) are additive homomorphisms $\mathbb{R} \to \mathbb{R}$.)

Check: the failure $\varphi(0) \neq 0$ was the early-warning sign, and it is genuinely inconsistent with Proposition 1.6.4(1) – exactly why no hom can do this.

Worked Example 1.6.14 (Another non-hom: $x \mapsto x^2$ on a nonabelian group)**.** Decide whether $\varphi : \mathrm{GL}_2(\mathbb{R}) \to \mathrm{GL}_2(\mathbb{R})$, $A \mapsto A^2$, is a homomorphism.

Recognition. "Verify a map." Squaring is a homomorphism iff the group is abelian (it forces $xyxy = x^2y^2$, i.e. $yx = xy$). $\mathrm{GL}_2(\mathbb{R})$ is nonabelian, so we expect failure and must show one explicit pair of non-commuting matrices.

Solution. For a homomorphism we would need $(AB)^2 = A^2B^2$ for all A, B, i.e. $ABAB = AABB$, i.e. (cancel one A left, one B right) $BA = AB$. Pick non-commuting

$$A = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right), \qquad B = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right).$$

Then

$$AB = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right), \qquad (AB)^2 = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)^2 = \left(\begin{smallmatrix} 5 & 3 \\ 3 & 2 \end{smallmatrix}\right).$$

Meanwhile

$$A^2 = \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right), \quad B^2 = \left(\begin{smallmatrix} 1 & 0 \\ 2 & 1 \end{smallmatrix}\right), \quad A^2B^2 = \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 0 \\ 2 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 5 & 2 \\ 2 & 1 \end{smallmatrix}\right).$$

Since $(AB)^2 = \left(\begin{smallmatrix} 5 & 3 \\ 3 & 2 \end{smallmatrix}\right) \neq \left(\begin{smallmatrix} 5 & 2 \\ 2 & 1 \end{smallmatrix}\right) = A^2B^2$, φ is *not* a homomorphism.

Check: the off-diagonal entries already disagree ($3 \neq 2$), confirming the inequality, and the failure traces back exactly to $AB \neq BA$.

Worked Example 1.6.15 (No nontrivial homomorphism $\mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/7\mathbb{Z}$)**.** Show the only homomorphism $\varphi : \mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/7\mathbb{Z}$ is the trivial one, $\varphi \equiv \bar{0}$.

Recognition. This is the headline application of order divisibility. $\mathbb{Z}/5\mathbb{Z} = \langle \bar{1} \rangle$ is cyclic, so φ is pinned down by $\varphi(\bar{1})$, and $|\varphi(\bar{1})| \mid |\bar{1}| = 5$. The trigger from the Method: 5 is prime, so the only divisors are 1 and 5; check whether $\mathbb{Z}/7\mathbb{Z}$ has any element of order 5.

Solution. $\mathbb{Z}/5\mathbb{Z}$ is cyclic generated by $\bar{1}$, with $|\bar{1}| = 5$. For a homomorphism, Proposition 1.6.7(1) gives $|\varphi(\bar{1})| \mid 5$, so $|\varphi(\bar{1})| \in \{1, 5\}$.

Now $\varphi(\bar{1}) \in \mathbb{Z}/7\mathbb{Z}$, a group of order 7. By Lagrange every element order divides 7, hence $|\varphi(\bar{1})| \in \{1, 7\}$. The only value common to $\{1, 5\}$ and $\{1, 7\}$ is 1. Therefore $|\varphi(\bar{1})| = 1$, i.e. $\varphi(\bar{1}) = \bar{0}$ (the identity of $\mathbb{Z}/7\mathbb{Z}$).

Since $\bar{1}$ generates $\mathbb{Z}/5\mathbb{Z}$, for any k, $\varphi(\bar{k}) = \varphi(k \cdot \bar{1}) = k\,\varphi(\bar{1}) = k \cdot \bar{0} = \bar{0}$. So φ is the trivial homomorphism, and there is no nontrivial one.

Check: $\gcd(5, 7) = 1$; the slogan is "$\mathbb{Z}/m\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ admits only the trivial hom when $\gcd(m, n) = 1$," confirmed here. Sanity: the trivial map $\bar{k} \mapsto \bar{0}$ *is* a homomorphism (it sends every product to $\bar{0} = \bar{0} + \bar{0}$), so the count of homs is exactly one, not zero.

Worked Example 1.6.16 (Possible images of a generator: homs $\mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$)**.** Determine all possible values of $\varphi(\bar{1})$ for a homomorphism $\varphi : \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$, and how many homomorphisms there are.

Recognition. Order divisibility, constructive direction. $\mathbb{Z}/6\mathbb{Z} = \langle \bar{1} \rangle$ with $|\bar{1}| = 6$, so $\varphi(\bar{1})$ may be any $h \in \mathbb{Z}/4\mathbb{Z}$ with $|h| \mid 6$ – the Method says: list the legal targets, then each gives exactly one hom.

Solution. Elements of $\mathbb{Z}/4\mathbb{Z} = \{\bar{0}, \bar{1}, \bar{2}, \bar{3}\}$ with their additive orders: $|\bar{0}| = 1$, $|\bar{1}| = 4$, $|\bar{2}| = 2$, $|\bar{3}| = 4$.

We need $|\varphi(\bar{1})| \mid 6$. The divisors of 6 are $\{1, 2, 3, 6\}$. Match against the orders above:

$$|\bar{0}| = 1 \mid 6 \text{ (ok)}, \quad |\bar{2}| = 2 \mid 6 \text{ (ok)}, \quad |\bar{1}| = 4 \nmid 6, \quad |\bar{3}| = 4 \nmid 6.$$

So $\varphi(\bar{1}) \in \{\bar{0}, \bar{2}\}$. (Equivalently: solvability of $6h = 0$ in $\mathbb{Z}/4\mathbb{Z}$ forces $2h = 0$, i.e. $h \in \{\bar{0}, \bar{2}\}$ – the same answer, since $6h = 2h$ in $\mathbb{Z}/4\mathbb{Z}$.)

Each choice does extend to a hom: $\varphi(\bar{k}) = k\,\varphi(\bar{1})$ is well defined because $6\,\varphi(\bar{1}) = \bar{0}$ in both cases ($6\bar{0} = \bar{0}$, $6\bar{2} = \overline{12} = \bar{0}$). Hence there are exactly **2** homomorphisms $\mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$:

$$\varphi_0 : \bar{k} \mapsto \bar{0}, \qquad \varphi_1 : \bar{k} \mapsto \overline{2k}.$$

Check the nontrivial one φ_1 on a product: $\varphi_1(\bar{2} + \bar{5}) = \varphi_1(\bar{1}) = \bar{2}$ and $\varphi_1(\bar{2}) + \varphi_1(\bar{5}) = \bar{4} + \overline{10} = \bar{0} + \bar{2} = \bar{2}$. Match. General count fact: $\#\mathrm{Hom}(\mathbb{Z}/m\mathbb{Z}, \mathbb{Z}/n\mathbb{Z}) = \gcd(m, n)$; here $\gcd(6, 4) = 2$. Confirmed.

Worked Example 1.6.17 (Order divisibility kills a proposed value in D_8)**.** In the dihedral group $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$, decide whether there is a homomorphism $\varphi : \mathbb{Z}/3\mathbb{Z} \to D_8$ with $\varphi(\bar{1}) = r$.

Recognition. Order divisibility, the "rule it out" direction. $\mathbb{Z}/3\mathbb{Z} = \langle \bar{1} \rangle$ with $|\bar{1}| = 3$. The Method: any value $\varphi(\bar{1}) = y$ must satisfy $|y| \mid 3$. Compute $|r|$ in D_8 and compare.

Solution. In D_8, r has order 4 (since $r^4 = 1$ and $r, r^2, r^3 \neq 1$): $|r| = 4$. For the proposed hom, Proposition 1.6.7(1) requires

$$|\varphi(\bar{1})| \mid |\bar{1}| = 3, \qquad \text{but } |\varphi(\bar{1})| = |r| = 4, \quad 4 \nmid 3.$$

This is a contradiction, so *no* homomorphism $\mathbb{Z}/3\mathbb{Z} \to D_8$ can send $\bar{1} \mapsto r$.

What *can* $\bar{1}$ map to? We need an element of D_8 of order dividing 3. The 8 elements of D_8 are the four rotations $1, r, r^2, r^3$ and the four reflections s, rs, r^2s, r^3s. Their orders are: 1 for the identity; 4 for r and r^3; 2 for r^2; and 2 for each of the four reflections (each $r^k s$ satisfies $(r^k s)^2 = 1$ via $sr = r^{-1}s$). No element has order 3 – indeed $3 \nmid |D_8| = 8$, by Lagrange. The only order dividing 3 is 1, so $\varphi(\bar{1}) = 1$ and the only hom $\mathbb{Z}/3\mathbb{Z} \to D_8$ is trivial.

Check: $3 = |\bar{1}|$ does not divide $8 = |D_8|$, so by Lagrange-style counting there can be no element of order 3 to receive a faithful image – fully consistent with the order-divisibility verdict.

Worked Example 1.6.18 (Using injectivity to read off equal orders)**.** Let $\varphi : \mathbb{Z} \to \mathbb{R}^\times$ be the homomorphism $\varphi(n) = 2^n$ (from $(\mathbb{Z}, +)$ to $(\mathbb{R}^\times, \cdot)$). Verify it is a homomorphism, show it is injective, and conclude $|\varphi(n)| = |n|$ for every n.

Recognition. Two methods at once: "verify a map" (mixed operations: source $+$, target $\cdot$) and order divisibility part (2) (injective $\implies$ orders are *equal*, not just divide). The trigger for equality is injectivity, which we get from a trivial kernel.

Solution. Homomorphism: for $m, n \in \mathbb{Z}$, $\varphi(m+n) = 2^{m+n} = 2^m 2^n = \varphi(m)\varphi(n)$. Good.

Kernel. $\varphi(n) = 1 \iff 2^n = 1 \iff n = 0$, so $\ker\varphi = \{0\} = \{1_G\}$; hence φ is injective.

Orders. In $(\mathbb{Z}, +)$ every nonzero element has infinite order and 0 has order 1. By Proposition 1.6.7(2) (injective case), $|\varphi(n)| = |n|$ for all n:

$$|\varphi(0)| = |2^0| = |1| = 1 = |0|,$$

and for $n \neq 0$, $2^n \neq 1$ and no positive power $(2^n)^k = 2^{nk}$ equals 1 (as $nk \neq 0$), so $|2^n| = \infty = |n|$.

Check: image $\varphi(\mathbb{Z}) = \{2^n \mid n \in \mathbb{Z}\} = \{\ldots, \frac{1}{4}, \frac{1}{2}, 1, 2, 4, \ldots\}$, an infinite cyclic subgroup of $\mathbb{R}^\times$; injective hom from $\mathbb{Z}$, so $\mathbb{Z} \cong \langle 2 \rangle$. Consistent with "injective $\implies$ orders preserved exactly."

$$1 \longrightarrow 0 \hookrightarrow \mathbb{Z} \xhookrightarrow{n \mapsto 2^n} \mathbb{R}^\times$$

Diagram explanation. Objects: 1 is the trivial group; $0 = \{0\} \leq \mathbb{Z}$ is the trivial subgroup of $\mathbb{Z}$ (the kernel of φ, written additively as 0); $\mathbb{Z} = (\mathbb{Z}, +)$ is the source; $\mathbb{R}^\times$ is the multiplicative group of nonzero reals.

Arrows: $1 \to 0$ inserts the additive identity 0 into $\mathbb{Z}$. The hooked inclusion $0 \hookrightarrow \mathbb{Z}$ is the inclusion of the trivial subgroup. The hooked arrow $\mathbb{Z} \hookrightarrow \mathbb{R}^\times$, $n \mapsto 2^n$, is the homomorphism φ from the example; it is injective (hence the hook), because $2^n = 1$ in $\mathbb{R}^\times$ only for $n = 0$.

What commutes: Exactness at 0: trivially exact since the map from the trivial group is injective. Exactness at $\mathbb{Z}$: $\ker(\varphi) = \ker(n \mapsto 2^n) = \{0\} = \mathrm{im}(0 \hookrightarrow \mathbb{Z})$. This is the content of "φ has trivial kernel."

Why it commutes: $2^n = 1$ in $\mathbb{R}^\times$ iff $n = 0$, since $2 > 1$ implies $2^n > 1$ for $n > 0$ and $2^n < 1$ for $n < 0$. Hence the kernel is $\{0\}$, which is exactly the image of the trivial inclusion. The two-hook sequence expresses φ being injective.

Why this matters here: The diagram closes the worked example by recording both the triviality of the kernel and the injectivity of φ in the standard diagrammatic shorthand. It also illustrates a general principle: a sequence $1 \to 0 \hookrightarrow \mathbb{Z} \xrightarrow{f} \mathbb{R}^\times$ with two hooks means f is injective, which by Proposition 1.6.7(2) forces $|f(n)| = |n|$ for all n.

Concrete example: Replace 2 by any real $a > 1$: the map $n \mapsto a^n$ is an injective homomorphism $(\mathbb{Z}, +) \to (\mathbb{R}^\times, \cdot)$ for the same reason ($a^n = 1$ iff $n = 0$), so the same two-hook sequence holds.

Common pitfall: The node labelled 0 looks like the number zero, but it is the trivial *group* $\{0\}$ (or equivalently $\{1_\mathbb{Z}\}$ in additive notation). Writing the trivial group as 0 instead of 1 is standard for additive groups; do not confuse the group element $0 \in \mathbb{Z}$ with the trivial group containing only that element.

Takeaway: The point of this diagram is that the two hooks together encode injectivity of φ in a single exact sequence, making it immediate that 2^n inherits the order of n via Proposition 1.6.7(2).

(The hooked φ records injectivity: a hom is injective $\iff \ker = \{1_G\}$.)

Caution. "φ determined by $\varphi(\bar{1})$" only works because the source is *cyclic*. For a non-cyclic source you must specify (compatible) images of a generating set and check the defining relations; you cannot pick generator images freely.

Further examples: identifying groups up to isomorphism

Section 1.6 of the book stays deliberately concrete. Having fixed the language of *isomorphic* groups, it records the simple structural quantities an isomorphism must preserve and then spends most of its energy on explicit examples: identifying two groups, or two descriptions of one group. We collect that concrete layer here.

Remark 1.6.2 (Isomorphic means "the same group up to renaming"). Recall (Definition 1.6.2) that $G \cong H$ means there is a bijective homomorphism $\varphi : G \to H$. The working picture: φ is a *dictionary* that translates each element of G into an element of H in a way that converts the multiplication table of G into that of H. Isomorphic groups have the same algebraic properties; only the *names* of the elements (and possibly the

symbol for the operation) differ. To show $G \cong H$ you *produce* a map $\varphi : G \to H$ and check it is a bijective homomorphism. To show $G \ncong H$ you exhibit a group-theoretic property held by one but not the other (Proposition 1.6.19 lists the usual candidates): one preserved quantity that disagrees rules out *all* possible bijections at once, with no single map examined.

Proposition 1.6.19 (What an isomorphism preserves)**.** *Let $\varphi : G \to H$ be an isomorphism. Then:*

(1) $|G| = |H|$ (as cardinalities; φ is a bijection);

(2) G is abelian if and only if H is abelian;

(3) for every $x \in G$, $|\varphi(x)| = |x|$; hence for each n, G and H have the same number *of elements of order n;*

(4) G is cyclic if and only if H is cyclic.

Proof. (1) Immediate from φ being a bijection.

(2) Suppose G is abelian and let $a, b \in H$. Write $a = \varphi(x)$, $b = \varphi(y)$ (possible, φ onto). Then

$$ab = \varphi(x)\varphi(y) = \varphi(xy) = \varphi(yx) = \varphi(y)\varphi(x) = ba,$$

so H is abelian. The converse applies the same argument to φ^{-1}, which is an isomorphism by Proposition 1.6.5.

(3) This is Proposition 1.6.7(2) applied to the injective map φ. The counting statement follows because φ restricts to a bijection between $\{x \in G \mid |x| = n\}$ and $\{a \in H \mid |a| = n\}$.

(4) If $G = \langle x \rangle$ is cyclic, then for any $a \in H$ we have $a = \varphi(x^k) = \varphi(x)^k$ for some k (using surjectivity and Proposition 1.6.4(3)), so $H = \langle \varphi(x) \rangle$ is cyclic. The converse again uses φ^{-1}. □

Remark 1.6.3 (The two readings of $\mathbb{Z}/n\mathbb{Z}$). Throughout the book $\mathbb{Z}/n\mathbb{Z}$ denotes the additive group of integers modulo n, while $\langle x \rangle$ with $|x| = n$ is an abstract cyclic group of order n. Proposition 1.6.19(4) plus the explicit isomorphism $\bar{k} \mapsto x^k$ (Worked Example 1.6.20 below) is what licenses the constant practice of treating these two as "the same group." The isomorphism is the dictionary; the equality $\langle x \rangle \cong \mathbb{Z}/n\mathbb{Z}$ is its certificate.

Worked Example 1.6.20 (Every cyclic group of order n is $\cong \mathbb{Z}/n\mathbb{Z}$)**.** Let $G = \langle x \rangle$ be a cyclic group with $|x| = n < \infty$. Show $G \cong \mathbb{Z}/n\mathbb{Z}$ via an explicit isomorphism, and state the infinite analogue.

Recognition. This is the book's foundational "identify two descriptions of one group" example. The recognition: a cyclic group is completely controlled by the order of its generator, so the map must be "residue $\mapsto$ power," $\bar{k} \mapsto x^k$. The only thing to verify carefully is that this is *well defined* (different exponents k for the same class must give the same element) – that is exactly where $|x| = n$ enters.

Solution. Define $\varphi : \mathbb{Z}/n\mathbb{Z} \to G$ by $\varphi(\bar{k}) = x^k$.

Well defined. If $\bar{k} = \bar{\ell}$ in $\mathbb{Z}/n\mathbb{Z}$ then $n \mid (k - \ell)$, say $k - \ell = nq$. Since $x^n = 1$, $x^k = x^{\ell + nq} = x^\ell (x^n)^q = x^\ell \cdot 1 = x^\ell$. So the value does not depend on the representative.

Homomorphism. $\varphi(\bar{k} + \bar{\ell}) = \varphi(\overline{k+\ell}) = x^{k+\ell} = x^k x^\ell = \varphi(\bar{k})\varphi(\bar{\ell})$.

Bijection. It is onto since every element of $G = \langle x \rangle$ is a power $x^k = \varphi(\bar{k})$. It is one-to-one since $|\mathbb{Z}/n\mathbb{Z}| = n = |x| = |G|$ (the powers $x^0, \ldots, x^{n-1}$ are distinct), so a surjection between equal finite sets is a bijection. Hence $G \cong \mathbb{Z}/n\mathbb{Z}$.

Infinite case. If instead $|x| = \infty$, the same rule $\varphi : \mathbb{Z} \to G$, $\varphi(k) = x^k$, is a homomorphism, and now $\varphi(k) = \varphi(\ell) \implies x^{k-\ell} = 1 \implies k = \ell$ (infinite order means no nontrivial relation), so it is injective; surjectivity is automatic, giving $G \cong \mathbb{Z}$.

Check: orders match elementwise, $|\varphi(\bar{1})| = |x| = n = |\bar{1}|$, consistent with Proposition 1.6.19(3). This is the precise sense of Remark 1.6.3: "the" cyclic group of order n is $\mathbb{Z}/n\mathbb{Z}$.

Worked Example 1.6.21 (Identifying $(\mathbb{Z}/8\mathbb{Z})^\times$ with the Klein four-group V_4)**.** Show $(\mathbb{Z}/8\mathbb{Z})^\times = \{\bar{1}, \bar{3}, \bar{5}, \bar{7}\}$ (multiplication mod 8) is isomorphic to the Klein four-group $V_4 = \{1, a, b, c\}$ in which every non-identity element has order 2 and $ab = c,\ bc = a,\ ca = b$.

Recognition. "Identify two descriptions." Both groups have order 4 and are abelian; the deciding feature is the order profile. We already computed in the fragment that every element of $(\mathbb{Z}/8\mathbb{Z})^\times$ squares to $\bar{1}$, so $(\mathbb{Z}/8\mathbb{Z})^\times$ has exponent 2 – the fingerprint of V_4, not of the cyclic $\mathbb{Z}/4\mathbb{Z}$. We build the dictionary by matching the three order-2 elements.

Solution. Orders in $(\mathbb{Z}/8\mathbb{Z})^\times$: $|\bar{1}| = 1$ and $|\bar{3}| = |\bar{5}| = |\bar{7}| = 2$ (each squares to $\bar{1}$). So $(\mathbb{Z}/8\mathbb{Z})^\times$ has *three* elements of order 2 – exactly like V_4, and unlike $\mathbb{Z}/4\mathbb{Z}$ (which has a single element of order 2). Define

$$\varphi : (\mathbb{Z}/8\mathbb{Z})^\times \to V_4, \qquad \bar{1} \mapsto 1, \quad \bar{3} \mapsto a, \quad \bar{5} \mapsto b, \quad \bar{7} \mapsto c.$$

This is a bijection of 4-element sets. To check it is a homomorphism it suffices (both groups abelian, generated by order-2 elements) to verify the products of distinct non-identity elements. In $(\mathbb{Z}/8\mathbb{Z})^\times$:

$$\bar{3} \cdot \bar{5} = \overline{15} = \bar{7}, \quad \bar{5} \cdot \bar{7} = \overline{35} = \bar{3}, \quad \bar{7} \cdot \bar{3} = \overline{21} = \bar{5},$$

which φ sends to $ab = c,\ bc = a,\ ca = b$ – precisely the V_4 table. Hence $(\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$.

Check: $|(\mathbb{Z}/8\mathbb{Z})^\times| = 4 = |V_4|$, both abelian, both exponent 2 – all of Proposition 1.6.19 agrees. In particular $(\mathbb{Z}/8\mathbb{Z})^\times \ncong \mathbb{Z}/4\mathbb{Z}$, since $\mathbb{Z}/4\mathbb{Z}$ is cyclic and $(\mathbb{Z}/8\mathbb{Z})^\times$ is not (Proposition 1.6.19(4)).

Worked Example 1.6.22 ($\mathbb{Z} \times \mathbb{Z}$ is not cyclic, so $\mathbb{Z} \ncong \mathbb{Z} \times \mathbb{Z}$)**.** Use a preserved invariant to show $\mathbb{Z} \ncong \mathbb{Z} \times \mathbb{Z}$ (with coordinatewise addition), even though both are infinite abelian groups.

Recognition. "Show two groups are *not* isomorphic," per Remark 1.6.2: find a property held by one and not the other. Cardinality and abelianness do not separate them. The separating invariant is *cyclicity*, which is preserved by Proposition 1.6.19(4).

Solution. $\mathbb{Z} = \langle 1 \rangle$ is cyclic. We claim $\mathbb{Z} \times \mathbb{Z}$ is not. Suppose for contradiction $\mathbb{Z} \times \mathbb{Z} = \langle (a, b) \rangle$ for some (a, b). Every element would then be an integer multiple $k(a, b) = (ka, kb)$. Applying this to $(1, 0)$ gives some k with $kb = 0$ and $ka = 1$; from $ka = 1$ we get $k \neq 0$, so $kb = 0$ forces $b = 0$. Applying it to $(0, 1)$ gives some ℓ with $\ell a = 0$ and $\ell b = 1$; but $b = 0$ makes $\ell b = 0 \neq 1$, a contradiction. So no single generator exists and $\mathbb{Z} \times \mathbb{Z}$ is not cyclic.

Since cyclicity is an isomorphism invariant, a cyclic group and a non-cyclic group cannot be isomorphic: $\mathbb{Z} \ncong \mathbb{Z} \times \mathbb{Z}$.

Check: this is the negative half of Remark 1.6.2 in action – one invariant (cyclicity) disagreeing rules out every possible bijection at once, with no need to inspect any particular map.

Worked Example 1.6.23 (Conjugation is an automorphism)**.** Fix g in a group G and define $\varphi_g : G \to G$ by $\varphi_g(x) = gxg^{-1}$. Show φ_g is an isomorphism of G with itself (an *automorphism*), and that it is the identity for all g exactly when G is abelian.

Recognition. "Verify a map," but now source and target are the same group and the map is built from a fixed element. The recognition: conjugation interleaves $g^{-1}g = 1$ in the middle, so it respects products automatically; bijectivity comes for free from the explicit inverse $\varphi_{g^{-1}}$.

Solution. Homomorphism. For $x, y \in G$,

$$\varphi_g(xy) = g(xy)g^{-1} = gx(g^{-1}g)yg^{-1} = (gxg^{-1})(gyg^{-1}) = \varphi_g(x)\varphi_g(y).$$

Bijection. $\varphi_{g^{-1}}(\varphi_g(x)) = g^{-1}(gxg^{-1})g = x$, and likewise $\varphi_g(\varphi_{g^{-1}}(x)) = x$, so φ_g is invertible with inverse $\varphi_{g^{-1}}$. Hence φ_g is an automorphism of G.

When is it trivial? $\varphi_g = \mathrm{id} \iff gxg^{-1} = x$ for all $x \iff gx = xg$ for all x, i.e. g commutes with everything. So $\varphi_g = \mathrm{id}$ for *every* g exactly when every element commutes with every other, i.e. G is abelian.

Check: φ_g preserves orders (Proposition 1.6.19(3)), which recovers the familiar fact that conjugate elements have equal order, $|gxg^{-1}| = |x|$.

Worked Example 1.6.24 (An isomorphism need not be unique: two isomorphisms $\mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$)**.** Exhibit two *different* isomorphisms $\mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$, illustrating that "$G \cong H$" asserts existence, not uniqueness, of the dictionary.

Recognition. A conceptual point dressed as a computation: the relation $\cong$ only requires *some* isomorphism. For a cyclic source, a homomorphism $\mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$ is determined by where the generator $\bar{1}$ goes, and any generator-to-generator assignment works. We just list two legal targets.

Solution. A homomorphism $\varphi : \mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$ is fixed by $\varphi(\bar{1}) = \bar{c}$, giving $\varphi(\bar{k}) = \overline{ck}$. It is an isomorphism iff $\bar{c}$ generates $\mathbb{Z}/5\mathbb{Z}$, i.e. $\gcd(c, 5) = 1$. Take

$$\varphi(\bar{k}) = \overline{k} \quad (c = 1,\ \text{the identity}), \qquad \psi(\bar{k}) = \overline{2k} \quad (c = 2).$$

Both are bijections (multiplication by a unit mod 5 permutes the residues) and both are homomorphisms ($\overline{c(k+\ell)} = \overline{ck} + \overline{c\ell}$). They differ: $\varphi(\bar{1}) = \bar{1} \neq \bar{2} = \psi(\bar{1})$.

Check: the legal targets are the $c \in \{1, 2, 3, 4\}$ with $\gcd(c, 5) = 1$, namely all four of them, so there are exactly 4 isomorphisms $\mathbb{Z}/5\mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$ (these form the group $\mathrm{Aut}(\mathbb{Z}/5\mathbb{Z})$). So "$\mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/5\mathbb{Z}$" is witnessed four times over – existence of one suffices for the relation.

Remark 1.6.4 (Homomorphic image vs. isomorphic copy). It is worth separating two phrases. "H is a *homomorphic image* of G" means there is a surjective homomorphism $G \to H$ (information may be lost: the kernel collapses). "G and H are *isomorphic*" means there is a *bijective* homomorphism (no information lost). Every isomorphism is in particular a surjection, so an isomorphic copy is a homomorphic image, but not conversely: $\mathbb{Z}/n\mathbb{Z}$ is a homomorphic image of $\mathbb{Z}$ (reduction mod n, in the fragment) yet $\mathbb{Z}/n\mathbb{Z} \ncong \mathbb{Z}$ for any n by cardinality. The fragment's order-divisibility theorem is precisely the constraint that the *lossy* case must obey.

Isomorphism: a structure-preserving bijection and the invariants it preserves

Definition 1.6.25. A map $\varphi\colon G \to H$ between groups is an *isomorphism* if

1. φ is a bijection, and
2. φ is a homomorphism: $\varphi(xy) = \varphi(x)\varphi(y)$ for all $x, y \in G$.

We write $G \cong H$ and call G, H *isomorphic*. The single equation $\varphi(xy) = \varphi(x)\varphi(y)$ is exactly the assertion that the following square commutes, where m_G, m_H are the multiplication maps:

$$\begin{array}{ccc} G \times G & \xrightarrow{m_G} & G \\ {\scriptstyle \varphi\times\varphi}\downarrow & & \downarrow{\scriptstyle \varphi} \\ H \times H & \xrightarrow[m_H]{} & H \end{array}$$

Diagram explanation. Objects: Four corners: upper-left $G \times G$ and upper-right G are Cartesian products and the group G; lower-left $H \times H$ and lower-right H are the same for H. All four are groups (or products of groups).

Arrows: $m_G\colon G \times G \to G$ is the multiplication map of G, sending $(x, y) \mapsto xy$. $m_H\colon H \times H \to H$ is the multiplication map of H. The left vertical arrow $\varphi \times \varphi\colon G \times G \to H \times H$ sends $(x, y) \mapsto (\varphi(x), \varphi(y))$, applying φ componentwise. The right vertical arrow $\varphi\colon G \to H$ is the candidate isomorphism.

What commutes: The square commutes: $\varphi \circ m_G = m_H \circ (\varphi \times \varphi)$. Concretely, top-then-right equals left-then-bottom.

Why it commutes: Take $(x, y) \in G \times G$. Top path: $m_G(x, y) = xy$ in G, then $\varphi(xy)$. Left-bottom path: $(\varphi \times \varphi)(x, y) = (\varphi(x), \varphi(y))$, then $m_H(\varphi(x), \varphi(y)) = \varphi(x)\varphi(y)$. These agree exactly when $\varphi(xy) = \varphi(x)\varphi(y)$, which is the homomorphism condition.

Why this matters here: This square *is* the definition of homomorphism written categorically. The diagram makes visible that φ intertwines the two multiplication maps; checking that the square commutes is precisely step 2 of the "prove $G \cong H$" method.

Concrete example: $\varphi = \exp\colon (\mathbb{R}, +) \to (\mathbb{R}^{>0}, \cdot)$. Here m_G is addition, m_H is multiplication, and $e^{x+y} = e^x e^y$ is exactly the commutativity of this square.

Common pitfall: Students sometimes check $\varphi(xy) = \varphi(x)\varphi(y)$ only on generators and forget to verify well-definedness; or they confirm the square commutes on a few elements and claim the diagram "proves" φ is an isomorphism — but bijectivity is a separate obligation not encoded in the square.

Takeaway: The point of this diagram is that the single equation $\varphi(xy) = \varphi(x)\varphi(y)$ is equivalent to the commutativity of this square, turning the analytic homomorphism condition into a clean diagrammatic statement.

Reading the top-right path: multiply in G, then push to H. Reading the left-bottom path: push each factor to H, then multiply there. Commutativity says "transport then multiply" equals "multiply then transport."

Remark 1.6.5. Isomorphism is an equivalence relation (id_G is an isomorphism; φ^{-1} of an isomorphism is an isomorphism; a composite of isomorphisms is one). Two isomorphic groups are "the same" for every property defined purely from the multiplication. The properties below are *isomorphism invariants*: if $G \cong H$ they must agree.

1. **Order:** $|G| = |H|$ (a bijection preserves cardinality).
2. **Abelian-ness:** G abelian $\iff$ H abelian.
3. **Multiset of element orders:** for every n, the number of $x \in G$ with $|x| = n$ equals the number of $y \in H$ with $|y| = n$.
4. **Number of subgroups** (and of subgroups of each order), and the whole subgroup lattice up to relabeling.
5. **Being cyclic.**

Proposition 1.6.26. *Let $\varphi\colon G \to H$ be an isomorphism. Then for all $x \in G$:*

$$\varphi(1_G) = 1_H, \qquad \varphi(x^{-1}) = \varphi(x)^{-1}, \qquad |\varphi(x)| = |x|.$$

Moreover G is abelian iff H is, and G is cyclic iff H is.

Proof. From $\varphi(1_G) = \varphi(1_G \cdot 1_G) = \varphi(1_G)\varphi(1_G)$, cancel $\varphi(1_G)$ in H to get $\varphi(1_G) = 1_H$. Then $1_H = \varphi(1_G) = \varphi(xx^{-1}) = \varphi(x)\varphi(x^{-1})$, so $\varphi(x^{-1}) = \varphi(x)^{-1}$.

For orders, $\varphi(x^n) = \varphi(x)^n$ by induction. Hence $x^n = 1_G \implies \varphi(x)^n = 1_H$. Conversely, since φ is injective with $\varphi(1_G) = 1_H$, $\varphi(x)^n = 1_H = \varphi(1_G)$ forces $x^n = 1_G$. Thus $\{n : x^n = 1\} = \{n : \varphi(x)^n = 1\}$, so the least positive such n agrees: $|\varphi(x)| = |x|$ (and both are infinite together).

If G is abelian and $a, b \in H$, write $a = \varphi(x), b = \varphi(y)$ (surjectivity); then $ab = \varphi(x)\varphi(y) = \varphi(xy) = \varphi(yx) = \varphi(y)\varphi(x) = ba$. By symmetry ($\varphi^{-1}$ is an isomorphism) the converse holds. If $G = \langle g \rangle$ then $H = \varphi(G) = \langle \varphi(g) \rangle$ is cyclic; symmetrically for the converse. □

Method (To PROVE $G \cong H$: build an explicit bijective homomorphism)**.** *Trigger.* You suspect two concretely given groups are the same, or the problem says "show $G \cong H$."

1. **Guess the map.** Match generators of G to elements of H that satisfy the same relations; or use a known structural formula (exp, log, $g^k \mapsto k$, a permutation action).
2. **Check well-defined + homomorphism:** verify $\varphi(xy) = \varphi(x)\varphi(y)$ for all $x, y \in G$, i.e. that the multiplication square commutes. If φ is defined by images of generators, it suffices (and is necessary) to check that these images satisfy the defining relations of G; checking the product rule only on pairs of generators is not enough.
3. **Check bijective.** Easiest route: show φ is injective ($\ker \varphi = \{1\}$, i.e. $\varphi(x) = 1 \implies x = 1$) AND $|G| = |H|$ finite; or exhibit an explicit two-sided inverse map.

Method (To DISPROVE $G \cong H$: exhibit a differing invariant)**.** *Trigger.* Two groups of the *same order* that you suspect are different (different orders are settled by $|G| \neq |H|$ immediately).

1. Compare $|G|$ vs $|H|$. If unequal, done.
2. Is exactly one abelian? If so, done.
3. Compare the *multiset of element orders*: tabulate "how many elements of order $1, 2, 3, 4, \ldots$" in each. One mismatch kills the isomorphism. (This is the workhorse.)
4. Compare the number of subgroups of a fixed order, or whether one is cyclic and the other is not.

Why it works: by Proposition 1.6.26 an isomorphism would carry each invariant across unchanged, so a single disagreement is a contradiction.

Caution. A map that happens to be a bijection of *sets* is not enough unless it also respects multiplication; conversely a bijective *set* map respecting multiplication is automatically an isomorphism — but check both halves. Equal order alone does not prove $G \cong H$ in general (e.g. $\mathbb{Z}/4\mathbb{Z} \ncong V_4$).

Worked examples: PROVING $G \cong H$

Worked Example 1.6.27 (Every cyclic group of order n is $\mathbb{Z}/n\mathbb{Z}$)**.** Let $G = \langle x \rangle$ with $|x| = n < \infty$. Show $\mathbb{Z}/n\mathbb{Z} \cong \langle x \rangle$.

Recognition. "Cyclic of order n" is the trigger: a single generator with one relation $x^n = 1$ matches the single generator $\bar{1}$ of $\mathbb{Z}/n\mathbb{Z}$ with relation $n \cdot \bar{1} = \bar{0}$. Use the generator-matching recipe and the universal triangle through $\mathbb{Z}$.

Solution. Define $\varphi\colon \mathbb{Z}/n\mathbb{Z} \to \langle x \rangle$ by $\varphi(\bar{k}) = x^k$. *Well-defined:* if $\bar{k} = \bar{\ell}$ then $n \mid k - \ell$, and $|x| = n \implies x^{k-\ell} = 1 \implies x^k = x^\ell$. *Homomorphism:* $\varphi(\bar{k} + \bar{\ell}) = \varphi(\overline{k+\ell}) = x^{k+\ell} = x^k x^\ell = \varphi(\bar{k})\varphi(\bar{\ell})$. *Bijective:* both sides have exactly n elements, and φ is surjective since $\{x^0, \ldots, x^{n-1}\} = \langle x \rangle$; a surjection between equal finite sets is a bijection.

This is the unique homomorphism filling the triangle: let $\pi\colon \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ be reduction and $k \mapsto x^k$ the map $\mathbb{Z} \to \langle x \rangle$. Since $\ker(k \mapsto x^k) = n\mathbb{Z} = \ker \pi$, the dashed φ exists and is unique:

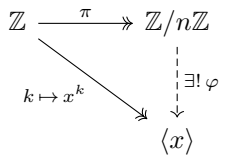

Diagram explanation. Objects: Three groups: $\mathbb{Z}$ (the free cyclic group, upper-left), $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/n\mathbb{Z}$ (the quotient, upper-right), and $\langle x \rangle$ (the cyclic subgroup of G generated by x with $|x| = n$, lower-right corner). All are cyclic groups.

Arrows: $\pi\colon \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ is the canonical surjection (reduction mod n), $\pi(k) = \bar{k}$. The diagonal arrow $k \mapsto x^k\colon \mathbb{Z} \to \langle x \rangle$ sends an integer to the corresponding power of x. The dashed arrow $\varphi\colon \mathbb{Z}/n\mathbb{Z} \to \langle x \rangle$ is the induced map, $\varphi(\bar{k}) = x^k$; it exists uniquely because $\ker \pi = n\mathbb{Z}$ is contained in $\ker(k \mapsto x^k) = n\mathbb{Z}$. Well-definedness: if $\bar{k} = \bar{\ell}$ then $n \mid k - \ell$, so $x^{k-\ell} = (x^n)^{(k-\ell)/n} = 1^{(k-\ell)/n} = 1$, giving $x^k = x^\ell$; the coset representative does not affect the output.

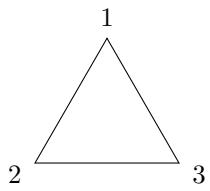
What commutes: The triangle commutes: $\varphi \circ \pi =$ the diagonal map. That is, $\varphi(\pi(k)) = \varphi(\bar{k}) = x^k$ for all $k \in \mathbb{Z}$.

Why it commutes: Chase $k \in \mathbb{Z}$: along the top then down, $k \xrightarrow{\pi} \bar{k} \xrightarrow{\varphi} x^k$. Along the diagonal directly, $k \mapsto x^k$. Both land at x^k, which is the definition of φ.

Why this matters here: This triangle is the *universal property of the quotient* $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/n\mathbb{Z}$ in action: any homomorphism out of $\mathbb{Z}$ whose kernel contains $n\mathbb{Z}$ factors uniquely through $\mathbb{Z}/n\mathbb{Z}$. The worked example uses this to show the isomorphism φ exists, is unique, and inherits bijectivity from the surjectivity of π together with $|\mathbb{Z}/n\mathbb{Z}| = |\langle x \rangle| = n$.

Concrete example: $n = 4$, $x = (1\,2\,3\,4) \in S_4$ of order 4. The triangle gives $\varphi(\bar{k}) = (1\,2\,3\,4)^k$: $\varphi(\bar{1}) = (1\,2\,3\,4)$, $\varphi(\bar{2}) = (1\,3)(2\,4)$, $\varphi(\bar{3}) = (1\,4\,3\,2)$, $\varphi(\bar{0}) = e$, matching $\mathbb{Z}/4\mathbb{Z}$.

Common pitfall: The dashed arrow is induced by the universal property, not defined by hand; students sometimes write $\varphi(k) = x^k$ with $k \in \mathbb{Z}$ rather than $k \in \mathbb{Z}/n\mathbb{Z}$, ignoring that well-definedness on cosets must be checked (different representatives of $\bar{k}$ give the same x^k only because $|x| = n$).



Takeaway: The point of this diagram is that the unique dashed factor $\varphi\colon \mathbb{Z}/n\mathbb{Z} \to \langle x \rangle$ supplied by the universal property of $\mathbb{Z}/n\mathbb{Z}$ is automatically the desired isomorphism, because the kernel condition $\ker(k \mapsto x^k) = n\mathbb{Z} = \ker \pi$ forces both the existence and the injectivity of φ.

Check. $\varphi(\bar{1}) = x$ has order n in $\langle x \rangle$, matching $|\bar{1}| = n$ in $\mathbb{Z}/n\mathbb{Z}$; orders agree as Proposition 1.6.26 demands.

Worked Example 1.6.28 ($S_3 \cong D_6$)**.** Show the symmetric group S_3 is isomorphic to the dihedral group D_6 of the triangle (here D_6 has order 6, $r^3 = s^2 = 1$, $sr = r^{-1}s$).

Recognition. Both act faithfully on 3 objects: S_3 permutes $\{1, 2, 3\}$; D_6 permutes the 3 vertices of an equilateral triangle. "Symmetries of a triangle = all permutations of its vertices" is the trigger. Match generators.

Solution. Label the triangle's vertices $1, 2, 3$:

The rotation r by 120° sends $1 \to 2 \to 3 \to 1$, i.e. the cycle $(1\,2\,3)$. The reflection s fixing vertex 1 swaps $2, 3$, i.e. $(2\,3)$. Define $\varphi\colon D_6 \to S_3$ on generators by $\varphi(r) = (1\,2\,3)$, $\varphi(s) = (2\,3)$, extended by $\varphi(r^a s^b) = (1\,2\,3)^a (2\,3)^b$.

Relations match (so φ is a well-defined homomorphism): in S_3, $(1\,2\,3)^3 = e$, $(2\,3)^2 = e$, and multiplying right-to-left $(2\,3)(1\,2\,3) = (1\,3)$ while $(1\,2\,3)^{-1}(2\,3) = (1\,3\,2)(2\,3) = (1\,3)$, so $\varphi(sr) = \varphi(s)\varphi(r) = \varphi(r)^{-1}\varphi(s) = \varphi(r^{-1}s)$, mirroring $r^3 = s^2 = 1$, $sr = r^{-1}s$. *Bijective:* the 6 words $r^a s^b$ $(0 \le a \le 2,\ 0 \le b \le 1)$ map to the 6 distinct permutations

$$e,\ (1\,2\,3),\ (1\,3\,2),\ (2\,3),\ (1\,2),\ (1\,3),$$

which is all of S_3; $|D_6| = 6 = |S_3|$, so this is a bijection.

Check via the order multiset: S_3 has 1 identity, 3 transpositions (order 2), 2 three-cycles (order 3). D_6 has 1, the reflections $s, rs, r^2 s$ (order 2, three of them), and r, r^2 (order 3, two of them). Multisets $\{1, 2, 2, 2, 3, 3\}$ agree. Consistent.

Worked Example 1.6.29 ($(\mathbb{R}, +) \cong (\mathbb{R}^{>0}, \cdot)$ via exp)**.** Show the additive group of reals is isomorphic to the multiplicative group of positive reals.

Recognition. The trigger is the law $e^{x+y} = e^x e^y$: a function turning "+" into "·" is exactly a homomorphism $(\mathbb{R}, +) \to (\mathbb{R}^{>0}, \cdot)$. Add an inverse (log) to get the isomorphism.

Solution. Let $\varphi(x) = e^x$. *Homomorphism:* $\varphi(x + y) = e^{x+y} = e^x e^y = \varphi(x)\varphi(y)$, the commuting square

$$\begin{array}{ccc} \mathbb{R} \times \mathbb{R} & \xrightarrow{\quad + \quad} & \mathbb{R} \\ {\scriptstyle \exp \times \exp}\downarrow & & \downarrow{\scriptstyle \exp} \\ \mathbb{R}^{>0} \times \mathbb{R}^{>0} & \xrightarrow[(s,t) \mapsto st]{} & \mathbb{R}^{>0} \end{array}$$

Diagram explanation. Objects: Four corners: $\mathbb{R} \times \mathbb{R}$ (pairs of reals, upper-left), $\mathbb{R}$ (reals, upper-right), $\mathbb{R}^{>0} \times \mathbb{R}^{>0}$ (pairs of positive reals, lower-left), $\mathbb{R}^{>0}$ (positive reals, lower-right). The upper row carries the additive group structure; the lower row carries the multiplicative group structure.

Arrows: Top horizontal: addition $+\colon \mathbb{R} \times \mathbb{R} \to \mathbb{R}$, $(x, y) \mapsto x + y$. Bottom horizontal: multiplication $\cdot\colon \mathbb{R}^{>0} \times \mathbb{R}^{>0} \to \mathbb{R}^{>0}$, $(s, t) \mapsto st$. Left vertical: $\exp \times \exp\colon \mathbb{R} \times \mathbb{R} \to \mathbb{R}^{>0} \times \mathbb{R}^{>0}$, $(x, y) \mapsto (e^x, e^y)$, applying exp componentwise. Right vertical: $\exp\colon \mathbb{R} \to \mathbb{R}^{>0}$, $x \mapsto e^x$, the candidate isomorphism.

What commutes: $\exp \circ (+) = (\cdot) \circ (\exp \times \exp)$. Spelled out: for all $(x, y) \in \mathbb{R} \times \mathbb{R}$, $e^{x+y} = e^x \cdot e^y$.

Why it commutes: Take $(x, y) \in \mathbb{R} \times \mathbb{R}$. Top-right path: add first to get $x + y$, then apply exp to get e^{x+y}. Left-bottom path: apply exp componentwise to get (e^x, e^y), then multiply to get $e^x e^y$. These are equal by the fundamental law of exponents $e^{x+y} = e^x e^y$, which is exactly the homomorphism equation for exp.

Why this matters here: This square makes the homomorphism condition $\varphi(x + y) = \varphi(x) \cdot \varphi(y)$ into a commutative diagram. It also highlights the structural asymmetry: the two groups have different operations ($+$ vs. $\cdot$), and the square shows exp translates one into the other rather than preserving a single operation.

Concrete example: $x = 1$, $y = 1$: top-right gives $e^2 \approx 7.389$; left-bottom gives $e \cdot e = e^2$. They match. More concretely, $x = \ln 2$, $y = \ln 3$: $e^{\ln 2 + \ln 3} = e^{\ln 6} = 6 = 2 \cdot 3$.

Common pitfall: The two vertical arrows are *different* maps ($\exp \times \exp$ on pairs vs. exp on singles); confusing them leads to thinking only one exp appears. Also, this square verifies the homomorphism property only – bijectivity (shown by ln being a two-sided inverse) is separate.

Takeaway: The point of this diagram is that the law $e^{x+y} = e^x e^y$ is precisely the commutativity of this square, so exp is a homomorphism from the additive group $(\mathbb{R}, +)$ to the multiplicative group $(\mathbb{R}^{>0}, \cdot)$ by definition.

Bijective: $\ln\colon \mathbb{R}^{>0} \to \mathbb{R}$ satisfies $\ln(e^x) = x$ and $e^{\ln t} = t$ for $t > 0$, a two-sided inverse, so φ is a bijection (and ln is the inverse isomorphism, $\ln(st) = \ln s + \ln t$).

Check. Identities correspond, $\varphi(0) = e^0 = 1$, the identity of $(\mathbb{R}^{>0}, \cdot)$. Inverses: $\varphi(-x) = e^{-x} = (e^x)^{-1}$. Both groups are abelian and torsion-free (only the identity has finite order), consistent with Proposition 1.6.26.

Worked Example 1.6.30 ($(\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$ (units mod 8))**.** Show $(\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$, the Klein four-group.

Recognition. Compute squares. If *every* non-identity element squares to the identity, the group is a product of copies of $\mathbb{Z}/2\mathbb{Z}$; with 4 elements that forces V_4 (the only non-cyclic group of order 4). The all-elements-order-≤ 2 pattern is the trigger.

Solution. The units mod 8 are $(\mathbb{Z}/8\mathbb{Z})^\times = \{\bar{1}, \bar{3}, \bar{5}, \bar{7}\}$ (those coprime to 8), so $|(\mathbb{Z}/8\mathbb{Z})^\times| = 4$. Square each:

$$\bar{1}^2 = \bar{1}, \quad \bar{3}^2 = \bar{9} = \bar{1}, \quad \bar{5}^2 = \overline{25} = \bar{1}, \quad \bar{7}^2 = \overline{49} = \bar{1}.$$

Every element has order dividing 2, so $(\mathbb{Z}/8\mathbb{Z})^\times$ has no element of order 4 and is therefore not cyclic. The only group of order 4 in which all elements satisfy $x^2 = 1$ is $V_4 = \{1, a, b, ab\}$. Define $\varphi\colon (\mathbb{Z}/8\mathbb{Z})^\times \to V_4$ by

$$\bar{1} \mapsto 1, \quad \bar{3} \mapsto a, \quad \bar{5} \mapsto b, \quad \bar{7} \mapsto ab.$$

Homomorphism check (both groups abelian, every square the identity). The nontrivial products in $(\mathbb{Z}/8\mathbb{Z})^\times$ are

$$\bar{3} \cdot \bar{5} = \overline{15} = \bar{7}, \qquad \bar{3} \cdot \bar{7} = \overline{21} = \bar{5}, \qquad \bar{5} \cdot \bar{7} = \overline{35} = \bar{3},$$

and the matching products in V_4 are

$$a \cdot b = ab, \qquad a \cdot (ab) = a^2 b = b, \qquad b \cdot (ab) = ab^2 = a.$$

Under φ the left columns map to the right columns ($\bar{7} \mapsto ab$, $\bar{5} \mapsto b$, $\bar{3} \mapsto a$), so every product is respected. *Bijective:* the assignment above is a bijection of 4-element sets.

Check. Order multisets both equal $\{1, 2, 2, 2\}$ ($\bar{3}, \bar{5}, \bar{7}$ each order 2; a, b, ab each order 2). Both non-cyclic, abelian. Consistent.

Worked Example 1.6.31 ($\mathrm{GL}_1(\mathbb{R}) \cong (\mathbb{R}^\times, \cdot)$ — a quick structural identification)**.** Show the group of invertible 1×1 real matrices is isomorphic to $(\mathbb{R}^\times, \cdot)$, the nonzero reals under multiplication.

Recognition. A 1×1 matrix is just a scalar, and matrix multiplication is scalar multiplication; invertibility means nonzero. The "forget the brackets" identification is the trigger — a tautological isomorphism.

Solution. Define $\varphi\colon \mathrm{GL}_1(\mathbb{R}) \to \mathbb{R}^\times$ by $\varphi\big([a]\big) = a$ (necessarily $a \neq 0$). *Homomorphism:* $\varphi([a][b]) = \varphi([ab]) = ab = \varphi([a])\varphi([b])$. *Bijective:* $a \mapsto [a]$ is an explicit two-sided inverse $\mathbb{R}^\times \to \mathrm{GL}_1(\mathbb{R})$. *Check.* φ sends the identity matrix [1] to 1, and $\varphi([a]^{-1}) = \varphi([a^{-1}]) = a^{-1}$. Both abelian. Consistent.

Worked examples: DISPROVING $G \cong H$ by an invariant

Worked Example 1.6.32 ($\mathbb{Z}/4\mathbb{Z} \ncong V_4$ (different element-order counts))**.** Both have order 4. Show they are not isomorphic.

Recognition. Same order, both abelian — order and abelian-ness do not separate them. Escalate to the *multiset of element orders*, the standard next move.

Solution. Element orders in $\mathbb{Z}/4\mathbb{Z} = \{\bar{0}, \bar{1}, \bar{2}, \bar{3}\}$: $|\bar{0}| = 1$; $|\bar{2}| = 2$ since $\bar{2} + \bar{2} = \bar{4} = \bar{0}$; $|\bar{1}| = 4$ ($\bar{1}, \bar{2}, \bar{3}, \bar{0}$); $|\bar{3}| = 4$ similarly. Multiset: $\{1, 2, 4, 4\}$ — in particular *one* element of order 2 and *two* of order 4.

In $V_4 = \{1, a, b, ab\}$ every non-identity element has order 2: $a^2 = b^2 = (ab)^2 = 1$. Multiset: $\{1, 2, 2, 2\}$ — *three* elements of order 2 and *none* of order 4.

The counts of order-2 elements (1 vs 3), equivalently of order-4 elements (2 vs 0), differ. By Proposition 1.6.26 an isomorphism preserves the order of each element, hence these counts; the mismatch is a contradiction. Therefore $\mathbb{Z}/4\mathbb{Z} \ncong V_4$. *Check.* Indeed $\mathbb{Z}/4\mathbb{Z}$ is cyclic (generated by $\bar{1}$) while V_4 is not, a second invariant confirming the split.

Worked Example 1.6.33 ($Q_8 \ncong D_8$ (count of order-2 elements))**.** Both have order 8 and are non-abelian. Show they are not isomorphic.

Recognition. Order and (non)abelian-ness coincide, so they are useless here. Count elements of order 2 — the decisive invariant for these two famous order-8 groups.

Solution. $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$**.** Here $(-1)^2 = 1$, and $i^2 = j^2 = k^2 = -1$, so $i^4 = j^4 = k^4 = 1$. Orders: $|1| = 1$; $|-1| = 2$; each of $\pm i, \pm j, \pm k$ has order 4 (square is $-1 \neq 1$). Multiset: $\{1, 2, 4, 4, 4, 4, 4, 4\}$. *Exactly one* element of order 2, namely -1.

$D_8 = \{1, r, r^2, r^3, s, rs, r^2s, r^3s\}$**,** $r^4 = s^2 = 1$, $sr = r^{-1}s$. Orders: $|r| = 4$, $|r^2| = 2$, $|r^3| = 4$; each reflection $r^a s$ satisfies $(r^a s)^2 = r^a s r^a s = r^a r^{-a} s^2 = 1$, so s, rs, r^2s, r^3s all have order 2. Multiset: $\{1, 2, 2, 2, 2, 2, 4, 4\}$. *Five* elements of order 2 (r^2, s, rs, r^2s, r^3s).

Order-2 counts: 1 in Q_8 versus 5 in D_8. An isomorphism would force these equal, contradiction. Hence $Q_8 \ncong D_8$. *Check.* order-4 counts also disagree (6 vs 2), and Q_8 has a unique element of order 2 while D_8 has many — both confirm the conclusion.

Worked Example 1.6.34 ($\mathbb{Z} \ncong \mathbb{Q}$ (cyclic / not cyclic))**.** Both are infinite abelian groups under addition. Show $(\mathbb{Z}, +) \ncong (\mathbb{Q}, +)$.

Recognition. Same cardinality (both countable), same abelian-ness — those do not decide it. Use "cyclic vs. not cyclic," which is an isomorphism invariant even for infinite groups.

Solution. $\mathbb{Z} = \langle 1 \rangle$ is cyclic. Suppose $\mathbb{Q} = \langle p/q \rangle$ were cyclic, generated by p/q (in lowest terms, $q > 0$). Every element would be $n \cdot (p/q) = np/q$ for $n \in \mathbb{Z}$. But $\dfrac{p}{2q} \in \mathbb{Q}$ is not of this form: $np/q = p/(2q)$ would need $2np = p$, i.e. $2n = 1$ (note $p \neq 0$, since $\langle 0 \rangle = \{0\} \neq \mathbb{Q}$), impossible for integer n. So $\mathbb{Q}$ is not cyclic. Since "cyclic" transfers across isomorphisms (Proposition 1.6.26) and $\mathbb{Z}$ is cyclic while $\mathbb{Q}$ is not, $\mathbb{Z} \ncong \mathbb{Q}$. *Check.* Consistently, in $\mathbb{Z}$ every nonzero element generates a finite-index subgroup, whereas $\mathbb{Q}$ is divisible (every element is $2\cdot$ something) — another invariant separating them.

Worked Example 1.6.35 ($\mathbb{Z}/6\mathbb{Z} \ncong S_3$ (abelian vs. non-abelian))**.** Both have order 6. Show they are not isomorphic.

Recognition. When the order ties, check abelian-ness first — it is the cheapest invariant. One of these is abelian and the other is not.

Solution. $\mathbb{Z}/6\mathbb{Z}$ is abelian (addition mod 6 commutes). S_3 is not: multiplying right-to-left, $(1\,2)(1\,3) = (1\,3\,2)$ while $(1\,3)(1\,2) = (1\,2\,3)$, and $(1\,3\,2) \neq (1\,2\,3)$. "Abelian" is an isomorphism invariant (Proposition 1.6.26); an abelian group cannot be isomorphic to a non-abelian one. Hence $\mathbb{Z}/6\mathbb{Z} \ncong S_3$. *Check (second invariant).* $\mathbb{Z}/6\mathbb{Z}$ is cyclic with an element of order 6 ($\bar{1}$); S_3 has element orders only in $\{1, 2, 3\}$ (no order-6 element), so the order multisets differ too: $\{1, 2, 3, 3, 6, 6\}$ vs. $\{1, 2, 2, 2, 3, 3\}$.

Worked Example 1.6.36 ($\mathbb{Z}/8\mathbb{Z} \ncong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ (largest element order))**.** Both abelian of order 8. Show they are not isomorphic.

Recognition. Same order, both abelian. Compare the maximum element order (a clean special case of the order-multiset invariant): a cyclic group of order 8 must contain an element of order 8.

Solution. $\mathbb{Z}/8\mathbb{Z}$ is cyclic: $|\bar{1}| = 8$. In $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, the order of (a, b) is $\operatorname{lcm}(|a|, |b|)$, where $|a| \mid 4$ and $|b| \mid 2$, so $|(a, b)| = \operatorname{lcm}(|a|, |b|) \mid \operatorname{lcm}(4, 2) = 4$. Thus *no* element of $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ has order 8, while $\mathbb{Z}/8\mathbb{Z}$ has $\varphi(8) = 4$ of them ($\bar{1}, \bar{3}, \bar{5}, \bar{7}$). The order-8 count differs (4 vs 0), so by Proposition 1.6.26 no isomorphism exists: $\mathbb{Z}/8\mathbb{Z} \ncong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. *Check.* Equivalently $\mathbb{Z}/8\mathbb{Z}$ is cyclic and $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ is not, since a finite abelian group is cyclic iff it has an element of order equal to the group order.

Caution. Matching "one element of order 2 here with one element of order 2 there" is necessary but a full isomorphism must match *all* counts simultaneously and respect multiplication. Conversely, to *disprove* you need only *one* invariant to differ — never try to check "all $|G|!$ bijections."

Remark 1.6.6. For cyclic targets the isomorphism is always the dashed completion of a triangle through $\mathbb{Z}$. Given any $g \in G$ with $|g| = n$, the surjection $\pi\colon \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ and $k \mapsto g^k$ share kernel $n\mathbb{Z}$, yielding a unique injective $\varphi\colon \mathbb{Z}/n\mathbb{Z} \to G$ with image $\langle g \rangle$:

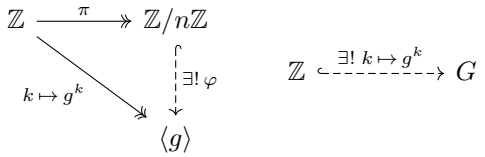


Diagram explanation. Objects: Left triangle: $\mathbb{Z}$ (free cyclic group, top-left), $\mathbb{Z}/n\mathbb{Z}$ (cyclic quotient of order n, top-right), $\langle g \rangle$ (cyclic subgroup of G generated by g with $|g| = n$, bottom). Right diagram: $\mathbb{Z}$ (left) and G (right, containing an element g of infinite order).

Arrows: Left triangle – $\pi\colon \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ is the surjective quotient map $k \mapsto \bar{k}$. The diagonal $k \mapsto g^k\colon \mathbb{Z} \to \langle g \rangle$ is the evaluation homomorphism. The dashed $\varphi\colon \mathbb{Z}/n\mathbb{Z} \hookrightarrow \langle g \rangle$ is the unique injective homomorphism induced by the universal property of $\mathbb{Z}/n\mathbb{Z}$; it is well-defined because $\ker(k \mapsto g^k) = n\mathbb{Z} = \ker \pi$, so choosing a different representative $k + n$ for $\bar{k}$ gives $g^{k+n} = g^k g^n = g^k \cdot 1 = g^k$. Right diagram – $k \mapsto g^k\colon \mathbb{Z} \to G$ is an isomorphism onto $\langle g \rangle$ when $|g| = \infty$; it is dashed here to emphasize it is the unique such map, with trivial kernel since $g^k = e$ forces $k = 0$.

What commutes: Left triangle: $\varphi \circ \pi = (k \mapsto g^k)$, i.e. $\varphi(\bar{k}) = g^k$ for all k. Right diagram is a single arrow (no non-trivial commutativity condition, but its uniqueness is its content).

Why it commutes: For the left triangle, chase $k \in \mathbb{Z}$: top-right π gives $\bar{k}$, then $\varphi(\bar{k}) = g^k$; diagonal directly gives g^k. Both paths agree by definition of φ. This is forced: any map $\mathbb{Z}/n\mathbb{Z} \to \langle g \rangle$ making the triangle commute must send $\bar{k}$ to g^k, giving uniqueness.

Why this matters here: This remark summarizes the *complete classification of cyclic groups.* The left triangle shows every cyclic group of finite order n is $\mathbb{Z}/n\mathbb{Z}$ (the unique group completing the triangle). The right arrow shows every cyclic group of infinite order is $\mathbb{Z}$. Together they say there is, up to isomorphism, exactly one cyclic group of each order.

Concrete example: $G = (\mathbb{R}^{>0}, \cdot)$, $g = e$ (base of ln), $|g| = \infty$: the right diagram gives $k \mapsto e^k\colon \mathbb{Z} \to \mathbb{R}^{>0}$, an injective homomorphism with image $\{e^k : k \in \mathbb{Z}\}$. For the finite case: $G = S_3$, $g = (1\,2\,3)$, $n = 3$; the triangle yields $\varphi(\bar{k}) = (1\,2\,3)^k$, an isomorphism $\mathbb{Z}/3\mathbb{Z} \cong \langle (1\,2\,3) \rangle$.

Common pitfall: The dashed hook φ in the left triangle is injective but need not be surjective onto all of G – it lands in $\langle g \rangle$, not all of G. Students sometimes conclude $\mathbb{Z}/n\mathbb{Z} \cong G$ when the triangle only gives $\mathbb{Z}/n\mathbb{Z} \cong \langle g \rangle \leq G$. Also, the two diagrams handle two separate cases ($|g|$ finite vs. infinite); they must not be conflated.

Takeaway: The point of this diagram is that for any cyclic group, the universal property of $\mathbb{Z}$ (or $\mathbb{Z}/n\mathbb{Z}$) automatically supplies the unique isomorphism, showing every cyclic group is either $\mathbb{Z}/n\mathbb{Z}$ for some $n \geq 1$ or $\mathbb{Z}$, with no other possibilities.

The right-hand diagram is the infinite-order analogue: if $|g| = \infty$ then $k \mapsto g^k$ is an isomorphism $\mathbb{Z} \cong \langle g \rangle$. This is why "cyclic of order n" and "cyclic of infinite order" are complete isomorphism classifications: every cyclic group is $\mathbb{Z}/n\mathbb{Z}$ or $\mathbb{Z}$.

Isomorphism as relabeling: roots of unity, products, and the limits of invariants

Remark 1.6.7. The informal reading of $G \cong H$ is that G and H are "the same group except for the names of the elements." Relabel each $x \in G$ as $\varphi(x)$ and the multiplication table of G becomes the multiplication table of H: the entry in row x, column y of G's table is xy, and φ sends it to $\varphi(xy) = \varphi(x)\varphi(y)$, which sits in row $\varphi(x)$, column $\varphi(y)$ of H's table. So the homomorphism condition is precisely "φ carries one Cayley table onto the other." This is the picture behind every isomorphism proof below; for a fully worked instance see the $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \cong V_4$ example.

Worked Example 1.6.37 ($\mathbb{Z} \cong 2\mathbb{Z}$ (the even integers))**.** Show that the additive group $(\mathbb{Z}, +)$ is isomorphic to its subgroup $2\mathbb{Z} = \{\ldots, -4, -2, 0, 2, 4, \ldots\}$ of even integers, even though $2\mathbb{Z} < \mathbb{Z}$ is a proper subgroup.

Recognition. The point is that an infinite group can be isomorphic to a proper subgroup of itself — impossible in the finite case, where $|G| = |H|$ forbids $H < G$. The trigger is "doubling" as a structure-preserving relabeling: every even integer is uniquely $2n$.

Solution. Define $\varphi\colon \mathbb{Z} \to 2\mathbb{Z}$ by $\varphi(n) = 2n$. *Homomorphism:* $\varphi(m+n) = 2(m+n) = 2m+2n = \varphi(m)+\varphi(n)$. *Bijective:* φ is injective ($2m = 2n \implies m = n$) and surjective (every even integer is $2n$ for some $n \in \mathbb{Z}$); the explicit inverse is $k \mapsto k/2$, defined on $2\mathbb{Z}$ and integer-valued there.

Check. $\varphi(0) = 0$, the identity of $2\mathbb{Z}$; $\varphi(-n) = -2n = -\varphi(n)$. Both groups are infinite cyclic, $\mathbb{Z} = \langle 1\rangle$ and $2\mathbb{Z} = \langle 2\rangle$, and φ sends the generator 1 to the generator 2, as an isomorphism of cyclic groups must. The order of G being infinite is exactly what permits $G \cong H$ with $H < G$.

Worked Example 1.6.38 ($\mathbb{Z}/n\mathbb{Z} \cong \mu_n$, the nth roots of unity)**.** Let $\mu_n = \{\, z \in \mathbb{C} : z^n = 1 \,\}$ be the group of complex nth roots of unity under multiplication. Show $\mathbb{Z}/n\mathbb{Z} \cong \mu_n$.

Recognition. This realizes the abstract cyclic group $\mathbb{Z}/n\mathbb{Z}$ concretely inside $\mathbb{C}^\times$. The trigger is De Moivre: $\zeta = e^{2\pi i/n}$ satisfies $\zeta^n = 1$ and has order exactly n, so $\mu_n = \langle\zeta\rangle$ is cyclic of order n. "Addition of exponents mod n becomes multiplication of powers of ζ" is the matching.

Solution. Put $\zeta = e^{2\pi i/n}$, so $\mu_n = \{1, \zeta, \zeta^2, \ldots, \zeta^{n-1}\}$ (n distinct points). Define $\varphi\colon \mathbb{Z}/n\mathbb{Z} \to \mu_n$ by $\varphi(\bar{k}) = \zeta^k$. *Well-defined:* if $\bar{k} = \bar{\ell}$ then $n \mid k-\ell$, and $\zeta^n = 1 \implies \zeta^{k-\ell} = 1 \implies \zeta^k = \zeta^\ell$. *Homomorphism:* $\varphi(\bar{k}+\bar{\ell}) = \zeta^{k+\ell} = \zeta^k\zeta^\ell = \varphi(\bar{k})\varphi(\bar{\ell})$, so addition mod n is sent to multiplication in $\mathbb{C}^\times$. *Bijective:* the n values $\zeta^0, \ldots, \zeta^{n-1}$ are distinct and exhaust μ_n, and $|\mathbb{Z}/n\mathbb{Z}| = n = |\mu_n|$.

Check. $\varphi(\bar{1}) = \zeta$ has order n in μ_n (its powers $1, \zeta, \ldots, \zeta^{n-1}$ are distinct, $\zeta^n = 1$), matching $|\bar{1}| = n$; orders of generators agree as Proposition 1.6.26 requires.

Worked Example 1.6.39 ($\mathrm{Sym}(\Delta) \cong S_3$ for any 3-element set Δ)**.** A symmetric group is determined up to isomorphism by the *cardinality* of the underlying set, not by the names of its points. Show that if $\Delta = \{a, b, c\}$ then $\mathrm{Sym}(\Delta) \cong S_3$, where $S_3 = \mathrm{Sym}(\{1, 2, 3\})$.

Recognition. Whenever two sets Δ, Ω admit a bijection $\theta\colon \Delta \to \Omega$, relabeling via θ turns permutations of Δ into permutations of Ω. The trigger is "conjugate by the relabeling bijection."

Solution. Fix the bijection $\theta\colon \Delta \to \{1, 2, 3\}$, $a \mapsto 1$, $b \mapsto 2$, $c \mapsto 3$. Define $\varphi\colon \mathrm{Sym}(\Delta) \to S_3$ by $\varphi(\sigma) = \theta\,\sigma\,\theta^{-1}$ (a permutation of $\{1, 2, 3\}$, since it is a composite of bijections). *Homomorphism:* for $\sigma, \tau \in \mathrm{Sym}(\Delta)$,

$$\varphi(\sigma\tau) = \theta\,\sigma\tau\,\theta^{-1} = \theta\,\sigma\,\theta^{-1}\theta\,\tau\,\theta^{-1} = \varphi(\sigma)\varphi(\tau),$$

the cancellation $\theta^{-1}\theta = \mathrm{id}$ supplying the middle step. *Bijective:* the map $\rho \mapsto \theta^{-1}\rho\,\theta$ is a two-sided inverse $S_3 \to \mathrm{Sym}(\Delta)$. *Check.* $\varphi(\mathrm{id}_\Delta) = \theta\ \mathrm{id}\ \theta^{-1} = \mathrm{id}_{\{1,2,3\}}$; the transposition $(a\,b)$ of Δ maps to $\theta(a\,b)\theta^{-1} = (1\,2)$, a transposition of the same cycle type, so element orders are preserved. The same argument gives $\mathrm{Sym}(\Delta) \cong S_n$ whenever $|\Delta| = n$.

Worked Example 1.6.40 ($\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \cong V_4$ via Cayley tables)**.** Confirm directly from multiplication tables that the abstract Klein four-group $V_4 = \{1, a, b, ab\}$ (all non-identity elements of order 2) is isomorphic to $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

Recognition. This is the table-matching technique of Remark 1.6.7 made fully explicit: write both tables, then find a bijection of the headers carrying one table onto the other.

Solution. Coordinates in $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ are $(0,0), (1,0), (0,1), (1,1)$ with componentwise addition mod 2. Set

$$\varphi(0,0) = 1, \quad \varphi(1,0) = a, \quad \varphi(0,1) = b, \quad \varphi(1,1) = ab.$$

Tables (group elements as headers, products in the body):

$\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}$	$(0,0)$	$(1,0)$	$(0,1)$	$(1,1)$
$(0,0)$	$(0,0)$	$(1,0)$	$(0,1)$	$(1,1)$
$(1,0)$	$(1,0)$	$(0,0)$	$(1,1)$	$(0,1)$
$(0,1)$	$(0,1)$	$(1,1)$	$(0,0)$	$(1,0)$
$(1,1)$	$(1,1)$	$(0,1)$	$(1,0)$	$(0,0)$

V_4	1	a	b	ab
1	1	a	b	ab
a	a	1	ab	b
b	b	ab	1	a
ab	ab	b	a	1

Applying φ to the left table cell-by-cell reproduces the right table exactly: e.g. $(1,0)+(0,1)=(1,1)$ maps to $a\cdot b=ab$, and $(1,0)+(1,0)=(0,0)$ maps to $a\cdot a=1$. Since φ is a bijection of headers and turns one table into the other, it is an isomorphism.

Check. Both tables are symmetric (abelian) and have the identity on the diagonal (every element its own inverse, order ≤ 2); the order multisets are both $\{1,2,2,2\}$. Consistent.

Worked Example 1.6.41 ($\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}\cong\mathbb{Z}/6\mathbb{Z}$ (a coprime product is cyclic))**.** Show $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}\cong\mathbb{Z}/6\mathbb{Z}$, even though it is a product of two smaller cyclic groups.

Recognition. "Built as a direct product" does not prevent a group from being cyclic. The trigger is coprimality: $\gcd(2,3)=1$, so the element $(\bar{1},\bar{1})$ should have order $\operatorname{lcm}(2,3)=6$, the full group order, forcing cyclicity.

Solution. Compute the order of $(\bar{1},\bar{1})\in\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}$. Adding it to itself:

$$(1,1),\ (0,2),\ (1,0),\ (0,1),\ (1,2),\ (0,0),$$

six distinct elements before returning to $(0,0)$, so $|(\bar{1},\bar{1})|=6=|\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}|$. Hence $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}=\langle(\bar{1},\bar{1})\rangle$ is cyclic of order 6, and every cyclic group of order 6 is isomorphic to $\mathbb{Z}/6\mathbb{Z}$ (Worked Example "Every cyclic group of order n is $\mathbb{Z}/n\mathbb{Z}$"). Explicitly $\varphi\colon\mathbb{Z}/6\mathbb{Z}\to\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}$, $\varphi(\bar{k})=k\cdot(\bar{1},\bar{1})$, is an isomorphism.

Check. The order multiset of $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}$ is $\{1,2,3,3,6,6\}$ (one element of order 2: $(1,0)$; two of order 3: $(0,1),(0,2)$; two of order 6: $(1,1),(1,2)$), identical to that of $\mathbb{Z}/6\mathbb{Z}$. Contrast $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}$, where $\gcd(2,2)=2\neq 1$ and no element reaches order 4, so that product is *not* cyclic — coprimality is essential.

Remark 1.6.8. Two reminders that a homomorphism need not be an isomorphism. The reduction map $\pi\colon\mathbb{Z}\to\mathbb{Z}/n\mathbb{Z}$, $\pi(a)=\bar{a}$, is a homomorphism but not injective for $n\geq 1$ ($\pi(n)=\bar{0}=\pi(0)$); here $|\mathbb{Z}|\neq|\mathbb{Z}/n\mathbb{Z}|$ blocks $\cong$ outright. The trivial map $\varphi\colon G\to H$, $\varphi(g)=1_H$ for all g, is always a homomorphism ($1_H=1_H\cdot 1_H$) but is an isomorphism only when $|G|=|H|=1$. In the other direction, a bijection that is *not* a homomorphism also fails: no set bijection $\mathbb{Z}/4\mathbb{Z}\to V_4$ can respect multiplication, since the two groups are not isomorphic at all.

Remark 1.6.9. The invariants of Remark 1.6.5 run only one way: matching them does *not* prove $G\cong H$. Same order is not enough ($\mathbb{Z}/4\mathbb{Z}$ and V_4 both have order 4 but are not isomorphic), and same order together with both being abelian is still not enough (again $\mathbb{Z}/4\mathbb{Z}\ncong V_4$). A single *disagreement* of any invariant disproves isomorphism instantly (Proposition 1.6.26); full *agreement* of a finite list of invariants is only evidence, and an actual isomorphism must still be exhibited.

Exercises (from the text).

1. φ a homomorphism. (a) $\varphi(x^n)=\varphi(x)^n$ ($n\in\mathbb{Z}^+$); (b) deduce it for all $n\in\mathbb{Z}$.
2. If φ is an isomorphism, prove $|\varphi(x)|=|x|$. True for a mere homomorphism?
3. φ isomorphism $\Rightarrow$ (G abelian iff H abelian). What extra hypothesis suffices for a homomorphism?
4. Prove $\mathbb{R}^\times$ and $\mathbb{C}^\times$ are not isomorphic.
5. Prove additive $\mathbb{R}$ and $\mathbb{Q}$ are not isomorphic.
6. Prove additive $\mathbb{Z}$ and $\mathbb{Q}$ are not isomorphic.
7. Prove D_8 and Q_8 are not isomorphic.
8. Prove $S_n\ncong S_m$ when $n\neq m$.
9. Prove D_{24} and S_4 are not isomorphic.
10. Show $S_\Delta\cong S_\Omega$ when $|\Delta|=|\Omega|$, via $\varphi(\sigma)=\theta\sigma\theta^{-1}$.
11. Prove $A\times B\cong B\times A$.
12. $G=A\times B$, $H=B\times C$: prove $G\times C\cong A\times H$.
13. φ a homomorphism: $\varphi(G)\leq H$, and if injective $G\cong\varphi(G)$.
14. $\ker\varphi$ is a subgroup, and φ injective iff $\ker\varphi=\{1\}$.

15. $\pi : \mathbb{R}^2 \to \mathbb{R}$, $\pi(x, y) = x$: find $\ker \pi$.
16. Projections π_1, π_2 of $A \times B$: find their kernels.
17. $g \mapsto g^{-1}$ is a homomorphism iff G is abelian.
18. $g \mapsto g^2$ is a homomorphism iff G is abelian.
19. $z \mapsto z^k$ (fixed $k > 1$) on the group of all roots of unity in $\mathbb{C}^\times$: surjective homomorphism, not an isomorphism.
20. Prove $\mathrm{Aut}(G)$ is a group under composition.
21. $q \mapsto kq$ ($k \in \mathbb{Q}^\times$) is an automorphism of $\mathbb{Q}$.
22. A abelian: $a \mapsto a^k$ is a homomorphism; an automorphism for $k = -1$.
23. G finite with a fixed-point-free order-2 automorphism $\Rightarrow G$ abelian.
24. G finite, $x \neq y$ of order 2 generating $G \Rightarrow G \cong D_{2n}$, $n = |xy|$.
25. $\varphi(r) =$ rotation matrix, $\varphi(s) =$ reflection: homomorphism $D_{2n} \to GL_2(\mathbb{R})$, injective.
26. $\varphi(i), \varphi(j)$ in $GL_2(\mathbb{C})$: homomorphism $Q_8 \to GL_2(\mathbb{C})$, injective.

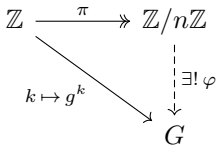
Additional exercises.

1. Decide whether each map is a homomorphism; if it is, find ker and image.
   (a) $\varphi : \mathbb{Z} \to \mathbb{Z}$ by $\varphi(n) = n + 1$.
   (b) $\varphi : \mathbb{R} \to \mathbb{R}$ (under $+$) by $\varphi(x) = 2x$.
   (c) $\varphi : \mathbb{Z} \to \mathbb{Q}^\times$ (the latter under $\times$) by $\varphi(n) = 2^n$.
   (d) $\varphi : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$ by $\varphi(A) = \det A$.
   (e) $\varphi : G \to G$ by $\varphi(g) = g^{-1}$, where G is an arbitrary group (state exactly which G make this a homomorphism).
2. Let $\varphi : G \to H$ be a homomorphism. Prove directly from the defining identity $\varphi(xy) = \varphi(x)\varphi(y)$ that $\varphi(1_G) = 1_H$ and $\varphi(g^{-1}) = \varphi(g)^{-1}$ for all $g \in G$, and conclude that $\varphi(g^n) = \varphi(g)^n$ for every $n \in \mathbb{Z}$.
3. Let $\varphi : G \to H$ be a homomorphism and let $g \in G$ have finite order $|g| = n$. Show $|\varphi(g)|$ divides n. Give an explicit example with $G = \mathbb{Z}/12\mathbb{Z}$, $H = \mathbb{Z}/12\mathbb{Z}$, and a g of order 12 whose image has order exactly 3, and identify the homomorphism you used.
4. Determine, with proof, whether the following pairs of groups are isomorphic.
   (a) $\mathbb{Z}/4\mathbb{Z}$ and V_4.
   (b) $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ and $\mathbb{Z}/6\mathbb{Z}$.
   (c) $(\mathbb{Z}/8\mathbb{Z})^\times$ and $\mathbb{Z}/4\mathbb{Z}$.
   (d) D_8 and Q_8.
   (e) S_3 and $\mathbb{Z}/6\mathbb{Z}$.

   For each non-isomorphic pair, name one isomorphism invariant (order count by element order, abelian-or-not, number of subgroups, etc.) that distinguishes them.
5. Let $\varphi : G \to H$ be an isomorphism. Prove that for each $k \geq 1$ the number of elements of order k in G equals the number in H. Then use this to show $(\mathbb{Z}/15\mathbb{Z})^\times \ncong \mathbb{Z}/8\mathbb{Z}$ by tabulating the orders of all elements on both sides.
6. Recall $\mathrm{Aut}(G)$ is the group of isomorphisms $G \to G$ under composition.
   (a) Compute $\mathrm{Aut}(\mathbb{Z}/8\mathbb{Z})$ and identify it up to isomorphism with a familiar group of order 4.

(b) Show that for the Klein four-group, $\mathrm{Aut}(V_4) \cong S_3$, by describing how an automorphism permutes the three nonidentity elements.

7. For a fixed $g \in G$ let $\psi_g : G \to G$ be conjugation, $\psi_g(x) = gxg^{-1}$. Prove $\psi_g \in \mathrm{Aut}(G)$, that $g \mapsto \psi_g$ is a homomorphism $G \to \mathrm{Aut}(G)$, and compute its kernel. (Its image is $\mathrm{Inn}(G)$.)

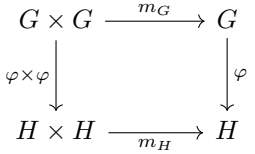


Commutative-diagram exercises.

1. (Universal property of $\mathbb{Z}$.) Let G be any group and $g \in G$. Show there is a unique homomorphism $\varphi : \mathbb{Z} \to G$ with $\varphi(1) = g$, namely $\varphi(k) = g^k$, making the triangle commute:

State precisely what "$\varphi(1) = g$" forces and why uniqueness follows.

2. (Universal property of $\mathbb{Z}/n\mathbb{Z}$.) Fix $g \in G$ with $g^n = 1$. Show the diagonal map $k \mapsto g^k$ factors uniquely through the quotient $\pi : \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$, i.e. there is a unique homomorphism $\varphi : \mathbb{Z}/n\mathbb{Z} \to G$ with $\varphi \circ \pi$ equal to the diagonal:

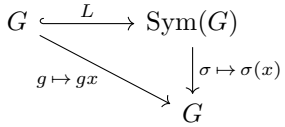


Show the condition $g^n = 1$ is exactly what is needed for φ to be well defined, and use this to build the isomorphism $\mathbb{Z}/6\mathbb{Z} \cong \langle g \rangle$ when $|g| = 6$.

3. (Kernel as an exact sequence.) Let $\varphi : G \to H$ be a homomorphism with kernel $K = \ker \varphi$ and let $\iota : K \hookrightarrow G$ be the inclusion. Verify that

$$1 \longrightarrow \ker \varphi \xhookrightarrow{\iota} G \xrightarrow{\varphi} H$$

is exact at $\ker \varphi$ and at G (i.e. ι is injective and $\operatorname{im} \iota = \ker \varphi$). Then prove φ is injective if and only if $\ker \varphi = \{1\}$, and restate this as: the sequence extends to $1 \to G \xrightarrow{\varphi} H$ being exact at G precisely when K is trivial.



4. (Naturality square.) A map $\varphi : G \to H$ is a homomorphism if and only if the multiplication square commutes, where m_G, m_H are the group multiplications:

Prove both directions by chasing a general element $(x, y) \in G \times G$ around the square, and explain in one sentence why commutativity of this single square encodes the entire homomorphism axiom.

5. (Permutation representation / left regular action.) For $g \in G$ define $\lambda_g : G \to G$ by $\lambda_g(x) = gx$.

   (a) Show $\lambda_g \in \mathrm{Sym}(G)$ and that $L : G \to \mathrm{Sym}(G)$, $L(g) = \lambda_g$, is an injective homomorphism, so that for each fixed $x \in G$ the triangle

   commutes (Cayley's theorem). State $\ker L$.

(b) Take $G = \mathbb{Z}/3\mathbb{Z} = \{0, 1, 2\}$ and write each λ_g explicitly as a permutation in cycle notation, exhibiting L as an isomorphism onto a subgroup of S_3.

1.7 Group Actions

Group actions: the two axioms, the permutation representation, kernels, and faithfulness

Definition 1.7.1 (Left group action)**.** Let G be a group and A a nonempty set. A *left action* of G on A is a map $G \times A \to A$, written $(g, a) \mapsto g \cdot a$, satisfying the two axioms

$$\textbf{(A1)} \quad 1 \cdot a = a \ \text{ for all } a \in A, \qquad \textbf{(A2)} \quad (gh) \cdot a = g \cdot (h \cdot a) \ \text{ for all } g, h \in G,\ a \in A.$$

We say "G acts on A."

Definition 1.7.2 (Permutation representation, kernel, faithful)**.** Given an action, for each $g \in G$ define $\sigma_g \colon A \to A$ by $\sigma_g(a) = g \cdot a$. The *permutation representation* is the map

$$\rho \colon G \to \mathrm{Sym}(A), \qquad \rho(g) = \sigma_g = \big(a \mapsto g \cdot a\big).$$

Its *kernel* is $\ker \rho = \{g \in G : g \cdot a = a \text{ for all } a \in A\}$, also called the *kernel of the action*. The action is *faithful* when $\ker \rho = 1$.

Theorem 1.7.3 (Actions $\leftrightarrow$ homomorphisms to $\mathrm{Sym}(A)$)**.** *Let G be a group and A a nonempty set.*

(a) If $G \times A \to A$ is a left action, then each $\sigma_g \in \mathrm{Sym}(A)$ and the map $\rho \colon G \to \mathrm{Sym}(A)$, $g \mapsto \sigma_g$, is a group homomorphism.

(b) Conversely, if $\rho \colon G \to \mathrm{Sym}(A)$ is any homomorphism, then $g \cdot a := \rho(g)(a)$ defines a left action whose representation is ρ.

Thus left actions of G on A correspond bijectively to homomorphisms $G \to \mathrm{Sym}(A)$. Moreover the action is faithful iff ρ is injective, and in that case $G \cong \rho(G) \leq \mathrm{Sym}(A)$.

Proof. (a) Each σ_g is a bijection: by (A2) and (A1), $\sigma_g \circ \sigma_{g^{-1}}(a) = g \cdot (g^{-1} \cdot a) = (gg^{-1}) \cdot a = 1 \cdot a = a$ and symmetrically $\sigma_{g^{-1}} \circ \sigma_g = \mathrm{id}_A$, so σ_g has two-sided inverse $\sigma_{g^{-1}}$, hence $\sigma_g \in \mathrm{Sym}(A)$. For the homomorphism property, (A2) reads, for all a, $\sigma_{gh}(a) = (gh) \cdot a = g \cdot (h \cdot a) = \sigma_g(\sigma_h(a)) = (\sigma_g \circ \sigma_h)(a)$, so $\rho(gh) = \sigma_{gh} = \sigma_g \circ \sigma_h = \rho(g)\rho(h)$.

(b) Set $g \cdot a := \rho(g)(a)$. Then $1 \cdot a = \rho(1)(a) = \mathrm{id}_A(a) = a$, giving (A1); and $(gh) \cdot a = \rho(gh)(a) = (\rho(g)\rho(h))(a) = \rho(g)\big(\rho(h)(a)\big) = g \cdot (h \cdot a)$, giving (A2). Its representation sends g to $a \mapsto \rho(g)(a) = \rho(g)$, recovering ρ.

Finally $\ker \rho = \{g : \sigma_g = \mathrm{id}_A\} = \{g : g \cdot a = a\ \forall a\}$, so faithful $\iff$ $\ker \rho = 1$ $\iff$ ρ injective. When injective, the first isomorphism theorem gives $G \cong \rho(G) \leq \mathrm{Sym}(A)$. □

The correspondence is exactly the commutative triangle: "act, then read off the permutation" agrees with "apply the homomorphism."

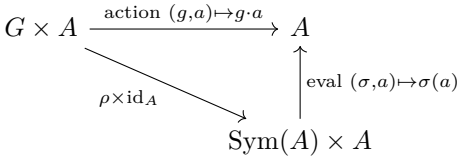


Diagram explanation. Objects: Three nodes. $G \times A$ is the Cartesian product of the group G and the set A; elements are pairs (g, a). A is the set being acted on. $\mathrm{Sym}(A) \times A$ is the product of the symmetric group on A with A itself; elements are pairs (σ, a) where σ is a bijection.

Arrows: Top arrow (horizontal): the given action map $(g, a) \mapsto g \cdot a$; it sends a group element together with a set element to the result of the group acting. Left-to-lower-right arrow (diagonal): $\rho \times \mathrm{id}_A$, the product of

the permutation representation $\rho\colon G \to \mathrm{Sym}(A)$ with the identity on A; it sends (g, a) to $(\rho(g), a) = (\sigma_g, a)$. Right vertical arrow (going up): the evaluation map $(\sigma, a) \mapsto \sigma(a)$; it applies a permutation to an element.

What commutes: The triangle commutes: the top map equals the composition of the diagonal followed by the vertical, i.e. $\mathrm{eval} \circ (\rho \times \mathrm{id}_A) = \text{action}$. In formulas: $(\rho(g), a) \mapsto \rho(g)(a) = \sigma_g(a) = g \cdot a$.

Why it commutes: Take a generic pair $(g, a) \in G \times A$. The diagonal sends it to $(\sigma_g, a) \in \mathrm{Sym}(A) \times A$; the vertical evaluation then gives $\sigma_g(a) = g \cdot a$. The top arrow sends (g, a) directly to $g \cdot a$. These are equal by the very definition $\sigma_g(a) := g \cdot a$ (Definition 1.7.2). The definition of the permutation representation is precisely the equation that makes this triangle commute.

Why this matters here: This diagram is the visual statement of Theorem 1.7.3: acting via the original group action is the same as first applying the permutation representation ρ to get a bijection, then evaluating that bijection. It encodes the equivalence between "acting" and "having a homomorphism into $\mathrm{Sym}(A)$", the central result of this section.

Concrete example: Take $G = \mathbb{Z}/4\mathbb{Z}$ acting on $A = \mathbb{Z}/4\mathbb{Z}$ by addition (the regular action). Then $\rho(1) = \sigma_1 = (0\,1\,2\,3) \in \mathrm{Sym}(\mathbb{Z}/4\mathbb{Z})$ (this is $(1\,2\,3\,4) \in S_4$ under the labeling $i \leftrightarrow i+1$ used below). The pair $(g, a) = (1, 0)$: the top arrow gives $1 + 0 = 1$; the diagonal gives $(\sigma_1, 0)$ and evaluation gives $\sigma_1(0) = 1$. Same answer.

Common pitfall: Students sometimes think this diagram asserts that ρ is an isomorphism or that $\mathrm{Sym}(A) \times A$ and $G \times A$ are identified. They are not: the diagram only records that the two routes from $G \times A$ to A agree. The map ρ need not be injective or surjective.

Takeaway: The point of this diagram is that the permutation representation ρ is not extra data layered on top of the action but is exactly the action itself, repackaged as a homomorphism.

And the kernel sits in the factorization below (here $\overline{\rho}$ is the induced injection $G/\ker\rho \hookrightarrow \mathrm{Sym}(A)$):

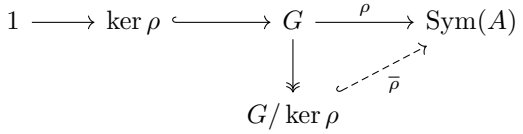

Diagram explanation. Objects: Five nodes. 1 is the trivial group. $\ker\rho$ is the kernel of the permutation representation, a normal subgroup of G. G is the group acting on A. $G/\ker\rho$ is the quotient group obtained by collapsing the kernel; elements are cosets $g\ker\rho$. $\mathrm{Sym}(A)$ is the symmetric group on A, the target of ρ.

Arrows: $1 \to \ker\rho$: inclusion of the trivial group (begins the exact sequence). Hooked arrow $\ker\rho \hookrightarrow G$: the inclusion of the kernel as a subgroup. Horizontal $\rho\colon G \to \mathrm{Sym}(A)$: the permutation representation. Vertical two-headed arrow $G \twoheadrightarrow G/\ker\rho$: the canonical surjection $\pi\colon g \mapsto g\ker\rho$. Dashed hooked arrow $\overline{\rho}\colon G/\ker\rho \hookrightarrow \mathrm{Sym}(A)$: the induced injective homomorphism, $\overline{\rho}(g\ker\rho) := \rho(g)$.

What commutes: The triangle: $\rho = \overline{\rho} \circ \pi$, i.e. $\rho(g) = \overline{\rho}(g\ker\rho)$. The top row is exact: $\mathrm{im}(1 \to \ker\rho) = \{1\} = \ker(\ker\rho \hookrightarrow G)$, and $\mathrm{im}(\ker\rho \hookrightarrow G) = \ker\rho = \ker\rho$.

Why it commutes: Well-definedness of $\overline{\rho}$: if $g\ker\rho = g'\ker\rho$ then $g^{-1}g' \in \ker\rho$, so $\rho(g^{-1}g') = \mathrm{id}$, giving $\rho(g) = \rho(g')$; thus $\overline{\rho}$ does not depend on the choice of coset representative. With $\overline{\rho}$ well-defined, $\overline{\rho}(\pi(g)) = \overline{\rho}(g\ker\rho) = \rho(g)$, which is the commutativity relation. Injectivity: $\overline{\rho}(g\ker\rho) = \mathrm{id}$ iff $\rho(g) = \mathrm{id}$ iff $g \in \ker\rho$ iff $g\ker\rho = \ker\rho$ is the identity coset.

Why this matters here: This is the first isomorphism theorem applied to ρ: every action factors as surjection-onto-quotient followed by an injection, making $G/\ker\rho$ isomorphic to the image $\rho(G) \leq \mathrm{Sym}(A)$. It explains why the action is faithful iff $\ker\rho = 1$.

Concrete example: D_8 acting on the two diagonals: $\rho\colon D_8 \to S_2$, $\ker\rho = \{1, r^2, s, sr^2\} \cong V_4$. Then $\overline{\rho}\colon D_8/V_4 \hookrightarrow S_2$ is an isomorphism $\mathbb{Z}/2\mathbb{Z} \cong S_2$.

Common pitfall: The dashed arrow $\overline{\rho}$ is injective (not an isomorphism onto all of $\mathrm{Sym}(A)$), because ρ need not be surjective. Students sometimes expect $G/\ker\rho \cong \mathrm{Sym}(A)$; the correct statement is $G/\ker\rho \cong \rho(G)$, a subgroup.

Takeaway: The point of this diagram is that every permutation representation factors canonically through its own quotient, giving an *injective* representation of $G/\ker\rho$ and pinpointing exactly which part of G the action "sees."

Method (Verify an action, build ρ, find the kernel, decide faithfulness)**.** Given a candidate map $G \times A \to A$:

1. **(A1)** Check $1 \cdot a = a$ for every a (just plug in the identity).
2. **(A2)** Check $(gh) \cdot a = g \cdot (h \cdot a)$ for all g, h, a; do the two sides separately and compare. This is where a fake "action" usually dies.
3. **Build ρ.** For each g, write $\sigma_g = (a \mapsto g \cdot a)$ as an explicit permutation of A (in cycle notation if A is finite and labeled $1, \ldots, n$).
4. **Kernel.** Solve $g \cdot a = a$ *simultaneously for all* a; the set of such g is $\ker \rho$ (a normal subgroup of G).
5. **Faithful?** The action is faithful iff that kernel is $\{1\}$ iff distinct g give distinct permutations σ_g.

Trigger. Use this checklist whenever you are handed a rule "$g \cdot a = \ldots$" and asked "is it an action / what is its permutation representation / is it faithful?"

Caution. Right-to-left composition matters: (A2) forces $\rho(gh) = \rho(g)\rho(h)$ *in that order.* A *right* action $a \cdot (gh) = (a \cdot g) \cdot h$ instead gives an anti-homomorphism; to convert a right action to a left one use $g \cdot a := a \cdot g^{-1}$, not $a \cdot g$.

Example family 1: the left regular action and Cayley's theorem

Theorem 1.7.4 (Cayley)**.** *Every group G acts on itself by left multiplication, $g \cdot x = gx$. This action is faithful, so $\rho\colon G \hookrightarrow \mathrm{Sym}(G)$ embeds G as a subgroup of $\mathrm{Sym}(G)$. If $|G| = n$ then $G \cong$ a subgroup of S_n.*

Proof. (A1): $1 \cdot x = 1x = x$. (A2): $(gh) \cdot x = (gh)x = g(hx) = g \cdot (h \cdot x)$ by associativity. Kernel: $g \cdot x = x$ for all x means $gx = x$ for all x; taking $x = 1$ gives $g = 1$, so $\ker \rho = 1$ and ρ is injective. With $|G| = n$, choosing a labeling $G \leftrightarrow \{1, \ldots, n\}$ gives $\mathrm{Sym}(G) \cong S_n$, so $G \cong \rho(G) \leq S_n$. □

$$G \xhookrightarrow{\rho\,:\,g \mapsto (x \mapsto gx)} \mathrm{Sym}(G)$$

Diagram explanation. Objects: Two nodes. G is the group viewed simultaneously as the group acting and as the set being acted on (the regular action uses the group as its own set). $\mathrm{Sym}(G)$ is the symmetric group of all bijections from the underlying set of G to itself; its order is $|G|!$ if G is finite.

Arrows: A single hooked arrow $\rho\colon G \hookrightarrow \mathrm{Sym}(G)$, labeled by its formula. The hook denotes injectivity. For each $g \in G$, $\rho(g)$ is the bijection $x \mapsto gx$ (left multiplication by g). This is the permutation representation of the left regular action.

What commutes: There is only one arrow, so commutativity is not the key property; the essential statement is that ρ is a *homomorphism* and is *injective*: $\rho(gh)(x) = (gh)x = g(hx) = \rho(g)(\rho(h)(x))$, so $\rho(gh) = \rho(g)\rho(h)$; and $\rho(g) = \mathrm{id}$ iff $gx = x$ for all x iff $g = 1$ (take $x = 1$).

Why it commutes: The homomorphism property comes directly from associativity in G: $\rho(gh) = \sigma_{gh}$ and $\sigma_{gh}(x) = (gh)x = g(hx) = \sigma_g(\sigma_h(x)) = (\rho(g)\rho(h))(x)$. Injectivity follows because left-multiplying by any $g \neq 1$ moves the identity element 1 to $g \neq 1$, so no nonidentity element is in the kernel.

Why this matters here: This is Cayley's theorem (Theorem 1.7.4) summarized in one arrow: every group embeds into a symmetric group. The diagram records the embedding without specifying $|G|$, making the result universal.

Concrete example: $G = \mathbb{Z}/4\mathbb{Z}$: $\rho(1) = (1\,2\,3\,4)$ as computed in the worked example below. The image $\rho(\mathbb{Z}/4\mathbb{Z}) = \langle (1\,2\,3\,4) \rangle \leq S_4$ is a cyclic subgroup of order 4. The hook reflects that ρ is injective and $\mathbb{Z}/4\mathbb{Z} \cong \langle (1\,2\,3\,4) \rangle$.

Common pitfall: The arrow is into $\mathrm{Sym}(G)$, which treats G as a bare set of $|G|$ elements. Students confuse the two roles of G: as a group (source of ρ) and as a set (on which $\mathrm{Sym}(G)$ acts). The bijection $\rho(g)$ is *not* a group homomorphism of G; it is just a permutation.

Takeaway: The point of this diagram is that the left regular action is always faithful, which is why every group embeds as a concrete subgroup of a symmetric group.

Worked Example 1.7.5 (Left regular action of $\mathbb{Z}/4\mathbb{Z}$, representation into S_4)**.** Take $G = \mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}$ acting on itself, $g \cdot x = g + x$. Label elements by $0 \leftrightarrow 1,\ 1 \leftrightarrow 2,\ 2 \leftrightarrow 3,\ 3 \leftrightarrow 4$. Compute ρ and $\ker \rho$.

Recognition. "G on itself by the group operation" is the left regular action; Cayley (Thm. 1.7.4) says it is automatically an action and faithful. The work is to write each σ_g as an explicit element of S_4.

Solution. Axioms come free from Cayley. Now $\sigma_g(x) = g + x \pmod 4$.

- $g = 0$: $x \mapsto x$, so $\sigma_0 = \mathrm{id} = ()$.
- $g = 1$: $0 \mapsto 1 \mapsto 2 \mapsto 3 \mapsto 0$, i.e. labels $1 \mapsto 2 \mapsto 3 \mapsto 4 \mapsto 1$, so $\sigma_1 = (1\,2\,3\,4)$.
- $g = 2$: $0 \mapsto 2, 1 \mapsto 3, 2 \mapsto 0, 3 \mapsto 1$, so $\sigma_2 = (1\,3)(2\,4)$.
- $g = 3$: $0 \mapsto 3 \mapsto 2 \mapsto 1 \mapsto 0$, so $\sigma_3 = (1\,4\,3\,2)$.

So $\rho(\mathbb{Z}/4\mathbb{Z}) = \{(), (1\,2\,3\,4), (1\,3)(2\,4), (1\,4\,3\,2)\} = \langle (1\,2\,3\,4) \rangle$, a cyclic subgroup of S_4 of order 4. Kernel: $\sigma_g = \mathrm{id}$ forces $g + x = x$ for all x, i.e. $g = 0$, so $\ker \rho = \{0\} = 1$ and the action is faithful. *Check.* $\sigma_1^2 = (1\,2\,3\,4)^2 = (1\,3)(2\,4) = \sigma_2$ and $\rho(1 + 1) = \rho(2) = \sigma_2$ – the homomorphism property holds. ρ has image of order $4 = |\mathbb{Z}/4\mathbb{Z}|$, confirming injectivity.

Worked Example 1.7.6 (Left regular action of V_4, representation into S_4)**.** Let $V_4 = \{1, a, b, c\}$ with $a^2 = b^2 = c^2 = 1$, $ab = c$. Label $1 \leftrightarrow 1, a \leftrightarrow 2, b \leftrightarrow 3, c \leftrightarrow 4$. Find $\rho(V_4) \leq S_4$.

Recognition. Same regular action; faithful by Cayley. We just tabulate left-multiplication columns.

Solution. Since V_4 is abelian with $ab = c$, the products are $ac = a(ab) = a^2b = b$, $bc = b(ab) = ab^2 = a$, and similarly $ca = b$, $cb = a$. Left-multiply by a: $a \cdot 1 = a,\ a \cdot a = 1,\ a \cdot b = ab = c,\ a \cdot c = ac = b$. So σ_a sends $1 \mapsto 2, 2 \mapsto 1, 3 \mapsto 4, 4 \mapsto 3$, i.e. $\sigma_a = (1\,2)(3\,4)$. Left-multiply by b: $b \cdot 1 = b,\ b \cdot a = ba = ab = c,\ b \cdot b = 1,\ b \cdot c = bc = a$, so $\sigma_b : 1 \mapsto 3, 3 \mapsto 1, 2 \mapsto 4, 4 \mapsto 2$, i.e. $\sigma_b = (1\,3)(2\,4)$. And $c \cdot 1 = c,\ c \cdot a = ca = b,\ c \cdot b = cb = a,\ c \cdot c = 1$, so $\sigma_c = (1\,4)(2\,3)$. Hence

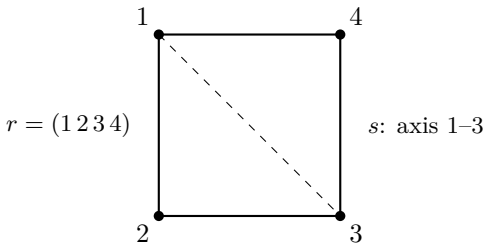
$$\rho(V_4) = \{(), (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\} \leq S_4,$$

the standard copy of V_4 in S_4. Kernel $= 1$ (regular actions are faithful). *Check.* $\sigma_a\sigma_b = (1\,2)(3\,4) \cdot (1\,3)(2\,4)$; apply right factor then left: $1 \mapsto 3 \mapsto 4, 2 \mapsto 4 \mapsto 3, 3 \mapsto 1 \mapsto 2, 4 \mapsto 2 \mapsto 1$ gives $(1\,4)(2\,3) = \sigma_c = \rho(ab)$. Consistent.

Worked Example 1.7.7 (Left regular action of S_3, image inside S_6)**.** Cayley embeds S_3 (order 6) into S_6. Compute σ_g for the transposition $g = (1\,2) \in S_3$, where S_3 acts on its own 6 elements.

Recognition. Regular action of a nonabelian group; faithful. The subtlety is that the indices "$1 \ldots 6$" label the *group elements*, not the points S_3 originally permuted.

Solution. List $S_3 = \{e_1{=}1, e_2{=}(1\,2), e_3{=}(1\,3), e_4{=}(2\,3), e_5{=}(1\,2\,3), e_6{=}(1\,3\,2)\}$. With $g = (1\,2)$ compute ge_i (product in S_3, composing right to left): $ge_1 = (1\,2) = e_2$; $ge_2 = (1\,2)(1\,2) = 1 = e_1$; $ge_3 = (1\,2)(1\,3) = (1\,3\,2) = e_6$; $ge_4 = (1\,2)(2\,3) = (1\,2\,3) = e_5$; $ge_5 = (1\,2)(1\,2\,3) = (2\,3) = e_4$; $ge_6 = (1\,2)(1\,3\,2) = (1\,3) = e_3$. So on the labels, $\sigma_g = (1\,2)(3\,6)(4\,5) \in S_6$. This is a product of three transpositions, hence an odd permutation moving all 6 points (no fixed points) – indeed every nonidentity element of a regular action is *fixed-point-free*. *Check.* $g^2 = 1$ in S_3, and $\sigma_g^2 = \big((1\,2)(3\,6)(4\,5)\big)^2 = ()$, matching $\rho(g^2) = \rho(1) = \mathrm{id}$. The kernel is trivial since $ge_1 = e_2 \neq e_1$ already for $g = e_2$, etc.



Worked Example 1.7.8 (Why "left mult" is needed: $g \cdot x = xg$ is *not* a left action)**.** Show that $g \cdot x := xg$ on G fails (A2) unless G is abelian, and fix it.

Recognition. Test (A2) literally; a swapped order is the classic trap that produces an anti-homomorphism.

Solution. $(gh) \cdot x = x(gh) = xgh$, but $g \cdot (h \cdot x) = g \cdot (xh) = (xh)g = xhg$. These agree for all x iff $gh = hg$ for all g, h, i.e. iff G abelian. So for nonabelian G it is not a left action. **Fix:** $g \cdot x := xg^{-1}$ *is* a left action: $(gh) \cdot x = x(gh)^{-1} = xh^{-1}g^{-1} = (xh^{-1})g^{-1} = g \cdot (h \cdot x)$, and $1 \cdot x = x1^{-1} = x$. *Check.* Kernel of the fixed action: $xg^{-1} = x$ for all $x \Rightarrow g^{-1} = 1 \Rightarrow g = 1$, so it is also faithful (this is the right regular action recast on the left).

Example family 2: D_8 on the square, and S_n on $\{1, \dots, n\}$

Label the vertices of the square cyclically $1, 2, 3, 4$. The generator r is rotation by $90°$ (counterclockwise) and s is the reflection fixing the diagonal through vertices 1 and 3.

Proposition 1.7.9 (D_8 acts faithfully on the 4 vertices)**.** *D_8 acts on $A = \{1, 2, 3, 4\}$ by its geometric action on the square's vertices. The representation $\rho\colon D_8 \to S_4$ is injective ($\ker \rho = 1$), and $\rho(r) = (1\,2\,3\,4)$, $\rho(s) = (2\,4)$.*

Proof. Symmetries of the square permute its vertices, and composing symmetries composes the permutations, so (A1),(A2) hold and ρ is a homomorphism. Rotation by $90°$ sends $1 \to 2 \to 3 \to 4 \to 1$, so $\rho(r) = (1\,2\,3\,4)$. The reflection across the 1–3 diagonal fixes $1, 3$ and swaps $2, 4$, so $\rho(s) = (2\,4)$. A symmetry fixing all four vertices is the identity, so $\ker \rho = 1$ and ρ is injective; thus $D_8 \cong \rho(D_8) \leq S_4$, the image being a Sylow 2-subgroup of S_4. □

Worked Example 1.7.10 (Build the full table $\rho\colon D_8 \to S_4$ and check the relations)**.** Write $\rho(g)$ for all eight $g \in D_8 = \{1, r, r^2, r^3, s, sr, sr^2, sr^3\}$ and verify $sr = r^{-1}s$ at the level of permutations.

Recognition. We have the generators' images (Prop. 1.7.9); since ρ is a homomorphism, every other image is a product. Use $\rho(sr^k) = \rho(s)\rho(r)^k = SR^k$, composing right to left.

Solution. With $R := \rho(r) = (1\,2\,3\,4)$ and $S := \rho(s) = (2\,4)$ we first record the rotation powers $R^2 = (1\,3)(2\,4)$, $R^3 = (1\,4\,3\,2)$. Now compute each $\rho(sr^k) = SR^k$ by applying R^k first, then S.

- $k = 0$: $\rho(s) = S = (2\,4)$.
- $k = 1$: SR. Apply R then S: $1 \mapsto 2 \mapsto 4$, $4 \mapsto 1 \mapsto 1$, so $1 \leftrightarrow 4$; $2 \mapsto 3 \mapsto 3$, $3 \mapsto 4 \mapsto 2$, so $2 \leftrightarrow 3$. Hence $\rho(sr) = (1\,4)(2\,3)$.
- $k = 2$: SR^2. Apply R^2 then S: $1 \mapsto 3 \mapsto 3$, $3 \mapsto 1 \mapsto 1$, so $1 \leftrightarrow 3$; $2 \mapsto 4 \mapsto 2$ and $4 \mapsto 2 \mapsto 4$ are fixed. Hence $\rho(sr^2) = (1\,3)$.
- $k = 3$: SR^3. Apply R^3 then S: $1 \mapsto 4 \mapsto 2$, $2 \mapsto 1 \mapsto 1$, so $1 \mapsto 2 \mapsto 1$ gives $1 \leftrightarrow 2$; $3 \mapsto 2 \mapsto 4$, $4 \mapsto 3 \mapsto 3$, so $3 \leftrightarrow 4$. Hence $\rho(sr^3) = (1\,2)(3\,4)$.

The complete table is

g	1	r	r^2	r^3	s	sr	sr^2	sr^3
$\rho(g)$	$()$	$(1\,2\,3\,4)$	$(1\,3)(2\,4)$	$(1\,4\,3\,2)$	$(2\,4)$	$(1\,4)(2\,3)$	$(1\,3)$	$(1\,2)(3\,4)$

Verify $sr = r^{-1}s$**:** LHS $= \rho(sr) = (1\,4)(2\,3)$. RHS $= R^{-1}S$ with $R^{-1} = (1\,4\,3\,2)$: apply $S = (2\,4)$ then R^{-1}: $1 \mapsto 1 \mapsto 4$, $4 \mapsto 2 \mapsto 1$, so $1 \leftrightarrow 4$; $2 \mapsto 4 \mapsto 3$, $3 \mapsto 3 \mapsto 2$, so $2 \leftrightarrow 3$. Thus $R^{-1}S = (1\,4)(2\,3) =$ LHS. *Check.* All 8 images are distinct, reconfirming $\ker \rho = 1$.

Worked Example 1.7.11 (D_8 acting on the 2 diagonals: a non-faithful action)**.** Let D_8 act on the set $A = \{d_{13}, d_{24}\}$ of the square's two diagonals. Compute $\rho\colon D_8 \to S_2$ and its kernel.

Recognition. Same group, smaller set, so the rep lands in S_2 (order 2) while $|D_8| = 8$; a counting clash ($8 > 2$) forces a nontrivial kernel – a textbook non-faithful action.

Solution. r (rotate $90°$) sends diagonal 1–3 to 2–4, so it swaps $d_{13} \leftrightarrow d_{24}$: $\rho(r) = (d_{13}\,d_{24})$. The reflection s across 1–3 fixes that axis and maps the other diagonal to itself, so $\rho(s) = \mathrm{id}$. Since r, s generate D_8, the

image is $\langle (d_{13}\, d_{24}) \rangle = S_2$. The homomorphism $\rho\colon D_8 \to S_2$ is onto S_2, so by the first isomorphism theorem $|\ker \rho| = 8/2 = 4$. Explicitly $g \in \ker \rho$ iff g fixes each diagonal: these are $\{1, r^2, s, sr^2\}$ (check: r^2 rotates 180° fixing both diagonals; s and sr^2 are the two reflections through the diagonals). So $\ker \rho = \{1, r^2, s, sr^2\} \cong V_4$, the action is *not* faithful. *Check.* $|\{1, r^2, s, sr^2\}| = 4$ matches $8/|\operatorname{im} \rho| = 8/2 = 4$, and one verifies this set is a subgroup (indeed normal, as kernels must be).

Worked Example 1.7.12 (S_n on $\{1, \dots, n\}$ is faithful)**.** The natural action $\sigma \cdot i = \sigma(i)$ of S_n on $A = \{1, \dots, n\}$. Show it is an action and compute its kernel.

Recognition. "$\sigma \cdot i = \sigma(i)$" is the defining/tautological action; ρ is the identity map $S_n \to \operatorname{Sym}(A) = S_n$, the cleanest possible representation.

Solution. (A1): $1 \cdot i = \mathrm{id}(i) = i$. (A2): $(\sigma\tau) \cdot i = (\sigma\tau)(i) = \sigma(\tau(i)) = \sigma \cdot (\tau \cdot i)$ – this is literally how composition in S_n is defined. So $\rho(\sigma) = \sigma$ and $\rho = \mathrm{id}_{S_n}$. Kernel: $\sigma(i) = i$ for all i means $\sigma = \mathrm{id}$, so $\ker \rho = 1$ and the action is faithful (trivially, ρ is a bijection). *Check.* For $n = 3$, $\rho((1\,2)) = (1\,2)$, and distinct group elements give distinct permutations because they *are* those permutations.

Worked Example 1.7.13 (A subgroup action: A_4 on $\{1, 2, 3, 4\}$, still faithful)**.** Restrict the natural S_4-action to A_4. Is it faithful? What is $\rho(A_4)$?

Recognition. Restricting a faithful action to a subgroup stays faithful, because the kernel only shrinks: $\ker(\rho|_H) = H \cap \ker \rho$.

Solution. The restriction sends $\sigma \in A_4$ to $\sigma \in S_4$, so $\rho|_{A_4}$ is the inclusion $A_4 \hookrightarrow S_4$. Kernel $= A_4 \cap \ker(\text{natural}) = A_4 \cap \{1\} = \{1\}$, so faithful; $\rho(A_4) = A_4 \leq S_4$. *Check.* E.g. $(1\,2\,3) \in A_4$ maps to the nonidentity $(1\,2\,3)$, so it is not in the kernel; only id fixes all four points.

Example family 3: conjugation, with kernel $Z(G)$

Proposition 1.7.14 (Conjugation action)**.** *G acts on itself by conjugation $g \cdot x := gxg^{-1}$. The representation $\rho\colon G \to \operatorname{Sym}(G)$ has image inside $\operatorname{Aut}(G)$ (each σ_g is the inner automorphism $x \mapsto gxg^{-1}$), and*

$$\ker \rho = Z(G) = \{g \in G : gx = xg \ \forall x \in G\}.$$

Hence ρ induces $G/Z(G) \cong \operatorname{Inn}(G) \leq \operatorname{Aut}(G)$, and the action is faithful iff $Z(G) = 1$.

Proof. (A1): $1 \cdot x = 1x1^{-1} = x$. (A2): $(gh) \cdot x = (gh)x(gh)^{-1} = g(hxh^{-1})g^{-1} = g \cdot (h \cdot x)$. Each σ_g respects multiplication: $\sigma_g(xy) = g(xy)g^{-1} = (gxg^{-1})(gyg^{-1}) = \sigma_g(x)\sigma_g(y)$, so $\sigma_g \in \operatorname{Aut}(G)$. Kernel: $gxg^{-1} = x$ for all $x \iff gx = xg$ for all $x \iff g \in Z(G)$. The first isomorphism theorem gives $G/Z(G) \cong \rho(G) = \operatorname{Inn}(G)$. □

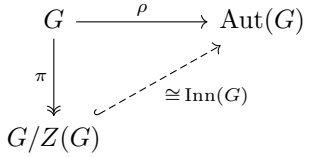


Diagram explanation. Objects: Three nodes. G is the group acting on itself by conjugation. $\operatorname{Aut}(G)$ is the automorphism group of G (all group isomorphisms $G \to G$); it is the ambient target because each conjugation $x \mapsto gxg^{-1}$ is an automorphism. $G/Z(G)$ is the quotient of G by its center $Z(G) = \ker \rho$; elements are cosets $gZ(G)$.

Arrows: Top horizontal $\rho\colon G \to \operatorname{Aut}(G)$: the conjugation representation sending g to the inner automorphism $\iota_g\colon x \mapsto gxg^{-1}$; its image is $\operatorname{Inn}(G)$. Left vertical two-headed arrow $\pi\colon G \twoheadrightarrow G/Z(G)$: the canonical quotient map, surjective. Dashed hooked arrow $G/Z(G) \hookrightarrow \operatorname{Aut}(G)$, labeled $\cong \operatorname{Inn}(G)$: the induced injection $\overline{\rho}(gZ(G)) := \iota_g$, which is an isomorphism onto $\operatorname{Inn}(G)$.

What commutes: $\rho = \overline{\rho} \circ \pi$: i.e. $\iota_g = \overline{\rho}(gZ(G))$ for all $g \in G$, so the two paths from G to $\operatorname{Aut}(G)$ agree.

Why it commutes: Well-definedness: if $gZ(G) = g'Z(G)$ then $g^{-1}g' \in Z(G)$, so $g^{-1}g'$ commutes with every x; then $g'^{-1}xg' = g^{-1}xg$ for all x, i.e. $\iota_{g'} = \iota_g$. Hence $\overline{\rho}$ is independent of the coset representative. Commutativity

then holds by construction. Injectivity: $\overline{\rho}(gZ(G)) = \mathrm{id}$ iff $gxg^{-1} = x$ for all x iff $g \in Z(G)$ iff $gZ(G)$ is the identity coset.

Why this matters here: This is the first isomorphism theorem for the conjugation action of Proposition 1.7.14: it identifies $\mathrm{Inn}(G)$ concretely as $G/Z(G)$, explaining why large centers produce small inner automorphism groups and why $Z(G) = 1$ forces the action to be faithful.

Concrete example: $G = D_8$: $Z(D_8) = \{1, r^2\}$, so $G/Z(G) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} = V_4$ and $\mathrm{Inn}(D_8) \cong V_4$ (four inner automorphisms). The coset rZ maps to $\iota_r \in \mathrm{Aut}(D_8)$, the automorphism conjugating by r.

Common pitfall: The hooked arrow lands in $\mathrm{Aut}(G)$, not in $\mathrm{Sym}(G)$; inner automorphisms are group automorphisms, not arbitrary bijections. Also, $G/Z(G) \cong \mathrm{Inn}(G)$ is an isomorphism of groups, but $G/Z(G)$ is not a subgroup of G itself; it lives inside $\mathrm{Aut}(G)$.

Takeaway: The point of this diagram is that the inner automorphism group is always isomorphic to G modulo its center, so the center measures exactly how much of G is "invisible" to the conjugation action.

Worked Example 1.7.15 (Conjugation on D_8: kernel is $Z(D_8) = \{1, r^2\}$)**.** For $G = D_8$ compute the kernel of the conjugation action and decide faithfulness.

Recognition. By Prop. 1.7.14 the kernel is the center; for D_8 the center is known to be $\{1, r^2\}$, so we expect a nontrivial kernel (not faithful).

Solution. Use $sr = r^{-1}s$. For g central we need g to commute with both r and s. r commutes with r, r^2, r^3; does r commute with s? $rs = sr^{-1}$ (from $sr = r^{-1}s \Rightarrow rs = sr^{-1}$), and $rs = sr$ iff $sr^{-1} = sr$ iff $r^{-1} = r$ iff $r^2 = 1$, false. So $s \notin Z$. Test r^2: $r^2 s = sr^{-2} = sr^2$ (since $r^4 = 1 \Rightarrow r^{-2} = r^2$), and r^2 commutes with r. Hence $r^2 \in Z$. One checks no reflection is central, so $Z(D_8) = \{1, r^2\}$. Therefore $\ker\rho = \{1, r^2\}$, $|\mathrm{Inn}(D_8)| = 8/2 = 4$, and the conjugation action is *not* faithful. *Check.* r^2 conjugates trivially: $r^2 s r^{-2} = sr^{-2}r^{-2} = sr^{-4} = s$, and $r^2 r r^{-2} = r$, so $\sigma_{r^2} = \mathrm{id}$, confirming $r^2 \in \ker\rho$.

Worked Example 1.7.16 (Conjugation on Q_8: kernel $Z(Q_8) = \{\pm 1\}$)**.** Find the kernel of conjugation on $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$.

Recognition. Again the kernel is the center; for Q_8 the center is $\{\pm 1\}$.

Solution. $g \in Z(Q_8)$ iff g commutes with i and j. Now $ij = k$ but $ji = -k$, so i, j do not commute; thus $i, j, k \notin Z$. The elements ± 1 are central (1 trivially, and $(-1)x = x(-1) = -x$). So $Z(Q_8) = \{1, -1\}$ and $\ker\rho = \{\pm 1\}$; the action is not faithful and $\mathrm{Inn}(Q_8) \cong Q_8/\{\pm 1\} \cong V_4$ (order 4). *Check.* $(-1)i(-1)^{-1} = (-1)i(-1) = i$, so $\sigma_{-1} = \mathrm{id}$, i.e. $-1 \in \ker\rho$. And $iji^{-1} = ij(-i) = (ij)(-i) = k(-i) = -(ki) = -j \neq j$, so $i \notin \ker\rho$ – the kernel really is just $\{\pm 1\}$.

Worked Example 1.7.17 (Conjugation on S_3 is faithful ($Z(S_3) = 1$))**.** Show conjugation makes S_3 act faithfully on itself, and identify $\mathrm{Inn}(S_3)$.

Recognition. Faithful iff $Z(G) = 1$; for S_n with $n \geq 3$ the center is trivial.

Solution. Suppose $g \in Z(S_3)$. Conjugation by g preserves cycle type, and if g commutes with the transposition $(1\,2)$ then $g(1\,2)g^{-1} = (1\,2)$, i.e. g fixes the pair $\{1, 2\}$; commuting with $(2\,3)$ likewise fixes $\{2, 3\}$. The only g fixing $\{1, 2\}$ and $\{2, 3\}$ setwise and lying in S_3 is $g = 1$. So $Z(S_3) = 1$, $\ker\rho = 1$, the action is faithful, and $\mathrm{Inn}(S_3) \cong S_3/Z(S_3) = S_3$, of order 6. *Check.* $(1\,2)(1\,2\,3)(1\,2)^{-1} = (2\,1\,3) = (1\,3\,2) \neq (1\,2\,3)$, so $(1\,2)$ acts nontrivially – consistent with a trivial kernel.

Worked Example 1.7.18 (Conjugation on an abelian group is trivial (maximally non-faithful))**.** Describe the conjugation action of an abelian G (say $G = \mathbb{Z}/6\mathbb{Z}$) and its kernel.

Recognition. If G is abelian, every $gxg^{-1} = x$, so the action is the trivial action and the kernel is all of G – the extreme opposite of faithful.

Solution. For abelian G: $g \cdot x = gxg^{-1} = gg^{-1}x = x$ for all g, x. Thus $\sigma_g = \mathrm{id}$ for every g, ρ is the constant map to id, and $\ker\rho = Z(G) = G$ (consistent with $Z(G) = G$ for abelian G). For $G = \mathbb{Z}/6\mathbb{Z}$, $\rho(\mathbb{Z}/6\mathbb{Z}) = \{\mathrm{id}\}$ and $\ker\rho = \mathbb{Z}/6\mathbb{Z}$. *Check.* $\mathrm{Inn}(\mathbb{Z}/6\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}/Z(\mathbb{Z}/6\mathbb{Z}) = \mathbb{Z}/6\mathbb{Z}/\mathbb{Z}/6\mathbb{Z} = 1$, the trivial group, exactly as "no nontrivial inner automorphisms" predicts.

Worked Example 1.7.19 (A coset action and its core: S_3 on cosets of $H = \langle(1\,2)\rangle$)**.** Let $G = S_3$ act by left multiplication on the left cosets of $H = \langle(1\,2)\rangle$, i.e. on $A = \{H, (1\,3)H, (2\,3)H\}$ (three cosets). Find $\rho\colon S_3 \to \mathrm{Sym}(A)$ and $\ker\rho$.

Recognition. Action on cosets $g\cdot(xH) = (gx)H$ is a standard action; its kernel is the *normal core* $\bigcap_{x\in S_3} xHx^{-1}$, the largest normal subgroup of G contained in H.

Solution. First name the three cosets. Composing right to left,

$$\begin{aligned} c_1 &= H = \{1, (1\,2)\},\\ c_2 &= (1\,3)H = \{(1\,3),\ (1\,3)(1\,2)\} = \{(1\,3), (1\,2\,3)\},\\ c_3 &= (2\,3)H = \{(2\,3),\ (2\,3)(1\,2)\} = \{(2\,3), (1\,3\,2)\}. \end{aligned}$$

Now act by the generators, computing $g \cdot c = (g \cdot \mathrm{rep})H$ and reading off which coset contains the result.

- $g = (1\,2\,3)$: $g\cdot 1 = (1\,2\,3) \in c_2$; $g\cdot(1\,3) = (1\,2\,3)(1\,3) = (2\,3) \in c_3$; $g\cdot(2\,3) = (1\,2\,3)(2\,3) = (1\,2) \in c_1$. So $\rho((1\,2\,3)) = (c_1\, c_2\, c_3)$.
- $g = (1\,2)$: $g\cdot 1 = (1\,2) \in c_1$; $g\cdot(1\,3) = (1\,2)(1\,3) = (1\,3\,2) \in c_3$; $g\cdot(2\,3) = (1\,2)(2\,3) = (1\,2\,3) \in c_2$. So $\rho((1\,2)) = (c_2\, c_3)$.
- $g = (1\,3)$: $g\cdot 1 = (1\,3) \in c_2$; $g\cdot(1\,3) = 1 \in c_1$; $g\cdot(2\,3) = (1\,3)(2\,3) = (1\,3\,2) \in c_3$, so c_3 is fixed. Hence $\rho((1\,3)) = (c_1\, c_2)$.

Thus ρ sends $(1\,2\,3) \mapsto (c_1\, c_2\, c_3)$, $(1\,2) \mapsto (c_2\, c_3)$, $(1\,3) \mapsto (c_1\, c_2)$, and these already generate all of $\mathrm{Sym}(A) \cong S_3$. Hence ρ is onto, and since $|S_3| = 6 = |\mathrm{Sym}(A)|$ it is an isomorphism, so $\ker\rho = 1$: the action is faithful. Equivalently $\ker\rho = \mathrm{core}(H) = \bigcap_x xHx^{-1}$, and as $|H| = 2$ with H not normal this intersection is trivial.
Check. The core is the largest normal subgroup inside H; the only normal subgroups of S_3 are 1, A_3, S_3, and the only one contained in the 2-element H is 1. For a genuinely non-faithful coset action take $G = Q_8$ on the four cosets of $H = \langle -1\rangle$: there $\langle -1\rangle \trianglelefteq Q_8$, so $\mathrm{core}(H) = \langle -1\rangle = Z(Q_8) \neq 1$ and $\ker\rho = \langle -1\rangle$.

Caution. "Faithful" is about the *whole* action: $\ker\rho = \{g : g\cdot a = a \text{ for } \mathbf{all}\ a\}$. One element g fixing one point a (a *stabilizer*) is unrelated; do not confuse $\ker\rho = \bigcap_a G_a$ (intersection of all stabilizers) with a single stabilizer G_a.

Remark 1.7.1 (The three diagrams to keep in mind). (1) An action *is* a homomorphism $\rho\colon G \to \mathrm{Sym}(A)$ (Thm. 1.7.3); (2) the regular action gives Cayley's embedding $G \hookrightarrow \mathrm{Sym}(G)$ (Thm. 1.7.4); (3) every action factors as $G \twoheadrightarrow G/\ker\rho \hookrightarrow \mathrm{Sym}(A)$:

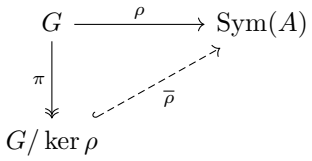

Diagram explanation. Objects: Three nodes. G is the group performing any given action on a set A. $\mathrm{Sym}(A)$ is the symmetric group on the set A, the universal target for permutation representations of groups acting on A. $G/\ker\rho$ is the quotient of G by the kernel of the permutation representation ρ; it is the "effective" part of G that acts non-trivially.

Arrows: Top horizontal $\rho\colon G \to \mathrm{Sym}(A)$: the permutation representation of the given action. Left vertical two-headed $\pi\colon G \twoheadrightarrow G/\ker\rho$: the canonical surjection $g \mapsto g\ker\rho$, which collapses elements that act identically. Dashed hooked $\overline{\rho}\colon G/\ker\rho \hookrightarrow \mathrm{Sym}(A)$: the induced injective map $\overline{\rho}(g\ker\rho) := \rho(g)$, guaranteed by the universal property of the quotient since $\ker\rho \subseteq \ker\rho$.

What commutes: The triangle: $\rho = \overline{\rho}\circ\pi$, meaning $\rho(g) = \overline{\rho}(g\ker\rho)$ for every $g \in G$.

Why it commutes: Well-definedness of $\overline{\rho}$: if $g\ker\rho = g'\ker\rho$ then $g^{-1}g' \in \ker\rho$, so $\rho(g^{-1}g') = \mathrm{id}$, hence $\rho(g) = \rho(g')$; the output of $\overline{\rho}$ does not depend on which representative of the coset is used. Commutativity then reads $\overline{\rho}(\pi(g)) = \overline{\rho}(g\ker\rho) = \rho(g)$, which is immediate. Injectivity of $\overline{\rho}$: $\overline{\rho}(g\ker\rho) = \mathrm{id}$ iff $\rho(g) = \mathrm{id}$ iff $g \in \ker\rho$.

Why this matters here: This is the master diagram of the whole section: it says every group action factors universally as a surjection (onto the quotient by the kernel) followed by an injection (into $\mathrm{Sym}(A)$). The action is faithful iff $\ker\rho = 1$ iff π is an isomorphism iff the bottom-left vertex equals G.

Concrete example: Conjugation action of $G = D_8$ on itself: $\ker\rho = Z(D_8) = \{1, r^2\}$, so $G/\ker\rho \cong V_4$ and $\overline{\rho}\colon V_4 \hookrightarrow \mathrm{Aut}(D_8)$ is the injective map whose image is $\mathrm{Inn}(D_8)$. The quotient π collapses each coset $\{g, gr^2\}$ to a single element of V_4.

Common pitfall: Students sometimes read $\overline{\rho}$ as an isomorphism onto $\mathrm{Sym}(A)$. It is only injective; $\rho(G)$ is typically a *proper* subgroup of $\mathrm{Sym}(A)$ (e.g., the image of D_8 acting on 4 vertices is a subgroup of S_4 of order 8, not all 24 elements).

Takeaway: The point of this diagram is that every action, no matter how non-faithful, contains a faithful action of the quotient $G/\ker\rho$ inside it, and this quotient is the largest quotient of G that acts faithfully on A.

The action is faithful exactly when π is an isomorphism, i.e. when the left arrow has trivial kernel.

D&F's example list: trivial action, scalar multiplication, and D_{2n} on n vertices

The fragment above already states the two axioms (Def. 1.7.1), defines the permutation representation, kernel, and faithfulness (Def. 1.7.2), proves the action–homomorphism correspondence (Thm. 1.7.3), and works the left regular action (Cayley, Thm. 1.7.4), the natural S_n-action, and D_8 on the square. We do not repeat those. What follows adds the remaining entries from D&F's own running list in 1.7 that the fragment lacks: the trivial action, the scalar-multiplication action, and the general D_{2n} on the n vertices.

Remark 1.7.2 (D&F's numbering and the name "permutation representation"). D&F state the axioms with associativity first: **(1)** $g_1 \cdot (g_2 \cdot a) = (g_1 g_2) \cdot a$ and **(2)** $1 \cdot a = a$ for all a. This is the same content as Def. 1.7.1 (our (A1),(A2) in the other order). D&F write the associated homomorphism as $\varphi\colon G \to S_A$ with $\varphi(g)\colon a \mapsto g{\cdot}a$, call it the *permutation representation associated to the action*, and call $\ker\varphi = \{g : g{\cdot}a = a\ \forall a\}$ the *kernel of the action*; faithful means this kernel is the identity. We use ρ and $\mathrm{Sym}(A)$ above for D&F's φ and S_A.

Definition 1.7.20 (Trivial action)**.** For any group G and nonempty set A, the rule $g \cdot a = a$ for all $g \in G$, $a \in A$, is an action, the *trivial action* of G on A. Each $\sigma_g = \mathrm{id}_A$, so ρ is the constant map $g \mapsto \mathrm{id}_A$ and $\ker\rho = G$; it is faithful only when $G = 1$.

Worked Example 1.7.21 (D&F Example: the trivial action and what it "sees")**.** Verify that $g \cdot a = a$ is an action of any G on any nonempty A, and identify its kernel.

Recognition. This is Def. 1.7.20; the only work is to confirm the two axioms and read off $\ker\rho$, which exhibits the extreme opposite of a faithful action.

Solution. Axiom (A1): $1 \cdot a = a$ by definition. Axiom (A2): $g \cdot (h \cdot a) = g \cdot a = a$ and $(gh) \cdot a = a$, so the two sides agree. Every σ_g is id_A, hence $\rho\colon G \to \mathrm{Sym}(A)$ is the constant map onto $\{\mathrm{id}_A\}$ and $\ker\rho = \{g : g \cdot a = a\ \forall a\} = G$. *Check.* The action is faithful $\iff$ $\ker\rho = 1$ $\iff$ $G = 1$; for $|G| > 1$ the trivial action is maximally non-faithful, which is why a nontrivial action is required to "see" anything about G. This is the opposite extreme to the faithful regular and natural actions worked above.

Worked Example 1.7.22 (D&F Example: $F^\times$ acting on a vector space by scalar multiplication)**.** Let V be a vector space over a field F and let $G = F^\times = F \setminus \{0\}$ act on $A = V$ by $a \cdot v = av$ (scalar multiplication). Check the axioms and find the kernel.

Recognition. D&F give this as the prototype where the "set" V carries extra structure but the acting group is just the multiplicative group of scalars; the vector-space axioms supply (A1),(A2) directly.

Solution. Axiom (A1): $1 \cdot v = 1v = v$ for all v, by the unit axiom of a vector space. Axiom (A2): for $a, b \in F^\times$, $a \cdot (b \cdot v) = a(bv) = (ab)v = (ab) \cdot v$, the associativity of scalar multiplication. So this is an action of $F^\times$ on V. Kernel: $a \cdot v = v$ for *all* $v \in V$ means $av = v$, i.e. $(a - 1)v = 0$ for all v; choosing any $v \neq 0$ forces $a = 1$. Hence $\ker\rho = \{1\}$ and (for $V \neq 0$) the action is faithful. *Check.* Each nonzero scalar a gives the bijection $v \mapsto av$ of V with inverse $v \mapsto a^{-1}v$, confirming $\sigma_a \in \mathrm{Sym}(V)$; distinct scalars scale some $v \neq 0$ differently, so ρ is injective.

Worked Example 1.7.23 (D&F Example: D_{2n} acting on the n vertices of a regular n-gon)**.** Show D_{2n} acts on the set $A = \{1, 2, \ldots, n\}$ of vertices, written cyclically, and describe σ_r and σ_s for the standard generators (D&F's convention $r^n = s^2 = 1$, $sr = r^{-1}s$, with s fixing vertex 1).

Recognition. D&F introduce D_{2n} as the symmetries of the regular n-gon, so the action on vertices is the defining one; it motivates writing each symmetry as a permutation. The D_8 table (Prop. 1.7.9) is the special case $n = 4$, which we do not redo here.

Solution. Each symmetry of the n-gon carries vertices to vertices bijectively, and composing symmetries composes their vertex permutations, so (A1),(A2) hold (the symmetry doing nothing is the identity permutation). For the rotation r by $2\pi/n$,

$$\sigma_r = (1\,2\,3\,\cdots\,n),$$

an n-cycle. For the reflection s fixing vertex 1,

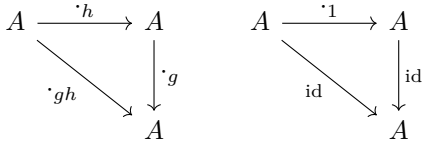
$$\sigma_s = (2\;n)(3\;n{-}1)(4\;n{-}2)\cdots,$$

fixing vertex 1 and pairing k with $n{+}2{-}k$ (so for even n the middle vertex $\frac{n}{2}+1$ is also fixed; for odd n only vertex 1 is fixed). Since the generators map to nonidentity permutations and a symmetry fixing every vertex is the identity, $\ker\rho = 1$ and $\rho\colon D_{2n} \to S_n$ is injective, so $D_{2n} \cong \rho(D_{2n}) \leq S_n$. *Check.* For $n = 4$, $\sigma_r = (1\,2\,3\,4)$ and $\sigma_s = (2\,4)$ (the pair $k \leftrightarrow n{+}2{-}k$ gives $2 \leftrightarrow 4$, with $1, 3$ fixed), recovering the D_8 data of Prop. 1.7.9; for $n = 5$, $\sigma_s = (2\,5)(3\,4)$; the relation $sr = r^{-1}s$ becomes $\sigma_s\sigma_r = \sigma_r^{-1}\sigma_s$ in S_n, the permutation identity verified there.

Remark 1.7.3 (Reading the example list). Across D&F's list the single fact at work is the correspondence of Thm. 1.7.3: an action of G on A is the same data as a homomorphism $G \to \mathrm{Sym}(A)$, and the kernel of the action equals the kernel of that homomorphism, so "faithful" means "injective." The examples populate the full range: the trivial action (ρ constant, $\ker\rho = G$); scalar multiplication, the natural S_n-action, the left regular action, and D_{2n} on vertices (ρ injective, $\ker\rho = 1$); and the coset and conjugation actions worked above (intermediate kernels, the normal core and $Z(G)$).

Exercises (from the text).

1. $F^\times$ acts on F by $g \cdot a = ga$; state the axioms used.
2. Show $\mathbb{Z}$ acts on itself by $z \cdot a = z + a$.
3. Show $\mathbb{R}$ acts on $\mathbb{R}^2$ by $r \cdot (x, y) = (x + ry, y)$.
4. Fix a: show the kernel and $G_a = \{g : g \cdot a = a\}$ are subgroups.
5. Kernel of an action = kernel of its permutation representation.
6. G acts faithfully iff the kernel is $\{1\}$.
7. Show the scalar action on a vector space is faithful.
8. How do $(1\,2)$ and $(1\,2\,3)$ act on the six 2-subsets of $\{1, 2, 3, 4\}$?
9. Repeat for ordered k-tuples.
10. For which k is the action of S_n on (a) k-subsets, (b) k-tuples faithful?
11. Cycle decompositions of the eight elements of D_8 on the square's vertices.
12. For n even, find the kernel of D_{2n} on opposite-vertex pairs.
13. Find the kernel of the left regular action.
14. $g \cdot a = ag$ is not a left action when G is non-abelian.
15. $g \cdot a = ag^{-1}$ *is* a left action.
16. $g \cdot a = gag^{-1}$ is a left action (conjugation).
17. Conjugation by g is an automorphism; deduce $|x| = |gxg^{-1}|$.
18. $a \sim b \iff a = hb$ is an equivalence relation.
19. $H \leq G$ acts by left multiplication; deduce Lagrange's theorem.



20. Rigid motions of a tetrahedron embed in S_4.
21. Rigid motions of a cube $\cong S_4$.
22. Rigid motions of an octahedron $\cong S_4$; dual to the cube.
23. Why is the cube's action on 3 pairs of opposite faces not faithful?

Additional exercises.

1. Let $G = D_8 = \langle r, s\rangle$ act on the four vertices $\{1,2,3,4\}$ of the square (labeled counterclockwise) in the natural way, with r the rotation sending $1 \mapsto 2 \mapsto 3 \mapsto 4 \mapsto 1$ and s the reflection fixing the diagonal through vertices 1 and 3. For each of r, s, rs, and r^2, write the resulting permutation of $\{1,2,3,4\}$ in cycle notation. Then verify directly that $\sigma_r\sigma_s = \sigma_{rs}$ (composing permutations right-to-left), confirming the action is a homomorphism on these elements.
2. Let G act on itself by *left multiplication*: $g \cdot x = gx$ for $g, x \in G$. Prove this is a (left) group action, and prove it is *faithful* for every group G. Then show that for G nontrivial this action has no fixed points, i.e. there is no $x \in G$ with $g \cdot x = x$ for all $g \in G$.
3. Let G act on itself by *conjugation*: $g \cdot x = gxg^{-1}$. Verify the two axioms of a group action. Show that the kernel of this action (the set of g acting trivially, i.e. $gxg^{-1} = x$ for all x) equals $Z(G)$. Compute this kernel explicitly when $G = Q_8$ and when $G = S_3$.
4. Let $G = (\mathbb{Z}/8\mathbb{Z})^\times = \{\bar1, \bar3, \bar5, \bar7\}$ act on the set $A = \mathbb{Z}/8\mathbb{Z}$ by $\bar a \cdot \bar x = \overline{ax}$.
   (a) Check this is a well-defined action.
   (b) Compute the orbit and the stabilizer of $\bar2$, and of $\bar1$.
   (c) Determine the kernel of the action, i.e. the set of $\bar a$ with $\overline{ax} = \bar x$ for all $\bar x \in \mathbb{Z}/8\mathbb{Z}$.
5. Let G act on a set A, and fix $a \in A$. Recall the stabilizer $G_a = \{g \in G \mid g \cdot a = a\}$.
   (a) Prove $G_a \le G$.
   (b) Prove that if $b = g \cdot a$ lies in the orbit of a, then $G_b = gG_ag^{-1}$. Conclude that points in the same orbit have conjugate stabilizers.
6. Suppose G acts on a set A. Define a relation on A by $a \sim b$ iff $b = g \cdot a$ for some $g \in G$. Prove $\sim$ is an equivalence relation (its classes are the orbits). Then, for the action of $G = \langle(1\,2\,3)\rangle \le S_5$ on $A = \{1,2,3,4,5\}$, list all orbits explicitly.
7. Let $G = S_4$ act on the set A of the three unordered partitions of $\{1,2,3,4\}$ into two pairs, namely $\{\{1,2\},\{3,4\}\}$, $\{\{1,3\},\{2,4\}\}$, $\{\{1,4\},\{2,3\}\}$, by relabeling points. This gives a homomorphism $\varphi : S_4 \to \mathrm{Sym}(A) \cong S_3$.
   (a) Compute the images $\varphi((1\,2))$ and $\varphi((1\,2\,3))$ as permutations of the three partitions.
   (b) Show φ is surjective.
   (c) Identify $\ker\varphi$ as an explicit subgroup of S_4 and give its order.

Commutative-diagram exercises.

1. Let G be a group and A a set. Let $\varphi : G \to \mathrm{Sym}(A)$ be a homomorphism, and define $g \cdot a = \varphi(g)(a)$. Prove that this defines a group action by checking the two diagrams below commute for all $g, h \in G$ (here $\cdot_g : A \to A$ denotes $a \mapsto g \cdot a$, and id is the identity map of A):

Conversely, prove that any action $G \times A \to A$ arises this way from a unique homomorphism $G \to \mathrm{Sym}(A)$, and state precisely what "the action is faithful" means about that homomorphism.

2. (Cayley's theorem via the regular representation.) Let G be a group and let $\lambda : G \to \mathrm{Sym}(G)$ be the permutation representation of the left-multiplication action $g \cdot x = gx$, so $\lambda(g)$ is the map $x \mapsto gx$.

   (a) Show λ is a homomorphism by verifying the triangle commutes for all g, h:

$$\begin{array}{ccc} G & \xrightarrow{\lambda(h)} & G \\ & \searrow^{\lambda(gh)} & \downarrow{\scriptstyle \lambda(g)} \\ & & G \end{array}$$

   (b) Show $\ker \lambda = 1$ and conclude λ is injective, so G embeds as a subgroup of $\mathrm{Sym}(G)$:

$$1 \longrightarrow G \xhookrightarrow{\lambda} \mathrm{Sym}(G)$$

   (c) When $|G| = n$, deduce that G is isomorphic to a subgroup of S_n.

3. (Kernel of an action.) Let G act on A with permutation representation $\varphi : G \to \mathrm{Sym}(A)$.

   (a) Prove $\ker \varphi = \bigcap_{a \in A} G_a$, the intersection of all point stabilizers, and that $\ker \varphi \trianglelefteq G$.

   (b) Using the first isomorphism theorem, fill in the unique dashed map making the diagram commute, and state what it is:

$$\begin{array}{ccc} G & \xrightarrow{\pi} & G/\ker\varphi \\ & \searrow^{\varphi} & \downarrow{\scriptstyle \exists!\, \overline{\varphi}} \\ & & \mathrm{Sym}(A) \end{array}$$

   (c) Conclude that $G/\ker\varphi$ is isomorphic to a subgroup of $\mathrm{Sym}(A)$.

4. Let G be a group and $H \leq G$ with $[G : H] = n$. Let G act on the set $A = \{gH \mid g \in G\}$ of left cosets by $g \cdot (xH) = (gx)H$, with permutation representation $\pi_H : G \to \mathrm{Sym}(A) \cong S_n$.

   (a) Verify this is a well-defined action.

   (b) Show $\ker \pi_H = \bigcap_{x \in G} xHx^{-1}$, the largest normal subgroup of G contained in H.

   (c) Specialize to $G = S_3$ and $H = \langle (1\,2) \rangle$ (so $n = 3$). Describe π_H explicitly and identify $\ker \pi_H$.

5. Let $\varphi : G \to \mathrm{Sym}(A)$ and $\psi : G \to \mathrm{Sym}(B)$ be two permutation representations, and suppose $f : A \to B$ is a bijection that is G-equivariant, i.e. $f(g \cdot a) = g \cdot f(a)$ for all $g \in G$, $a \in A$. Show this is equivalent to the commutativity of the square

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ {\scriptstyle \varphi(g)}\downarrow & & \downarrow{\scriptstyle \psi(g)} \\ A & \xrightarrow[f]{} & B \end{array}$$

   for every $g \in G$. Deduce that if such an f exists then $\ker \varphi = \ker \psi$, and that $\psi(g) = f \circ \varphi(g) \circ f^{-1}$ exhibits the two representations as conjugate inside $\mathrm{Sym}(A)$ once B is identified with A via f.

1.8 Graded Problem Bank

Easy

DF 1.1.1 Determine which operations are associative: (a) $a * b = a - b$ on $\mathbb{Z}$; (b) $a * b = a + b + ab$ on $\mathbb{R}$; (c) $a * b = \frac{a+b}{5}$ on $\mathbb{Q}$; (d) $(a, b) * (c, d) = (ad + bc, bd)$ on $\mathbb{Z} \times \mathbb{Z}$; (e) $a * b = \frac{a}{b}$ on $\mathbb{Q} - \{0\}$.

DF 1.1.2 Which operations in the preceding problem are commutative?

DF 1.1.6 Which are groups under addition: lowest-terms rationals with (a) odd denominator, (b) even denominator; (c) $|x| < 1$; (d) $|x| \geq 1$ together with 0; (e) denominators 1 or 2; (f) denominators $1, 2$, or 3.

DF 1.1.11 Find the orders of every element of the additive group $\mathbb{Z}/12\mathbb{Z}$.

DF 1.1.12 Find the orders of $\bar{1}, \overline{-1}, \bar{5}, \bar{7}, \overline{-7}, \overline{13}$ in $(\mathbb{Z}/12\mathbb{Z})^\times$.

DF 1.1.13 Find the orders of $\bar{1}, \bar{2}, \bar{6}, \bar{9}, \overline{10}, \overline{12}, \overline{-1}, \overline{-10}, \overline{-18}$ in $\mathbb{Z}/36\mathbb{Z}$.

DF 1.1.14 Find the orders of $\bar{1}, \overline{-1}, \bar{5}, \overline{13}, \overline{-13}, \overline{17}$ in $(\mathbb{Z}/36\mathbb{Z})^\times$.

DF 1.1.16 Prove $x^2 = 1$ iff $|x|$ is 1 or 2.

DF 1.1.17 If $|x| = n$, prove $x^{-1} = x^{n-1}$.

DF 1.1.20 Show that x and x^{-1} have the same order.

DF 1.2.1 Compute the order of each element of (a) D_6, (b) D_8, (c) D_{10}.

DF 1.2.8 Find the order of the cyclic subgroup $\langle r \rangle \leq D_{2n}$.

DF 1.2.14 Find a set of generators for $\mathbb{Z}$.

DF 1.2.15 Find generators and relations for $\mathbb{Z}/n\mathbb{Z}$.

DF 1.3.2 For the permutations σ, τ of $\{1, \ldots, 15\}$ in the text, find $\sigma, \tau, \sigma^2, \sigma\tau, \tau\sigma, \tau^2\sigma$.

DF 1.3.3 Compute the order of each permutation in DF 1.3.1 and DF 1.3.2.

DF 1.3.4 Compute the order of each element in (a) S_3, (b) S_4.

DF 1.3.5 Find the order of $(1\,12\,8\,10\,4)(2\,13)(5\,11\,7)(6\,9)$.

DF 1.3.6 Find the cycle decomposition of each order-4 element of S_4.

DF 1.3.7 Find the cycle decomposition of each order-2 element of S_4.

DF 1.4.1 Prove $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$.

DF 1.4.2 List all elements of $\mathrm{GL}_2(\mathbb{F}_2)$ and their orders.

DF 1.4.3 Show $\mathrm{GL}_2(\mathbb{F}_2)$ is non-abelian.

DF 1.5.1 Compute the order of each element of Q_8.

DF 1.6.15 For $\pi : \mathbb{R}^2 \to \mathbb{R}$, $\pi(x, y) = x$, find $\ker \pi$.

DF 1.6.16 Find the kernels of the projections π_1, π_2 of $A \times B$.

DF 1.7.1 $F^\times$ acts on F by $g \cdot a = ga$; state the axioms used.

DF 1.7.2 Show $\mathbb{Z}$ acts on itself by $z \cdot a = z + a$.

DF 1.7.3 Show $\mathbb{R}$ acts on $\mathbb{R}^2$ by $r \cdot (x, y) = (x + ry, y)$.

Artin 1.1 Prove the law $ab = a$ on a set S is associative; for which S does it have an identity?

Artin 2.1 Make a multiplication table for the symmetric group S_3.

Artin 3.1 For $a = 123$, $b = 321$, compute $d = \gcd(a, b)$ and write $d = ra + sb$.

Artin 4.2 An nth root of unity is z with $z^n = 1$: (a) the nth roots of unity form a cyclic subgroup of $\mathbb{C}^\times$ of order n; (b) determine the product of all of them.

Artin 4.9 How many elements of order 2 does S_4 contain?

Artin 6.5 Decide whether $A = \left(\begin{smallmatrix} \frac{1}{2} & \frac{3}{2} \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} \frac{1}{2} & \frac{1}{4} \end{smallmatrix}\right)$ are conjugate in $\mathrm{GL}_2(\mathbb{R})$.

Fraleigh 0.1 Describe $\{x \in \mathbb{R} \mid x^2 = 3\}$ by listing its elements.

Fraleigh 0.2 Describe $\{m \in \mathbb{Z} \mid m^2 + m = 6\}$ by listing its elements.

Fraleigh 0.3 Describe $\{m \in \mathbb{Z} \mid mn = 60 \text{ for some } n \in \mathbb{Z}\}$ by listing its elements.

Fraleigh 0.4 Describe $\{x \in \mathbb{Z} \mid x^2 - 10x + 16 \leq 0\}$ by listing its elements.

Fraleigh 0.11 List the elements of $\{a, b, c\} \times \{1, 2, c\}$.

Fraleigh 0.16 List the elements of the power set of each of $\varnothing, \{a\}, \{a, b\}, \{a, b, c\}$ and give its cardinality.

Fraleigh 1.1 With $*$ given by Table 1.31, compute $b * d$, $c * c$, and $[(a * c) * e] * a$.

Fraleigh 1.4 For the table operation $*$, decide whether $*$ is commutative and why.

Fraleigh 1.7 Decide associativity, commutativity, and existence of an identity for $a * b = a - b$ on $\mathbb{Z}$.

Fraleigh 1.8 Same questions for $a * b = 2ab + 3$ on $\mathbb{Q}$.

Fraleigh 1.9 Same questions for $a * b = ab + a + b$ on $\mathbb{Z}$.

Fraleigh 1.10 Same questions for $a * b = 2^{ab}$ on $\mathbb{Z}^+$.

Fraleigh 1.11 Same questions for $a * b = a^b$ on $\mathbb{Z}^+$.

Fraleigh 1.21 On $\mathbb{Z}^+$, decide whether $a * b = b^a$ is a binary operation.

Fraleigh 1.22 On $\mathbb{R}^+$, decide whether $a * b = 2^a - b$ is a binary operation.

Fraleigh 2.1 Decide whether $a * b = ab$ on $\mathbb{Z}$ gives a group; if not, name the first failing axiom.

Fraleigh 2.2 Same for $a * b = a + b$ on $2\mathbb{Z}$.

Fraleigh 2.3 Same for $a * b = \sqrt{ab}$ on $\mathbb{R}^+$.

Fraleigh 2.4 Same for $a * b = ab$ on $\mathbb{Q}$.

Fraleigh 2.5 Same for $a * b = a/b$ on $\mathbb{R}^\times$.

Fraleigh 2.6 Same for $a * b = |ab|$ on $\mathbb{C}$.

Fraleigh 3.1 Compute i^3 and write the answer in the form $a + bi$.

Fraleigh 3.3 Compute i^{26} in the form $a + bi$.

Fraleigh 3.5 Compute $(3 - 2i)(6 + i)$ in the form $a + bi$.

Fraleigh 3.10 Find $|5 - 12i|$.

Fraleigh 3.16 Find all solutions in $\mathbb{C}$ of $z^4 = 1$.

Fraleigh 3.18 Find all solutions in $\mathbb{C}$ of $z^3 = -125$.

Fraleigh 3.22 Compute $10 +_{17} 16$ using modular addition.

Fraleigh 3.29 Solve $x +_{10} 7 = 3$ in $\mathbb{Z}/10\mathbb{Z}$.

Fraleigh 4.1 For the given $\sigma, \tau \in S_6$, compute the product $\tau\sigma$.

Fraleigh 4.6 Compute σ^6 for the given $\sigma \in S_6$.

Fraleigh 4.10 Convert the given permutations $\sigma, \tau, \mu \in S_6$ to disjoint cycle notation.

Fraleigh 4.11 Convert $(1, 4, 5)(2, 3)$, $(1, 8, 5)(2, 6, 7, 3, 4)$, $(1, 2, 3)(4, 5)(6, 7, 8)$ in S_8 to two-row notation.

Fraleigh 4.24 Determine whether $f_1(x) = x + 1$ is a permutation of $\mathbb{R}$.

Fraleigh 4.25 Determine whether $f_2(x) = x^2$ is a permutation of $\mathbb{R}$.

Fraleigh 8.1 Determine whether $\varphi : \mathbb{Z}/10\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$, $\varphi(x) = x \bmod 2$, is a homomorphism.

Fraleigh 8.3 Determine whether $\varphi : \mathbb{Q}^\times \to \mathbb{Q}^\times$, $\varphi(x) = |x|$, is a homomorphism.

Fraleigh 8.11 Compute the kernel of $\varphi : \mathbb{Z} \to \mathbb{Z}/8\mathbb{Z}$ with $\varphi(1) = 6$.

Fraleigh 8.12 Compute the kernel of $\varphi : \mathbb{Z} \to \mathbb{Z}$ with $\varphi(1) = 12$.

Fraleigh 8.17 Find all orbits of $\left(\begin{smallmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 5 & 1 & 3 & 6 & 2 & 4 \end{smallmatrix}\right)$.

Fraleigh 8.23 Express the given permutation of $\{1, \ldots, 8\}$ as disjoint cycles and as a product of transpositions.

Medium

DF 1.1.3 Prove that addition of residue classes in $\mathbb{Z}/n\mathbb{Z}$ is associative.

DF 1.1.4 Prove that multiplication of residue classes in $\mathbb{Z}/n\mathbb{Z}$ is associative.

DF 1.1.5 Prove for all $n > 1$ that $\mathbb{Z}/n\mathbb{Z}$ is not a group under multiplication.

DF 1.1.7 On $G = \{x \in \mathbb{R} \mid 0 \leq x < 1\}$ with $x * y =$ fractional part of $x + y$, show $*$ is well defined and G is abelian.

DF 1.1.8 For $G = \{z \in \mathbb{C} \mid z^n = 1 \text{ for some } n \in \mathbb{Z}^+\}$, show (a) it is a group under multiplication; (b) not a group under addition.

DF 1.1.9 For $G = \{a + b\sqrt{2} \mid a, b \in \mathbb{Q}\}$, show (a) it is a group under addition; (b) the nonzero elements form a group under multiplication.

DF 1.1.10 Prove a finite group is abelian iff its group table is symmetric.

DF 1.1.15 Prove $(a_1 a_2 \cdots a_n)^{-1} = a_n^{-1} a_{n-1}^{-1} \cdots a_1^{-1}$.

DF 1.1.18 Prove $xy = yx \iff y^{-1}xy = x \iff x^{-1}y^{-1}xy = 1$.

DF 1.1.19 For $x \in G$, $a, b \in \mathbb{Z}^+$: (a) $x^{a+b} = x^a x^b$ and $(x^a)^b = x^{ab}$; (b) $(x^a)^{-1} = x^{-a}$; (c) extend (a) to all integers.

DF 1.1.21 G finite, $|x| = n$ odd; prove $x = (x^2)^k$ for some k.

DF 1.1.22 Prove $|x| = |g^{-1}xg|$, and deduce $|ab| = |ba|$.

DF 1.1.24 If a, b commute, prove $(ab)^n = a^n b^n$ for all $n \in \mathbb{Z}$.

DF 1.1.25 Prove that if $x^2 = 1$ for all $x \in G$, then G is abelian.

DF 1.1.26 If $\varnothing \neq H \subseteq G$ is closed under the operation and inverses, prove H is a subgroup.

DF 1.1.27 Prove $\{x^n \mid n \in \mathbb{Z}\}$ is a subgroup (the cyclic subgroup $\langle x \rangle$).

DF 1.1.28 Verify the group axioms for $A \times B$.

DF 1.1.29 Prove $A \times B$ is abelian iff both A and B are.

DF 1.1.30 Show $(a, 1), (1, b)$ commute and $|(a, b)| = \operatorname{lcm}(|a|, |b|)$.

DF 1.1.32 If $|x| = n$, prove $1, x, \ldots, x^{n-1}$ are distinct, and $|x| \leq |G|$.

DF 1.1.34 If x has infinite order, prove the powers x^n are distinct.

DF 1.1.35 If $|x| = n$, show every power of x lies in $\{1, x, \ldots, x^{n-1}\}$.

DF 1.2.2 Show that if $x \in D_{2n}$ is not a power of r, then $rx = xr^{-1}$.

DF 1.2.3 Show every non-rotation in D_{2n} has order 2; deduce $D_{2n} = \langle s, sr \rangle$.

DF 1.2.6 Let x, y have order 2 and $t = xy$; prove $tx = xt^{-1}$.

DF 1.2.9 Show the rigid motions of a tetrahedron form a group of order 12.

DF 1.2.10 Show the rigid motions of a cube have order 24.

DF 1.2.16 Show $\langle x_1, y_1 \mid x_1^2 = y_1^2 = (x_1 y_1)^2 = 1 \rangle$ is the dihedral group D_4.

DF 1.3.1 For $\sigma : 1 \to 3, 2 \to 4, 3 \to 5, 4 \to 2, 5 \to 1$ and $\tau : 1 \to 5, 2 \to 3, 3 \to 2, 4 \to 4, 5 \to 1$, find the cycle decompositions of $\sigma, \tau, \sigma^2, \sigma\tau, \tau\sigma, \tau^2\sigma$.

DF 1.3.9 For which i is the ith power of a (a) 12-, (b) 8-, (c) 14-cycle again a full cycle?

DF 1.3.10 If $\sigma = (a_1 \cdots a_m)$, show $\sigma^i(a_k) = a_{k+i}$ and $|\sigma| = m$.

DF 1.3.8 Prove that if $\Omega = \{1, 2, 3, \dots\}$ then S_Ω is infinite.

DF 1.3.13 Prove an element of S_n has order 2 iff its cycle type is disjoint 2-cycles.

DF 1.3.15 Prove the order of a permutation equals the lcm of its cycle lengths.

DF 1.3.18 Find all n for which S_5 has an element of order n.

DF 1.3.19 Find all n for which S_7 has an element of order n.

DF 1.3.20 Find generators and relations for S_3.

DF 1.4.4 Show $\mathbb{Z}/n\mathbb{Z}$ is not a field when n is composite.

DF 1.4.5 Show $\mathrm{GL}_n(F)$ is finite iff F is finite.

DF 1.4.9 Prove 2×2 real matrix multiplication is associative.

DF 1.4.10 For $G = \left\{ \left(\begin{smallmatrix} a & b \\ 0 & c \end{smallmatrix}\right) : a, c \neq 0 \right\}$, show closure, find inverses, and deduce $G \leq \mathrm{GL}_2(\mathbb{R})$.

DF 1.5.2 Write out the group tables for S_3, D_8, and Q_8.

DF 1.5.3 Find a set of generators and relations for Q_8.

DF 1.6.1 For a homomorphism φ: (a) $\varphi(x^n) = \varphi(x)^n$ $(n \in \mathbb{Z}^+)$; (b) deduce it for all $n \in \mathbb{Z}$.

DF 1.6.2 If φ is an isomorphism, prove $|\varphi(x)| = |x|$; is this true for a mere homomorphism?

DF 1.6.3 If φ is an isomorphism, prove G abelian iff H abelian; what hypothesis suffices for a homomorphism?

DF 1.6.4 Prove $\mathbb{R}^\times$ and $\mathbb{C}^\times$ are not isomorphic.

DF 1.6.5 Prove additive $\mathbb{R}$ and $\mathbb{Q}$ are not isomorphic.

DF 1.6.6 Prove additive $\mathbb{Z}$ and $\mathbb{Q}$ are not isomorphic.

DF 1.6.7 Prove D_8 and Q_8 are not isomorphic.

DF 1.6.8 Prove $S_n \ncong S_m$ when $n \neq m$.

DF 1.6.11 Prove $A \times B \cong B \times A$.

DF 1.6.12 For $G = A \times B$, $H = B \times C$, prove $G \times C \cong A \times H$.

DF 1.6.13 For a homomorphism φ, show $\varphi(G) \leq H$, and if injective $G \cong \varphi(G)$.

DF 1.6.14 Show $\ker \varphi$ is a subgroup, and φ is injective iff $\ker \varphi = \{1\}$.

DF 1.6.17 Show $g \mapsto g^{-1}$ is a homomorphism iff G is abelian.

DF 1.6.18 Show $g \mapsto g^2$ is a homomorphism iff G is abelian.

DF 1.6.19 For a fixed integer $k > 1$, show $z \mapsto z^k$ on the roots of unity is a surjective homomorphism, not an isomorphism.

DF 1.6.20 Prove $\mathrm{Aut}(G)$ is a group under composition.

DF 1.6.21 Show $q \mapsto kq$ $(k \in \mathbb{Q}^\times)$ is an automorphism of $\mathbb{Q}$.

DF 1.6.22 For A abelian, show $a \mapsto a^k$ is a homomorphism, an automorphism for $k = -1$.

DF 1.7.4 Fix a; show the kernel of an action and $G_a = \{g : g \cdot a = a\}$ are subgroups.

DF 1.7.5 Show the kernel of an action equals the kernel of its permutation representation.

DF 1.7.6 Show G acts faithfully iff the kernel is $\{1\}$.

DF 1.7.7 Show the scalar action on a vector space is faithful.

DF 1.7.8 How do $(1\,2)$ and $(1\,2\,3)$ act on the six 2-subsets of $\{1,2,3,4\}$?

DF 1.7.11 Find the cycle decompositions of the eight elements of D_8 on the square's vertices.

DF 1.7.13 Find the kernel of the left regular action.

DF 1.7.14 Show $g \cdot a = ag$ is not a left action when G is non-abelian.

DF 1.7.15 Show $g \cdot a = ag^{-1}$ is a left action.

DF 1.7.16 Show $g \cdot a = gag^{-1}$ is a left action (conjugation).

DF 1.7.17 Show conjugation by g is an automorphism; deduce $|x| = |gxg^{-1}|$.

DF 1.7.18 Show $a \sim b \iff a = hb$ is an equivalence relation.

Artin 1.3 For the shift map $s(n) = n+1$ on $\mathbb{Z}^+$, prove s has no right inverse but infinitely many left inverses.

Artin 2.2 If S has an associative law with identity, prove the invertible elements form a group.

Artin 2.3 For $x, y, z, w \in G$: (a) solve $xyzw = 1$ for y; (b) does $xyz = 1$ force $yzx = 1$? force $yxz = 1$?

Artin 2.4 Decide which of the listed pairs $H \subseteq G$ make H a subgroup of G.

Artin 2.5 Show that if $H \subseteq G$ has any identity, it must be the identity of G; same for inverses.

Artin 2.6 Define G° with $a * b = ba$ on the same set; prove G° is a group.

Artin 3.2 If a, b are positive integers with $a + b$ prime, prove $\gcd(a, b) = 1$.

Artin 4.1 If a has order 7 and $a^3b = ba^3$, prove $ab = ba$.

Artin 4.3 Prove that ab and ba have the same order.

Artin 4.5 Prove that every subgroup of a cyclic group is cyclic, working with exponents.

Artin 4.6 (a) For cyclic groups of orders $6, 5, 8$, how many elements generate the group? (b) Describe the count for arbitrary order n.

Artin 4.7 If x, y, xy all have order 2, prove $H = \{1, x, y, xy\}$ is a subgroup of order 4.

Artin 4.10 Show by example that a product of elements of finite order need not have finite order; what if the group is abelian?

Artin 5.1 If $\varphi : G \to G'$ is surjective, prove that G cyclic implies G' cyclic, and G abelian implies G' abelian.

Artin 5.2 Prove $K \cap H$ is a subgroup of H, and is normal in H when $K \trianglelefteq G$.

Artin 5.3 For $\varphi : U \to F^\times$ sending an upper triangular A to a^2, prove φ is a homomorphism and find its kernel and image.

Artin 5.4 For $f : \mathbb{R} \to \mathbb{C}^\times$, $f(x) = e^{ix}$, prove f is a homomorphism and find its kernel and image.

Artin 6.1 For G' the group of matrices $\left(\begin{smallmatrix} 1 & x \\ 0 & 1 \end{smallmatrix}\right)$, decide whether $x \mapsto$ this matrix is an isomorphism $\mathbb{R} \to G'$.

Artin 6.2 Describe all homomorphisms $\mathbb{Z} \to \mathbb{Z}$; determine which are injective, surjective, isomorphisms.

Artin 6.4 Prove that in any group ab and ba are conjugate.

Artin 6.7 For $H \leq G$ and fixed g, prove gHg^{-1} is a subgroup of G.

Artin 6.9 Prove a group G and its opposite group G° are isomorphic.

Artin 6.11 If $\{1, a\}$ is a normal subgroup of G, prove a is in the center.

Artin 7.1 Prove $a \sim b$ iff $b = gag^{-1}$ for some g is an equivalence relation on G.

Fraleigh 1.42 For associative $*$, show $H = \{a \in S \mid a * x = x * a \text{ for all } x\}$ is closed under $*$.

Fraleigh 2.10 For $n \in \mathbb{Z}^+$ and $n\mathbb{Z} = \{nm \mid m \in \mathbb{Z}\}$: (a) show $\langle n\mathbb{Z}, + \rangle$ is a group; (b) show $n\mathbb{Z} \cong \mathbb{Z}$.

Fraleigh 2.19 On $S = \mathbb{R} \setminus \{-1\}$ with $a * b = a + b + ab$: (a) show $*$ is a binary operation; (b) show $\langle S, * \rangle$ is a group; (c) solve $2 * x * 3 = 7$.

Fraleigh 2.28 If $a \neq e$ has order 2 in a group, prove $b^{-1}ab$ has order 2 for any b.

Fraleigh 2.29 If a finite group has even order, prove there is $a \neq e$ with $a * a = e$.

Fraleigh 2.31 Prove a group has exactly one idempotent element.

Fraleigh 2.32 Prove that if $x * x = e$ for all x, then G is abelian.

Fraleigh 2.33 By induction, prove $(ab)^n = a^n b^n$ in an abelian group.

Fraleigh 2.36 In a finite group, prove that for any a there is $n \in \mathbb{Z}^+$ with $a^n = e$.

Fraleigh 2.37 If $(ab)^2 = a^2 b^2$ in a group, prove $ab = ba$.

Fraleigh 2.39 If $abc = e$ in a group, prove $bca = e$.

Fraleigh 2.42 Prove $(a^{-1})^{-1} = a$.

Fraleigh 3.35 Prove or disprove: for any n and $a \in \mathbb{Z}/n\mathbb{Z}$, $x +_n x = a$ has at most two solutions.

Fraleigh 3.44 Prove that $\langle \mathbb{Z}/n\mathbb{Z}, +_n \rangle$ is associative without using associativity of U_n.

Fraleigh 4.14 Write the group table for D_3 and compare with S_3; are they isomorphic?

Fraleigh 4.18 Verify that $H = \{\iota, \mu, \rho^2, \mu\rho^2\} \subseteq D_4$ is a group.

Fraleigh 4.30 In D_n prove $\rho^k \mu = \mu \rho^{n-k}$.

Fraleigh 4.31 Show S_n is nonabelian for $n \geq 3$.

Fraleigh 8.35 If $\varphi : G \to G'$ is a homomorphism and $a \in \ker \varphi$, show $gag^{-1} \in \ker \varphi$ for all g.

Fraleigh 8.36 Prove a homomorphism φ is one-to-one iff $\ker \varphi$ is trivial.

Fraleigh 8.37 For a homomorphism φ, show $\varphi(a) = \varphi(b)$ iff $a^{-1}b \in \ker \varphi$.

Fraleigh 8.39 If $\varphi : G \to G'$ and $\gamma : G' \to G''$ are homomorphisms, show $\gamma \circ \varphi$ is a homomorphism.

Fraleigh 8.48 Show that if σ is a cycle of odd length, then σ^2 is a cycle.

Hard

DF 1.1.23 $|x| = n$, $n = st$; prove $|x^s| = t$.

DF 1.1.31 Prove a finite group of even order contains an element of order 2.

DF 1.1.33 For $|x| = n$: (a) n odd $\Rightarrow x^i \neq x^{-i}$ $(1 \leq i \leq n-1)$; (b) $n = 2k \Rightarrow x^i = x^{-i}$ iff $i = k$ $(1 \leq i \leq n-1)$.

DF 1.1.36 If $G = \{1, a, b, c\}$ has order 4 with no element of order 4, show the table is unique and G is abelian.

DF 1.2.4 If $n = 2k \geq 4$, show $z = r^k$ has order 2 and is the unique nonidentity central element.

DF 1.2.5 If $n \geq 3$ is odd, show only the identity commutes with all of D_{2n}.

DF 1.2.7 Show $\langle a, b \mid a^2 = b^2 = (ab)^n = 1 \rangle$ presents D_{2n} via $a = s$, $b = sr$.

DF 1.2.11 Show the rigid motions of an octahedron have order 24.

DF 1.2.12 Show the rigid motions of a dodecahedron have order 60.

DF 1.2.13 Show the rigid motions of an icosahedron have order 60.

DF 1.2.17 For $X_{2n} = \langle x, y \mid x^n = y^2 = 1,\ xy = yx^2 \rangle$, find the order for $n = 3k$ and for $\gcd(3, n) = 1$.

DF 1.2.18 For $Y = \langle u, v \mid u^4 = v^3 = 1,\ uv = v^2 u^2 \rangle$, show $Y = 1$.

DF 1.3.11 Show σ^i for an m-cycle is an m-cycle iff $\gcd(i, m) = 1$.

DF 1.3.12 (a) Is $(1\,2)(3\,4)(5\,6)(7\,8)(9\,10)$ a power of an n-cycle ($n \geq 10$)? (b) $(1\,2)(3\,4\,5)$, $n \geq 5$?

DF 1.3.14 p prime: order p iff disjoint p-cycles; give a counterexample for composite order.

DF 1.3.16 Count the number of m-cycles in S_n ($n \geq m$).

DF 1.3.17 Count the products of two disjoint 2-cycles in S_n ($n \geq 4$).

DF 1.4.6 If $|F| = q$, prove $|\mathrm{GL}_n(F)| < q^{n^2}$.

DF 1.4.7 p prime: prove $|\mathrm{GL}_2(\mathbb{F}_p)| = p^4 - p^3 - p^2 + p$.

DF 1.4.8 Show $\mathrm{GL}_n(F)$ is non-abelian for all $n \geq 2$.

DF 1.4.11 For the Heisenberg group $H(F)$, compute XY, find X^{-1}, and show $|H(F)| = |F|^3$.

DF 1.6.9 Prove D_{24} and S_4 are not isomorphic.

DF 1.6.10 Show $S_\Delta \cong S_\Omega$ when $|\Delta| = |\Omega|$, via $\varphi(\sigma) = \theta\sigma\theta^{-1}$.

DF 1.6.23 Show a fixed-point-free order-2 automorphism of a finite group G forces G abelian.

DF 1.6.24 If $x \neq y$ have order 2 and generate a finite group G, prove $G \cong D_{2n}$ with $n = |xy|$.

DF 1.6.25 Show $\varphi(r) =$ rotation, $\varphi(s) =$ reflection gives an injective homomorphism $D_{2n} \to \mathrm{GL}_2(\mathbb{R})$.

DF 1.6.26 Show $\varphi(i), \varphi(j)$ in $\mathrm{GL}_2(\mathbb{C})$ give an injective homomorphism $Q_8 \to \mathrm{GL}_2(\mathbb{C})$.

DF 1.7.9 How do $(1\,2)$ and $(1\,2\,3)$ act on the ordered k-tuples of $\{1, 2, 3, 4\}$?

DF 1.7.10 For which k is the action of S_n on (a) k-subsets, (b) k-tuples faithful?

DF 1.7.12 For n even, find the kernel of the action of D_{2n} on opposite-vertex pairs.

DF 1.7.19 $H \leq G$ acts by left multiplication; deduce Lagrange's theorem.

DF 1.7.20 Show the rigid motions of a tetrahedron embed in S_4.

DF 1.7.21 Show the rigid motions of a cube are isomorphic to S_4.

DF 1.7.22 Show the rigid motions of an octahedron are isomorphic to S_4, dual to the cube.

DF 1.7.23 Explain why the cube's action on the 3 pairs of opposite faces is not faithful.

Artin 3.3 (a) Define gcd of a set $\{a_1, \ldots, a_n\}$ and prove it is an integer combination; (b) if gcd $= d$, prove $\gcd(a_1/d, \ldots, a_n/d) = 1$.

Artin 4.4 Describe all groups G that contain no proper subgroup.

Artin 4.8 (a) Prove the elementary matrices of the first and third types generate $\mathrm{GL}_n(\mathbb{R})$; (b) those of the first type generate $\mathrm{SL}_n(\mathbb{R})$.

Artin 4.11 (a) Prove the transpositions generate S_n; (b) for $n \geq 3$, the 3-cycles generate A_n.

Artin 5.6 Determine the center of $\mathrm{GL}_n(\mathbb{R})$.

Artin 6.3 Show $f = 1/x$ and $g = (x-1)/x$ generate a group of functions isomorphic to S_3.

Artin 6.6 Decide whether $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 1 & 5 \\ 0 & 1 \end{smallmatrix}\right)$ are conjugate in $\mathrm{GL}_2(\mathbb{R})$; in $\mathrm{SL}_2(\mathbb{R})$.

Artin 6.8 Prove $A \mapsto (A^{\mathrm{t}})^{-1}$ is an automorphism of $\mathrm{GL}_n(\mathbb{R})$.

Artin 6.10 Find all automorphisms of (a) a cyclic group of order 10; (b) S_3.

Artin M.2 (a) Prove every group of even order has an element of order 2; (b) prove every group of order 21 has an element of order 3.

Artin M.3 Classify groups of order 6 by cases: contains an element of order 6; of order 3 but not 6; all elements of order 1 or 2.

Artin M.4 Classify the semigroups (with identity) generated by a single element.

Artin M.5 Prove that a finite semigroup in which the cancellation law holds is a group.

Artin M.12 (postage stamp) For relatively prime positive a, b: (a) every large enough n is $ra + sb$ with r, s positive; (b) determine the largest integer not of this form.

Artin M.13 (a game) Starting from $(1, 1)$, a move sends (a, b) to $(a + b, b)$ or $(a, a + b)$; determine the reachable points.

Fraleigh 1.30 For associative commutative $*$, prove $(a * b) * (c * d) = [(d * c) * a] * b$ using only the triple associative law.

Fraleigh 1.44 If $*$ satisfies $x * x = x$ and $(x * y) * z = (y * z) * x$ for all x, y, z, show $*$ is associative and commutative.

Fraleigh 2.20 Show there are exactly two nonisomorphic group structures on a set of 4 elements; find their tables and an isomorphism among the isomorphic ones.

Fraleigh 2.34 If $a * b = b * a^{-1}$ in a group, prove $b * a = a^{-1} * b$.

Fraleigh 2.35 If $ab = ba^3$ in a group, rewrite $(ab)^2$ in the form $b^k a^r$.

Fraleigh 2.40 Prove that a set with an associative operation satisfying the left identity and left inverse axioms is a group.

Fraleigh 2.41 Prove a nonempty set with an associative $*$ in which $a * x = b$ and $y * a = b$ always have solutions is a group.

Fraleigh 2.45 If G has n elements and $A \subseteq G$ has more than $n/2$ elements, prove every $g \in G$ equals $a * b$ for some $a, b \in A$.

Fraleigh 8.38 Using the kernel cosets, prove that if $\varphi : G \to G'$ is onto with $|G|$ prime, then φ is an isomorphism or G' is trivial.

Fraleigh 8.40 Show $\varphi[G]$ is abelian iff $xyx^{-1}y^{-1} \in \ker \varphi$ for all x, y.

Fraleigh 8.41 For $n \geq 3$ prove: (a) every permutation in S_n is a product of at most $n - 1$ transpositions; (b) every non-cycle, at most $n - 2$.

Fraleigh 8.50 Show S_n is generated by $\{(1, 2), (1, 2, 3, \ldots, n)\}$.

Fraleigh 8.53 Prove every finite group is isomorphic to a subgroup of $\mathrm{GL}_n(\mathbb{R})$ for some n.

Fraleigh 8.55 An inversion of $\sigma \in S_n$ is a pair $i < j$ with $\sigma(i) > \sigma(j)$; prove the even/odd theorem by counting how a transposition changes the number of inversions.

Chapter 2

Subgroups

2.1 Definition and Examples

Subgroups: definition and recognition

Definition 2.1.1. Let G be a group under an operation $\cdot$. A subset $H \subseteq G$ is a *subgroup* of G, written $H \leq G$, if H is itself a group under the operation $\cdot$ restricted to H. We write $H < G$ when $H \leq G$ and $H \neq G$ (a *proper* subgroup). Every group has the two *trivial* subgroups $\{1\}$ and G itself.

The bare definition is awkward to use directly, because checking "H is a group" seems to require re-checking associativity, the existence of an identity, and the existence of inverses. The next proposition reduces all of this to three concrete conditions, and then to two.

Proposition 2.1.2 (Subgroup Criterion, long form)**.** *Let G be a group and $H \subseteq G$. Then $H \leq G$ if and only if all three of the following hold:*

(0) $H \neq \varnothing$ (equivalently $1 \in H$);

(1) H is closed under products: for all $a, b \in H$, $ab \in H$;

(2) H is closed under inverses: for all $a \in H$, $a^{-1} \in H$.

Proof. ($\Longrightarrow$) If $H \leq G$ then H is a group, so it is nonempty, its operation lands inside H (giving (1)), and each $a \in H$ has an inverse in H (giving (2)).

($\Longleftarrow$) Assume (0),(1),(2). By (1) the restricted operation is a genuine binary operation on H. Associativity holds in H because it already holds for *all* elements of G, in particular for elements of H. Since $H \neq \varnothing$, pick $a \in H$; by (2) $a^{-1} \in H$, and by (1) $aa^{-1} = 1 \in H$, so H contains an identity. For each $a \in H$, (2) gives $a^{-1} \in H$, which is a two-sided inverse. Hence H is a group, i.e. $H \leq G$. □

Proposition 2.1.3 (Identity and inverses agree)**.** *If $H \leq G$ then the identity 1_H of H equals the identity 1_G of G, and for $h \in H$ the inverse of h computed in H equals the inverse h^{-1} computed in G.*

Proof. In H we have $1_H\, 1_H = 1_H$. Viewing this equation in G and multiplying both sides on the right by $(1_H)^{-1}$ (the inverse in G, which exists since $1_H \in G$) gives $1_H = 1_G$. For $h \in H$ let h' be its inverse in H, so $hh' = 1_H = 1_G$. Multiplying on the left in G by h^{-1} gives $h' = h^{-1}$. □

Remark 2.1.1. Conditions (1) and (2) of Proposition 2.1.2 can be merged into one (the "one-step" test): a *nonempty* $H \subseteq G$ is a subgroup iff $ab^{-1} \in H$ for all $a, b \in H$. Indeed, taking $a = b$ gives $1 \in H$; taking $a = 1$ gives $b^{-1} \in H$ for all $b \in H$; and then $a(b^{-1})^{-1} = ab \in H$ gives closure. For *finite* H one may even drop (2): a nonempty finite subset closed under products is a subgroup, because powers $a, a^2, a^3, \ldots$ must repeat, forcing some $a^k = 1$ and $a^{-1} = a^{k-1} \in H$.

Method (The "Is H a subgroup?" checklist)**.** *Recognition trigger.* Use this whenever you are handed a subset H of a known group G and asked whether $H \leq G$, or asked to *prove* some described set is a subgroup. Do NOT re-verify associativity — it is inherited from G for free.

1. **Nonempty / identity.** Exhibit a concrete element of H; the cleanest is to show $1_G \in H$. If $1_G \notin H$, stop: H is *not* a subgroup.

2. **Closed under products.** Take arbitrary $a, b \in H$ (write out what membership means), form ab, and verify ab satisfies the defining condition of H.

3. **Closed under inverses.** Take arbitrary $a \in H$, form a^{-1}, and verify $a^{-1} \in H$.

Shortcuts. If H is *finite* and nonempty, step (3) is automatic once step (2) holds (Remark 2.1.1). To disprove, it suffices to break *one* clause with a single explicit counterexample.

Caution. "Nonempty" is not optional. The empty set is closed under products and inverses vacuously, yet $\varnothing$ is not a group (no identity). Always actually produce an element — showing $1_G \in H$ kills two birds, since it proves nonemptiness too.

Caution. A subset can contain 1_G and still fail to be a subgroup. Containing the identity gives you step (1) only; you must still check closure under products *and* inverses. See the non-example $\{1, s, sr\} \subseteq D_8$ below.

Worked Example 2.1.4 ($n\mathbb{Z} \leq \mathbb{Z}$)**.** Fix $n \in \mathbb{Z}$ and let $n\mathbb{Z} = \{nk \mid k \in \mathbb{Z}\}$. Show $n\mathbb{Z} \leq (\mathbb{Z}, +)$.

Recognition. A described subset of a known group $(\mathbb{Z}, +)$: run the three-clause checklist. The operation is written additively, so "product ab" means the sum $a + b$, "identity 1" means 0, and "inverse a^{-1}" means $-a$.

Solution. Nonempty/identity: $0 = n \cdot 0 \in n\mathbb{Z}$, so $0 \in n\mathbb{Z}$ and $n\mathbb{Z} \neq \varnothing$. *Closed under +:* take $a, b \in n\mathbb{Z}$, say $a = nk$ and $b = n\ell$ with $k, \ell \in \mathbb{Z}$. Then $a + b = nk + n\ell = n(k + \ell)$, and $k + \ell \in \mathbb{Z}$, so $a + b \in n\mathbb{Z}$. *Closed under inverses:* for $a = nk \in n\mathbb{Z}$ we have $-a = -nk = n(-k)$ with $-k \in \mathbb{Z}$, so $-a \in n\mathbb{Z}$. All three clauses hold, hence $n\mathbb{Z} \leq \mathbb{Z}$. *Check.* For $n = 3$, $6, 9 \in 3\mathbb{Z}$ and $6 + 9 = 15 = 3 \cdot 5 \in 3\mathbb{Z}$; also $-6 = 3 \cdot (-2) \in 3\mathbb{Z}$. Note $n\mathbb{Z} = \mathbb{Z}$ when $n = \pm 1$ and $n\mathbb{Z} = \{0\}$ when $n = 0$.

Worked Example 2.1.5 ($\mathrm{SL}_n(\mathbb{R}) \leq \mathrm{GL}_n(\mathbb{R})$)**.** Let $\mathrm{SL}_n(\mathbb{R}) = \{A \in \mathrm{GL}_n(\mathbb{R}) \mid \det A = 1\}$. Show it is a subgroup of $\mathrm{GL}_n(\mathbb{R})$ (invertible real $n \times n$ matrices under multiplication).

Recognition. A subset cut out by a condition ($\det = 1$) inside a matrix group. Run the checklist, using the multiplicativity of det: $\det(AB) = \det(A)\det(B)$ and $\det(A^{-1}) = (\det A)^{-1}$.

Solution. Identity: $\det(I) = 1$, so $I \in \mathrm{SL}_n(\mathbb{R})$ and the set is nonempty. *Closed under products:* if $A, B \in \mathrm{SL}_n(\mathbb{R})$ then $\det A = \det B = 1$, so $\det(AB) = \det(A)\det(B) = 1 \cdot 1 = 1$, hence $AB \in \mathrm{SL}_n(\mathbb{R})$ (and AB is invertible, so it lies in $\mathrm{GL}_n(\mathbb{R})$). *Closed under inverses:* if $A \in \mathrm{SL}_n(\mathbb{R})$ then $\det A = 1 \neq 0$, so A^{-1} exists, and $\det(A^{-1}) = 1/\det(A) = 1/1 = 1$, hence $A^{-1} \in \mathrm{SL}_n(\mathbb{R})$. Therefore $\mathrm{SL}_n(\mathbb{R}) \leq \mathrm{GL}_n(\mathbb{R})$. *Check.* $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ has $\det A = 2 - 1 = 1$, and $A^{-1} = \left(\begin{smallmatrix} 1 & -1 \\ -1 & 2 \end{smallmatrix}\right)$ has $\det = 2 - 1 = 1$; both lie in $\mathrm{SL}_2(\mathbb{R})$.

Worked Example 2.1.6 (Torsion subgroup of an abelian group)**.** Let G be abelian and set $T = \{g \in G \mid |g| < \infty\}$ (the elements of finite order). Show $T \leq G$.

Recognition. Described as "all elements satisfying a finiteness condition." The condition is about orders, so the tool is: $|g| < \infty$ means $g^m = 1$ for some $m \geq 1$. We will need commutativity to combine two finite-order elements — this is exactly where abelianness is used.

Solution. Identity: $|1| = 1 < \infty$, so $1 \in T$ and $T \neq \varnothing$. *Closed under products:* let $a, b \in T$, say $a^m = 1$ and $b^n = 1$ with $m, n \geq 1$. Since G is abelian, a and b commute, so $(ab)^{mn} = a^{mn}b^{mn} = (a^m)^n(b^n)^m = 1^n \cdot 1^m = 1$. Thus $|ab|$ divides mn, in particular $|ab| < \infty$, so $ab \in T$. *Closed under inverses:* if $a \in T$ with $a^m = 1$, then $(a^{-1})^m = (a^m)^{-1} = 1^{-1} = 1$, so $|a^{-1}| < \infty$ and $a^{-1} \in T$. Hence $T \leq G$. *Check.* In $G = (\mathbb{Z}/15\mathbb{Z})^\times$ (abelian, order 8), 2 has order 4 ($2, 4, 8, 16 \equiv 1$) and 4 has order 2; their product $2 \cdot 4 = 8$ has order 4 ($8, 64 \equiv 4, 512 \equiv 2, \ldots$ returns to 1 at the 4th power), again of finite order, consistent with $T = G$ here.

Caution. The torsion set need NOT be a subgroup if G is *nonabelian*: in $\mathrm{GL}_2(\mathbb{R})$, $a = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ and $b = \left(\begin{smallmatrix} -1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ both have order 2, but $ab = \left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix}\right)$ has infinite order. Commutativity is essential in the closure step above.

Worked Example 2.1.7 (NON-example: the odd integers)**.** Let $O = \{\text{odd integers}\} = \{\ldots, -3, -1, 1, 3, \ldots\} \subseteq \mathbb{Z}$. Decide whether $O \leq (\mathbb{Z}, +)$.

Recognition. A described subset of $(\mathbb{Z}, +)$: run the checklist, but as soon as one clause fails we may stop and declare "not a subgroup." Quickest clause to test for O is the identity, since 0 is even.

Solution. Identity fails: the additive identity of $\mathbb{Z}$ is 0, which is even, so $0 \notin O$. By Proposition 2.1.3 a subgroup must contain $1_G = 0$, so O is *not* a subgroup. *Closure also fails, independently:* $1 \in O$ and $3 \in O$ but $1 + 3 = 4 \notin O$ (sum of two odds is even). *Conclusion.* $O \not\leq \mathbb{Z}$: it lacks the identity 0 (although $O \neq \varnothing$) and fails clause (1). *Check.* Two failures confirm each other; a single one already suffices.

Worked Example 2.1.8 (NON-example vs example inside D_8)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$, compare the subsets $A = \{1, s\}$ and $B = \{1, s, sr\}$.

Recognition. Two finite subsets of a finite group. By the finite shortcut (Remark 2.1.1), once a nonempty finite set is closed under products it is automatically a subgroup, so closure under products is the decisive test. Use the relation $srs = r^{-1}$, i.e. $sr = r^{-1}s$, to simplify products.

Solution. For $A = \{1, s\}$: it is nonempty and finite. Products: $1 \cdot 1 = 1$, $1 \cdot s = s$, $s \cdot 1 = s$, and $s \cdot s = s^2 = 1$. Every product lands in A, so A is closed; being finite and nonempty, $A \leq D_8$ (indeed $|s| = 2$ so $A = \langle s \rangle$). *For $B = \{1, s, sr\}$:* test closure. Compute $s \cdot (sr) = (ss)r = s^2 r = r$. But $r \notin B$ (the elements of B are 1, s, and sr, none equal to r since $r \neq 1$, $r \neq s$, and $r \neq sr$ as that would force $s = 1$). Closure under products fails, so $B \not\leq D_8$. *Check.* $|B| = 3$ does not divide $|D_8| = 8$, so by Lagrange's theorem (Chapter 3) B could never have been a subgroup — consistent with our direct computation.

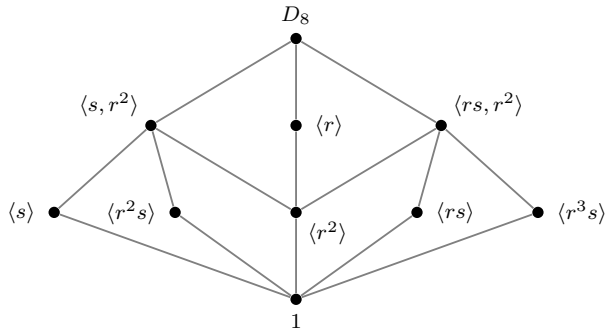
Worked Example 2.1.9 (The unit circle $S^1 \leq \mathbb{C}^\times$)**.** Let $S^1 = \{z \in \mathbb{C}^\times \mid |z| = 1\}$ where $\mathbb{C}^\times = \mathbb{C} \setminus \{0\}$ under multiplication. Show $S^1 \leq \mathbb{C}^\times$.

Recognition. A subset of the multiplicative group $\mathbb{C}^\times$ cut out by the condition $|z| = 1$. The relevant tool is multiplicativity of modulus: $|zw| = |z|\,|w|$ and $|z^{-1}| = |z|^{-1}$ for $z \neq 0$.

Solution. Identity: $|1| = 1$, so $1 \in S^1$ and $S^1 \neq \varnothing$. *Closed under products:* if $z, w \in S^1$ then $|z| = |w| = 1$, so $|zw| = |z|\,|w| = 1 \cdot 1 = 1$, hence $zw \in S^1$. *Closed under inverses:* if $z \in S^1$ then $z \neq 0$ and $|z^{-1}| = 1/|z| = 1/1 = 1$, so $z^{-1} \in S^1$. Therefore $S^1 \leq \mathbb{C}^\times$. *Check.* $z = \frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}i$ has $|z|^2 = \frac{1}{2} + \frac{1}{2} = 1$; its inverse is its conjugate $\bar{z} = \frac{\sqrt{2}}{2} - \frac{\sqrt{2}}{2}i$, which also has modulus 1 and lies in S^1.

Worked Example 2.1.10 (A bare-definition / one-step variation: $\langle i \rangle \leq Q_8$)**.** In $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, show $H = \{1, i, -1, -i\}$ is a subgroup, using the one-step test $ab^{-1} \in H$.

Recognition. We are told to use the one-step criterion (Remark 2.1.1): for nonempty H, $H \leq G$ iff $ab^{-1} \in H$ for all $a, b \in H$. Trigger: a finite explicit subset and an instruction (or convenience) to do a single combined check. Recall in Q_8: $i^2 = -1$, $i^{-1} = -i$, $(-1)^{-1} = -1$, $(-i)^{-1} = i$.



Solution. $H \neq \varnothing$ since $1 \in H$. Note $H = \{i^0, i^1, i^2, i^3\} = \langle i \rangle$, the cyclic group generated by i (as i has order 4: $i, i^2 = -1, i^3 = -i, i^4 = 1$). For any $a, b \in H$, both are powers of i, say $a = i^p, b = i^q$; then $ab^{-1} = i^p (i^q)^{-1} = i^{p-q}$, which is again a power of i and hence in H. Thus the one-step condition holds and $H \leq Q_8$. *Check, a sample:* $a = i$, $b = -1 = i^2$ give $ab^{-1} = i \cdot (-1)^{-1} = i \cdot (-1) = -i \in H$; and $a = -i$, $b = i$ give $ab^{-1} = (-i)(i^{-1}) = (-i)(-i) = i^2 = -1 \in H$. Both land in H, as predicted.

Closure-check table. The decisive computation in the D_8 non-example is a closure table: list the candidate elements down the side and across the top, fill in each product, and a subset is closed exactly when *every* entry lies back in the subset. For $B = \{1, s, sr\} \subseteq D_8$ the table immediately exposes the escape $s \cdot sr = r \notin B$.

$\cdot$	1	s	sr
1	1	s	sr
s	s	1	$\mathbf{r}$
sr	sr	$\mathbf{r^{-1}}$	1

The bold entries r and $r^{-1} = r^3$ both lie *outside* B, so B is not closed; even one such entry would disqualify it. The entries are computed from $sr = r^{-1}s$: namely $s \cdot sr = s^2 r = r$, and $sr \cdot s = s(rs) = s(sr^{-1}) = s^2 r^{-1} = r^{-1}$. The remaining product $sr \cdot sr = s\,r\,s\,r = s(rs)r = s(sr^{-1})r = s^2 r^{-1} r = r^{-1} r = 1$ lands back in B, but the two off-list entries r and r^{-1} already break closure.

Subgroup lattice of D_8 (for orientation). Subgroups of G are partially ordered by inclusion; the bottom is the trivial subgroup 1 and the top is G. For D_8 this lattice is:

The five order-2 subgroups $\langle s\rangle, \langle r^2 s\rangle, \langle r^2\rangle, \langle rs\rangle, \langle r^3 s\rangle$ sit just above 1; the three order-4 subgroups (two copies of V_4 and the cyclic $\langle r\rangle$) sit just below D_8. Notice $\{1, s, sr\}$ from the non-example appears *nowhere*: it is not a node because it is not closed, vividly confirming that "contains 1" is far from sufficient.

The subgroup criterion

Checking the four group axioms (closure, associativity, identity, inverses) by hand is tedious. The Subgroup Criterion collapses everything into a single test, because associativity is inherited free from G and the identity is forced by the single condition once H is nonempty.

Proposition 2.1.11. *Let G be a group and $H \subseteq G$. Then $H \leq G$ if and only if*

$$\textit{(a)}\quad H \neq \varnothing, \qquad \textit{and} \qquad \textit{(b)}\quad \forall\, x, y \in H,\ \ xy^{-1} \in H.$$

Proof. ($\implies$) If $H \leq G$ then H contains the identity, so $H \neq \varnothing$, giving (a). For $x, y \in H$, subgroup closure under inverses gives $y^{-1} \in H$, and closure under the product gives $xy^{-1} \in H$, giving (b).

($\impliedby$, that is the substantive direction) Assume (a) and (b). By (a) pick some $a \in H$. Apply (b) with $x = y = a$: then $aa^{-1} = 1 \in H$, so H contains the identity. Next, for any $a \in H$, apply (b) with $x = 1$ and $y = a$: $1 \cdot a^{-1} = a^{-1} \in H$, so H is closed under inverses. Finally, for $a, b \in H$ we have just shown $b^{-1} \in H$; apply (b) with $x = a$, $y = b^{-1}$ to get $a(b^{-1})^{-1} = ab \in H$, so H is closed under the product. Associativity holds in H because it holds in G and $H \subseteq G$. Thus H is a group under the operation of G, i.e. $H \leq G$. □

Remark 2.1.2. The single condition (b) is doing triple duty: $x = y$ forces $1 \in H$; $x = 1$ forces inverses; and then x, y^{-1} forces products. This is why it is called the *one-step* subgroup test.

Method (One-step criterion vs. the full definition)**.** *Recognition trigger.* You are handed a *subset* H of a known group G and asked "is H a subgroup?" Do NOT re-verify associativity — it is inherited. Instead:

1. **Nonempty.** Exhibit one explicit element of H (usually check $1 \in H$; that already settles (a)).
2. **One-step closure.** Take *arbitrary* $x, y \in H$, write the defining property each satisfies, and compute xy^{-1}. Show xy^{-1} satisfies the same defining property.
3. Conclude $H \leq G$ by Proposition 2.1.11.

When to use which: use the one-step criterion whenever H is described by a *closed-form condition* (a determinant value, a modulus, a divisibility, a matrix shape). Use the raw two-step version (check products and inverses separately) only when computing xy^{-1} in one shot is awkward and splitting is clearer. Never bother re-proving associativity.

Caution. The criterion is $xy^{-1} \in H$, not $xy \in H$. A subset closed under products only (e.g. $\mathbb{Z}_{\geq 0} \subseteq \mathbb{Z}$) need not be a subgroup. Closure under products alone suffices ONLY in the finite case (Proposition 2.1.17 below).

Worked Example 2.1.12 ($n\mathbb{Z} \leq \mathbb{Z}$)**.** Show that $n\mathbb{Z} = \{nk \mid k \in \mathbb{Z}\}$ is a subgroup of $(\mathbb{Z}, +)$ for every integer $n \geq 0$.

Recognition. $n\mathbb{Z}$ is a subset of the group $\mathbb{Z}$ defined by a closed-form condition ("is a multiple of n"), so the one-step criterion applies. The operation is $+$, so "xy^{-1}" here means $x - y$.

Solution. **(a) Nonempty:** $0 = n \cdot 0 \in n\mathbb{Z}$. **(b) One-step:** take $x, y \in n\mathbb{Z}$, say $x = na$ and $y = nb$ with $a, b \in \mathbb{Z}$. Then

$$x - y = na - nb = n(a - b),$$

and $a - b \in \mathbb{Z}$, so $x - y \in n\mathbb{Z}$. By Proposition 2.1.11, $n\mathbb{Z} \leq \mathbb{Z}$.
Check. With $n = 3$, $x = 6$, $y = 15$: $x - y = -9 = 3 \cdot (-3) \in 3\mathbb{Z}$. Correct.

Worked Example 2.1.13 ($\{A \in \mathrm{GL}_n(\mathbb{R}) \mid \det A = \pm 1\}$)**.** Let $H = \{A \in \mathrm{GL}_n(\mathbb{R}) \mid \det A \in \{1, -1\}\}$. Show $H \leq \mathrm{GL}_n(\mathbb{R})$.

Recognition. H is a subset of the group $\mathrm{GL}_n(\mathbb{R})$ cut out by the condition $\det A = \pm 1$. The trigger is the closed-form determinant condition; use the one-step test with the multiplicativity $\det(AB) = \det A \det B$ and $\det(A^{-1}) = (\det A)^{-1}$.

Solution. **(a) Nonempty:** $\det I = 1$, so $I \in H$. **(b) One-step:** take $A, B \in H$, so $\det A = \pm 1$ and $\det B = \pm 1$. Then B is invertible (determinant nonzero) and

$$\det(AB^{-1}) = \det A \cdot \det(B^{-1}) = \det A \cdot (\det B)^{-1} = (\pm 1) \cdot (\pm 1)^{-1} = \pm 1,$$

since $(\pm 1)^{-1} = \pm 1$ in $\mathbb{R}$. Hence $AB^{-1} \in H$, and by Proposition 2.1.11, $H \leq \mathrm{GL}_n(\mathbb{R})$.
Check. $A = \mathrm{diag}(1, -1)$ has $\det = -1$, $B = \mathrm{diag}(-1, 1)$ has $\det = -1$; $B^{-1} = B$, $AB^{-1} = \mathrm{diag}(-1, -1)$ with $\det = 1 \in \{\pm 1\}$. Correct. (Note H properly contains $\mathrm{SL}_n(\mathbb{R})$, the determinant-1 subgroup.)

Worked Example 2.1.14 (The unit circle $\{z \in \mathbb{C}^\times \mid |z| = 1\}$)**.** Let $S = \{z \in \mathbb{C}^\times \mid |z| = 1\}$. Show $S \leq \mathbb{C}^\times$, the multiplicative group of nonzero complex numbers.

Recognition. Subset of the group $(\mathbb{C}^\times, \cdot)$ defined by the closed-form modulus condition $|z| = 1$. One-step test; use $|zw| = |z|\,|w|$ and $|z^{-1}| = |z|^{-1}$. Here "xy^{-1}" is $zw^{-1} = z/w$.

Solution. **(a) Nonempty:** $|1| = 1$, so $1 \in S$. **(b) One-step:** take $z, w \in S$, so $|z| = |w| = 1$ and $w \neq 0$. Then

$$\left|zw^{-1}\right| = |z| \cdot |w^{-1}| = |z| \cdot |w|^{-1} = 1 \cdot 1^{-1} = 1,$$

so $zw^{-1} \in S$. By Proposition 2.1.11, $S \leq \mathbb{C}^\times$.
Check. $z = i$, $w = \frac{1+i}{\sqrt{2}}$ both have modulus 1; $zw^{-1} = i \cdot \frac{1-i}{\sqrt{2}} = \frac{i+1}{\sqrt{2}}$, with modulus $\frac{\sqrt{2}}{\sqrt{2}} = 1$. Correct.

Worked Example 2.1.15 (Unipotent upper-triangular matrices)**.** Let $U = \left\{ \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \mid a \in \mathbb{R} \right\} \subseteq \mathrm{GL}_2(\mathbb{R})$ (upper triangular, 1's on the diagonal). Show $U \leq \mathrm{GL}_2(\mathbb{R})$.

Recognition. Subset of $\mathrm{GL}_2(\mathbb{R})$ defined by a matrix *shape* condition. One-step test; the trick is to compute the inverse of such a matrix explicitly, then multiply.

Solution. Write $M(a) = \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix}$. **(a) Nonempty:** $M(0) = I \in U$. **(b) One-step:** take $M(a), M(b) \in U$. First, $\det M(b) = 1 \neq 0$ so it is invertible, and

$$M(b)^{-1} = \begin{pmatrix} 1 & -b \\ 0 & 1 \end{pmatrix} = M(-b).$$

Then

$$M(a)M(b)^{-1} = \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & -b \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & a-b \\ 0 & 1 \end{pmatrix} = M(a-b) \in U.$$

By Proposition 2.1.11, $U \leq \mathrm{GL}_2(\mathbb{R})$.
Check. $a = 5$, $b = 2$: $M(5)M(2)^{-1} = M(3)$, which has 1's on the diagonal and lies in U. Indeed $a \mapsto M(a)$ is a bijection $\mathbb{R} \to U$ with $M(a)M(b) = M(a+b)$, so U is just $(\mathbb{R}, +)$ in disguise. Correct.

Worked Example 2.1.16 (A non-example: $xy^{-1} \notin H$)**.** In $G = (\mathbb{Z}, +)$, let $H = \{n \in \mathbb{Z} \mid n \geq 0\} = \mathbb{Z}_{\geq 0}$ (the nonnegative integers). Decide whether $H \leq \mathbb{Z}$.

Recognition. This is a *disproof* task. H is nonempty and closed under the product $(+)$, which tempts one into thinking it is a subgroup — but the criterion demands $xy^{-1} \in H$, i.e. $x - y \in H$. To refute (b), exhibit a single pair $x, y \in H$ with $x - y \notin H$.

Solution. **(a)** $0 \in H$, so nonempty: fine. **(b) fails:** take $x = 1 \in H$, $y = 2 \in H$. Then

$$xy^{-1} = x - y = 1 - 2 = -1 \notin H,$$

since $-1 < 0$. So condition (b) of Proposition 2.1.11 fails for the explicit pair $(1, 2)$. Therefore $H \not\leq \mathbb{Z}$.
Check. The underlying reason is that H contains no inverses: $1 \in H$ but $-1 \notin H$. This is exactly the pitfall above — closure under products is not enough for an infinite set.

The finite subgroup criterion

When H is *finite*, even less is required: closure under the product alone forces inverses to appear automatically, because the powers $x, x^2, x^3, \ldots$ cannot all be distinct.

Proposition 2.1.17. *Let G be a group and let H be a* finite *nonempty subset of G that is closed under the operation of G (i.e. $xy \in H$ for all $x, y \in H$). Then $H \leq G$.*

Proof. By Proposition 2.1.11 it suffices to show that for each $x \in H$ we have $x^{-1} \in H$ (closure under products then gives $xy^{-1} \in H$). Fix $x \in H$. By closure, all positive powers $x, x^2, x^3, \ldots$ lie in H. Since H is finite, these cannot all be distinct, so there exist integers $i < j$ with $x^i = x^j$. Cancelling in G gives $x^{j-i} = 1$ with $n := j - i \geq 1$, so $1 = x^n \in H$. If $n = 1$ then $x = 1$ and $x^{-1} = 1 = x \in H$. If $n \geq 2$ then

$$x \cdot x^{n-1} = x^n = 1 \quad \Longrightarrow \quad x^{-1} = x^{n-1},$$

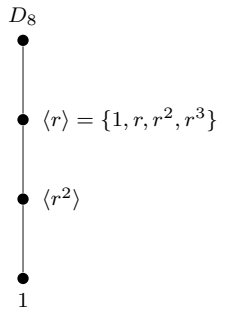
and $x^{n-1} \in H$ because $n - 1 \geq 1$ is a positive power. Either way $x^{-1} \in H$, completing the proof. □

Remark 2.1.3. Finiteness is essential: $\mathbb{Z}_{\geq 0} \subseteq \mathbb{Z}$ from the last worked example is nonempty and closed under $+$, but is not a subgroup — it is infinite, so the powers $x, 2x, 3x, \ldots$ never repeat and inverses never get forced.

Method (When the finite criterion saves work)**.** *Recognition trigger.* H is a *finite* subset of G (e.g. an explicitly listed finite set, or any subset of a finite group) and you want to prove $H \leq G$. Then:

1. Confirm H is nonempty and finite.
2. Check closure under the product ONLY: verify $xy \in H$ for all $x, y \in H$ (for a small explicit set, fill in the multiplication table; for a structured set, give a closure argument).
3. Invoke Proposition 2.1.17; inverses and the identity come for free.

Use this whenever checking $x^{-1} \in H$ separately would be extra labor — the finite criterion lets you skip the inverse check entirely.



Worked Example 2.1.18 ($\{1, r, r^2, r^3\} = \langle r \rangle \leq D_8$ via the finite criterion)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$, let $H = \{1, r, r^2, r^3\}$. Show $H \leq D_8$.

Recognition. H is a finite (4-element) subset of the finite group D_8. The finite criterion (Proposition 2.1.17) applies: just check closure under the product; do not bother with inverses.

Solution. **Nonempty and finite:** $|H| = 4$. **Closure:** every element of H is a power r^i with $0 \leq i \leq 3$, and $r^i r^j = r^{i+j} = r^{(i+j) \bmod 4}$ since $r^4 = 1$. The exponent $(i + j) \bmod 4 \in \{0, 1, 2, 3\}$, so $r^i r^j \in H$ always. Concretely:

$\cdot$	1	r	r^2	r^3
1	1	r	r^2	r^3
r	r	r^2	r^3	1
r^2	r^2	r^3	1	r
r^3	r^3	1	r	r^2

Every entry lies in H, so H is closed under the product. By Proposition 2.1.17, $H \leq D_8$. (Indeed $H = \langle r \rangle$, the cyclic rotation subgroup of order 4.)
Check. Inverses appear automatically, as promised: $r^{-1} = r^3$, $(r^2)^{-1} = r^2$, $(r^3)^{-1} = r$, all in H. Correct.

Worked Example 2.1.19 ($\langle i \rangle = \{1, i, -1, -i\} \leq Q_8$)**.** In $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$ and $ij = k$, let $H = \{1, i, -1, -i\}$. Show $H \leq Q_8$.

Recognition. H is a finite 4-element subset of the finite group Q_8. Finite criterion: check closure under multiplication only.

Solution. **Nonempty, finite:** $|H| = 4$. **Closure:** the elements are the powers of i: $i^0 = 1,\ i^1 = i,\ i^2 = -1,\ i^3 = -i,\ i^4 = 1$, so $H = \{i^0, i^1, i^2, i^3\}$ and $i^a i^b = i^{(a+b) \bmod 4} \in H$. The table:

$\cdot$	1	i	-1	$-i$
1	1	i	-1	$-i$
i	i	-1	$-i$	1
-1	-1	$-i$	1	i
$-i$	$-i$	1	i	-1

All entries lie in H, so H is closed. By Proposition 2.1.17, $H \leq Q_8$.
Check. $i^{-1} = -i = i^3 \in H$ and $(-1)^{-1} = -1 \in H$, confirming inverses came for free. Correct.

Worked Example 2.1.20 ($V_4 = \{1, r^2, s, sr^2\} \leq D_8$)**.** In D_8 let $H = \{1, r^2, s, sr^2\}$. Show $H \leq D_8$.

Recognition. Finite 4-element subset of finite D_8; check product-closure only. Here we must use the relation $sr = r^{-1}s = r^3 s$ to move s past r, and $r^4 = 1$, $s^2 = 1$.

Solution. **Nonempty, finite:** $|H| = 4$. **Closure:** note r^2 commutes with s, since $sr^2 = (sr)r = r^3 sr = r^3 r^3 s = r^6 s = r^2 s$ (using $sr = r^3 s$ twice and $r^6 = r^2$). So $sr^2 = r^2 s$, and each element squares as $1^2 = 1$, $(r^2)^2 = r^4 = 1$, $s^2 = 1$, $(sr^2)^2 = sr^2 sr^2 = s(r^2 s)r^2 = s(sr^2)r^2 = s^2 r^4 = 1$. The products:

$\cdot$	1	r^2	s	sr^2
1	1	r^2	s	sr^2
r^2	r^2	1	sr^2	s
s	s	sr^2	1	r^2
sr^2	sr^2	s	r^2	1

For instance $r^2 \cdot s = r^2 s = sr^2 \in H$, and $s \cdot sr^2 = s^2 r^2 = r^2 \in H$, and $sr^2 \cdot s = sr^2 s = s\, sr^2 = r^2$ (using $r^2 s = sr^2$). Every entry is in H, so H is closed. By Proposition 2.1.17, $H \leq D_8$. (This is a Klein four-group V_4 inside D_8.)
Check. The table is symmetric with 1 on the diagonal, so each element is its own inverse, all inside H. Correct.

Worked Example 2.1.21 (Finite criterion needs finiteness: where the power argument stalls)**.** Take $G = (\mathbb{Q}^\times, \cdot)$ and $H = \{2^k \mid k \in \mathbb{Z}_{\geq 0}\} = \{1, 2, 4, 8, \dots\}$. Is H closed under multiplication? Does the finite criterion apply? Decide whether $H \leq \mathbb{Q}^\times$.

Recognition. This probes the *hypothesis* of Proposition 2.1.17: H is closed under products but *infinite*, so the finite criterion does not apply — and we expect inverses to be missing. Fall back to the one-step criterion to disprove.

Solution. **Closure under product:** $2^a \cdot 2^b = 2^{a+b} \in H$ for $a, b \geq 0$, so yes, H is closed under multiplication. But H is infinite, so Proposition 2.1.17 gives no conclusion. **One-step test fails:** take $x = 1 \in H$ and $y = 2 \in H$; then

$$xy^{-1} = 1 \cdot 2^{-1} = \tfrac{1}{2} \notin H,$$

since $\frac{1}{2} = 2^{-1}$ has a negative exponent and H contains only nonnegative powers. So condition (b) of Proposition 2.1.11 fails, and $H \not\leq \mathbb{Q}^\times$.
Check. Tracing the proof of Proposition 2.1.17, the powers $2, 2^2, 2^3, \ldots$ are all distinct (no repeat $x^i = x^j$), so the argument that forces x^{-1} never triggers — exactly because H is infinite. Correct, and it shows the finiteness hypothesis cannot be dropped.

Caution. Do not apply the finite criterion to a finite *subset of an infinite group* without first checking closure carefully, and never apply it to an infinite set. The set $\{1, 2, 4, \ldots\}$ above is closed under products yet is not a subgroup — its infiniteness is the whole reason.

Further subgroup examples: chains, exponent sets, and unions

The subgroup relation is *transitive*: if $K \leq H$ and $H \leq G$ then $K \leq G$, since the one-step condition $xy^{-1} \in K$ for $x, y \in K$ holds inside H and the products are computed with the operation of G throughout. Dummit & Foote open the section with the basic chains this produces.

Worked Example 2.1.22 (The chains $\mathbb{Z} \leq \mathbb{Q} \leq \mathbb{R} \leq \mathbb{C}$ and $\mathbb{Q}^\times \leq \mathbb{R}^\times \leq \mathbb{C}^\times$)**.** Show that under addition $\mathbb{Z} \leq \mathbb{Q} \leq \mathbb{R} \leq \mathbb{C}$, and that under multiplication $\mathbb{Q}^\times \leq \mathbb{R}^\times \leq \mathbb{C}^\times$ (nonzero elements).

Recognition. Each link is a subset of a known group closed under the operation, so run the one-step criterion (Proposition 2.1.11) on each inclusion; transitivity then chains them. Additively "xy^{-1}" means $x - y$; multiplicatively it means x/y.

Solution. Additive chain. For $\mathbb{Z} \leq \mathbb{Q}$: $0 \in \mathbb{Z}$, and for $x, y \in \mathbb{Z}$, $x - y \in \mathbb{Z}$. For $\mathbb{Q} \leq \mathbb{R}$: $0 \in \mathbb{Q}$, and a difference of rationals is rational. For $\mathbb{R} \leq \mathbb{C}$: $0 \in \mathbb{R}$, and a difference of reals is real. By Proposition 2.1.11 each is a subgroup, and by transitivity $\mathbb{Z} \leq \mathbb{C}$ as well. *Multiplicative chain.* For $\mathbb{Q}^\times \leq \mathbb{R}^\times$: $1 \in \mathbb{Q}^\times$, and for nonzero rationals x, y the quotient x/y is a nonzero rational. For $\mathbb{R}^\times \leq \mathbb{C}^\times$: $1 \in \mathbb{R}^\times$, and a quotient of nonzero reals is a nonzero real. So $\mathbb{Q}^\times \leq \mathbb{R}^\times \leq \mathbb{C}^\times$, hence $\mathbb{Q}^\times \leq \mathbb{C}^\times$. *Check.* The additive and multiplicative chains are genuinely different containments — e.g. $\frac{1}{2} \in \mathbb{Q}$ but $\frac{1}{2} \notin \mathbb{Z}$, while $\frac{1}{2} \in \mathbb{Q}^\times$; and $0 \in \mathbb{C}$ lies in every additive stage but in *no* multiplicative stage, since $\mathbb{C}^\times = \mathbb{C} \setminus \{0\}$.

D&F also single out, for an *abelian* group, the elements killed by a fixed exponent — a sharper companion to the torsion subgroup treated above. (The torsion subgroup collected the x with $x^m = 1$ for *some* m; here the exponent n is fixed.)

Worked Example 2.1.23 ($H_n = \{x \mid x^n = 1\}$ in an abelian group)**.** Let G be abelian and fix an integer $n \geq 1$. Let $H_n = \{x \in G \mid x^n = 1\}$. Show $H_n \leq G$.

Recognition. A subset of G cut out by the closed-form condition $x^n = 1$; use the one-step criterion (Proposition 2.1.11), expanding $(xy^{-1})^n$ with commutativity.

Solution. **(a) Nonempty:** $1^n = 1$, so $1 \in H_n$. **(b) One-step:** take $x, y \in H_n$, so $x^n = 1$ and $y^n = 1$. Since G is abelian, x and y^{-1} commute, so

$$(xy^{-1})^n = x^n (y^{-1})^n = x^n (y^n)^{-1} = 1 \cdot 1^{-1} = 1,$$

hence $xy^{-1} \in H_n$. By Proposition 2.1.11, $H_n \leq G$. *Check.* In $G = (\mathbb{Z}/15\mathbb{Z})^\times$ (abelian, order 8) with $n = 2$,

$$H_2 = \{x \mid x^2 \equiv 1 \pmod{15}\} = \{1, 4, 11, 14\},$$

since $4^2 = 16 \equiv 1$, $11^2 = 121 \equiv 1$, $14^2 = 196 \equiv 1$, while $2, 7, 8, 13$ all square to 4. And it is closed: $4 \cdot 11 = 44 \equiv 14 \in H_2$, $4 \cdot 4 = 16 \equiv 1 \in H_2$, as predicted. (Commutativity is essential: in a nonabelian group $\{x \mid x^n = 1\}$ can fail to be a subgroup, exactly as the torsion set did.)

A *union* of subgroups, by contrast, is almost never a subgroup.

Remark 2.1.4. If $H, K \leq G$ then $H \cup K \leq G$ if and only if $H \subseteq K$ or $K \subseteq H$. Indeed, if neither contains the other, pick $h \in H \setminus K$ and $k \in K \setminus H$; the product hk cannot lie in H (else $k = h^{-1}(hk) \in H$) nor in K (else $h = (hk)k^{-1} \in K$), so $hk \notin H \cup K$ and closure fails. The *intersection* $H \cap K$ is, by contrast, always a subgroup, by a single one-step check valid in both H and K at once.

Worked Example 2.1.24 (A union of two subgroups that fails closure)**.** In the Klein four-group $V_4 = \{1, a, b, ab\}$ (every nonidentity element of order 2, $ab = ba$), let $H = \{1, a\}$ and $K = \{1, b\}$. Show $H, K \leq V_4$ but $H \cup K \not\leq V_4$.

Recognition. Each of H, K is finite and closed under products, hence a subgroup (Proposition 2.1.17); the union illustrates Remark 2.1.4 since neither contains the other. To disprove, exhibit a product of an H-element and a K-element that escapes the union.

Solution. $H = \{1, a\} = \langle a \rangle$ and $K = \{1, b\} = \langle b \rangle$ are subgroups (each is $\{1, x\}$ with $x^2 = 1$, closed under products). Now $H \cup K = \{1, a, b\}$. Take $a \in H \cup K$ and $b \in H \cup K$: their product is ab, and $ab \notin \{1, a, b\}$ (it is the fourth, distinct element of V_4). So $H \cup K$ is not closed under products, hence $H \cup K \not\leq V_4$. *Check.* Neither $H \subseteq K$ nor $K \subseteq H$ holds, exactly the situation Remark 2.1.4 predicts will fail; and $|H \cup K| = 3$ does not divide $|V_4| = 4$, a second confirmation via Lagrange (Chapter 3).

Further worked examples

More on the Subgroup Criterion (Proposition 2.1.11).

Worked Example 2.1.25 (the diagonal $\Delta \leq G \times G$)**.** Show $\Delta = \{(g, g) \mid g \in G\}$ is a subgroup of $G \times G$.

Recognition. A described subset of the known group $G \times G$; apply the one-step criterion. Membership means "both coordinates equal."

Solution. Nonempty: $(1, 1) \in \Delta$. For $(g, g), (h, h) \in \Delta$,

$$(g, g)(h, h)^{-1} = (g, g)(h^{-1}, h^{-1}) = (gh^{-1},\, gh^{-1}) \in \Delta,$$

since the two coordinates agree. By the criterion $\Delta \leq G \times G$. *Check.* $g \mapsto (g, g)$ shows $|\Delta| = |G|$.

Worked Example 2.1.26 (upper-triangular invertible matrices)**.** Show $B = \left\{ \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right) \mid ad \neq 0 \right\} \leq \mathrm{GL}_2(\mathbb{R})$.

Recognition. A subset of $\mathrm{GL}_2(\mathbb{R})$ cut out by "lower-left entry $= 0$." One-step criterion, using that triangular $\times$ triangular is triangular and the inverse of a triangular matrix is triangular.

Solution. Nonempty: $I \in B$. Product: $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)\left(\begin{smallmatrix} a' & b' \\ 0 & d' \end{smallmatrix}\right) = \left(\begin{smallmatrix} aa' & ab'+bd' \\ 0 & dd' \end{smallmatrix}\right) \in B$ (and $aa', dd' \neq 0$). Inverse: $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)^{-1} = \left(\begin{smallmatrix} 1/a & -b/(ad) \\ 0 & 1/d \end{smallmatrix}\right) \in B$. Hence $B \leq \mathrm{GL}_2(\mathbb{R})$.

More on the finite criterion (Proposition 2.1.17).

Worked Example 2.1.27 ($\{\overline{0}, \overline{3}, \overline{6}, \overline{9}\} \leq \mathbb{Z}/12\mathbb{Z}$)**.** Show $H = \{\overline{0}, \overline{3}, \overline{6}, \overline{9}\}$ is a subgroup of $\mathbb{Z}/12\mathbb{Z}$.

Recognition. H is *finite* and nonempty inside the finite group $\mathbb{Z}/12\mathbb{Z}$, so the finite criterion applies: only closure under $+$ must be checked.

Solution. Sums of multiples of 3 are multiples of 3 mod 12: e.g. $\overline{3} + \overline{9} = \overline{12} = \overline{0}$ and $\overline{6} + \overline{9} = \overline{15} = \overline{3}$. So H is closed under $+$; being finite and nonempty, $H \leq \mathbb{Z}/12\mathbb{Z}$. *Check.* $H = \langle \overline{3} \rangle$, the order-4 subgroup.

Maps and commutative diagrams

Three structural facts of this section are cleanest when drawn as diagrams of homomorphisms and inclusions.
(a) Transitivity of $\leq$ is composition of inclusions. If $K \leq H$ and $H \leq G$ then $K \leq G$, because the inclusion $K \hookrightarrow G$ is the composite of $K \hookrightarrow H$ and $H \hookrightarrow G$.

$$K \hookrightarrow H \hookrightarrow G$$

Diagram explanation. Objects: Three groups: K (a subgroup of H), H (a subgroup of G), and G (the ambient group). Each is a group under the same operation.

Arrows: The left arrow $K \hookrightarrow H$ is the inclusion map $\iota_1 : k \mapsto k$, viewing k as an element of H. The right arrow $H \hookrightarrow G$ is the inclusion $\iota_2 : h \mapsto h$, viewing h as an element of G. Both are injective group homomorphisms (inclusions); the composite $\iota_2 \circ \iota_1 : K \hookrightarrow G$ sends $k \mapsto k$ directly, establishing $K \leq G$.

What commutes: There is a single directed path from K to G: the composite $\iota_2 \circ \iota_1$. The diagram records that this composite is itself an inclusion, i.e. $\iota_2 \circ \iota_1 = \iota_{K \hookrightarrow G}$, the direct inclusion of K into G.

Why it commutes: Take any $k \in K$. Along the unique path: first $k \mapsto k \in H$, then $k \mapsto k \in G$. The composite sends $k \mapsto k \in G$, which is exactly the direct inclusion. The agreement is trivial because all three maps are identity-on-elements inclusions; composing two identity-on-elements maps is still identity-on-elements.

Why this matters here: This diagram records the proof of transitivity of $\leq$: to show $K \leq G$ it suffices to exhibit the factoring $K \hookrightarrow H \hookrightarrow G$, because a composite of injective group homomorphisms is an injective group homomorphism. The author places it here to make the transitivity argument visual and to signal that inclusion is a genuine category-theoretic morphism, not just a set-containment symbol.

Concrete example: Take $K = 4\mathbb{Z} \leq H = 2\mathbb{Z} \leq G = \mathbb{Z}$ (all under addition). The chain $4\mathbb{Z} \hookrightarrow 2\mathbb{Z} \hookrightarrow \mathbb{Z}$ gives $4\mathbb{Z} \leq \mathbb{Z}$ by transitivity: $8 - 4 = 4 \in 4\mathbb{Z}$, so $4\mathbb{Z}$ passes the one-step test directly in $\mathbb{Z}$.

Common pitfall: Students sometimes read the two arrows as saying K must be *normal* in G, or that some quotient exists. The arrows here are plain inclusions (hooked arrows $\hookrightarrow$), not quotient or surjection arrows; they record only that elements of K sit inside H sit inside G, with no normality claimed.

Takeaway: The point of this diagram is that transitivity of the subgroup relation is just composition of inclusion homomorphisms, turning a textual argument into a one-glance arrow-chase.

(b) The intersection of subgroups is a pullback. For $H, K \leq G$ the subgroup $H \cap K$ is the largest one mapping into both H and K compatibly with their inclusions into G. This "universal corner" is precisely why $H \cap K \leq G$ (Exercise: intersections of subgroups are subgroups).

$$\begin{array}{ccc} H \cap K & \hookrightarrow & H \\ \downarrow & & \downarrow \\ K & \hookrightarrow & G \end{array}$$

Diagram explanation. Objects: Four groups: the intersection $H \cap K$ (upper-left), the subgroup $H \leq G$ (upper-right), the subgroup $K \leq G$ (lower-left), and the ambient group G (lower-right). Each arrow goes by inclusion.

Arrows: Top arrow: $H \cap K \hookrightarrow H$, the inclusion $x \mapsto x$ into H. Left arrow: $H \cap K \hookrightarrow K$, the inclusion $x \mapsto x$ into K. Right arrow: $H \hookrightarrow G$, viewing H as a subset of G. Bottom arrow: $K \hookrightarrow G$, viewing K as a subset of G. All four are injective group homomorphisms.

What commutes: Going right then down equals going down then right: $\iota_{H \to G} \circ \iota_{H \cap K \to H} = \iota_{K \to G} \circ \iota_{H \cap K \to K}$. Both composites send any $x \in H \cap K$ to $x \in G$ by definition.

Why it commutes: Let $x \in H \cap K$. Path right-then-down: $x \mapsto x \in H \mapsto x \in G$. Path down-then-right: $x \mapsto x \in K \mapsto x \in G$. Both equal $x \in G$ because all maps are identity-on-elements inclusions; the square commutes trivially.

Why this matters here: The square records the *universal property of the pullback*: $H \cap K$ is the largest subgroup of G that maps (by inclusion) into *both* H and K consistently. Any subgroup $L \leq G$ with $L \subseteq H$ and $L \subseteq K$ factors uniquely through $H \cap K$. This is the categorical reason $H \cap K$ is automatically a subgroup — it is the limit (pullback) of the diagram $H \hookrightarrow G \hookleftarrow K$ in the category of groups.

Concrete example: In $G = \mathbb{Z}_{12}$, let $H = \langle \overline{4} \rangle = \{\overline{0}, \overline{4}, \overline{8}\}$ and $K = \langle \overline{6} \rangle = \{\overline{0}, \overline{6}\}$. Then $H \cap K = \{\overline{0}\} = \langle \overline{0} \rangle$, which is the trivial subgroup. The four inclusions commute: any element of $\{\overline{0}\}$ maps to $\overline{0} \in G$ along both paths.

Common pitfall: Students sometimes expect this square to prove that the diagram has a unique filler or that $H \cap K$ is *normal*. It does neither: the square only records compatibility of inclusions. Normality requires a separate check; and the universal property says $H \cap K$ is the *largest* common sub-object, not the only one.

Takeaway: The point of this diagram is that the intersection of two subgroups is their categorical pullback in the ambient group, making $H \cap K \leq G$ a corollary of limit-preservation rather than a separate verification.

(c) A kernel is automatically a subgroup: $\mathrm{SL}_n = \ker \det$. The determinant $\det : \mathrm{GL}_n(F) \to F^\times$ is a homomorphism, and $\mathrm{SL}_n(F)$ is exactly its kernel. This gives a short exact sequence and is the slickest proof that $\mathrm{SL}_n(F) \leq \mathrm{GL}_n(F)$ — no checklist needed, because kernels of homomorphisms are always subgroups.

$$1 \longrightarrow \mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F) \xrightarrow{\det} F^\times \longrightarrow 1$$

Diagram explanation. Objects: Five nodes: the trivial group 1 (repeated at both ends), the special linear group $\mathrm{SL}_n(F) = \{A \in \mathrm{GL}_n(F) \mid \det A = 1\}$ (a normal subgroup), the general linear group $\mathrm{GL}_n(F)$ of invertible $n \times n$ matrices over a field F, and the multiplicative group $F^\times = F \setminus \{0\}$ of nonzero field elements.

Arrows: The leftmost arrow $1 \to \mathrm{SL}_n(F)$ is the unique map sending the trivial group's element to the identity matrix I. The arrow $\mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F)$ is the inclusion $A \mapsto A$. The arrow $\mathrm{GL}_n(F) \xrightarrow{\det} F^\times$ is the determinant homomorphism $A \mapsto \det A$. The rightmost arrow $F^\times \to 1$ is the unique map to the trivial group.

What commutes: This is a short exact sequence, so exactness holds at each internal node. At $\mathrm{SL}_n(F)$: $\mathrm{im}(1 \to \mathrm{SL}_n(F)) = \{I\} = \ker(\mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F))$, i.e. the inclusion is injective. At $\mathrm{GL}_n(F)$: $\mathrm{im}(\mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F)) = \mathrm{SL}_n(F) = \ker(\det)$, since $\det A = 1 \iff A \in \mathrm{SL}_n(F)$. At $F^\times$: $\mathrm{im}(\det) = F^\times$ (det is surjective: any $c \in F^\times$ is achieved by $\mathrm{diag}(c, 1, \ldots, 1)$).

Why it commutes: For the kernel condition at $\mathrm{GL}_n(F)$: if $A \in \mathrm{SL}_n(F)$ then $\det A = 1$, so $A \in \ker(\det)$; conversely if $\det A = 1$ then $A \in \mathrm{SL}_n(F)$. This is the definition of $\mathrm{SL}_n(F)$. The exactness at $F^\times$ follows because $\mathrm{diag}(c, 1, \ldots, 1)$ has determinant c for any $c \neq 0$.

Why this matters here: The diagram gives the shortest proof that $\mathrm{SL}_n(F) \leq \mathrm{GL}_n(F)$: kernels of homomorphisms are always subgroups (since $\phi(xy^{-1}) = \phi(x)\phi(y)^{-1} = 1 \cdot 1^{-1} = 1$ when $\phi(x) = \phi(y) = 1$), so no three-clause checklist is needed. The author places it here to show that the determinant constraint "$\det = 1$" is not just an algebraic coincidence but an instance of a general structural principle about kernels.

Concrete example: Take $n = 2$ and $F = \mathbb{R}$. The matrix $A = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 1/2 \end{smallmatrix}\right)$ has $\det A = 1$, so $A \in \mathrm{SL}_2(\mathbb{R})$; its image under det is $1 \in \mathbb{R}^\times$. The matrix $B = \left(\begin{smallmatrix} 3 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ has $\det B = 3 \neq 1$, so $B \notin \mathrm{SL}_2(\mathbb{R})$; det maps B to 3, which is a nonzero element of $\mathbb{R}^\times$, demonstrating surjectivity.

Common pitfall: Students sometimes think the short exact sequence says $\mathrm{GL}_n(F) \cong \mathrm{SL}_n(F) \times F^\times$ (a direct product splitting). That is false in general, even though this particular sequence always splits: $c \mapsto \mathrm{diag}(c, 1, \ldots, 1)$ is a homomorphism $F^\times \to \mathrm{GL}_n(F)$ that is a section of det, so $\mathrm{GL}_n(F) \cong \mathrm{SL}_n(F) \rtimes F^\times$ is a *semi*direct product. The complement need not be normal and the product need not be direct: e.g. $\mathrm{GL}_2(\mathbb{F}_3) \ncong \mathrm{SL}_2(\mathbb{F}_3) \times \mathbb{F}_3^\times$, since their centers have orders 2 and 4. A short exact sequence records a quotient relationship, not a product decomposition.

Takeaway: The point of this diagram is that $\mathrm{SL}_n(F)$ is the kernel of the determinant homomorphism, so its subgroup status is an immediate instance of the general principle that kernels are always subgroups, bypassing any direct verification.

Exercises (from the text).

1. Prove each is a subgroup: (a) $\{a + ai \mid a \in \mathbb{R}\} \leq (\mathbb{C}, +)$; (b) the unit circle $\{z \in \mathbb{C} \mid |z| = 1\} \leq \mathbb{C}^\times$; (c) $\{a/b \in \mathbb{Q} \mid b \mid n\} \leq (\mathbb{Q}, +)$ (n fixed); (d) $\{a/b \in \mathbb{Q} \mid \gcd(b, n) = 1\} \leq (\mathbb{Q}, +)$; (e) $\{x \in \mathbb{R}^\times \mid x^2 \in \mathbb{Q}\} \leq \mathbb{R}^\times$.
2. Prove each is *not* a subgroup: (a) the 2-cycles in S_n ($n \geq 3$); (b) the reflections in D_{2n}; (c) $\{x \in G \mid |x| = n\} \cup \{1\}$, n composite and G a group containing an element of order n; (d) the odd integers together with 0; (e) $\{x \in \mathbb{R} \mid x^2 \in \mathbb{Q}\}$ in $(\mathbb{R}, +)$.
3. Show $\{1, r^2, s, sr^2\}$ and $\{1, r^2, sr, sr^3\}$ are subgroups of D_8.
4. Exhibit a group G and an infinite subset H closed under the operation but not a subgroup.
5. Prove a group of order $n > 2$ has no subgroup of order $n - 1$.
6. G abelian: prove the torsion set $\{g \mid |g| < \infty\} \leq G$; give a non-abelian example where this set is not a subgroup.

7. Fix $n > 1$. Find the torsion subgroup of $\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$, and show the elements of infinite order together with 1 do not form a subgroup.
8. For $H, K \leq G$, prove $H \cup K \leq G \iff H \subseteq K$ or $K \subseteq H$.
9. Prove $\mathrm{SL}_n(F) = \{A \in \mathrm{GL}_n(F) \mid \det A = 1\} \leq \mathrm{GL}_n(F)$.
10. (a) Prove $H \cap K \leq G$ for $H, K \leq G$; (b) prove the intersection of any nonempty family of subgroups is a subgroup.
11. Prove $\{(a, 1)\}$, $\{(1, b)\}$, and (when $B = A$) the diagonal $\{(a, a)\}$ are subgroups of $A \times B$.
12. A abelian, $n \in \mathbb{Z}$: prove $A^n = \{a^n\}$ and $A[n] = \{a \mid a^n = 1\}$ are subgroups.
13. $H \leq (\mathbb{Q}, +)$ with $1/x \in H$ for all $x \in H \setminus \{0\}$: prove $H = 0$ or $H = \mathbb{Q}$.
14. Show $\{x \in D_{2n} \mid x^2 = 1\}$ is not a subgroup ($n \geq 3$).
15. Prove the union of an ascending chain $H_1 \leq H_2 \leq \cdots$ of subgroups is a subgroup.
16. Prove the upper-triangular matrices in $\mathrm{GL}_n(F)$ form a subgroup.
17. Prove the upper-triangular matrices with 1's on the diagonal form a subgroup of $\mathrm{GL}_n(F)$.

Additional exercises.

1. Prove the subgroups of $(\mathbb{Z}, +)$ are exactly the $n\mathbb{Z}$ ($n \geq 0$), and that $n\mathbb{Z} \subseteq m\mathbb{Z} \iff m \mid n$.
2. Prove that a group with exactly two subgroups (1 and G) is isomorphic to $\mathbb{Z}/p\mathbb{Z}$ for some prime p.
3. Exhibit a group G and subgroups H, K for which HK is *not* a subgroup.
4. Without using the finite criterion, prove: if $H \subseteq G$ is finite, nonempty, and closed under products, then H is closed under inverses.
5. For $H \leq G$, prove $\{g \in G \mid gH = Hg\}$ is a subgroup of G containing H.

Commutative-diagram exercises.

1. Show that for $H, K \leq G$ the square with corners $H \cap K$, H, K, G (all arrows inclusions) commutes, and that $H \cap K$ is universal among subgroups mapping compatibly into H and K — i.e. it is the pullback of $H \hookrightarrow G \hookleftarrow K$.
2. Let $\varphi : G \to L$ be a homomorphism and $M \leq L$. Prove the preimage $\varphi^{-1}(M) \leq G$, and draw the pullback square exhibiting $\varphi^{-1}(M)$ as $G \times_L M$.
3. Prove that the composite of two injective homomorphisms is injective, and interpret the transitivity $K \leq H \leq G \implies K \leq G$ as composing the inclusions $K \hookrightarrow H \hookrightarrow G$.
4. Show $\ker \varphi \leq G$ for any homomorphism $\varphi : G \to L$ by exhibiting the exact sequence $1 \to \ker \varphi \to G \to L$; apply this to $\det : \mathrm{GL}_n(F) \to F^\times$ to reprove $\mathrm{SL}_n(F) \leq \mathrm{GL}_n(F)$ without the checklist.

2.2 Centralizers, Normalizers, Stabilizers, and Kernels

Centralizers: $C_G(A)$ and $C_G(a)$

Definition 2.2.1. Let G be a group and $A \subseteq G$ a nonempty subset. The *centralizer of A in G* is

$$C_G(A) = \{g \in G \mid gag^{-1} = a \text{ for all } a \in A\} = \{g \in G \mid ga = ag \text{ for all } a \in A\}.$$

When $A = \{a\}$ is a single element we write $C_G(a) = \{g \in G \mid gag^{-1} = a\} = \{g \in G \mid ga = ag\}$. Thus $C_G(a)$ is the set of all elements that commute with a, and $C_G(A)$ is the set of elements that commute with *every* element of A. The two displayed descriptions agree because $gag^{-1} = a \iff ga = ag$ (multiply on the right by g).

Proposition 2.2.2. *For any nonempty $A \subseteq G$, $C_G(A) \leq G$.*

Proof. We use the subgroup criterion. First $1 \in C_G(A)$ since $1a1^{-1} = a$ for all $a \in A$, so $C_G(A) \neq \varnothing$.

Closure. Suppose $x, y \in C_G(A)$ and fix $a \in A$. Then $xa = ax$ and $ya = ay$, so

$$(xy)a = x(ya) = x(ay) = (xa)y = (ax)y = a(xy).$$

Hence xy commutes with every $a \in A$, i.e. $xy \in C_G(A)$.

Inverses. Suppose $x \in C_G(A)$ and fix $a \in A$. From $xa = ax$, multiply on the left and right by x^{-1}:

$$x^{-1}(xa)x^{-1} = x^{-1}(ax)x^{-1} \implies ax^{-1} = x^{-1}a.$$

So $x^{-1}a = ax^{-1}$ for all $a \in A$, i.e. $x^{-1} \in C_G(A)$. By the subgroup criterion $C_G(A) \leq G$. □

Remark 2.2.1. Two facts make computations fast. (1) *Intersection formula:* since $g \in C_G(A)$ iff g commutes with each $a \in A$,

$$C_G(A) = \bigcap_{a \in A} C_G(a).$$

(2) *Generators suffice:* if $A = \langle S \rangle$ then $C_G(A) = C_G(S)$, because an element commuting with each generator commutes with every product of generators and their inverses. In particular $C_G(\langle x \rangle) = C_G(x)$.

Method (How to compute a centralizer $C_G(a)$ (and $C_G(A)$))**.** Use this whenever you must find all elements commuting with a fixed element a (or with a whole subset A).

1. **Single element $C_G(a)$.** Test each $g \in G$ (or each coset/type of element) by checking $ga = ag$. In a group given by generators and relations (e.g. D_{2n} with $sr = r^{-1}s$, or Q_8), push every product to a normal form and compare; do not test brute force if a relation settles it.
2. **Powers are free.** Every power of a commutes with a, so $\langle a \rangle \subseteq C_G(a)$ automatically. You only need to test elements *outside* $\langle a \rangle$.
3. **Use the relation to predict failures.** In D_{2n}, $sr^k = r^{-k}s$, so a reflection sr^j commutes with r^k iff $r^k = r^{-k}$, i.e. iff $r^{2k} = 1$. This tells you instantly which rotations are centralized by reflections.
4. **Subset A: intersect.** Compute $C_G(a)$ for each a in a generating set S of A, then take $\bigcap_{a \in S} C_G(a)$ (Remark 2.2.1).
5. *Sanity checks.* The answer must be a subgroup (closed, contains 1, contains inverses), must contain $\langle a \rangle$, and (by Lagrange) its order must divide $|G|$.

Caution. $C_G(a)$ is the set of elements that commute *with* a, not the set of elements that commute with *everything* (that is the center $Z(G) = C_G(G)$). Also $C_G(a)$ need not be abelian, and need not equal $\langle a \rangle$.

Throughout the dihedral examples we use $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$, with the eight elements $\{1, r, r^2, r^3, s, sr, sr^2, sr^3\}$. The master relation, applied k times, gives the normal form

$$s\,r^k = r^{-k}\,s \qquad \text{(equivalently } r^k s = s\,r^{-k}\text{)},$$

which we will use repeatedly.

Worked Example 2.2.3 ($C_{D_8}(r) = \langle r \rangle$)**.** Compute the centralizer of the rotation r in D_8.

Recognition. This is a single-element centralizer in a group with a relation $sr = r^{-1}s$. By the method, powers of r are free ($\langle r \rangle \subseteq C_{D_8}(r)$); the relation predicts that a reflection commutes with r^k iff $r^{2k} = 1$, so we only need to test the reflections and apply that test with $k = 1$.

Solution. The rotations $\{1, r, r^2, r^3\} = \langle r \rangle$ all commute with r (powers of the same element commute). Now test a reflection sr^j:

$$(sr^j)\,r = sr^{\,j+1}, \qquad r\,(sr^j) = (rs)r^j = (sr^{-1})r^j = sr^{\,j-1},$$

using $rs = sr^{-1}$. These are equal iff $r^{\,j+1} = r^{\,j-1}$, i.e. $r^2 = 1$. But $|r| = 4$, so $r^2 \neq 1$ and *no* reflection commutes with r. Hence

$$C_{D_8}(r) = \{1, r, r^2, r^3\} = \langle r \rangle.$$

Check. $\langle r \rangle$ is a subgroup of order 4, and $4 \mid 8$. It contains r. Consistent.

Worked Example 2.2.4 ($C_{D_8}(s) = \{1, s, r^2, sr^2\}$)**.** Compute the centralizer of the reflection s in D_8.

Recognition. Single-element centralizer again. Now $a = s$ is a reflection; $\langle s\rangle = \{1, s\}$ is free. We must test each rotation r^k (does r^k commute with s?) and each reflection sr^j. The relation $r^k s = sr^{-k}$ does the rotation tests in one line.

Solution. Rotations. r^k commutes with s iff $r^k s = sr^k$. But $r^k s = sr^{-k}$, so we need $sr^{-k} = sr^k$, i.e. $r^{2k} = 1$. With $|r| = 4$ this holds iff $4 \mid 2k$, i.e. k even: $k = 0, 2$. So 1 and r^2 commute with s, while r, r^3 do not.

Reflections. Test sr^j:

$$(sr^j)s = s(r^j s) = s(sr^{-j}) = s^2 r^{-j} = r^{-j}, \qquad s(sr^j) = s^2 r^j = r^j.$$

Equal iff $r^{-j} = r^j$, i.e. $r^{2j} = 1$, i.e. j even: $j = 0, 2$. So s (the $j = 0$ case) and sr^2 commute with s, while sr, sr^3 do not. Collecting:

$$C_{D_8}(s) = \{1,\ s,\ r^2,\ sr^2\}.$$

Check. Order 4, and $4 \mid 8$. It contains s. It is closed: e.g. $r^2 \cdot s = sr^{-2} = sr^2$ (since $r^{-2} = r^2$) is in the set, and $(sr^2)^2 = sr^2 sr^2 = s(r^2 s)r^2 = s(sr^{-2})r^2 = s^2 r^{-2} r^2 = 1$. So it is the Klein four-group $\{1, r^2, s, sr^2\}$. Consistent.

Worked Example 2.2.5 ($C_{D_8}(r^2) = D_8$)**.** Compute the centralizer of r^2 in D_8.

Recognition. Single-element centralizer. The key trigger: r^2 has order 2, so $r^{-2} = r^2$. The relation r^2-with-reflection test reduces to $r^{2k} = 1$ with $k = 2$, which is automatically true since $r^4 = 1$. Expect everything to commute, i.e. $r^2 \in Z(D_8)$.

Solution. Rotations commute with r^2 trivially (powers of r). *Reflections:* test sr^j against r^2:

$$(sr^j)r^2 = sr^{j+2}, \qquad r^2(sr^j) = (r^2 s)r^j = (sr^{-2})r^j = sr^{j-2}.$$

Since $r^{-2} = r^2$ (as $r^4 = 1$), we have $sr^{j-2} = sr^{j+2}$, so the two are equal for *every* j. Thus every reflection commutes with r^2, and

$$C_{D_8}(r^2) = D_8.$$

Check. This says $r^2 \in Z(D_8)$, which is the known center of D_8. Order $8 = |D_8|$, divides $|D_8|$. Consistent.

Worked Example 2.2.6 ($C_{S_3}\big((1\,2)\big) = \{1, (1\,2)\}$)**.** Compute the centralizer of the transposition $(1\,2)$ in S_3.

Recognition. Single-element centralizer in $S_3 = \{1, (1\,2), (1\,3), (2\,3), (1\,2\,3), (1\,3\,2)\}$. No slick relation; scan all six elements and test $g\,(1\,2) = (1\,2)\,g$ by composing permutations (apply right factor first).

Solution. $\langle(1\,2)\rangle = \{1, (1\,2)\}$ is free (both commute with $(1\,2)$). Test the rest.

$$(1\,3)(1\,2) = (1\,2\,3), \quad (1\,2)(1\,3) = (1\,3\,2) \ \Rightarrow\ \text{unequal, } (1\,3) \notin C.$$

$$(2\,3)(1\,2) = (1\,3\,2), \quad (1\,2)(2\,3) = (1\,2\,3) \ \Rightarrow\ \text{unequal, } (2\,3) \notin C.$$

$$(1\,2\,3)(1\,2) = (1\,3), \quad (1\,2)(1\,2\,3) = (2\,3) \ \Rightarrow\ \text{unequal, } (1\,2\,3) \notin C.$$

$$(1\,3\,2)(1\,2) = (2\,3), \quad (1\,2)(1\,3\,2) = (1\,3) \ \Rightarrow\ \text{unequal, } (1\,3\,2) \notin C.$$

Hence $C_{S_3}\big((1\,2)\big) = \{1, (1\,2)\} = \langle(1\,2)\rangle$. *Check.* Order 2, and $2 \mid 6$. As a sample composition verification: $(1\,3)(1\,2)$ computed right-to-left: $(1\,2)$ first sends $1 \mapsto 2$, then $(1\,3)$ fixes 2, so $1 \mapsto 2$; $2 \mapsto 1 \mapsto 3$; $3 \mapsto 3 \mapsto 1$; that is $(1\,2\,3)$. Consistent.

Worked Example 2.2.7 ($C_{Q_8}(i) = \{\pm 1, \pm i\} = \langle i\rangle$)**.** Compute the centralizer of i in $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, where $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$, and $ji = -k$, $kj = -i$, $ik = -j$.

Recognition. Single-element centralizer. ± 1 are central, and powers of i (namely $1, i, -1, -i$) are free. The quaternion relations $ij = -ji$, $ik = -ki$ are the trigger: distinct "imaginary" generators anticommute, so j, k (and their negatives) cannot commute with i.

Solution. $\langle i\rangle = \{1, i, i^2, i^3\} = \{1, i, -1, -i\}$ all commute with i. Test j and k:

$$ij = k, \qquad ji = -k \ \Rightarrow\ ij \neq ji, \text{ so } j \notin C_{Q_8}(i),$$

$$ik = -j, \qquad ki = j \;\Rightarrow\; ik \neq ki, \text{ so } k \notin C_{Q_8}(i).$$

Since $-j = (-1)j$ and -1 is central, $-j$ commutes with i iff j does; likewise $-k$. So $\pm j, \pm k$ are all excluded. Therefore

$$C_{Q_8}(i) = \{1, -1, i, -i\} = \langle i \rangle.$$

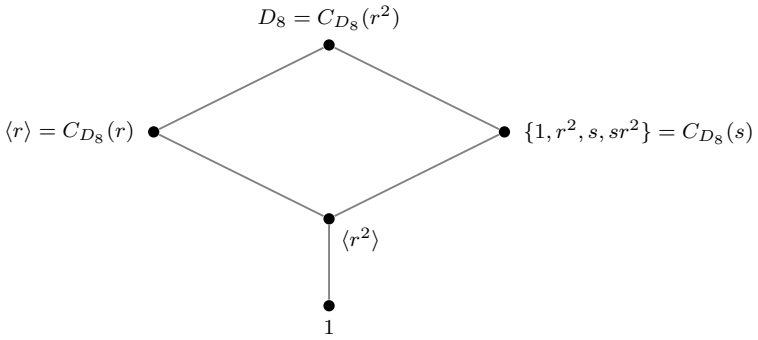
Check. $\langle i \rangle$ has order 4, $4 \mid 8$, contains i, and is cyclic hence abelian (consistent with being a centralizer that contains i). Consistent.

Worked Example 2.2.8 ($C_{D_8}(\langle r \rangle) = \langle r \rangle$ via the subset rule)**.** Compute the centralizer of the *subgroup* $A = \langle r \rangle = \{1, r, r^2, r^3\}$ in D_8.

Recognition. This is a subset centralizer. By Remark 2.2.1(2), A is generated by $S = \{r\}$, so $C_{D_8}(\langle r \rangle) = C_{D_8}(r)$ – no need to intersect over all four rotations. (If you prefer, $C_{D_8}(A) = \bigcap_{a \in A} C_{D_8}(a)$, and the smallest of these governs.)

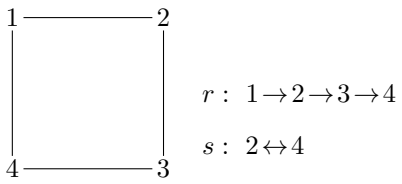
Solution. Since $\langle r \rangle = \langle S \rangle$ with $S = \{r\}$, an element centralizes all of $\langle r \rangle$ iff it centralizes the single generator r. By the worked computation $C_{D_8}(r) = \langle r \rangle$ (first example above),

$$C_{D_8}(\langle r \rangle) = C_{D_8}(r) = \langle r \rangle = \{1, r, r^2, r^3\}.$$



Cross-check by intersection. Using $C_{D_8}(A) = \bigcap_{a \in A} C_{D_8}(a)$:

$$C_{D_8}(1) = D_8, \quad C_{D_8}(r) = \langle r \rangle, \quad C_{D_8}(r^2) = D_8, \quad C_{D_8}(r^3) = \langle r \rangle,$$



(the last because $r^3 = r^{-1}$ generates the same cyclic group, so its centralizer equals that of r). The intersection is $D_8 \cap \langle r \rangle \cap D_8 \cap \langle r \rangle = \langle r \rangle$. Both methods agree. *Check.* Order 4, $4 \mid 8$, contains $\langle r \rangle$. Consistent.

Caution. When A is a subgroup, do not assume $C_G(A) \supseteq A$; that holds only when A is abelian (then every element of A commutes with every other, so $A \subseteq C_G(A)$). For $A = \langle r \rangle$ above, A is abelian and indeed $\langle r \rangle \subseteq C_{D_8}(\langle r \rangle)$ – in fact equality. But for a nonabelian A you would lose this containment.

The lattice below summarizes the D_8 centralizers computed above. The full group D_8 sits on top (it is $C_{D_8}(r^2)$); the two order-4 subgroups $\langle r \rangle = C_{D_8}(r)$ and the Klein group $C_{D_8}(s) = \{1, r^2, s, sr^2\}$ are in the middle; the trivial group is at the bottom.

The picture below records the dihedral action used in every D_8 computation: r rotates the square $1 \to 2 \to 3 \to 4$ and the reflection s fixes the vertices $1, 3$ (swapping $2, 4$), which is why the relation $sr = r^{-1}s$ governs all the commuting checks.

The center $Z(G)$ (D&F 2.2)

Definition 2.2.9. Let G be a group. The *center* of G is

$$Z(G) = \{g \in G \mid gx = xg \text{ for all } x \in G\}.$$

Equivalently $Z(G) = C_G(G)$ (the centralizer of the whole group in itself), and since an element commutes with everything iff it commutes with every single element separately,

$$Z(G) = \bigcap_{a \in G} C_G(a).$$

Proposition 2.2.10. *For any group G, $Z(G) \leq G$, and $Z(G)$ is abelian. Moreover $Z(G) \trianglelefteq G$ (it is a normal subgroup).*

Proof. Nonempty: $1x = x = x1$ for all x, so $1 \in Z(G)$. Closed: if $g, h \in Z(G)$ and $x \in G$ then $(gh)x = g(hx) = g(xh) = (gx)h = (xg)h = x(gh)$, so $gh \in Z(G)$. Inverses: if $g \in Z(G)$ then $gx = xg$ for all x; multiply on both sides by g^{-1} to get $xg^{-1} = g^{-1}x$, so $g^{-1} \in Z(G)$. Hence $Z(G) \leq G$ by the subgroup criterion. It is abelian because any two of its elements each commute with everything in G, in particular with each other. For normality: if $g \in Z(G)$ and $a \in G$ then $aga^{-1} = aga^{-1} = gaa^{-1} = g \in Z(G)$ (using $ag = ga$), so $aZ(G)a^{-1} \subseteq Z(G)$ for every a; thus $Z(G) \trianglelefteq G$. □

Remark 2.2.2. $Z(G)$ measures how far G is from being abelian: $Z(G) = G$ exactly when G is abelian, and a "small" center signals a highly noncommutative group. Note $Z(G) = \bigcap_a C_G(a)$ is an intersection of subgroups, hence automatically a subgroup — this is the practical formula we exploit below.

Method (How to compute $Z(G)$ from a generating set)**.** *Recognition trigger.* Use this whenever you are asked for $Z(G)$ and $G = \langle S \rangle$ for a small generating set S (e.g. $D_{2n} = \langle r, s \rangle$, $Q_8 = \langle i, j \rangle$, $S_3 = \langle (1\,2), (1\,2\,3) \rangle$, $\mathrm{GL}_n(\mathbb{F})$ generated by elementary/transvection-type matrices).

1. **Reduce the test set.** An element g is central iff $gx = xg$ for *all* $x \in G$. But if g commutes with each generator in S, it commutes with every product of generators and their inverses, hence with all of G. So

$$Z(G) = \bigcap_{x \in S} C_G(x).$$

   You only need to test commutation against the generators.

2. **Parametrize a general element** g of G (e.g. $g = r^k$ or $g = r^k s$ in D_{2n}; $g = \sum$ of basis quaternions; $g =$ general matrix).

3. **Impose** $gx = xg$ **for each generator** $x \in S$ and solve the resulting equations for the parameters.

4. **Collect the surviving** g**'s**; that set is $Z(G)$. Always finish with $|Z(G)|$ and a sanity check (does 1 lie in it? is the answer a subgroup?).

Theorem 2.2.11 (Center of the dihedral group)**.** *Let $D_{2n} = \langle r, s \mid r^n = s^2 = 1,\ srs = r^{-1} \rangle$ with $n \geq 3$. Then*

$$Z(D_{2n}) = \begin{cases} \{1\}, & n \text{ odd}, \\ \{1, r^{n/2}\}, & n \text{ even}. \end{cases}$$

Proof. By the method box, $Z = C(r) \cap C(s)$. *Step 1 (rotations).* For r^k: r^k commutes with r automatically; and $sr^k s^{-1} = (srs)^k = (r^{-1})^k = r^{-k}$, so r^k commutes with s iff $r^{-k} = r^k$, i.e. $r^{2k} = 1$, i.e. $n \mid 2k$. For $0 \leq k < n$ this forces $k = 0$, or $k = n/2$ when n is even. *Step 2 (reflections).* For a reflection $r^k s$: it does not commute with r, since $r(r^k s) = r^{k+1}s$ while $(r^k s)r = r^k(sr) = r^k r^{-1} s = r^{k-1}s$, and $r^{k+1}s = r^{k-1}s$ would force $r^2 = 1$, impossible for $n \geq 3$. So no reflection is central. Combining, $Z = \{1\}$ if n is odd and $Z = \{1, r^{n/2}\}$ if n is even. □

Caution. Do not confuse $Z(G)$ with $C_G(a)$ for a single element a. The centralizer $C_G(a)$ can be large (it always contains $\langle a\rangle$) even when $Z(G) = 1$. For example in S_3, $C_{S_3}((1\,2\,3)) = \langle(1\,2\,3)\rangle$ has order 3, yet $Z(S_3) = 1$. The center is the intersection of *all* the centralizers, so it is typically much smaller.

Worked Example 2.2.12 ($Z(D_8) = \{1, r^2\}$)**.** Compute the center of $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1}\rangle$ (the symmetries of the square, order 8).

Recognition. D_8 is generated by $S = \{r, s\}$, so by the method box $Z = C(r) \cap C(s)$: test each of the 8 elements against just r and s. This is the $n = 4$ (even) case of Theorem 2.2.11, predicting $\{1, r^{n/2}\} = \{1, r^2\}$.

Solution. The 8 elements are $\{1, r, r^2, r^3, s, rs, r^2s, r^3s\}$.

Rotations r^k vs s. Using $sr^ks = r^{-k}$, we have $r^ks = sr^{-k}$, so r^k commutes with s iff $r^{-k} = r^k$, i.e. $r^{2k} = 1$, i.e. $4 \mid 2k$, i.e. $k \in \{0, 2\}$. Thus among rotations only 1 and r^2 pass the s-test (and all rotations commute with r). So central rotations: $\{1, r^2\}$.

Reflections r^ks vs r. Compute $r \cdot (r^ks) = r^{k+1}s$ and $(r^ks) \cdot r = r^k(sr) = r^kr^{-1}s = r^{k-1}s$. These differ ($r^{k+1}s \neq r^{k-1}s$ since $r^2 \neq 1$), so *no* reflection commutes with r. All four reflections are excluded.

Hence $Z(D_8) = \{1, r^2\}$, of order 2. *Check.* r^2 is central because $r^2s = sr^{-2} = sr^2$ (as $r^4 = 1 \Rightarrow r^{-2} = r^2$), and r^2 commutes with r; and $\{1, r^2\} = \langle r^2\rangle$ is indeed a subgroup. Matches Theorem 2.2.11.

Worked Example 2.2.13 ($Z(Q_8) = \{1, -1\}$)**.** Compute the center of $Q_8 = \{\pm1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$ (and $ji = -k$, etc.).

Recognition. $Q_8 = \langle i, j\rangle$, so $Z = C(i) \cap C(j)$. The defining relations are anticommutation rules ($ji = -ij$), which is exactly the signal that the noncentral generators fail to commute; only ±1 are scalar.

Solution. Recall the products are anticommutative: $ij = k$, $ji = -k$, $jk = i$, $kj = -i$, $ki = j$, $ik = -j$.

Test i against j: $ij = k$ but $ji = -k \neq k$. So $i \notin Z$. Likewise $\pm i$ fail.

Test j against i: same computation, $ij \neq ji$, so $j \notin Z$; likewise $\pm j$ fail.

Test k against i: $ki = j$ but $ik = -j \neq j$, so $k \notin Z$; likewise $\pm k$ fail.

Test ±1: 1 commutes with everything; -1 commutes with everything because $-1 = (-1) \cdot 1$ is a scalar: $(-1)x = -x = x(-1)$ for all x. So $\pm1 \in Z$.

Hence $Z(Q_8) = \{1, -1\}$, order 2. *Check.* Every element of Q_8 squares to ±1, and $i^2 = j^2 = k^2 = -1$, so -1 commutes with all squares and is genuinely central; the set $\{1, -1\} = \langle -1\rangle$ is a subgroup. (Aside: $Q_8/Z \cong V_4$, consistent with $|Z| = 2$.)

Worked Example 2.2.14 ($Z(S_3) = 1$)**.** Compute the center of the symmetric group S_3.

Recognition. $S_3 = \langle(1\,2), (1\,2\,3)\rangle$, so $Z = C((1\,2)) \cap C((1\,2\,3))$. Symmetric groups S_n for $n \geq 3$ are nonabelian, and the quick test is: a single pair of generators that fail to commute already kills most elements.

Solution. The six elements: $1, (1\,2), (1\,3), (2\,3), (1\,2\,3), (1\,3\,2)$. We compose permutations right-to-left (apply the rightmost factor first).

A central element must commute with the transposition $\tau = (1\,2)$ and the 3-cycle $\sigma = (1\,2\,3)$. First note σ and τ do not commute:

$$\sigma\tau = (1\,2\,3)(1\,2) = (1\,3), \qquad \tau\sigma = (1\,2)(1\,2\,3) = (2\,3),$$

and $(1\,3) \neq (2\,3)$. So neither σ nor τ is central.

Transpositions. By symmetry each transposition fails: e.g. check $(1\,3)$ against σ: $\sigma(1\,3) = (1\,2\,3)(1\,3) = (2\,3)$ while $(1\,3)\sigma = (1\,3)(1\,2\,3) = (1\,2)$; unequal, so $(1\,3) \notin Z$. Similarly $(2\,3) \notin Z$.

3-cycles. $\sigma = (1\,2\,3)$ already fails against τ above. Its inverse $\sigma^2 = (1\,3\,2)$: $\tau\sigma^2 = (1\,2)(1\,3\,2) = (1\,3)$ while $\sigma^2\tau = (1\,3\,2)(1\,2) = (2\,3)$; unequal, so $(1\,3\,2) \notin Z$.

Only 1 survives. Hence $Z(S_3) = \{1\}$. *Check.* $|S_3| = 6$ is nonabelian, and a nonabelian group cannot have $Z = G$, so $Z \neq S_3$; $S_3 \cong D_6$ is the $n = 3$ (odd) dihedral case, where Theorem 2.2.11 gives $Z = 1$. Consistent.

Worked Example 2.2.15 ($Z(\mathrm{GL}_n(\mathbb{F})) = \{\lambda I \mid \lambda \in \mathbb{F}^\times\}$ (scalar matrices))**.** Show the center of $\mathrm{GL}_n(\mathbb{F})$ ($n \geq 2$, $\mathbb{F}$ a field) consists exactly of the nonzero scalar matrices λI, $\lambda \neq 0$.

Recognition. $\mathrm{GL}_n(\mathbb{F})$ is generated by elementary matrices, but the cleanest test set is the transvections $E_{ij} = I + e_{ij}$ ($i \neq j$), where e_{ij} has a single 1 in position (i, j). Commuting with all of these is what forces a matrix to be scalar; this is the "intersect centralizers of a generating set" method for a matrix group.

Solution. Let $A = (a_{pq}) \in \mathrm{GL}_n(\mathbb{F})$. It suffices that A commute with each $E_{ij} = I + e_{ij}$, i.e. with each e_{ij} (subtracting I). Use the rule $e_{ij}e_{kl} = \delta_{jk}e_{il}$.

Step 1: compute the commutator condition. $Ae_{ij} = e_{ij}A$ as matrices. Now $(Ae_{ij})_{pq} = \sum_t a_{pt}(e_{ij})_{tq} = a_{pi}\delta_{jq}$, which is nonzero only in column j, where its p-th entry is a_{pi}. And $(e_{ij}A)_{pq} = \sum_t (e_{ij})_{pt}a_{tq} = \delta_{ip}a_{jq}$, nonzero only in row i, where its q-th entry is a_{jq}. Setting $Ae_{ij} = e_{ij}A$:

$$a_{pi}\,\delta_{jq} = \delta_{ip}\,a_{jq} \qquad \text{for all } p, q.$$

Step 2: read off the entries. Take $p \neq i$ and $q = j$: LHS $= a_{pi}$, RHS $= \delta_{ip}a_{jj} = 0$, so $a_{pi} = 0$ for all $p \neq i$ — column i is zero off the diagonal. Take $p = i$, $q \neq j$: LHS $= a_{ii}\delta_{jq} = 0$, RHS $= a_{jq}$, so $a_{jq} = 0$ for $q \neq j$ — row j is zero off the diagonal. Since this holds for all $i \neq j$, A is diagonal. Take $p = i, q = j$: $a_{ii} = a_{jj}$. So all diagonal entries are equal: $A = \lambda I$.

Step 3: invertibility. $\lambda I \in \mathrm{GL}_n(\mathbb{F})$ iff $\det(\lambda I) = \lambda^n \neq 0$ iff $\lambda \neq 0$. Conversely every λI ($\lambda \neq 0$) commutes with all matrices, so lies in the center.

Hence $Z(\mathrm{GL}_n(\mathbb{F})) = \{\lambda I \mid \lambda \in \mathbb{F}^\times\} \cong \mathbb{F}^\times$. *Check.* For $n = 1$, $\mathrm{GL}_1(\mathbb{F}) = \mathbb{F}^\times$ is abelian and the statement degenerates to $Z = G$, consistent. For $n = 2$, e.g. $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right)$ do not commute, confirming non-scalar matrices are excluded.

Worked Example 2.2.16 ($Z(G) = G$ iff G abelian; e.g. $Z(\mathbb{Z}/n\mathbb{Z}) = \mathbb{Z}/n\mathbb{Z}$)**.** Show that $Z(G) = G$ if and only if G is abelian, and illustrate with $G = \mathbb{Z}/n\mathbb{Z}$ and with a nonabelian contrast.

Recognition. The trigger is the phrase "$Z(G) = G$." By definition $g \in Z(G)$ means g commutes with everything; $Z(G) = G$ says *every* element commutes with everything, which is precisely the definition of abelian. Whenever G is given as abelian (e.g. $\mathbb{Z}/n\mathbb{Z}$, any cyclic or product of cyclic groups), you may immediately write $Z(G) = G$.

Solution. *($\Rightarrow$)* If $Z(G) = G$ then every $g \in G$ satisfies $gx = xg$ for all $x \in G$; in particular for any $a, b \in G$, $ab = ba$, so G is abelian. *($\Leftarrow$)* If G is abelian then $gx = xg$ holds for all g, x, so every $g \in Z(G)$, giving $Z(G) = G$ (and $Z(G) \subseteq G$ always). Hence the equivalence.

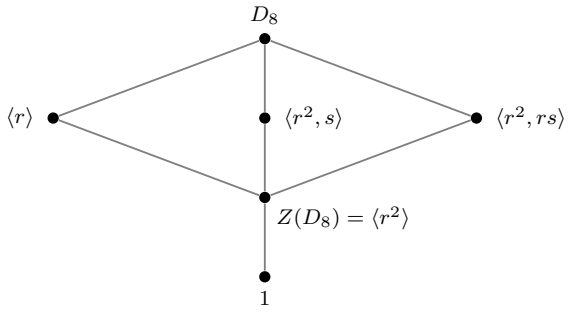
Example $\mathbb{Z}/n\mathbb{Z}$. The group $\mathbb{Z}/n\mathbb{Z} = \{\overline{0}, \overline{1}, \ldots, \overline{n-1}\}$ under addition has $\overline{a} + \overline{b} = \overline{a+b} = \overline{b} + \overline{a}$ for all a, b, so it is abelian; therefore $Z(\mathbb{Z}/n\mathbb{Z}) = \mathbb{Z}/n\mathbb{Z}$. Concretely for $n = 6$: $\overline{2} + \overline{5} = \overline{7} = \overline{1} = \overline{5} + \overline{2}$, illustrating commutativity for a sample pair.

Contrast. For a nonabelian G, $Z(G) < G$ strictly: e.g. $Z(D_8) = \{1, r^2\} \neq D_8$ since $|Z| = 2 < 8$. *Check.* The equivalence is logically airtight (it is just the definitions of "central" and "abelian" lined up), and $|Z(\mathbb{Z}/n\mathbb{Z})| = n = |\mathbb{Z}/n\mathbb{Z}|$ confirms equality.

Worked Example 2.2.17 ($Z(D_{12}) = \{1, r^3\}$ (the $n = 6$ even case))**.** Compute $Z(D_{12})$, the center of the symmetries of a regular hexagon, $D_{12} = \langle r, s \mid r^6 = s^2 = 1,\ srs = r^{-1}\rangle$.

Recognition. D_{12} has $n = 6$, which is *even*, so Theorem 2.2.11 predicts $Z = \{1, r^{n/2}\} = \{1, r^3\}$. We verify directly by intersecting $C(r) \cap C(s)$ over the generators $\{r, s\}$, exhibiting exactly why r^3 survives and the others do not.

Solution. The 12 elements are $\{r^k,\ r^k s : 0 \leq k \leq 5\}$.



Rotations r^k vs s. As before $r^k s = sr^{-k}$, so r^k commutes with s iff $r^{2k} = 1$, i.e. $6 \mid 2k$, i.e. $3 \mid k$. For $0 \leq k \leq 5$ this gives $k \in \{0, 3\}$, i.e. $r^0 = 1$ and r^3. (Both automatically commute with r.) So central rotations are $\{1, r^3\}$.

Why r^3 works explicitly: $r^3 s = sr^{-3} = sr^3$ since $r^{-3} = r^{6-3} = r^3$. Good.

Why, say, r^2 fails: $r^2 s = sr^{-2} = sr^4 \neq sr^2$ (since $r^4 \neq r^2$), so $r^2 \notin Z$. Likewise r, r^4, r^5 fail the s-test.

Reflections $r^k s$ vs r. $r(r^k s) = r^{k+1}s$ and $(r^k s)r = r^{k-1}s$; these are unequal because $r^2 \neq 1$. So no reflection commutes with r, and all six reflections are excluded.

Hence $Z(D_{12}) = \{1, r^3\}$, order 2. *Check.* $\{1, r^3\} = \langle r^3 \rangle$ with $(r^3)^2 = r^6 = 1$, a subgroup of order 2; and $n = 6$ even gives $r^{n/2} = r^3$, matching Theorem 2.2.11 exactly.

The diagram shows $Z(D_8) = \langle r^2 \rangle$ sitting at the bottom of the lattice, directly above the trivial subgroup: it is the intersection of the three index-2 subgroups $\langle r \rangle$, $\langle r^2, s \rangle$, $\langle r^2, rs \rangle$ (the four reflection subgroups of order 2, not drawn here, are also minimal nontrivial subgroups, but each lies in only one of them). This pictures Proposition 2.2.10 (the center is a normal subgroup, here of order 2) and the $n = 4$ even case of Theorem 2.2.11.

Caution. A reflection $r^k s$ in D_{2n} is *never* central for $n \geq 3$, even when n is even — the lone central nontrivial element is the half-turn rotation $r^{n/2}$. Students sometimes guess that "s commutes with the half-turn so s is central"; but centrality requires commuting with *every* element, and s fails against r (since $rs = sr^{-1} \neq sr$).

Normalizers and the setwise stabilizer

Let G be a group and $A \subseteq G$ a nonempty subset. For $g \in G$ write

$$gAg^{-1} = \{\, gag^{-1} \mid a \in A \,\},$$

the *conjugate* of A by g. This is the image of A under the bijection $x \mapsto gxg^{-1}$ of G (conjugation by g), so $|gAg^{-1}| = |A|$ always.

Definition 2.2.18. The *normalizer* of A in G is

$$N_G(A) = \{\, g \in G \mid gAg^{-1} = A \,\}.$$

Equivalently, $g \in N_G(A)$ iff conjugation by g permutes A among itself *as a set*: $gAg^{-1} = A$ (setwise), not necessarily $gag^{-1} = a$ for each a (pointwise). Recall the *centralizer* $C_G(A) = \{g \mid gag^{-1} = a \text{ for all } a \in A\} = \{g \mid ga = ag \ \forall a \in A\}$.

Remark 2.2.3. The single inclusion $gAg^{-1} \subseteq A$ already forces the reverse inclusion automatically: since $x \mapsto gxg^{-1}$ is injective and A is finite (in our examples), $gAg^{-1} \subseteq A$ with equal cardinality gives $gAg^{-1} = A$. For infinite A you must check both inclusions, or equivalently $gAg^{-1} \subseteq A$ AND $g^{-1}Ag \subseteq A$.

Proposition 2.2.19. *For any nonempty $A \subseteq G$,*

$$C_G(A) \leq N_G(A) \leq G,$$

and moreover A itself is contained in $N_G(A)$ whenever A is a subgroup. If $A = H$ is a subgroup then $N_G(H)$ is the largest subgroup of G in which H is normal, and $H \trianglelefteq N_G(H)$.

Proof. $N_G(A) \leq G$. $1A1^{-1} = A$, so $1 \in N_G(A)$. If $g, h \in N_G(A)$ then $(gh)A(gh)^{-1} = g(hAh^{-1})g^{-1} = gAg^{-1} = A$, so $gh \in N_G(A)$. If $gAg^{-1} = A$, conjugate by g^{-1}: $g^{-1}Ag = g^{-1}(gAg^{-1})g = A$, so $g^{-1} \in N_G(A)$. Hence $N_G(A) \leq G$.

$C_G(A) \leq N_G(A)$. $C_G(A) \leq G$ by the same argument (identity is in it, and it is closed under products and inverses). If $g \in C_G(A)$ then $gag^{-1} = a \in A$ for every $a \in A$, so $gAg^{-1} = A$; thus $g \in N_G(A)$. Since $C_G(A) \subseteq N_G(A)$ and both are subgroups of G, $C_G(A) \leq N_G(A)$.

$H \trianglelefteq N_G(H)$. For H a subgroup, every $h \in H$ satisfies $hHh^{-1} = H$ (subgroups are conjugation-closed by themselves), so $H \subseteq N_G(H)$, hence $H \leq N_G(H)$. The defining condition $gHg^{-1} = H$ for all $g \in N_G(H)$ is exactly normality of H in $N_G(H)$. If $H \trianglelefteq K \leq G$ then $kHk^{-1} = H$ for all $k \in K$, so $K \subseteq N_G(H)$; thus $N_G(H)$ is the largest such K. □

Method (How to compute $N_G(H)$)**.** Use this whenever you must decide which g conjugate a subgroup H *onto itself as a set* (e.g. to find the largest subgroup in which H is normal, or to detect normality).

1. **Free wins first.** $H \subseteq N_G(H)$ always, and $C_G(H) \subseteq N_G(H)$ always. List those elements; they are in for free.
2. **Index-2 shortcut.** If $[G : H] = 2$ then $H \trianglelefteq G$, so $N_G(H) = G$. Stop. (Two cosets H and gH; the only options force $gH = Hg$.)
3. **Generator test.** Write $H = \langle a \rangle$ (or list generators). For *finite* H, $gHg^{-1} = H$ iff $gag^{-1} \in H$ for each generator a (a homomorphic image of a generating set generates the image, so $gHg^{-1} \subseteq H$, and $|gHg^{-1}| = |H|$). So test ONLY the generators, not every element. (For infinite H this gives only $gHg^{-1} \subseteq H$; also test $g^{-1}ag \in H$.)
4. **Setwise, not pointwise.** You only need gag^{-1} to land *somewhere* in H, not back at a. (Pointwise would be the centralizer.)
5. **Assemble a subgroup.** $N_G(H)$ is a subgroup containing H; use Lagrange to limit its possible order, then confirm with coset reps.

Caution. $N_G(H) = G$ does NOT mean G is abelian or that H is central. It means H is *normal*: $gHg^{-1} = H$ setwise. Conjugation may still scramble the elements of H (e.g. send $r \mapsto r^{-1}$), as long as it stays inside H.

Caution. Do not confuse $gag^{-1} \in H$ (normalizer condition) with $gag^{-1} = a$ (centralizer condition). Testing the wrong one is the most common error: a generator can be moved to another element of H and still be normalized.

Worked Example 2.2.20 ($N_{D_8}(\langle s \rangle) = \{1, s, r^2, sr^2\}$)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$, compute the normalizer of the reflection subgroup $\langle s \rangle = \{1, s\}$.

Recognition. Here $\langle s \rangle = \{1, s\}$ has order 2 but index 4, so the index-2 shortcut does not apply; we must run the generator test. The single generator is s, so $g \in N_{D_8}(\langle s \rangle)$ iff $gsg^{-1} \in \{1, s\}$. Since gsg^{-1} is a conjugate of s it has order 2 and is $\neq 1$, so the condition collapses to the setwise check $gsg^{-1} = s$, i.e. g commutes with s. For this tiny subgroup the normalizer equals the centralizer $C_{D_8}(s)$.

Solution. Use the relation $srs^{-1} = r^{-1}$, equivalently $sr = r^{-1}s$, and $sr^k s^{-1} = r^{-k}$. Conjugate s by each of the 8 elements r^k and sr^k ($k = 0, 1, 2, 3$).

Rotations: $r^k s r^{-k}$. Since $rs = sr^{-1}$ we get $r^k s = sr^{-k}$, hence $r^k s r^{-k} = sr^{-k}r^{-k} = sr^{-2k}$. So:

$$1 \cdot s \cdot 1 = s, \quad rsr^{-1} = sr^{-2}, \quad r^2 s r^{-2} = sr^{-4} = s, \quad r^3 s r^{-3} = sr^{-6} = sr^2.$$

Thus among rotations, 1 and r^2 give s (good); r, r^3 give $sr^{-2} = sr^2 \notin \langle s \rangle$ (bad).

Reflections: $(sr^k)s(sr^k)^{-1}$. Compute $(sr^k)^{-1} = r^{-k}s$. Then

$$(sr^k)s(r^{-k}s) = s(r^k s r^{-k})s = s(sr^{-2k})s = ssr^{-2k}s = r^{-2k}s = sr^{2k},$$

using $r^{-2k}s = sr^{2k}$. For $k = 0$: s. For $k = 2$: $sr^4 = s$. For $k = 1$: $sr^2 \notin \langle s \rangle$. For $k = 3$: $sr^6 = sr^2 \notin \langle s \rangle$. So s and sr^2 work.

The elements fixing $\langle s \rangle$ setwise are exactly $\{1, r^2, s, sr^2\}$. Check it is a subgroup: $s \cdot r^2 = sr^2$, $(sr^2)^2 = sr^2 sr^2 = s(r^2 s)r^2 = s(sr^{-2})r^2 = 1$, and r^2, s commute since $r^2 s = sr^{-2} = sr^2$. This is a Klein four-group $\{1, s, r^2, sr^2\} \cong V_4$, order 4, index 2 in D_8.

Sanity check. The bad rotation gives $rsr^{-1} = sr^{-2} = sr^2 \notin \langle s \rangle$, confirming $r \notin N_{D_8}(\langle s \rangle)$, as required. And $|N_{D_8}(\langle s \rangle)| = 4$ divides 8. Note $\langle s \rangle \trianglelefteq N_{D_8}(\langle s \rangle)$ but $\langle s \rangle$ is NOT normal in D_8.

Worked Example 2.2.21 ($N_{D_8}(\langle r \rangle) = D_8$ via index 2)**.** In D_8 compute the normalizer of the rotation subgroup $\langle r \rangle = \{1, r, r^2, r^3\}$.

Recognition. The trigger is the *index-2 shortcut*: $|\langle r \rangle| = 4$ and $|D_8| = 8$, so $[D_8 : \langle r \rangle] = 2$. Any subgroup of index 2 is normal, hence its normalizer is the whole group. No element-by-element work is needed.

Solution. $[D_8 : \langle r \rangle] = 8/4 = 2$, so by the index-2 theorem $\langle r \rangle \trianglelefteq D_8$, i.e. $g\langle r \rangle g^{-1} = \langle r \rangle$ for all g. Therefore $N_{D_8}(\langle r \rangle) = D_8$.

For a direct confirmation of the setwise condition, the only nontrivial generator to test is r against the reflection s: $srs^{-1} = r^{-1} = r^3 \in \langle r\rangle$. Since s and r generate D_8 and both normalize $\langle r\rangle$ ($rrr^{-1} = r \in \langle r\rangle$ trivially), every element does.

Sanity check. $|N_{D_8}(\langle r\rangle)| = 8$ divides 8, and $\langle r\rangle \subseteq N_{D_8}(\langle r\rangle)$ as it must. Contrast with the previous example: $\langle r\rangle$ is normal but $\langle s\rangle$ is not.

Worked Example 2.2.22 ($N_{S_3}(\langle(1\,2\,3)\rangle) = S_3$)**.** Compute the normalizer in S_3 of the 3-cycle subgroup $H = \langle(1\,2\,3)\rangle = \{e, (1\,2\,3), (1\,3\,2)\}$.

Recognition. Again the *index-2 shortcut*: $|H| = 3$, $|S_3| = 6$, so $[S_3 : H] = 2$. Index 2 forces normality; $N_{S_3}(H) = S_3$. We can also confirm with the conjugation-of-cycles rule $\sigma(1\,2\,3)\sigma^{-1} = (\sigma(1)\,\sigma(2)\,\sigma(3))$.

Solution. Since $[S_3 : H] = 6/3 = 2$, $H \trianglelefteq S_3$ and so $N_{S_3}(H) = S_3$.

Direct generator test: $H = \langle(1\,2\,3)\rangle$, so check $\sigma(1\,2\,3)\sigma^{-1}$ for a transposition, say $\sigma = (1\,2)$:

$$(1\,2)(1\,2\,3)(1\,2) = (\,(1\,2)(1)\ (1\,2)(2)\ (1\,2)(3)\,) = (2\,1\,3) = (1\,3\,2) \in H.$$

It landed on the other 3-cycle (setwise inside H), not back on $(1\,2\,3)$, yet that is fine for the normalizer. Every transposition behaves the same way, and the powers of $(1\,2\,3)$ obviously normalize H, so all 6 elements normalize H.

Sanity check. $|N_{S_3}(H)| = 6$ divides 6; $H \subseteq N_{S_3}(H)$. Note $C_{S_3}(H) = H$ here (a transposition does NOT commute with $(1\,2\,3)$, since it inverts it), so $C_{S_3}(H) = \langle(1\,2\,3)\rangle < N_{S_3}(H) = S_3$ strictly.

Worked Example 2.2.23 ($N_{S_3}(\langle(1\,2)\rangle) = \langle(1\,2)\rangle$)**.** Compute the normalizer in S_3 of the transposition subgroup $K = \langle(1\,2)\rangle = \{e, (1\,2)\}$.

Recognition. $|K| = 2$, index 3 (odd, $\neq 2$), so no shortcut; run the generator test on $(1\,2)$ using $\sigma(1\,2)\sigma^{-1} = (\sigma(1)\,\sigma(2))$. A conjugate of $(1\,2)$ is again a transposition; it lies in $K = \{e, (1\,2)\}$ iff it equals $(1\,2)$. So here the setwise test again reduces to fixing $(1\,2)$.

Solution. Conjugate $(1\,2)$ by each $\sigma \in S_3$, using $\sigma(1\,2)\sigma^{-1} = (\sigma(1)\,\sigma(2))$:

$$\begin{array}{ll} e : (1\,2) \in K & (1\,2) : (1\,2) \in K \\ (1\,3) : (3\,2) = (2\,3) \notin K & (2\,3) : (1\,3) \notin K \\ (1\,2\,3) : (2\,3) \notin K & (1\,3\,2) : (3\,1) = (1\,3) \notin K \end{array}$$

(For $(1\,2\,3)$: it sends $1 \mapsto 2, 2 \mapsto 3$, so $(1\,2) \mapsto (2\,3)$.) Only e and $(1\,2)$ keep the conjugate inside K. Hence $N_{S_3}(K) = \{e, (1\,2)\} = K$.

Sanity check. $|N_{S_3}(K)| = 2$ divides 6; $K \subseteq N_{S_3}(K)$ as required, and equality says K is its own normalizer (self-normalizing). This matches the fact that $\langle(1\,2)\rangle$ is NOT normal in S_3 (it has 3 distinct conjugates).

Worked Example 2.2.24 ($N_{Q_8}(\langle i\rangle) = Q_8$)**.** In $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$, $ji = -k$, compute $N_{Q_8}(\langle i\rangle)$ where $\langle i\rangle = \{1, i, -1, -i\}$.

Recognition. $|\langle i\rangle| = 4$, $|Q_8| = 8$, so $[Q_8 : \langle i\rangle] = 2$: *index-2 shortcut* gives $N_{Q_8}(\langle i\rangle) = Q_8$. In fact *every* subgroup of Q_8 is normal, so this is expected. We confirm with the generator test on i.

Solution. $[Q_8 : \langle i\rangle] = 8/4 = 2 \Rightarrow \langle i\rangle \trianglelefteq Q_8 \Rightarrow N_{Q_8}(\langle i\rangle) = Q_8$.

Confirm setwise by conjugating the generator i by j (the element outside $\langle i\rangle$): using $ji = -k$ and $j^{-1} = -j$,

$$j\,i\,j^{-1} = (ji)(-j) = (-k)(-j) = kj.$$

Now $kj = -i$ (since $jk = i \Rightarrow kj = -i$). So $jij^{-1} = -i \in \langle i\rangle$. Conjugation by j sends $i \mapsto -i$ (inverts it) but stays inside $\langle i\rangle$, exactly the setwise condition. Since i, j generate Q_8 and both normalize $\langle i\rangle$, all of Q_8 does.

Sanity check. $|N_{Q_8}(\langle i\rangle)| = 8$ divides 8; $\langle i\rangle \subseteq N_{Q_8}(\langle i\rangle)$. Note $C_{Q_8}(\langle i\rangle) = \langle i\rangle$ (since j anticommutes with i: $ij = k$, $ji = -k$, so $ij \neq ji$), giving a strict inclusion $C_{Q_8}(\langle i\rangle) = \langle i\rangle < N_{Q_8}(\langle i\rangle) = Q_8$.

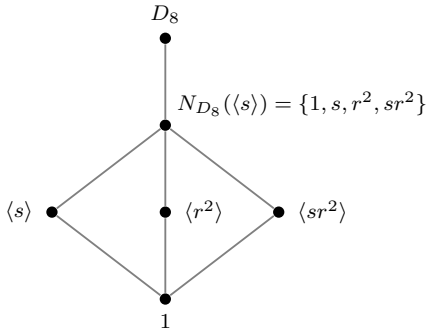
Worked Example 2.2.25 (Strict inclusion $C_G(H) < N_G(H)$ in D_8)**.** Exhibit a subgroup H of $G = D_8$ with $C_G(H)$ strictly smaller than $N_G(H)$, and show the setwise check that lets $N_G(H)$ grow.

Recognition. We want a g that is in $N_G(H)$ but not $C_G(H)$: it must move a generator of H to a *different* element of H (so setwise OK, pointwise fails). Take $H = \langle r^2\rangle = \{1, r^2\}$ in D_8. Since r^2 is central in D_8,

actually $C_{D_8}(r^2) = D_8$; that is no good for a strict gap with this H. Instead take $H = \langle r \rangle = \{1, r, r^2, r^3\}$, whose generator r is moved by s: $srs^{-1} = r^{-1} \neq r$ but $r^{-1} \in H$.

Solution. Let $H = \langle r \rangle$. From Example with the index-2 shortcut, $N_{D_8}(H) = D_8$ (order 8). Now compute $C_{D_8}(H) = C_{D_8}(r)$, the elements commuting with r:

- Rotations r^k all commute with r: $r^k r = r r^k$. So $\{1, r, r^2, r^3\} \subseteq C_{D_8}(r)$.
- A reflection sr^k: $(sr^k)r = sr^{k+1}$ while $r(sr^k) = (rs)r^k = (sr^{-1})r^k = sr^{k-1}$. These are equal iff $r^{k+1} = r^{k-1}$ iff $r^2 = 1$, false. So no reflection commutes with r.



Hence $C_{D_8}(r) = \langle r \rangle$, order 4. Therefore

$$C_{D_8}(H) = \langle r \rangle \ < \ N_{D_8}(H) = D_8, \qquad 4 < 8.$$

The setwise check that grows the normalizer: $s \in N_{D_8}(H)$ because $srs^{-1} = r^{-1} = r^3 \in H$ (and $sr^2s^{-1} = r^{-2} = r^2 \in H$, $sr^3s^{-1} = r \in H$), so $sHs^{-1} = \{1, r^3, r^2, r\} = H$ setwise; but $s \notin C_{D_8}(H)$ since $srs^{-1} = r^3 \neq r$.

Sanity check. $C_{D_8}(H) = \langle r \rangle < N_{D_8}(H) = D_8$ is consistent with Proposition 2.2.19 ($C_G \leq N_G$), the orders $4 \mid 8$ both divide $|D_8|$, and the inclusion is strict exactly because conjugation by s inverts the generator while keeping H invariant as a set.

Lattice of the three nested subgroups. For $H = \langle s \rangle$ in D_8, the chain $\langle s \rangle \leq N_{D_8}(\langle s \rangle) \leq D_8$ from the first worked example sits inside the subgroup lattice as follows (here $N_{D_8}(\langle s \rangle) = \{1, s, r^2, sr^2\}$ has index 2, and $\langle s \rangle$ has index 2 inside it):

The picture shows why $\langle s \rangle$ is not normal in D_8 but is normal in $N_{D_8}(\langle s \rangle)$: the normalizer is the *largest* intermediate subgroup (here the Klein four-group $\cong V_4$) in which $\langle s \rangle$ sits normally, and the single edge $N_{D_8}(\langle s \rangle) - D_8$ has index 2.

Stabilizers and kernels of a group action

A group action turns abstract group elements into concrete symmetries of a set. Two subgroups fall out of any action for free: the *stabilizer* of a point (everything that fixes that point) and the *kernel* (everything that fixes *every* point). This section pins down exactly what these are, proves they are subgroups, and – crucially – shows that the normalizer $N_G(A)$ and centralizer $C_G(A)$ from D&F 2.2 are nothing more than a stabilizer and a kernel for the conjugation action.

Definition 2.2.26. A **(left) action** of a group G on a set A is a map $G \times A \to A$, written $g \cdot a$, such that

$$g_1 \cdot (g_2 \cdot a) = (g_1 g_2) \cdot a \quad \text{and} \quad 1 \cdot a = a$$

for all $g_1, g_2 \in G$ and all $a \in A$. Equivalently (by D&F 1.7), $g \mapsto \sigma_g$, where $\sigma_g(a) = g \cdot a$, is a homomorphism $G \to S_A$ (the symmetric group on A).

Definition 2.2.27. Let G act on A. For a point $a \in A$ the **stabilizer** of a is

$$G_a = \{\, g \in G \mid g \cdot a = a \,\}.$$

The **kernel** of the action is

$$\ker = \{\, g \in G \mid g \cdot a = a \text{ for all } a \in A \,\} = \bigcap_{a \in A} G_a.$$

The action is **faithful** if $\ker = 1$. The kernel is exactly the kernel of the associated homomorphism $G \to S_A$, $g \mapsto \sigma_g$.

Proposition 2.2.28. *For each $a \in A$ the stabilizer $G_a \leq G$. Consequently* $\ker = \bigcap_{a \in A} G_a \leq G$.

Proof. Use the subgroup criterion. First $1 \in G_a$ since $1 \cdot a = a$, so $G_a \neq \varnothing$. Let $x, y \in G_a$, so $x \cdot a = a$ and $y \cdot a = a$. From $y \cdot a = a$ apply y^{-1}: $y^{-1} \cdot a = y^{-1} \cdot (y \cdot a) = (y^{-1}y) \cdot a = 1 \cdot a = a$, so $y^{-1} \in G_a$. Then $(xy^{-1}) \cdot a = x \cdot (y^{-1} \cdot a) = x \cdot a = a$, so $xy^{-1} \in G_a$. Hence $G_a \leq G$. An arbitrary intersection of subgroups is a subgroup, so $\ker = \bigcap_a G_a \leq G$. □

Remark 2.2.4. The kernel is in fact *normal*: it is the kernel of the homomorphism $G \to S_A$, and kernels of homomorphisms are normal subgroups (D&F 3.1). A single stabilizer G_a need not be normal – see the conjugation examples, where $G_a = C_G(a)$ can fail to be normal.

Conjugation actions recover $N_G(A)$ and $C_G(A)$

D&F 1.7 gives two conjugation actions of G. Both make the bookkeeping of Section 2.2 transparent.

Theorem 2.2.29. *Let G be a group.*

(a) G acts on the set $\mathcal{P}(G)$ of subsets of G by $g \cdot S = gSg^{-1}$. For a fixed subset $A \subseteq G$ the stabilizer of A under this action is the ***normalizer***

$$\mathrm{Stab}(A) = \{\, g \in G \mid gAg^{-1} = A \,\} = N_G(A).$$

(b) G acts on the set G itself by $g \cdot a = gag^{-1}$. For a fixed subset $A \subseteq G$, the subgroup fixing every *point of A – i.e. the kernel of the restricted action of $N_G(A)$ on the set A – is the* ***centralizer***

$$\{\, g \mid gag^{-1} = a \ \forall a \in A \,\} = \{\, g \mid ga = ag \ \forall a \in A \,\} = C_G(A).$$

In particular the stabilizer of a single point a under conjugation is $\mathrm{Stab}(a) = C_G(a) = C_G(\{a\})$.

Proof. (a) By Definition 2.2.27, $\mathrm{Stab}(A) = \{g \mid g \cdot A = A\} = \{g \mid gAg^{-1} = A\}$, which is verbatim the definition of $N_G(A)$ in D&F 2.2. By Proposition 2.2.28 it is a subgroup.

(b) For the conjugation action on points, g fixes a iff $gag^{-1} = a$ iff $ga = ag$. Intersecting over all $a \in A$,

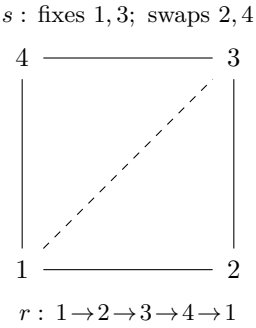
$$\bigcap_{a \in A} G_a = \{\, g \mid ga = ag \ \forall a \in A \,\} = C_G(A),$$

which is the definition of the centralizer. As an intersection of stabilizers (each a subgroup by Proposition 2.2.28) it is a subgroup; since $C_G(A) \leq N_G(A)$ (Proposition 2.2.19), it is the kernel of the conjugation action of $N_G(A)$ on the set A (in general G itself does not act on A, since gAg^{-1} need not equal A). Taking $A = \{a\}$ gives $\mathrm{Stab}(a) = C_G(a)$. □

Method (Stabilizer vs. kernel: which one is it, and how to compute it)**.** *Recognition trigger.* You have a group G acting on a set A (a literal action like "S_n permutes $\{1, \ldots, n\}$," or a conjugation action). Ask which question is being posed:

1. *Which g fix ONE chosen point a?* $\Rightarrow$ stabilizer G_a.
2. *Which g fix EVERY point at once?* $\Rightarrow$ kernel $= \bigcap_a G_a$.

Recipe to compute a stabilizer G_a.



1. Write down the action rule $g \cdot a$ explicitly.
2. Set $g \cdot a = a$ and solve for the constraint on g.
3. Collect all such g; verify it is a subgroup (Prop. 2.2.28 guarantees it, but listing elements is a check).
4. Identify the abstract group (often S_{n-1}, a small cyclic/reflection group, or a matrix block group).

Recipe to compute a kernel. Either (a) intersect the stabilizers $\bigcap_a G_a$, or (b) find ker of the homomorphism $G \to S_A$ – i.e. which g induce the identity permutation. The action is *faithful* exactly when this is $\{1\}$. **Conjugation dictionary.** Conjugation on subsets: $\mathrm{Stab}(A) = N_G(A)$. Conjugation on points of A: kernel $= C_G(A)$; single point: $\mathrm{Stab}(a) = C_G(a)$.

Caution. "Stabilizer" fixes a point *setwise/as a point*, not pointwise-inside-it. For conjugation on subsets, $g \in N_G(A)$ only requires $gAg^{-1} = A$ as a *set* – elements may be permuted. Requiring each element to be fixed gives the smaller $C_G(A)$. Always $C_G(A) \leq N_G(A)$, and the inclusion is often strict.

The D_8 action on the square

The dihedral group $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$ (order 8, symmetries of a square) acts on the four vertices labeled $1, 2, 3, 4$ counterclockwise. Here r rotates by $90°$, sending $1 \mapsto 2 \mapsto 3 \mapsto 4 \mapsto 1$, and s is the reflection fixing vertices 1 and 3 (the diagonal through them) and swapping 2 and 4.

Worked Example 2.2.30 (S_n on $\{1, \ldots, n\}$: $\mathrm{Stab}(n) \cong S_{n-1}$)**.** Let S_n act on $A = \{1, 2, \ldots, n\}$ in the natural way, $\sigma \cdot i = \sigma(i)$. Compute the stabilizer of the point n and identify it up to isomorphism.

Recognition. We are asked for the permutations fixing ONE chosen point n – trigger 1 of the method box, so this is a stabilizer G_n, not a kernel. The action rule is just "apply the permutation," so set $\sigma(n) = n$.

Solution. Set the defining condition: $\sigma \in (S_n)_n$ iff $\sigma \cdot n = n$ iff $\sigma(n) = n$. Such a σ permutes $\{1, \ldots, n\}$ but pins n, hence it permutes the remaining $n - 1$ symbols $\{1, \ldots, n-1\}$ arbitrarily and bijectively. The map

$$\Phi : (S_n)_n \to S_{\{1,\ldots,n-1\}} = S_{n-1}, \qquad \Phi(\sigma) = \sigma|_{\{1,\ldots,n-1\}}$$

is well defined (restriction of a bijection fixing n is a bijection of the rest), a homomorphism (restriction respects composition), injective (a σ fixing n is determined by its action on the other $n - 1$ points), and surjective (any permutation of $\{1, \ldots, n-1\}$ extends by $n \mapsto n$). Hence $(S_n)_n \cong S_{n-1}$.

Check. Orders: $|(S_n)_n| = (n-1)! = |S_{n-1}|$, consistent. Also the orbit-stabilizer count $|S_n| = |\text{orbit of } n| \cdot |(S_n)_n| = n \cdot (n-1)! = n!$ is correct, since the orbit of n is all of $\{1, \ldots, n\}$ (size n).

Worked Example 2.2.31 (D_8 on the 4 vertices: a vertex stabilizer has order 2)**.** With the labeling above, D_8 acts on $A = \{1, 2, 3, 4\}$. Compute $\mathrm{Stab}(1)$.

Recognition. Single chosen point (1) under a geometric action $\Rightarrow$ stabilizer. To find it, list how each of the 8 elements moves vertex 1 and keep those returning $1 \mapsto 1$.

Solution. The reflection s fixes vertex 1, so $s \cdot 1 = 1$. Hence for every k we have $r^k s \cdot 1 = r^k \cdot (s \cdot 1) = r^k \cdot 1$, so the reflection block $\{s, rs, r^2s, r^3s\}$ moves vertex 1 in exactly the same pattern as the rotation block $\{1, r, r^2, r^3\}$. Using $r^k \cdot 1$ with $r : 1 \mapsto 2 \mapsto 3 \mapsto 4 \mapsto 1$ gives the table

g	1	r	r^2	r^3	s	rs	r^2s	r^3s
$g \cdot 1$	1	2	3	4	1	2	3	4

The elements sending $1 \mapsto 1$ are exactly $\{1,\ s\}$. Therefore

$$\mathrm{Stab}(1) = \{1, s\} = \langle s \rangle,$$

of order 2.

Check. Orbit-stabilizer: the orbit of 1 is all four vertices (rotations reach them), so $|D_8| = |\text{orbit}| \cdot |\mathrm{Stab}(1)| = 4 \cdot 2 = 8$. Correct. By symmetry every vertex stabilizer has order 2; for instance $\mathrm{Stab}(2) = \{1,\ r^2s\}$, the reflection fixing the diagonal through 2 and 4.

Worked Example 2.2.32 ($\mathrm{GL}_n(\mathbb{F})$ on $\mathbb{F}^n$: stabilizer of e_1)**.** Let $G = \mathrm{GL}_n(\mathbb{F})$ act on column vectors $\mathbb{F}^n$ by $M \cdot v = Mv$. Compute $\mathrm{Stab}(e_1)$, where $e_1 = (1, 0, \ldots, 0)^{\mathsf{T}}$.

Recognition. One fixed vector $e_1 \Rightarrow$ stabilizer. The action is matrix-times-vector, so set $Me_1 = e_1$ and read off the constraint on the entries of M.

Solution. The product Me_1 is the *first column* of M. So $Me_1 = e_1$ forces the first column of M to be $(1, 0, \ldots, 0)^{\mathsf{T}}$. Writing M in block form with this first column,

$$M = \begin{pmatrix} 1 & * \\ 0 & B \end{pmatrix}, \qquad B \in \mathrm{GL}_{n-1}(\mathbb{F}),\ * \in \mathbb{F}^{1\times(n-1)},$$

where the 0 is the column of $n-1$ zeros below the leading 1. Invertibility of M: expanding, $\det M = 1 \cdot \det B = \det B$, so M is invertible iff B is invertible. The bottom-left block is forced to be 0 by $Me_1 = e_1$, while the top-right row $*$ is free. Hence

$$\mathrm{Stab}(e_1) = \left\{ \begin{pmatrix} 1 & v^{\mathsf{T}} \\ 0 & B \end{pmatrix} \;\middle|\; B \in \mathrm{GL}_{n-1}(\mathbb{F}),\ v \in \mathbb{F}^{n-1} \right\}.$$

This is the affine group $\mathrm{AGL}_{n-1}(\mathbb{F}) \cong \mathbb{F}^{n-1} \rtimes \mathrm{GL}_{n-1}(\mathbb{F})$ (the row v^{T} records a translation acting on the last $n-1$ coordinates).

Check. Take $n = 2$, $\mathbb{F} = \mathbb{F}_2$. Then $\mathrm{Stab}(e_1) = \{\left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)\}$ (here $B \in \mathrm{GL}_1(\mathbb{F}_2) = \{1\}$ and $v \in \{0, 1\}$), order 2. Orbit-stabilizer: $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$ and the orbit of e_1 is the set of nonzero vectors $\{e_1, e_2, e_1 + e_2\}$ (size 3), so $6 = 3 \cdot 2$. Correct.

Worked Example 2.2.33 (Kernel of the D_8 vertex action is 1 (faithfulness))**.** Show that the action of D_8 on the four vertices $\{1, 2, 3, 4\}$ is faithful, i.e. its kernel is trivial.

Recognition. "Fix EVERY point" / "faithful" $\Rightarrow$ kernel, computed as $\bigcap_a G_a$ or as $\ker(D_8 \to S_4)$. We intersect the vertex stabilizers.

Solution. From the previous example, $\mathrm{Stab}(1) = \{1, s\}$. Compute another: $\mathrm{Stab}(2)$. Using $g \cdot 2$ for each g: $r \cdot 2 = 3$, $r^2 \cdot 2 = 4$, $r^3 \cdot 2 = 1$, and $s \cdot 2 = 4$ (the reflection across the 1–3 axis swaps $2, 4$), $r^2s \cdot 2 = r^2 \cdot (s \cdot 2) = r^2 \cdot 4 = 2$. So $\mathrm{Stab}(2) = \{1,\ r^2s\}$. Now intersect:

$$\ker = \bigcap_a G_a \subseteq \mathrm{Stab}(1) \cap \mathrm{Stab}(2) = \{1, s\} \cap \{1, r^2s\} = \{1\},$$

since $s \neq r^2s$ (else $r^2 = 1$, false). Thus the kernel is already trivial after two vertices, so $\ker = 1$ and the action is faithful.

Equivalently, the homomorphism $D_8 \to S_4$ is injective: $|D_8| = 8$ maps injectively into $|S_4| = 24$, realizing D_8 as the symmetry subgroup of the square inside S_4.

Check. A nonidentity symmetry of a square must move at least one vertex (rotations move all four; reflections move at least two). So no nonidentity element fixes all vertices – consistent with $\ker = 1$.

Worked Example 2.2.34 (Conjugation: $\mathrm{Stab}(a) = C_G(a)$ and $\mathrm{Stab}(A) = N_G(A)$ in D_8)**.** In $G = D_8$ let $a = s$ (a single reflection) and let $A = \langle r \rangle = \{1, r, r^2, r^3\}$ (the rotation subgroup). Using conjugation actions, compute $\mathrm{Stab}(s) = C_G(s)$ and $\mathrm{Stab}(A) = N_G(A)$.

Recognition. Conjugation on a point ⇒ stabilizer = centralizer (Thm. 2.2.29(b)). Conjugation on a subset ⇒ stabilizer = normalizer (Thm. 2.2.29(a)). So compute $\{g \mid gsg^{-1} = s\}$ and $\{g \mid gAg^{-1} = A\}$.

Solution. Centralizer of s. We need $gs = sg$. The standard relations give $sr = r^{-1}s$ and more generally $r^k s = sr^{-k}$. Test each g:

- $g = r^k$: $r^k s = sr^{-k}$, which equals sr^k iff $r^{-k} = r^k$ iff $r^{2k} = 1$ iff $k \in \{0, 2\}$. So $1, r^2$ commute with s.
- $g = s$: $s \cdot s = s \cdot s$ trivially, so $s \in C_G(s)$.
- $g = r^2 s$: $(r^2 s)s = r^2$, and $s(r^2 s) = sr^2 s = r^{-2} = r^2$. Equal, so $r^2 s \in C_G(s)$.
- $g = rs$, $r^3 s$: e.g. $(rs)s = r$ while $s(rs) = srs = r^{-1} = r^3 \neq r$. Not in $C_G(s)$. Similarly $r^3 s$ fails.

Hence $C_G(s) = \mathrm{Stab}(s) = \{1, r^2, s, r^2 s\}$, order 4 (a Klein four-group $\cong V_4$).

Normalizer of $A = \langle r \rangle$. We need $gAg^{-1} = A$ as a set. Since $A = \langle r \rangle$ is the unique cyclic subgroup of order 4, every conjugate gAg^{-1} is again a subgroup of order 4; the only such cyclic subgroup is A itself (the other order-4 subgroups of D_8 are the two Klein fours $\{1, r^2, s, r^2 s\}$ and $\{1, r^2, rs, r^3 s\}$, not equal to $\langle r \rangle$, and conjugation preserves the property "cyclic"). Therefore $gAg^{-1} = A$ for *all* $g \in D_8$, giving $N_G(A) = \mathrm{Stab}(A) = D_8$.

Check. Consistency with the dictionary $C_G(A) \leq N_G(A)$ and $|G| = |\text{orbit}| \cdot |\text{Stab}|$: the conjugacy class (orbit) of s is $\{s, r^2 s\}$ (since $rsr^{-1} = r^2 s$), size 2, and $|D_8| = 8 = 2 \cdot 4 = |\text{class of } s| \cdot |C_G(s)|$. Correct. For A: orbit under conjugation is $\{A\}$ (size 1) and $8 = 1 \cdot |N_G(A)| = 1 \cdot 8$. Correct, confirming $A \trianglelefteq D_8$ (index 2).

Worked Example 2.2.35 (Kernel as $C_G(A)$: centralizer of a subset in Q_8)**.** Let $G = Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ act on itself by conjugation, and let $A = \{i, j\}$. Compute the centralizer $C_G(A)$, exhibiting it as the intersection $\bigcap_{a \in A} G_a$ of the point stabilizers, i.e. the kernel of the conjugation action of $N_G(A)$ on A (G itself does not act on A: $jij^{-1} = -i \notin A$).

Recognition. "Fix every element of A under conjugation" ⇒ kernel of the conjugation-on-points action $= C_G(A)$ (Thm. 2.2.29(b)). Compute $C_G(i) \cap C_G(j)$.

Solution. Recall in Q_8: $i^2 = j^2 = k^2 = -1$, $ij = k$, $ji = -k$, and -1 is central. Compute $C_G(i) = \{g \mid gi = ig\}$. Since i commutes with $\pm 1, \pm i$ and anticommutes with $\pm j, \pm k$ (e.g. $ji = -ij$), we get $C_G(i) = \{\pm 1, \pm i\} = \langle i \rangle$, order 4. Likewise $C_G(j) = \{\pm 1, \pm j\} = \langle j \rangle$, order 4. Intersect:

$$C_G(A) = C_G(i) \cap C_G(j) = \{\pm 1, \pm i\} \cap \{\pm 1, \pm j\} = \{\pm 1\} = Z(Q_8).$$

So the only elements conjugation-fixing both i and j are ± 1.

Check. Since i, j generate Q_8 (as $ij = k$), centralizing both means centralizing everything, so $C_G(\{i, j\}) = C_G(Q_8) = Z(Q_8) = \{\pm 1\}$. This matches. It is moreover normal in Q_8, indeed central; but being the kernel of the action of $N_G(A)$ on A only guarantees $C_G(A) \trianglelefteq N_G(A)$ — e.g. $C_{S_3}((1\,2)) = \langle (1\,2) \rangle$ is not normal in S_3.

Remark 2.2.5. Each "check" above used **orbit-stabilizer**: $|G| = |\mathcal{O}_a| \cdot |G_a|$, where $\mathcal{O}_a$ is the orbit of a. For conjugation on points this reads $|G| = |\text{conjugacy class of } a| \cdot |C_G(a)|$, the class equation input (D&F 4.3). Stabilizers and kernels are the gateway: the stabilizer measures "how much of G is wasted fixing a," and the kernel measures "how much of G acts invisibly."

The conjugation homomorphism $N_G(A) \to S_A$ and faithfulness

The bookkeeping of Section 2.2 is governed by a single homomorphism: conjugation by an element of $N_G(A)$ permutes A, and the elements that act as the identity permutation are exactly $C_G(A)$. This packages the chain $C_G(A) \leq N_G(A)$ of Proposition 2.2.19 as a kernel statement and lets us read off the conjugation permutation explicitly in the running D_8 example.

Proposition 2.2.36 (The $N_G(A) \to S_A$ homomorphism)**.** *Let A be a nonempty subset of G. There is a homomorphism*

$$\varphi:\ N_G(A) \longrightarrow S_A, \qquad \varphi(g) = \sigma_g, \quad \sigma_g(a) = gag^{-1},$$

whose kernel is exactly $C_G(A)$. Consequently $C_G(A) \trianglelefteq N_G(A)$, with $C_G(A)$ the elements of $N_G(A)$ that fix A pointwise *under conjugation and $N_G(A)$ those that fix A* setwise*.*

Proof. For $g \in N_G(A)$ the map $\sigma_g : A \to A$, $a \mapsto gag^{-1}$, is a well-defined bijection of A: it lands in A because $gAg^{-1} = A$, and its inverse is $\sigma_{g^{-1}}$, which also maps A to A since $g^{-1} \in N_G(A)$. Thus $\sigma_g \in S_A$. It is a homomorphism: for $g, h \in N_G(A)$ and $a \in A$,

$$\sigma_{gh}(a) = (gh)a(gh)^{-1} = g(hah^{-1})g^{-1} = \sigma_g\big(\sigma_h(a)\big),$$

so $\varphi(gh) = \sigma_g\sigma_h = \varphi(g)\varphi(h)$. Finally $g \in \ker\varphi$ iff $\sigma_g = \mathrm{id}_A$ iff $gag^{-1} = a$ for all $a \in A$ iff $g \in C_G(A)$. A kernel is a normal subgroup of its domain, so $C_G(A) \trianglelefteq N_G(A)$. □

Remark 2.2.6. If G is abelian then $ga = ag$ for all g, a, so $C_G(A) = N_G(A) = G$ for every subset A and every subgroup is normal. Hence φ is trivial and the homomorphism of Proposition 2.2.36 carries information only in *non*abelian groups: there it measures, via $N_G(A)/C_G(A) \cong \operatorname{im}\varphi \leq S_A$, exactly how conjugation reshuffles A as a set.

Worked Example 2.2.37 (Reading off φ for $A = \langle r\rangle$ in D_8: every reflection inverts $\langle r\rangle$)**.** With $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1}\rangle$ and $A = \{1, r, r^2, r^3\} = \langle r\rangle$, the centralizer and normalizer are already known: $C_{D_8}(A) = \langle r\rangle$ (Worked Example 2.2.3, $C_{D_8}(r) = \langle r\rangle$) and $N_{D_8}(A) = D_8$ (index 2). Use Proposition 2.2.36 to identify the permutation $\varphi(g) \in S_A$.

Recognition. The kernel of φ is $C_{D_8}(A) = \langle r\rangle$, so φ collapses the rotations and is determined by what a single reflection does to A. The relation $sr^k s^{-1} = r^{-k}$ gives that action in one line.

Solution. The rotations $\langle r\rangle = \ker\varphi$ act trivially: $r^j r^k r^{-j} = r^k$ for all j, k. For a reflection sr^j,

$$(sr^j)\, r^k\, (sr^j)^{-1} = s\, r^k\, s^{-1} = r^{-k},$$

so *every* reflection induces the same permutation $1 \mapsto 1,\ r \mapsto r^3,\ r^2 \mapsto r^2,\ r^3 \mapsto r$, i.e. the transposition of r and r^3 fixing $1, r^2$. Thus

$$\operatorname{im}\varphi = \{\mathrm{id}_A,\ (r\ \ r^3)\} \leq S_A, \qquad |\operatorname{im}\varphi| = 2.$$

Check. $|\operatorname{im}\varphi| = [N_{D_8}(A) : C_{D_8}(A)] = 8/4 = 2$, consistent with $N_{D_8}(A)/C_{D_8}(A) \cong \operatorname{im}\varphi$. Conjugation by s moves r to the *different* element $r^3 \in A$ – allowed setwise (so $s \in N_{D_8}(A)$) but not pointwise (so $s \notin C_{D_8}(A)$), which is precisely the strict gap $C_{D_8}(A) = \langle r\rangle \ < \ N_{D_8}(A) = D_8$.

Worked Example 2.2.38 (Centralizer table of S_3 and the center as their intersection)**.** For $S_3 = \{1, (1\,2), (1\,3), (2\,3), (1\,2\,3), (1\,3\,2)\}$, tabulate $C_{S_3}(a)$ by cycle type and read off $Z(S_3) = \bigcap_a C_{S_3}(a)$ together with the orbit-stabilizer identity $|S_3| = |\text{class of } a| \cdot |C_{S_3}(a)|$.

Recognition. The center is the intersection of all centralizers ($Z(G) = C_G(G)$, Definition 2.2.9). Since $(1\,2)$ and $(1\,2\,3)$ generate S_3 it suffices to intersect their two centralizers, both already computed ($C_{S_3}((1\,2)) = \langle(1\,2)\rangle$ and a 3-cycle centralizes only the cyclic group it generates). The new content is the table and the class-size cross-check.

Solution. One representative per conjugacy class:

a	$C_{S_3}(a)$	$\lvert C_{S_3}(a)\rvert$	$\lvert\text{class of } a\rvert$
1	S_3	6	1
$(1\,2)$	$\{1, (1\,2)\}$	2	3
$(1\,2\,3)$	$\{1, (1\,2\,3), (1\,3\,2)\}$	3	2

(the entries for $(1\,3), (2\,3)$ match $(1\,2)$, and $(1\,3\,2)$ matches $(1\,2\,3)$). Intersecting over the two generators,

$$Z(S_3) = C_{S_3}\big((1\,2)\big) \cap C_{S_3}\big((1\,2\,3)\big) = \{1, (1\,2)\} \cap \{1, (1\,2\,3), (1\,3\,2)\} = \{1\}.$$

Check. The orders 2 and 3 are coprime, so the two centralizers meet only in 1; and each row satisfies orbit-stabilizer $|\text{class}| \cdot |C_{S_3}(a)| = |S_3| = 6$ ($1 \cdot 6 = 3 \cdot 2 = 2 \cdot 3 = 6$). Consistent with $Z(S_3) = 1$.

Worked Example 2.2.39 (Conjugation as a permutation representation $\varphi : G \to S_G$, with $\ker\varphi = Z(G)$)**.** Let G act on itself by conjugation, $g \cdot a = gag^{-1}$, with permutation representation $\varphi : G \to S_G$, $\varphi(g) = \sigma_g$ (this is the $A = G$ case of the conjugation action in Theorem 2.2.29). Identify $\ker\varphi$ and confirm faithfulness amounts to $Z(G) = 1$.

Recognition. "Acts trivially on every point" selects the kernel; "fixes one chosen point" selects a stabilizer. For conjugation on all of G, Theorem 2.2.29(b) already gives $\mathrm{Stab}(a) = C_G(a)$; intersecting over every point gives the kernel, which is the new identification with $Z(G)$.

Solution. $g \in \ker\varphi$ iff $\sigma_g = \mathrm{id}_G$ iff $gag^{-1} = a$ for all $a \in G$ iff g commutes with every element of G, i.e.

$$\ker\varphi = \bigcap_{a\in G} \mathrm{Stab}(a) = \bigcap_{a\in G} C_G(a) = \{g \mid ga = ag\ \forall a \in G\} = Z(G),$$

matching $Z(G) = C_G(G)$ of Definition 2.2.9. Hence the conjugation representation $\varphi : G \to S_G$ is *faithful* (its kernel is 1) iff $Z(G) = 1$. *Check.* For $G = S_3$ the table above gives $Z(S_3) = 1$, so $S_3 \hookrightarrow S_6$ by conjugation; for $G = D_8$ one has $Z(D_8) = \{1, r^2\} \neq 1$ (Theorem 2.2.11), so the conjugation representation of D_8 is not faithful, its kernel being $\langle r^2\rangle$.

Caution. "g acts trivially" ($\sigma_g = \mathrm{id}$, i.e. $g \in \ker$) is a statement about one element; "the action is faithful" ($\ker = 1$) is a statement about the whole action. For conjugation on G these read: a single g acts trivially iff $g \in Z(G)$, while the action is faithful iff $Z(G) = 1$. So the kernel measures exactly the failure of faithfulness, and for the conjugation representation that kernel is precisely $Z(G)$.

Further worked examples

More centralizers (Definition 2.2.1).

Worked Example 2.2.40 ($C_{S_4}\big((1\,2)(3\,4)\big)$)**.** Compute the centralizer of $\tau = (1\,2)(3\,4)$ in S_4.

Recognition. Single-element centralizer in S_n: σ commutes with τ iff $\sigma\tau\sigma^{-1} = \tau$. Since $\sigma\tau\sigma^{-1} = (\sigma 1\,\sigma 2)(\sigma 3\,\sigma 4)$, this holds iff σ *preserves the partition* $\{\{1,2\},\{3,4\}\}$.

Solution. The permutations preserving $\{\{1,2\},\{3,4\}\}$ may swap the two blocks and may flip inside a block:

$$\{e,\ (1\,2),\ (3\,4),\ (1\,2)(3\,4),\ (1\,3)(2\,4),\ (1\,4)(2\,3),\ (1\,3\,2\,4),\ (1\,4\,2\,3)\},$$

of order 8 (a copy of D_8). So $|C_{S_4}(\tau)| = 8$. *Check.* $8 \mid 24$, and the number of conjugates of τ is $24/8 = 3$ — exactly the three $(2,2)$-elements.

Worked Example 2.2.41 ($C_{Q_8}(j)$)**.** Find the centralizer of j in $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$.

Recognition. Single-element centralizer; use $ij = k$, $ji = -k$, so i and k *anti*commute with j while $\pm 1, \pm j$ commute with it.

Solution. j commutes with $1, -1, j, -j$, but $ij = k \neq -k = ji$, so $\pm i, \pm k \notin C$. Thus $C_{Q_8}(j) = \{\pm 1, \pm j\} = \langle j\rangle$, order 4. *Check.* $\langle j\rangle \leq C_{Q_8}(j)$ always; here they are equal.

More centers (Theorem 2.2.11).

Worked Example 2.2.42 ($Z(D_{16})$)**.** Find the center of D_{16} (symmetries of the octagon; $r^8 = s^2 = 1$, $sr = r^{-1}s$).

Recognition. D_{2n} with $n = 8$ *even*, so Theorem 2.2.11 predicts $Z = \{1, r^{n/2}\} = \{1, r^4\}$. Verify by intersecting $C(r) \cap C(s)$.

Solution. No reflection is central (sr^k commutes with r only if $r^2 = 1$, false). A rotation r^a commutes with s iff $r^a = r^{-a}$, i.e. $r^{2a} = 1$, i.e. $a \in \{0, 4\}$. Hence $Z(D_{16}) = \{1, r^4\}$. *Check.* $r^4 = r^{-4}$ has order 2, so $sr^4 = r^4 s$.

More normalizers (Definition 2.2.18).

Worked Example 2.2.43 ($N_{S_4}(\langle(1\,2\,3\,4)\rangle)$)**.** Compute the normalizer of $H = \langle(1\,2\,3\,4)\rangle = \{e, (1234), (13)(24), (1432)\}$ in S_4.

Recognition. Setwise stabilizer of H under conjugation. A conjugate of a 4-cycle is a 4-cycle, so test which σ keep the *set* H.

Solution. $\sigma(1234)\sigma^{-1} = (\sigma 1\,\sigma 2\,\sigma 3\,\sigma 4) \in H$ iff it equals (1234) or (1432), i.e. iff σ is a symmetry of the cycle $1-2-3-4$ (a rotation or a reflection). These are $\langle(1234), (13)\rangle$, of order 8. So $|N_{S_4}(H)| = 8$. *Check.* $H \leq N$, index $24/8 = 3$ = number of conjugate cyclic subgroups of order 4.

Stabilizers, and an orbit–stabilizer preview (Definition 2.2.27).

Worked Example 2.2.44 (counting S_5 through a stabilizer)**.** S_5 acts on $\{1, \ldots, 5\}$. Find $|\mathrm{Stab}(5)|$ and recount $|S_5|$.

Recognition. The action is transitive (the orbit of 5 is all of $\{1, \ldots, 5\}$), so $|G| = |\text{orbit}| \cdot |\text{Stab}|$ (orbit–stabilizer, previewed below).

Solution. $\mathrm{Stab}(5) = \{\sigma \mid \sigma(5) = 5\}$ is the copy of S_4 on $\{1, 2, 3, 4\}$, so $|\mathrm{Stab}(5)| = 24$. The orbit has size 5, so $|S_5| = 5 \cdot 24 = 120 = 5!$.

The recount above is an instance of the *orbit–stabilizer bijection*: for G acting on S, cosets of G_s correspond to points of the orbit of s. We will prove this in Chapter 4; as a diagram it is

$$G/G_s \xrightarrow[gG_s \mapsto g\cdot s]{\sim} \mathrm{orbit}(s),$$

so $|\mathrm{orbit}(s)| = [G : G_s]$ — the principle behind every counting argument of this kind.

Diagram explanation. Objects: G/G_s is the set of left cosets of the stabilizer G_s in G (not a group in general, just a set of cosets). $\mathrm{orbit}(s) = \{g \cdot s \mid g \in G\}$ is the orbit of s under the action, a subset of the set A on which G acts.

Arrows: The single arrow labeled $\sim$ is the bijection $\Phi : G/G_s \to \mathrm{orbit}(s)$, $gG_s \mapsto g \cdot s$. It is an induced map from the quotient: it takes a coset gG_s and evaluates g at s. The label $\sim$ signals that this arrow is a bijection (an isomorphism of sets).

What commutes: There is only one path from G/G_s to $\mathrm{orbit}(s)$, so the diagram records a single well-defined map rather than a path-equality. The content is the two-sided inverse: Φ is injective (if $g \cdot s = h \cdot s$ then $h^{-1}g \in G_s$ so $gG_s = hG_s$) and surjective (every $g \cdot s$ in the orbit is hit by the coset gG_s).

Why it commutes: Well-definedness of Φ is the key step: if $gG_s = hG_s$ then $h^{-1}g \in G_s$, i.e. $(h^{-1}g) \cdot s = s$, so $g \cdot s = h \cdot (h^{-1}g \cdot s) = h \cdot s$. Thus the formula $gG_s \mapsto g \cdot s$ does not depend on which representative of the coset we pick – this is the well-definedness check for a quotient-induced map.

Why this matters here: This diagram is placed immediately after the D_8-on-vertices and S_5 examples to explain why those counting arguments work: the coset count $[G : G_s]$ equals the orbit size because the bijection Φ matches them one-to-one. Every orbit- stabilizer equation $|G| = |\text{orbit}| \cdot |G_s|$ is a consequence of this bijection together with Lagrange's theorem ($|G| = [G : G_s] \cdot |G_s|$).

Concrete example: Take $G = S_3$ acting on $\{1, 2, 3\}$ by evaluation, $s = 1$. Then $G_1 = \{e, (2\,3)\} \cong \mathbb{Z}/2$ (order 2), and the orbit of 1 is $\{1, 2, 3\}$ (size 3). The bijection sends $eG_1 \mapsto 1$, $(1\,2)G_1 \mapsto 2$, $(1\,3)G_1 \mapsto 3$, confirming three cosets $\leftrightarrow$ three orbit elements.

Common pitfall: Students sometimes confuse G/G_s (a set of cosets, not a quotient group) with the orbit itself. The arrow Φ is a *bijection of sets*, not a group isomorphism; G/G_s inherits a group structure only when $G_s \trianglelefteq G$.

Takeaway: The point of this diagram is that the orbit of s is in bijection with the set of cosets of the stabilizer, so computing the size of an orbit always reduces to counting cosets.

Maps and commutative diagrams

The centralizer, normalizer, and kernel of this section are all instances of a single idea: *turn the situation into a homomorphism and look at its kernel.*

(a) An action is a homomorphism to a symmetric group. An action of G on a set S is the same thing as a homomorphism $\rho : G \to \mathrm{Sym}(S)$, $g \mapsto (s \mapsto g \cdot s)$ (Definition 2.2.26). The stabilizer G_s is the set of g fixing s, and the kernel of the action is $\ker \rho = \bigcap_{s \in S} G_s$ — an intersection of subgroups, hence a subgroup (Proposition 2.2.28).

$$G \xrightarrow{\ \rho\ } \mathrm{Sym}(S)$$

Diagram explanation. Objects: G is the group acting. $\mathrm{Sym}(S)$ is the symmetric group on the set S (all bijections $S \to S$ under composition). This is the universal target for any action of G on S.

Arrows: The single arrow $\rho : G \to \mathrm{Sym}(S)$ sends g to the bijection $\sigma_g : S \to S$, $\sigma_g(s) = g \cdot s$. It is the *permutation representation* of the action. It is a homomorphism: $\rho(gh) = \sigma_{gh} = \sigma_g \circ \sigma_h = \rho(g)\rho(h)$, which follows from the axiom $g \cdot (h \cdot s) = (gh) \cdot s$.

What commutes: There is one arrow, so no path-equality to state. The structural fact is $\rho(g_1 g_2) = \rho(g_1) \circ \rho(g_2)$ (homomorphism property), and $\ker \rho = \bigcap_{s \in S} G_s$ (the elements acting trivially on every point).

Why it commutes: Chase g_1, g_2 through ρ: $\rho(g_1 g_2)(s) = (g_1 g_2) \cdot s = g_1 \cdot (g_2 \cdot s) = \rho(g_1)(\rho(g_2)(s))$, using the associativity axiom of the action. The kernel condition $\rho(g) = \mathrm{id}_S$ unpacks to $g \cdot s = s$ for all s, i.e. $g \in G_s$ for every s, which is the definition of the kernel.

Why this matters here: This single arrow encodes the entire action, and it explains why the kernel $\ker \rho = \bigcap_s G_s$ is automatically a normal subgroup (kernels of homomorphisms are always normal). It also sets up parts (b) and (c) below, where we specialize ρ to conjugation actions to obtain $C_G(A)$ and $Z(G)$ as kernels.

Concrete example: Let $G = D_8$ act on the four vertices $\{1, 2, 3, 4\}$. Then $\rho : D_8 \to S_4$ sends $r \mapsto (1\,2\,3\,4)$ and $s \mapsto (2\,4)$. The kernel is trivial (the action is faithful), as shown in the worked example on faithfulness above.

Common pitfall: The diagram looks like a one-object category map, which may suggest ρ must be injective. It need not be: ρ is injective iff the action is *faithful* (kernel $= 1$). A non-faithful action has a nontrivial kernel; the map ρ merely records that every g gives a bijection of S, not that different g give different bijections.

Takeaway: The point of this diagram is that every group action is secretly a group homomorphism into a symmetric group, so any action can be analyzed using the kernel–image decomposition theorem for homomorphisms.

(b) The centralizer is the kernel of a conjugation action. Restrict conjugation to $N_G(A)$: it permutes A, giving $c : N_G(A) \to \mathrm{Sym}(A)$ with $C_G(A) = \ker c$ (Theorem 2.2.29). This explains the tower $C_G(A) \le N_G(A) \le G$ of Proposition 2.2.19 at a glance.

$$1 \longrightarrow C_G(A) \hookrightarrow N_G(A) \xrightarrow{\ c\ } \mathrm{Sym}(A)$$

Diagram explanation. Objects: 1 is the trivial group. $C_G(A)$ is the centralizer of A in G: elements acting pointwise trivially on A by conjugation. $N_G(A)$ is the normalizer: elements mapping A to itself setwise by conjugation. $\mathrm{Sym}(A)$ is the group of all bijections of the set A.

Arrows: The arrow $1 \to C_G(A)$ is the inclusion of the trivial element (recording that $1 \in C_G(A)$; exactness at $C_G(A)$ says that the inclusion $C_G(A) \hookrightarrow N_G(A)$ is injective, while $C_G(A) = \ker c$ is exactness at $N_G(A)$). The hooked arrow $C_G(A) \hookrightarrow N_G(A)$ is the subgroup inclusion from Proposition 2.2.19. The arrow $c : N_G(A) \to \mathrm{Sym}(A)$ is the conjugation homomorphism $c(g) = \sigma_g$ where $\sigma_g(a) = gag^{-1}$; it is well defined on $N_G(A)$ because $gAg^{-1} = A$ for $g \in N_G(A)$.

What commutes: This is a *left-exact sequence*: $\mathrm{im}(C_G(A) \hookrightarrow N_G(A)) = \ker(c)$. That is, $C_G(A)$ is exactly the set of $g \in N_G(A)$ with $c(g) = \mathrm{id}_A$: $gag^{-1} = a$ for all $a \in A$.

Why it commutes: For the exactness at $N_G(A)$: if $g \in C_G(A)$ then $gag^{-1} = a$ for all $a \in A$, so $\sigma_g = \mathrm{id}_A$, giving $C_G(A) \subseteq \ker c$. Conversely if $c(g) = \mathrm{id}_A$ then $gag^{-1} = a$ for all a, so $g \in C_G(A)$; thus $\ker c \subseteq C_G(A)$. Well-definedness of c: for $g \in N_G(A)$, σ_g maps $A \to A$ since $gAg^{-1} = A$, so conjugation lands inside A – the normalizer condition is precisely what guarantees c is defined on A.

Why this matters here: This diagram is the punchline of the entire Section 2.2 bookkeeping: it packages the chain $C_G(A) \le N_G(A)$ from Proposition 2.2.19 as a single kernel statement, and the first-isomorphism theorem then gives $N_G(A)/C_G(A) \cong \mathrm{im}\, c \le \mathrm{Sym}(A)$, measuring how much conjugation permutes A beyond the trivial action.

Concrete example: Take $G = D_8$, $A = \langle r \rangle = \{1, r, r^2, r^3\}$. Then $N_{D_8}(A) = D_8$, $C_{D_8}(A) = \langle r \rangle$, and $c(s)$ is the transposition $(r\ r^3)$ in $\mathrm{Sym}(A)$ (swapping r and r^3, fixing 1 and r^2). So $\operatorname{im} c = \{e, (r\ r^3)\}$ and $D_8/\langle r \rangle \cong \mathbb{Z}/2$, consistent with $[D_8 : \langle r \rangle] = 2$.

Common pitfall: Students sometimes think the sequence ends: is it also right-exact? No – c need not be surjective. Here $\operatorname{im} c \subsetneq \mathrm{Sym}(A)$ (only one nontrivial permutation of A arises by conjugation). Also, do not confuse the inclusion $C_G(A) \hookrightarrow N_G(A)$ (a subgroup containment) with an isomorphism.

Takeaway: The point of this diagram is that $C_G(A)$ is the kernel of the conjugation action of $N_G(A)$ on A, so the tower $C_G(A) \leq N_G(A)$ is not an accident but an instance of the general fact that kernels of homomorphisms are normal subgroups.

(c) The center is the kernel of conjugation on all of G. Taking $A = G$ above, $g \mapsto (x \mapsto gxg^{-1})$ is a homomorphism $G \to \mathrm{Aut}(G)$ whose kernel is $Z(G)$. Thus $Z(G) \trianglelefteq G$ for free.

$$1 \longrightarrow Z(G) \hookrightarrow G \xrightarrow{\phi} \mathrm{Aut}(G)$$

Diagram explanation. Objects: 1 is the trivial group (starting point of the sequence). $Z(G)$ is the center of G: the normal subgroup of elements commuting with every $x \in G$. G is the group itself. $\mathrm{Aut}(G)$ is the group of all automorphisms (bijective homomorphisms $G \to G$), the target for the inner-automorphism representation.

Arrows: $1 \to Z(G)$ records that $1 \in Z(G)$ and (exactness at $Z(G)$) that the inclusion $Z(G) \hookrightarrow G$ is injective, starting the left-exact sequence. The inclusion $Z(G) \hookrightarrow G$ is the subgroup inclusion from Proposition 2.2.10. The arrow $\phi : G \to \mathrm{Aut}(G)$ is the *inner automorphism map*: $\phi(g) = \iota_g$ where $\iota_g(x) = gxg^{-1}$. Each ι_g is an automorphism of G (a bijective homomorphism), and ϕ is a homomorphism: $\iota_{gh} = \iota_g \circ \iota_h$.

What commutes: This is a left-exact sequence: $\ker \phi = Z(G)$, i.e. $\operatorname{im}(Z(G) \hookrightarrow G) = \ker \phi$. In plain language: $g \in \ker \phi$ iff $\iota_g = \mathrm{id}_G$ iff $gxg^{-1} = x$ for all $x \in G$ iff $g \in Z(G)$.

Why it commutes: Exactness at G: $g \in Z(G)$ means $gx = xg$ for all x, so $gxg^{-1} = x$, hence $\iota_g = \mathrm{id}_G \in \ker \phi$. Conversely $\iota_g = \mathrm{id}_G$ means $gxg^{-1} = x$ for all x, i.e. $gx = xg$ for all x, so $g \in Z(G)$. Well- definedness of ϕ: ι_g is a bijection (with inverse $\iota_{g^{-1}}$) and a homomorphism ($\iota_g(xy) = gxyg^{-1} = (gxg^{-1})(gyg^{-1}) = \iota_g(x)\iota_g(y)$), so $\iota_g \in \mathrm{Aut}(G)$.

Why this matters here: This is the $A = G$ specialization of diagram (b): taking the conjugation action on all of G turns the normalizer into G (since $G \trianglelefteq G$) and the centralizer into $Z(G)$. It gives $Z(G) \trianglelefteq G$ for free (kernels are normal), and the first-isomorphism theorem yields $G/Z(G) \cong \mathrm{Inn}(G) \leq \mathrm{Aut}(G)$, a fundamental formula relating the structure of G to its automorphisms.

Concrete example: For $G = D_8$: $Z(D_8) = \{1, r^2\}$ (order 2), so $\ker \phi = \langle r^2 \rangle$ and ϕ is not injective. The quotient $D_8/\{1, r^2\} \cong V_4$ (the Klein four-group), so $\mathrm{Inn}(D_8) \cong V_4$, and there are exactly four distinct inner automorphisms of D_8.

Common pitfall: Students sometimes think ϕ is surjective (i.e. $\mathrm{Aut}(G) = \mathrm{Inn}(G)$). This is false in general: $\mathrm{Aut}(G)$ may contain outer automorphisms not of the form ι_g. For $G = V_4$, for instance, $\mathrm{Inn}(V_4) = 1$ (since V_4 is abelian) while $\mathrm{Aut}(V_4) \cong S_3$ has order 6.

Takeaway: The point of this diagram is that $Z(G)$ is the kernel of the inner- automorphism representation $G \to \mathrm{Aut}(G)$, so the center measures precisely how far G is from acting faithfully on itself by conjugation.

Exercises (from the text).

1. Prove $C_G(A) = \{g \mid g^{-1}ag = a\ \forall a \in A\}$.
2. Prove $C_G(Z(G)) = G$, and deduce $N_G(Z(G)) = G$.
3. Prove $A \subseteq B \implies C_G(B) \leq C_G(A)$.
4. For S_3, D_8, Q_8, compute the centralizer of each element and the center of each.
5. Show $C_G(A) = A$ and $N_G(A) = G$ for: (a) S_3, $A = \langle (1\,2\,3) \rangle$; (b) D_8, $A = \{1, s, r^2, sr^2\}$; (c) D_{10}, $A = \langle r \rangle$.
6. (a) Prove $H \leq N_G(H)$ (and that this can fail if H is not a subgroup); (b) prove $H \leq C_G(H) \iff H$ is abelian.

7. For $n \geq 3$: (a) $Z(D_{2n}) = 1$ if n is odd; (b) $Z(D_{2n}) = \{1, r^k\}$ if $n = 2k$.
8. $G = S_n$, $G_i = \{\sigma \mid \sigma(i) = i\}$: prove $G_i \leq G$ using group actions and find $|G_i|$.
9. Define $N_H(A) = \{h \in H \mid hAh^{-1} = A\}$; prove $N_H(A) = N_G(A) \cap H \leq H$.
10. Let $|H| = 2$. Prove $N_G(H) = C_G(H)$, and deduce that $N_G(H) = G \implies H \leq Z(G)$.
11. Prove $Z(G) \leq N_G(A)$ for every subset A.
12. S_4 acts on $\mathbb{Z}[x_1, \ldots, x_4]$ by $\sigma \cdot x_i = x_{\sigma(i)}$. Find the stabilizers of x_4, of $x_1 + x_2$, and of $x_1x_2 + x_3x_4$ (the last is $\cong D_8$).
13. Verify that the analogous action of S_n on $\mathbb{Z}[x_1, \ldots, x_n]$ is a group action.
14. Prove that the center of the Heisenberg group $H(F)$ is isomorphic to $(F, +)$.

Additional exercises.

1. Prove $C_G(A) = C_G(\langle A \rangle)$ for every subset A.
2. Prove $Z(G) = \bigcap_{a \in G} C_G(a)$.
3. Prove that if $G/Z(G)$ is cyclic then G is abelian (so $Z(G) = G$).
4. Compute $C_{S_n}(\sigma)$ for an n-cycle σ, and find its order.
5. Give a group G and $H \leq G$ with $N_G(H) < N_G(N_G(H))$.

Commutative-diagram exercises.

1. For an action of G on S, write the permutation representation $\rho : G \to \mathrm{Sym}(S)$ and prove $\mathrm{Stab}(s) = \rho^{-1}\big(\mathrm{Stab}_{\mathrm{Sym}(S)}(s)\big)$; deduce $\ker \rho = \bigcap_{s \in S} \mathrm{Stab}(s)$.
2. Prove $C_G(A) = \ker\big(N_G(A) \xrightarrow{c} \mathrm{Sym}(A)\big)$, where c is conjugation, and conclude $C_G(A) \trianglelefteq N_G(A)$. Draw the resulting exact sequence.
3. Prove the conjugation map $G \to \mathrm{Aut}(G)$, $g \mapsto (x \mapsto gxg^{-1})$, is a homomorphism with kernel $Z(G)$; identify its image $\mathrm{Inn}(G)$ and draw $1 \to Z(G) \to G \to \mathrm{Inn}(G) \to 1$.
4. (Orbit–stabilizer) For G acting on S, construct the bijection $G/G_s \to \mathrm{orbit}(s)$, $gG_s \mapsto g \cdot s$, verify it is well defined and injective, and draw the commuting triangle $G \to G/G_s \to \mathrm{orbit}(s)$.

2.3 Cyclic Groups and Cyclic Subgroups

Cyclic groups: definition, order, and the gcd lemma

Definition 2.3.1. A group H is *cyclic* if there exists $x \in H$ with $H = \langle x \rangle = \{x^n \mid n \in \mathbb{Z}\}$; such an x is a *generator*. We write the abstract cyclic group of order n as Z_n, and use $\mathbb{Z}$ for the infinite cyclic group.

Two free facts fall out of the definition immediately. First, a cyclic group is *abelian*: any two elements of $\langle x \rangle$ are powers x^a, x^b, and $x^a x^b = x^{a+b} = x^{b+a} = x^b x^a$. Second, $\langle x \rangle = \langle x^{-1} \rangle$, because $x = (x^{-1})^{-1}$ lies in $\langle x^{-1} \rangle$ and conversely, so each generates the other's group.

Caution. "Cyclic" is much stronger than "abelian." V_4 is abelian but *not* cyclic: no single element has order 4, so no element generates all of V_4. Cyclic $\implies$ abelian, never the reverse.

Proposition 2.3.2 (Order of a cyclic group equals the order of its generator)**.** *Let x be an element of a group.*

1. *If $|x| = n < \infty$, then $\langle x \rangle = \{1, x, x^2, \ldots, x^{n-1}\}$ and these n powers are distinct, so $|\langle x \rangle| = n$.*
2. *If $|x| = \infty$, then the powers x^k ($k \in \mathbb{Z}$) are all distinct, so $\langle x \rangle$ is infinite.*

Proof. (1) Let $|x| = n$. For any $t \in \mathbb{Z}$, divide $t = qn + k$ with $0 \le k \le n-1$ (division algorithm). Then $x^t = (x^n)^q x^k = 1^q x^k = x^k$, so every power of x equals one of $1, x, \dots, x^{n-1}$; hence $\langle x \rangle \subseteq \{1, x, \dots, x^{n-1}\}$, and the reverse inclusion is clear. These n powers are distinct: if $x^i = x^j$ with $0 \le i < j \le n-1$, then $x^{j-i} = 1$ with $0 < j - i < n$, contradicting that n is the *least* positive integer with $x^n = 1$. So $|\langle x \rangle| = n$.

(2) If $|x| = \infty$ and $x^i = x^j$ with $i < j$, then $x^{j-i} = 1$ with $j - i > 0$, forcing x to have finite order, a contradiction. So all powers are distinct and $\langle x \rangle$ is infinite. □

Lemma 2.3.3 (gcd Lemma)**.** *Let x be a group element. If $x^m = 1$ and $x^n = 1$, then $x^{\gcd(m,n)} = 1$. Consequently, if $|x| = d < \infty$, then $x^m = 1$ if and only if $d \mid m$.*

Proof. By Bézout, write $\gcd(m, n) = am + bn$ for some $a, b \in \mathbb{Z}$. Then

$$x^{\gcd(m,n)} = x^{am+bn} = (x^m)^a (x^n)^b = 1^a \, 1^b = 1.$$

For the consequence: if $d \mid m$, say $m = dk$, then $x^m = (x^d)^k = 1$. Conversely if $x^m = 1$, apply the first part to m and d (both kill x): $x^{\gcd(m,d)} = 1$. But $0 < \gcd(m, d) \le d$ (as $d \ge 1$) and d is the *least* positive integer with $x^d = 1$, so $\gcd(m, d) = d$, i.e. $d \mid m$. □

Theorem 2.3.4 (Classification of cyclic groups)**.** *Any two cyclic groups of the same order are isomorphic. In particular every finite cyclic group of order n is isomorphic to Z_n (e.g. $\mathbb{Z}/n\mathbb{Z}$ under $+$), and every infinite cyclic group is isomorphic to $\mathbb{Z}$.*

Proof. Let $H = \langle x \rangle$ and $K = \langle y \rangle$ with $|\langle x \rangle| = |\langle y \rangle|$. Define $\varphi : H \to K$ by $\varphi(x^a) = y^a$. *Well-defined and injective (finite case $|x| = |y| = n$):* $x^a = x^b \iff x^{a-b} = 1 \iff n \mid (a - b)$ (Lemma 2.3.3) $\iff y^{a-b} = 1 \iff y^a = y^b$; the chain of equivalences gives both well-definedness and injectivity. (Infinite case: $x^a = x^b \iff a = b \iff y^a = y^b$ by Proposition 2.3.2(2).) It is surjective since every $y^a \in K$ is hit, and a homomorphism since $\varphi(x^a x^b) = \varphi(x^{a+b}) = y^{a+b} = y^a y^b$. Hence φ is an isomorphism, so $H \cong K$. □

Method (How to recognize a cyclic group and reduce a power x^t)**.** *Recognition trigger.* Use this whenever a group (or subgroup) is presented as "all powers of a single element," or you can exhibit one element whose order equals the order $|G|$ of the (finite) group, e.g. $n = |\mu_n|$. Concretely:

1. **Find a candidate generator** x and compute $|x| = n$ (least $n > 0$ with $x^n = 1$).
2. **Check it fills the group:** if G is finite and $|x| = |G|$, then $|\langle x \rangle| = |x| = |G|$ (Prop. 2.3.2), so $G = \langle x \rangle$ is cyclic with $G = \{1, x, \dots, x^{n-1}\}$.
3. **To reduce a power x^t:** divide $t = qn + k$ with $0 \le k < n$ (division algorithm); then $x^t = (x^n)^q x^k = x^k$. The reduced exponent is $k = t \bmod n$.
4. **To test $x^t = 1$:** by the gcd Lemma 2.3.3, $x^t = 1 \iff n \mid t$.

Worked Example 2.3.5 ($\langle (1\,2\,3) \rangle$ is cyclic of order 3 in S_3)**.** Show $H = \langle \sigma \rangle$ with $\sigma = (1\,2\,3) \in S_3$ is cyclic of order 3 and list its elements.

Recognition. H is presented as "all powers of one element," so it is cyclic *by Definition 2.3.1.* To get $|H|$, use Proposition 2.3.2: compute $|\sigma|$, the least positive power that is the identity.

Solution. Compute powers of $\sigma = (1\,2\,3)$:

$$\sigma^1 = (1\,2\,3), \quad \sigma^2 = (1\,3\,2), \quad \sigma^3 = (1\,2\,3)(1\,2\,3)(1\,2\,3) = e.$$

Indeed σ sends $1 \to 2 \to 3 \to 1$, so applying it three times returns every point to itself: $\sigma^3 = e$, and $\sigma^1, \sigma^2 \ne e$. Thus $|\sigma| = 3$. By Prop. 2.3.2(1), $H = \{e, \sigma, \sigma^2\} = \{e, (1\,2\,3), (1\,3\,2)\}$ has order 3. *Check.* The three listed elements are distinct and closed: $\sigma^2 \cdot \sigma = \sigma^3 = e$, consistent with a cyclic group of order 3. By Theorem 2.3.4, $H \cong Z_3$.

Worked Example 2.3.6 (Reduce r^{103} in D_8)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$ (the symmetries of the square, so $|r| = 4$), simplify r^{103}.

Recognition. This is a pure power-reduction: the element r generates a cyclic subgroup $\langle r \rangle$ with $|r| = 4$. *Apply step 3 of the Method box* (division algorithm), valid because $r^4 = 1$.

Solution. Divide the exponent by $n = |r| = 4$:

$$103 = 4 \cdot 25 + 3, \qquad 0 \leq 3 < 4.$$

Then

$$r^{103} = r^{4 \cdot 25 + 3} = (r^4)^{25}\, r^3 = 1^{25}\, r^3 = r^3.$$

So $r^{103} = r^3$ (and since $r^3 = r^{-1}$, equivalently $r^{103} = r^{-1}$). *Check via the gcd test:* $r^{103} = 1$ would require $4 \mid 103$; but $103 = 4 \cdot 25 + 3$ is not divisible by 4, consistent with $r^{103} = r^3 \neq 1$. Also $103 \equiv 3 \pmod 4$, matching $k = 3$.

Worked Example 2.3.7 (The nth roots of unity $\mu_n \leq \mathbb{C}^\times$ are cyclic)**.** Let $\mu_n = \{z \in \mathbb{C}^\times \mid z^n = 1\}$. Show μ_n is a cyclic group of order n under multiplication.

Recognition. A subgroup is cyclic exactly when one element's powers exhaust it (Def. 2.3.1). Here $\mu_n = \{e^{2\pi i k/n}\}$; the natural generator candidate is the primitive root $\zeta = e^{2\pi i/n}$. Verify $|\zeta| = n$ and invoke Prop. 2.3.2.

Solution. First, μ_n is a group: if $z^n = w^n = 1$ then $(zw)^n = z^n w^n = 1$ and $(z^{-1})^n = (z^n)^{-1} = 1$, so it is closed under products and inverses. Let $\zeta = e^{2\pi i/n}$. Then $\zeta^k = e^{2\pi i k/n}$, and these satisfy $(\zeta^k)^n = e^{2\pi i k} = 1$, so $\zeta^k \in \mu_n$ for all k. Order of ζ: $\zeta^k = 1 \iff e^{2\pi i k/n} = 1 \iff n \mid k$, so the least positive such k is n; thus $|\zeta| = n$. By Prop. 2.3.2(1), $\langle \zeta \rangle = \{1, \zeta, \ldots, \zeta^{n-1}\}$ has n distinct elements, all in μ_n. Since a degree-n polynomial $z^n - 1$ has at most n roots in the field $\mathbb{C}$, $|\mu_n| \leq n$; combined with $|\langle \zeta \rangle| = n$ we get $\mu_n = \langle \zeta \rangle$. *Check.* For $n = 4$, $\zeta = i$ and $\langle i \rangle = \{1, i, -1, -i\}$, exactly the four solutions of $z^4 = 1$. By Theorem 2.3.4, $\mu_n \cong Z_n$.

Worked Example 2.3.8 (Largest possible order from $x^{18} = 1$ and $x^{30} = 1$)**.** Suppose a group element x satisfies $x^{18} = 1$ and $x^{30} = 1$. What is the largest possible value of $|x|$?

Recognition. Two relations of the form $x^m = 1$ scream the *gcd Lemma 2.3.3*: the order must divide every exponent that kills x, hence divides their gcd. The trigger is "x raised to two known exponents equals 1."

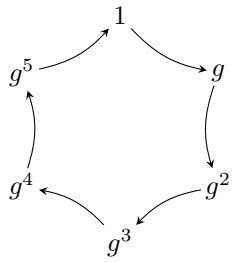
Solution. By the consequence of Lemma 2.3.3, $|x| \mid 18$ and $|x| \mid 30$, so $|x| \mid \gcd(18, 30)$. Compute

$$18 = 2 \cdot 3^2, \quad 30 = 2 \cdot 3 \cdot 5, \quad \gcd(18, 30) = 2 \cdot 3 = 6.$$

(Or directly: the Lemma gives $x^{\gcd(18,30)} = x^6 = 1$, so $|x| \mid 6$.) Hence $|x| \leq 6$, and 6 is achievable (take $x = \zeta = e^{2\pi i/6}$, which has order 6 and satisfies $6 \mid 18$, $6 \mid 30$). So the largest possible order is $\boxed{6}$. *Check.* $6 \mid 18$ ($18 = 6 \cdot 3$) and $6 \mid 30$ ($30 = 6 \cdot 5$), so $x^{18} = (x^6)^3 = 1$ and $x^{30} = (x^6)^5 = 1$ as required.

Worked Example 2.3.9 ($(\mathbb{Z}, +)$ is cyclic with generators ± 1)**.** Show that $(\mathbb{Z}, +)$ is an infinite cyclic group, and determine all of its generators.

Recognition. Additively, "powers of x" means "integer multiples kx." To prove cyclic, find one element whose multiples give all of $\mathbb{Z}$ (Def. 2.3.1). To find *all* generators, ask which g has $\langle g \rangle = \mathbb{Z}$.



Solution. Take $x = 1$. Its integer multiples are $k \cdot 1 = k$ for $k \in \mathbb{Z}$, which is all of $\mathbb{Z}$, so $\mathbb{Z} = \langle 1 \rangle$ is cyclic. Since no positive multiple $k \cdot 1 = k$ equals the identity 0 for $k > 0$, the order is infinite, matching Prop. 2.3.2(2). Generators: $\langle g \rangle = \{kg \mid k \in \mathbb{Z}\} = g\mathbb{Z}$, and $g\mathbb{Z} = \mathbb{Z}$ requires $1 \in g\mathbb{Z}$, i.e. $g \mid 1$, forcing $g = \pm 1$. Both work: $\langle -1 \rangle = \{-k \mid k \in \mathbb{Z}\} = \mathbb{Z}$, consistent with the identity $\langle x \rangle = \langle x^{-1} \rangle$ (here $x^{-1} = -1$). *Check.* $\langle 2 \rangle = 2\mathbb{Z} = \{\ldots, -2, 0, 2, \ldots\} \neq \mathbb{Z}$ (it misses odd integers), confirming 2 is *not* a generator and that only ± 1 are.

Worked Example 2.3.10 (A group of prime order is cyclic)**.** Let $|G| = p$ with p prime. Prove G is cyclic; in fact $G = \langle x \rangle$ for *any* $x \neq 1$.

Recognition. "Prime order" plus "is it cyclic" points to Prop. 2.3.2: a nonidentity element generates a subgroup whose size is $|x|$, and the only divisors of a prime are 1 and p. (Here we use Lagrange: $|\langle x \rangle| \mid |G|$.)

Solution. Since $p \geq 2$, pick $x \in G$ with $x \neq 1$. Let $H = \langle x \rangle$. By Lagrange's theorem $|H| = |\langle x \rangle|$ divides $|G| = p$, so $|H| \in \{1, p\}$. But $x \neq 1$ gives $\{1, x\} \subseteq H$, so $|H| \geq 2$, ruling out $|H| = 1$. Therefore $|H| = p = |G|$, and since $H \subseteq G$ with equal finite cardinality, $H = G$. Thus $G = \langle x \rangle$ is cyclic, and by Prop. 2.3.2 $|x| = p$. *Check.* $G = Z_5 = \mathbb{Z}/5\mathbb{Z}$; any nonzero element, say 2, generates: $2, 4, 6 \equiv 1, 8 \equiv 3, 10 \equiv 0$, i.e. $\langle 2 \rangle = \{0, 2, 4, 1, 3\} = \mathbb{Z}/5\mathbb{Z}$. By Theorem 2.3.4, every group of order p is isomorphic to Z_p.

The structure of a finite cyclic group $Z_n = \langle g \rangle$ is exactly that of a clock with n positions: multiplying by g advances one tick, $g^n = 1$ returns to start. Below is $Z_6 = \langle g \rangle = \{1, g, g^2, g^3, g^4, g^5\}$, with each arrow showing the action $x \mapsto x \cdot g$.

Caution. When reducing x^t, reduce the *exponent* mod $|x|$, not mod $|G|$ unless x generates all of G. In D_8, $|r| = 4$ (so reduce mod 4), even though $|D_8| = 8$; using 8 only gives $r^{103} = r^7$, which is true (as $4 \mid 8$) but must still be reduced to r^3.

The order of a power

If we know $|x| = n$, what is $|x^a|$? The answer is governed entirely by a single gcd computation. This one proposition is the engine behind counting generators of a cyclic group, finding all elements of a given order, and reading off the subgroup lattice of $\mathbb{Z}/n\mathbb{Z}$.

Proposition 2.3.11. *Let x be an element of a group G and let $a \in \mathbb{Z}$.*

1. *If $|x| = n < \infty$, then $|x^a| = \dfrac{n}{\gcd(n, a)}$.*
2. *If $|x| = \infty$ and $a \neq 0$, then $|x^a| = \infty$.*

Proof. (1) Write $d = \gcd(n, a)$, and set $a = da'$, $n = dn'$ with $\gcd(a', n') = 1$. We claim $|x^a| = n' = n/d$. First, $(x^a)^{n'} = x^{an'} = x^{da'n'} = x^{a'n} = (x^n)^{a'} = 1^{a'} = 1$, so $|x^a|$ divides n'. Conversely, suppose $(x^a)^k = 1$, i.e. $x^{ak} = 1$. Since $|x| = n$, this forces $n \mid ak$, that is $dn' \mid da'k$, hence $n' \mid a'k$. As $\gcd(a', n') = 1$, Euclid's lemma gives $n' \mid k$. Thus every k killing x^a is a multiple of n', so $|x^a| = n' = n/d$.
(2) Suppose $|x| = \infty$ and $a \neq 0$. If $(x^a)^k = x^{ak} = 1$ for some $k > 0$, then $ak \neq 0$ would be a positive or negative integer with $x^{ak} = 1$, contradicting that no nonzero power of x is the identity. Hence no positive k works and $|x^a| = \infty$. □

Remark 2.3.1. The factor that shrinks the order is $\gcd(n, a)$, *not* a. Powering by a "uses up" only the part of a that overlaps n; the coprime part a' is invisible to the order because it is a unit modulo n'.

Method (Compute the order of a power x^a when $|x| = n$ is known)**.** *Recognition trigger.* Use this whenever you must find the order of a power of an element *whose own order you already know* – e.g. $|x^a|$ with $|x| = n$ given, $|\overline{a}|$ in $\mathbb{Z}/n\mathbb{Z}$ (here the "base" is $\overline{1}$ with order n and $\overline{a} = a \cdot \overline{1}$), or $|r^a|$ in D_{2n} with $|r| = n$. Also for $|\sigma^a|$ where σ is a single n-cycle in S_m.

1. Identify $n = |x|$ (the order of the *base*) and the exponent a. In $\mathbb{Z}/n\mathbb{Z}$, the operation is addition, so x^a means the element $\overline{a} = \underbrace{\overline{1} + \cdots + \overline{1}}_{a}$ and n is the modulus.
2. Compute $d = \gcd(n, a)$ (Euclidean algorithm).
3. Output $|x^a| = n/d$.

4. *Check.* Verify $d \mid n$ so the answer is an integer, and confirm $(x^a)^{n/d} = x^{an/d} = x^{(a/d)n} = 1$ since $d \mid a$.

Caution. Do **not** answer n/a. The shrink factor is $\gcd(n, a)$, never a alone. E.g. $|\overline{8}|$ in $\mathbb{Z}/12\mathbb{Z}$ is $12/\gcd(12, 8) = 12/4 = 3$, not $12/8$ (which is not even an integer). Only when $a \mid n$ *and* $\gcd(n, a) = a$ do n/a and $n/\gcd(n, a)$ coincide.

Worked Example 2.3.12 ($|\overline{8}|$ in $\mathbb{Z}/12\mathbb{Z}$)**.** Compute the order of $\overline{8}$ in $\mathbb{Z}/12\mathbb{Z}$.

Recognition. The ambient group $\mathbb{Z}/12\mathbb{Z}$ is cyclic of order 12, generated by $\overline{1}$ with $|\overline{1}| = 12$. The element $\overline{8} = 8 \cdot \overline{1}$ is a "power" (additive multiple) of the order-12 generator, so this is exactly the order-of-a-power setup with $n = 12$, $a = 8$.

Solution. Step 1: $n = 12$, $a = 8$. Step 2: $d = \gcd(12, 8) = 4$ (since $12 = 1 \cdot 8 + 4$, $8 = 2 \cdot 4$). Step 3: $|\overline{8}| = 12/4 = 3$. Check: $3 \cdot \overline{8} = \overline{24} = \overline{0}$, and the smaller multiples $1 \cdot \overline{8} = \overline{8} \neq \overline{0}$, $2 \cdot \overline{8} = \overline{16} = \overline{4} \neq \overline{0}$. So the order is indeed 3. ■

Worked Example 2.3.13 ($|\overline{30}|$ in $\mathbb{Z}/54\mathbb{Z}$)**.** Compute the order of $\overline{30}$ in $\mathbb{Z}/54\mathbb{Z}$.

Recognition. Cyclic group of order 54; $\overline{30} = 30 \cdot \overline{1}$ is a multiple of the order-54 generator. Order-of-a-power with $n = 54$, $a = 30$.

Solution. Step 1: $n = 54$, $a = 30$. Step 2: $d = \gcd(54, 30)$. Euclid: $54 = 1 \cdot 30 + 24$, $30 = 1 \cdot 24 + 6$, $24 = 4 \cdot 6$, so $d = 6$. Step 3: $|\overline{30}| = 54/6 = 9$. Check: $9 \cdot \overline{30} = \overline{270}$, and $270 = 5 \cdot 54$, so $\overline{270} = \overline{0}$. A proper divisor would have to divide 9; e.g. $3 \cdot \overline{30} = \overline{90} = \overline{90 - 54} = \overline{36} \neq \overline{0}$. So the order is 9. ■

Worked Example 2.3.14 ($|r^6|$ where $|r| = 12$ in D_{24})**.** In the dihedral group D_{24} of order 24 (so $r^{12} = 1$, $|r| = 12$), compute $|r^6|$.

Recognition. The base is the rotation r with known order $|r| = 12$, and r^6 is an honest power of it. This is the multiplicative version of the same rule, $n = 12$, $a = 6$. (We do not need s at all; r^6 lives in the rotation subgroup $\langle r \rangle$.)

Solution. Step 1: $n = 12$, $a = 6$. Step 2: $d = \gcd(12, 6) = 6$. Step 3: $|r^6| = 12/6 = 2$. Check: $(r^6)^2 = r^{12} = 1$, and $r^6 \neq 1$ (since $6 < 12$). So $|r^6| = 2$; indeed r^6 is the unique rotation of order 2, the half-turn. ■

Worked Example 2.3.15 ($|\overline{9}|$ in $\mathbb{Z}/24\mathbb{Z}$)**.** Compute the order of $\overline{9}$ in $\mathbb{Z}/24\mathbb{Z}$.

Recognition. Cyclic of order 24, base $\overline{1}$ of order 24, and $\overline{9} = 9 \cdot \overline{1}$. Order-of-a-power with $n = 24$, $a = 9$. The tempting wrong move $24/9$ is not an integer – a red flag that you must use gcd, not a.

Solution. Step 1: $n = 24$, $a = 9$. Step 2: $d = \gcd(24, 9)$. Euclid: $24 = 2 \cdot 9 + 6$, $9 = 1 \cdot 6 + 3$, $6 = 2 \cdot 3$, so $d = 3$. Step 3: $|\overline{9}| = 24/3 = 8$. Check: $8 \cdot \overline{9} = \overline{72} = \overline{0}$ since $72 = 3 \cdot 24$. Halving: $4 \cdot \overline{9} = \overline{36} = \overline{12} \neq \overline{0}$, so the order is not 4; it is the full 8. ■

Worked Example 2.3.16 ($|(1\,2\,3\,4\,5\,6)^4|$ in S_6)**.** Let $\sigma = (1\,2\,3\,4\,5\,6) \in S_6$. Compute $|\sigma^4|$.

Recognition. A single 6-cycle has order 6, so $|\sigma| = 6$ is known; σ^4 is a power of it. Order-of-a-power with $n = 6$, $a = 4$. (Bonus: the proposition gives the order instantly, and we can cross-check via the explicit cycle structure.)

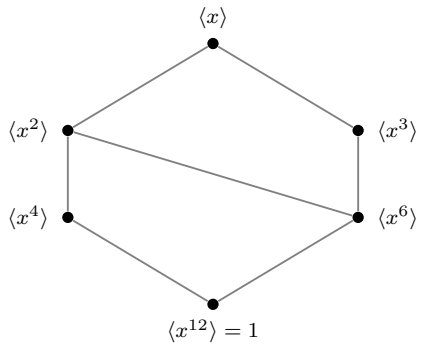
Solution. Step 1: $n = |\sigma| = 6$ (length of the cycle), $a = 4$. Step 2: $d = \gcd(6, 4) = 2$. Step 3: $|\sigma^4| = 6/2 = 3$. Check (explicit cycle structure): σ sends $i \mapsto i + 1 \pmod 6$, so σ^4 sends $i \mapsto i + 4 \pmod 6$. Tracking $1 \mapsto 5 \mapsto 3 \mapsto 1$ and $2 \mapsto 6 \mapsto 4 \mapsto 2$ gives

$$\sigma^4 = (1\,5\,3)(2\,6\,4),$$

a product of two disjoint 3-cycles, whose order is $\operatorname{lcm}(3, 3) = 3$. Matches. ■

Worked Example 2.3.17 (All a with $|x^a| = n$ (generators preview))**.** Let $|x| = n$. Find exactly which exponents $a \in \{0, 1, \ldots, n - 1\}$ satisfy $|x^a| = n$. Apply it to $n = 12$.

Recognition. We want the power x^a to have the *full* order n, i.e. x^a generates $\langle x \rangle$. By the proposition $|x^a| = n/\gcd(n, a)$, demanding this equal n is a gcd condition – the recognition trigger is "solve for the exponent that makes the order maximal."



Solution. We need $\dfrac{n}{\gcd(n,a)} = n$, i.e. $\gcd(n,a) = 1$. So

$$|x^a| = n \iff \gcd(n,a) = 1.$$

The number of such a in $\{0, 1, \ldots, n-1\}$ is Euler's $\varphi(n)$; these are precisely the generators of the cyclic group $\langle x \rangle$.

For $n = 12$: the a with $\gcd(12, a) = 1$ are $a \in \{1, 5, 7, 11\}$, giving $\varphi(12) = 4$ generators. Check: e.g. $|x^5| = 12/\gcd(12, 5) = 12/1 = 12$ (full order, good), whereas $|x^4| = 12/\gcd(12, 4) = 12/4 = 3 \neq 12$ (not a generator), confirming $a = 4$ is correctly excluded. ■

Remark 2.3.2. The map $a \mapsto n/\gcd(n, a)$ shows the possible orders of elements of a cyclic group $\langle x \rangle$ of order n are exactly the divisors of n: as $\gcd(n, a)$ ranges over the divisors $d \mid n$, the order n/d ranges over all divisors of n. The next diagram shows this for $n = 12$: each subgroup $\langle x^d \rangle = \langle x^{n/(n/d)} \rangle$ has order n/d, and the lattice of subgroups of $\langle x \rangle$ mirrors the divisor lattice of 12.

Here $|\langle x \rangle| = 12$, $|\langle x^2 \rangle| = 6$, $|\langle x^3 \rangle| = 4$, $|\langle x^4 \rangle| = 3$, $|\langle x^6 \rangle| = 2$, $|\langle x^{12} \rangle| = 1$ – precisely the orders $12/\gcd(12, a)$ realized as a varies, one subgroup per divisor of 12.

Caution. When computing $|\overline{a}|$ in $\mathbb{Z}/n\mathbb{Z}$, take the gcd with the *modulus* n, not with anything you mentally simplified $\overline{a}$ to. For instance in $\mathbb{Z}/24\mathbb{Z}$, $|\overline{30}| = |\overline{6}| = 24/\gcd(24, 6) = 4$; reducing 30 to 6 first is fine, but you must still pair it with $n = 24$, never with 30 or with a different modulus.

Generators of cyclic groups: $\langle x^a \rangle = \langle x \rangle$, counting via φ

This section answers one precise question: given a cyclic group $\langle x \rangle$, exactly which powers x^a are themselves generators? The clean answer is governed entirely by $\gcd(a, n)$ when $|x| = n$, and the count is Euler's $\varphi(n)$.

Definition 2.3.18. Let G be a group and $x \in G$. We say x *generates* G, and call x a *generator*, if $G = \langle x \rangle = \{x^k : k \in \mathbb{Z}\}$. A group with at least one generator is *cyclic*.

Proposition 2.3.19. *Let $G = \langle x \rangle$ be cyclic and let $a \in \mathbb{Z}$.*

1. *If $|x| = n < \infty$, then $\langle x^a \rangle = \langle x \rangle$ if and only if $\gcd(a, n) = 1$. Consequently the number of generators of G equals $\varphi(n)$, the count of residues in $\{1, 2, \ldots, n\}$ coprime to n.*
2. *If $|x| = \infty$, then $\langle x^a \rangle = \langle x \rangle$ if and only if $a = \pm 1$. Thus an infinite cyclic group has exactly two generators, x and x^{-1}.*

Proof. **(1)** Recall the order formula: for $|x| = n$, one has $|x^a| = n/\gcd(a, n)$, so $\left|\langle x^a \rangle\right| = n/\gcd(a, n)$. Now $\langle x^a \rangle = \langle x \rangle$ iff these subgroups have equal order, i.e. iff $n/\gcd(a, n) = n$, i.e. iff $\gcd(a, n) = 1$.

For the count: every element of $G = \langle x \rangle$ is x^a for a unique residue $a \in \{0, 1, \ldots, n-1\}$, and x^a is a generator iff $\gcd(a, n) = 1$. The number of such a is by definition $\varphi(n)$. (Equivalently, working in $\mathbb{Z}/n\mathbb{Z}$, the generators are exactly the units $(\mathbb{Z}/n\mathbb{Z})^\times$.)

(2) Suppose $|x| = \infty$, so the map $k \mapsto x^k$ is injective and $\langle x^a \rangle = \{x^{ak} : k \in \mathbb{Z}\} = \{x^m : m \in a\mathbb{Z}\}$. Then $\langle x^a \rangle = \langle x \rangle$ iff $a\mathbb{Z} = \mathbb{Z}$ iff a is a unit of $\mathbb{Z}$, i.e. $a = \pm 1$. Since $x \neq x^{-1}$ here (else $x^2 = 1$, contradicting infinite order), there are exactly two generators. □

Remark 2.3.3. The model case is $G = \mathbb{Z}/n\mathbb{Z} = \langle \overline{1} \rangle$ under addition, where $x = \overline{1}$ and "x^a" becomes "$a \cdot \overline{1} = \overline{a}$." Proposition 2.3.19(1) then reads: $\overline{a}$ generates $\mathbb{Z}/n\mathbb{Z}$ iff $\gcd(a, n) = 1$. So the generators of $\mathbb{Z}/n\mathbb{Z}$ are precisely the residues coprime to n, and there are $\varphi(n)$ of them.

Method (Find all generators of a cyclic group of order n (and count them))**.** *Trigger.* Use this whenever you must list/count generators of $\mathbb{Z}/n\mathbb{Z}$, or decide which x^a generate a cyclic group $\langle x \rangle$ with $|x| = n$.

1. Identify $n = |x|$ (for $\mathbb{Z}/n\mathbb{Z}$, n is the modulus).
2. A power x^a (resp. residue $\overline{a}$) is a generator $\iff$ $\gcd(a, n) = 1$. List all $a \in \{1, 2, \ldots, n\}$ (or $\{0, \ldots, n-1\}$) with $\gcd(a, n) = 1$.
3. The *number* of generators is $\varphi(n)$. To compute $\varphi(n)$ fast, factor $n = p_1^{e_1} \cdots p_r^{e_r}$ and use
$$\varphi(n) = \prod_{i=1}^{r} (p_i^{e_i} - p_i^{e_i - 1}) = n \prod_{i=1}^{r} \Big(1 - \tfrac{1}{p_i}\Big).$$
4. Sanity check: $\varphi(n)$ should equal the length of the list from step 2.

Method (Compute $\varphi(n)$ from the prime factorization)**.** *Trigger.* You need the *count* of generators/units mod n but listing them is impractical.

1. Factor $n = p_1^{e_1} \cdots p_r^{e_r}$ into distinct primes.
2. For each prime power use $\varphi(p^e) = p^e - p^{e-1} = p^{e-1}(p - 1)$.
3. Multiply: φ is multiplicative on coprime factors, so $\varphi(n) = \prod_i \varphi(p_i^{e_i})$.
4. Special case worth memorizing: $\varphi(p) = p - 1$ for p prime.

Caution. $\gcd(a, n) = 1$ is required, *not* "a is prime" and *not* "$a < n$." E.g. $\overline{9}$ generates $\mathbb{Z}/10\mathbb{Z}$ (since $\gcd(9, 10) = 1$) even though 9 is composite, while $\overline{2}, \overline{4}, \overline{6}, \overline{8}$ do not. Always test the gcd, never primality.

Worked Example 2.3.20 (All generators of $\mathbb{Z}/12\mathbb{Z}$)**.** List every generator of $\mathbb{Z}/12\mathbb{Z}$.

Recognition. This is the model case of Proposition 2.3.19(1) via Remark 2.3.3: generators of $\mathbb{Z}/n\mathbb{Z}$ are the residues $\overline{a}$ with $\gcd(a, n) = 1$. Trigger: "generators of $\mathbb{Z}/n\mathbb{Z}$" $\implies$ "residues coprime to n."

Solution. Here $n = 12 = 2^2 \cdot 3$. Test $\gcd(a, 12)$ for $a = 1, \ldots, 11$:

a	1	2	3	4	5	6	7	8	9	10	11
$\gcd(a, 12)$	1	2	3	4	1	6	1	4	3	2	1

The a with gcd 1 are $a = 1, 5, 7, 11$. So the generators are
$$\overline{1},\ \overline{5},\ \overline{7},\ \overline{11}.$$

Check. Count = 4, and $\varphi(12) = \varphi(2^2)\varphi(3) = (4 - 2)(3 - 1) = 2 \cdot 2 = 4$. Match. As a spot-verify that $\overline{5}$ generates: $1 \cdot \overline{5} = \overline{5},\ 2 \cdot \overline{5} = \overline{10},\ 3 \cdot \overline{5} = \overline{3},\ 4 \cdot \overline{5} = \overline{8},\ 5 \cdot \overline{5} = \overline{1}$, and continuing hits all 12 residues since $|\overline{5}| = 12/\gcd(5, 12) = 12$.

Worked Example 2.3.21 (All generators of $\mathbb{Z}/10\mathbb{Z}$)**.** List every generator of $\mathbb{Z}/10\mathbb{Z}$ and confirm the count.

Recognition. Same trigger as the previous example: "generators of $\mathbb{Z}/n\mathbb{Z}$" $\implies$ residues coprime to $n = 10$. Use Proposition 2.3.19(1)/Remark 2.3.3.

Solution. Here $n = 10 = 2 \cdot 5$. The residues $a \in \{1, \ldots, 9\}$ with $\gcd(a, 10) = 1$ avoid the factors 2 and 5:
$$a = 1,\ 3,\ 7,\ 9 \quad \text{(we drop } 2, 4, 6, 8 \text{ even, and } 5\text{)}.$$
So the generators are
$$\overline{1},\ \overline{3},\ \overline{7},\ \overline{9}.$$

Check. $\varphi(10) = \varphi(2)\varphi(5) = (2 - 1)(5 - 1) = 1 \cdot 4 = 4$, matching the four listed. Verify $\overline{3}$ is a generator: $|\overline{3}| = 10/\gcd(3, 10) = 10/1 = 10$, so $\langle \overline{3} \rangle = \mathbb{Z}/10\mathbb{Z}$; indeed $\overline{3}, \overline{6}, \overline{9}, \overline{2}, \overline{5}, \overline{8}, \overline{1}, \overline{4}, \overline{7}, \overline{0}$ runs through all residues.

Worked Example 2.3.22 (Number of generators of $\mathbb{Z}/49000\mathbb{Z}$)**.** How many generators does $\mathbb{Z}/49000\mathbb{Z}$ have? (Listing is hopeless; count via φ.)

Recognition. The trigger is a *count* request with a large modulus: use the second method box, $\varphi(n)$ from the prime factorization, since the number of generators of $\mathbb{Z}/n\mathbb{Z}$ is $\varphi(n)$ by Proposition 2.3.19(1).

Solution. Factor: $49000 = 49 \cdot 1000 = 7^2 \cdot (2^3 \cdot 5^3) = 2^3 \cdot 5^3 \cdot 7^2$. Use $\varphi(p^e) = p^e - p^{e-1}$ on each prime power:

$$\varphi(2^3) = 8 - 4 = 4, \qquad \varphi(5^3) = 125 - 25 = 100, \qquad \varphi(7^2) = 49 - 7 = 42.$$

By multiplicativity,

$$\varphi(49000) = 4 \cdot 100 \cdot 42 = 400 \cdot 42 = 16800.$$

Check. Via the product form: $49000\big(1 - \frac{1}{2}\big)\big(1 - \frac{1}{5}\big)\big(1 - \frac{1}{7}\big) = 49000 \cdot \frac{1}{2} \cdot \frac{4}{5} \cdot \frac{6}{7} = 49000 \cdot \frac{24}{70} = 49000 \cdot \frac{12}{35} = 1400 \cdot 12 = 16800$. Match. So $\mathbb{Z}/49000\mathbb{Z}$ has $\boxed{16800}$ generators.

Worked Example 2.3.23 (Which x^a generate $\langle x \rangle$ when $|x| = 18$)**.** Let $|x| = 18$. For which exponents a with $0 \le a \le 17$ is x^a a generator of $\langle x \rangle$?

Recognition. Now the group is abstract cyclic of order 18, not literally $\mathbb{Z}/18\mathbb{Z}$, but Proposition 2.3.19(1) applies verbatim: x^a generates iff $\gcd(a, 18) = 1$. Trigger: "$|x| = n$, which x^a generate" $\implies$ gcd test against n.

Solution. Here $n = 18 = 2 \cdot 3^2$. The valid $a \in \{0, \dots, 17\}$ are those coprime to 18, i.e. avoiding factors 2 and 3:

$$a = 1,\ 5,\ 7,\ 11,\ 13,\ 17.$$

So the generators are $x,\ x^5,\ x^7,\ x^{11},\ x^{13},\ x^{17}$. *Check.* $\varphi(18) = \varphi(2)\varphi(3^2) = (2-1)(9-3) = 1 \cdot 6 = 6$, matching the six listed. Spot-verify x^{12} is *not* a generator: $\gcd(12, 18) = 6$, so $|x^{12}| = 18/6 = 3 \neq 18$; indeed $\langle x^{12} \rangle = \{1, x^{12}, x^6\}$ has order 3.

Worked Example 2.3.24 (Generators of $(\mathbb{Z}, +)$)**.** Find all generators of the infinite cyclic group $(\mathbb{Z}, +) = \langle 1 \rangle$.

Recognition. The trigger is "infinite order": $|1| = \infty$ in $(\mathbb{Z}, +)$, so Proposition 2.3.19(2) applies and only ± 1 can generate. Do *not* try a gcd-with-n test; there is no finite n.

Solution. Writing the group additively, "x^a" for $x = 1$ is the multiple $a \cdot 1 = a$, and $\langle a \rangle = a\mathbb{Z} = \{\dots, -2a, -a, 0, a, 2a, \dots\}$. We need $a\mathbb{Z} = \mathbb{Z}$. The only integers a with $a\mathbb{Z} = \mathbb{Z}$ are the units of $\mathbb{Z}$, namely $a = \pm 1$:

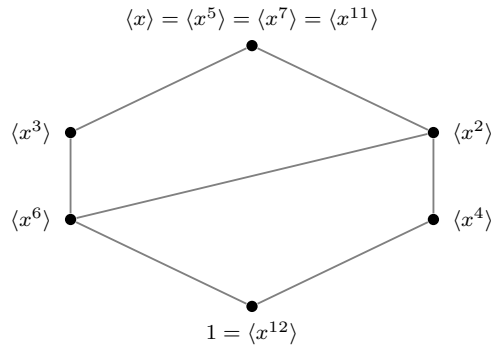
$$\langle 1 \rangle = \mathbb{Z}, \qquad \langle -1 \rangle = \mathbb{Z},$$

while for $|a| \ge 2$ we get a proper subgroup (e.g. $\langle 2 \rangle = 2\mathbb{Z}$ misses every odd integer). So the only generators are $\boxed{\pm 1}$. *Check.* An infinite cyclic group has exactly two generators by Proposition 2.3.19(2); here $1 \neq -1$, consistent. Contrast: 0 is not a generator since $\langle 0 \rangle = \{0\}$.

Worked Example 2.3.25 (The formula $\varphi(p^k) = p^k - p^{k-1}$, with $p^k = 27$)**.** Derive $\varphi(p^k) = p^k - p^{k-1}$ and apply it to count generators of $\mathbb{Z}/27\mathbb{Z}$.

Recognition. Trigger: the modulus is a prime power p^k. Counting units/generators reduces to "how many residues are coprime to p^k," and the only obstruction is divisibility by p. This is the building block of the φ method box.

Solution. An integer $a \in \{1, \dots, p^k\}$ fails $\gcd(a, p^k) = 1$ exactly when $p \mid a$. The multiples of p in that range are $p, 2p, \dots, p^{k-1} \cdot p = p^k$, which number p^{k-1}. Hence the coprime residues number



$$\varphi(p^k) = p^k - p^{k-1} = p^{k-1}(p-1).$$

For $p = 3,\ k = 3$, i.e. $p^k = 27$:

$$\varphi(27) = 27 - 9 = 18 = 3^2(3-1) = 9 \cdot 2.$$

So $\mathbb{Z}/27\mathbb{Z}$ has 18 generators (the residues $1, 2, 4, 5, 7, 8, 10, 11, 13, 14, 16, 17, 19, 20, 22, 23, 25, 26$, i.e. everything not divisible by 3). *Check.* The non-generators are the multiples of 3 in $\{1, \dots, 27\}$: $3, 6, 9, 12, 15, 18, 21, 24, 27$, exactly $9 = 3^{3-1}$ of them, and $27 - 9 = 18$. Match.

The subgroup lattice below records the orders that actually occur as $|x^a| = n/\gcd(a,n)$ for $\langle x\rangle$ with $|x| = 12$; the generators ($\gcd = 1$) all sit at the top vertex $\langle x\rangle$, since each generates the whole group.

Caution. Two distinct exponents can give the *same* subgroup. In the lattice above $\langle x^2\rangle$ and $\langle x^{10}\rangle$ coincide (both have order 6, and $\gcd(2,12) = \gcd(10,12) = 2$). The four exponents $a = 1, 5, 7, 11$ all yield the *single* top subgroup $\langle x\rangle$; "$\varphi(12) = 4$ generators" counts *elements* x^a, not distinct subgroups.

The subgroup lattice of a cyclic group

Everything in this section flows from one structural fact: a cyclic group has *exactly one* subgroup of each order dividing the group order, and these are precisely all of them. Concretely, the lattice of subgroups of $\mathbb{Z}/n\mathbb{Z}$ is a perfect copy of the lattice of divisors of n, turned upside down. Once you internalize the dictionary

$$\text{subgroups of } \langle x\rangle \iff \text{divisors of } n, \qquad \langle x^a\rangle = \langle x^{\gcd(a,n)}\rangle,$$

listing subgroups becomes pure arithmetic with gcd and divisors.

Theorem 2.3.26 (Subgroups of a cyclic group, D&F 2.3 Thm. 7)**.** *Let $H = \langle x\rangle$ be cyclic.*

1. *Every subgroup of H is cyclic. More precisely, if $K \le H$ and $K \neq \{1\}$, then $K = \langle x^d\rangle$ where d is the smallest positive integer with $x^d \in K$.*
2. *If $|x| = \infty$, then the distinct subgroups are $\langle x^d\rangle$ for $d = 0, 1, 2, \ldots$, all distinct.*
3. *If $|x| = n < \infty$, then for each positive divisor $d \mid n$ there is a* unique *subgroup of order d, namely $\langle x^{n/d}\rangle$. These are all of the subgroups, so the subgroups of $\langle x\rangle$ correspond bijectively to the positive divisors of n.*

Proof. (1) Let $K \le \langle x\rangle$. If $K = \{1\} = \langle x^0\rangle$ we are done; otherwise pick the least positive d with $x^d \in K$ (such d exists by well-ordering). Then $\langle x^d\rangle \le K$. Conversely take any $x^a \in K$ and divide: $a = qd + r$ with $0 \le r < d$. Then $x^r = x^a(x^d)^{-q} \in K$, and minimality of d forces $r = 0$, so $x^a = (x^d)^q \in \langle x^d\rangle$. Hence $K = \langle x^d\rangle$ is cyclic.

(2) If $|x| = \infty$ and $\langle x^d\rangle = \langle x^e\rangle$ with $d, e > 0$, then $x^d = x^{ek}$ for some k, so $d = ek$, i.e. $e \mid d$, and symmetrically $d \mid e$, giving $d = e$; also $\langle x^0\rangle = 1$ differs from every $\langle x^e\rangle$ with $e > 0$, since $x^e \neq 1$. Distinct d give distinct subgroups, and by (1) every subgroup is some $\langle x^d\rangle$.

(3) Now $|x| = n$. By the order formula $|x^k| = n/\gcd(k,n)$. For $d \mid n$, set $k = n/d$; then $\gcd(n/d, n) = n/d$, so $|x^{n/d}| = n/(n/d) = d$, giving a subgroup of order d. For uniqueness, suppose $K \le \langle x\rangle$ has $|K| = d$. By (1) $K = \langle x^m\rangle$ with m the least positive exponent in K; the same minimality argument as in (1) shows $m \mid n$ (divide n by m: $x^n = 1 \in K$ forces remainder 0). Then $|K| = |x^m| = n/\gcd(m,n) = n/m = d$, so $m = n/d$ and $K = \langle x^{n/d}\rangle$. Thus the subgroup of order d is unique. Finally every subgroup has order dividing n (Lagrange), so $d \mapsto \langle x^{n/d}\rangle$ is a bijection from divisors of n to subgroups. □

Proposition 2.3.27 (The gcd collapse and the containment rule)**.** *Let $|x| = n$ and write everything multiplicatively (additively in $\mathbb{Z}/n\mathbb{Z}$ this is $\overline{a}$).*

1. *$\langle x^a\rangle = \langle x^{\gcd(a,n)}\rangle$, and this subgroup has order $n/\gcd(a,n)$.*

2. $\langle x^a\rangle \le \langle x^b\rangle \iff \gcd(b,n) \mid \gcd(a,n)$. *Equivalently, writing* $|\langle x^a\rangle| = n/\gcd(a,n)$, *containment of the smaller into the larger matches divisibility of orders.*

Proof. (1) Let $g = \gcd(a,n)$. Since $g \mid a$, $x^a \in \langle x^g\rangle$, so $\langle x^a\rangle \le \langle x^g\rangle$. Conversely Bezout gives $g = au+nv$, hence $x^g = (x^a)^u(x^n)^v = (x^a)^u \in \langle x^a\rangle$, so $\langle x^g\rangle \le \langle x^a\rangle$. Thus they are equal; the order is $|x^g| = n/\gcd(g,n) = n/g$ since $g \mid n$.

(2) By (1) we may assume $a = \gcd(a,n)$ and $b = \gcd(b,n)$ are divisors of n. Then $\langle x^a\rangle \le \langle x^b\rangle$ iff $x^a \in \langle x^b\rangle$ iff $x^a = x^{bk}$ for some k iff $n \mid a - bk$ for some k iff $\gcd(b,n) = b \mid a = \gcd(a,n)$ (the last by elementary number theory, since $b \mid n$). Note $\langle x^a\rangle \le \langle x^b\rangle$ means the a-subgroup is contained in the b-subgroup; as $|\langle x^a\rangle| = n/a$ and $|\langle x^b\rangle| = n/b$, $b \mid a$ says $n/a \mid n/b$, i.e. the order of the contained group divides the order of the container. □

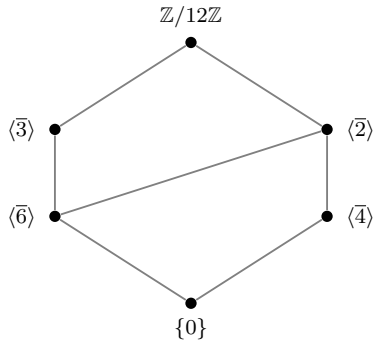
Remark 2.3.4. Translation to $\mathbb{Z}/n\mathbb{Z}$ (additive): x^k becomes $\overline{k} = k \cdot \overline{1}$, the subgroup $\langle x^{n/d}\rangle$ becomes $\langle\overline{n/d}\rangle = \{0,\ n/d,\ 2(n/d), \dots\}$, and the order formula reads $|\overline{k}| = n/\gcd(k,n)$. The collapse is $\langle\overline{a}\rangle = \langle\overline{\gcd(a,n)}\rangle$.

Method (List ALL subgroups of $\mathbb{Z}/n\mathbb{Z}$ (and draw the lattice))**.** *Recognition trigger.* The group is cyclic of finite order n (e.g. $\mathbb{Z}/n\mathbb{Z}$, or any $\langle x\rangle$ with $|x| = n$), and you must enumerate subgroups, find a specific subgroup of a given order, or decide a containment.

1. **Find the divisors** $d_1 < d_2 < \dots$ of n. There is exactly one subgroup per divisor, so #subgroups = #divisors of $n = \tau(n)$.
2. **Order → generator.** The unique subgroup of order d is $\langle\overline{n/d}\rangle$ (the cyclic span of the step n/d). Its elements are the multiples of n/d in $\mathbb{Z}/n\mathbb{Z}$.
3. **Generator → order.** For an arbitrary $\overline{a}$, first collapse: $\langle\overline{a}\rangle = \langle\overline{\gcd(a,n)}\rangle$, and $|\overline{a}| = n/\gcd(a,n)$.
4. **Containment.** $\langle\overline{a}\rangle \le \langle\overline{b}\rangle \iff \gcd(b,n) \mid \gcd(a,n)$. Equivalently $|\langle\overline{a}\rangle| \,\big|\, |\langle\overline{b}\rangle|$ (smaller order sits inside larger order).
5. **Lattice.** Draw the divisor lattice of n *upside down*, with $\langle\overline{s}\rangle$ at the divisor s: $\mathbb{Z}/n\mathbb{Z} = \langle\overline{1}\rangle$ (order n) goes on top, $\{0\} = \langle\overline{n}\rangle$ (order 1) at the bottom; an edge goes between two subgroups when one order divides the other with prime index.

Caution. The subgroup of order d is $\langle\overline{n/d}\rangle$, NOT $\langle\overline{d}\rangle$. Mixing these up is the single most common error: in $\mathbb{Z}/12\mathbb{Z}$ the order-3 subgroup is $\langle\overline{4}\rangle = \{0,4,8\}$, while $\langle\overline{3}\rangle = \{0,3,6,9\}$ has order 4. Always convert via $d \leftrightarrow n/d$.

Caution. The containment direction is reversed from divisibility of the *generators-as-steps*: a *smaller* step n/d generates a *larger* subgroup. Trust the order test: $\langle\overline{a}\rangle \le \langle\overline{b}\rangle$ exactly when $|\langle\overline{a}\rangle|$ divides $|\langle\overline{b}\rangle|$ (a smaller order alone is not enough: in $\mathbb{Z}/12\mathbb{Z}$, $\langle\overline{4}\rangle$ of order 3 is not inside $\langle\overline{3}\rangle$ of order 4), and you check it via $\gcd(b,n) \mid \gcd(a,n)$.



Worked Example 2.3.28 (All subgroups of $\mathbb{Z}/12\mathbb{Z}$)**.** List every subgroup of $\mathbb{Z}/12\mathbb{Z}$, give its order and generator, and draw the lattice.

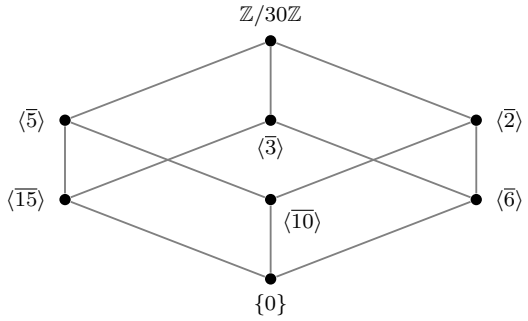
Recognition. $\mathbb{Z}/12\mathbb{Z}$ is cyclic of order $n = 12$, so Theorem 2.3.26(3) applies: subgroups correspond exactly to divisors of 12. Trigger met (cyclic, finite, "list all subgroups"), so run the Method box.

Solution. Divisors of 12: $1, 2, 3, 4, 6, 12$, so there are $\tau(12) = 6$ subgroups. Use "order $d \Rightarrow$ generator $\overline{12/d}$":

$d = \lvert H\rvert$	$12/d$	$H = \langle\overline{12/d}\rangle$
1	12	$\{0\}$
2	6	$\langle\overline{6}\rangle = \{0,6\}$
3	4	$\langle\overline{4}\rangle = \{0,4,8\}$
4	3	$\langle\overline{3}\rangle = \{0,3,6,9\}$
6	2	$\langle\overline{2}\rangle = \{0,2,4,6,8,10\}$
12	1	$\langle\overline{1}\rangle = \mathbb{Z}/12\mathbb{Z}$

Containments by the order rule ($d_1 \mid d_2 \Rightarrow$ order-d_1 inside order-d_2): $\{0\} \subset$ everything; $\langle\overline{6}\rangle \subset \langle\overline{2}\rangle$ (since $2 \mid 6$) and $\langle\overline{6}\rangle \subset \langle\overline{3}\rangle$ (since $2 \mid 4$); $\langle\overline{4}\rangle \subset \langle\overline{2}\rangle$ ($3 \mid 6$); $\langle\overline{3}\rangle \subset \langle\overline{1}\rangle$, etc.

(Orders bottom-up: 1; 2, 3; 4, 6; 12.) *Check.* 6 subgroups $= \tau(12)$; each listed order divides 12 exactly once. Correct.



Worked Example 2.3.29 (All subgroups of $\mathbb{Z}/30\mathbb{Z}$)**.** List every subgroup of $\mathbb{Z}/30\mathbb{Z}$ with order and generator, and draw the lattice.

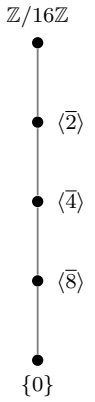
Recognition. Cyclic of order $30 = 2 \cdot 3 \cdot 5$. Theorem 2.3.26(3): subgroups $\leftrightarrow$ divisors of 30. Method box applies.

Solution. Divisors of 30: $1, 2, 3, 5, 6, 10, 15, 30$, so $\tau(30) = 8$ subgroups. Generator of the order-d subgroup is $\overline{30/d}$:

d	$30/d$	$H = \langle\overline{30/d}\rangle$
1	30	$\{0\}$
2	15	$\langle\overline{15}\rangle = \{0, 15\}$
3	10	$\langle\overline{10}\rangle = \{0, 10, 20\}$
5	6	$\langle\overline{6}\rangle = \{0, 6, 12, 18, 24\}$
6	5	$\langle\overline{5}\rangle$
10	3	$\langle\overline{3}\rangle$
15	2	$\langle\overline{2}\rangle$
30	1	$\langle\overline{1}\rangle = \mathbb{Z}/30\mathbb{Z}$

Containment by orders: $2 \mid 6, 10$; $3 \mid 6, 15$; $5 \mid 10, 15$; $6 \mid 30$; $10 \mid 30$; $15 \mid 30$. So the lattice is the cube of divisors of 30 (a Boolean lattice on the primes $2, 3, 5$), flipped.

Bottom row orders $2, 3, 5$ (the primes); middle row $6, 10, 15$ (products of two primes); $\langle\overline{5}\rangle$ has order 6, $\langle\overline{3}\rangle$ order 10, $\langle\overline{2}\rangle$ order 15. *Check.* $8 = \tau(30)$ subgroups, and the lattice is the standard 2^3 Boolean cube as expected for a product of 3 distinct primes. Correct.



Worked Example 2.3.30 (All subgroups of $\mathbb{Z}/16\mathbb{Z}$ (a chain))**.** List every subgroup of $\mathbb{Z}/16\mathbb{Z}$ and draw the lattice.

Recognition. Cyclic of order $16 = 2^4$, a prime power. For $n = p^k$ the divisors are totally ordered ($1 \mid p \mid p^2 \mid \dots$), so by Theorem 2.3.26(3) the subgroup lattice is a single chain. Recognizing n is a prime power is the trigger for "chain."

Solution. Divisors of 16: $1, 2, 4, 8, 16$, so $\tau(16) = 5$ subgroups, each containing the previous:

d	$16/d$	$H = \langle\overline{16/d}\rangle$
1	16	$\{\overline{0}\}$
2	8	$\langle\overline{8}\rangle = \{\overline{0}, \overline{8}\}$
4	4	$\langle\overline{4}\rangle = \{\overline{0}, \overline{4}, \overline{8}, \overline{12}\}$
8	2	$\langle\overline{2}\rangle = \{\overline{0}, \overline{2}, \overline{4}, \ldots, \overline{14}\}$
16	1	$\mathbb{Z}/16\mathbb{Z}$

Each order divides the next ($1 \mid 2 \mid 4 \mid 8 \mid 16$), so by the order rule we get a totally ordered chain $\{\overline{0}\} \subset \langle\overline{8}\rangle \subset \langle\overline{4}\rangle \subset \langle\overline{2}\rangle \subset \mathbb{Z}/16\mathbb{Z}$.

Check. $5 = \tau(16)$, and a p-group cyclic lattice must be a chain — confirmed, no branching. Correct.

Worked Example 2.3.31 (Collapsing $\langle\overline{18}\rangle$ in $\mathbb{Z}/24\mathbb{Z}$)**.** Identify the subgroup $\langle\overline{18}\rangle$ of $\mathbb{Z}/24\mathbb{Z}$: find its order, a canonical generator, and list its elements.

Recognition. An arbitrary generator $\overline{18}$ with $18 \nmid 24$ — this is the trigger for Proposition 2.3.27(1), the gcd collapse $\langle\overline{a}\rangle = \langle\overline{\gcd(a, n)}\rangle$.

Solution. Here $n = 24$, $a = 18$. Compute $\gcd(18, 24)$: $24 = 18 + 6$, $18 = 3 \cdot 6$, so $\gcd = 6$. By the collapse rule,

$$\langle\overline{18}\rangle = \langle\overline{\gcd(18, 24)}\rangle = \langle\overline{6}\rangle, \qquad |\overline{18}| = \frac{24}{\gcd(18, 24)} = \frac{24}{6} = 4.$$

Elements: multiples of 6 in $\mathbb{Z}/24\mathbb{Z}$, namely $\{\overline{0}, \overline{6}, \overline{12}, \overline{18}\}$. Sanity from the other side: $\overline{18} = 3 \cdot \overline{6}$ and $\gcd(3, 4) = 1$, so $\overline{18}$ is itself a generator of the order-4 group $\langle\overline{6}\rangle$ — consistent. *Check.* $\langle\overline{18}\rangle = \{\overline{0}, \overline{18}, \overline{36} = \overline{12}, \overline{54} = \overline{6}, \overline{72} = \overline{0}\} = \{\overline{0}, \overline{18}, \overline{12}, \overline{6}\}$, four elements, matches order 4. Correct.

Worked Example 2.3.32 (The unique subgroup of order 6 in $\mathbb{Z}/30\mathbb{Z}$)**.** Find *the* subgroup of order 6 in $\mathbb{Z}/30\mathbb{Z}$ and explain why it is the only one.

Recognition. Asked for a subgroup of a specified order $d = 6$ in a cyclic group with $6 \mid 30$. Theorem 2.3.26(3) guarantees existence and *uniqueness*, and names it $\langle\overline{n/d}\rangle$.

Solution. Since $6 \mid 30$, the unique order-6 subgroup is

$$\langle\overline{30/6}\rangle = \langle\overline{5}\rangle = \{\overline{0}, \overline{5}, \overline{10}, \overline{15}, \overline{20}, \overline{25}\}.$$

Verify the order: $|\overline{5}| = 30/\gcd(5, 30) = 30/5 = 6$. Uniqueness: if K had order 6 then by the theorem $K = \langle\overline{30/6}\rangle = \langle\overline{5}\rangle$; there is no choice. As a cross-check on the "which generator" question, any $\overline{a}$ with $\gcd(a, 30) = 5$ generates this same group: e.g. $\gcd(25, 30) = 5$, so $\langle\overline{25}\rangle = \langle\overline{5}\rangle$ too (different generator, same subgroup). *Check.* $\{\overline{0}, \overline{5}, \overline{10}, \overline{15}, \overline{20}, \overline{25}\}$ has 6 elements and is closed (sums of multiples of 5 are multiples of 5). Correct.

Worked Example 2.3.33 (A containment decided purely by the gcd rule)**.** In $\mathbb{Z}/36\mathbb{Z}$, decide whether $\langle\overline{8}\rangle \le \langle\overline{6}\rangle$ or $\langle\overline{6}\rangle \le \langle\overline{8}\rangle$ (or neither), without listing all elements.

Recognition. Two generators given, asked about containment in a cyclic group — exactly Proposition 2.3.27(2): $\langle\overline{a}\rangle \le \langle\overline{b}\rangle \iff \gcd(b,n) \mid \gcd(a,n)$.

Solution. Here $n = 36$. Compute the two gcds:

$$\gcd(8,36) = 4, \qquad \gcd(6,36) = 6.$$

So $\langle\overline{8}\rangle = \langle\overline{4}\rangle$ has order $36/4 = 9$, and $\langle\overline{6}\rangle$ has order $36/6 = 6$. Test $\langle\overline{8}\rangle \le \langle\overline{6}\rangle$: need $\gcd(6,36) = 6 \mid \gcd(8,36) = 4$? No, $6 \nmid 4$. Test $\langle\overline{6}\rangle \le \langle\overline{8}\rangle$: need $\gcd(8,36) = 4 \mid 6$? No, $4 \nmid 6$. **Neither contains the other.** Cross-check by orders: $|\langle\overline{8}\rangle| = 9$ and $|\langle\overline{6}\rangle| = 6$, and $9 \nmid 6$, $6 \nmid 9$, so by Lagrange neither can contain the other — consistent. Their intersection is the largest common subgroup, of order $\gcd(9,6) = 3$, namely $\langle\overline{12}\rangle$ (since the order-3 subgroup is $\langle\overline{36/3}\rangle = \langle\overline{12}\rangle$). *Check.* $\overline{12}$ = gcd-driven meet; 12 is a multiple of both 4 and 6, so $\langle\overline{12}\rangle \subseteq$ both, of order $36/12 = 3$. Correct.

Worked Example 2.3.34 (Subgroups of $\langle x\rangle$ when $|x| = 20$ (abstract cyclic, not $\mathbb{Z}/n\mathbb{Z}$))**.** Let $G = \langle x\rangle$ with $|x| = 20$. Find all subgroups, the generator and order of each, and locate $\langle x^{14}\rangle$.

Recognition. G is cyclic of order 20 but written multiplicatively; the same theorem applies verbatim with $x^{n/d}$ in place of $\overline{n/d}$. Last part needs the gcd collapse.

Solution. Divisors of 20: $1, 2, 4, 5, 10, 20$, giving $\tau(20) = 6$ subgroups $\langle x^{20/d}\rangle$ of order d:

d	$20/d$	$H = \langle x^{20/d}\rangle$
1	20	$\{1\}$
2	10	$\langle x^{10}\rangle$
4	5	$\langle x^5\rangle$
5	4	$\langle x^4\rangle$
10	2	$\langle x^2\rangle$
20	1	$\langle x\rangle = G$

Now locate $\langle x^{14}\rangle$: $\gcd(14,20) = 2$, so $\langle x^{14}\rangle = \langle x^2\rangle$, of order $20/2 = 10$ — the order-10 subgroup in the table. *Check.* $x^{14} = (x^2)^7$ and $\gcd(7,10) = 1$, so x^{14} generates the whole order-10 group $\langle x^2\rangle$; consistent. The lattice mirrors $\mathbb{Z}/20\mathbb{Z}$: bottom $\{1\}$; atoms $\langle x^{10}\rangle$ (order 2) and $\langle x^4\rangle$ (order 5); etc., the same shape as the divisor lattice of 20. *Check.* $6 = \tau(20)$ subgroups, all orders divide 20. Correct.

Further examples: order under inversion/conjugation, coprime products, and a full order table

The single identity $|\langle x\rangle| = |x|$ of Proposition 2.3.2 means every question about the *size* of a cyclic group is a question about the *order* of a generator. Two concrete models of the abstract Z_n recur throughout: $\mathbb{Z}/n\mathbb{Z}$ (additive) and μ_n (the nth roots of unity, multiplicative).

Remark 2.3.5. "Isomorphic" is not "equal." Theorem 2.3.4 says any two cyclic groups of the same order are isomorphic, but they may be genuinely different groups sitting in different ambient sets. For instance $\langle(1\,2\,3)\rangle \le S_3$, $\mu_3 \le \mathbb{C}^\times$, and $\mathbb{Z}/3\mathbb{Z}$ are three distinct cyclic groups of order 3; all are isomorphic to Z_3, none is literally another. The isomorphism $x^a \mapsto y^a$ of Theorem 2.3.4 is what carries computations from one model to another.

Proposition 2.3.35 (Order is inversion- and conjugation-invariant)**.** *Let x, y, g be elements of a group G.*

1. $|x| = |x^{-1}|$.
2. $|gxg^{-1}| = |x|$, *and more generally* $|xy| = |yx|$.

Proof. (1) Since $(x^{-1})^n = (x^n)^{-1}$, we have $x^n = 1 \iff (x^{-1})^n = 1$; the two elements are killed by exactly the same exponents, hence have the same order (this also reproves $\langle x\rangle = \langle x^{-1}\rangle$).

(2) Since $(gxg^{-1})^n = gx^ng^{-1}$, we have $(gxg^{-1})^n = 1 \iff x^n = 1$, giving $|gxg^{-1}| = |x|$. For the last claim, $yx = x^{-1}(xy)x$ is a conjugate of xy, so $|xy| = |x^{-1}(xy)x| = |yx|$. □

Proposition 2.3.36 (Order of a product of commuting elements of coprime order)**.** *Let x, y be elements of a group with $xy = yx$, $|x| = m < \infty$, $|y| = n < \infty$, and $\gcd(m, n) = 1$. Then $|xy| = mn$, and $\langle x, y\rangle = \langle xy\rangle$ is cyclic of order mn.*

Proof. Since x, y commute, $(xy)^{mn} = x^{mn}y^{mn} = (x^m)^n(y^n)^m = 1$, so $|xy| \mid mn$. Let $k = |xy|$, so $x^k y^k = 1$, i.e. $x^k = y^{-k}$. Then $x^{kn} = (x^k)^n = (y^{-k})^n = (y^n)^{-k} = 1$, so $m \mid kn$; as $\gcd(m, n) = 1$ this forces $m \mid k$. Symmetrically $n \mid k$, and $\gcd(m, n) = 1$ gives $mn \mid k$. Hence $k = mn$ and $\langle xy\rangle$ has order mn.

For $\langle x, y\rangle = \langle xy\rangle$: the inclusion $\langle xy\rangle \leq \langle x, y\rangle$ is clear. Conversely, $(xy)^m = x^m y^m = y^m$, and by Proposition 2.3.11 $|y^m| = n/\gcd(n, m) = n$, so $\langle (xy)^m\rangle = \langle y^m\rangle = \langle y\rangle$ and thus $y \in \langle xy\rangle$. Likewise $(xy)^n = x^n$ has order $m/\gcd(m, n) = m$, so $x \in \langle xy\rangle$. Hence $\langle x, y\rangle \leq \langle xy\rangle$, giving equality. □

Worked Example 2.3.37 (The infinite cyclic group $\langle r\rangle$ inside a rotation group)**.** Let r be "rotation of the plane about the origin by 1 radian" inside the group G of rotations about the origin (composition). Show $\langle r\rangle$ is infinite cyclic, and contrast with rotation by a rational multiple of π.

Recognition. "All powers of one element" triggers Definition 2.3.1; deciding finite vs. infinite is exactly Proposition 2.3.2, i.e. whether some positive power is the identity.

Solution. Composing k copies of r rotates by k radians, the identity element being rotation by 0. Then $r^k = 1$ iff k is an integer multiple of 2π. But k is itself a positive integer and 2π is irrational, so $k = 2\pi \cdot (\text{integer})$ is impossible for $k \neq 0$. Hence no positive power of r is the identity: $|r| = \infty$ and $\langle r\rangle \cong \mathbb{Z}$ by Theorem 2.3.4. *Contrast:* if instead ρ is rotation by $2\pi/n$, then $\rho^n = 1$ and $|\rho| = n$, so $\langle \rho\rangle = \mu_n \cong Z_n$ is finite. *Check.* The dividing line is rationality of (angle)$/2\pi$ — rational gives a finite cyclic group, irrational gives the infinite one, matching Proposition 2.3.2.

Worked Example 2.3.38 (Building an element of order 15 from orders 3 and 5)**.** In $\mathbb{Z}/15\mathbb{Z}$, exhibit an element of order 15 as a sum of an order-3 and an order-5 element, illustrating Proposition 2.3.36.

Recognition. Two commuting elements (everything commutes in $\mathbb{Z}/15\mathbb{Z}$) of coprime orders 3 and 5 — the trigger for Proposition 2.3.36, which predicts the product/sum has order $3 \cdot 5 = 15$.

Solution. Take $x = \overline{5}$ and $y = \overline{3}$ in $\mathbb{Z}/15\mathbb{Z}$ (written additively, so "xy" is $x + y$). Their orders are

$$|\overline{5}| = \frac{15}{\gcd(5, 15)} = \frac{15}{5} = 3, \qquad |\overline{3}| = \frac{15}{\gcd(3, 15)} = \frac{15}{3} = 5,$$

with $\gcd(3, 5) = 1$. By Proposition 2.3.36, $\overline{5} + \overline{3} = \overline{8}$ has order $3 \cdot 5 = 15$, so $\overline{8}$ generates $\mathbb{Z}/15\mathbb{Z}$. *Check.* Directly $|\overline{8}| = 15/\gcd(8, 15) = 15/1 = 15$, confirming $\overline{8}$ is a generator, and $\langle \overline{8}\rangle = \langle \overline{5}, \overline{3}\rangle = \mathbb{Z}/15\mathbb{Z}$, consistent with the proposition's $\langle x, y\rangle = \langle xy\rangle$. *Pitfall it guards:* coprimality is essential — $\overline{5} + \overline{10} = \overline{0}$ has order 1, not $3 \cdot 3 = 9$, because $|\overline{5}| = |\overline{10}| = 3$ are not coprime.

Worked Example 2.3.39 (Cyclic or not: $\mathbb{Z}/8\mathbb{Z}$, V_4, and is $\mathbb{Z}/8\mathbb{Z} \cong \mathbb{Z}/9\mathbb{Z}$?)**.** Decide whether $\mathbb{Z}/8\mathbb{Z}$ and $V_4 = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ are cyclic, and whether $\mathbb{Z}/8\mathbb{Z} \cong \mathbb{Z}/9\mathbb{Z}$.

Recognition. "Is it cyclic" and "are these two isomorphic" both reduce to the order of a generator (Prop. 2.3.2) and the classification (Thm. 2.3.4); equal order is necessary for isomorphism, and an element of order $|G|$ is necessary for cyclic.

Solution. $\mathbb{Z}/8\mathbb{Z} = \langle \overline{1}\rangle$ has the order-8 element $\overline{1}$, so it is cyclic of order 8 ($\cong Z_8$). The Klein group V_4 has order 4, and every nonidentity element satisfies $g^2 = 1$, so the largest order present is $2 < 4$: by Proposition 2.3.2 no element generates, hence V_4 is *not* cyclic (reinforcing the earlier pitfall: abelian $\not\Rightarrow$ cyclic). Finally $\mathbb{Z}/8\mathbb{Z} \cong \mathbb{Z}/9\mathbb{Z}$ is *false* on sight: $|\mathbb{Z}/8\mathbb{Z}| = 8 \neq 9 = |\mathbb{Z}/9\mathbb{Z}|$, and isomorphic groups have equal order. *Check.* Both $\mathbb{Z}/8\mathbb{Z}$ and $\mathbb{Z}/9\mathbb{Z}$ *are* cyclic (each has a generator of full order), so they are isomorphic to Z_8 and Z_9 respectively — isomorphic to each other only if $8 = 9$, which fails.

Worked Example 2.3.40 (A full order table: orders of every element of $\mathbb{Z}/12\mathbb{Z}$)**.** Tabulate $|\overline{a}| = 12/\gcd(a, 12)$ for every $\overline{a} \in \mathbb{Z}/12\mathbb{Z}$, and read off how many elements there are of each order.

Recognition. One gcd per element via Proposition 2.3.11; the trigger is "orders of all elements of a cyclic group," whose answer is organized by the divisors of n.

Solution. For each a, $|\overline{a}| = 12/\gcd(a, 12)$:

a	0	1	2	3	4	5	6	7	8	9	10	11
$\gcd(a,12)$	12	1	2	3	4	1	6	1	4	3	2	1
$\lvert\overline{a}\rvert$	1	12	6	4	3	12	2	12	3	4	6	12

Grouping by order:

order d	elements	count $= \varphi(d)$
1	$\overline{0}$	$1 = \varphi(1)$
2	$\overline{6}$	$1 = \varphi(2)$
3	$\overline{4}, \overline{8}$	$2 = \varphi(3)$
4	$\overline{3}, \overline{9}$	$2 = \varphi(4)$
6	$\overline{2}, \overline{10}$	$2 = \varphi(6)$
12	$\overline{1}, \overline{5}, \overline{7}, \overline{11}$	$4 = \varphi(12)$

Check. The counts sum to $1 + 1 + 2 + 2 + 2 + 4 = 12 = |\mathbb{Z}/12\mathbb{Z}|$, illustrating $\sum_{d|n} \varphi(d) = n$; the number of elements of order d is exactly $\varphi(d)$ for each divisor d of 12, since they are the generators of the unique order-d subgroup (Theorem 2.3.26(3)). The four order-12 elements are precisely the generators of $\mathbb{Z}/12\mathbb{Z}$ found earlier.

Remark 2.3.6. The last example exhibits the general count: in a cyclic group of order n, the number of elements of order d (for each $d \mid n$) is $\varphi(d)$, and $\sum_{d|n} \varphi(d) = n$. Each such element generates the unique subgroup of order d (Theorem 2.3.26(3)), so "elements of order d" = "generators of the order-d subgroup," of which there are $\varphi(d)$ by Proposition 2.3.19.

Worked Example 2.3.41 (Locating a subgroup by a single generator: $\langle x^9 \rangle$ when $|x| = 15$)**.** Let $|x| = 15$. Identify $\langle x^9 \rangle$: its order, the canonical generator $x^{n/d}$, and which divisor-d subgroup it is.

Recognition. One generator x^9 with $9 \nmid 15$ — the gcd collapse $\langle x^a \rangle = \langle x^{\gcd(a,n)} \rangle$ of Proposition 2.3.27(1) names the subgroup.

Solution. $n = 15$, $a = 9$, $\gcd(9, 15) = 3$. Collapse:

$$\langle x^9 \rangle = \langle x^3 \rangle, \qquad |x^9| = \frac{15}{\gcd(9,15)} = \frac{15}{3} = 5.$$

So $\langle x^9 \rangle$ is the unique subgroup of order $d = 5$, with canonical generator $x^{n/d} = x^{15/5} = x^3$ — matching the collapse. *Check.* $x^9 = (x^3)^3$ and $\gcd(3, 5) = 1$, so x^9 generates the same order-5 group as x^3; and $5 \mid 15$, so Theorem 2.3.26(3) guarantees this order-5 subgroup exists and is unique. Correct.

Further worked examples

More on the order of a power (Proposition 2.3.11): $|x^a| = n/\gcd(n, a)$.

Worked Example 2.3.42 ($|\overline{18}|$ in $\mathbb{Z}/30\mathbb{Z}$)**.** *Recognition.* Order of a power in a cyclic group, $n = 30$, $a = 18$.

Solution. $\gcd(30, 18) = 6$, so $|\overline{18}| = 30/6 = 5$. *Check.* $5 \cdot \overline{18} = \overline{90} = \overline{0}$, and no smaller positive multiple is 0.

Worked Example 2.3.43 ($|x^9|$ when $|x| = 24$)**.** *Recognition.* Order of a power, $n = 24$, $a = 9$. (24/9 is not an integer — a flag to use gcd.)

Solution. $\gcd(24, 9) = 3$, so $|x^9| = 24/3 = 8$. *Check.* $(x^9)^8 = x^{72} = (x^{24})^3 = 1$, and $(x^9)^4 = x^{36} = x^{12} \neq 1$.

Worked Example 2.3.44 ($|(1\,2\,3\,4\,5\,6\,7)^3|$ in S_7)**.** *Recognition.* A 7-cycle σ has order 7 (prime); order of the power σ^3 with $n = 7$, $a = 3$.

Solution. $\gcd(7, 3) = 1$, so $|\sigma^3| = 7/1 = 7$. *Check.* For prime order every nonidentity power has the same order 7.

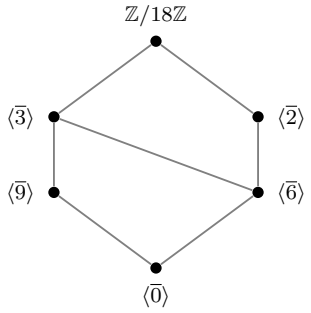
More generators and Euler's φ (Proposition 2.3.19).

Worked Example 2.3.45 (all generators of $\mathbb{Z}/14\mathbb{Z}$)**.** *Recognition.* Generators of $\mathbb{Z}/n\mathbb{Z}$ are the residues coprime to n; here $n = 14 = 2 \cdot 7$.

Solution. $\gcd(a, 14) = 1$ for $a \in \{1, 3, 5, 9, 11, 13\}$, so these are the generators; there are $\varphi(14) = \varphi(2)\varphi(7) = 1 \cdot 6 = 6$ of them.

Worked Example 2.3.46 (the number of generators of $\mathbb{Z}/360\mathbb{Z}$)**.** *Recognition.* Count generators $= \varphi(n)$; use the prime factorization $360 = 2^3 \cdot 3^2 \cdot 5$.

Solution. $\varphi(360) = \varphi(2^3)\varphi(3^2)\varphi(5) = (8-4)(9-3)(4) = 4 \cdot 6 \cdot 4 = 96$. So $\mathbb{Z}/360\mathbb{Z}$ has 96 generators.



More subgroup structure (Theorem 2.3.26): one subgroup per divisor.

Worked Example 2.3.47 (all subgroups of $\mathbb{Z}/18\mathbb{Z}$)**.** *Recognition.* Cyclic of order 18, so subgroups $\leftrightarrow$ divisors of 18; the subgroup of order d is $\langle \overline{18/d} \rangle$.

Solution. Divisors $1, 2, 3, 6, 9, 18$ give exactly six subgroups:

$$\langle \overline{0} \rangle \ (1),\ \langle \overline{9} \rangle \ (2),\ \langle \overline{6} \rangle \ (3),\ \langle \overline{3} \rangle \ (6),\ \langle \overline{2} \rangle \ (9),\ \langle \overline{1} \rangle = \mathbb{Z}/18\mathbb{Z} \ (18).$$

Their lattice is the divisor lattice of $18 = 2 \cdot 3^2$:

Worked Example 2.3.48 ($\langle \overline{8} \rangle$ in $\mathbb{Z}/20\mathbb{Z}$, and the unique subgroup of order 4)**.** *Recognition.* Use $\langle \overline{a} \rangle = \langle \overline{\gcd(a, n)} \rangle$, then the divisor rule for the order-d subgroup.

Solution. $\langle \overline{8} \rangle = \langle \overline{\gcd(8, 20)} \rangle = \langle \overline{4} \rangle$, of order $20/4 = 5$. The unique subgroup of order 4 is $\langle \overline{20/4} \rangle = \langle \overline{5} \rangle$ (indeed $|\overline{5}| = 20/\gcd(20, 5) = 20/5 = 4$). *Check.* $4 \mid 20$, and by Theorem 2.3.26 there is exactly one such subgroup.

More on the gcd lemma (Lemma 2.3.3).

Worked Example 2.3.49 (combining two relations)**.** Suppose $x^{24} = 1$ and $x^{36} = 1$. What does this force about $|x|$?

Recognition. Two vanishing powers; the gcd lemma says $x^{\gcd(m,n)} = 1$.

Solution. $\gcd(24, 36) = 12$, so $x^{12} = 1$ and therefore $|x| \mid 12$. *Check.* $12 \mid 24$ and $12 \mid 36$, consistent; e.g. an element of order exactly 12 realizes both relations.

First-isomorphism preview. The surjection $\mathbb{Z} \to \langle x \rangle$, $k \mapsto x^k$, has kernel $n\mathbb{Z}$ (where $n = |x|$), so it induces an isomorphism $\mathbb{Z}/n\mathbb{Z} \xrightarrow{\sim} \langle x \rangle$. This is the First Isomorphism Theorem (Chapter 3) in its simplest instance, and it is exactly why "cyclic of order n" is the same as "$\mathbb{Z}/n\mathbb{Z}$":

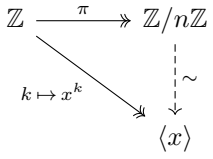


Diagram explanation. Objects: Three groups: $\mathbb{Z}$ (the infinite cyclic group of integers), $\mathbb{Z}/n\mathbb{Z}$ (the quotient group $\mathbb{Z}/n\mathbb{Z}$, a cyclic group of order n), and $\langle x \rangle$ (a cyclic subgroup of some ambient group G, also of order n).

Arrows: The top arrow $\pi : \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ is the canonical quotient map $k \mapsto \overline{k}$, killing the subgroup $n\mathbb{Z}$. The diagonal arrow $k \mapsto x^k$ is the evaluation surjection from $\mathbb{Z}$ onto $\langle x \rangle$ (every element of $\langle x \rangle$ is some x^k). The right vertical dashed arrow $\mathbb{Z}/n\mathbb{Z} \xrightarrow{\sim} \langle x \rangle$ is the *induced* isomorphism $\overline{k} \mapsto x^k$; it is dashed because its existence is what the diagram asserts.

What commutes: The triangle commutes: $(\sim) \circ \pi = (k \mapsto x^k)$, i.e. sending k first to $\overline{k}$ and then mapping $\overline{k} \mapsto x^k$ gives the same result as sending $k \mapsto x^k$ directly.

Why it commutes: Start with $k \in \mathbb{Z}$. Along the top-then-right path: $k \overset{\pi}{\mapsto} \overline{k} \overset{\sim}{\mapsto} x^k$. Along the diagonal: $k \mapsto x^k$. Both land at x^k. Well-definedness of $\sim$: if $\overline{k} = \overline{k'}$ then $n \mid k - k'$, so $x^{k-k'} = 1$ (since $|x| = n$), giving $x^k = x^{k'}$; the map does not depend on the choice of representative in the coset.

Why this matters here: This is the First Isomorphism Theorem at its simplest: the surjection $\mathbb{Z} \to \langle x \rangle$ has kernel exactly $n\mathbb{Z}$, so the quotient $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/n\mathbb{Z}$ is isomorphic to $\langle x \rangle$. The diagram *is* the proof that cyclic of order n means $\mathbb{Z}/n\mathbb{Z}$, justifying the Classification Theorem.

Concrete example: Take $G = S_3$, $x = (1\,2\,3)$, $n = 3$. The map $k \mapsto (1\,2\,3)^k$ surjects $\mathbb{Z}$ onto $\langle (1\,2\,3) \rangle = \{e, (1\,2\,3), (1\,3\,2)\}$ with kernel $3\mathbb{Z}$, and $\mathbb{Z}/3\mathbb{Z} \xrightarrow{\sim} \langle (1\,2\,3) \rangle$ sends $\overline{0} \mapsto e$, $\overline{1} \mapsto (1\,2\,3)$, $\overline{2} \mapsto (1\,3\,2)$.

Common pitfall: The dashed isomorphism requires $|x| = n$ exactly (not merely $x^n = 1$). If $x^n = 1$ but $|x| = d < n$, the induced map is not injective; only when the kernel of $k \mapsto x^k$ is *exactly* $n\mathbb{Z}$ does the quotient become an isomorphism.

Takeaway: The point of this diagram is that a cyclic group of order n is canonically isomorphic to $\mathbb{Z}/n\mathbb{Z}$ via the unique map induced by sending the generator $\overline{1}$ to x.

Maps and commutative diagrams

Almost every result of this section is the statement that a diagram of homomorphisms commutes. Reading them this way turns the proofs into one-line observations.

(a) The universal property of $\mathbb{Z}$. For any group G and any $g \in G$ there is a *unique* homomorphism $\mathbb{Z} \to G$ with $1 \mapsto g$, necessarily $k \mapsto g^k$. (To define a homomorphism out of $\mathbb{Z}$ you only choose where the generator goes; out of Z_n the image g must also satisfy $g^n = 1$, see (c).)

$$\mathbb{Z} \overset{\exists!\ k \mapsto g^k}{\dashrightarrow} G$$

Diagram explanation. Objects: $\mathbb{Z}$ is the infinite cyclic group (under addition), the free object on one generator 1. G is any group with a chosen element g.

Arrows: The single dashed arrow $\mathbb{Z} \to G$ labeled $\exists!\ k \mapsto g^k$ is the *unique* group homomorphism sending $1 \in \mathbb{Z}$ to $g \in G$. It is dashed because the arrow is asserted to exist and to be unique; it is forced by the requirement $1 \mapsto g$ and the homomorphism property: $k = \underbrace{1 + \cdots + 1}_{k}$, so $k \mapsto g^k$ is the only possible formula.

What commutes: There is only one arrow, so no non-trivial path equality. The content is existence and uniqueness: any homomorphism $\varphi : \mathbb{Z} \to G$ is determined by $\varphi(1)$, and every element $g \in G$ is a valid target, so there are as many homomorphisms as elements of G.

Why it commutes: Uniqueness: suppose $\varphi, \psi : \mathbb{Z} \to G$ both send $1 \mapsto g$. Then $\varphi(k) = \varphi(1)^k = g^k = \psi(1)^k = \psi(k)$, so $\varphi = \psi$. Existence: define $\varphi(k) = g^k$; check $\varphi(j + k) = g^{j+k} = g^j g^k = \varphi(j)\varphi(k)$. No well-definedness issue: $\mathbb{Z}$ has no relations, so no coset-checking is needed.

Why this matters here: This universal property is why $\mathbb{Z}$ is the "free cyclic group." Every cyclic group $\langle x \rangle$ in this section arises as a quotient of $\mathbb{Z}$ by the kernel of the map $k \mapsto x^k$, tying the Classification Theorem directly to this diagram.

Concrete example: $G = \mu_6 \leq \mathbb{C}^\times$, $g = e^{2\pi i/6}$. The unique homomorphism $\mathbb{Z} \to \mu_6$ sends $k \mapsto e^{2\pi i k/6}$; it is surjective with kernel $6\mathbb{Z}$, recovering $\mu_6 \cong \mathbb{Z}/6\mathbb{Z}$.

Common pitfall: Students sometimes think you need to "check" the homomorphism property for this universal map. You do not: the formula $k \mapsto g^k$ is the only possibility, and it is automatically a homomorphism by the laws of exponents. The only choice is $g = \varphi(1)$.

Takeaway: The point of this diagram is that to give a homomorphism out of $\mathbb{Z}$ is exactly the same as choosing a single element g of the target group.

(b) From $\mathbb{Z}$ onto $\langle x\rangle$. The map $k \mapsto x^k$ is surjective onto $\langle x\rangle$ and factors through the inclusion $\langle x\rangle \hookrightarrow G$. Its kernel is $n\mathbb{Z}$ with $n = |x|$, which is exactly the content of $|\langle x\rangle| = |x|$ (Proposition 2.3.2).

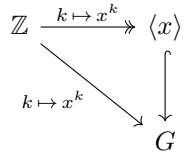

Diagram explanation. Objects: $\mathbb{Z}$ (infinite cyclic group), $\langle x\rangle$ (a cyclic subgroup of G generated by the element x), and G (the ambient group). All three are groups; $\langle x\rangle$ is a subgroup of G.

Arrows: The top horizontal arrow $\mathbb{Z} \twoheadrightarrow \langle x\rangle$, $k \mapsto x^k$, is a surjective group homomorphism whose kernel is $n\mathbb{Z}$ where $n = |x|$. The right vertical arrow $\langle x\rangle \hookrightarrow G$ is the inclusion (injective map sending each element to itself). The diagonal arrow $k \mapsto x^k$ from $\mathbb{Z}$ to G is the composite of the two preceding maps.

What commutes: The triangle commutes: (inclusion) $\circ$ (surjection) = (diagonal), i.e. $\iota \circ (k \mapsto x^k) = (k \mapsto x^k)$ as maps $\mathbb{Z} \to G$. Both routes from $\mathbb{Z}$ to G give the same element x^k.

Why it commutes: For $k \in \mathbb{Z}$: the top-then-right path sends $k \mapsto x^k \in \langle x\rangle \mapsto x^k \in G$. The diagonal sends $k \mapsto x^k \in G$. These agree trivially because the inclusion does nothing to the element. The real content is that the top arrow *is* a surjection: every $x^k \in \langle x\rangle$ is the image of $k \in \mathbb{Z}$, and the kernel $\ker(k \mapsto x^k) = \{k : x^k = 1\} = n\mathbb{Z}$ by the gcd Lemma.

Why this matters here: This diagram makes precise that $\langle x\rangle$ is "$\mathbb{Z}$ mod the relation $x^n = 1$": the surjection $\mathbb{Z} \twoheadrightarrow \langle x\rangle$ with kernel $n\mathbb{Z}$ is the mechanism behind the First Isomorphism preview and behind the proof that $|\langle x\rangle| = |x|$ in Proposition 2.3.2.

Concrete example: $G = D_8$, $x = r$ (rotation by 90°), $n = |r| = 4$. The map $k \mapsto r^k$ surjects $\mathbb{Z}$ onto $\{1, r, r^2, r^3\} = \langle r\rangle$ with kernel $4\mathbb{Z}$; the inclusion $\langle r\rangle \hookrightarrow D_8$ embeds these four rotations into the eight-element group.

Common pitfall: Both arrows labeled $k \mapsto x^k$ look identical but land in different groups ($\langle x\rangle$ versus G). The top arrow is genuinely surjective (every element of $\langle x\rangle$ is hit), while the diagonal is generally not surjective onto G unless G itself is cyclic generated by x.

Takeaway: The point of this diagram is that the surjection $\mathbb{Z} \twoheadrightarrow \langle x\rangle$ separates the "definition of $\langle x\rangle$ as all powers of x" from the "position of $\langle x\rangle$ inside G," and the kernel $n\mathbb{Z}$ records exactly when two exponents give the same power.

(c) The universal property of Z_n. If $g^n = 1$ then $k \mapsto g^k$ vanishes on $n\mathbb{Z}$, so it descends through the quotient $\pi : \mathbb{Z} \twoheadrightarrow Z_n$ to a unique $\varphi : Z_n \to G$. (This is precisely D&F Exercises 2.3.18–19: a homomorphism out of Z_n is the same as an element of order dividing n.)

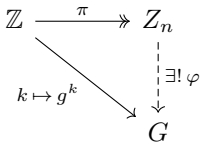

Diagram explanation. Objects: $\mathbb{Z}$ (infinite cyclic group), $Z_n = \mathbb{Z}/n\mathbb{Z}$ (the abstract cyclic group of order n, with generator $\overline{1}$), and G (any group containing an element g with $g^n = 1$, i.e. $|g|$ divides n).

Arrows: $\pi : \mathbb{Z} \twoheadrightarrow Z_n$ is the canonical surjective quotient map $k \mapsto \overline{k}$ with kernel $n\mathbb{Z}$. The diagonal $k \mapsto g^k$ is a homomorphism $\mathbb{Z} \to G$ that kills $n\mathbb{Z}$ (since $g^n = 1$ forces $g^{nk} = 1$ for all $k \in \mathbb{Z}$). The dashed vertical arrow $\varphi : Z_n \to G$, $\overline{k} \mapsto g^k$, is the *unique* induced homomorphism; it is dashed because the diagram asserts its existence.

What commutes: The triangle commutes: $\varphi \circ \pi = (k \mapsto g^k)$, i.e. $\varphi(\overline{k}) = g^k$ for all $k \in \mathbb{Z}$.

Why it commutes: Well-definedness of φ: if $\overline{k} = \overline{k'}$ then $n \mid k - k'$, so $g^{k-k'} = (g^n)^{(k-k')/n} = 1^{(k-k')/n} = 1$, giving $g^k = g^{k'}$. Hence $\varphi(\overline{k}) = g^k$ does not depend on the choice of representative. Uniqueness: any $\psi : Z_n \to G$ with $\psi \circ \pi = k \mapsto g^k$ must satisfy $\psi(\overline{1}) = g$, forcing $\psi(\overline{k}) = g^k = \varphi(\overline{k})$.

Why this matters here: This is the universal property that classifies all homomorphisms out of Z_n: they correspond exactly to elements $g \in G$ with $|g| \mid n$. It is the engine behind the exercises on homomorphisms from cyclic groups and the reason the classification of cyclic groups is so effective.

Concrete example: $G = \mu_{12} \leq \mathbb{C}^\times$, $g = e^{2\pi i/4} = i$, $n = 4$ (so $g^4 = 1$). The induced map $\varphi : Z_4 \to \mu_{12}$ sends $\overline{k} \mapsto i^k$, embedding Z_4 into μ_{12} as the subgroup $\{1, i, -1, -i\} = \mu_4$.

Common pitfall: The condition is $g^n = 1$ (order *divides* n), not $|g| = n$. If $|g| < n$ then φ is not injective; in particular φ need not be an isomorphism. The diagram gives a homomorphism regardless; the isomorphism case requires $|g| = n$ exactly.

Takeaway: The point of this diagram is that a homomorphism out of Z_n into G is the same as a choice of element $g \in G$ satisfying $g^n = 1$, with the quotient map π doing all the well-definedness work.

(d) Any two cyclic groups of the same order are isomorphic (Theorem 2.3.4). Both $\langle x \rangle$ and $\langle y \rangle$ are $\mathbb{Z}$ modulo the same subgroup $n\mathbb{Z}$, so $x^k \mapsto y^k$ is a well-defined isomorphism making the triangle commute.

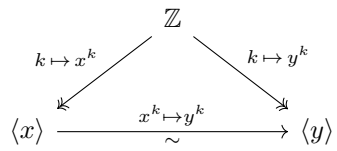

Diagram explanation. Objects: $\mathbb{Z}$ (the apex, infinite cyclic group of integers), $\langle x \rangle$ (a cyclic group of order n generated by x, lower-left), and $\langle y \rangle$ (a second cyclic group of order n generated by y, lower-right). The two groups may live in entirely different ambient groups.

Arrows: The left surjection $k \mapsto x^k : \mathbb{Z} \twoheadrightarrow \langle x \rangle$ has kernel $n\mathbb{Z}$. The right surjection $k \mapsto y^k : \mathbb{Z} \twoheadrightarrow \langle y \rangle$ has the same kernel $n\mathbb{Z}$. The bottom isomorphism $\sim$: $\langle x \rangle \to \langle y \rangle$, $x^k \mapsto y^k$, is the map induced by the two surjections sharing the same kernel.

What commutes: The triangle commutes: $(x^k \mapsto y^k) \circ (k \mapsto x^k) = (k \mapsto y^k)$, i.e. going left-then-bottom equals going right directly from $\mathbb{Z}$ to $\langle y \rangle$.

Why it commutes: For $k \in \mathbb{Z}$: left-then-bottom sends $k \mapsto x^k \mapsto y^k$. Right sends $k \mapsto y^k$. These agree. Well-definedness of the bottom map: if $x^k = x^{k'}$ then $x^{k-k'} = 1$, so $n \mid k - k'$ (gcd Lemma), hence $y^{k-k'} = 1$ and $y^k = y^{k'}$. Both surjections share kernel $n\mathbb{Z}$, so the induced map between the quotients is an isomorphism by the First Isomorphism Theorem.

Why this matters here: This is Theorem 2.3.4 diagrammatically: the two cyclic groups of the same order are interchangeable because they are both quotients of $\mathbb{Z}$ by the same relation $n = 0$. The triangle records exactly why $x^k \mapsto y^k$ is a legitimate isomorphism, not just a set bijection.

Concrete example: $\langle x \rangle = \mu_3 = \{1, \omega, \omega^2\} \leq \mathbb{C}^\times$ (cube roots of unity) and $\langle y \rangle = \langle (1\,2\,3) \rangle \leq S_3$. Both have order 3; the isomorphism $\omega^k \mapsto (1\,2\,3)^k$ sends $1 \mapsto e$, $\omega \mapsto (1\,2\,3)$, $\omega^2 \mapsto (1\,3\,2)$, and both groups are quotients of $\mathbb{Z}$ by $3\mathbb{Z}$.

Common pitfall: The isomorphism $x^k \mapsto y^k$ is *not* canonical in a unique-choice sense when there are multiple generators: replacing x by another generator x^a (with $\gcd(a, n) = 1$) gives a different isomorphism. The diagram shows one particular isomorphism, determined by the choice of how to assign generators.

Takeaway: The point of this diagram is that any two cyclic groups of order n are both quotients of the same $\mathbb{Z}$ by the same $n\mathbb{Z}$, so they are automatically isomorphic via the map that matches generator to generator.

(e) "φ is a homomorphism" is the commuting of one square: it respects multiplication. Checking this square is the only real content in (d).

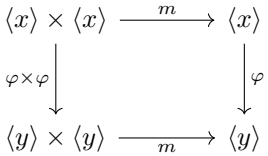

Diagram explanation. Objects: Upper-left and lower-left are product groups $\langle x\rangle \times \langle x\rangle$ and $\langle y\rangle \times \langle y\rangle$ respectively; upper-right is $\langle x\rangle$ and lower-right is $\langle y\rangle$. Here $\varphi : \langle x\rangle \to \langle y\rangle$ is the isomorphism $x^k \mapsto y^k$ from diagram (d), both cyclic of order n.

Arrows: Both horizontal arrows labeled m are the group multiplication maps: $m(x^j, x^k) = x^{j+k}$ on the top, $m(y^j, y^k) = y^{j+k}$ on the bottom. The left vertical arrow is $\varphi \times \varphi : (x^j, x^k) \mapsto (y^j, y^k)$ (applying φ to each component). The right vertical arrow is $\varphi : x^k \mapsto y^k$.

What commutes: Down-then-right equals right-then-down: $\varphi(m(x^j, x^k)) = m(\varphi(x^j), \varphi(x^k))$, i.e. $\varphi(x^{j+k}) = y^j y^k$. Explicitly: $y^{j+k} = y^j y^k$, which holds in $\langle y\rangle$.

Why it commutes: Chase (x^j, x^k) from upper-left. Right-then-down: $m(x^j, x^k) = x^{j+k} \overset{\varphi}{\mapsto} y^{j+k}$. Down-then-right: $(x^j, x^k) \overset{\varphi\times\varphi}{\longmapsto} (y^j, y^k) \overset{m}{\mapsto} y^{j+k}$. Both give y^{j+k}. The commutativity holds because φ is defined by matching exponents, and exponent arithmetic $(j + k)$ is the same in both groups.

Why this matters here: The text says "checking this square is the only real content" in the isomorphism proof. In the abstract, a map is a homomorphism if and only if this naturality square commutes; the square makes the condition $\varphi(ab) = \varphi(a)\varphi(b)$ into a diagram rather than a sentence, which is the standard categorical encoding of "structure-preserving map."

Concrete example: $\langle x\rangle = \mathbb{Z}/3\mathbb{Z}$ (additive), $\langle y\rangle = \mu_3$ (multiplicative), $\varphi(\overline{k}) = \omega^k$. Top row: $(\overline{1}, \overline{1}) \overset{m}{\mapsto} \overline{2}$. Right column: $\overline{2} \overset{\varphi}{\mapsto} \omega^2$. Left-then-bottom: $(\overline{1}, \overline{1}) \overset{\varphi\times\varphi}{\longmapsto} (\omega, \omega) \overset{m}{\mapsto} \omega^2$. Both give ω^2.

Common pitfall: Students sometimes think "φ is a bijection" is sufficient for an isomorphism. This diagram shows the extra condition: the square must commute. A bijection that does not preserve multiplication is not a homomorphism; this square failing to commute would detect that failure.

Takeaway: The point of this diagram is that "φ is a homomorphism" is exactly the statement that applying φ before or after multiplying gives the same answer, packaged as a commutative square involving the multiplication maps of both groups.

(f) Subgroups $\leftrightarrow$ divisors (Theorem 2.3.26). For $Z_n = \langle x\rangle$, the assignment $d \mapsto \langle x^{n/d}\rangle$ is an inclusion-preserving bijection from the divisors of n to the subgroups of Z_n; this is why the subgroup lattice of Z_n *is* the divisor lattice of n.

$$\{\, d : d \mid n \,\} \xrightarrow[d \mapsto \langle x^{n/d}\rangle]{\sim} \{\text{subgroups of } Z_n\}$$

Diagram explanation. Objects: The domain is the set of positive divisors of n (a finite set of integers, viewed here as a poset under divisibility). The codomain is the set of all subgroups of the cyclic group $Z_n = \langle x\rangle$ of order n (a set of groups, ordered by inclusion). Both sets have the same cardinality $\tau(n)$ (number of divisors of n).

Arrows: The single arrow, labeled $\sim$ and $d \mapsto \langle x^{n/d}\rangle$, is the bijection sending each divisor d of n to the unique subgroup of Z_n of order d. Its inverse sends a subgroup $K \le Z_n$ to $|K|$. The arrow is labeled $\sim$ because it is a bijection and it is also order-preserving in both directions (an isomorphism of posets): $d_1 \mid d_2$ if and only if $\langle x^{n/d_1}\rangle \le \langle x^{n/d_2}\rangle$.

What commutes: There is one arrow, so the content is bijectivity and the poset-isomorphism condition: $d_1 \mid d_2 \iff \langle x^{n/d_1}\rangle \le \langle x^{n/d_2}\rangle$. Equivalently, the induced map on the divisor lattice of n is identical to the subgroup lattice of Z_n.

Why it commutes: Injectivity: distinct divisors $d \neq d'$ give $\langle x^{n/d}\rangle \neq \langle x^{n/d'}\rangle$ because $|\langle x^{n/d}\rangle| = d \neq d' = |\langle x^{n/d'}\rangle|$. Surjectivity: every subgroup of Z_n is cyclic (Theorem 2.3.26(1)) hence equals $\langle x^{n/d}\rangle$ for some divisor d of n by the uniqueness argument in Theorem 2.3.26(3). Poset-preservation: $d_1 \mid d_2 \Rightarrow n/d_2 \mid n/d_1 \Rightarrow \langle x^{n/d_1}\rangle \le \langle x^{n/d_2}\rangle$ by the containment rule.

Why this matters here: This is the capstone of the section on subgroups of cyclic groups. It makes precise the slogan "the subgroup lattice of Z_n is the divisor lattice of n upside-down," justifying every lattice diagram in this chapter and giving a complete structural description of Z_n.

Concrete example: $n = 12$. Divisors $1, 2, 3, 4, 6, 12$ map to $\langle x^{12}\rangle, \langle x^6\rangle, \langle x^4\rangle, \langle x^3\rangle, \langle x^2\rangle, \langle x\rangle$ with orders $1, 2, 3, 4, 6, 12$. The divisibility $2 \mid 6$ matches the containment $\langle x^6\rangle \le \langle x^2\rangle$, visible in the lattice drawn earlier in this section.

Common pitfall: The divisor d labels the *order* of the subgroup, not the step size of the generator. The generator is $x^{n/d}$, not x^d. Confusing these reverses the labeling: in $\mathbb{Z}/12\mathbb{Z}$, the order-3 subgroup is $\langle\overline{4}\rangle$ (step $4 = 12/3$), not $\langle\overline{3}\rangle$.

Takeaway: The point of this diagram is that divisors of n and subgroups of Z_n are in perfect order-preserving bijective correspondence, so any question about subgroup containment in a cyclic group is purely a question about divisibility.

(g) Automorphisms of Z_n. An automorphism must send a generator to a generator (Proposition 2.3.19), and $a \mapsto (\sigma_a : x \mapsto x^a)$ is a group isomorphism. So the symmetries of a cyclic group are the units mod n.

$$(\mathbb{Z}/n\mathbb{Z})^\times \xrightarrow[a \mapsto \sigma_a]{\sim} \mathrm{Aut}(Z_n)$$

Diagram explanation. Objects: The domain $(\mathbb{Z}/n\mathbb{Z})^\times = (\mathbb{Z}/n\mathbb{Z})^\times$ is the group of units modulo n under multiplication: the residues $\overline{a}$ with $\gcd(a, n) = 1$, which has order $\varphi(n)$. The codomain $\mathrm{Aut}(Z_n)$ is the group of all group automorphisms of $Z_n = \langle x\rangle$ under composition; it also has order $\varphi(n)$ by Proposition 2.3.19.

Arrows: The single isomorphism arrow, labeled $\sim$ and $a \mapsto \sigma_a$, sends a unit $\overline{a} \in (\mathbb{Z}/n\mathbb{Z})^\times$ to the automorphism $\sigma_a : Z_n \to Z_n$ defined by $\sigma_a(x^k) = x^{ak}$. Since $\gcd(a, n) = 1$, the element x^a is a generator of Z_n (Proposition 2.3.19(1)), so σ_a is indeed an automorphism.

What commutes: Again one arrow, so the content is: (1) σ_a is a well-defined automorphism for each $\gcd(a, n) = 1$; (2) $a \mapsto \sigma_a$ is a group homomorphism: $\sigma_a \circ \sigma_b = \sigma_{ab}$, i.e. $\sigma_a(\sigma_b(x^k)) = \sigma_a(x^{bk}) = x^{abk} = \sigma_{ab}(x^k)$; (3) the map is a bijection, so a group isomorphism.

Why it commutes: Well-definedness of σ_a: if $x^k = x^{k'}$ in Z_n then $n \mid k - k'$, hence $n \mid a(k - k')$ and $x^{ak} = x^{ak'}$. Injectivity of $a \mapsto \sigma_a$: if $\sigma_a = \sigma_b$ then $x^a = \sigma_a(x) = \sigma_b(x) = x^b$, so $n \mid a - b$, giving $\overline{a} = \overline{b}$ in $(\mathbb{Z}/n\mathbb{Z})^\times$. Surjectivity: every automorphism ϕ sends the generator x to a generator x^a with $\gcd(a, n) = 1$, and then $\phi = \sigma_a$.

Why this matters here: This diagram closes the story of cyclic groups by computing their automorphism group. It explains why $|\mathrm{Aut}(Z_n)| = \varphi(n)$ and why the symmetries of a cyclic group are governed by units modulo n, connecting group theory to number theory.

Concrete example: $n = 8$, $(\mathbb{Z}/8\mathbb{Z})^\times = \{\overline{1}, \overline{3}, \overline{5}, \overline{7}\} \cong \mathbb{Z}/2 \times \mathbb{Z}/2$ (the Klein four-group). The four automorphisms of $Z_8 = \langle x\rangle$ are σ_1 (identity), $\sigma_3 : x \mapsto x^3$, $\sigma_5 : x \mapsto x^5$, $\sigma_7 : x \mapsto x^7 = x^{-1}$. Composition corresponds to multiplication of units: $\sigma_3 \circ \sigma_3 = \sigma_9 = \sigma_1$ since $3^2 = 9 \equiv 1 \pmod 8$.

Common pitfall: An automorphism of Z_n is completely determined by where it sends the generator x; but only sending x to another generator (an element of order n) gives an automorphism. Sending x to x^2 when n is even yields an endomorphism that is not an automorphism because x^2 does not generate Z_n.

Takeaway: The point of this diagram is that the symmetry group of the cyclic group Z_n is isomorphic to the multiplicative group of units mod n, so group-theoretic symmetry reduces to number-theoretic coprimality.

Exercises (from the text).

1. Find all subgroups of $Z_{45} = \langle x\rangle$, giving a generator for each, and describe the containments.
2. If $x \in G$ is finite with $|x| = |G|$, prove $G = \langle x\rangle$; give an infinite counterexample.
3. Find all generators of $\mathbb{Z}/48\mathbb{Z}$.
4. Find all generators of $\mathbb{Z}/202\mathbb{Z}$.
5. Find the number of generators of $\mathbb{Z}/49000\mathbb{Z}$.
6. In $\mathbb{Z}/48\mathbb{Z}$, list the elements of $\langle\bar{a}\rangle$ for each $\bar{a}$, and all inclusions among subgroups.
7. Use $\mathbb{Z}/48\mathbb{Z} \cong Z_{48}$ to list all subgroups of Z_{48}.
8. For which a does $1 \mapsto x^a$ extend to an isomorphism $\mathbb{Z}/48\mathbb{Z} \to Z_{48}$?
9. For which a does $1 \mapsto x^a$ extend to a homomorphism $\mathbb{Z}/48\mathbb{Z} \to Z_{36}$? Can it be surjective?
10. Find $|\overline{30}|$ in $\mathbb{Z}/54\mathbb{Z}$, and list the elements and orders of $\langle\overline{30}\rangle$.

11. Find all cyclic subgroups of D_8 and a non-cyclic proper subgroup.
12. Prove $Z_2 \times Z_2$, $Z_2 \times \mathbb{Z}$, and $\mathbb{Z} \times \mathbb{Z}$ are not cyclic.
13. Prove $\mathbb{Z} \times Z_2 \ncong \mathbb{Z}$ and $\mathbb{Q} \times Z_2 \ncong \mathbb{Q}$.
14. For $\sigma = (1\,2 \cdots 12)$, compute σ^a for $a = 13, 65, 626, 1195, -6, -81, -570, -1211$.
15. Prove $\mathbb{Q} \times \mathbb{Q}$ is not cyclic.
16. $|x| = n$, $|y| = m$, $xy = yx$: prove $|xy| \mid \operatorname{lcm}(m, n)$; show this can fail without commuting, and give commuting x, y with $|xy| \neq \operatorname{lcm}(m, n)$.
17. Find a presentation of Z_n with one generator.
18. If $h^n = 1$ in H, prove there is a unique homomorphism $Z_n \to H$ with $x \mapsto h$.
19. For $h \in H$, prove there is a unique homomorphism $\mathbb{Z} \to H$ with $1 \mapsto h$.
20. p prime, $x^{p^n} = 1 \implies |x| = p^m$ for some $m \leq n$.
21. p an odd prime: show $1 + p$ has order p^{n-1} in $(\mathbb{Z}/p^n\mathbb{Z})^\times$.
22. $n \geq 3$: show 5 has order 2^{n-2} in $(\mathbb{Z}/2^n\mathbb{Z})^\times$.
23. Show $(\mathbb{Z}/2^n\mathbb{Z})^\times$ is not cyclic for $n \geq 3$.
24. G finite, $x \in G$: prove $g \in N_G(\langle x \rangle) \iff gxg^{-1} = x^a$ for some $a \in \mathbb{Z}$.
25. G cyclic of order n, $\gcd(k, n) = 1$: prove $x \mapsto x^k$ is surjective, and extend the conclusion to any finite group of order n.
26. $\operatorname{Aut}(Z_n)$: prove $\sigma_a : x \mapsto x^a$ is an automorphism $\iff \gcd(a, n) = 1$, and $\operatorname{Aut}(Z_n) \cong (\mathbb{Z}/n\mathbb{Z})^\times$, abelian of order $\varphi(n)$.

Additional exercises.

1. Prove that for each $d \mid n$, a cyclic group of order n has exactly $\varphi(d)$ elements of order d; deduce $\sum_{d|n} \varphi(d) = n$.
2. Prove $\mathbb{Q}$ is not cyclic and has no maximal subgroup.
3. Prove a finite group G with at most n solutions to $x^n = 1$ for every $n \mid |G|$ is cyclic. (Hence every finite subgroup of $F^\times$, F a field, is cyclic.)
4. Determine all n for which $(\mathbb{Z}/n\mathbb{Z})^\times$ is cyclic.
5. Prove that two finite cyclic groups are isomorphic iff they have the same order, using only the order and isomorphism propositions of this section.

Commutative-diagram exercises.

1. (Universal property of $\mathbb{Z}$) Prove that for each $g \in G$ there is a unique homomorphism $\mathbb{Z} \to G$ with $1 \mapsto g$; deduce a natural bijection $\operatorname{Hom}(\mathbb{Z}, G) \leftrightarrow G$.
2. (Universal property of Z_n) Prove $\operatorname{Hom}(Z_n, G) \leftrightarrow \{g \in G \mid g^n = 1\}$ by showing $k \mapsto g^k$ descends through $\pi : \mathbb{Z} \twoheadrightarrow Z_n$ iff $g^n = 1$; draw the factorization triangle.
3. Show the map $\mathbb{Z} \to \langle x \rangle$, $k \mapsto x^k$, induces an isomorphism $\mathbb{Z}/n\mathbb{Z} \to \langle x \rangle$ when $|x| = n$, and draw the triangle. (This is the First Isomorphism Theorem in one case.)
4. Exhibit the isomorphism between two cyclic groups of order n as the dashed arrow completing the $\mathbb{Z}$-triangle $\langle x \rangle \leftarrow \mathbb{Z} \to \langle y \rangle$, and verify the triangle commutes.
5. Prove $a \mapsto \sigma_a$ (where $\sigma_a(x) = x^a$) is an isomorphism $(\mathbb{Z}/n\mathbb{Z})^\times \to \operatorname{Aut}(Z_n)$ by checking that the square $\sigma_a \circ \sigma_b = \sigma_{ab}$ commutes.
6. Define $\varphi : \mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ by $\overline{1} \mapsto \overline{3}$. Compute $\varphi(\overline{5})$ and $\varphi(\overline{8})$, verify φ is a well-defined homomorphism (the relation $12 \cdot \overline{1} = \overline{0}$ must map to $\overline{0}$), and find $\ker \varphi$.

2.4 Subgroups Generated by Subsets

Subgroups generated by subsets ($\langle A\rangle$)

This section answers a single concrete question: given a subset A of a group G, what is the *smallest* subgroup of G that contains A? We build it two ways — from the outside (intersect all subgroups containing A) and from the inside (take all finite words in the elements of A and their inverses) — and prove the two descriptions agree.

Proposition 2.4.1. *Let G be a group and let $\{H_i\}_{i\in I}$ be a nonempty collection of subgroups of G. Then $K=\bigcap_{i\in I} H_i$ is a subgroup of G.*

Proof. Use the subgroup criterion (nonempty; closed under xy^{-1}). Each $H_i \le G$ contains 1, so $1 \in H_i$ for every i, hence $1 \in K$ and $K \neq \varnothing$. Now take $x, y \in K$. For each i we have $x, y \in H_i$, and since H_i is a subgroup, $xy^{-1} \in H_i$. As this holds for every i, we get $xy^{-1} \in \bigcap_i H_i = K$. By the one-step subgroup test, $K \le G$. □

Caution. The same argument fails for *unions*: $\langle 2\rangle \cup \langle 3\rangle$ in $\mathbb{Z}$ contains 2 and 3 but not $2+3=5$, so it is not a subgroup. Intersections of subgroups are always subgroups; unions almost never are.

Definition 2.4.2. Let $A \subseteq G$. The **subgroup generated by** A is

$$\langle A\rangle \;=\; \bigcap_{\substack{H\le G\\ A\subseteq H}} H,$$

the intersection of all subgroups of G that contain A. The collection being intersected is nonempty because G itself is such an H, so by Proposition 2.4.1 $\langle A\rangle$ is a subgroup. We call A a *generating set*, and elements of A *generators*. If $A=\{a_1,\dots,a_n\}$ we write $\langle a_1,\dots,a_n\rangle$.

By construction $\langle A\rangle$ is the **smallest** subgroup containing A, in the precise sense: $A \subseteq \langle A\rangle$, and if $K \le G$ with $A \subseteq K$, then $\langle A\rangle \subseteq K$ (because K is one of the H's being intersected). That "outside" definition is clean but useless for computation. The next theorem gives the computable "inside" description.

Theorem 2.4.3 (Word description of $\langle A\rangle$)**.** *Let $A \subseteq G$ be nonempty. Then*

$$\langle A\rangle \;=\; \big\{\, a_1^{\varepsilon_1}a_2^{\varepsilon_2}\cdots a_k^{\varepsilon_k} \;\mid\; k\ge 0,\ a_i\in A,\ \varepsilon_i\in\{+1,-1\}\,\big\},$$

*the set of all finite **words** in the elements of A and their inverses (the empty word $k=0$ denotes 1). If $A=\varnothing$ then $\langle A\rangle=\{1\}$.*

Proof. Write W for the set of words on the right. We show $W \le G$, then $A \subseteq W$, then $W=\langle A\rangle$.

W is a subgroup. It contains the empty word 1, so $W\neq\varnothing$. If $x=a_1^{\varepsilon_1}\cdots a_k^{\varepsilon_k}$ and $y=b_1^{\delta_1}\cdots b_m^{\delta_m}$ are words, then their concatenation xy is again a word, so W is closed under products. Also $x^{-1}=a_k^{-\varepsilon_k}\cdots a_1^{-\varepsilon_1}$ is a word (reverse the letters and flip each sign), so W is closed under inverses. Hence $W \le G$.

W contains A. Each $a\in A$ equals the length-one word a^{+1}, so $A\subseteq W$.

Minimality forces equality. Since W is a subgroup containing A, the "smallest" property of $\langle A\rangle$ gives $\langle A\rangle \subseteq W$. Conversely, let H be *any* subgroup with $A\subseteq H$. Then H contains every a_i and (being a subgroup) every a_i^{-1}, hence every product $a_1^{\varepsilon_1}\cdots a_k^{\varepsilon_k}$; thus $W\subseteq H$. Taking $H=\langle A\rangle$ gives $W\subseteq\langle A\rangle$. Therefore $W=\langle A\rangle$.

If $A=\varnothing$, the only word is the empty word, so $W=\{1\}=\langle A\rangle$. □

Corollary 2.4.4 (Abelian case: words collapse to integer combinations)**.** *If G is abelian, written additively, and $A=\{a_1,\dots,a_n\}$, then*

$$\langle A\rangle = \{\, m_1a_1+m_2a_2+\cdots+m_na_n \;\mid\; m_i\in\mathbb{Z}\,\}.$$

In particular $\langle a\rangle=\{ma\mid m\in\mathbb{Z}\}=a\mathbb{Z}$ for a single element.

Proof. In an abelian group we may sort the letters of any word and collect repeats: a word in $a_1, \dots, a_n$ and their inverses can be rearranged (commutativity) into a_1's together, then a_2's, and so on, and each block of m_i copies of $a_i^{\pm 1}$ sums to $m_i a_i$ with $m_i \in \mathbb{Z}$. Conversely each integer combination is visibly such a word. The result follows from Theorem 2.4.3. □

Theorem 2.4.5 (The case $G = \mathbb{Z}$)**.** *For integers a, b not both 0, in $(\mathbb{Z}, +)$ we have $\langle a, b\rangle = \langle \gcd(a, b)\rangle = \gcd(a, b)\,\mathbb{Z}$. More generally $\langle a_1, \dots, a_n\rangle = \langle \gcd(a_1, \dots, a_n)\rangle$.*

Proof. Let $d = \gcd(a, b)$. By Corollary 2.4.4, $\langle a, b\rangle = \{ma + nb \mid m, n \in \mathbb{Z}\}$. Since $d \mid a$ and $d \mid b$, every $ma + nb$ is a multiple of d, so $\langle a, b\rangle \subseteq d\mathbb{Z} = \langle d\rangle$. Conversely, by Bézout there exist $m_0, n_0 \in \mathbb{Z}$ with $m_0 a + n_0 b = d$, so $d \in \langle a, b\rangle$, hence $\langle d\rangle = d\mathbb{Z} \subseteq \langle a, b\rangle$. Therefore $\langle a, b\rangle = \langle d\rangle$. Induction on n (using $\gcd(a_1, \dots, a_n) = \gcd(\gcd(a_1, \dots, a_{n-1}), a_n)$) gives the general statement. □

Method (How to compute $\langle A\rangle$ by hand (word closure))**.** Use this whenever you see "$\langle \cdot \rangle$," "the subgroup generated by," or "smallest subgroup containing."

1. **Seed.** Start the candidate set S with 1, every generator $a \in A$, and every inverse a^{-1}.
2. **Close under products.** Multiply pairs from S (in both orders if G is nonabelian) and adjoin any new elements. Repeat until S stops growing. Finiteness of G (or a known order bound) guarantees this halts.
3. **Read off the subgroup.** The stabilized S *is* $\langle A\rangle$, by Theorem 2.4.3.
4. **Identify it.** Compute $|S|$, check whether it is abelian, and match against a known group (V_4, $\mathbb{Z}_n$, S_3, Q_8, …). If $|S| = |G|$ then $\langle A\rangle = G$.
5. *Shortcuts.* In an abelian group, replace words by integer combinations (Cor. 2.4.4); in $\mathbb{Z}$ use $\langle a, b\rangle = \langle \gcd(a, b)\rangle$ (Thm. 2.4.5); in $\mathbb{Z}/n\mathbb{Z}$ use $\langle \overline{a}, \overline{b}\rangle = \langle \overline{\gcd(a, b, n)}\rangle$.

Recognizing $\langle A\rangle = G$**:** it suffices that the generators reach an element of order $|G|$ (cyclic case), or that the closure already exhausts a known basis/generating pattern of G.

Worked Example 2.4.6 ($\langle 2, 3\rangle = \mathbb{Z}$)**.** Show that 2 and 3 generate all of $\mathbb{Z}$.

Recognition. Ambient group is $\mathbb{Z}$ (abelian, additive). The trigger "$\langle a, b\rangle$ in $\mathbb{Z}$" fires Theorem 2.4.5: the answer is $\langle \gcd(a, b)\rangle$. Compute the gcd.

Solution. By Theorem 2.4.5, $\langle 2, 3\rangle = \langle \gcd(2, 3)\rangle = \langle 1\rangle = 1 \cdot \mathbb{Z} = \mathbb{Z}$. Explicit Bézout witness: $(-1)\cdot 2 + (1)\cdot 3 = 1$, so $1 \in \langle 2, 3\rangle$; once 1 is present, every integer $m = m \cdot 1 \in \langle 2, 3\rangle$. *Check.* $\gcd(2, 3) = 1$ and $\langle 1\rangle = \mathbb{Z}$, consistent. Also $5 = 3 + 2$, $4 = 2 + 2$, $-1 = 2 - 3$ are all reachable, as expected.

Worked Example 2.4.7 ($\langle 4, 6\rangle = 2\mathbb{Z}$)**.** Compute $\langle 4, 6\rangle$ in $\mathbb{Z}$.

Recognition. Same trigger as the previous example: a two-generator subgroup of $(\mathbb{Z}, +)$. Apply $\langle a, b\rangle = \langle \gcd(a, b)\rangle$.

Solution. $\gcd(4, 6) = 2$, so $\langle 4, 6\rangle = \langle 2\rangle = 2\mathbb{Z} = \{\dots, -4, -2, 0, 2, 4, \dots\}$. Bézout witness for 2: $(-1)\cdot 4 + (1)\cdot 6 = 2$, so $2 \in \langle 4, 6\rangle$, giving $2\mathbb{Z} \subseteq \langle 4, 6\rangle$. Conversely every $4m + 6n = 2(2m + 3n)$ is even, so $\langle 4, 6\rangle \subseteq 2\mathbb{Z}$. *Check.* Both generators are even, so no odd number can appear — $1 \notin \langle 4, 6\rangle$, matching $\langle 4, 6\rangle = 2\mathbb{Z} \neq \mathbb{Z}$. And $2 = 6 - 4 \in \langle 4, 6\rangle$, confirming 2 is attained.

Worked Example 2.4.8 ($\langle \overline{4}, \overline{6}\rangle = \langle \overline{2}\rangle$ in $\mathbb{Z}/12\mathbb{Z}$)**.** Find $\langle \overline{4}, \overline{6}\rangle$ inside $\mathbb{Z}/12\mathbb{Z}$.

Recognition. Ambient group is $\mathbb{Z}/12\mathbb{Z}$ (abelian, additive mod 12). For $\mathbb{Z}/n\mathbb{Z}$ the gcd rule must include the modulus: $\langle \overline{a}, \overline{b}\rangle = \langle \overline{\gcd(a, b, n)}\rangle$, because adding the relation $n \equiv 0$ is the same as throwing n into the gcd.

Solution. Compute $\gcd(4, 6, 12) = \gcd(\gcd(4, 6), 12) = \gcd(2, 12) = 2$. Hence $\langle \overline{4}, \overline{6}\rangle = \langle \overline{2}\rangle = \{\overline{0}, \overline{2}, \overline{4}, \overline{6}, \overline{8}, \overline{10}\}$, a subgroup of order 6. Word/integer-combination check that $\overline{2}$ is reachable: $\overline{6} - \overline{4} = \overline{2}$. And $\overline{2}$ generates the listed set by repeated addition. *Check.* $|\langle \overline{2}\rangle| = 12/\gcd(2, 12) = 12/2 = 6$, matching the six listed residues. Every generator lies in it: $\overline{4} = 2 \cdot \overline{2}$, $\overline{6} = 3 \cdot \overline{2}$. Good.

Worked Example 2.4.9 ($\langle\overline{3},\overline{5}\rangle = \mathbb{Z}/12\mathbb{Z}$ (tricky: coprime generators))**.** Compute $\langle\overline{3},\overline{5}\rangle$ in $\mathbb{Z}/12\mathbb{Z}$.

Recognition. Two-generator subgroup of $\mathbb{Z}/12\mathbb{Z}$; use $\langle\overline{a},\overline{b}\rangle = \langle\overline{\gcd(a,b,n)}\rangle$. The subtlety: even though 3 alone does not generate $\mathbb{Z}/12\mathbb{Z}$, the gcd of the two generators with the modulus may still be 1.

Solution. $\gcd(3,5,12) = \gcd(\gcd(3,5),12) = \gcd(1,12) = 1$, so $\langle\overline{3},\overline{5}\rangle = \langle\overline{1}\rangle = \mathbb{Z}/12\mathbb{Z}$. Explicit reach: $\overline{5}-\overline{3} = \overline{2}$ and $\overline{3}-\overline{2} = \overline{1}$, so $\overline{1} \in \langle\overline{3},\overline{5}\rangle$, and $\overline{1}$ generates everything. *Check.* $\langle\overline{3}\rangle = \{\overline{0},\overline{3},\overline{6},\overline{9}\}$ has order 4 and $\langle\overline{5}\rangle = \mathbb{Z}/12\mathbb{Z}$ already (since $\gcd(5,12) = 1$); so together they certainly fill $\mathbb{Z}/12\mathbb{Z}$. Consistent.

Worked Example 2.4.10 ($\langle(1\,2),(2\,3)\rangle = S_3$)**.** Show the transpositions $(1\,2)$ and $(2\,3)$ generate S_3.

Recognition. Ambient group is S_3, which is nonabelian, so we cannot use gcd or integer combinations — we must do honest **word closure** (Method box, products in both orders). The trigger is two specific elements with "$\langle\cdot\rangle$."

Solution. Seed: $1, (1\,2), (2\,3)$ (each transposition is its own inverse). Multiply (D&F convention: rightmost permutation acts first):

$$(1\,2)(2\,3) = (1\,2\,3), \qquad (2\,3)(1\,2) = (1\,3\,2).$$

Adjoin these two 3-cycles. One more product gives the last missing element:

$$(1\,2)\,(1\,2\,3) = (2\,3) \quad \text{(already have)}; \qquad (1\,2\,3)(1\,2) = (1\,3).$$

Now the closure is $\{1, (1\,2), (1\,3), (2\,3), (1\,2\,3), (1\,3\,2)\}$, which is all 6 elements of S_3, and further products produce nothing new. *Check.* $|S_3| = 3! = 6$ and our closure has 6 elements, so $\langle(1\,2),(2\,3)\rangle = S_3$. (Indeed adjacent transpositions generate S_n in general.)

Worked Example 2.4.11 ($\langle s, r^2\rangle = \{1, r^2, s, sr^2\} \cong V_4$ in D_8)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1}\rangle$, compute $\langle s, r^2\rangle$.

Recognition. Nonabelian ambient D_8: do word closure. Key relations to apply during closure: $s^2 = 1$, $r^4 = 1$, and the conjugation rule $sr = r^{-1}s$, i.e. $r^2 s = sr^{-2} = sr^2$ (since $r^{-2} = r^2$ in D_8).

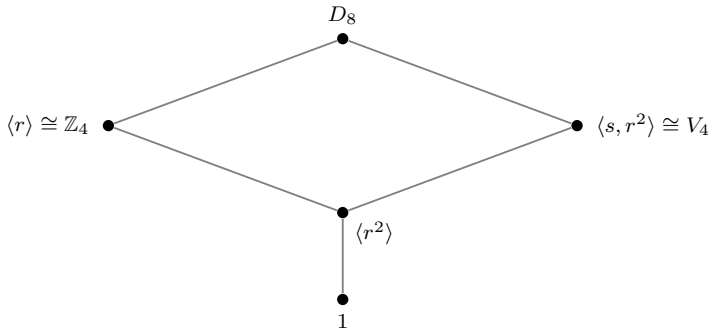
Solution. Seed: $1,\ s$ $(s^{-1} = s),\ r^2$ $((r^2)^{-1} = r^{-2} = r^2)$. Form products:

$$s \cdot r^2 = sr^2, \qquad r^2 \cdot s = sr^{-2} = sr^2 \quad \text{(same element, so the set is commutative here)}.$$

Check the new element squares to 1: $(sr^2)^2 = sr^2sr^2 = s(r^2s)r^2 = s(sr^{-2})r^2 = s^2r^{-2}r^2 = 1$. Also $(r^2)^2 = r^4 = 1$. No further products escape: $\{1, r^2, s, sr^2\}$ is closed. *Check.* The closure has 4 elements, all of order dividing 2, and it is abelian (we saw $s\,r^2 = r^2\,s$). A group of order 4 with every non-identity element of order 2 is the Klein four-group, so $\langle s, r^2\rangle \cong V_4$. Sanity: $|D_8| = 8$, and $4 \mid 8$ as Lagrange demands.

Worked Example 2.4.12 ($\langle i, j\rangle = Q_8$)**.** In $Q_8 = \{\pm1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$ (and $ji = -k$, etc.), compute $\langle i, j\rangle$.

Recognition. Nonabelian ambient Q_8: word closure, products in both orders, using the quaternion multiplication relations. Trigger: "$\langle i, j\rangle$."



Solution. Seed: $1,\ i,\ i^{-1} = -i$ (since $i^2 = -1 \Rightarrow i^{-1} = -i$), $\ j,\ j^{-1} = -j$. Generate:

$$ij = k, \qquad ji = -k, \qquad i^2 = -1, \qquad (-1)\cdot 1 = -1.$$

Adjoining k and -1, then $-k = (-1)k$, $-i = (-1)i$, $-j = (-1)j$, the set becomes $\{\pm1, \pm i, \pm j, \pm k\}$. Every further product stays inside (e.g. $jk = i$, $kj = -i$, $ki = j$), so the closure is all 8 units. *Check.* $|\langle i, j\rangle| = 8 = |Q_8|$, so $\langle i, j\rangle = Q_8$. Note $j \notin \langle i\rangle = \{\pm1, \pm i\}$ (order 4), so a single generator is genuinely insufficient — both i and j are needed.

Caution. In a *nonabelian* group you may not reorder letters: $\langle i, j\rangle$ in Q_8 needs both $ij = k$ *and* $ji = -k$. Skipping the reversed products (or trying to "collect exponents" as in the abelian case) will undercount the subgroup. Only after you prove the elements commute — as with $\{1, r^2, s, sr^2\}$ in D_8 — may you treat the closure abelianly.

Lattice picture. The two dihedral examples sit inside the subgroup lattice of D_8. Below, $\langle s, r^2\rangle \cong V_4$ is the order-4 subgroup on the right; $\langle r\rangle \cong \mathbb{Z}_4$ is cyclic; the bottom is 1 and the top is D_8.

Every chain rises from 1 to D_8, and $\langle r^2\rangle = \{1, r^2\}$ is the common order-2 subgroup through which both the cyclic and the V_4 branch pass — exactly the element r^2 we reused as a generator in the V_4 example.

Further examples and the book's language

D&F fixes a little vocabulary around generating sets and works several standard generating-set examples at an elementary level. We collect the items the section above did not already record.

Remark 2.4.1 (Generated-by language and "finitely generated"). Beyond the notation $\langle A\rangle$ and $\langle a_1, \ldots, a_n\rangle$ already fixed in Definition 2.4.2, D&F uses two phrasings throughout:

- *G is generated by A* (equivalently *A generates G*) means $\langle A\rangle = G$.
- A group G is called *finitely generated* if $G = \langle A\rangle$ for some finite set A.

The single-element case $\langle x\rangle$ is exactly the cyclic subgroup studied in the previous section; the present construction is its generalization to arbitrary A, and the next example checks that the two uses of the symbol $\langle x\rangle$ agree.

Worked Example 2.4.13 ($\langle x\rangle$ recovers the cyclic subgroup)**.** For a single element $x \in G$ (with G possibly nonabelian), verify that the word description of $\langle\{x\}\rangle$ collapses to $\{x^n \mid n \in \mathbb{Z}\}$.

Recognition. Single generator, $A = \{x\}$. Theorem 2.4.3 (word description) applies: words use only the one letter x and its inverse x^{-1}, so commutativity of the ambient group is irrelevant here.

Solution. A word $a_1^{\varepsilon_1} \cdots a_k^{\varepsilon_k}$ with every $a_i = x$ is $x^{\varepsilon_1} x^{\varepsilon_2} \cdots x^{\varepsilon_k} = x^{\varepsilon_1 + \cdots + \varepsilon_k}$, an integer power of x. Conversely every x^n ($n \in \mathbb{Z}$) is such a word: take n copies of x if $n > 0$, of x^{-1} if $n < 0$, and the empty word if $n = 0$. Hence $\langle\{x\}\rangle = \{x^n \mid n \in \mathbb{Z}\} = \langle x\rangle$. *Check.* This matches the cyclic-subgroup meaning of $\langle x\rangle$ from the prior section, so writing $\langle x\rangle$ for both is consistent. If $|x| = m < \infty$ the distinct powers are $1, x, \ldots, x^{m-1}$, recovering $|\langle x\rangle| = |x|$.

Worked Example 2.4.14 ($\mathbb{Z} = \langle 1\rangle$ and $\mathbb{Z}/n\mathbb{Z} = \langle\overline{1}\rangle$)**.** Exhibit single generators for the basic cyclic groups $\mathbb{Z}$ and $\mathbb{Z}/n\mathbb{Z}$.

Recognition. One generator suffices for a cyclic group; here G is cyclic with a named candidate generator, so $\langle x\rangle = G$ reduces to checking that x reaches every element.

Solution. In $(\mathbb{Z}, +)$, every integer is $m = m \cdot 1$, an integer multiple of 1, so $\langle 1\rangle = \{m \cdot 1 \mid m \in \mathbb{Z}\} = \mathbb{Z}$. In $(\mathbb{Z}/n\mathbb{Z}, +)$, every class is $\overline{m} = m \cdot \overline{1}$, so $\langle\overline{1}\rangle = \mathbb{Z}/n\mathbb{Z}$. *Check.* For $\mathbb{Z}/n\mathbb{Z}$ this agrees with $|\langle\overline{1}\rangle| = n/\gcd(1, n) = n = |\mathbb{Z}/n\mathbb{Z}|$. More generally $\overline{a}$ generates $\mathbb{Z}/n\mathbb{Z}$ iff $\gcd(a, n) = 1$; for $n = 12$ the generators are $\overline{1}, \overline{5}, \overline{7}, \overline{11}$, the four units mod 12.

Worked Example 2.4.15 ($D_{2n} = \langle r, s\rangle$)**.** In $D_{2n} = \langle r, s \mid r^n = s^2 = 1,\ sr = r^{-1}s\rangle$, show that the rotation r and reflection s generate the whole group.

Recognition. Nonabelian ambient D_{2n}. The defining relations name $\{r, s\}$ as a generating set, so the task is to confirm the word closure already has all $2n$ elements. The tool is the master relation $r^k s = s\, r^{-k}$, used to put every word into normal form.

Solution. Take any word in r, s, r^{-1}, s^{-1}. Since $s^{-1} = s$, every letter is a power of r or a single s. Using $r^k s = s\, r^{-k}$ one moves each s leftward past the r-powers; since $s^2 = 1$, at most one s survives. Thus every

element reduces to r^i or $s\,r^i$ with $0 \le i \le n-1$. These are the n rotations $1, r, \dots, r^{n-1}$ and the n reflections $s, sr, \dots, sr^{n-1}$, i.e. all $2n$ elements. Hence $\langle r, s\rangle = D_{2n}$. *Check.* The count is $n+n = 2n = |D_{2n}|$. Concretely in D_8 ($n = 4$) the eight elements $\{1, r, r^2, r^3, s, sr, sr^2, sr^3\}$ are all reached, matching $|D_8| = 8$ and the normal form used throughout these notes.

Worked Example 2.4.16 (A single reflection generates only an order-2 subgroup)**.** In D_{2n}, compute $\langle s\rangle$ for a reflection s.

Recognition. Single generator s with $s^2 = 1$, so $|s| = 2$; by the single-generator description $\langle s\rangle = \{s^n \mid n \in \mathbb{Z}\}$ has order $|s|$.

Solution. Since $s^2 = 1$, the powers of s are $s^0 = 1$ and $s^1 = s$, so $\langle s\rangle = \{1, s\}$, a subgroup of order 2. *Check.* $2 \mid 2n$, as Lagrange requires, and a single reflection cannot produce any rotation r^i with $i \not\equiv 0$, confirming $\langle s\rangle \neq D_{2n}$ for $n \ge 2$. So two generators (such as r, s) are genuinely needed to reach all of D_{2n}.

Proposition 2.4.17 (Pairwise-commuting generators)**.** *Let $A = \{a_1, \dots, a_n\} \subseteq G$ and suppose the generators commute pairwise, $a_i a_j = a_j a_i$ for all i, j. Then every element of $\langle A\rangle$ can be written in the collected form*

$$a_1^{m_1} a_2^{m_2} \cdots a_n^{m_n}, \qquad m_1, \dots, m_n \in \mathbb{Z},$$

and $\langle A\rangle$ is abelian.

Proof. By Theorem 2.4.3 each element of $\langle A\rangle$ is a word in the $a_i^{\pm 1}$. Because the generators commute pairwise, any two adjacent letters may be swapped; repeatedly swapping sorts every word so that all $a_1^{\pm 1}$ come first, then all $a_2^{\pm 1}$, and so on, and within the a_i-block the exponents add to a single integer m_i, giving $a_1^{m_1} \cdots a_n^{m_n}$. Two such collected expressions commute, since each a_i commutes with every a_j, so $\langle A\rangle$ is abelian. (This refines Corollary 2.4.4: there the whole group was abelian, here only the chosen generators need commute.) □

Remark 2.4.2 (Using "smallest" to identify $\langle A\rangle$ without listing words). Definition 2.4.2 packages $\langle A\rangle$ as an intersection so that, to prove a candidate set K equals $\langle A\rangle$, one need not enumerate words: show $K \le G$ and $A \subseteq K$ (forcing $\langle A\rangle \subseteq K$ by the smallest property), then show every generator's contributions land in $\langle A\rangle$ (forcing $K \subseteq \langle A\rangle$). The $D_{2n} = \langle r, s\rangle$ and $\mathbb{Z} = \langle 1\rangle$ computations above are both instances of this two-inclusion pattern.

Further worked examples

More generated subgroups (Theorem 2.4.3; $\mathbb{Z}$-case Theorem 2.4.5).

Worked Example 2.4.18 ($\langle 6, 8, 10\rangle$ in $\mathbb{Z}$)**.** *Recognition.* Generated subgroup of $(\mathbb{Z}, +)$ from several integers; in $\mathbb{Z}$ every subgroup is $\langle d\rangle = d\mathbb{Z}$, and $\langle a_1, \dots, a_k\rangle = \langle \gcd(a_1, \dots, a_k)\rangle$.

Solution. $\gcd(6, 8, 10) = 2$, so $\langle 6, 8, 10\rangle = 2\mathbb{Z}$. *Check.* $2 = 8 - 6 \in \langle 6, 8\rangle$, so all even numbers arise; and $6, 8, 10$ are even, so nothing odd arises. Hence exactly $2\mathbb{Z}$.

Worked Example 2.4.19 ($\langle \overline{3}, \overline{5}\rangle$ in $\mathbb{Z}/15\mathbb{Z}$)**.** *Recognition.* Generated subgroup in a cyclic group; reduce to a single generator via gcd with the modulus.

Solution. $\langle \overline{3}, \overline{5}\rangle \ni \overline{5} - \overline{3} = \overline{2}$ and $\overline{3} - \overline{2} = \overline{1}$, so the subgroup contains $\overline{1}$ and equals all of $\mathbb{Z}/15\mathbb{Z}$. (Equivalently $\gcd(3, 5, 15) = 1$.) *Check.* $\overline{3}$ alone has order 5 and $\overline{5}$ alone has order 3; together they generate order divisible by $\operatorname{lcm}(5, 3) = 15$.

Worked Example 2.4.20 ($\langle (1\,2)(3\,4),\ (1\,3)(2\,4)\rangle$ in A_4)**.** *Recognition.* Subgroup generated by two elements of order 2; close under products (these two commute, so the result is small).

Solution. The product $(1\,2)(3\,4) \cdot (1\,3)(2\,4) = (1\,4)(2\,3)$, and squares are e, so

$$\langle (1\,2)(3\,4), (1\,3)(2\,4)\rangle = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\} \cong V_4,$$

of order 4. *Check.* The three nonidentity elements have order 2 and pairwise products give the third, the Klein four-group pattern.

Maps and commutative diagrams

The phrase "smallest subgroup containing A" is a universal property, and universal properties are diagrams.
(a) The universal property of $\langle A\rangle$. $\langle A\rangle$ is the smallest subgroup containing A: for *every* subgroup H with $A \subseteq H$, the inclusion of A into H factors uniquely through $A \hookrightarrow \langle A\rangle$ (Definition 2.4.2). Equivalently, $\langle A\rangle \leq H$ whenever $A \subseteq H$.

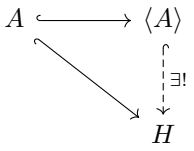


Diagram explanation. Objects: Three groups appear: the subset A (treated as a discrete set sitting inside G), the subgroup $\langle A\rangle \leq G$ (the smallest subgroup containing A, as in Definition 2.4.2), and an arbitrary subgroup $H \leq G$ that happens to contain A.

Arrows: The top horizontal arrow $A \hookrightarrow \langle A\rangle$ is the set inclusion of A into the subgroup it generates. The diagonal arrow $A \hookrightarrow H$ is the inclusion of A into H (given by hypothesis $A \subseteq H$). The dashed vertical arrow $\langle A\rangle \to H$ is the unique subgroup inclusion $\langle A\rangle \hookrightarrow H$; it is an inclusion of subgroups, not merely a set map. The $\exists!$ label records that this arrow is *uniquely determined*: there is exactly one group homomorphism from $\langle A\rangle$ to H that restricts to the given inclusion of A.

What commutes: The triangle commutes: the diagonal equals the vertical composed with the horizontal, i.e. the inclusion $A \hookrightarrow H$ equals the composite $A \hookrightarrow \langle A\rangle \hookrightarrow H$.

Why it commutes: Take any $a \in A$. Along the top-then-down path: a maps to itself in $\langle A\rangle$ (top inclusion), then maps to itself in H (the unique inclusion $\langle A\rangle \hookrightarrow H$ sends $a \mapsto a$ since it is a subgroup inclusion extending the given map on A). Along the diagonal: a maps directly to itself in H. Both paths send $a \mapsto a \in H$, so they agree. Well-definedness of the dashed arrow: since $\langle A\rangle$ is generated by A and every $a \in A$ already lies in H, any word $a_1^{\varepsilon_1} \cdots a_k^{\varepsilon_k}$ in $\langle A\rangle$ maps to the same word in H (which is a subgroup, so the word lands in H); no ambiguity arises.

Why this matters here: This diagram is the diagrammatic restatement of the "smallest" property proved right before it: $\langle A\rangle \leq H$ whenever $A \subseteq H \leq G$. The dashed arrow encodes minimality – $\langle A\rangle$ maps *into* every H containing A, not the other way around. It is placed here to show that Definition 2.4.2 is a universal property, not just a set-theoretic construction.

Concrete example: Take $G = S_3$, $A = \{(1\,2), (2\,3)\}$, $H = S_3$. Then $\langle A\rangle = S_3$ and the dashed arrow is id_{S_3}. Or take $H = \langle (1\,2), (1\,3), (2\,3)\rangle = S_3$ and $A = \{(1\,2)\}$; then $\langle A\rangle = \{e, (1\,2)\} \leq S_3 = H$, and the inclusion is the obvious one.

Common pitfall: Students sometimes read the dashed arrow as an isomorphism or as a surjection. It is only an inclusion $\langle A\rangle \hookrightarrow H$; it need not be surjective (e.g. $\langle (1\,2)\rangle \subsetneq S_3$). The $\exists!$ refers to uniqueness of the *inclusion*, not to an isomorphism.

Takeaway: The point of this diagram is that the universal property of $\langle A\rangle$ is precisely the statement that $\langle A\rangle$ is the initial object in the category of subgroups of G containing A.

(b) Generation is functorial. A homomorphism $f : G \to K$ carries $\langle A\rangle$ onto $\langle f(A)\rangle$, because f of a word in A is a word in $f(A)$ (Theorem 2.4.3). Every square below commutes; in particular generators map to generators.

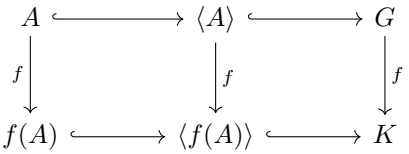

Diagram explanation. Objects: Six objects in a 2×3 grid. Top row: subset $A \subseteq G$, the subgroup $\langle A\rangle \leq G$, and the ambient group G. Bottom row: image set $f(A) \subseteq K$, the subgroup $\langle f(A)\rangle \leq K$, and the ambient group K. Here $f : G \to K$ is a group homomorphism.

Arrows: The two horizontal inclusions in the top row are $A \hookrightarrow \langle A\rangle \hookrightarrow G$ (set inclusion then subgroup inclusion). Similarly $f(A) \hookrightarrow \langle f(A)\rangle \hookrightarrow K$ in the bottom row. The three vertical arrows are all labeled f: the leftmost sends $a \mapsto f(a)$, the middle restricts f to $\langle A\rangle$ (which is again denoted f since it is the same map on a subset of G), and the rightmost is $f : G \to K$ itself.

What commutes: Each of the two squares commutes independently. Left square: $f \circ \iota_{A,\langle A\rangle} = \iota_{f(A),\langle f(A)\rangle} \circ f$, i.e. including A into $\langle A\rangle$ and then applying f gives the same result as applying f to A and then including $f(A)$ into $\langle f(A)\rangle$. Right square: $f \circ \iota_{\langle A\rangle,G} = \iota_{\langle f(A)\rangle,K} \circ f|_{\langle A\rangle}$, i.e. including $\langle A\rangle$ into G then applying f equals restricting f to $\langle A\rangle$ then including into K.

Why it commutes: For the left square, take $a \in A$. Down-then-right: $a \mapsto f(a) \in f(A) \hookrightarrow \langle f(A)\rangle$. Right-then-down: $a \in A \hookrightarrow \langle A\rangle$, then $f(a) \in \langle f(A)\rangle$. Both paths give $f(a)$ sitting in $\langle f(A)\rangle$, so they agree. The key fact: f sends every generator $a \in A$ to $f(a) \in f(A)$, and since f is a homomorphism it sends every word $a_1^{\varepsilon_1} \cdots a_k^{\varepsilon_k}$ to $f(a_1)^{\varepsilon_1} \cdots f(a_k)^{\varepsilon_k}$, which is a word in $f(A)$, hence in $\langle f(A)\rangle$. This is exactly Theorem 2.4.3 applied to f.

Why this matters here: This diagram encodes the sentence "$f(\langle A\rangle) = \langle f(A)\rangle$" in a way that also records where each inclusion sits. It confirms that generating sets behave well under homomorphisms: the image of the generated subgroup is the subgroup generated by the image of the generating set. This is used implicitly whenever one argues that a homomorphism is surjective by checking it hits a generating set.

Concrete example: Let $G = \mathbb{Z}$, $K = \mathbb{Z}/6\mathbb{Z}$, $f(n) = \overline{n}$ the reduction map, $A = \{2\}$. Then $\langle A\rangle = 2\mathbb{Z}$, $f(A) = \{\overline{2}\}$, $\langle f(A)\rangle = \langle\overline{2}\rangle = \{\overline{0}, \overline{2}, \overline{4}\}$. The left square sends $2 \mapsto \overline{2}$ both ways; the right square confirms $f(2\mathbb{Z}) = \{\overline{0}, \overline{2}, \overline{4}\} = \langle\overline{2}\rangle$, as the diagram predicts.

Common pitfall: Students sometimes write $f(\langle A\rangle) = \langle A\rangle$ (confusing image with domain), or assume $f(\langle A\rangle) = K$ merely because f is surjective (for $A = \{2\}$ above, $f(\langle A\rangle) = \{\overline{0}, \overline{2}, \overline{4}\} \neq \mathbb{Z}/6\mathbb{Z}$). The correct statement is $f(\langle A\rangle) = \langle f(A)\rangle$, which equals K only when $f(A)$ generates K.

Takeaway: The point of this diagram is that a group homomorphism is compatible with generation, carrying the subgroup generated by A to the subgroup generated by the image of A.

(c) The universal property of the free group. The "most general" group generated by a set S is the free group $F(S)$: any set map $S \to G$ extends to a *unique* homomorphism $F(S) \to G$. This is the precise meaning of "the generators satisfy no relations," and it is why $S_n = \langle(1\,2), (1\,2\cdots n)\rangle$ etc. are described by giving generators and relations.

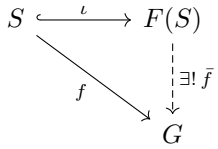

Diagram explanation. Objects: Three objects. The set S (not yet a group – just a generating alphabet, e.g. $S = \{a, b\}$ for a two-generator free group). The free group $F(S)$, the group of all reduced words in $S \cup S^{-1}$ with no relations other than $ss^{-1} = 1$. The target group G, an arbitrary group equipped with a set map $f : S \to G$.

Arrows: $\iota : S \to F(S)$ is the canonical inclusion sending each letter $s \in S$ to the length-one word $s \in F(S)$ (the set-theoretic embedding, not a group homomorphism since S is not a group). $f : S \to G$ is any set map (possibly $f(s_1) = f(s_2)$ for distinct s_1, s_2; no homomorphism condition required on f since S has no group structure). The dashed arrow $\bar{f} : F(S) \to G$ is the *unique group homomorphism* extending f: it sends the word $s_1^{\varepsilon_1} \cdots s_k^{\varepsilon_k}$ to $f(s_1)^{\varepsilon_1} \cdots f(s_k)^{\varepsilon_k} \in G$.

What commutes: The triangle commutes: $\bar{f} \circ \iota = f$, i.e. restricting $\bar{f}$ to the generating set $S \subset F(S)$ recovers the original set map f.

Why it commutes: For any $s \in S$, $\bar{f}(\iota(s)) = \bar{f}(s) = f(s)$ by the definition of $\bar{f}$ (it is defined to send each generator s of $F(S)$ to $f(s)$, and then extended to all words by the homomorphism rule). Uniqueness: any homomorphism $h : F(S) \to G$ satisfying $h \circ \iota = f$ must send $s \mapsto f(s)$ for each s; since $F(S)$ is generated by S, this determines h on all of $F(S)$ (a homomorphism is determined by its values on generators), so $h = \bar{f}$.

Why this matters here: This diagram explains why generators and relations suffice to define a group homomorphism out of any group $G = \langle a_1, \ldots, a_n \mid \text{relations}\rangle$: one first defines a set map on the generators, extends freely to $F(S)$ via $\bar{f}$, and then checks the relations are preserved (which forces $\bar{f}$ to factor through

the quotient G). The author places it here to make precise the phrase "no relations" and to connect subgroup generation to the broader framework of presentations.

Concrete example: Let $S = \{x\}$ (one letter), $G = \mathbb{Z}/6\mathbb{Z}$, $f(x) = \overline{2}$. Then $F(S) = \mathbb{Z}$ (the free group on one generator is $\mathbb{Z}$), and $\bar{f} : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ sends $n \mapsto \overline{2n}$, a group homomorphism. The triangle: $\bar{f}(\iota(x)) = \bar{f}(1) = \overline{2} = f(x)$. The image is $\langle\overline{2}\rangle = \{\overline{0}, \overline{2}, \overline{4}\}$, a proper subgroup of $\mathbb{Z}/6\mathbb{Z}$.

Common pitfall: The map $\iota : S \to F(S)$ is a set map, not a group homomorphism (since S has no group structure). Students sometimes write "ι is a homomorphism," which is meaningless. Also, $\bar{f}$ need not be injective or surjective: the free group is big (it surjects onto every group generated by $|S|$ elements), but $\bar{f}$ can collapse much of $F(S)$ depending on what relations hold in G.

Takeaway: The point of this diagram is that specifying a group homomorphism out of $F(S)$ is the same as specifying a set map out of S, making the free group the universal group generated by the set S with no constraints.

Exercises (from the text).

1. Prove $H \leq G \implies \langle H\rangle = H$.
2. Prove $A \subseteq B \implies \langle A\rangle \leq \langle B\rangle$, and give $A \subsetneq B$ with $\langle A\rangle = \langle B\rangle$.
3. Prove that if H is abelian then $\langle H, Z(G)\rangle$ is abelian; give an abelian H with $\langle H, C_G(H)\rangle$ *not* abelian.
4. Prove $H \leq G \implies H = \langle H \setminus \{1\}\rangle$.
5. Prove two distinct elements of order 2 in S_3 generate S_3.
6. Prove $\langle(1\,2), (1\,2)(3\,4)\rangle$ is non-cyclic of order 4.
7. Prove $\langle(1\,2), (1\,3)(2\,4)\rangle \cong D_8$.
8. Prove $S_4 = \langle(1\,2\,3\,4), (1\,2\,4\,3)\rangle$.
9. Prove $\mathrm{SL}_2(\mathbb{F}_3) = \langle \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right), \left(\begin{smallmatrix}1&0\\1&1\end{smallmatrix}\right)\rangle$.
10. Prove the subgroup of $\mathrm{SL}_2(\mathbb{F}_3)$ generated by $\left(\begin{smallmatrix}1&1\\1&-1\end{smallmatrix}\right)$ and $\left(\begin{smallmatrix}-1&1\\1&1\end{smallmatrix}\right)$ is $\cong Q_8$.
11. Prove $\mathrm{SL}_2(\mathbb{F}_3) \ncong S_4$ (both of order 24).
12. Prove the upper-triangular subgroup of $\mathrm{GL}_3(\mathbb{F}_2)$ is $\cong D_8$.
13. Prove $(\mathbb{Q}^+, \cdot) = \langle\{1/p \mid p \text{ prime}\}\rangle$.
14. Finitely generated groups: (a) finite groups are f.g.; (b) $\mathbb{Z}$ is f.g.; (c) a f.g. subgroup of $\mathbb{Q}$ is cyclic; (d) $\mathbb{Q}$ is not f.g.
15. Exhibit a proper non-cyclic subgroup of $\mathbb{Q}$.
16. Maximal subgroups: (a) every proper subgroup of a finite group lies in a maximal one; (b) the rotation subgroup of D_{2n} is maximal; (c) H is maximal in $Z_n = \langle x\rangle \iff H = \langle x^p\rangle$ for a prime $p \mid n$.
17. (Zorn) Prove every nontrivial finitely generated group has a maximal subgroup.
18. Prüfer group $\mathbb{Z}_{p^\infty} = \{z \in \mathbb{C} \mid z^{p^n} = 1 \text{ some } n\}$, $H_k = \{z \mid z^{p^k} = 1\}$: prove $H_k \leq H_m \iff k \leq m$; each H_k is cyclic; every proper subgroup is some H_k; and $\mathbb{Z}_{p^\infty}$ is not f.g.
19. A nontrivial abelian group is *divisible* if every element has a kth root for each $k \neq 0$. Prove $(\mathbb{Q}, +)$ is divisible and no nontrivial finite abelian group is.
20. For nontrivial abelian A, B, prove $A \times B$ is divisible $\iff$ both A and B are divisible.

Additional exercises.

1. Prove $\langle A \cup B\rangle = \langle\langle A\rangle \cup \langle B\rangle\rangle$.
2. Prove $\langle A\rangle = \bigcup_{F \subseteq A \text{ finite}} \langle F\rangle$.
3. Prove that the free group on two generators is infinite and non-abelian.

4. Prove that the unipotent upper-triangular group in $\mathrm{GL}_3(\mathbb{F}_p)$ is generated by the two elementary matrices $I + E_{12}$ and $I + E_{23}$.

5. Prove that a subgroup of a finitely generated *abelian* group is finitely generated. (Contrast: this can fail for non-abelian groups.)

Commutative-diagram exercises.

1. (Universal property of $\langle A\rangle$) Prove that if $A \subseteq H \leq G$ then $\langle A\rangle \leq H$, and phrase it diagrammatically: the inclusion $A \hookrightarrow H$ factors uniquely through $A \hookrightarrow \langle A\rangle$.

2. Prove generation is functorial: for a homomorphism $f : G \to K$, $f(\langle A\rangle) = \langle f(A)\rangle$. Check that each square of the functoriality diagram commutes, and deduce that f carries a generating set of G to a generating set of $f(G)$.

3. (Universal property of the free group) Using that any set map $S \to G$ extends uniquely to a homomorphism $F(S) \to G$, prove every group generated by a set S is a quotient of $F(S)$; draw the surjection $F(S) \twoheadrightarrow G$.

4. Prove $\langle A \cup B\rangle = \langle \langle A\rangle \cup \langle B\rangle\rangle$ and interpret both sides as the join $\langle A\rangle \vee \langle B\rangle$ in the subgroup lattice.

2.5 The Lattice of Subgroups

The subgroup lattice: Hasse diagrams, joins, and meets

Every group G has a collection $\mathcal{L}(G)$ of all its subgroups. This collection is partially ordered by inclusion ($H \leq K$ means H is a subgroup of K), and it has enough structure to be drawn as a single picture — the *Hasse diagram* — from which every containment, every intersection, and every "smallest subgroup containing two given ones" can be read off by eye. This section sets up that picture and the two operations (meet and join) that make $\mathcal{L}(G)$ a lattice.

Definition 2.5.1. For a group G, write $H \leq K$ to mean H is a subgroup of K. The relation $\leq$ on the set $\mathcal{L}(G)$ of all subgroups of G is a *partial order*: it is reflexive ($H \leq H$), antisymmetric ($H \leq K$ and $K \leq H$ force $H = K$), and transitive ($H \leq K \leq L$ gives $H \leq L$).

Definition 2.5.2. Let $B < A$ (so B is a proper subgroup of A). We say A *covers* B, written $B \lessdot A$, if there is no subgroup C with $B < C < A$ — that is, nothing strictly between them. The *Hasse diagram* of G has one vertex per subgroup, drawn so that B sits lower than A whenever $B < A$, and an edge (segment) joins B to A exactly when A covers B. The trivial subgroup $1 = \{e\}$ is the unique bottom vertex; G is the unique top vertex.

Remark 2.5.1. We do *not* draw an edge for every containment, only for coverings. A containment $B < A$ that is not a covering is recovered from the diagram as an *upward path* of two or more edges. For instance in $\mathbb{Z}/12\mathbb{Z}$ we have $\langle 6\rangle < \mathbb{Z}/12\mathbb{Z}$ but the edge from $\langle 6\rangle$ does not go straight to the top; the containment is read off as a path through $\langle 2\rangle$ or through $\langle 3\rangle$. This is why Hasse diagrams stay readable: transitivity is encoded by paths, not by a tangle of extra segments.

Definition 2.5.3. Let $H, K \leq G$.

- The *meet* of H and K is their intersection $H \cap K$. It is the *largest* subgroup contained in both: it lies below both H and K in the diagram, and any subgroup below both lies below $H \cap K$.
- The *join* of H and K is $\langle H, K\rangle$, the smallest subgroup containing both. It is the intersection of all subgroups that contain $H \cup K$; concretely it is the set of all finite products $x_1 x_2 \cdots x_m$ with each $x_i \in H \cup K$. It is the *smallest* subgroup lying above both H and K.

We write $H \wedge K = H \cap K$ and $H \vee K = \langle H, K\rangle$.

Proposition 2.5.4. *For any nonempty family $\{H_i\}_{i\in I}$ of subgroups of G, the intersection $\bigcap_{i\in I} H_i$ is a subgroup of G. Consequently $H \cap K$ and $\langle H, K\rangle$ both exist and are subgroups, so $\mathcal{L}(G)$ is a* lattice*: every pair has a meet and a join.*

Proof. Let $D = \bigcap_i H_i$. Since $e \in H_i$ for every i, $e \in D$, so $D \neq \varnothing$. If $a, b \in D$ then $a, b \in H_i$ for each i; each H_i is a subgroup, so $ab^{-1} \in H_i$ for each i, hence $ab^{-1} \in D$. By the subgroup criterion $D \leq G$. For the join, let $\mathcal{S}$ be the (nonempty, since $G \in \mathcal{S}$) collection of all subgroups containing $H \cup K$; then $\langle H, K \rangle = \bigcap_{S \in \mathcal{S}} S$ is a subgroup by the first part, and it is by construction the smallest subgroup above both H and K. The meet $H \cap K$ is the case of two subgroups. □

Proposition 2.5.5. *Let $G = \mathbb{Z}/n\mathbb{Z} = \langle x \rangle$ be cyclic of order n. For each divisor $d \mid n$ there is exactly one subgroup of order d, namely $\langle x^{n/d} \rangle$, and these are* all *the subgroups. Containment matches divisibility:*

$$\langle x^{n/d_1} \rangle \leq \langle x^{n/d_2} \rangle \quad \iff \quad d_1 \mid d_2.$$

Hence the Hasse diagram of $\mathbb{Z}/n\mathbb{Z}$ is exactly the divisor lattice *of n: vertices are the divisors of n, with d_1 below d_2 when $d_1 \mid d_2$, and a covering edge when d_2/d_1 is prime.*

Proof. By the classification of subgroups of a cyclic group, every subgroup of $\langle x \rangle$ is cyclic of the form $\langle x^m \rangle$, and $\langle x^m \rangle = \langle x^{\gcd(m,n)} \rangle$ has order $n/\gcd(m,n)$. As $\gcd(m,n)$ ranges over the divisors of n, the order $n/\gcd(m,n)$ ranges over the divisors of n, each occurring for a unique subgroup; so there is exactly one subgroup of each order $d \mid n$, equal to $\langle x^{n/d} \rangle$. For containment, $\langle x^{n/d_1} \rangle \leq \langle x^{n/d_2} \rangle$ holds iff the order d_1 divides the order d_2 (a subgroup of a cyclic group of order d_2 has order dividing d_2, and there is a unique one of each such order), i.e. iff $d_1 \mid d_2$. A covering corresponds to a divisibility $d_1 \mid d_2$ with no divisor strictly between, i.e. d_2/d_1 prime. □

Method (How to build the subgroup lattice (Hasse diagram) of a finite group)**.** Use this whenever you are asked to "draw the lattice of subgroups" or to read a join/meet off a picture.

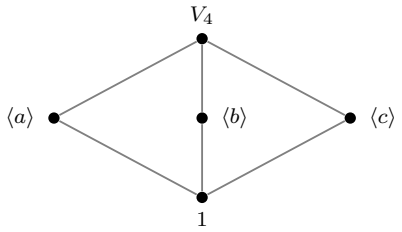
1. **List all subgroups, grouped by order.** By Lagrange every subgroup order divides $|G|$, so you only need to search orders $d \mid |G|$. For cyclic $G = \mathbb{Z}/n\mathbb{Z}$ this is automatic: one subgroup $\langle x^{n/d} \rangle$ per divisor d (Proposition 2.5.5). For non-cyclic G, find all subgroups of each allowed order directly (e.g. all cyclic $\langle g \rangle$, then larger ones).

2. **Place vertices vertically by order.** Bottom row: the trivial group 1 (order 1). Top: G (order $|G|$). Subgroups of equal order sit at the same height; larger order sits higher.

3. **Draw covering edges only.** Join B up to A iff $B < A$ with nothing in between (Definition 2.5.2). A quick test: if $B < A$ and the index $[A : B]$ is prime, then A covers B (no room for an intermediate subgroup by Lagrange). Never draw an edge for a containment that already factors through a third subgroup.

4. **Read joins and meets off the picture.** $H \wedge K = H \cap K$ is the highest vertex lying below both H and K (their highest common lower bound). $H \vee K = \langle H, K \rangle$ is the lowest vertex lying above both. "Below/above" means reachable by a downward/upward path of edges.

Caution. Do not put an edge from 1 straight up to G unless G has *no* proper nontrivial subgroups (i.e. G is cyclic of prime order). If any subgroup sits between them, that edge is wrong — the containment $1 < G$ is a multi-edge path, not a covering.



Worked Example 2.5.6 (Lattice of V_4)**.** Draw the subgroup lattice of the Klein four-group $V_4 = \{1, a, b, c\}$ with $a^2 = b^2 = c^2 = 1$ and $ab = c$.

Recognition. This is a request to "build the lattice" (the four-step Method). $|V_4| = 4$, so by Lagrange the only possible subgroup orders are $1, 2, 4$. There is no element of order 4 (every non-identity element is an involution), so V_4 is non-cyclic; its order-2 subgroups must be found directly.

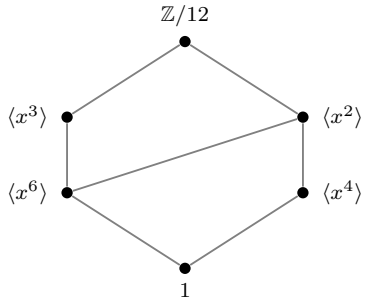
Solution. Step 1 (subgroups by order). Order 1: $\{1\}$. Order 4: V_4 itself. Order 2: each is generated by an involution, $\langle a \rangle = \{1, a\}$, $\langle b \rangle = \{1, b\}$, $\langle c \rangle = \{1, c\}$. These three are distinct, and there are no others (any subgroup of order 2 is $\{1, g\}$ with $g^2 = 1$, $g \neq 1$). Total: 5 subgroups.

Step 2 (heights). Bottom 1; middle row $\langle a \rangle, \langle b \rangle, \langle c \rangle$ (order 2); top V_4.

Step 3 (covering edges). Each $\langle a \rangle, \langle b \rangle, \langle c \rangle$ contains 1 with index 2 (prime), so each covers 1: three edges up from the bottom. Each is contained in V_4 with index 2 (prime), so V_4 covers each: three edges to the top. No edge from 1 to V_4 directly.

Check. The "diamond" shape has 1 at bottom, three pairwise-incomparable atoms, and V_4 on top, which matches the known fact that $V_4 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ has exactly three subgroups of order 2. Sanity: 3 middle +2 (1 and V_4) = 5 subgroups.

Worked Example 2.5.7 (Divisor lattice of $\mathbb{Z}/12\mathbb{Z}$)**.** Draw the subgroup lattice of $\mathbb{Z}/12\mathbb{Z} = \langle x\rangle$, $|x| = 12$.



Recognition. G is cyclic, so Proposition 2.5.5 applies: subgroups $\leftrightarrow$ divisors of 12, and the Hasse diagram *is* the divisor lattice of 12. No element-by-element search is needed.

Solution. Step 1. Divisors of 12 are $1, 2, 3, 4, 6, 12$, giving one subgroup of each order:

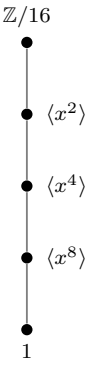
$$1 = \langle x^{12}\rangle,\ \langle x^6\rangle\ (|2|),\ \langle x^4\rangle\ (|3|),\ \langle x^3\rangle\ (|4|),\ \langle x^2\rangle\ (|6|),\ \langle x\rangle = \mathbb{Z}/12\mathbb{Z}.$$

Step 2. Heights by order: 1 at the bottom; $\langle x^6\rangle$ (order 2) and $\langle x^4\rangle$ (order 3) low; $\langle x^3\rangle$ (order 4) and $\langle x^2\rangle$ (order 6) high; $\mathbb{Z}/12\mathbb{Z}$ on top.

Step 3 (coverings via prime index). $1 \lessdot \langle x^6\rangle$ (index 2), $1 \lessdot \langle x^4\rangle$ (index 3). Then $\langle x^6\rangle \lessdot \langle x^2\rangle$ (orders $2 \mid 6$, ratio 3) and $\langle x^6\rangle \lessdot \langle x^3\rangle$ (orders $2 \mid 4$, ratio 2); $\langle x^4\rangle \lessdot \langle x^2\rangle$ (orders $3 \mid 6$, ratio 2). Finally $\langle x^3\rangle \lessdot \mathbb{Z}/12\mathbb{Z}$ (index 3) and $\langle x^2\rangle \lessdot \mathbb{Z}/12\mathbb{Z}$ (index 2). The result is a 2×3 "grid" (product of a 2-chain and a 3-chain), matching $12 = 2^2 \cdot 3$.

Check. Six subgroups, matching the six divisors of 12. Every maximal chain from 1 to $\mathbb{Z}/12\mathbb{Z}$ has two index-2 steps and one index-3 step (e.g. $1 \to \langle x^4\rangle \to \langle x^2\rangle \to \mathbb{Z}/12\mathbb{Z}$ has indices $3, 2, 2$), confirming the 2×3 grid for $12 = 2^2 \cdot 3$.

Worked Example 2.5.8 (Chain lattice of $\mathbb{Z}/16\mathbb{Z}$)**.** Draw the subgroup lattice of $\mathbb{Z}/16\mathbb{Z} = \langle x\rangle$, $|x| = 16$.



Recognition. Cyclic group, so Proposition 2.5.5 again: subgroups $\leftrightarrow$ divisors of 16. Since $16 = 2^4$ has divisors $1, 2, 4, 8, 16$ that form a single divisibility chain, the lattice will be a straight *chain* (totally ordered).

Solution. Step 1. Divisors $1, 2, 4, 8, 16$ give:

$$1 = \langle x^{16}\rangle,\ \langle x^8\rangle\ (|2|),\ \langle x^4\rangle\ (|4|),\ \langle x^2\rangle\ (|8|),\ \langle x\rangle = \mathbb{Z}/16\mathbb{Z}.$$

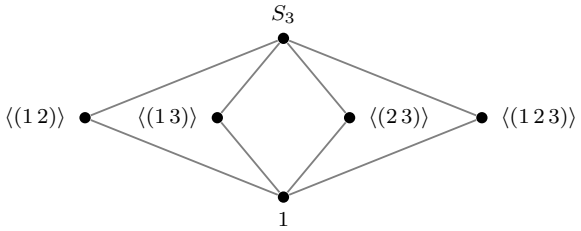
Step 2–3. Each order divides the next, and consecutive ratios are all 2 (prime), so every consecutive pair is a covering and there are no incomparable subgroups:

$$1 \lessdot \langle x^8\rangle \lessdot \langle x^4\rangle \lessdot \langle x^2\rangle \lessdot \mathbb{Z}/16\mathbb{Z}.$$

Check. Five subgroups for the five divisors of 16. A prime-power cyclic group $\mathbb{Z}/p^k\mathbb{Z}$ always has a chain lattice of length k; here $p = 2, k = 4$ gives a chain of 4 edges, as drawn.

Worked Example 2.5.9 (Lattice of S_3)**.** Draw the subgroup lattice of S_3 (the symmetric group on $\{1, 2, 3\}$, order 6).

Recognition. $|S_3| = 6$, so Lagrange allows subgroup orders $1, 2, 3, 6$. S_3 is non-cyclic, so we search by order: order-2 subgroups come from transpositions, the order-3 subgroup from a 3-cycle. This is the Method's Step 1 done by hand.



Solution. Step 1 (subgroups). The six elements are e, the transpositions $(1\,2), (1\,3), (2\,3)$ (each of order 2), and the 3-cycles $(1\,2\,3), (1\,3\,2)$ (each of order 3).

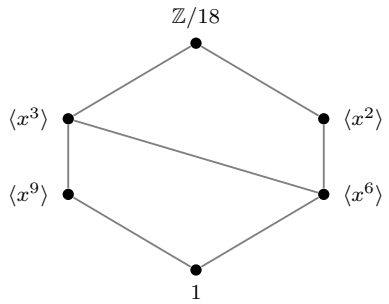
- Order 1: $\{e\}$.
- Order 2: $\langle (1\,2) \rangle = \{e, (1\,2)\}$, $\langle (1\,3) \rangle = \{e, (1\,3)\}$, $\langle (2\,3) \rangle = \{e, (2\,3)\}$ — three of them.
- Order 3: $\langle (1\,2\,3) \rangle = \{e, (1\,2\,3), (1\,3\,2)\}$ — exactly one, since $(1\,3\,2) = (1\,2\,3)^2$ generates the same group.
- Order 6: S_3 itself.

Total 6 subgroups.

Step 2. Bottom 1; middle row the three order-2 groups and the one order-3 group; top S_3.

Step 3 (coverings). Each order-2 subgroup covers 1 (index 2, prime) and is covered by S_3 (index 3, prime). The order-3 subgroup covers 1 (index 3) and is covered by S_3 (index 2). No two distinct middle subgroups are comparable (different prime orders, or two order-2 groups share only e), so no horizontal edges.

Check. Six subgroups. The unique order-3 subgroup is the alternating group A_3, normal of index 2; the three order-2 subgroups are conjugate. Counting elements: 1 identity +3 transpositions +2 three-cycles = 6, consistent with $|S_3| = 6$.



Worked Example 2.5.10 (Lattice of $\mathbb{Z}/18\mathbb{Z}$ (type p^2q))**.** Draw the subgroup lattice of $\mathbb{Z}/18\mathbb{Z} = \langle x \rangle$, $|x| = 18 = 2 \cdot 3^2$.

Recognition. Cyclic of order 18, so Proposition 2.5.5: subgroups $\leftrightarrow$ divisors of 18. With $18 = 2 \cdot 3^2$ the divisor lattice is a 2×3 grid (a 2-chain from the prime 2 crossed with a 3-chain from 3^2), the same *shape* as $\mathbb{Z}/12\mathbb{Z}$ but with the chains swapped in length.

Solution. Step 1. Divisors $1, 2, 3, 6, 9, 18$ give one subgroup each:

$$1 = \langle x^{18} \rangle,\ \langle x^9 \rangle\ (|2|),\ \langle x^6 \rangle\ (|3|),\ \langle x^3 \rangle\ (|6|),\ \langle x^2 \rangle\ (|9|),\ \langle x \rangle = \mathbb{Z}/18\mathbb{Z}.$$

Step 2–3 (coverings via prime index). $1 \lessdot \langle x^9\rangle$ (index 2), $1 \lessdot \langle x^6\rangle$ (index 3). Then $\langle x^9\rangle \lessdot \langle x^3\rangle$ (orders $2 \mid 6$, ratio 3); $\langle x^6\rangle \lessdot \langle x^3\rangle$ (orders $3 \mid 6$, ratio 2) and $\langle x^6\rangle \lessdot \langle x^2\rangle$ (orders $3 \mid 9$, ratio 3). Finally $\langle x^3\rangle \lessdot \mathbb{Z}/18\mathbb{Z}$ (index 3) and $\langle x^2\rangle \lessdot \mathbb{Z}/18\mathbb{Z}$ (index 2). Note the order-9 branch $1 \to \langle x^6\rangle \to \langle x^2\rangle$ is a length-2 chain (powers of 3), while the order-2 direction adds a single rung.

Check. Six subgroups for six divisors. The 3-part $\{1, \langle x^6\rangle, \langle x^2\rangle\}$ forms a chain of length 2 (since $3^2 \mid 18$), and crossing with the 2-part gives the grid; this is the generic shape of $\mathbb{Z}/p^2q\mathbb{Z}$.

Method (How to read a join $H \vee K$ and meet $H \wedge K$ off a Hasse diagram)**.** Use this whenever a problem gives you two specific subgroups and asks for their intersection or the subgroup they generate.

1. **Locate H and K as vertices.**
2. **Meet $H \wedge K = H \cap K$:** trace downward from both. The meet is the *highest* vertex reachable by a downward path from H *and* from K. If their only common lower vertex is 1, then $H \cap K = 1$.
3. **Join $H \vee K = \langle H, K\rangle$:** trace upward from both. The join is the *lowest* vertex reachable by an upward path from H *and* from K. If their only common upper vertex is G, then $\langle H, K\rangle = G$.
4. **Confirm by orders if unsure:** $|H \cap K|$ divides $\gcd(|H|, |K|)$; and $|\langle H, K\rangle|$ is a multiple of $\operatorname{lcm}(|H|, |K|)$ dividing $|G|$. Often this pins the answer.

Caution. $H \vee K = \langle H, K\rangle$ is *not* the set product $HK = \{hk\}$ in general, and not the union $H \cup K$ (a union of two subgroups is almost never a subgroup). Read the join as the lowest common *upper* vertex, or compute it as all products of elements from $H \cup K$.

Worked Example 2.5.11 (Reading joins and meets off the S_3 and V_4 lattices)**.** Using the lattices already drawn, compute (a) $\langle(1\,2)\rangle \vee \langle(1\,3)\rangle$ and $\langle(1\,2)\rangle \wedge \langle(1\,3)\rangle$ in S_3; (b) $\langle(1\,2)\rangle \vee \langle(1\,2\,3)\rangle$ in S_3; (c) $\langle a\rangle \vee \langle b\rangle$ and $\langle a\rangle \wedge \langle b\rangle$ in V_4.

Recognition. Each part names two specific subgroups and asks for their join or meet, so this is the reading-off Method. We locate the vertices in the diagrams from the previous worked examples and trace up (join) or down (meet), then confirm with the order test $|H \cap K| \mid \gcd$ and $\operatorname{lcm} \mid |\langle H, K\rangle|$.

Solution. (a) In S_3. **Meet:** $\langle(1\,2)\rangle = \{e, (1\,2)\}$ and $\langle(1\,3)\rangle = \{e, (1\,3)\}$ share only e below them; the highest common lower vertex is 1. So

$$\langle(1\,2)\rangle \wedge \langle(1\,3)\rangle = \langle(1\,2)\rangle \cap \langle(1\,3)\rangle = \{e\} = 1.$$

(Order check: $|H \cap K|$ divides $\gcd(2, 2) = 2$, and the only shared element is e, so it is 1.) **Join:** trace upward from both order-2 vertices; their only common upper vertex is the top, S_3. So $\langle(1\,2)\rangle \vee \langle(1\,3)\rangle = S_3$. *Confirm directly:* the product $(1\,2)(1\,3) = (1\,3\,2)$ is a 3-cycle, so $\langle(1\,2), (1\,3)\rangle$ contains an element of order 3 and an element of order 2; its order is a multiple of $\operatorname{lcm}(2, 3) = 6$ dividing 6, hence 6, giving all of S_3.

(b) In S_3. $\langle(1\,2)\rangle$ has order 2, $\langle(1\,2\,3)\rangle$ has order 3. Upward, the only common vertex above both is S_3, so $\langle(1\,2)\rangle \vee \langle(1\,2\,3)\rangle = S_3$. (Order check: $|\langle H, K\rangle|$ is a multiple of $\operatorname{lcm}(2, 3) = 6$ and divides 6, so it equals $6 = |S_3|$.) Their meet is 1 since $\gcd(2, 3) = 1$ forces $H \cap K = \{e\}$.

(c) In V_4. **Meet:** $\langle a\rangle = \{1, a\}$ and $\langle b\rangle = \{1, b\}$ share only 1, so $\langle a\rangle \wedge \langle b\rangle = 1$. **Join:** upward from both order-2 atoms, the only common upper vertex is the top, so $\langle a\rangle \vee \langle b\rangle = V_4$. *Confirm:* $ab = c \notin \langle a\rangle \cup \langle b\rangle$, so

$\langle a, b\rangle$ properly contains $\langle a\rangle$, has order a multiple of $\mathrm{lcm}(2,2) = 2$ exceeding 2 and dividing 4, hence 4; thus $\langle a, b\rangle = V_4$.

Check. In all parts the meet of two distinct atoms is the bottom 1 and the join of two distinct atoms is the top of the relevant lattice — exactly what "lowest common upper / highest common lower vertex" predicts when the two subgroups are incomparable atoms whose join is the whole group.

Worked Example 2.5.12 (A meet and join inside $\mathbb{Z}/12\mathbb{Z}$)**.** In $\mathbb{Z}/12\mathbb{Z} = \langle x\rangle$ compute $\langle x^4\rangle \wedge \langle x^6\rangle$ and $\langle x^4\rangle \vee \langle x^6\rangle$, where $\langle x^4\rangle$ has order 3 and $\langle x^6\rangle$ has order 2.

Recognition. Two named subgroups of a cyclic group; use the reading-off Method on the $\mathbb{Z}/12\mathbb{Z}$ grid, and double-check with the cyclic shortcut $\langle x^a\rangle \cap \langle x^b\rangle = \langle x^{\mathrm{lcm}(a,b)}\rangle$ and $\langle x^a, x^b\rangle = \langle x^{\gcd(a,b)}\rangle$.

Solution. Meet (down). On the grid, $\langle x^4\rangle$ (order 3) and $\langle x^6\rangle$ (order 2) have only 1 below both. So $\langle x^4\rangle \wedge \langle x^6\rangle = 1$. *Shortcut check.* $\langle x^4\rangle \cap \langle x^6\rangle = \langle x^{\mathrm{lcm}(4,6)}\rangle = \langle x^{12}\rangle = \langle e\rangle = 1$. Agrees; also $\gcd(2,3) = 1$ forces the trivial meet.

Join (up). Upward from order-3 and order-2 vertices, the lowest common upper vertex is $\langle x^2\rangle$ (order 6). So $\langle x^4\rangle \vee \langle x^6\rangle = \langle x^2\rangle$. *Shortcut check.* $\langle x^4, x^6\rangle = \langle x^{\gcd(4,6)}\rangle = \langle x^2\rangle$, of order $12/\gcd(2,12) = 6$. Agrees, and $6 = \mathrm{lcm}(2,3)$ as the order test demands.

Check. Meet has order $1 \mid \gcd(2,3) = 1$; join has order 6, a multiple of $\mathrm{lcm}(2,3) = 6$ dividing 12. Both consistent. Note $\langle x^2\rangle \neq \mathbb{Z}/12\mathbb{Z}$ here: the join of two proper subgroups need not be the whole group — contrast with the S_3 transpositions, whose join *was* everything.

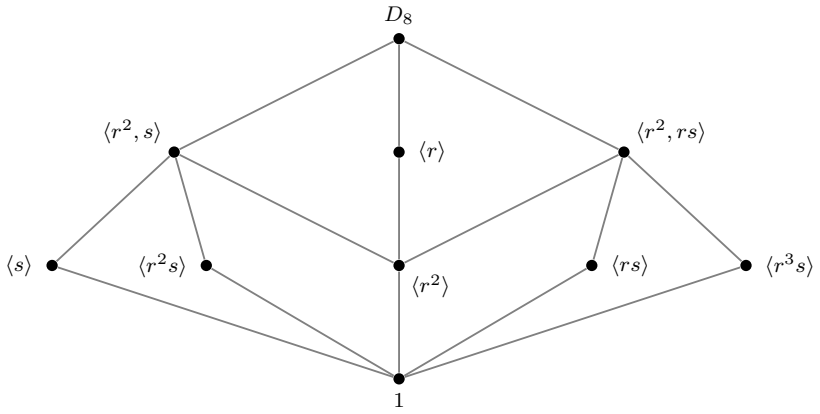
Using subgroup lattices: D_8, Q_8, and $\mathbb{Z}/24\mathbb{Z}$

The subgroup lattice of a finite group G is the Hasse diagram of all subgroups of G ordered by inclusion: the trivial subgroup 1 at the bottom, G at the top, and an upward edge H—K exactly when $H < K$ with no subgroup strictly between them. Once drawn, the lattice is a single picture from which we can read inclusions and indices, and which (together with a few conjugation checks) locates normal subgroups and normalizers. This section builds the three canonical lattices and turns them into computational tools.

Definition 2.5.13. In the subgroup lattice of G, we draw an edge H—K (with H below K) precisely when $H < K$ and there is no subgroup L with $H < L < K$. We say K *covers* H.

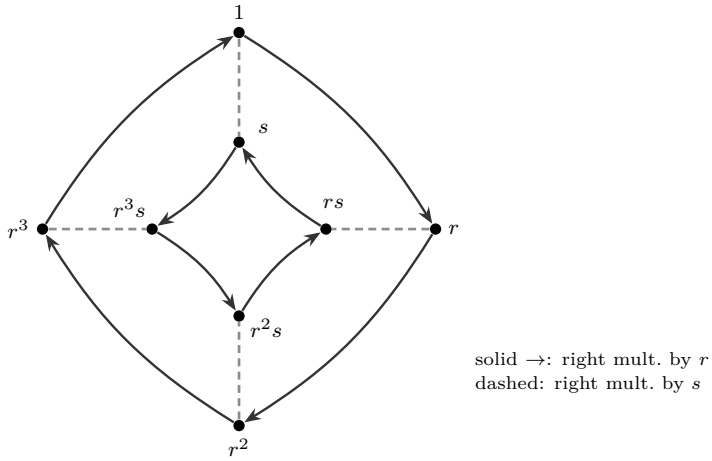
The lattice of D_8 and its ten subgroups

Write $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1}\rangle$; then $r^{-1} = r^3$, and the eight elements are



$$1,\ r,\ r^2,\ r^3,\ s,\ rs,\ r^2s,\ r^3s.$$

We first list every subgroup by order.



Proposition 2.5.14. *D_8 has exactly ten subgroups: the trivial group 1; the whole group D_8; one cyclic order-4 subgroup $\langle r\rangle = \{1, r, r^2, r^3\}$ and two Klein four-groups $\langle r^2, s\rangle = \{1, r^2, s, r^2s\}$ and $\langle r^2, rs\rangle = \{1, r^2, rs, r^3s\}$; and five order-2 subgroups $\langle r^2\rangle, \langle s\rangle, \langle rs\rangle, \langle r^2s\rangle, \langle r^3s\rangle$.*

Proof. By Lagrange every proper nontrivial subgroup has order 2 or 4. An order-2 subgroup is $\langle x\rangle$ for an element x of order 2; the five involutions are r^2, s, rs, r^2s, r^3s (the elements r, r^3 have order 4), giving five order-2 subgroups. An order-4 subgroup H has index 2, hence is normal, and is either cyclic or Klein four. The only elements of order 4 are r, r^3, both generating $\langle r\rangle$, so there is exactly one cyclic order-4 subgroup. A Klein four subgroup consists of 1 and three commuting involutions; since r^2 is central and $s \cdot r^2s = r^2$, $\{1, r^2, s, r^2s\}$ and $\{1, r^2, rs, r^3s\}$ are subgroups, and conversely a Klein four subgroup contains at most one rotation besides 1 (namely r^2), hence two distinct commuting reflections r^is, r^js. Since $(r^is)(r^js) = r^{i-j}$ and $(r^js)(r^is) = r^{j-i}$, these commute iff $r^{2(i-j)} = 1$, i.e. iff $i \equiv j \pmod 2$ (e.g. $s(rs) = srs = r^{-1} = r^3$ while $(rs)s = r$, so s and rs do not commute). So the pair is $\{s, r^2s\}$ or $\{rs, r^3s\}$, and the subgroup is one of the two above; hence no others exist. Total: $1 + 5 + 3 + 1 = 10$. □

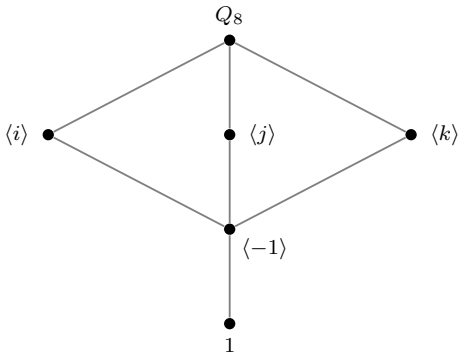
The covering relations: each order-2 subgroup sits under the order-4 subgroup(s) containing it. Note $\langle r^2\rangle$ is the *center* $Z(D_8)$ and lies inside all three order-4 subgroups, while each of $\langle s\rangle, \langle r^2s\rangle$ lies only in $\langle r^2, s\rangle$ and each of $\langle rs\rangle, \langle r^3s\rangle$ only in $\langle r^2, rs\rangle$.

The same group is laid out below as a *Cayley graph*: the eight elements are the vertices, the solid arrows are right-multiplication by r (a 4-cycle on the outer rotations and, in the *opposite* sense, on the inner reflections, since $sr = r^{-1}s$), and the dashed edges are right-multiplication by the involution s, joining each rotation r^k to the reflection $r^k s$.

Worked Example 2.5.15 (List the subgroups of D_8 by order)**.** Produce the full subgroup list of D_8 organized by order, and confirm the count is ten.

Recognition. The trigger is "small group, want all subgroups." Use Lagrange to bound the possible orders $(1, 2, 4, 8)$, then enumerate order-2 subgroups via involutions and order-4 subgroups via the cyclic-vs-Klein dichotomy. This is exactly Proposition 2.5.14's method applied as a checklist.

Solution. Order 1*:* 1. *Order* 8*:* D_8. *Order* 2*:* find all x with $x^2 = 1,\ x \neq 1$. Check each non-identity element: r, r^3 have order 4; r^2 has order 2; $s^2 = 1$; $(rs)^2 = rsrs = r(srs) = r \cdot r^{-1} = 1$ and likewise $(r^2 s)^2 = (r^3 s)^2 = 1$. So the involutions are $r^2, s, rs, r^2 s, r^3 s$, giving five subgroups. *Order* 4*:* cyclic ones need order-4 elements r, r^3, both giving $\langle r\rangle$ (one subgroup); Klein ones are $\{1, r^2, s, r^2 s\}$ and $\{1, r^2, rs, r^3 s\}$ (two subgroups). *Total* $= 1 + 1 + 5 + 1 + 2 = 10$.



Check. Every involution appears in at least one order-4 subgroup (r^2 in all three; $s, r^2 s$ in $\langle r^2, s\rangle$; $rs, r^3 s$ in $\langle r^2, rs\rangle$), consistent with the lattice edges. Count 10 matches Proposition 2.5.14.

The lattice of Q_8: every subgroup is normal

Recall $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$, and $ji = -k$ etc. Here -1 is the unique element of order 2 and is central.

Proposition 2.5.16. *Q_8 has exactly six subgroups:* 1, $\langle -1\rangle = \{\pm 1\}$, $\langle i\rangle = \{\pm 1, \pm i\}$, $\langle j\rangle = \{\pm 1, \pm j\}$, $\langle k\rangle = \{\pm 1, \pm k\}$*, and* Q_8*. Every subgroup is normal.*

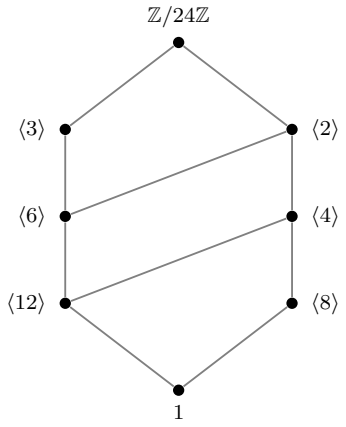
Proof. The only element of order 2 is -1 (since $i^2 = j^2 = k^2 = -1 \neq 1$), giving the unique order-2 subgroup $\langle -1 \rangle$. The order-4 subgroups are cyclic generated by an order-4 element; the order-4 elements are $\pm i, \pm j, \pm k$, and $\langle i \rangle = \langle -i \rangle$, $\langle j \rangle = \langle -j \rangle$, $\langle k \rangle = \langle -k \rangle$, giving three. With 1 and Q_8 that is six. Each order-4 subgroup has index 2, hence is normal; $\langle -1 \rangle = Z(Q_8)$ is normal as the center; and $1, Q_8$ are normal. So all six are normal. □

The single order-2 subgroup $\langle -1 \rangle$ is forced to sit beneath all three order-4 subgroups, giving Q_8 its distinctive "diamond with a stem" shape; contrast D_8, whose five order-2 subgroups fan out.

Worked Example 2.5.17 (The lattice of Q_8 and universal normality)**.** Draw the subgroup lattice of Q_8 and explain why every subgroup is normal.

Recognition. "Every subgroup normal" is triggered by two recognizable patterns combined: (a) index-2 subgroups are automatically normal, and (b) a subgroup contained in the center, or equal to it, is normal. In Q_8 all proper nontrivial subgroups are either index 2 or the center, so both triggers cover everything.

Solution. By Proposition 2.5.16 the subgroups are $1, \langle -1 \rangle, \langle i \rangle, \langle j \rangle, \langle k \rangle, Q_8$. For normality: 1 and Q_8 are always normal. The three order-4 subgroups have index $|Q_8|/4 = 2$, and any subgroup of index 2 is normal (its two cosets are H and $G \setminus H$, the same as left or right). Finally $\langle -1 \rangle$ is the center, and $gZg^{-1} = Z$ for the center Z of any group, so $\langle -1 \rangle \trianglelefteq Q_8$. Hence all six subgroups are normal.



Check. A direct conjugation, e.g. $j\,i\,j^{-1}$: since $ji = -k$ and $j^{-1} = -j$, we get $jij^{-1} = (-k)(-j) = kj = -i \in \langle i \rangle$. Thus $j\langle i \rangle j^{-1} = \langle i \rangle$, confirming $\langle i \rangle \trianglelefteq Q_8$ as predicted.

The lattice of $\mathbb{Z}/24\mathbb{Z}$: a divisor lattice

Theorem 2.5.18. *Let $G = \langle x \rangle$ be cyclic of order n. For each divisor $d \mid n$ there is exactly one subgroup of order d, namely $\langle x^{n/d} \rangle$, and these are all the subgroups. Consequently $H \leq K$ in the lattice iff $|H| \mid |K|$, so the subgroup lattice of $\mathbb{Z}/n\mathbb{Z}$ is isomorphic to the lattice of divisors of n under divisibility.*

Proof. A subgroup of $\langle x \rangle$ is cyclic, of the form $\langle x^a \rangle$, and $|\langle x^a \rangle| = n/\gcd(a, n)$, which runs over all divisors of n as a varies. If $\langle x^a \rangle$ and $\langle x^b \rangle$ both have order d, then both equal $\langle x^{n/d} \rangle$ (the unique subgroup of order d), so each order occurs once. Containment $\langle x^{n/d} \rangle \leq \langle x^{n/e} \rangle$ holds iff $d \mid e$, i.e. iff orders divide, which is exactly the divisor lattice. □

For $n = 24 = 2^3 \cdot 3$ the divisors are $1, 2, 3, 4, 6, 8, 12, 24$ (eight of them, since 24 has $(3+1)(1+1) = 8$ divisors), so $\mathbb{Z}/24\mathbb{Z}$ has eight subgroups, one of each order. Writing the additive generator $1 \in \mathbb{Z}/24\mathbb{Z}$ as x, the order-d subgroup is $\langle 24/d \rangle$.

Here $\langle 12\rangle$ has order 2, $\langle 8\rangle$ order 3, $\langle 6\rangle$ order 4, $\langle 4\rangle$ order 6, $\langle 3\rangle$ order 8, $\langle 2\rangle$ order 12. The shape is the 4×2 grid of divisors of $2^3 \cdot 3$.

Caution. In $\mathbb{Z}/n\mathbb{Z}$ the subgroup "$\langle m\rangle$" means the cyclic subgroup generated by the residue m, and $|\langle m\rangle| = n/\gcd(m,n)$, *not* n/m. For $\mathbb{Z}/24\mathbb{Z}$, $\langle 6\rangle$ has order $24/\gcd(6,24) = 24/6 = 4$, but $\langle 8\rangle$ has order $24/\gcd(8,24) = 24/8 = 3$. Compute the gcd; do not just divide by the label.

Worked Example 2.5.19 (Subgroup of $\mathbb{Z}/24\mathbb{Z}$ of each order, and one containment)**.** List the eight subgroups of $\mathbb{Z}/24\mathbb{Z}$ with their orders, and decide whether $\langle 6\rangle \leq \langle 2\rangle$.

Recognition. Cyclic group of order 24 $\Rightarrow$ Theorem 2.5.18: subgroups correspond to divisors of 24, and containment is divisibility of orders. The containment question is answered purely by "does $|\langle 6\rangle|$ divide $|\langle 2\rangle|$?"

Solution. Divisors of 24: $1, 2, 3, 4, 6, 8, 12, 24$. Order-d subgroup is $\langle 24/d\rangle$:

d	1	2	3	4	6	8	12	24
$\langle 24/d\rangle$	$\langle 24\rangle = 1$	$\langle 12\rangle$	$\langle 8\rangle$	$\langle 6\rangle$	$\langle 4\rangle$	$\langle 3\rangle$	$\langle 2\rangle$	$\langle 1\rangle$

Now $|\langle 6\rangle| = 24/\gcd(6,24) = 4$ and $|\langle 2\rangle| = 24/\gcd(2,24) = 12$. Since $4 \mid 12$, Theorem 2.5.18 gives $\langle 6\rangle \leq \langle 2\rangle$.

Check directly: $\langle 6\rangle = \{0, 6, 12, 18\}$ and $\langle 2\rangle = \{0, 2, 4, \ldots, 22\}$; indeed $6, 12, 18$ are even, so $\langle 6\rangle \subseteq \langle 2\rangle$. Consistent.

Reading normal subgroups and normalizers off a lattice

Method (Using the lattice to (a) spot normal subgroups and (b) locate $N_G(H)$)**.** *Recognition trigger.* Use this whenever you have the lattice drawn and want normality or a normalizer *without* brute-force conjugating every element.

(a) Normal subgroups.

1. Any subgroup of index 2 (one level below the top, with $|G : H| = 2$) is normal — mark it immediately.
2. The center $Z(G)$ and any subgroup contained in $Z(G)$ is normal; locate $Z(G)$ as the largest subgroup every node is "compatible" with (in D_8 and Q_8 this is the unique central involution's group).
3. A subgroup that is the *unique* subgroup of its order is characteristic, hence normal (conjugation permutes same-order subgroups, and a singleton orbit is fixed).
4. For the remaining small subgroups, conjugation permutes the subgroups of each fixed order; $H \trianglelefteq G$ iff that orbit is $\{H\}$. Read off the same-order siblings from the lattice and test whether a single conjugation moves H to a sibling.

(b) The normalizer $N_G(H)$.

1. $N_G(H)$ is a subgroup with $H \leq N_G(H) \leq G$, so it lies on the chain *above* H in the lattice — only those finitely many candidates can occur.

2. $H \trianglelefteq G \Leftrightarrow N_G(H) = G$ (top). If H is not normal, $N_G(H)$ is a *proper* subgroup containing H.

3. Test candidates from largest down: $g \in N_G(H)$ iff $gHg^{-1} = H$. The first proper overgroup K with every generator of K normalizing H, and with no larger overgroup doing so, is $N_G(H)$.

4. Sanity: $|G : N_G(H)|$ equals the number of distinct conjugates gHg^{-1} (the orbit size), which you can also count among the same-order siblings in the lattice.

Worked Example 2.5.20 (All normal subgroups of D_8 from the lattice)**.** Using the D_8 lattice, find every normal subgroup and justify each.

Recognition. Apply Method (a) point-by-point: index-2 rule for the order-4 row, center rule for $\langle r^2 \rangle$, uniqueness for $\langle r \rangle$, and the same-order-orbit test for the order-2 reflections.

Solution. Index 2 (order 4): $\langle r \rangle, \langle r^2, s \rangle, \langle r^2, rs \rangle$ each have index $8/4 = 2$, hence are normal. *Center:* $Z(D_8) = \langle r^2 \rangle$ (since r^2 commutes with r and with s as $sr^2s = r^{-2} = r^2$), and the center is always normal, so $\langle r^2 \rangle \trianglelefteq D_8$. *Trivial cases:* 1 and D_8. *Reflection subgroups* $\langle s \rangle, \langle rs \rangle, \langle r^2 s \rangle, \langle r^3 s \rangle$ *(order 2):* these are not normal. Conjugate $\langle s \rangle$ by r: $rsr^{-1} = r(sr^{-1})$, and $sr^{-1} = sr^3 = r^{-3}s = rs$; hence $rsr^{-1} = r \cdot rs = r^2 s \notin \langle s \rangle$. So $r\langle s \rangle r^{-1} = \langle r^2 s \rangle \neq \langle s \rangle$, and similarly conjugation by r sends $\langle rs \rangle$ to $\langle r^3 s \rangle$ (since $r(rs)r^{-1} = r^3 s$), swapping that pair. Each reflection subgroup has a 2-element conjugacy orbit, so none is normal.

Thus the normal subgroups are exactly $1,\ \langle r^2 \rangle,\ \langle r \rangle,\ \langle r^2, s \rangle,\ \langle r^2, rs \rangle,\ D_8$ — six of the ten.

Check. The quotient $D_8/\langle r^2 \rangle$ has order 4 and is abelian ($\cong V_4$), consistent with $\langle r^2 \rangle = [D_8, D_8]$ being normal; and the three index-2 subgroups being normal matches the rule. The four reflection subgroups split into two orbits of size 2 ($\{\langle s \rangle, \langle r^2 s \rangle\}$ and $\{\langle rs \rangle, \langle r^3 s \rangle\}$), accounting for the non-normal ones.

Worked Example 2.5.21 ($N_{D_8}(\langle s \rangle)$ via the lattice)**.** Compute $N_{D_8}(\langle s \rangle)$ by restricting to the overgroups of $\langle s \rangle$, then verify.

Recognition. $\langle s \rangle$ is a non-normal order-2 subgroup (from the previous example), so by Method (b) its normalizer is a *proper* overgroup: read the chain above $\langle s \rangle$ in the lattice. The only overgroups of $\langle s \rangle$ are $\langle s \rangle$ itself, $\langle r^2, s \rangle$, and D_8.

Solution. Candidates from the lattice: $\langle s \rangle \leq N \leq D_8$ with $N \in \{\langle s \rangle, \langle r^2, s \rangle, D_8\}$. We know $N \neq D_8$ (not normal). Test $\langle r^2, s \rangle = \{1, r^2, s, r^2 s\}$: its generators are r^2 and s.

- $s \in N_{D_8}(\langle s \rangle)$ trivially ($s\langle s \rangle s^{-1} = \langle s \rangle$).
- r^2: $r^2 s r^{-2} = r^2 s r^2$. Since r^2 is central, $r^2 s r^2 = s r^2 r^2 = s r^4 = s \in \langle s \rangle$. So r^2 normalizes $\langle s \rangle$.

Every generator of $\langle r^2, s \rangle$ normalizes $\langle s \rangle$, so $\langle r^2, s \rangle \leq N_{D_8}(\langle s \rangle)$. Since the only larger subgroup is D_8, which does not normalize $\langle s \rangle$ (because $r\langle s \rangle r^{-1} = \langle r^2 s \rangle \neq \langle s \rangle$ from the previous example), we get

$$N_{D_8}(\langle s \rangle) = \langle r^2, s \rangle = \{1, r^2, s, r^2 s\}.$$

Check via orbit count: $|D_8 : N_{D_8}(\langle s \rangle)| = 8/4 = 2$, so $\langle s \rangle$ should have exactly 2 conjugates. Indeed its conjugates are $\langle s \rangle$ and $\langle r^2 s \rangle$, two subgroups — matching. (Note $N_{D_8}(\langle s \rangle) \supsetneq \langle s \rangle$ strictly even though $\langle s \rangle$ is not normal, illustrating $H \leq N_G(H) \leq G$.)

Worked Example 2.5.22 ($N_{Q_8}(\langle i \rangle)$ and $N_{\mathbb{Z}/24\mathbb{Z}}(\langle 6 \rangle)$)**.** Find both normalizers using the lattices.

Recognition. In an abelian group every subgroup is normal, so $N_G(H) = G$ automatically — that is the trigger for $\mathbb{Z}/24\mathbb{Z}$. In Q_8 every subgroup is normal (Proposition 2.5.16), so again $N_G(H) = G$. Both reduce to Method (b) step 2: normal $\Rightarrow$ normalizer is the top.

Solution. Q_8*:* $\langle i \rangle$ has index $8/4 = 2$, hence normal, so $N_{Q_8}(\langle i \rangle) = Q_8$. $\mathbb{Z}/24\mathbb{Z}$*:* $\mathbb{Z}/24\mathbb{Z}$ is abelian, so $g + \langle 6 \rangle - g = \langle 6 \rangle$ for all g (equivalently $g\langle 6 \rangle g^{-1} = \langle 6 \rangle$), giving $N_{\mathbb{Z}/24\mathbb{Z}}(\langle 6 \rangle) = \mathbb{Z}/24\mathbb{Z}$.

Check. Normalizer at the top of the lattice $\Leftrightarrow$ single conjugate $\Leftrightarrow |G : N_G(H)| = 1$. For $\langle i \rangle$: $jij^{-1} = -i \in \langle i \rangle$ as computed earlier, so conjugation fixes $\langle i \rangle$, giving one conjugate. For $\langle 6 \rangle$: abelian, one conjugate. Both consistent.

Worked Example 2.5.23 (A non-normal normalizer in S_3 for contrast)**.** In $S_3 = \{e, (12), (13), (23), (123), (132)\}$, draw the relevant overgroups and compute $N_{S_3}(\langle(12)\rangle)$.

Recognition. $\langle(12)\rangle$ is an order-2 subgroup of a non-abelian group, and the order-2 subgroups (transpositions) form one conjugacy orbit, so we expect a *proper* normalizer. By Method (b) read the chain above $\langle(12)\rangle$: the only overgroups are $\langle(12)\rangle$ and S_3 (no order-4 subgroup exists since $4 \nmid 6$).

Solution. Overgroups of $\langle(12)\rangle$ in the lattice: $\langle(12)\rangle$ (order 2) and S_3 (order 6); there is no subgroup of order 4 because $4 \nmid 6$. Is $\langle(12)\rangle \trianglelefteq S_3$? Conjugate by (123): $(123)(12)(123)^{-1} = (123)(12)(132)$. Computing, $(123)(12)(132) = (23) \notin \langle(12)\rangle$. So $\langle(12)\rangle$ is not normal, hence $N_{S_3}(\langle(12)\rangle) \neq S_3$. The only smaller overgroup is $\langle(12)\rangle$ itself, so

$$N_{S_3}(\langle(12)\rangle) = \langle(12)\rangle.$$

Check. $|S_3 : N| = 6/2 = 3$, predicting 3 conjugates; indeed the transpositions $(12), (13), (23)$ are all conjugate, giving exactly 3 subgroups $\langle(12)\rangle, \langle(13)\rangle, \langle(23)\rangle$. Consistent, and this shows $N_G(H) = H$ is possible (the lattice chain above H may have nothing strictly between H and G).

The same-lattice, non-isomorphic remark

A subgroup lattice does *not* determine a group up to isomorphism. The standard example: $Z_2 \times Z_8$ and the modular group of order 16,

$$M = M_{16} = \langle u, v \mid u^8 = v^2 = 1,\ vuv^{-1} = u^5 \rangle,$$

have isomorphic subgroup lattices but are not isomorphic groups.

Worked Example 2.5.24 (Why same lattice does not force isomorphism)**.** Explain how $Z_2 \times Z_8$ and M_{16} can share a subgroup lattice yet fail to be isomorphic, and give a concrete invariant that distinguishes them.

Recognition. The trigger is the phrase "same lattice, not isomorphic." The lattice records only *which subgroups contain which*; it is blind to *how* elements multiply (commutativity, conjugation). So to separate the two groups we must exhibit a group-theoretic invariant that the lattice cannot see — abelian vs. non-abelian is the cleanest.

Solution. Both groups have order 16, and their subgroup lattices coincide combinatorially: each has 11 subgroups, with exactly 1 of order 1, three of order 2, three of order 4, three of order 8, and 1 of order 16, arranged with identical inclusions (this is the content of the D&F remark). Crucially this is *not* because M_{16} has all subgroups normal — it does not: from $vuv^{-1} = u^5$ one gets $uvu^{-1} = u^4v$, so the order-2 subgroup $\langle v\rangle$ is non-normal, with conjugate $\langle u^4v\rangle$. The relation $vuv^{-1} = u^5$ does guarantee that u^5 generates the same cyclic subgroups as u (since $\gcd(5, 8) = 1$, e.g. $\langle u^5\rangle = \langle u\rangle$), so conjugation by v fixes every subgroup of $\langle u\rangle$; but that alone does not force equal lattices (in D_{16}, $srs^{-1} = r^7$ with $\gcd(7, 8) = 1$, yet D_{16} has 19 subgroups). The agreement is a direct check: writing $Z_2 \times Z_8 = \langle x\rangle \times \langle y\rangle$ with $|x| = 2$, $|y| = 8$, the bijection $u^iv^j \mapsto y^ix^j$ carries the 11 subgroups of M_{16} exactly onto the 11 subgroups of $Z_2 \times Z_8$ (e.g. $\langle uv\rangle = \{u^{2k}, u^{2k+1}v\} \mapsto \{y^{2k}, y^{2k+1}x\} = \langle xy\rangle$). Hence the lattices agree even though the multiplication does not.

But the groups differ on a lattice-invisible invariant:

- $Z_2 \times Z_8$ is *abelian*: every pair of elements commutes, so its center is the whole group and $|Z| = 16$.
- M_{16} is *non-abelian*: $vuv^{-1} = u^5 \neq u$ (since $u^5 \neq u$ as u has order 8), so u and v do not commute. Its center is $\langle u^2\rangle \cong Z_4$, of order 4.

Since $|Z(Z_2 \times Z_8)| = 16 \neq 4 = |Z(M_{16})|$, and the order of the center is an isomorphism invariant, the two groups are not isomorphic.

Check. An isomorphism must send center to center, so it would force $16 = |Z(Z_2 \times Z_8)| = |Z(M_{16})| = 4$, a contradiction. Equivalently, one group is abelian and the other is not — an invariant the bare inclusion lattice cannot record. This is precisely why we must verify isomorphism by group operations, never by lattice shape alone.

Caution. Never conclude "$G \cong H$ because they have the same subgroup lattice." The lattice forgets multiplication. $Z_2 \times Z_8$ vs. M_{16} (both order 16, identical lattices, one abelian and one not) is the canonical counterexample. Likewise, do not read commutativity or element orders off a Hasse diagram — it only encodes containments.

Further lattice examples

The divisor-lattice principle (Proposition 2.5.5) fixes the *shape* of every cyclic group's lattice once we know how $|G|$ factors. Before the specific numbers $\mathbb{Z}/12\mathbb{Z}, \mathbb{Z}/16\mathbb{Z}, \mathbb{Z}/18\mathbb{Z}, \mathbb{Z}/24\mathbb{Z}$ already drawn, it is worth recording the three generic shapes they instantiate: a prime, a prime square, and a product of two distinct primes. We then return to D_8 to read off joins and meets the earlier drawing did not compute.

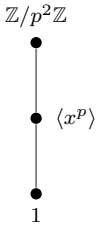
Worked Example 2.5.25 (The two smallest lattices: $\mathbb{Z}/1\mathbb{Z}$ and $\mathbb{Z}/p\mathbb{Z}$)**.** Draw the subgroup lattices of the trivial group and of a cyclic group $\mathbb{Z}/p\mathbb{Z}$ of prime order.

Recognition. These are the base cases. A group has the single-vertex lattice iff it is trivial; it has the two-vertex "single edge" lattice iff it has *no* proper nontrivial subgroup, which for finite groups (by Lagrange) means prime order.

Solution. Trivial group. $\mathbb{Z}/1\mathbb{Z} = \{1\}$ has only itself as a subgroup, so the lattice is a single point.

Prime order. By Lagrange every subgroup of $\mathbb{Z}/p\mathbb{Z}$ has order 1 or p, so the only subgroups are 1 and $\mathbb{Z}/p\mathbb{Z}$ itself. Since $[\,\mathbb{Z}/p\mathbb{Z} : 1\,] = p$ is prime, $\mathbb{Z}/p\mathbb{Z}$ covers 1: a single edge.

Check. The single-edge lattice is exactly the case where the pitfall "do not draw 1 straight to G" is *allowed*: there is no proper nontrivial subgroup to interrupt it. For $p = 2, 3, 5, \ldots$ the picture is identical, since the lattice sees only the divisor structure $1 \mid p$.



Worked Example 2.5.26 (The lattice of $\mathbb{Z}/p^2\mathbb{Z}$ as a chain)**.** Draw the subgroup lattice of a cyclic group $\mathbb{Z}/p^2\mathbb{Z} = \langle x \rangle$ of order p^2 (p prime).

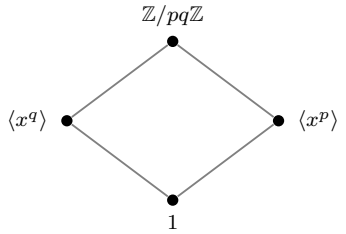
Recognition. Cyclic of order p^2, so by Proposition 2.5.5 subgroups correspond to the divisors $1, p, p^2$, which form a single divisibility chain. This is the generic shape behind the concrete $\mathbb{Z}/16\mathbb{Z}$ chain already drawn; here we record the general p^2 picture.

Solution. The divisors of p^2 are $1, p, p^2$, giving exactly three subgroups:

$$1 = \langle x^{p^2} \rangle, \qquad \langle x^p \rangle \ (|p|), \qquad \langle x \rangle = \mathbb{Z}/p^2\mathbb{Z}.$$

Each consecutive ratio is p (prime), so each is a covering and the lattice is a 2-edge chain.

Check. Three subgroups for the three divisors of p^2, and the lattice is totally ordered because p^2 is a prime power. Taking $p = 2$ recovers the bottom of the $\mathbb{Z}/16\mathbb{Z}$ chain; in general $\mathbb{Z}/p^k\mathbb{Z}$ gives a chain of length k.



Worked Example 2.5.27 (The lattice of $\mathbb{Z}/pq\mathbb{Z}$ for distinct primes)**.** Draw the subgroup lattice of a cyclic group $\mathbb{Z}/pq\mathbb{Z} = \langle x \rangle$ where $p \neq q$ are primes.

Recognition. Cyclic of order pq with $p \neq q$, so the divisors are $1, p, q, pq$ and the divisor lattice is a "diamond" (a length-1 chain crossed with a length-1 chain). This is the standard contrast to the prime-power chain.

Solution. The divisors $1, p, q, pq$ give one subgroup of each order:

$$1 = \langle x^{pq} \rangle, \qquad \langle x^q \rangle \ (|p|), \qquad \langle x^p \rangle \ (|q|), \qquad \langle x \rangle = \mathbb{Z}/pq\mathbb{Z}.$$

Coverings: $1 \lessdot \langle x^q \rangle$ (index p) and $1 \lessdot \langle x^p \rangle$ (index q); then $\langle x^q \rangle \lessdot \mathbb{Z}/pq\mathbb{Z}$ (index q) and $\langle x^p \rangle \lessdot \mathbb{Z}/pq\mathbb{Z}$ (index p). The order-p and order-q vertices are incomparable ($p \nmid q$ and $q \nmid p$), so no edge joins them.

Check. Four subgroups for four divisors; the shape is the same "diamond" as V_4, but now the two atoms have *different* orders p and q (in V_4 all three atoms had order 2, and there were three of them). Taking $p = 2, q = 3$ gives the lattice of $\mathbb{Z}/6\mathbb{Z}$.

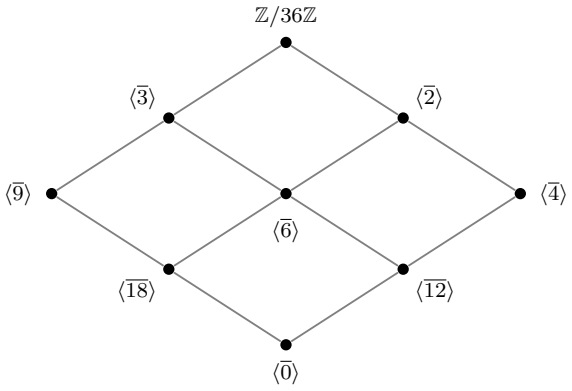
Worked Example 2.5.28 (Reading joins and meets off the D_8 lattice)**.** Using the D_8 lattice already drawn, compute (a) $\langle s \rangle \vee \langle r^2 s \rangle$, (b) $\langle s \rangle \vee \langle rs \rangle$, and (c) $\langle r \rangle \cap \langle r^2, s \rangle$.

Recognition. Each part names two specific subgroups of D_8 and asks for a join or an intersection, so this is the reading-off Method applied to the flagship non-abelian example. We trace up for joins, down for meets, and confirm with element computations using $sr = r^{-1}s$.

Solution. (a) $\langle s \rangle \vee \langle r^2 s \rangle$. Both $\langle s \rangle = \{1, s\}$ and $\langle r^2 s \rangle = \{1, r^2 s\}$ lie under the single order-4 subgroup $\langle r^2, s \rangle = \{1, r^2, s, r^2 s\}$, and that is the lowest common upper vertex. So $\langle s \rangle \vee \langle r^2 s \rangle = \langle r^2, s \rangle$. *Confirm:* $s \cdot r^2 s = r^{-2} = r^2$ (using $sr^2 = r^{-2}s$), so the join contains r^2, hence contains $\{1, r^2, s, r^2 s\}$; its order is a multiple of $\mathrm{lcm}(2, 2) = 2$ exceeding 2 and dividing 8, and the Klein group of order 4 is the smallest such, giving $\langle r^2, s \rangle$.

(b) $\langle s \rangle \vee \langle rs \rangle$. Here $\langle s \rangle$ sits under $\langle r^2, s \rangle$ only, while $\langle rs \rangle$ sits under $\langle r^2, rs \rangle$ only; their only common upper vertex is the top. So $\langle s \rangle \vee \langle rs \rangle = D_8$. *Confirm:* $s \cdot rs = (sr)s = r^{-1}s\,s = r^{-1} = r^3$, an element of order 4, so the join contains $\langle r \rangle$ as well as the involution $s \notin \langle r \rangle$; its order is a multiple of 4 strictly exceeding 4 and dividing 8, hence $8 = |D_8|$.

(c) $\langle r \rangle \cap \langle r^2, s \rangle$. Tracing down from the cyclic order-4 subgroup $\langle r \rangle = \{1, r, r^2, r^3\}$ and from the Klein order-4 subgroup $\langle r^2, s \rangle = \{1, r^2, s, r^2 s\}$, the highest common lower vertex is $\langle r^2 \rangle$. So $\langle r \rangle \cap \langle r^2, s \rangle = \langle r^2 \rangle$. *Confirm:* the common elements are exactly $\{1, r^2\} = \langle r^2 \rangle$, since $r, r^3 \notin \langle r^2, s \rangle$ and $s, r^2 s \notin \langle r \rangle$.



Check. In (a) two incomparable atoms under a *common* order-4 group join to that group, not to D_8 — contrast (b), where the two atoms lie under *different* order-4 groups and so are forced all the way to the top. Part (c) shows the meet of the two "different kinds" of order-4 subgroup is the center $\langle r^2 \rangle = Z(D_8)$, the unique nontrivial subgroup lying below all three order-4 subgroups, exactly as the lattice picture displays.

Further worked examples

More lattices (Theorem 2.5.18; divisor lattices).

Worked Example 2.5.29 (the lattice of $\mathbb{Z}/36\mathbb{Z}$)**.** *Recognition.* Cyclic of order $36 = 2^2 \cdot 3^2$, so subgroups $\leftrightarrow$ divisors of 36, and the lattice is the divisor lattice — a 3×3 grid.

Solution. The nine divisors $1, 2, 3, 4, 6, 9, 12, 18, 36$ give nine subgroups, the order-d one being $\langle \overline{36/d} \rangle$:

The three "columns" are the powers of 2 in the order; the three "rows" the powers of 3. *Check.* $\langle\overline{9}\rangle$ has order $36/\gcd(36,9) = 4$, sitting above $\langle\overline{18}\rangle$ (order 2) as a 2^2 vs 2^1 step.

Reading a normalizer off a lattice (using $C_G \leq N_G$ and "index 2 $\Rightarrow$ normal").

Worked Example 2.5.30 ($N_{D_8}(\langle s\rangle)$ from the lattice)**.** *Recognition.* Locate $\langle s\rangle$ in the D_8 lattice and find the largest subgroup in which it is normal. The subgroups lying above $\langle s\rangle$ are $\langle s, r^2\rangle$ (order 4) and D_8.

Solution. $\langle s, r^2\rangle = \{1, r^2, s, r^2 s\}$ has index 2, hence is normal and $\langle s\rangle \trianglelefteq \langle s, r^2\rangle$; but $\langle s\rangle$ is *not* normal in D_8 (its conjugates are $\langle s\rangle$ and $\langle r^2 s\rangle$). Therefore $N_{D_8}(\langle s\rangle) = \langle s, r^2\rangle$, of order 4. *Check.* $rsr^{-1} = sr^{-2} = sr^2 \notin \langle s\rangle$ (so $r \notin N$), while $r^2 sr^{-2} = s$ (so $r^2 \in N$).

Maps and commutative diagrams

The lattice itself is a diagram; two more diagrams capture how joins/meets and isomorphisms interact with it.
(a) Join and meet form a diamond. For $H, K \leq G$ the meet is $H \cap K$ (the largest subgroup below both) and the join is $\langle H, K\rangle$ (the smallest subgroup above both), giving a commuting diamond of inclusions (Definition 2.5.3). "Reading a join" means tracing the two upward edges to their first common vertex.

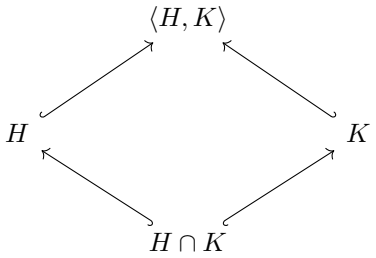


Diagram explanation. Objects: Four vertices, all subgroups of G. Bottom vertex: $H \cap K$, the meet (intersection), itself a subgroup by Proposition 2.5.4. Left vertex: H. Right vertex: K. Top vertex: $\langle H, K\rangle$, the join (the smallest subgroup of G containing both H and K). All four are subgroups; $H \cap K \leq H, K \leq \langle H, K\rangle \leq G$.

Arrows: Four hooked inclusion arrows. Bottom-left $\hookrightarrow$: $H \cap K \hookrightarrow H$ (inclusion, $H \cap K \leq H$). Bottom-right $\hookrightarrow$: $H \cap K \hookrightarrow K$ (inclusion, $H \cap K \leq K$). Top-left $\hookrightarrow$: $H \hookrightarrow \langle H, K\rangle$ (inclusion, $H \leq \langle H, K\rangle$). Top-right $\hookrightarrow$: $K \hookrightarrow \langle H, K\rangle$ (inclusion, $K \leq \langle H, K\rangle$). All four are canonical set inclusions; no quotient or induced map is present.

What commutes: Both paths from $H \cap K$ to $\langle H, K\rangle$ agree: going via H gives $H \cap K \hookrightarrow H \hookrightarrow \langle H, K\rangle$, and going via K gives $H \cap K \hookrightarrow K \hookrightarrow \langle H, K\rangle$. Since all arrows are inclusions, both composites are the same set-inclusion $H \cap K \subseteq \langle H, K\rangle$. Similarly the two "upward" inclusions of H and K into $\langle H, K\rangle$ commute trivially.

Why it commutes: Take any $x \in H \cap K$. Via the left path: $x \in H \cap K \subseteq H \subseteq \langle H, K\rangle$, so x maps to itself in $\langle H, K\rangle$. Via the right path: $x \in H \cap K \subseteq K \subseteq \langle H, K\rangle$, same element x in $\langle H, K\rangle$. The two paths agree

because inclusions are identity-on-elements; there is nothing to check beyond $H \cap K \subseteq H$ and $H \cap K \subseteq K$, both obvious from the definition of intersection.

Why this matters here: This diamond is the visual definition of a lattice: it records that $\mathcal{L}(G)$ has both a greatest lower bound ($H \cap K$) and a least upper bound ($\langle H, K\rangle$) for every pair H, K. The diagram places the four objects in their correct relative position so that "reading a meet" means going to the bottom vertex and "reading a join" means going to the top, exactly the reading-off Method described just before. Without this picture the abstract lattice axioms are hard to parse at a glance.

Concrete example: Take $G = S_3$, $H = \langle(12)\rangle$, $K = \langle(13)\rangle$. Then $H \cap K = \{e\} = 1$ (bottom), $\langle H, K\rangle = S_3$ (top, since the join of two distinct transpositions is the whole group), and the diamond has atoms $\langle(12)\rangle$ and $\langle(13)\rangle$ in the middle. All four inclusion arrows are the set inclusions $\{e\} \subset \{e, (12)\} \subset S_3$ and $\{e\} \subset \{e, (13)\} \subset S_3$.

Common pitfall: Students sometimes read the top vertex as the set-union $H \cup K$ or the product set $HK = \{hk : h \in H, k \in K\}$, neither of which need be a subgroup. The top vertex is $\langle H, K\rangle$, the subgroup *generated* by $H \cup K$; in the S_3 example $\langle(12)\rangle \cup \langle(13)\rangle = \{e, (12), (13)\}$ is not a subgroup, but $\langle\langle(12)\rangle, \langle(13)\rangle\rangle = S_3$ is.

Takeaway: The point of this diagram is that the meet-join diamond makes visible, in a single picture, that every pair of subgroups has a greatest lower bound (intersection) and a least upper bound (generated subgroup), the two operations that make $\mathcal{L}(G)$ a lattice.

(b) Isomorphic groups have identical lattices. An isomorphism $\varphi : G \to G'$ sends each subgroup H to $\varphi(H)$ and preserves all inclusions, so it induces an isomorphism of subgroup lattices: the square below commutes for every $H \leq G$.

$$\begin{array}{ccc} H & \hookrightarrow & G \\ {\scriptstyle \varphi|_H}\downarrow{\scriptstyle \sim} & & {\scriptstyle \varphi}\downarrow{\scriptstyle \sim} \\ \varphi(H) & \hookrightarrow & G' \end{array}$$

Diagram explanation. Objects: Four vertices. Top-left: H, a subgroup of G. Top-right: G, a group. Bottom-left: $\varphi(H)$, the image of H under φ, which is a subgroup of G' (isomorphisms send subgroups to subgroups). Bottom-right: G', a group isomorphic to G.

Arrows: Top horizontal $\hookrightarrow$: the inclusion $H \hookrightarrow G$ (canonical, $H \leq G$). Right vertical $\varphi : G \xrightarrow{\sim} G'$: a group isomorphism, bijective and a homomorphism. Left vertical $\varphi|_H$: the restriction of φ to H, $h \mapsto \varphi(h)$; it is an isomorphism of H onto its image $\varphi(H) \leq G'$ (marked $\sim$). Bottom horizontal $\hookrightarrow$: the inclusion $\varphi(H) \hookrightarrow G'$.

What commutes: The square commutes: the two paths from H to G' are equal. Top-then-right: $H \hookrightarrow G \xrightarrow{\varphi} G'$, sending $h \in H$ to $\varphi(h) \in G'$. Left-then-bottom: $H \xrightarrow{\varphi|_H} \varphi(H) \hookrightarrow G'$, sending any $h \in H$ to $\varphi(h) \in \varphi(H) \subseteq G'$. Both give $h \mapsto \varphi(h)$.

Why it commutes: Take any $h \in H$. Along the top-then-right path: h is viewed in G via inclusion, then φ sends it to $\varphi(h) \in G'$. Along the left-then-bottom path: H is mapped to its image $\varphi(H) \subseteq G'$, and $h \in H$ lands at $\varphi(h) \in \varphi(H)$, then the inclusion puts it in G'. Both agree because φ is a function: the image of h under φ is the same regardless of which route we describe it.

Why this matters here: This diagram encodes the key fact that an isomorphism φ not only identifies G with G' as groups but also identifies their entire subgroup lattices: every $H \leq G$ corresponds to $\varphi(H) \leq G'$, and inclusion is preserved. This is why the remark "isomorphic groups have identical lattices" is diagrammatically immediate — φ induces a lattice isomorphism $\mathcal{L}(G) \to \mathcal{L}(G')$. It also sets up the punch line: the converse fails because the lattice forgets multiplication.

Concrete example: Take $G = \mathbb{Z}/6\mathbb{Z}$, $G' = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ (isomorphic by the Chinese remainder theorem), and $H = \langle\bar{2}\rangle \leq \mathbb{Z}/6\mathbb{Z}$ of order 3. The isomorphism $\varphi : \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ sends $\bar{2} \mapsto (\bar{0}, \bar{2})$, so $\varphi(H) = \{(\bar{0}, \bar{0}), (\bar{0}, \bar{1}), (\bar{0}, \bar{2})\} = \{\bar{0}\} \times \mathbb{Z}/3\mathbb{Z} \leq \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. The square commutes: $\varphi(\bar{2}) = (\bar{0}, \bar{2})$ by either path.

Common pitfall: The left arrow is the restriction $\varphi|_H$, not an inclusion. Students sometimes read it as an inclusion $H \hookrightarrow G'$, but H need not be a subgroup of G' — only $\varphi(H)$ is. The lattice map $H \mapsto \varphi(H)$ acts on subgroups, not on elements, so it is not an arrow of this square: the square is drawn once for each $H \leq G$.

Takeaway: The point of this diagram is that an isomorphism $\varphi : G \xrightarrow{\sim} G'$ induces a bijection on subgroup lattices, making every inclusion $H \leq G$ correspond to $\varphi(H) \leq G'$, which is why isomorphic groups always have identical subgroup lattices.

The converse fails: $Z_2 \times Z_8$ and the modular group M of order 16 have identical lattices but are not isomorphic, so the lattice alone cannot recover the group.

Exercises (from the text).

1. For $H, K \leq G$, exhibit all possible sublattices showing only $G, 1, H, K$ and their joins/meets; describe what distinguishes the cases.
2. In D_{16}, list all subgroups (a) contained in $\langle sr^2, r^4\rangle$; (b) contained in $\langle sr^7, r^4\rangle$; (c) containing $\langle r^4\rangle$; (d) containing $\langle s\rangle$.
3. Show $\langle s, r^2\rangle \leq D_8$ is isomorphic to V_4.
4. Use the lattice to find all 12 pairs of elements that generate D_8.
5. Use the lattice to find all 8 elements x with $D_{16} = \langle x, s\rangle$.
6. Use lattices to find the centralizer of every element of (a) D_8; (b) Q_8; (c) S_3; (d) D_{16}.
7. Find $Z(D_{16})$.
8. Find the normalizer of every subgroup of (a) S_3; (b) Q_8.
9. Draw the lattices of subgroups of (a) $\mathbb{Z}/16\mathbb{Z}$; (b) $\mathbb{Z}/24\mathbb{Z}$; (c) $\mathbb{Z}/48\mathbb{Z}$.
10. Classify groups of order 4: prove $|G| = 4 \implies G \cong Z_4$ or $G \cong V_4$.
11. For the quasidihedral group $QD_{16} = \langle a, \tau \mid a^8 = \tau^2 = 1,\ a\tau = \tau a^3\rangle$, fill in the missing subgroups of its (non-planar) lattice, each with ≤ 2 generators.
12. Draw the lattice of $Z_2 \times Z_4$, each subgroup with ≤ 2 generators.
13. Draw the lattice of $Z_2 \times Z_8$, each subgroup with ≤ 2 generators.
14. For the modular group $M = M_{16} = \langle u, v \mid u^8 = v^2 = 1,\ vuv^{-1} = u^5\rangle$ of order 16, show its lattice matches that of $Z_2 \times Z_8$, yet $M \ncong Z_2 \times Z_8$.
15. Describe the isomorphism type of each of the three order-8 subgroups of D_{16}.
16. Show that in QD_{16} every element of order 2 lies in $\langle \tau, a^2\rangle$.
17. Show that in M, $\{x \in M \mid x^2 = 1\}$ is a subgroup isomorphic to V_4.
18. Find the centralizer of every element of QD_{16}.
19. Find $N_{D_{16}}(\langle s, r^4\rangle)$.
20. Find $N_{QD_{16}}(\langle \tau a\rangle)$ and $N_{QD_{16}}(\langle \tau, a^4\rangle)$.

Additional exercises.

1. Prove that the lattice of subgroups of $\mathbb{Z}/n\mathbb{Z}$ is the divisor lattice of n.
2. Show $\mathbb{Z}/p^2q\mathbb{Z}$ (p, q distinct primes) has exactly 6 subgroups, and draw the lattice.
3. Draw the lattice of S_3 and identify which subgroups are normal.
4. Verify directly in Q_8 that the join of $\langle i\rangle$ and $\langle j\rangle$ is Q_8 and the meet is $\langle -1\rangle$.
5. Using Exercise 14, give two non-isomorphic groups with identical subgroup lattices, and explain why the lattice cannot detect the difference.

Commutative-diagram exercises.

1. Draw the join/meet diamond for $H = \langle r\rangle$ and $K = \langle s\rangle$ in D_8; identify $H \cap K$ and $\langle H, K\rangle$, and read off $[D_8 : H]$.

2. Let $\varphi : G \to G'$ be an isomorphism. Prove $H \mapsto \varphi(H)$ is a lattice isomorphism by checking that the square with rows $H \hookrightarrow G$ and $\varphi(H) \hookrightarrow G'$ (and down-arrows φ) commutes for every $H \leq G$.
3. Draw the diamond for two distinct order-2 subgroups of V_4 and compute their join and meet.
4. Explain, using the lattice-isomorphism square, why the identical lattices of $Z_2 \times Z_8$ and the modular group M_{16} do *not* force the groups to be isomorphic — i.e. why no group isomorphism completes the square.

2.6 Graded Problem Bank

Easy

DF 2.1.1 Prove each is a subgroup: (a) $\{a + ai \mid a \in \mathbb{R}\} \leq (\mathbb{C}, +)$; (b) the unit circle $\{z \in \mathbb{C} \mid |z| = 1\} \leq \mathbb{C}^\times$; (c) $\{a/b \in \mathbb{Q} \mid b \mid n\} \leq (\mathbb{Q}, +)$ (n fixed); (d) $\{a/b \in \mathbb{Q} \mid \gcd(b, n) = 1\} \leq (\mathbb{Q}, +)$; (e) $\{x \in \mathbb{R}^\times \mid x^2 \in \mathbb{Q}\} \leq \mathbb{R}^\times$.

DF 2.1.2 Prove each is *not* a subgroup: (a) the 2-cycles in S_n ($n \geq 3$); (b) the reflections in D_{2n}; (c) $\{x \in G \mid |x| = n\} \cup \{1\}$, n composite and G containing an element of order n; (d) the odd integers together with 0; (e) $\{x \in \mathbb{R} \mid x^2 \in \mathbb{Q}\}$ in $(\mathbb{R}, +)$.

DF 2.1.3 Show $\{1, r^2, s, sr^2\}$ and $\{1, r^2, sr, sr^3\}$ are subgroups of D_8.

DF 2.1.9 Prove $\mathrm{SL}_n(F) = \{A \in \mathrm{GL}_n(F) \mid \det A = 1\} \leq \mathrm{GL}_n(F)$.

DF 2.1.11 Prove $\{(a, 1)\}$, $\{(1, b)\}$, and (when $B = A$) the diagonal $\{(a, a)\}$ are subgroups of $A \times B$.

DF 2.1.14 Show $\{x \in D_{2n} \mid x^2 = 1\}$ is not a subgroup ($n \geq 3$).

DF 2.2.1 Prove $C_G(A) = \{g \mid g^{-1}ag = a \ \forall a \in A\}$ is a subgroup.

DF 2.2.2 Prove $C_G(Z(G)) = G$, and deduce $N_G(Z(G)) = G$.

DF 2.2.4 For S_3, D_8, Q_8, compute the centralizer of each element and the center of each.

DF 2.3.3 Find all generators of $\mathbb{Z}/48\mathbb{Z}$.

DF 2.3.4 Find all generators of $\mathbb{Z}/202\mathbb{Z}$.

DF 2.3.5 Find the number of generators of $\mathbb{Z}/49000\mathbb{Z}$.

DF 2.3.10 Find $|\overline{30}|$ in $\mathbb{Z}/54\mathbb{Z}$, and list the elements and orders of $\langle\overline{30}\rangle$.

DF 2.3.11 Find all cyclic subgroups of D_8 and a non-cyclic proper subgroup.

DF 2.3.14 For $\sigma = (1\,2\,\cdots\,12)$, compute σ^a for $a = 13, 65, 626, 1195, -6, -81, -570, -1211$.

DF 2.4.1 Prove $H \leq G \implies \langle H \rangle = H$.

DF 2.4.5 Prove two distinct elements of order 2 in S_3 generate S_3.

DF 2.4.6 Prove $\langle (1\,2), (1\,2)(3\,4) \rangle$ is non-cyclic of order 4.

DF 2.5.3 Show $\langle s, r^2 \rangle \leq D_8$ is isomorphic to V_4.

DF 2.5.7 Find $Z(D_{16})$.

Artin 2.4 In which of these cases is H a subgroup of G? (a) $G = \mathrm{GL}_n(\mathbb{C})$, $H = \mathrm{GL}_n(\mathbb{R})$; (b) $G = \mathbb{R}^\times$, $H = \{1, -1\}$; (c) $G = (\mathbb{Z}, +)$, H the positive integers; (d) $G = \mathbb{R}^\times$, H the positive reals.

Artin 3.1 Let $a = 123$, $b = 321$. Compute $d = \gcd(a, b)$ and write $d = ra + sb$.

Artin 4.2 An nth root of unity is $z \in \mathbb{C}$ with $z^n = 1$. (a) Prove the nth roots of unity form a cyclic subgroup of $\mathbb{C}^\times$ of order n; (b) determine their product.

Artin 4.6 (a) For a cyclic group of order 6, how many elements generate it? Same for orders 5 and 8. (b) Describe the count for arbitrary order n.

Artin 4.9 How many elements of order 2 does S_4 contain?

Fraleigh 5.1 Determine whether $\mathbb{R}$ is a subgroup of $(\mathbb{C}, +)$.

Fraleigh 5.3 Determine whether $7\mathbb{Z}$ is a subgroup of $(\mathbb{C}, +)$.

Fraleigh 5.4 Determine whether the set $i\mathbb{R}$ of pure imaginary numbers (including 0) is a subgroup of $(\mathbb{C}, +)$.

Fraleigh 5.11 Determine whether the $n \times n$ real matrices with determinant -1 form a subgroup of $\mathrm{GL}(n, \mathbb{R})$.

Fraleigh 5.12 Determine whether the $n \times n$ real matrices with determinant ± 1 form a subgroup of $\mathrm{GL}(n, \mathbb{R})$.

Fraleigh 5.22 Describe all elements of the cyclic subgroup of $\mathrm{GL}(2, \mathbb{R})$ generated by $\left(\begin{smallmatrix} 0 & -1 \\ -1 & 0 \end{smallmatrix}\right)$.

Fraleigh 5.23 Describe all elements of the cyclic subgroup of $\mathrm{GL}(2, \mathbb{R})$ generated by $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$.

Fraleigh 5.27 Find the order of the cyclic subgroup of $\mathbb{Z}/4\mathbb{Z}$ generated by 3.

Fraleigh 5.30 Find the order of the cyclic subgroup of $\mathbb{Z}/10\mathbb{Z}$ generated by 8.

Fraleigh 5.31 Find the order of the cyclic subgroup of $\mathbb{Z}/16\mathbb{Z}$ generated by 12.

Fraleigh 5.32 Find the order of the cyclic subgroup of S_9 generated by $(2\,4\,6\,9)(3\,5\,7)$.

Fraleigh 6.1 Find the quotient and remainder when $n = 42$ is divided by $m = 9$.

Fraleigh 6.3 Find the quotient and remainder when $n = -37$ is divided by $m = 8$.

Fraleigh 6.5 Find the greatest common divisor of 32 and 24.

Fraleigh 6.7 Find the greatest common divisor of 360 and 420.

Fraleigh 6.8 Find the number of generators of a cyclic group of order 5.

Fraleigh 6.10 Find the number of generators of a cyclic group of order 24.

Fraleigh 6.11 Find the number of generators of a cyclic group of order 84.

Fraleigh 6.17 Find the number of elements in the cyclic subgroup of $\mathbb{Z}/30\mathbb{Z}$ generated by 25.

Fraleigh 6.18 Find the number of elements in the cyclic subgroup of $\mathbb{Z}/42\mathbb{Z}$ generated by 30.

Fraleigh 6.19 Find the number of elements in the cyclic subgroup $\langle i \rangle$ of $\mathbb{C}^\times$.

Fraleigh 6.22 Find the number of elements in the cyclic subgroup $\langle \rho^{10} \rangle$ of D_{24}.

Fraleigh 6.24 In S_{10}: (a) order of $(2\,4\,6\,7)$; (b) order of $(1\,4)(2\,3\,5)$ and $(1\,3)(2\,4\,6\,7\,8)$; (c)–(d) further products of disjoint cycles.

Fraleigh 6.25 Find the maximum possible order of an element of S_n for $n = 5$.

Fraleigh 6.26 Find the maximum possible order of an element of S_n for $n = 6$.

Fraleigh 6.31 Find all subgroups of $\mathbb{Z}/12\mathbb{Z}$ and draw the subgroup diagram.

Fraleigh 6.33 Find all subgroups of $\mathbb{Z}/8\mathbb{Z}$ and draw the subgroup diagram.

Fraleigh 6.34 Find all orders of subgroups of $\mathbb{Z}/6\mathbb{Z}$.

Fraleigh 6.36 Find all orders of subgroups of $\mathbb{Z}/12\mathbb{Z}$.

Fraleigh 6.38 Find all orders of subgroups of $\mathbb{Z}/17\mathbb{Z}$.

Fraleigh 6.47 Find the primitive nth roots of unity for $n = 4$.

Fraleigh 6.48 Find the primitive nth roots of unity for $n = 6$.

Fraleigh 7.1 List the elements of the subgroup of $\mathbb{Z}/12\mathbb{Z}$ generated by $\{2, 3\}$.

Fraleigh 7.2 List the elements of the subgroup of $\mathbb{Z}/12\mathbb{Z}$ generated by $\{4, 6\}$.

Fraleigh 7.3 List the elements of the subgroup of $\mathbb{Z}/25\mathbb{Z}$ generated by $\{4, 6\}$.

Fraleigh 7.5 List the elements of the subgroup of $\mathbb{Z}$ generated by $\{12, 42\}$.

Fraleigh 7.7 List the elements of the subgroup of D_8 generated by $\{\mu, \mu\rho^2\}$ (i.e. $\{s, sr^2\}$).

Medium

DF 2.1.4 Exhibit a group G and an infinite subset H closed under the operation but not a subgroup.

DF 2.1.5 Prove a group of order $n > 2$ has no subgroup of order $n - 1$.

DF 2.1.6 G abelian: prove the torsion set $\{g \mid |g| < \infty\} \leq G$; give a non-abelian example where this set is not a subgroup.

DF 2.1.7 For $n > 1$, find the torsion subgroup of $\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$, and show the elements of infinite order together with 1 do not form a subgroup.

DF 2.1.8 For $H, K \leq G$, prove $H \cup K \leq G \iff H \subseteq K$ or $K \subseteq H$.

DF 2.1.10 (a) Prove $H \cap K \leq G$ for $H, K \leq G$; (b) prove the intersection of any nonempty family of subgroups is a subgroup.

DF 2.1.12 A abelian, $n \in \mathbb{Z}$: prove $A^n = \{a^n\}$ and $A[n] = \{a \mid a^n = 1\}$ are subgroups.

DF 2.1.15 Prove the union of an ascending chain $H_1 \leq H_2 \leq \cdots$ of subgroups is a subgroup.

DF 2.1.16 Prove the upper-triangular matrices in $\mathrm{GL}_n(F)$ form a subgroup.

DF 2.1.17 Prove the upper-triangular matrices with 1's on the diagonal form a subgroup of $\mathrm{GL}_n(F)$.

DF 2.2.3 Prove $A \subseteq B \implies C_G(B) \leq C_G(A)$.

DF 2.2.5 Show $C_G(A) = A$ and $N_G(A) = G$ for: (a) S_3, $A = \langle(1\,2\,3)\rangle$; (b) D_8, $A = \{1, s, r^2, sr^2\}$; (c) D_{10}, $A = \langle r\rangle$.

DF 2.2.6 (a) Prove $H \leq N_G(H)$ (and that this can fail if H is not a subgroup); (b) prove $H \leq C_G(H) \iff H$ is abelian.

DF 2.2.9 Define $N_H(A) = \{h \in H \mid hAh^{-1} = A\}$; prove $N_H(A) = N_G(A) \cap H \leq H$.

DF 2.2.11 Prove $Z(G) \leq N_G(A)$ for every subset A.

DF 2.2.12 S_4 acts on $\mathbb{Z}[x_1, \ldots, x_4]$ by $\sigma \cdot x_i = x_{\sigma(i)}$. Find the stabilizers of x_4, of $x_1 + x_2$, and of $x_1x_2 + x_3x_4$.

DF 2.2.13 Verify that the action of S_n on $\mathbb{Z}[x_1, \ldots, x_n]$ is a group action.

DF 2.3.1 Find all subgroups of $Z_{45} = \langle x\rangle$, giving a generator for each, and describe the containments.

DF 2.3.2 If $x \in G$ is finite with $|x| = |G|$, prove $G = \langle x\rangle$; give an infinite counterexample.

DF 2.3.6 In $\mathbb{Z}/48\mathbb{Z}$, list the elements of $\langle\bar{a}\rangle$ for each $\bar{a}$, and all inclusions among subgroups.

DF 2.3.7 Use $\mathbb{Z}/48\mathbb{Z} \cong Z_{48}$ to list all subgroups of Z_{48}.

DF 2.3.8 For which a does $1 \mapsto x^a$ extend to an isomorphism $\mathbb{Z}/48\mathbb{Z} \to Z_{48}$?

DF 2.3.9 For which a does $1 \mapsto x^a$ extend to a homomorphism $\mathbb{Z}/48\mathbb{Z} \to Z_{36}$? Can it be surjective?

DF 2.3.12 Prove $Z_2 \times Z_2$, $Z_2 \times \mathbb{Z}$, and $\mathbb{Z} \times \mathbb{Z}$ are not cyclic.

DF 2.3.13 Prove $\mathbb{Z} \times Z_2 \ncong \mathbb{Z}$ and $\mathbb{Q} \times Z_2 \ncong \mathbb{Q}$.

DF 2.3.15 Prove $\mathbb{Q} \times \mathbb{Q}$ is not cyclic.

DF 2.3.17 Find a presentation of Z_n with one generator.

DF 2.3.18 If $h^n = 1$ in H, prove there is a unique homomorphism $Z_n \to H$ with $x \mapsto h$.

DF 2.3.19 For $h \in H$, prove there is a unique homomorphism $\mathbb{Z} \to H$ with $1 \mapsto h$.

DF 2.3.20 p prime, $x^{p^n} = 1 \implies |x| = p^m$ for some $m \leq n$.

DF 2.4.2 Prove $A \subseteq B \implies \langle A\rangle \leq \langle B\rangle$, and give $A \subsetneq B$ with $\langle A\rangle = \langle B\rangle$.

DF 2.4.4 Prove $H \leq G \implies H = \langle H \setminus \{1\}\rangle$.

DF 2.4.7 Prove $\langle (1\,2), (1\,3)(2\,4)\rangle \cong D_8$.

DF 2.4.8 Prove $S_4 = \langle (1\,2\,3\,4), (1\,2\,4\,3)\rangle$.

DF 2.4.13 Prove $(\mathbb{Q}^+, \cdot) = \langle \{1/p \mid p \text{ prime}\}\rangle$.

DF 2.4.15 Exhibit a proper non-cyclic subgroup of $\mathbb{Q}$.

DF 2.5.1 For $H, K \leq G$, exhibit all possible sublattices showing only $G, 1, H, K$ and their joins/meets; describe what distinguishes the cases.

DF 2.5.4 Use the lattice to find all 12 pairs of elements that generate D_8.

DF 2.5.5 Use the lattice to find all 8 elements x with $D_{16} = \langle x, s\rangle$.

DF 2.5.6 Use lattices to find the centralizer of every element of (a) D_8; (b) Q_8; (c) S_3; (d) D_{16}.

DF 2.5.8 Find the normalizer of every subgroup of (a) S_3; (b) Q_8.

DF 2.5.9 Draw the lattices of subgroups of (a) $\mathbb{Z}/16\mathbb{Z}$; (b) $\mathbb{Z}/24\mathbb{Z}$; (c) $\mathbb{Z}/48\mathbb{Z}$.

DF 2.5.15 Describe the isomorphism type of each of the three order-8 subgroups of D_{16}.

DF 2.5.19 Find $N_{D_{16}}(\langle s, r^4\rangle)$.

Artin 3.2 Prove that if a, b are positive integers whose sum is a prime p, then $\gcd(a, b) = 1$.

Artin 4.1 Let $a, b \in G$ with $|a| = 7$ and $a^3b = ba^3$. Prove $ab = ba$.

Artin 4.3 Prove that ab and ba have the same order in any group.

Artin 4.4 Describe all groups G that contain no proper subgroup.

Artin 4.7 Let $x, y \in G$ with x, y, xy all of order 2. Prove $\{1, x, y, xy\}$ is a subgroup of order 4.

Artin 4.10 Show by example that the product of two finite-order elements need not have finite order. What if the group is abelian?

Artin M.2 (a) Prove every group of even order contains an element of order 2; (b) prove every group of order 21 contains an element of order 3.

Fraleigh 5.20 Among $\mathbb{Z}, 12\mathbb{Z}, \mathbb{Q}^+, \mathbb{R}, \mathbb{R}^+, 3\mathbb{Z}$, etc. (nine listed groups), give the complete list of subgroup relations $G_i \leq G_j$.

Fraleigh 5.26 Decide which of $\langle \mathbb{Z}, +\rangle$, $\langle \mathbb{Q}, +\rangle$, $\langle \mathbb{Q}^+, \cdot\rangle$, $\langle 6\mathbb{Z}, +\rangle$, $\{6^n\}$, $\{a + b\sqrt{2} \mid a, b \in \mathbb{Z}\}$ are cyclic; list generators.

Fraleigh 5.41 For $B \subseteq A$, $b \in B$: determine whether $\{\sigma \in S_A \mid \sigma(b) = b\}$ is a subgroup of S_A.

Fraleigh 5.44 For $B \subseteq A$: determine whether $\{\sigma \in S_A \mid \sigma[B] = B\}$ is a subgroup of S_A.

Fraleigh 5.45 If $\varphi : G \to G'$ is an isomorphism and $H \leq G$, prove $\varphi[H] \leq G'$.

Fraleigh 5.47 If H, K are subgroups of an abelian group G, prove $\{hk \mid h \in H, k \in K\}$ is a subgroup.

Fraleigh 5.48 Find a group G and subgroups H, K for which the set $\{hk\}$ of the previous exercise is not a subgroup.

Fraleigh 5.53 In an abelian group G, prove the solutions of $x^2 = e$ form a subgroup.

Fraleigh 5.58 Let $a \in G$. Prove $H_a = \{x \in G \mid xa = ax\}$ is a subgroup.

Fraleigh 5.61 Prove that if $H \leq G$ and $K \leq G$, then $H \cap K \leq G$.

Fraleigh 5.62 Prove that every cyclic group is abelian.

Fraleigh 6.13 Find the number of automorphisms of $\mathbb{Z}/6\mathbb{Z}$.

Fraleigh 6.14 Find the number of automorphisms of $\mathbb{Z}/8\mathbb{Z}$.

Fraleigh 6.16 Find the number of automorphisms of $\mathbb{Z}/84\mathbb{Z}$.

Fraleigh 6.54 For integers r, s, show $\{nr + ms \mid n, m \in \mathbb{Z}\}$ is a subgroup of $\mathbb{Z}$.

Fraleigh 6.56 If ab has finite order n, show ba also has order n.

Fraleigh 6.62 For distinct primes p, q, find the number of generators of $\mathbb{Z}/pq\mathbb{Z}$.

Fraleigh 6.63 For a prime p and integer $r \geq 1$, find the number of generators of $\mathbb{Z}/p^r\mathbb{Z}$.

Fraleigh 6.66 Show $\mathbb{Z}/p\mathbb{Z}$ has no proper nontrivial subgroups when p is prime.

Fraleigh 7.13 Explain how to tell from a Cayley digraph whether the group is commutative.

Fraleigh 7.16 Does the small inside triangle in the Cayley digraph of $\mathbb{Z}/6\mathbb{Z}$ (with $S = \{2, 3\}$) exhibit a cyclic subgroup? Why or why not?

Fraleigh 7.18 Draw a Cayley digraph for $\mathbb{Z}/8\mathbb{Z}$ with generating set $S = \{2, 5\}$.

Fraleigh 7.22 Prove there are at least three different abelian groups of order 8.

Hard

DF 2.1.13 $H \leq (\mathbb{Q}, +)$ with $1/x \in H$ for all $x \in H \setminus \{0\}$: prove $H = 0$ or $H = \mathbb{Q}$.

DF 2.2.7 For $n \geq 3$: (a) $Z(D_{2n}) = 1$ if n is odd; (b) $Z(D_{2n}) = \{1, r^k\}$ if $n = 2k$.

DF 2.2.8 $G = S_n$, $G_i = \{\sigma \mid \sigma(i) = i\}$: prove $G_i \leq G$ via group actions and find $|G_i|$.

DF 2.2.10 Let $|H| = 2$. Prove $N_G(H) = C_G(H)$, and deduce $N_G(H) = G \implies H \leq Z(G)$.

DF 2.2.14 Prove the center of the Heisenberg group $H(F)$ is isomorphic to $(F, +)$.

DF 2.3.16 $|x| = n$, $|y| = m$, $xy = yx$: prove $|xy| \mid \operatorname{lcm}(m, n)$; show this can fail without commuting, and give commuting x, y with $|xy| \neq \operatorname{lcm}(m, n)$.

DF 2.3.21 p an odd prime: show $1 + p$ has order p^{n-1} in $(\mathbb{Z}/p^n\mathbb{Z})^\times$.

DF 2.3.22 $n \geq 3$: show 5 has order 2^{n-2} in $(\mathbb{Z}/2^n\mathbb{Z})^\times$.

DF 2.3.23 Show $(\mathbb{Z}/2^n\mathbb{Z})^\times$ is not cyclic for $n \geq 3$.

DF 2.3.24 G finite, $x \in G$: prove $g \in N_G(\langle x \rangle) \iff gxg^{-1} = x^a$ for some $a \in \mathbb{Z}$.

DF 2.3.25 G cyclic of order n, $\gcd(k, n) = 1$: prove $x \mapsto x^k$ is surjective, and extend to any finite group of order n.

DF 2.3.26 $\operatorname{Aut}(Z_n)$: prove $\sigma_a : x \mapsto x^a$ is an automorphism $\iff \gcd(a, n) = 1$, and $\operatorname{Aut}(Z_n) \cong (\mathbb{Z}/n\mathbb{Z})^\times$, abelian of order $\varphi(n)$.

DF 2.4.3 Prove that if H is abelian then $\langle H, Z(G) \rangle$ is abelian; give an abelian H with $\langle H, C_G(H) \rangle$ not abelian.

DF 2.4.9 Prove $\mathrm{SL}_2(\mathbb{F}_3) = \langle \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right) \rangle$.

DF 2.4.10 Prove the subgroup of $\mathrm{SL}_2(\mathbb{F}_3)$ generated by $\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} -1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ is $\cong Q_8$.

DF 2.4.11 Prove $\mathrm{SL}_2(\mathbb{F}_3) \ncong S_4$ (both of order 24).

DF 2.4.12 Prove the upper-triangular subgroup of $\mathrm{GL}_3(\mathbb{F}_2)$ is $\cong D_8$.

DF 2.4.14 Finitely generated groups: (a) finite groups are f.g.; (b) $\mathbb{Z}$ is f.g.; (c) a f.g. subgroup of $\mathbb{Q}$ is cyclic; (d) $\mathbb{Q}$ is not f.g.

DF 2.4.16 Maximal subgroups: (a) every proper subgroup of a finite group lies in a maximal one; (b) the rotation subgroup of D_{2n} is maximal; (c) H is maximal in $Z_n = \langle x \rangle \iff H = \langle x^p \rangle$ for a prime $p \mid n$.

DF 2.4.17 (Zorn) Prove every nontrivial finitely generated group has a maximal subgroup.

DF 2.4.18 Prüfer group $\mathbb{Z}_{p^\infty} = \{z \in \mathbb{C} \mid z^{p^n} = 1 \text{ some } n\}$, $H_k = \{z \mid z^{p^k} = 1\}$: prove $H_k \leq H_m \iff k \leq m$; each H_k is cyclic; every proper subgroup is some H_k; and $\mathbb{Z}_{p^\infty}$ is not f.g.

DF 2.4.19 A nontrivial abelian group is divisible if every element has a kth root for each $k \neq 0$. Prove $(\mathbb{Q}, +)$ is divisible and no nontrivial finite abelian group is.

DF 2.4.20 For nontrivial abelian A, B, prove $A \times B$ is divisible $\iff$ both A and B are divisible.

DF 2.5.2 In D_{16}, list all subgroups (a) contained in $\langle sr^2, r^4\rangle$; (b) contained in $\langle sr^7, r^4\rangle$; (c) containing $\langle r^4\rangle$; (d) containing $\langle s\rangle$.

DF 2.5.10 Classify groups of order 4: prove $|G| = 4 \implies G \cong Z_4$ or $G \cong V_4$.

DF 2.5.11 For $QD_{16} = \langle a, \tau \mid a^8 = \tau^2 = 1,\ a\tau = \tau a^3\rangle$, fill in the missing subgroups of its (non-planar) lattice, each with ≤ 2 generators.

DF 2.5.12 Draw the lattice of $Z_2 \times Z_4$, each subgroup with ≤ 2 generators.

DF 2.5.13 Draw the lattice of $Z_2 \times Z_8$, each subgroup with ≤ 2 generators.

DF 2.5.14 For $M = M_{16} = \langle u, v \mid u^8 = v^2 = 1,\ vuv^{-1} = u^5\rangle$ of order 16, show its lattice matches that of $Z_2 \times Z_8$, yet $M \ncong Z_2 \times Z_8$.

DF 2.5.16 Show that in QD_{16} every element of order 2 lies in $\langle \tau, a^2\rangle$.

DF 2.5.17 Show that in M, $\{x \in M \mid x^2 = 1\}$ is a subgroup isomorphic to V_4.

DF 2.5.18 Find the centralizer of every element of QD_{16}.

DF 2.5.20 Find $N_{QD_{16}}(\langle \tau a\rangle)$ and $N_{QD_{16}}(\langle \tau, a^4\rangle)$.

Artin 3.3 (a) Define the gcd of n integers $\{a_1, \ldots, a_n\}$; prove it exists and is an integer combination of the a_i. (b) If the gcd is d, prove $\gcd(a_1/d, \ldots, a_n/d) = 1$.

Artin 4.5 Prove that every subgroup of a cyclic group is cyclic, working with exponents and the description of subgroups of $(\mathbb{Z}, +)$.

Artin 4.8 (a) Prove the elementary matrices of the first and third types generate $\mathrm{GL}_n(\mathbb{R})$; (b) prove those of the first type generate $\mathrm{SL}_n(\mathbb{R})$.

Artin 4.11 (a) Adapt row reduction to prove the transpositions generate S_n; (b) prove that for $n \geq 3$ the 3-cycles generate A_n.

Artin M.3 Classify groups of order 6 via the cases: (i) an element of order 6 exists; (ii) an element of order 3 but none of order 6; (iii) all elements have order 1 or 2.

Artin M.12 (postage stamp) For positive coprime a, b: (a) prove every sufficiently large n is $ra + sb$ with r, s positive integers; (b) determine the largest integer not of this form.

Fraleigh 6.55 Prove that if G is a finite cyclic group and $H \neq K$ are subgroups, then $|H| \neq |K|$.

Fraleigh 6.58 Show that a group with only finitely many subgroups must be finite.

Fraleigh 6.59 Give a counterexample to the converse of "a subgroup of a cyclic group is cyclic": a non-cyclic G with every proper subgroup cyclic.

Fraleigh 6.60 If $a \in G$ generates a cyclic subgroup of order 2 and is the unique such element, show $ax = xa$ for all $x \in G$.

Fraleigh 6.61 Prove that if a cyclic group has an odd number of generators, then it has at most two elements.

Fraleigh 6.64 In a finite cyclic group of order n, show $x^m = e$ has exactly m solutions for each $m \mid n$.

Fraleigh 6.67 Let G be abelian with finite cyclic subgroups H, K of orders r, s. (a) If $\gcd(r, s) = 1$, G has a cyclic subgroup of order rs; (b) in general, of order $\mathrm{lcm}(r, s)$.

Fraleigh 7.21 Use Cayley digraphs to show that for $n \geq 3$ there is a nonabelian group with $2n$ elements generated by two elements of order 2.

Chapter 3

Quotient Groups and Homomorphisms

3.1 Definitions and Examples

Cosets and the quotient group G/N

Throughout, G is a group and $N \leq G$ a subgroup. We build a new group whose elements are the cosets of N, but this construction succeeds *only* when N is normal. This is the central tension of the section, so we develop it carefully.

Definition 3.1.1 (Left and right cosets)**.** For $g \in G$ the **left coset** of N containing g is

$$gN = \{\, gn \mid n \in N \,\},$$

and the **right coset** is $Ng = \{\, ng \mid n \in N \,\}$. The set of all left cosets is denoted G/N (read "G mod N"), and the number of left cosets is the **index** $[G : N]$.

Remark 3.1.1. Two left cosets are equal or disjoint, and $aN = bN \iff a^{-1}b \in N$. The cosets partition G, each has the same cardinality $|N|$, and when G is finite Lagrange's theorem gives $|G| = [G : N]\,|N|$. None of this requires N to be normal; normality is needed only to *multiply* cosets.

Definition 3.1.2 (The proposed product on G/N)**.** We attempt to make G/N a group by setting, for cosets $X = aN$ and $Y = bN$,

$$(aN)(bN) \;=\; (ab)N.$$

The issue: a coset has many names ($aN = a'N$ whenever $a^{-1}a' \in N$), so we must check the answer $(ab)N$ does not depend on which representatives a, b we chose. This is the **well-definedness** question.

Theorem 3.1.3 (Well-definedness of the coset product $\iff$ normality)**.** *Let $N \leq G$. The following are equivalent:*

(1) The product $(aN)(bN) = (ab)N$ is well defined on G/N (independent of representatives).

(2) $gNg^{-1} = N$ for all $g \in G$ (equivalently $gNg^{-1} \subseteq N$ for all g); i.e. $N \trianglelefteq G$.

(3) $gN = Ng$ for all $g \in G$ (every left coset is a right coset).

*When these hold, G/N with this product is a group, the **quotient group**, with identity $N = 1N$ and inverse $(aN)^{-1} = a^{-1}N$.*

Proof. (2) $\iff$ (3): $gNg^{-1} = N \iff gN = Ng$ on multiplying by g on the right. Moreover $gNg^{-1} \subseteq N$ for all g forces equality: applying the inclusion to g^{-1} gives $g^{-1}Ng \subseteq N$, i.e. $N \subseteq gNg^{-1}$, so $gNg^{-1} = N$.

(2) $\Rightarrow$ (1): Suppose $aN = a'N$ and $bN = b'N$, so $a' = an_1$ and $b' = bn_2$ with $n_1, n_2 \in N$. Then

$$a'b' = an_1bn_2 = ab\,(b^{-1}n_1b)\,n_2.$$

By (2), $b^{-1}n_1b \in b^{-1}Nb = N$, so $b^{-1}n_1b = n_3 \in N$ and $a'b' = ab\,n_3n_2 \in (ab)N$. Hence $a'b'N = abN$: the product is well defined.

(1) $\Rightarrow$ (2): Assume the product is well defined. Fix $g \in G$ and $n \in N$. Since $n \in N$ we have $nN = N = 1N$, so gn and g are two representatives of the same left coset: $(gn)N = gN$. Likewise $g^{-1}N = g^{-1}N$. Apply well-definedness to the two equal pairs $\big((gn)N,\ g^{-1}N\big)$ and $\big(gN,\ g^{-1}N\big)$:

$$\big((gn)N\big)\big(g^{-1}N\big) = \big(gN\big)\big(g^{-1}N\big) \implies (gng^{-1})N = (gg^{-1})N = N.$$

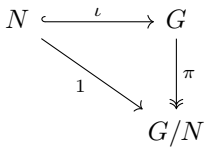
Thus $gng^{-1} \in N$. As $g \in G$ and $n \in N$ were arbitrary, $gNg^{-1} \subseteq N$ for all g, hence $N \trianglelefteq G$.

Group axioms when (2) holds: associativity is inherited from G, since

$$(aN)\big((bN)(cN)\big) = a(bc)N = (ab)c\,N = \big((aN)(bN)\big)(cN);$$

the identity is $N = 1N$ since $(aN)(1N) = aN$; and the inverse of aN is $a^{-1}N$ since $(aN)(a^{-1}N) = aa^{-1}N = N$. □

Remark 3.1.2 (Quotient group via fibers, D&F's viewpoint). Equivalently, when $N \trianglelefteq G$, the cosets are exactly the fibers of any homomorphism with kernel N, and "multiply the cosets" means "multiply the fibers as subsets": the subset product $(aN)(bN) = \{\, xy \mid x \in aN,\ y \in bN \,\}$ is itself a single coset, namely $(ab)N$. The subset product $XY = \{\, xy \mid x \in X,\ y \in Y \,\}$ being a single coset for all cosets X, Y is yet another equivalent of normality.



Theorem 3.1.4 (The natural projection)**.** *Let $N \trianglelefteq G$. The map*

$$\pi : G \longrightarrow G/N, \qquad \pi(g) = gN,$$

is a surjective homomorphism with $\ker \pi = N$*. Consequently N is normal in G* iff *it is the kernel of some homomorphism out of G, and $|G/N| = [G : N]$.*

Proof. Homomorphism: $\pi(gh) = (gh)N = (gN)(hN) = \pi(g)\pi(h)$, using the quotient product. Surjective: every coset gN equals $\pi(g)$. Kernel: $\pi(g) = N$ (the identity of G/N) $\iff$ $gN = N$ $\iff$ $g \in N$, so $\ker \pi = N$. The number of cosets is $[G : N]$ by definition, hence $|G/N| = [G : N]$. Finally, kernels are always normal, and π exhibits any normal N as a kernel, giving the "iff." □

The inclusion of N and the projection π fit into the triangle

in which $\pi \circ \iota$ collapses all of N to the identity coset N.

Diagram explanation. Objects: Three groups. N (upper left) is the normal subgroup; G (upper right) is the ambient group; G/N (bottom) is the quotient group, whose elements are the cosets gN.

Arrows: $\iota : N \hookrightarrow G$ is the inclusion (a hooked arrow), $\iota(n) = n$ – it just regards each element of N as an element of G. $\pi : G \twoheadrightarrow G/N$ is the natural projection (a two-headed arrow), $\pi(g) = gN$; it is the quotient/canonical map, surjective with $\ker \pi = N$. The unlabelled diagonal $N \to G/N$ marked "1" is the constant map sending every $n \in N$ to the identity coset $N = 1N$.

What commutes: Down-the-diagonal equals across-then-down: $\pi \circ \iota =$ (constant map 1), i.e. $(\pi \circ \iota)(n) = N$ for all $n \in N$.

Why it commutes: Take a generic $n \in N$. Right-then-down: $\iota(n) = n$, then $\pi(n) = nN$; but $n \in N$ forces $nN = N$, the identity coset. The diagonal sends n to N directly. Both paths land on the identity coset, so the triangle commutes. (The map $g \mapsto gN$ makes sense for any subgroup N; what $N \trianglelefteq G$ provides is the group structure on G/N, so that π is a homomorphism and $N = 1N$ is its identity element.)

Why this matters here: This records Theorem 3.1.4 pictorially: π kills exactly N. The triangle says "including N then projecting forgets all of N," which is the geometric content of $\ker\pi = N$ and the launching point for the isomorphism theorems.

Concrete example: $G = \mathbb{Z}$, $N = n\mathbb{Z}$, $G/N = \mathbb{Z}/n\mathbb{Z}$. Then ι embeds $n\mathbb{Z}$ in $\mathbb{Z}$, $\pi(a) = \overline{a}$, and $\pi \circ \iota$ sends every multiple of n to $\overline{0}$: e.g. for $n = 6$, $\iota(12) = 12$ and $\pi(12) = \overline{12} = \overline{0}$.

Common pitfall: Reading ι as an isomorphism onto its image and forgetting that π then crushes that image to one point; or thinking the triangle "proves" G/N is a group – it only displays the maps, assuming $N \trianglelefteq G$ already.

Takeaway: Including N into G and then projecting to G/N annihilates N entirely – π collapses exactly the kernel.

Encoded as a short exact sequence,

$$1 \longrightarrow N \xhookrightarrow{\iota} G \xrightarrow{\pi} G/N \longrightarrow 1,$$

where exactness at G says precisely $\operatorname{im}\iota = \ker\pi = N$.

Diagram explanation. Objects: Five terms read left to right: the trivial group 1, the normal subgroup N, the ambient group G, the quotient group G/N, and the trivial group 1 again. The two outer 1's are bookends that turn "ι injective" and "π surjective" into exactness statements.

Arrows: $1 \to N$ is the only (trivial) homomorphism; $\iota : N \hookrightarrow G$ is the inclusion; $\pi : G \twoheadrightarrow G/N$ is the natural projection $g \mapsto gN$; $G/N \to 1$ is again the trivial map. This is not a single commuting square but a chain in which the image of each arrow equals the kernel of the next.

What commutes: Exactness, node by node: at N, $\operatorname{im}(1 \to N) = \{1\} = \ker\iota$ (so ι is injective); at G, $\operatorname{im}\iota = N = \ker\pi$; at G/N, $\operatorname{im}\pi = G/N = \ker(G/N \to 1)$ (so π is surjective).

Why it commutes: The crucial middle equality: $\operatorname{im}\iota = N$ since ι is the inclusion, and $\ker\pi = \{g : gN = N\} = N$ by Theorem 3.1.4. A generic g has $\pi(g) = N$ iff $g \in N$ iff $g = \iota(n)$ for some n – so the elements killed by π are exactly those coming from ι. Normality of N is what makes the coset product well defined, and hence makes G/N a group and π a homomorphism in the first place.

Why this matters here: The short exact sequence is the compact dictionary entry "G/N is the cokernel of $N \hookrightarrow G$." It packages the whole section: N sits inside G as a kernel, and G/N is what is left after forgetting N. Every later isomorphism theorem is a statement about such sequences.

Concrete example: $1 \to n\mathbb{Z} \hookrightarrow \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/n\mathbb{Z} \to 1$. Exactness at $\mathbb{Z}$ says $\operatorname{im}(n\mathbb{Z} \hookrightarrow \mathbb{Z}) = n\mathbb{Z} = \ker(a \mapsto \overline{a})$, i.e. $\overline{a} = \overline{0} \iff n \mid a$.

Common pitfall: Thinking the sequence asserts $G \cong N \times G/N$ (a splitting) – it does not; it only records that N is a kernel and G/N the quotient. It also does not by itself prove $N \trianglelefteq G$; normality is the standing hypothesis that lets π exist.

Takeaway: The sequence is a one-line summary of the section: N is exactly the kernel of the projection onto G/N, sitting injectively inside G.

Method (Computing inside G/N: reduce representatives)**.** *Trigger.* You must add/multiply cosets, find the order of gN, or identify the isomorphism type of G/N.

1. **Multiply by representatives.** $(aN)(bN) = (ab)N$; just multiply a, b in G, then re-coset.
2. **Reduce mod N.** Replace the answer abN by the simplest name: $abN = cN$ whenever $c^{-1}(ab) \in N$. In $\mathbb{Z}$ this is "reduce mod n."
3. **Identity test.** $gN = N \iff g \in N$. So in G/N a relation $gN = 1$ means $g \in N$.
4. **Order of a coset.** $|gN|$ is the least $k \geq 1$ with $g^k \in N$ (it divides $|g|$ when g has finite order).
5. **Identify the type.** Compute $|G/N| = [G : N]$, then match generators/orders to a known group of that order.

Method (Verifying well-definedness of a coset operation)**.** *Trigger.* You are asked to show $(aN)(bN) = (ab)N$ makes sense, or to test whether a candidate N yields a quotient.

1. Take two names for each input: $a' = an_1$, $b' = bn_2$ with $n_1, n_2 \in N$.
2. Compute $a'b' = ab\,(b^{-1}n_1 b)\,n_2$ and ask: is $b^{-1}n_1 b \in N$?
3. If $N \trianglelefteq G$, yes for all b – well defined. If you can find g, n with $gng^{-1} \notin N$, the operation is *not* well defined; exhibit two representative choices giving different cosets.

Caution. The product $(aN)(bN) = (ab)N$ is **not** automatic. For a non-normal N it depends on the chosen representatives, so it is no operation at all. Always confirm $N \trianglelefteq G$ *before* computing in "G/N." A clean witness of failure: pick $a' = an$ with $n \in N$ but $b^{-1}nb \notin N$; then $(a'b)N \neq (ab)N$ even though $a'N = aN$.

Caution. $gN = Ng$ as *sets* does not mean $gn = ng$ for each n. Normality is a setwise condition: conjugation by g permutes N (i.e. $gNg^{-1} = N$), but it need not fix elements. Do not confuse normal with central.

Worked Example 3.1.5 ($\mathbb{Z}/n\mathbb{Z}$ as a quotient of $(\mathbb{Z}, +)$)**.** Take $G = (\mathbb{Z}, +)$ and $N = n\mathbb{Z} = \{\dots, -2n, -n, 0, n, 2n, \dots\}$ for a fixed $n \geq 1$. Describe G/N, its operation, and its order.

Recognition. Additive abelian group, so every subgroup is normal (Example below). The cosets are residue classes; this is the prototype of every quotient.

Solution. Since $\mathbb{Z}$ is abelian, $n\mathbb{Z} \trianglelefteq \mathbb{Z}$, so $\mathbb{Z}/n\mathbb{Z}$ is a group. A coset is

$$a + n\mathbb{Z} = \{\, a + nk \mid k \in \mathbb{Z} \,\} = \overline{a},$$

and $a + n\mathbb{Z} = b + n\mathbb{Z} \iff a - b \in n\mathbb{Z} \iff a \equiv b \pmod{n}$. By the division algorithm every integer is congruent to exactly one of $0, 1, \dots, n-1$, so the distinct cosets are $\overline{0}, \overline{1}, \dots, \overline{n-1}$ and $|\mathbb{Z}/n\mathbb{Z}| = [\mathbb{Z} : n\mathbb{Z}] = n$. The (well-defined) operation is

$$(a + n\mathbb{Z}) + (b + n\mathbb{Z}) = (a + b) + n\mathbb{Z}, \quad \text{i.e.} \quad \overline{a} + \overline{b} = \overline{a + b}.$$

Concretely with $n = 6$: $\overline{4} + \overline{5} = \overline{9} = \overline{3}$, and $\overline{2} + \overline{4} = \overline{6} = \overline{0}$. The projection is $\pi(a) = \overline{a}$, with $\ker \pi = 6\mathbb{Z}$. *Check.* $\overline{0}$ is the identity ($\overline{a} + \overline{0} = \overline{a}$); the inverse of $\overline{4}$ in $\mathbb{Z}/6\mathbb{Z}$ is $\overline{2}$ since $\overline{4} + \overline{2} = \overline{6} = \overline{0}$. And indeed $|\mathbb{Z}/6\mathbb{Z}| = 6 = [\mathbb{Z} : 6\mathbb{Z}]$. ■

Worked Example 3.1.6 (The two trivial quotients: G/G and $G/1$)**.** For any group G, identify G/G and $G/\{1\}$.

Recognition. Both G and $\{1\}$ are normal in G (the whole group and the trivial subgroup are always normal), so both quotients exist. This pins down the "boundary" behavior.

Solution. Case $N = G$. There is exactly one coset, $gG = G$ for every g, so $G/G = \{G\}$ has order $[G : G] = 1$; it is the trivial group. The projection $\pi : G \to G/G$ sends everything to the single element, with $\ker \pi = G$.

Case $N = \{1\}$. Each coset is $g\{1\} = \{g\}$, a singleton, so the cosets biject with G itself and the product $(\{a\})(\{b\}) = \{ab\}$ matches G's product. Thus $G/\{1\} \cong G$ via $g\{1\} \mapsto g$, and $[G : 1] = |G|$. The projection $\pi : G \to G/\{1\}$ is an isomorphism with $\ker \pi = \{1\}$. *Check.* Orders agree: $|G/G| = 1$ and $|G/\{1\}| = |G|$. These are the extreme cases of $|G/N| = [G : N]$: collapsing everything vs. collapsing nothing. ■

Worked Example 3.1.7 ($D_8/\langle r^2 \rangle$ has order 4 – identify it)**.** Let $G = D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$, and $N = \langle r^2 \rangle = \{1, r^2\}$. Show $N \trianglelefteq D_8$, compute G/N, and identify it up to isomorphism.

Recognition. Order-2 subgroup; test normality via conjugation, then use $|G/N| = [G : N]$ and the orders of cosets to match a group of order 4.

Solution. Normality. $r^2 \in Z(D_8)$: it commutes with r, and $sr^2s^{-1} = (srs^{-1})^2 = (r^{-1})^2 = r^{-2} = r^2$ (using $r^4 = 1$). A central subgroup is normal, so $N = \{1, r^2\} \trianglelefteq D_8$.

The cosets. $|D_8| = 8$, $|N| = 2$, so $[D_8 : N] = 4$. The four cosets are

$$N = \{1, r^2\}, \quad rN = \{r, r^3\}, \quad sN = \{s, sr^2\}, \quad rsN = \{rs, r^3 s\}.$$

Orders of coset elements. Each non-identity coset squares to N:

$$(rN)^2 = r^2N = N, \qquad (sN)^2 = s^2N = N, \qquad (rsN)^2 = (rs)^2N.$$

Now $(rs)^2 = rsrs = r(sr)s = r(r^{-1}s)s = s^2 = 1 \in N$, so $(rsN)^2 = N$ too. Hence every non-identity element of G/N has order 2. A group of order 4 in which every non-identity element has order 2 is the Klein four-group:

$$D_8/\langle r^2\rangle \cong V_4 = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}.$$

Check. The three involutions rN, sN, rsN together with N close up: $(rN)(sN) = rsN$, the fourth element – exactly the Klein four multiplication table. And $|G/N| = 4 = [D_8 : N]$. ■

Worked Example 3.1.8 ($G/Z(G)$ for $G = D_8$)**.** With $G = D_8$, recall $Z(D_8) = \{1, r^2\}$. Compute $G/Z(G)$ and identify it. Contrast with the previous example.

Recognition. Quotient by the center; here $Z(D_8) = \langle r^2\rangle$ literally equals the N of the last example, so reuse that computation – but the framing illustrates the "G/Z cyclic $\Rightarrow$ G abelian" lemma.

Solution. Since $Z(D_8) = \{1, r^2\} = \langle r^2\rangle$, this is the *same* quotient as before:

$$D_8/Z(D_8) \cong V_4 = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z},$$

of order $[D_8 : Z(D_8)] = 8/2 = 4$, with cosets N, rN, sN, rsN all of order ≤ 2.

Why this is consistent. A standard lemma says: if $G/Z(G)$ is cyclic then G is abelian. Here D_8 is *non*-abelian, so $G/Z(G)$ must *not* be cyclic – and indeed V_4 is not cyclic. The Klein four-group is exactly the non-cyclic group of order 4, so everything is forced. *Check.* If D_8/Z were cyclic of order 4 (i.e. $\mathbb{Z}/4\mathbb{Z}$), the lemma would make D_8 abelian, a contradiction. So $D_8/Z \cong V_4$, matching the direct computation. ■

Worked Example 3.1.9 (Every subgroup of an abelian group is normal)**.** Let G be abelian and $N \leq G$ any subgroup. Show $N \trianglelefteq G$, so G/N is always a group; then compute a concrete instance in $G = \mathbb{Z}/12\mathbb{Z}$.

Recognition. Abelian $\Rightarrow$ conjugation is trivial, so the normality test $gNg^{-1} = N$ holds automatically. Then apply the reduce-representatives method.

Solution. Normality. For $g \in G$ and $n \in N$, abelianness gives $gng^{-1} = gg^{-1}n = n \in N$, so $gNg^{-1} = N$ for every g. Hence every subgroup is normal and G/N is a group for all $N \leq G$.

Concrete instance. Take $G = \mathbb{Z}/12\mathbb{Z}$ (written additively) and $N = \langle\overline{4}\rangle = \{\overline{0}, \overline{4}, \overline{8}\}$, of order 3. Then $[G : N] = 12/3 = 4$, and the cosets are

$$N, \quad \overline{1} + N = \{\overline{1}, \overline{5}, \overline{9}\}, \quad \overline{2} + N = \{\overline{2}, \overline{6}, \overline{10}\}, \quad \overline{3} + N = \{\overline{3}, \overline{7}, \overline{11}\}.$$

The operation reduces representatives mod N: e.g. $(\overline{2} + N) + (\overline{3} + N) = \overline{5} + N = \overline{1} + N$ (since $\overline{5} - \overline{1} = \overline{4} \in N$), and $(\overline{3} + N) + (\overline{3} + N) = \overline{6} + N = \overline{2} + N$. Iterating $\overline{1} + N$ gives $\overline{1} + N,\ \overline{2} + N,\ \overline{3} + N,\ \overline{0} + N$ after four steps, i.e. order 4. Therefore

$$\mathbb{Z}/12\mathbb{Z}/\langle\overline{4}\rangle \cong \mathbb{Z}/4\mathbb{Z}.$$

Check. $|\overline{1} + N|$ is the least $k \geq 1$ with $k \cdot \overline{1} \in N = \langle\overline{4}\rangle$, i.e. $k \equiv 0, 4, 8 \pmod{12}$, giving $k = 4$. A group of order 4 with an element of order 4 is $\mathbb{Z}/4\mathbb{Z}$. Consistent with $[\mathbb{Z}/12\mathbb{Z} : N] = 4$. ■

Worked Example 3.1.10 (A non-example: when the product is *not* well defined)**.** In $G = S_3$ take $H = \langle(1\,2)\rangle = \{e, (1\,2)\}$ (order 2, *not* normal). Show directly that $(aH)(bH) = (ab)H$ fails to be well defined.

Recognition. Normality test fails: conjugating $(1\,2)$ by $(1\,2\,3)$ gives $(2\,3) \notin H$ (computed below); demonstrate failure by choosing two representatives of one coset and getting different output cosets.

Solution. Write $\sigma = (1\,2\,3)$ and $\tau = (1\,2)$, so $H = \{e, \tau\}$ and $S_3 = \{e, \sigma, \sigma^2, \tau, \sigma\tau, \sigma^2\tau\}$ (compose right-to-left, so the rightmost permutation acts first). Consider the coset $\sigma H = \{\sigma,\ \sigma\tau\}$, which has the two representatives σ and $\sigma\tau$.

Multiply on the right by σH using each representative:

$$(\sigma H)(\sigma H) \stackrel{?}{=} (\sigma \cdot \sigma)\, H = \sigma^2 H, \qquad \text{vs.} \qquad (\sigma\tau \cdot \sigma)\, H.$$

Compute $\sigma\tau\sigma$ directly, applying the rightmost factor first: $1 \mapsto 2 \mapsto 1 \mapsto 2,\ 2 \mapsto 3 \mapsto 3 \mapsto 1,\ 3 \mapsto 1 \mapsto 2 \mapsto 3$. Hence $\sigma\tau\sigma = (1\,2) = \tau \in H$, giving $(\sigma\tau\sigma)H = H$. But $\sigma^2 H = \{\sigma^2, \sigma^2\tau\} \neq H$ (since $\sigma^2 \notin H$). So the *same* pair of cosets $(\sigma H, \sigma H)$ produces *two different* answers, $\sigma^2 H$ and H, depending on representatives: the product is not well defined.

Where normality fails: computing $\sigma\,\tau\,\sigma^{-1}$ with $\sigma^{-1} = (1\,3\,2)$, applying the rightmost factor first: $1 \mapsto 3 \mapsto 3 \mapsto 1$, $2 \mapsto 1 \mapsto 2 \mapsto 3$, $3 \mapsto 2 \mapsto 1 \mapsto 2$, so $\sigma\tau\sigma^{-1} = (2\,3) \notin H$. Thus $\sigma H \sigma^{-1} \neq H$ and H is not normal, exactly as Theorem 3.1.3 predicts. *Check.* H has index 3; if a quotient existed it would have order 3, but no well-defined product exists, confirming S_3/H is *not* a group. ■

Remark 3.1.3 (Reading the projection geometrically). The map $\pi : G \twoheadrightarrow G/N$ "crushes" all of N to the identity and, more generally, crushes each coset to a single point. The fibers of π *are* the cosets, so G/N records exactly the information in G that survives forgetting differences-by-N. This is the structural meaning of a quotient and the launching point for the isomorphism theorems of D&F 3.2–3.3.

Normal subgroups and kernels

Throughout, G is a group and $H, N \leq G$ are subgroups. Recall that a (left) coset of H is a set $gH = \{gh : h \in H\}$, and a right coset is $Hg = \{hg : h \in H\}$. The central question of this section: when does the set of left cosets G/H carry a natural group structure? The answer is precisely when H is *normal*.

For $g \in G$ and $S \subseteq G$ we write $gSg^{-1} = \{gsg^{-1} : s \in S\}$, the *conjugate* of S by g. The map $s \mapsto gsg^{-1}$ is a bijection of G (its inverse is conjugation by g^{-1}), so $|gSg^{-1}| = |S|$ whenever S is finite.

Definition 3.1.11 (Normal subgroup)**.** A subgroup $N \leq G$ is *normal* in G, written $N \trianglelefteq G$, if $gNg^{-1} = N$ for every $g \in G$. Equivalently, g *normalizes* N for all g; the set of all such g is the *normalizer* $N_G(N) = \{g \in G : gNg^{-1} = N\}$, so $N \trianglelefteq G \iff N_G(N) = G$.

Definition 3.1.12 (Kernel of a homomorphism)**.** If $\varphi : G \to H$ is a homomorphism, its *kernel* is

$$\ker\varphi = \{g \in G : \varphi(g) = 1_H\} = \varphi^{-1}(\{1_H\}).$$

For $h \in \operatorname{im}\varphi$, the set $\varphi^{-1}(\{h\}) = \{g \in G : \varphi(g) = h\}$ is called the *fiber* of φ over h.

Theorem 3.1.13 (Equivalent characterizations of normality)**.** *Let $N \leq G$. The following are equivalent.*

(1) $N \trianglelefteq G$, i.e. $gNg^{-1} = N$ for all $g \in G$.

(2) $N_G(N) = G$ (every element of G normalizes N).

(3) $gN = Ng$ for all $g \in G$ (every left coset is a right coset).

(4) $gNg^{-1} \subseteq N$ for all $g \in G$.

(5) The operation $(uN)(vN) := (uv)N$ is well defined on the set of left cosets G/N.

(6) $N = \ker\varphi$ for some homomorphism φ with domain G.

Proof. (1) $\iff$ (2) is the definition of $N_G(N)$ unwound.

(1) $\implies$ (4) is immediate since $gNg^{-1} = N \subseteq N$.

(4) $\implies$ (1). Assume $gNg^{-1} \subseteq N$ for all g. Apply this with g^{-1} in place of g: $g^{-1}Ng \subseteq N$. Conjugating both sides by g (which preserves inclusions, being a bijection of G) gives $N = g(g^{-1}Ng)g^{-1} \subseteq gNg^{-1}$. Combined with $gNg^{-1} \subseteq N$ we get $gNg^{-1} = N$, so (1) holds.

(1) $\iff$ (3). If $gNg^{-1} = N$, then right-multiplying by g gives $gN = Ng$. Conversely if $gN = Ng$, right-multiply by g^{-1} to get $gNg^{-1} = N$.

(3) $\implies$ (5). Suppose every left coset equals a right coset. We must show $(uv)N$ depends only on the cosets uN and vN, not on the representatives. Suppose $uN = u'N$ and $vN = v'N$; we want $(uv)N = (u'v')N$. We have $u' = un_1$ and $v' = vn_2$ for some $n_1, n_2 \in N$. Then

$$u'v' = un_1vn_2.$$

Now $n_1v \in Nv = vN$ (using (3)), so $n_1v = vn_3$ for some $n_3 \in N$. Hence

$$u'v' = uvn_3n_2 \in (uv)N,$$

since $n_3n_2 \in N$. Therefore $(u'v')N = (uv)N$, and the product is well defined.

(5) $\Longrightarrow$ (6). If the product on G/N is well defined, one checks directly that G/N is a group: associativity is inherited from G, the identity is $1N = N$, and the inverse of uN is $u^{-1}N$. The map $\pi : G \to G/N$, $\pi(g) = gN$, is then a homomorphism because $\pi(uv) = (uv)N = (uN)(vN) = \pi(u)\pi(v)$. Its kernel is

$$\ker \pi = \{g : gN = N\} = \{g : g \in N\} = N,$$

using that $gN = N \iff g \in N$. So N is a kernel.

(6) $\Longrightarrow$ (1). This is the content of Proposition 3.1.14 below: any kernel is normal.

The cycle (1) $\Longrightarrow$ (4) $\Longrightarrow$ (1), (1) $\Longleftrightarrow$ (2) $\Longleftrightarrow$ (3), (3) $\Longrightarrow$ (5) $\Longrightarrow$ (6) $\Longrightarrow$ (1) closes all equivalences. □

Proposition 3.1.14 (Kernels are normal; fibers are cosets)**.** *Let $\varphi : G \to H$ be a homomorphism and set $K = \ker \varphi$. Then:*

(a) $K \leq G$ (the kernel is a subgroup);

(b) $K \trianglelefteq G$ (the kernel is normal);

(c) for each $a \in G$, the fiber of φ over $\varphi(a)$ is the coset $aK = Ka$:

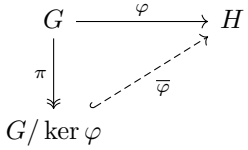
$$\varphi^{-1}(\{\varphi(a)\}) = aK = Ka.$$

In particular the fibers of φ are exactly *the cosets of K, and φ induces a bijection between G/K and $\operatorname{im} \varphi$.*

Proof. (a) First $\varphi(1_G) = 1_H$ (since $\varphi(1) = \varphi(1 \cdot 1) = \varphi(1)\varphi(1)$, cancel), so $1_G \in K$ and $K \neq \varnothing$. If $x, y \in K$ then $\varphi(xy^{-1}) = \varphi(x)\varphi(y)^{-1} = 1_H \cdot 1_H^{-1} = 1_H$, so $xy^{-1} \in K$. By the subgroup criterion $K \leq G$.

(b) Let $g \in G$ and $k \in K$. Then

$$\varphi(gkg^{-1}) = \varphi(g)\,\varphi(k)\,\varphi(g)^{-1} = \varphi(g)\,1_H\,\varphi(g)^{-1} = 1_H,$$



so $gkg^{-1} \in K$. Thus $gKg^{-1} \subseteq K$ for every g, which is characterization (4) of Theorem 3.1.13; hence $K \trianglelefteq G$.

(c) Fix $a \in G$ and let $b = \varphi(a)$. For $g \in G$:

$$\varphi(g) = b = \varphi(a) \iff \varphi(a)^{-1}\varphi(g) = 1_H \iff \varphi(a^{-1}g) = 1_H \iff a^{-1}g \in K \iff g \in aK.$$

So $\varphi^{-1}(\{b\}) = aK$. The same chain using $\varphi(g)\varphi(a)^{-1} = 1_H$ gives $\varphi^{-1}(\{b\}) = Ka$. Hence $aK = Ka$ (consistent with normality), and the fibers are precisely the cosets. Sending the fiber over b to b gives a well-defined bijection $G/K \to \operatorname{im} \varphi$, $aK \mapsto \varphi(a)$. □

The picture is that φ collapses each coset of K to a single point of $\operatorname{im} \varphi$, and the quotient map π is the universal way to do this collapsing.

$$1 \longrightarrow \ker \varphi \hookrightarrow G \xrightarrow{\varphi} \operatorname{im} \varphi \longrightarrow 1$$

The right-hand diagram is a *short exact sequence*: the image of each map equals the kernel of the next, encoding $\ker \varphi \trianglelefteq G$ and $G/\ker \varphi \cong \operatorname{im} \varphi$ in one line.

Diagram explanation. Objects: Three groups: G (the domain group), H (the codomain group, any group receiving φ), and $G/\ker \varphi$ (the quotient group whose elements are left cosets $g \ker \varphi$).

Arrows: (i) $\varphi : G \to H$, the given homomorphism, goes right along the top. (ii) $\pi : G \twoheadrightarrow G/\ker \varphi$, the canonical surjective quotient map, sends $g \mapsto g \ker \varphi$ and goes down. (iii) $\overline{\varphi} : G/\ker \varphi \xrightarrow{\cong} \operatorname{im} \varphi \subseteq H$, the induced map, goes up-right (dashed, marking that it is the unique map making the triangle commute); it sends $g \ker \varphi \mapsto \varphi(g)$.

What commutes: The triangle commutes: $\overline{\varphi} \circ \pi = \varphi$, i.e. for every $g \in G$, going down then diagonally equals going directly: $\overline{\varphi}(\pi(g)) = \overline{\varphi}(g \ker \varphi) = \varphi(g)$.

Why it commutes: Well-definedness of $\overline{\varphi}$ is the key point. If $g \ker \varphi = g' \ker \varphi$ then $g^{-1}g' \in \ker \varphi$, so $\varphi(g^{-1}g') = 1_H$, giving $\varphi(g') = \varphi(g)$. Thus $\overline{\varphi}(g \ker \varphi) = \varphi(g)$ does not depend on the choice of coset representative. Once $\overline{\varphi}$ is well defined, the equality $\overline{\varphi} \circ \pi = \varphi$ is immediate from the formula: $\overline{\varphi}(\pi(g)) = \overline{\varphi}(g \ker \varphi) = \varphi(g)$.

Why this matters here: This diagram is the geometric payoff of Proposition 3.1.14(c): the fibers of φ are exactly the cosets of $\ker \varphi$, so φ factors through the quotient $G/\ker \varphi$ in a bijective way. The dashed $\overline{\varphi}$ is an isomorphism $G/\ker \varphi \cong \operatorname{im} \varphi$, the First Isomorphism Theorem. The diagram organizes the collapse: π does the collapsing, $\overline{\varphi}$ does the embedding, and φ is their composite.

Concrete example: Take $G = \mathbb{Z}$, $H = \mathbb{Z}/n\mathbb{Z}$, $\varphi(a) = a \bmod n$. Then $\ker \varphi = n\mathbb{Z}$, $\pi(a) = a + n\mathbb{Z}$, and $\overline{\varphi}(a + n\mathbb{Z}) = a \bmod n$. The induced map $\overline{\varphi} : \mathbb{Z}/n\mathbb{Z} \xrightarrow{\cong} \mathbb{Z}/n\mathbb{Z}$ is the standard isomorphism; the triangle says reducing mod n and then applying $\overline{\varphi}$ equals φ directly.

Common pitfall: Students often conflate φ and $\overline{\varphi}$. The original $\varphi : G \to H$ need not be injective, but the induced $\overline{\varphi} : G/\ker \varphi \to \operatorname{im} \varphi$ is always injective (that injectivity is exactly what well-definedness plus the trivial-kernel check gives). Also, $\overline{\varphi}$ maps into $\operatorname{im} \varphi$, not all of H; it is an isomorphism onto $\operatorname{im} \varphi$, not onto H unless φ is already surjective.

Takeaway: The point of this diagram is that every homomorphism φ factors canonically through its own quotient $G/\ker \varphi$, producing an isomorphism $G/\ker \varphi \cong \operatorname{im} \varphi$ — the algebraic content of killing exactly the right elements to make the map injective.

Diagram explanation. Objects: Five terms: the trivial group 1 (written at both ends), $\ker \varphi$ (a normal subgroup of G, acting as the left end of the nontrivial part), G (the middle group), and $\operatorname{im} \varphi$ (a subgroup of H, the right nontrivial term).

Arrows: (i) $1 \to \ker \varphi$: the unique map from the trivial group, serving as a bookend. (ii) $\ker \varphi \hookrightarrow G$: the inclusion map $k \mapsto k$, a monomorphism (marked by the hooked arrowhead). (iii) $G \twoheadrightarrow \operatorname{im} \varphi$: the restriction of φ to its image, a surjection (marked by the two-headed arrowhead). (iv) $\operatorname{im} \varphi \to 1$: the unique map to the trivial group, the other bookend.

What commutes: Exactness at each node: (a) exactness at $\ker \varphi$: the kernel of the inclusion is trivial, equaling the image of $1 \to \ker \varphi$ (also trivial) — so the inclusion is injective; (b) exactness at G: $\operatorname{im}(\ker \varphi \hookrightarrow G) = \ker \varphi = \ker(\varphi|^{\operatorname{im} \varphi})$ (elements mapping to 1 are exactly those in $\ker \varphi$); (c) exactness at $\operatorname{im} \varphi$: $\operatorname{im}(G \twoheadrightarrow \operatorname{im} \varphi) = \operatorname{im} \varphi = \ker(\operatorname{im} \varphi \to 1)$ (everything maps to 1 in the trivial group), so the last map's kernel is all of $\operatorname{im} \varphi$.

Why it commutes: At the critical node G: an element g maps to 1 under φ iff $g \in \ker \varphi$, which is exactly the image of the inclusion. This is just the definition of $\ker \varphi$. The other exactness conditions are formal: the trivial group forces the inclusion to have trivial kernel (injective) and the surjection to have full image.

Why this matters here: This sequence packages the First Isomorphism Theorem in diagram form, adding the information that $\ker \varphi \trianglelefteq G$ (it is normal, hence the inclusion is a normal inclusion) and that the right-hand map is surjective onto $\operatorname{im} \varphi$. It is the standard way to record the structure of any homomorphism: the kernel on the left, the image on the right.

Concrete example: For $\operatorname{sgn} : S_n \to \{\pm 1\}$: the sequence is $1 \to A_n \hookrightarrow S_n \twoheadrightarrow \{\pm 1\} \to 1$. Exactness at S_n says the kernel of sgn is A_n (the image of the inclusion), which is correct by definition of A_n.

Common pitfall: A short exact sequence $1 \to N \to G \to Q \to 1$ does not mean $G \cong N \times Q$; it only says $N \trianglelefteq G$ and $G/N \cong Q$. The sequence can be non-split (e.g. $1 \to \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 1$ is non-split). Students also sometimes confuse "exact at G" with commutativity of a square; here there is no square — exactness is the condition im = ker at each interior node.

Takeaway: The point of this diagram is that the sequence $1 \to \ker \varphi \to G \to \operatorname{im} \varphi \to 1$ captures, in one compact line, both facts proved above — that $\ker \varphi$ is normal and that quotienting by it recovers $\operatorname{im} \varphi$ up to isomorphism.

The next figure shows the fibers of φ literally as the cosets of $K = \ker \varphi$, each mapped to one point of $\operatorname{im} \varphi$.

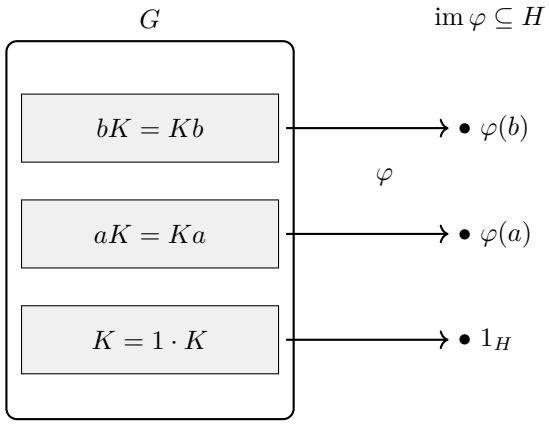


Diagram explanation. Objects: Two sets: the group G on the left (shown as a large rounded rectangle) and $\operatorname{im}\varphi \subseteq H$ on the right (shown as a column of points). Inside G the elements are partitioned into horizontal slabs; each slab is a coset of $K = \ker\varphi$: the bottom slab is $K = 1 \cdot K$ (the kernel itself), then $aK = Ka$, then $bK = Kb$. Each point on the right is one element of $\operatorname{im}\varphi$: 1_H, $\varphi(a)$, $\varphi(b)$.

Arrows: Three parallel horizontal arrows, each from the right edge of one coset-slab to the corresponding point in $\operatorname{im}\varphi$, all labeled φ. Each arrow represents the action of φ on an entire coset: every element inside the slab maps to the single target point. The equal signs $aK = Ka$ inside the slab labels record that left and right cosets coincide (normality).

What commutes: There is no composite path to equate; the diagram instead encodes the fiber identity $\varphi^{-1}(\{\varphi(a)\}) = aK = Ka$. Every element of the coset aK maps to the same value $\varphi(a)$, and no element outside aK maps there. The three arrows are thus a bijection between the set of cosets $\{K, aK, bK\}$ and the set of values $\{1_H, \varphi(a), \varphi(b)\}$.

Why it commutes: If $g \in aK$ then $g = an$ for some $n \in K = \ker\varphi$, so $\varphi(g) = \varphi(a)\varphi(n) = \varphi(a) \cdot 1_H = \varphi(a)$. Hence all elements of the same coset land at the same point. Conversely, if $\varphi(g) = \varphi(a)$ then $\varphi(a^{-1}g) = 1_H$, so $a^{-1}g \in K$, so $g \in aK$. Both directions confirm the fiber equals the coset.

Why this matters here: This picture is the visual proof of Proposition 3.1.14(c): the map φ partitions G into fibers, each fiber is a coset of K, and the induced map $G/K \to \operatorname{im}\varphi$ sending each coset to its common image is a bijection. It motivates why G/K is the "right" quotient for φ and sets up the First Isomorphism Theorem geometrically before its algebraic statement.

Concrete example: Take $\varphi = \det : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$ with $K = \mathrm{SL}_2(\mathbb{R})$. Each coset $A \cdot \mathrm{SL}_2(\mathbb{R})$ is the slab of matrices with determinant $\det(A)$, and φ collapses that entire slab to the single scalar $\det(A) \in \mathbb{R}^\times$. The three slabs in the picture correspond to K ($\det = 1$), aK ($\det = \det(a)$), and bK ($\det = \det(b)$).

Common pitfall: The picture might suggest that the three cosets K, aK, bK exhaust G; they are only a representative sample. In general G may have infinitely many cosets (when $\ker\varphi$ has infinite index). Also, the equal sign $aK = Ka$ in the slab label is a nontrivial fact — it holds because $K \trianglelefteq G$ — not something automatic for every subgroup.

Takeaway: The point of this diagram is that φ does not see individual elements, only cosets — it collapses each coset of $\ker\varphi$ to a single point, making the partition of G into cosets and the bijection $G/\ker\varphi \leftrightarrow \operatorname{im}\varphi$ visually immediate.

Method (Proving $N \trianglelefteq G$)**.** Three standard routes; pick whichever matches the data you have.

(A) Conjugation test. Show $gng^{-1} \in N$ for every $g \in G$ and every $n \in N$. By Theorem 3.1.13(4) the one-sided containment $gNg^{-1} \subseteq N$ (for *all* g) suffices — you need not separately prove $\supseteq$. Trigger: N given by an explicit description you can plug into a conjugate.

(B) Exhibit N as a kernel. Find a homomorphism $\varphi : G \to H$ with $\ker\varphi = N$. Then $N \trianglelefteq G$ for free by Proposition 3.1.14(b). Trigger: N is "everything killed by" some natural map (determinant, sign, reduction mod m, projection).

(C) Index 2. If $[G : N] = 2$ then $N \trianglelefteq G$ automatically (Worked Example below). Trigger: $|G| = 2|N|$, or N is "half" of G.

Bonus: characteristic subgroups (e.g. $Z(G)$, the commutator subgroup) are always normal, since every conjugation is an automorphism.

Worked Example 3.1.15 ($\mathrm{SL}_n = \ker(\det)$ is normal in GL_n)**.** Let F be a field. Show $\mathrm{SL}_n(F) = \{A \in \mathrm{GL}_n(F) : \det A = 1\} \trianglelefteq \mathrm{GL}_n(F)$.

Recognition. Method (B): SL_n is defined as "matrices killed by" the multiplicative behavior of det, so realize it as a kernel.

Solution. The determinant $\det : \mathrm{GL}_n(F) \to F^\times$ is a homomorphism into the multiplicative group of nonzero scalars, because $\det(AB) = \det(A)\det(B)$. Its kernel is

$$\ker(\det) = \{A : \det A = 1\} = \mathrm{SL}_n(F).$$

By Proposition 3.1.14(b) a kernel is normal, so $\mathrm{SL}_n(F) \trianglelefteq \mathrm{GL}_n(F)$. *Check (direct conjugation).* For $A \in \mathrm{SL}_n$ and any $g \in \mathrm{GL}_n$,

$$\det(gAg^{-1}) = \det(g)\det(A)\det(g)^{-1} = \det(g) \cdot 1 \cdot \det(g)^{-1} = 1,$$

so $gAg^{-1} \in \mathrm{SL}_n$, confirming normality via Method (A) as well.

Worked Example 3.1.16 ($A_n = \ker(\mathrm{sgn})$ is normal in S_n)**.** Show the alternating group $A_n \trianglelefteq S_n$ for $n \geq 2$.

Recognition. Method (B): A_n is exactly the even permutations, i.e. those sent to $+1$ by the sign map — a kernel.

Solution. The sign map $\mathrm{sgn} : S_n \to \{\pm 1\}$ (the latter a group under multiplication) is a homomorphism: $\mathrm{sgn}(\sigma\tau) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau)$. By definition

$$A_n = \{\sigma \in S_n : \mathrm{sgn}(\sigma) = 1\} = \ker(\mathrm{sgn}).$$

Hence $A_n \trianglelefteq S_n$ by Proposition 3.1.14(b). *Check (index 2).* For $n \geq 2$, sgn is onto $\{\pm 1\}$ (a transposition maps to -1), so $\mathrm{im}(\mathrm{sgn})$ has order 2 and the fibers of sgn are the two cosets A_n (even) and $(1\,2)A_n$ (odd). Thus $[S_n : A_n] = 2$, giving normality also by Method (C). For S_3: $|A_3| = 3$, $|S_3| = 6$, index 2, and indeed $A_3 = \{e, (1\,2\,3), (1\,3\,2)\}$ is normal.

Worked Example 3.1.17 (The center $Z(G) \trianglelefteq G$)**.** Show that $Z(G) = \{z \in G : zg = gz \text{ for all } g \in G\}$ is normal.

Recognition. Method (A): the defining property of $Z(G)$ controls exactly what conjugation does. (Also a kernel — see check.)

Solution. Let $z \in Z(G)$ and $g \in G$. Since z commutes with g,

$$gzg^{-1} = (gz)g^{-1} = (zg)g^{-1} = z(gg^{-1}) = z \in Z(G).$$

So $gZ(G)g^{-1} \subseteq Z(G)$ for all g, hence $Z(G) \trianglelefteq G$ by Theorem 3.1.13(4). *Stronger fact:* every conjugate of z equals z itself, so each element of $Z(G)$ is its own (singleton) conjugacy class. *Check (kernel description).* $Z(G) = \ker\left(G \xrightarrow{g \mapsto \text{conj. by } g} \mathrm{Aut}(G)\right)$, the kernel of the homomorphism $G \to \mathrm{Aut}(G)$ sending g to the inner automorphism $x \mapsto gxg^{-1}$; an element is in the kernel iff conjugation by it is the identity iff it is central. This re-proves $Z(G) \trianglelefteq G$ via Method (B). Concretely in D_8 (with $r^4 = s^2 = 1$): $Z(D_8) = \{1, r^2\}$, and indeed $sr^2s^{-1} = r^{-2} = r^2$, $rr^2r^{-1} = r^2$, so $\{1, r^2\} \trianglelefteq D_8$.

Worked Example 3.1.18 (Every index-2 subgroup is normal)**.** Let $H \leq G$ with $[G : H] = 2$. Show $H \trianglelefteq G$.

Recognition. Method (C): index 2 leaves no room for a left coset to differ from a right coset.

Solution. Index 2 means there are exactly two left cosets, namely H and $G \setminus H$ (the second is a single coset because the cosets partition G and there are only two). Likewise the two *right* cosets are H and $G \setminus H$. Take any $g \in G$.

- If $g \in H$: then $gH = H = Hg$.
- If $g \notin H$: then $gH \neq H$, so gH must be the other left coset, $gH = G \setminus H$. Similarly $Hg \neq H$ forces $Hg = G \setminus H$. Hence $gH = G \setminus H = Hg$.

In both cases $gH = Hg$, so by Theorem 3.1.13(3), $H \trianglelefteq G$. *Check.* This recovers $A_n \trianglelefteq S_n$ ($[S_n : A_n] = 2$) and $\langle r \rangle \trianglelefteq D_{2n}$ ($[D_{2n} : \langle r \rangle] = 2$, since $|\langle r \rangle| = n$ and $|D_{2n}| = 2n$) without any computation. *Caution:* index ≥ 3 does *not* force normality — $\langle s \rangle \leq D_8$ has index 4 and is not normal (next example), and $\langle (1\,2) \rangle \leq S_3$ has index 3 and is not normal.

Worked Example 3.1.19 (A non-normal subgroup: $\langle s \rangle \leq D_8$ and its conjugates)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$, show $H = \langle s \rangle = \{1, s\}$ is *not* normal, and list the conjugate subgroups.

Recognition. Method (A) used as a *disproof*: produce one g with $gsg^{-1} \notin H$.

Solution. We compute rsr^{-1}. From the relation $sr = r^{-1}s$ we get $rs = sr^{-1}$, and $r^{-1} = r^3$. Then

$$rsr^{-1} = (rs)r^{-1} = (sr^{-1})r^{-1} = sr^{-2} = sr^2.$$

Now $sr^2 \notin \{1, s\} = H$ (it is a reflection through a different axis), so $rHr^{-1} \neq H$ and therefore H is **not** normal in D_8. *Conjugates.* Since $sr^2 = r^{-2}s = r^2s$, conjugating $H = \{1, s\}$ by r gives $\{1, r^2s\}$, and conjugating by r^2 gives back $\{1, s\}$ (because $r^2sr^{-2} = s$). So the conjugacy class of H is the pair $\{1, s\},\ \{1, r^2s\}$. The remaining two reflection-subgroups $\{1, rs\},\ \{1, r^3s\}$ form a *separate* conjugacy class:

$$\{1, s\},\ \{1, r^2s\} \quad \text{(one conjugacy pair);} \qquad \{1, rs\},\ \{1, r^3s\} \quad \text{(another pair).}$$

Check via the normalizer. The normalizer is $N_{D_8}(H) = \{g : gHg^{-1} = H\}$. It contains H itself and the center element r^2 (since $r^2sr^{-2} = s$), so $N_{D_8}(H) = \{1, s, r^2, r^2s\}$, an order-4 subgroup. Hence the number of conjugates of H is $[D_8 : N_{D_8}(H)] = 8/4 = 2$, matching the pair $\{1, s\}, \{1, r^2s\}$ found above. Since $N_{D_8}(H) \neq D_8$, again $H \not\trianglelefteq D_8$.

Worked Example 3.1.20 (Reduction mod m: $m\mathbb{Z} = \ker(\mathbb{Z} \to \mathbb{Z}/m\mathbb{Z})$)**.** Show $m\mathbb{Z} \trianglelefteq \mathbb{Z}$ for any integer $m \geq 1$.

Recognition. Method (B), additive flavor: $m\mathbb{Z}$ is what reduction mod m kills.

Solution. The reduction map $\varphi : \mathbb{Z} \to \mathbb{Z}/m\mathbb{Z}$, $\varphi(a) = a \bmod m = \overline{a}$, is a homomorphism: $\varphi(a + b) = \overline{a + b} = \overline{a} + \overline{b} = \varphi(a) + \varphi(b)$. Its kernel is

$$\ker \varphi = \{a \in \mathbb{Z} : \overline{a} = \overline{0}\} = \{a : m \mid a\} = m\mathbb{Z}.$$

So $m\mathbb{Z} \trianglelefteq \mathbb{Z}$ by Proposition 3.1.14(b). *Check.* $\mathbb{Z}$ is abelian, so *every* subgroup is normal anyway ($gng^{-1} = ngg^{-1} = n$); the fibers of φ are the m cosets $\overline{0}, \overline{1}, \ldots, \overline{m-1}$, i.e. the residue classes, confirming Proposition 3.1.14(c).

Caution. **(1) One g is not enough.** To prove $N \trianglelefteq G$ you need $gng^{-1} \in N$ for *all* $g \in G$. Verifying it for a single g is not a proof of normality. Checking every g in a generating set T of G does suffice when N is finite (Exercise 29 below), but for infinite N one must in general also check the inverses t^{-1} ($t \in T$). On the other hand, one well-chosen g *is* enough to *disprove* normality.

(2) $gNg^{-1} \subseteq N$ for all g does give normality — but mind infinite groups. In Theorem 3.1.13 the one-sided test (4) works because the hypothesis is quantified over *all* g (we plugged in g^{-1} too). For a *fixed* g, the containment $gNg^{-1} \subseteq N$ alone does *not* force $gNg^{-1} = N$ when N is infinite. Standard example: in $G = \mathrm{GL}_2(\mathbb{Q})$ let $g = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ and $N = \{\left(\begin{smallmatrix} 1 & x \\ 0 & 1 \end{smallmatrix}\right) : x \in \mathbb{Z}\}$. Then $g\left(\begin{smallmatrix} 1 & x \\ 0 & 1 \end{smallmatrix}\right)g^{-1} = \left(\begin{smallmatrix} 1 & 2x \\ 0 & 1 \end{smallmatrix}\right)$, so $gNg^{-1} = \{\left(\begin{smallmatrix} 1 & 2x \\ 0 & 1 \end{smallmatrix}\right) : x \in \mathbb{Z}\} \subsetneq N$ — proper containment. (Of course this particular N is not normal in G; the point is that strict containment $gNg^{-1} \subsetneq N$ can genuinely happen, so for a single g "$\subseteq$" is weaker than "$=$". The quantified test in (4) closes the gap by also applying the inclusion at g^{-1}.)

(3) $gN = Ng$ does not mean $gn = ng$. Normality says the *sets* gN and Ng coincide, not that g commutes with each element of N. For each n there is *some* $n' \in N$ with $gn = n'g$, but typically $n' \neq n$.

Exercises (from the text).

1. Let $\varphi : G \to H$ be a homomorphism and let E be a subgroup of H. Prove that $\varphi^{-1}(E) \leq G$ (i.e., the preimage or pullback of a subgroup under a homomorphism is a subgroup). If $E \trianglelefteq H$ prove that $\varphi^{-1}(E) \trianglelefteq G$. Deduce that $\ker \varphi \trianglelefteq G$.

2. Let $\varphi : G \to H$ be a homomorphism of groups with kernel K and let $a, b \in \varphi(G)$. Let $X \in G/K$ be the fiber above a and let Y be the fiber above b, i.e., $X = \varphi^{-1}(a)$, $Y = \varphi^{-1}(b)$. Fix an element u of X (so $\varphi(u) = a$). Prove that if $XY = Z$ in the quotient group G/K and w is any member of Z, then there is some $v \in Y$ such that $uv = w$. [Show $u^{-1}w \in Y$.]

3. Let A be an abelian group and let B be a subgroup of A. Prove that A/B is abelian. Give an example of a non-abelian group G containing a proper normal subgroup N such that G/N is abelian.

4. Prove that in the quotient group G/N, $(gN)^a = g^a N$ for all $a \in \mathbb{Z}$.

5. Use the preceding exercise to prove that the order of the element gN in G/N is n, where n is the smallest positive integer such that $g^n \in N$ (and gN has infinite order if no such positive integer exists). Give an example to show that the order of gN in G/N may be strictly smaller than the order of g in G.

6. Define $\varphi : \mathbb{R}^\times \to \{\pm 1\}$ by letting $\varphi(x)$ be x divided by the absolute value of x. Describe the fibers of φ and prove that φ is a homomorphism.

7. Define $\pi : \mathbb{R}^2 \to \mathbb{R}$ by $\pi((x, y)) = x + y$. Prove that π is a surjective homomorphism and describe the kernel and fibers of π geometrically.

8. Let $\varphi : \mathbb{R}^\times \to \mathbb{R}^\times$ be the map sending x to the absolute value of x. Prove that φ is a homomorphism and find the image of φ. Describe the kernel and the fibers of φ geometrically.

9. Define $\varphi : \mathbb{C}^\times \to \mathbb{R}^\times$ by $\varphi(a + bi) = a^2 + b^2$. Prove that φ is a homomorphism and find the image of φ. Describe the kernel and the fibers of φ geometrically (as subsets of the plane).

10. Let $\varphi : \mathbb{Z}/8\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ by $\varphi(\overline{a}) = \overline{a}$. Show that this is a well defined, surjective homomorphism and describe its fibers and kernel explicitly (showing that φ is well defined involves the fact that $\overline{a}$ has a different meaning in the domain and range of φ).

11. Let F be a field and let $G = \left\{ \begin{pmatrix} a & b \\ 0 & c \end{pmatrix} \mid a, b, c \in F,\ ac \neq 0 \right\} \leq GL_2(F)$. (a) Prove that the map $\varphi : \begin{pmatrix} a & b \\ 0 & c \end{pmatrix} \mapsto a$ is a surjective homomorphism from G onto $F^\times$ (recall that $F^\times$ is the multiplicative group of nonzero elements in F). Describe the fibers and kernel of φ. (b) Prove that the map $\psi : \begin{pmatrix} a & b \\ 0 & c \end{pmatrix} \mapsto (a, c)$ is a surjective homomorphism from G onto $F^\times \times F^\times$. Describe the fibers and kernel of ψ. (c) Let $H = \left\{ \begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix} \mid b \in F \right\}$. Prove that H is isomorphic to the additive group of F.

12. Let G be the additive group of real numbers, let H be the multiplicative group of complex numbers of absolute value 1 (the unit circle S^1 in the complex plane) and let $\varphi : G \to H$ be the homomorphism $\varphi : r \mapsto e^{2\pi i r}$. Draw the points on a real line which lie in the kernel of φ. Describe similarly the elements in the fibers of φ above the points -1, i, and $e^{4\pi i/3}$ of H.

13. Repeat the preceding exercise with the map φ replaced by the map $\varphi : r \mapsto e^{4\pi i r}$.

14. Consider the additive quotient group $\mathbb{Q}/\mathbb{Z}$. (a) Show that every coset of $\mathbb{Z}$ in $\mathbb{Q}$ contains exactly one representative $q \in \mathbb{Q}$ in the range $0 \leq q < 1$. (b) Show that every element of $\mathbb{Q}/\mathbb{Z}$ has finite order but that there are elements of arbitrarily large order. (c) Show that $\mathbb{Q}/\mathbb{Z}$ is the torsion subgroup of $\mathbb{R}/\mathbb{Z}$ (cf. Exercise 6, Section 2.1). (d) Prove that $\mathbb{Q}/\mathbb{Z}$ is isomorphic to the multiplicative group of roots of unity in $\mathbb{C}^\times$.

15. Prove that a quotient of a divisible abelian group by any proper subgroup is also divisible. Deduce that $\mathbb{Q}/\mathbb{Z}$ is divisible (cf. Exercise 19, Section 2.4).

16. Let G be a group, let N be a normal subgroup of G and let $\overline{G} = G/N$. Prove that if $G = \langle x, y \rangle$ then $\overline{G} = \langle \overline{x}, \overline{y} \rangle$. Prove more generally that if $G = \langle S \rangle$ for any subset S of G, then $\overline{G} = \langle \overline{S} \rangle$.

17. Let the dihedral group of order 16 (whose lattice appears in Section 2.5) be given by the presentation $G = \langle r, s \mid r^8 = s^2 = 1,\ rs = sr^{-1} \rangle$ and let $\overline{G} = G/\langle r^4 \rangle$ be the quotient of G by the subgroup generated by r^4 (this subgroup is the center of G, hence is normal). (a) Show that the order of $\overline{G}$ is 8. (b) Exhibit each element of $\overline{G}$ in the form $\overline{s}^a \overline{r}^b$, for some integers a and b. (c) Find the order of each of the elements of $\overline{G}$ exhibited in (b). (d) Write each of the following elements of $\overline{G}$ in the form $\overline{s}^a \overline{r}^b$, for some integers a and b as in (b): $\overline{rs}$, $\overline{sr^{-2}s}$, $\overline{s^{-1}r^{-1}sr}$. (e) Prove that $\overline{H} = \langle \overline{s}, \overline{r^2} \rangle$ is a normal subgroup of $\overline{G}$ and $\overline{H}$ is isomorphic to the Klein 4-group. Describe the isomorphism type of the complete preimage of $\overline{H}$ in G. (f) Find the center of $\overline{G}$ and describe the isomorphism type of $\overline{G}/Z(\overline{G})$.

18. Let G be the quasidihedral group of order 16 (whose lattice was computed in Exercise 11 of Section 2.5): $G = \langle \sigma, \tau \mid \sigma^8 = \tau^2 = 1,\ \sigma\tau = \tau\sigma^3 \rangle$ and let $\overline{G} = G/\langle \sigma^4 \rangle$ be the quotient of G by the subgroup generated by σ^4 (this subgroup is the center of G, hence is normal). (a) Show that the order of $\overline{G}$ is 8. (b) Exhibit each element of $\overline{G}$ in the form $\overline{\tau}^a \overline{\sigma}^b$, for some integers a and b. (c) Find the order of each of the elements of $\overline{G}$ exhibited in (b). (d) Write each of the following elements of $\overline{G}$ in the form $\overline{\tau}^a \overline{\sigma}^b$, for some integers a and b as in (b): $\overline{\sigma\tau}$, $\overline{\tau\sigma^{-2}\tau}$, $\overline{\tau^{-1}\sigma^{-1}\tau\sigma}$. (e) Prove that $\overline{G} \cong D_8$.

19. Let G be the modular group of order 16 (whose lattice was computed in Exercise 14 of Section 2.5): $G = \langle u, v \mid u^2 = v^8 = 1,\ vu = uv^5 \rangle$ and let $\overline{G} = G/\langle v^4 \rangle$ be the quotient of G by the subgroup generated by v^4 (this subgroup is contained in the center of G, hence is normal). (a) Show that the order of $\overline{G}$ is 8. (b) Exhibit each element of $\overline{G}$ in the form $\overline{u}^a \overline{v}^b$, for some integers a and b. (c) Find the order of each of the elements of $\overline{G}$ exhibited in (b). (d) Write each of the following elements of $\overline{G}$ in the form $\overline{u}^a \overline{v}^b$, for some integers a and b as in (b): $\overline{vu}$, $\overline{uv^{-2}u}$, $\overline{u^{-1}v^{-1}uv}$. (e) Prove that $\overline{G}$ is abelian and is isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_4$.

20. Let $G = \mathbb{Z}/24\mathbb{Z}$ and let $\overline{G} = G/\langle \overline{12} \rangle$, where for each integer a we simplify notation by writing $\overline{a}$ as $\widetilde{a}$. (a) Show that $\overline{G} = \{\widetilde{0}, \widetilde{1}, \ldots, \widetilde{11}\}$. (b) Find the order of each element of $\overline{G}$. (c) Prove that $\overline{G} \cong \mathbb{Z}/12\mathbb{Z}$. (Thus $(\mathbb{Z}/24\mathbb{Z})/(12\mathbb{Z}/24\mathbb{Z}) \cong \mathbb{Z}/12\mathbb{Z}$, just as if we inverted and cancelled the $24\mathbb{Z}$'s.)

21. Let $G = \mathbb{Z}_4 \times \mathbb{Z}_4$ be given in terms of the following generators and relations: $G = \langle x, y \mid x^4 = y^4 = 1,\ xy = yx \rangle$. Let $\overline{G} = G/\langle x^2y^2 \rangle$ (note that every subgroup of the abelian group G is normal). (a) Show that the order of $\overline{G}$ is 8. (b) Exhibit each element of $\overline{G}$ in the form $\overline{x}^a \overline{y}^b$, for some integers a and b. (c) Find the order of each of the elements of $\overline{G}$ exhibited in (b). (d) Prove that $\overline{G} \cong \mathbb{Z}_4 \times \mathbb{Z}_2$.

22. (a) Prove that if H and K are normal subgroups of a group G then their intersection $H \cap K$ is also a normal subgroup of G. (b) Prove that the intersection of an arbitrary nonempty collection of normal subgroups of a group is a normal subgroup (do not assume the collection is countable).

23. Prove that the join (cf. Section 2.5) of any nonempty collection of normal subgroups of a group is a normal subgroup.

24. Prove that if $N \trianglelefteq G$ and H is any subgroup of G then $N \cap H \trianglelefteq H$.

25. (a) Prove that a subgroup N of G is normal if and only if $gNg^{-1} \subseteq N$ for all $g \in G$. (b) Let $G = GL_2(\mathbb{Q})$, let N be the subgroup of upper triangular matrices with integer entries and 1's on the diagonal, and let g be the diagonal matrix with entries $2, 1$. Show that $gNg^{-1} \subseteq N$ but g does not normalize N.

26. Let $a, b \in G$. (a) Prove that the conjugate of the product of a and b is the product of the conjugate of a and the conjugate of b. Prove that the order of a and the order of any conjugate of a are the same. (b) Prove that the conjugate of a^{-1} is the inverse of the conjugate of a. (c) Let $N = \langle S \rangle$ for some subset S of G. Prove that $N \trianglelefteq G$ if and only if $gSg^{-1} \subseteq N$ for all $g \in G$. (d) Deduce that if N is the cyclic group $\langle x \rangle$, then N is normal in G if and only if for each $g \in G$, $gxg^{-1} = x^k$ for some $k \in \mathbb{Z}$. (e) Let n be a positive integer. Prove that the subgroup N of G generated by all the elements of G of order n is a normal subgroup of G.

27. Let N be a finite subgroup of a group G. Show that $gNg^{-1} \subseteq N$ if and only if $gNg^{-1} = N$. Deduce that $N_G(N) = \{g \in G \mid gNg^{-1} \subseteq N\}$.

28. Let N be a finite subgroup of a group G and assume $N = \langle S \rangle$ for some subset S of G. Prove that an element $g \in G$ normalizes N if and only if $gSg^{-1} \subseteq N$.

29. Let N be a finite subgroup of G and suppose $G = \langle T \rangle$ and $N = \langle S \rangle$ for some subsets S and T of G. Prove that N is normal in G if and only if $tSt^{-1} \subseteq N$ for all $t \in T$.

30. Let $N \leq G$ and let $g \in G$. Prove that $gN = Ng$ if and only if $g \in N_G(N)$.

31. Prove that if $H \leq G$ and N is a normal subgroup of H then $H \leq N_G(N)$. Deduce that $N_G(N)$ is the largest subgroup of G in which N is normal (i.e., is the join of all subgroups H for which $N \trianglelefteq H$).

32. Prove that every subgroup of Q_8 is normal. For each subgroup find the isomorphism type of its corresponding quotient. [You may use the lattice of subgroups for Q_8 in Section 2.5.]

33. Find all normal subgroups of D_8 and for each of these find the isomorphism type of its corresponding quotient. [You may use the lattice of subgroups for D_8 in Section 2.5.]

34. Let $D_{2n} = \langle r, s \mid r^n = s^2 = 1,\ rs = sr^{-1} \rangle$ be the usual presentation of the dihedral group of order $2n$ and let k be a positive integer dividing n. (a) Prove that $\langle r^k \rangle$ is a normal subgroup of D_{2n}. (b) Prove that $D_{2n}/\langle r^k \rangle \cong D_{2k}$.

35. Prove that $SL_n(F) \trianglelefteq GL_n(F)$ and describe the isomorphism type of the quotient group (cf. Exercise 9, Section 2.1).

36. Prove that if $G/Z(G)$ is cyclic then G is abelian. [If $G/Z(G)$ is cyclic with generator $xZ(G)$, show that every element of G can be written in the form $x^a z$ for some integer $a \in \mathbb{Z}$ and some element $z \in Z(G)$.]

37. Let A and B be groups. Show that $\{(a, 1) \mid a \in A\}$ is a normal subgroup of $A \times B$ and the quotient of $A \times B$ by this subgroup is isomorphic to B.

38. Let A be an abelian group and let D be the (diagonal) subgroup $\{(a, a) \mid a \in A\}$ of $A \times A$. Prove that D is a normal subgroup of $A \times A$ and $(A \times A)/D \cong A$.

39. Suppose A is the non-abelian group S_3 and D is the diagonal subgroup $\{(a, a) \mid a \in A\}$ of $A \times A$. Prove that D is not normal in $A \times A$.

40. Let G be a group, let N be a normal subgroup of G and let $\overline{G} = G/N$. Prove that $\overline{x}$ and $\overline{y}$ commute in $\overline{G}$ if and only if $x^{-1}y^{-1}xy \in N$. (The element $x^{-1}y^{-1}xy$ is called the *commutator* of x and y and is denoted by $[x, y]$.)

41. Let G be a group. Prove that $N = \langle x^{-1}y^{-1}xy \mid x, y \in G \rangle$ is a normal subgroup of G and G/N is abelian (N is called the *commutator subgroup* of G).

42. Assume both H and K are normal subgroups of G with $H \cap K = 1$. Prove that $xy = yx$ for all $x \in H$ and $y \in K$. [Show $x^{-1}y^{-1}xy \in H \cap K$.]

43. Assume $\mathcal{P} = \{A_i \mid i \in I\}$ is any partition of G with the property that $\mathcal{P}$ is a group under the "quotient operation" defined as follows: to compute the product of A_i with A_j take any element a_i of A_i and any element a_j of A_j and let A_iA_j be the element of $\mathcal{P}$ containing a_ia_j (this operation is assumed to be well defined). Prove that the element of $\mathcal{P}$ that contains the identity of G is a normal subgroup of G and the elements of $\mathcal{P}$ are the cosets of this subgroup (so $\mathcal{P}$ is just a quotient group of G in the usual sense).

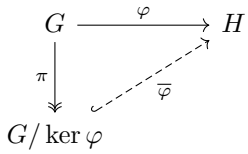
Practice problems (additional).

1. Let $G = \mathbb{Z}$ and $N = 12\mathbb{Z}$. List the elements of G/N, give the order of each coset, and identify G/N up to isomorphism.

2. In $\mathbb{Z}/30\mathbb{Z}$, compute the order of the cosets $\overline{6}$, $\overline{10}$, and $\overline{18}$. For each, find the subgroup $\langle \overline{x} \rangle$ it generates and its index in $\mathbb{Z}/30\mathbb{Z}$.

3. Let $G = D_8 = \langle r, s \rangle$ with $r^4 = s^2 = 1$, $sr = r^{-1}s$, and let $N = \langle r^2 \rangle = \{1, r^2\}$. Show $N \trianglelefteq G$, write out the four cosets of N, build the multiplication table of G/N, and identify G/N (is it $\mathbb{Z}/4\mathbb{Z}$ or the Klein four-group?).

4. Let $G = Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ and $N = \langle -1 \rangle = \{1, -1\}$. Show $N \trianglelefteq G$ and determine the isomorphism type of G/N.



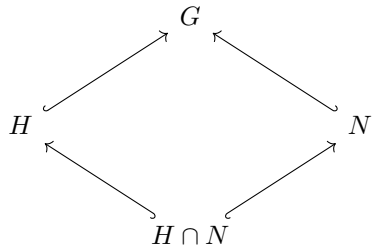
5. In $G = \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, let $N = \langle(\overline{2}, \overline{0})\rangle$. Compute $|N|$, list the cosets of N, and identify G/N.
6. Let $\varphi : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ be the natural projection $n \mapsto \overline{n}$. Find $\ker\varphi$, find $\operatorname{im}\varphi$, and use the First Isomorphism Theorem to identify $\mathbb{Z}/\ker\varphi$.
7. Define $\varphi : \mathbb{R} \to \mathbb{C}^\times$ by $\varphi(x) = e^{2\pi i x}$. Show φ is a homomorphism, compute $\ker\varphi$ and $\operatorname{im}\varphi$, and identify $\mathbb{R}/\ker\varphi$.
8. Let $\varphi : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$ be the determinant map. Identify $\ker\varphi$, identify $\operatorname{im}\varphi$, and state what the First Isomorphism Theorem gives for $\mathrm{GL}_2(\mathbb{R})/\mathrm{SL}_2(\mathbb{R})$.
9. Let $G = \mathbb{Z}/12\mathbb{Z}$. For each divisor $d \mid 12$ there is a unique subgroup of order d. List all subgroups of G, and for each subgroup H compute $[G : H]$ and identify G/H.
10. Let $N \trianglelefteq G$ with $[G : N] = 5$ and suppose $g \in G$ satisfies $g \notin N$. Prove that $G/N = \langle gN\rangle$, i.e. gN generates the quotient.
11. Suppose $|G| = 24$ and $N \trianglelefteq G$ with $|N| = 8$. Determine $|G/N|$ and all possible isomorphism types of G/N.
12. Let G be a group and $N \trianglelefteq G$. Prove that if G/N and N are both abelian and $N \leq Z(G)$, then for all $x, y \in G$ the commutator $[x, y] = x^{-1}y^{-1}xy$ lies in N.
13. Let $\varphi : G \to H$ be a homomorphism with $|G| = 20$ and $|H| = 12$. List all possible values of $|\operatorname{im}\varphi|$, justifying each by Lagrange's theorem applied to both G (via $\ker\varphi$) and H.
14. In $\mathbb{Z}/8\mathbb{Z}$, exhibit the unique chain of subgroups giving a composition series $1 \lhd H_1 \lhd H_2 \lhd \mathbb{Z}/8\mathbb{Z}$, and identify each composition factor.
15. Let $G = S_3$. Show that $A_3 \trianglelefteq S_3$ and that $S_3/A_3 \cong \mathbb{Z}/2\mathbb{Z}$. Identify the homomorphism $S_3 \to \{\pm 1\}$ whose kernel is A_3.
16. Let $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ (the Klein four-group). For each of the three subgroups N of order 2, identify G/N and verify $|G/N| = 2$.

Additional exercises.

1. Let $N \trianglelefteq G$. Prove that the order of the coset gN in G/N divides the order of g in G. Give an explicit example with $G = \mathbb{Z}/4\mathbb{Z}$, N of order 2, where the order of gN is strictly smaller than $|g|$.
2. (Cosets need not respect order naively.) Let $G = D_8 = \langle r, s\rangle$ and $N = \langle s\rangle$. Show that N is *not* normal in G by exhibiting $g \in G$ with $gNg^{-1} \neq N$, and conclude that the set of left cosets G/N is *not* a group under coset multiplication.
3. Let G be a group with $|G| = pq$ for primes $p < q$, and suppose $N \trianglelefteq G$ with $|N| = q$. Prove $G/N \cong \mathbb{Z}/p\mathbb{Z}$, and deduce that every element of G outside N has order divisible by p.
4. Let $\varphi : G \to H$ be a surjective homomorphism and let $M \trianglelefteq H$. Prove that $\varphi^{-1}(M) \trianglelefteq G$ and that $G/\varphi^{-1}(M) \cong H/M$. (This is the source of the lattice correspondence; prove it directly without quoting the Correspondence Theorem.)
5. Let $G = \mathbb{Z} \times \mathbb{Z}$ and $N = \langle(2, 0), (0, 3)\rangle$. Determine G/N as a direct product of cyclic groups and give its order.
6. Let G be a finite group and let $N \trianglelefteq G$ with $\gcd(|N|, [G : N]) = 1$. Prove that N is the unique subgroup of G of order $|N|$. (Hint: if $H \leq G$ with $|H| = |N|$, consider the image of H in G/N.)

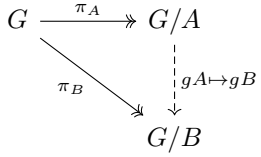
Commutative-diagram exercises.

1. Let $\varphi : G \to H$ be a homomorphism and $\pi : G \to G/\ker\varphi$ the natural projection. Prove there is a unique injective homomorphism $\overline{\varphi}$ making the triangle below commute, and that $\overline{\varphi}$ is an isomorphism onto $\operatorname{im}\varphi$:



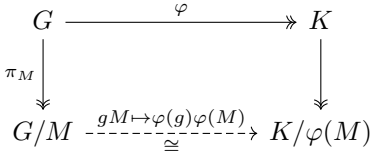
Apply this to $\varphi : \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ to recover $\mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/n\mathbb{Z}$.

2. For the homomorphism $\varphi : \mathbb{R} \to \mathbb{C}^\times$, $\varphi(x) = e^{2\pi i x}$, fill in the objects A and C so that the row below is a short exact sequence, and identify C:



$$1 \longrightarrow A \hookrightarrow \mathbb{R} \xrightarrow{\varphi} C \longrightarrow 1$$

where $A = \ker\varphi$ and $C = \operatorname{im}\varphi$.



3. Let $N \trianglelefteq G$ and $H \leq G$ with $H \cap N = \{1\}$ and $HN = G$. Using the diamond/diamond-isomorphism picture below, prove $H \cong G/N$ by showing the composite $H \hookrightarrow G \twoheadrightarrow G/N$ is an isomorphism:

4. Let $A, B \trianglelefteq G$ with $A \leq B$. Construct the diagram of natural projections below and prove the Third Isomorphism Theorem $(G/A)/(B/A) \cong G/B$ by exhibiting the dashed induced map, showing it is surjective with kernel B/A, and applying the First Isomorphism Theorem:

5. Let $\varphi : G \to K$ be surjective with kernel N, and let $M \trianglelefteq G$ with $N \leq M$. Show the square below commutes, where the bottom map is induced by φ. Prove the induced map is an isomorphism (its kernel is trivial), and separately verify the side fact $\varphi(M) \cong M/N$:

3.2 More on Cosets and Lagrange's Theorem

Lagrange's theorem and its corollaries

The single most useful counting fact in finite group theory: a subgroup's order divides the group's order. Everything in this section is a consequence of one clean idea — the *left cosets of H partition G into blocks of equal size $|H|$*.

Theorem 3.2.1 (Lagrange)**.** *Let G be a finite group and $H \leq G$. Then $|H|$ divides $|G|$, and the number of left cosets of H in G equals*

$$[G : H] = \frac{|G|}{|H|}.$$

Proof. Let $gH = \{gh : h \in H\}$ denote a left coset. Two facts drive the proof.

(1) The left cosets partition G. Each $g \in G$ lies in gH (take $h = 1$), so the cosets cover G. If $aH \cap bH \neq \varnothing$, pick $x = ah_1 = bh_2$; then $a = bh_2h_1^{-1} \in bH$, so $aH \subseteq bH$, and symmetrically $bH \subseteq aH$, giving $aH = bH$. Hence distinct cosets are disjoint.

(2) Every coset has exactly $|H|$ elements. The map $H \to gH$, $h \mapsto gh$, is a bijection: it is onto by definition of gH, and injective because $gh_1 = gh_2 \implies h_1 = h_2$ by left cancellation. Thus $|gH| = |H|$.

Let $k = [G : H]$ be the number of distinct left cosets and let $g_1H, \dots, g_kH$ be them. By (1) they are disjoint and by (2) each has size $|H|$, so

$$|G| = \sum_{i=1}^{k} |g_iH| = k\,|H|.$$

Therefore $|H| \mid |G|$ and $k = |G|/|H|$. □

Remark 3.2.1. The same proof with right cosets Hg shows there are equally many right cosets, so the index is unambiguous. The bijection $gH \mapsto Hg^{-1}$ matches left to right cosets. Lagrange's theorem needs no normality of H.

The partition is worth a picture: G is sliced into $[G : H]$ equal slabs, one of which is the subgroup $H = 1 \cdot H$ itself.

$$\begin{array}{ccc} H & \xrightarrow[\cong]{g_2\cdot} & g_2H \\ H & \xrightarrow[\cong]{g_3\cdot} & g_3H \\ & \vdots & \\ H & \xrightarrow[\cong]{g_k\cdot} & g_kH \end{array} \qquad |G| = \underbrace{|H| + \cdots + |H|}_{[G:H] \text{ terms}}.$$

Diagram explanation. Objects: Each node on the left is a copy of the subgroup $H \leq G$ (a finite group). Each node on the right is a left coset $g_iH = \{g_ih : h \in H\}$, a subset of G of equal size; cosets are *not* subgroups in general.

Arrows: Each horizontal arrow $H \to g_iH$, labelled $g_i\,\cdot$ and marked $\cong$, is the left-multiplication bijection $h \mapsto g_ih$. It is a bijection of *sets* (not a group homomorphism unless $g_i = 1$, since it sends 1 to g_i); the $\cong$ symbol here records equal cardinality, not isomorphism of groups.

What commutes: There is no composable path here; the diagram is a family of parallel bijections, not a square with two routes. The key equality it encodes is $|g_iH| = |H|$ for every i, established by the bijectivity of $h \mapsto g_ih$.

Why it commutes: The map $h \mapsto g_ih$ is injective because $g_ih_1 = g_ih_2$ implies $h_1 = h_2$ by left cancellation in G, and surjective by the definition of g_iH. Hence $|g_iH| = |H|$ for each $i = 2, \dots, k$.

Why this matters here: This picture is the visual heart of Lagrange's proof. The cosets $g_1H, \dots, g_kH$ partition G (proved just above the diagram), and each slab has the same size $|H|$. Adding sizes gives $|G| = k \cdot |H|$, so $|H|$ divides $|G|$ and $k = [G : H]$.

Concrete example: Take $G = S_3$, $H = \{e, (12)\}$ (order 2). The cosets are $H = \{e, (12)\}$, $(13)H = \{(13), (123)\}$, $(23)H = \{(23), (132)\}$; each has 2 elements and they partition S_3, giving $|S_3| = 3 \cdot 2 = 6$.

Common pitfall: Students sometimes read the $\cong$ label as a group isomorphism $H \cong g_iH$ and conclude g_iH is itself a subgroup. It is not: g_iH lacks the identity (unless $g_i \in H$) and the arrows are set-bijections only.

Takeaway: The point of this diagram is that every coset is an exact copy of H in size, so G is a disjoint union of $[G : H]$ equally-sized blocks, making divisibility of $|H|$ into $|G|$ immediate.

Method (Using Lagrange to constrain structure)**.** *Trigger.* You know $|G|$ and want to limit subgroup orders, element orders, or rule out a configuration.

1. **Subgroup orders** divide $|G|$: list the divisors of $|G|$; any $H \leq G$ has $|H|$ among them. (Existence is a separate question — see the pitfall.)
2. **Element orders** divide $|G|$: $|x| = |\langle x \rangle|$ divides $|G|$, so $x^{|G|} = 1$ for every x.
3. **Counting cosets:** $[G : H] = |G|/|H|$. Small index forces structure (index 2 $\implies$ $H \trianglelefteq G$; index = smallest prime dividing $|G|$ $\implies$ $H \trianglelefteq G$).

4. **Prime order $\implies$ cyclic** (no room for proper nontrivial subgroups).

Corollary 3.2.2 (Order of an element)**.** *If G is finite and $x \in G$, then $|x|$ divides $|G|$; consequently $x^{|G|} = 1$.*

Proof. $|x| = |\langle x \rangle|$ is the order of the cyclic subgroup $\langle x \rangle \leq G$, which divides $|G|$ by Lagrange. Write $|G| = |x| \cdot m$; then $x^{|G|} = (x^{|x|})^m = 1^m = 1$. □

Corollary 3.2.3 (Groups of prime order)**.** *If $|G| = p$ is prime, then G is cyclic; indeed $G = \langle x \rangle$ for any $x \neq 1$.*

Proof. Pick $x \neq 1$. Then $|x| \mid p$ and $|x| > 1$, so $|x| = p$. Hence $\langle x \rangle$ has p elements and $\langle x \rangle = G$, i.e. G is cyclic of order p, so $G \cong \mathbb{Z}/p\mathbb{Z}$. □

Corollary 3.2.4 (Euler–Fermat)**.** *For $n \geq 1$ and a coprime to n, $a^{\varphi(n)} \equiv 1 \pmod{n}$, where $\varphi(n) = |(\mathbb{Z}/n\mathbb{Z})^\times|$. In particular (Fermat) if p is prime and $p \nmid a$, then $a^{p-1} \equiv 1 \pmod{p}$.*

Proof. The group $G = (\mathbb{Z}/n\mathbb{Z})^\times = (\mathbb{Z}/n\mathbb{Z})^\times$ of units mod n has order $\varphi(n)$. The class $\overline{a}$ is a unit exactly when $\gcd(a, n) = 1$, and then by the previous corollary $\overline{a}^{\,\varphi(n)} = \overline{1}$, i.e. $a^{\varphi(n)} \equiv 1 \pmod{n}$. For $n = p$ prime, $\varphi(p) = p - 1$. □

Worked Example 3.2.5 (Possible subgroup orders when $|G| = 12$)**.** List every order a subgroup of a group G with $|G| = 12$ could have, and exhibit witnesses inside $\mathbb{Z}/12\mathbb{Z}$.

Recognition. Lagrange (Subgroup orders): possible $|H|$ lie among the divisors of $|G|$.

Solution. The divisors of 12 are $1, 2, 3, 4, 6, 12$. By Lagrange every subgroup order is one of these, and no other value (e.g. $5, 7, 8, \ldots$) can occur. In the *cyclic* group $\mathbb{Z}/12\mathbb{Z} = \langle 1 \rangle$ each divisor is actually realized, uniquely:

$\lvert H \rvert$	subgroup of $\mathbb{Z}/12\mathbb{Z}$	generator
1	$\{0\}$	0
2	$\{0, 6\}$	6
3	$\{0, 4, 8\}$	4
4	$\{0, 3, 6, 9\}$	3
6	$\{0, 2, 4, 6, 8, 10\}$	2
12	$\mathbb{Z}/12\mathbb{Z}$	1

Check. Each listed order divides 12, and $\langle d \rangle$ in $\mathbb{Z}/12\mathbb{Z}$ has order $12/\gcd(12, d)$ — e.g. $\langle 3 \rangle$ has order $12/\gcd(12, 3) = 12/3 = 4$. Lagrange forbids orders $5, 7, 8, 9, 10, 11$, consistent with none appearing. (Whether *every* divisor occurs in an arbitrary G of order 12 is a separate matter; in cyclic groups it always does.)

Worked Example 3.2.6 (Element orders in D_8)**.** With $|G| = 8$, which element orders are a priori possible, and which actually occur in the dihedral group $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$?

Recognition. Lagrange (Element orders): $|x| \mid |G|$.

Solution. Divisors of 8 are $1, 2, 4, 8$, so by Lagrange every element of D_8 has order in $\{1, 2, 4, 8\}$. Compute the actual orders:

$$|1| = 1, \quad |r| = 4,\ |r^2| = 2,\ |r^3| = 4, \qquad |r^k s| = 2 \ (k = 0, 1, 2, 3).$$

Indeed, using $sr^k = r^{-k}s$,

$$(r^k s)^2 = r^k s\, r^k s = r^k (r^{-k} s) s = s^2 = 1,$$

so each reflection is an involution. *Check.* Orders that occur are $\{1, 2, 4\}$, all dividing 8. Order 8 does *not* occur — D_8 has no element of order 8, so D_8 is non-cyclic, while $\mathbb{Z}/8\mathbb{Z}$ (also order 8) does have such an element. Lagrange permits order 8 but does not force it.

Caution. **The converse of Lagrange is FALSE.** If $d \mid |G|$ there need *not* be a subgroup of order d. The standard counterexample is A_4 (order 12) with $d = 6$ — see the next worked example. Lagrange gives a *necessary* condition on subgroup orders, never a sufficient one. (Partial converses do hold: Cauchy gives subgroups of prime order, and Sylow gives subgroups of prime-power order.)

Worked Example 3.2.7 (A_4 has no subgroup of order 6)**.** Prove the alternating group A_4 (with $|A_4| = 12$) has no subgroup H with $|H| = 6$, so the converse of Lagrange fails.

Recognition. Index-2 subgroups are normal, combined with counting elements by order.

Solution. Suppose $H \leq A_4$ with $|H| = 6$. Then $[A_4 : H] = 12/6 = 2$, and any subgroup of index 2 is normal, so $H \trianglelefteq A_4$.

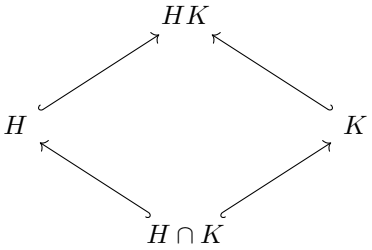
Recall the element structure of A_4: the identity (1 element), the three double transpositions $(12)(34)$, $(13)(24)$, $(14)(23)$ (order 2), and the eight 3-cycles (abc) (order 3). Count: $1 + 3 + 8 = 12$. ■

Since $H \trianglelefteq A_4$, the quotient A_4/H has order 2, so for every $x \in A_4$ we have $x^2 \in H$ (because $(xH)^2 = H$). Now take any 3-cycle σ, e.g. $\sigma = (123)$. Then

$$\sigma^2 = (132) \in H.$$

But σ^2 is again a 3-cycle, and as σ ranges over all eight 3-cycles, σ^2 also ranges over all eight 3-cycles: the map $\sigma \mapsto \sigma^2$ is a bijection on the set of 3-cycles, because every 3-cycle τ equals $(\tau^{-1})^2$ (for $|\tau| = 3$ we have $\tau^2 = \tau^{-1}$, also a 3-cycle). Hence *all eight* 3-cycles lie in H. Together with the identity that already gives 9 elements in H, contradicting $|H| = 6$.

Check. The contradiction $9 \leq 6$ is impossible, so no such H exists. The divisor $6 \mid 12$ yet there is no subgroup of order 6 — the converse of Lagrange is false.



Proposition 3.2.8 (Product formula)**.** *Let H, K be finite subgroups of a group G. Then for the subset $HK = \{hk : h \in H,\ k \in K\}$,*

$$|HK| = \frac{|H|\,|K|}{|H \cap K|}.$$

Proof. Consider $HK = \bigcup_{h \in H} hK$, a union of left cosets of K. Two such cosets coincide, $h_1K = h_2K$, iff $h_2^{-1}h_1 \in K$; since $h_2^{-1}h_1 \in H$ as well, this happens iff $h_2^{-1}h_1 \in H \cap K$. Thus the cosets hK are indexed by the *left cosets of $H \cap K$ in H*, of which there are $[H : H \cap K] = |H|/|H \cap K|$. Each coset hK contributes $|K|$ distinct elements, and distinct cosets are disjoint, so

$$|HK| = \frac{|H|}{|H \cap K|} \cdot |K| = \frac{|H|\,|K|}{|H \cap K|}. \qquad \square$$

The lattice picture and the counting are companions:

$$|HK| = \frac{|H|\,|K|}{|H \cap K|}.$$

Diagram explanation. Objects: Four subsets (or subgroups) of an ambient group G: the intersection $H \cap K$ at the bottom, the subgroups H and K in the middle, and the product set $HK = \{hk : h \in H,\, k \in K\}$ at the top. Note that HK is a set, not necessarily a subgroup; it is a subgroup exactly when $HK = KH$ (next proposition).

Arrows: All four arrows are subset inclusions (hooked arrows): $H \cap K \hookrightarrow H$, $H \cap K \hookrightarrow K$, $H \hookrightarrow HK$, and $K \hookrightarrow HK$. Each records a containment: e.g. every element of $H \cap K$ belongs to both H and K, and every element of H or K is already in HK.

What commutes: Both routes from $H \cap K$ to HK compose to the same inclusion: $(H \cap K \hookrightarrow H \hookrightarrow HK)$ and $(H \cap K \hookrightarrow K \hookrightarrow HK)$ both send $x \mapsto x$, agreeing because all maps are plain inclusions of sets.

Why it commutes: An element $x \in H \cap K$ satisfies $x \in H$ (top-left path) and $x \in K$ (top-right path); in both cases $x = x \cdot 1 \in HK$ (or $x = 1 \cdot x \in HK$). Both paths land at the same element of HK.

Why this matters here: The diamond encodes the algebraic content of the product formula $|HK| = |H||K|/|H \cap K|$. The proof shows the left H-cosets of K inside HK are indexed by left cosets of $H \cap K$ in H: the "overlap" $H \cap K$ is exactly the ambiguity counted out. The diagram makes the lattice structure visible and reminds the reader of all four sets involved.

Concrete example: In $G = S_4$, let $H = \{e, (12), (34), (12)(34)\} \cong V_4$ and $K = \{e, (13), (24), (13)(24)\} \cong V_4$. Then $H \cap K = \{e\}$, $|H| = |K| = 4$, $|HK| = 4 \cdot 4/1 = 16$, so this HK is a 16-element subset of S_4 that is not a subgroup (as $16 \nmid 24$). For a smaller picture, pick $H = \langle(12)\rangle$, $K = \langle(13)\rangle$; then $|H \cap K| = 1$, $|HK| = 4$, and the diamond has $H \cap K = \{e\}$ at the bottom.

Common pitfall: Students often assume HK is a subgroup from the diagram because it sits at the "top." The lattice shape suggests a subgroup lattice, but HK is a *set* here; the diagram records containment, not the subgroup structure of HK.

Takeaway: The point of this diagram is that the four sets $H \cap K \subseteq H, K \subseteq HK$ form a diamond, and the product formula $|HK| = |H||K|/|H \cap K|$ is the size-counterpart of that lattice shape.

Remark 3.2.2. HK is the product *set*; it need not be a subgroup. The criterion is exactly the next proposition.

Proposition 3.2.9 (When HK is a subgroup)**.** *For subgroups $H, K \leq G$, the set HK is a subgroup of G if and only if $HK = KH$.*

Proof. ($\Rightarrow$) If $HK \leq G$ it is closed under inverses, so $HK = (HK)^{-1} = \{(hk)^{-1}\} = \{k^{-1}h^{-1}\} = K^{-1}H^{-1} = KH$ (using $H^{-1} = H$, $K^{-1} = K$).

($\Leftarrow$) Suppose $HK = KH$. Then $1 = 1 \cdot 1 \in HK$. Closure: for $h_1k_1, h_2k_2 \in HK$, since $k_1h_2 \in KH = HK$ we may write $k_1h_2 = h'k'$ with $h' \in H$, $k' \in K$, hence

$$(h_1k_1)(h_2k_2) = h_1(k_1h_2)k_2 = h_1h'k'k_2 \in HK.$$

Inverses: $(hk)^{-1} = k^{-1}h^{-1} \in KH = HK$. Hence $HK \leq G$. □

Corollary 3.2.10. *If $H \trianglelefteq G$ or $K \trianglelefteq G$ (in particular if either is normal), then $HK = KH$, so $HK \leq G$.*

Proof. If $K \trianglelefteq G$ then $hK = Kh$ for all h, so $HK = \bigcup_h hK = \bigcup_h Kh = KH$; apply the proposition. Symmetrically if $H \trianglelefteq G$. □

Worked Example 3.2.11 (Compute $|HK|$ in S_4)**.** Inside $G = S_4$ let $H = \langle(1234)\rangle$ (a cyclic group of order 4) and $K = \langle(12)\rangle$ (order 2). Compute $|HK|$ and decide whether HK is a subgroup.

Recognition. Product formula for $|HK|$; the $HK = KH$ test for subgroup-ness.

Solution. First $H \cap K$. Elements of $H = \{e, (1234), (13)(24), (1432)\}$; the only element of order ≤ 2 here besides e is $(13)(24)$, and $K = \{e, (12)\}$. Since $(13)(24) \neq (12)$, we get $H \cap K = \{e\}$, so $|H \cap K| = 1$. Then

$$|HK| = \frac{|H|\,|K|}{|H \cap K|} = \frac{4 \cdot 2}{1} = 8.$$

Is HK a subgroup? If it were, by Lagrange $|HK| = 8$ would have to divide $|S_4| = 24$ — and $8 \mid 24$, so Lagrange alone does *not* rule it out. Test $HK = KH$ directly. Compute $(12)(1234)$ (composing right to left, the rightmost cycle acting first) and check membership in HK: tracking $1 \mapsto 2 \mapsto 1$, $2 \mapsto 3$, $3 \mapsto 4$, $4 \mapsto 1 \mapsto 2$ gives

$$(12)(1234) = (234) \quad \text{(a 3-cycle, order 3).}$$

This product lies in $(12)H \subseteq KH$. On the other hand $HK = H \cup H(12)$ (as $K = \{e, (12)\}$), and computing right to left, $(1234)(12) = (134)$, $(13)(24)(12) = (1423)$, $(1432)(12) = (243)$. Concretely

$$HK = \{e, (1234), (13)(24), (1432), (12), (134), (1423), (243)\},$$

and the 3-cycle (234) is not in this list. So $(12)(1234) \in KH$ but $\notin HK$, hence $HK \neq KH$ and HK **is not a subgroup**. (Directly: HK contains the 3-cycle (134), while a subgroup of order 8 has no element of order 3.) *Check.* $|HK| = 8$ as a set is correct (the eight listed elements are distinct), yet the set fails closure — exactly the situation the criterion predicts when $HK \neq KH$.

Worked Example 3.2.12 ($|HK|$ when the formula forces G)**.** In a group G with $|G| = p^2$ (p prime), let H, K be subgroups of order p with $H \neq K$. Show $HK = G$.

Recognition. Product formula plus Lagrange on $H \cap K$.

Solution. $H \cap K \leq H$, so $|H \cap K|$ divides p, i.e. equals 1 or p. If $|H \cap K| = p$ then $H \cap K = H = K$, contradicting $H \neq K$; hence $|H \cap K| = 1$. Then

$$|HK| = \frac{p \cdot p}{1} = p^2 = |G|,$$

so $HK = G$ as a set. *Check.* $|HK| = p^2 \leq |G| = p^2$ is forced to be equality, and $HK \subseteq G$ with equal sizes gives $HK = G$. (For instance in $\mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$, the "axes" $H = \mathbb{Z}/p\mathbb{Z} \times 0$ and $K = 0 \times \mathbb{Z}/p\mathbb{Z}$ have $H \cap K = 0$ and $H + K = \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$.)

Proposition 3.2.13 (Multiplicativity of the index)**.** *If $K \leq H \leq G$ with all indices finite, then*

$$[G : K] = [G : H] \cdot [H : K].$$

Proof. Finite case (via Lagrange). If G is finite,

$$[G : K] = \frac{|G|}{|K|} = \frac{|G|}{|H|} \cdot \frac{|H|}{|K|} = [G : H] \cdot [H : K].$$

General case (no finiteness of G). Let $g_1H, \ldots, g_aH$ be the $a = [G : H]$ distinct cosets of H, and $h_1K, \ldots, h_bK$ the $b = [H : K]$ distinct cosets of K in H. I claim $\{g_ih_jK\}_{i \leq a,\, j \leq b}$ are exactly the cosets of K in G, all distinct. Coverage: any $g \in G$ lies in some g_iH, so $g = g_ih$ with $h \in H$, and $h \in h_jK$ for some j, whence $g \in g_ih_jK$. Distinctness: if $g_ih_jK = g_{i'}h_{j'}K$ then projecting via $g \mapsto gH$ gives $g_iH = g_{i'}H$ (since $h_j, h_{j'}, K \subseteq H$), so $i = i'$; cancel g_i to get $h_jK = h_{j'}K$, so $j = j'$. Hence there are ab cosets: $[G : K] = ab = [G : H][H : K]$. □

Worked Example 3.2.14 (Multiplicativity in a chain inside $\mathbb{Z}/12\mathbb{Z}$)**.** Take $G = \mathbb{Z}/12\mathbb{Z}$, $H = \langle 2 \rangle = \{0, 2, 4, 6, 8, 10\}$ (order 6), $K = \langle 4 \rangle = \{0, 4, 8\}$ (order 3). Verify $[G : K] = [G : H][H : K]$.

Recognition. Index multiplicativity for a tower $K \leq H \leq G$.

Solution. First confirm the tower: $K = \{0, 4, 8\} \subseteq \{0, 2, 4, 6, 8, 10\} = H \subseteq G$. ■Compute each index by Lagrange:

$$[G : H] = \frac{12}{6} = 2, \quad [H : K] = \frac{6}{3} = 2, \quad [G : K] = \frac{12}{3} = 4.$$

Then $[G : H] \cdot [H : K] = 2 \cdot 2 = 4 = [G : K]$. ■*Check (cosets explicitly).* The 4 cosets of $K = \langle 4 \rangle$ in $\mathbb{Z}/12\mathbb{Z}$ are $\{0, 4, 8\}, \{1, 5, 9\}, \{2, 6, 10\}, \{3, 7, 11\}$, indeed 4 of them, matching $[G : K] = 4$.

Worked Example 3.2.15 (Deduce Fermat's little theorem)**.** Use Lagrange to prove: for prime p and integer a with $p \nmid a$, $a^{p-1} \equiv 1 \pmod{p}$; and for *all* a, $a^p \equiv a \pmod{p}$.

Recognition. Order-of-element corollary applied to the unit group $(\mathbb{Z}/p\mathbb{Z})^\times$.

Solution. The multiplicative group $(\mathbb{Z}/p\mathbb{Z})^\times = (\mathbb{Z}/p\mathbb{Z})^\times = \{\overline{1}, \ldots, \overline{p-1}\}$ has order $p - 1$ (every nonzero residue is a unit since p is prime). If $p \nmid a$ then $\overline{a} \in (\mathbb{Z}/p\mathbb{Z})^\times$, and by the corollary to Lagrange

$$\overline{a}^{\,p-1} = \overline{1}, \qquad \text{i.e.} \qquad a^{p-1} \equiv 1 \pmod{p}.$$

Multiplying by a: $a^p \equiv a \pmod{p}$ whenever $p \nmid a$. If instead $p \mid a$, then $a \equiv 0$ and $a^p \equiv 0 \equiv a \pmod{p}$ trivially. So $a^p \equiv a \pmod{p}$ for all integers a. *Check.* Take $p = 5$, $a = 2$: $2^4 = 16 \equiv 1 \pmod{5}$. ■ And $a = 3$: $3^5 = 243 = 5 \cdot 48 + 3 \equiv 3 \pmod{5}$. ■

Theorem 3.2.16 (Cauchy, abelian case)**.** *Let G be a finite* abelian *group and let p be a prime dividing $|G|$. Then G contains an element of order p (equivalently, a subgroup of order p).*

Proof. Induct on $|G|$. The base $|G| = p$ is the prime-order case (any $x \neq 1$ has order p). For the step, pick any $x \neq 1$ and let $n = |x| > 1$.

Case 1: $p \mid n$. Then $x^{n/p}$ has order exactly p, since $(x^{n/p})^p = x^n = 1$ while $x^{n/p} \neq 1$ (its order divides p and is > 1, hence equals p). Done.

Case 2: $p \nmid n$. Since G is abelian, $N = \langle x \rangle \trianglelefteq G$, and the quotient $\overline{G} = G/N$ has order $|G|/n$. As $p \mid |G|$ but $p \nmid n$, we get $p \mid |\overline{G}|$, and $|\overline{G}| < |G|$. By induction $\overline{G}$ has an element $\overline{y}$ of order p. Let $m = |y|$ in G; then in $\overline{G}$ we have $\overline{y}^{\,m} = \overline{y^m} = \overline{1}$, so $p = |\overline{y}| \mid m$. Now $y^{m/p}$ has order p in G by the same argument as Case 1. □

Remark 3.2.3. Cauchy's theorem holds for *all* finite groups (D&F prove the general case later via a clever group action on p-tuples); the abelian case above is the inductive heart. Together with Lagrange it gives a clean partial converse: *every prime divisor of $|G|$ is the order of some subgroup*, even though arbitrary divisors (like $6 \mid 12$ in A_4) may fail.

The exact-sequence viewpoint, used implicitly in Cauchy's induction, deserves a diagram: a normal subgroup $N \trianglelefteq G$ sits in a short exact sequence whose terms N and G/N have orders multiplying to $|G|$ (a Lagrange identity $|G| = |N| \cdot |G/N|$).

$$1 \longrightarrow N \hookrightarrow G \xrightarrow{\pi} G/N \longrightarrow 1, \qquad |G| = |N| \cdot |G/N|.$$

Diagram explanation. Objects: Five terms in a short exact sequence. 1 (the trivial group) appears at both ends as the zero object. N is a normal subgroup of G (required for the quotient to be a group). G is the ambient finite group. G/N is the quotient group whose elements are left cosets gN, with group operation $(g_1N)(g_2N) = (g_1g_2)N$; normality of N is exactly what makes this well-defined.

Arrows: The first arrow $1 \to N$ is the unique map from the trivial group (sends 1 to the identity of N). The second arrow $N \hookrightarrow G$ is the inclusion $n \mapsto n$ (a hooked arrow signals injective). The third arrow $\pi : G \twoheadrightarrow G/N$ is the canonical quotient map $g \mapsto gN$ (a double-headed arrow signals surjective). Well-definedness of π is automatic; but the *group* structure on G/N requires $N \trianglelefteq G$: if $g_1N = g_1'N$ then $g_1'^{-1}g_1 \in N$, and $(g_1g_2)N = (g_1'g_2)N$ follows because N absorbs conjugates. The last arrow $G/N \to 1$ sends everything to 1.

What commutes: Exactness, not commutativity of a square, is the content. At N: $\ker(\iota) = \{1\} = \mathrm{im}(1 \to N)$ (injective). At G: $\ker(\pi) = N = \mathrm{im}(\iota)$ (the kernel of the quotient map is exactly N). At G/N: $\ker(G/N \to 1) = G/N = \mathrm{im}(\pi)$ (surjective).

Why it commutes: $\ker(\pi) = N$ because $\pi(g) = gN = N$ iff $g \in N$. This is the fundamental property of the quotient map: elements of N are precisely those mapped to the identity coset. Injectivity of ι is clear; surjectivity of π is clear since every coset gN is the image of g.

Why this matters here: The short exact sequence packages the induction step of Cauchy's proof: from $N = \langle x \rangle \trianglelefteq G$ one passes to $\overline{G} = G/N$ of strictly smaller order, finds an order-p element there by induction, and lifts it back to G. The sequence also encodes Lagrange: $|G| = |N| \cdot |G/N|$ is the size-count of the three middle terms.

Concrete example: Take $G = \mathbb{Z}/6\mathbb{Z}$, $N = \langle 2 \rangle = \{0, 2, 4\} \cong \mathbb{Z}/3\mathbb{Z}$ (normal since G is abelian). The sequence is $0 \to \mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$. Here $\pi(k) = k \bmod 2$ (as cosets), $\ker(\pi) = \{0, 2, 4\} = N$, and $|G| = 3 \cdot 2$. ■

Common pitfall: Forgetting that $N \trianglelefteq G$ is required for the quotient to be a group. If N is merely a subgroup, π is still a well-defined map of sets onto {cosets}, but the middle term G/N has no group structure and the sequence is meaningless as an exact sequence of groups.

Takeaway: The point of this diagram is that a normal subgroup N sits as the kernel of a surjection π, packaging Lagrange's identity $|G| = |N| \cdot |G/N|$ as the exactness of a three-term sequence.

Worked Example 3.2.17 (Cauchy in $\mathbb{Z}/6\mathbb{Z}$ and a non-cyclic check)**.** Find elements of order 2 and order 3 in $G = \mathbb{Z}/6\mathbb{Z}$ (order $6 = 2 \cdot 3$), as Cauchy guarantees, and contrast with the Klein four-group V_4.

Recognition. Cauchy (abelian): each prime $p \mid |G|$ yields an element of order p.

Solution. For $G = \mathbb{Z}/6\mathbb{Z}$: $|3| = 6/\gcd(6, 3) = 2$, so 3 has order 2; and $|2| = 6/\gcd(6, 2) = 3$, so 2 has order 3. Both primes $2, 3 \mid 6$ are realized. *Check.* $3 + 3 = 6 \equiv 0$ (order 2 ■); $2 + 2 + 2 = 6 \equiv 0$ with $2, 4 \neq 0$ (order 3 ■). For $V_4 = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ of order $4 = 2^2$: the only prime divisor is 2, and indeed every nonidentity element $(1, 0), (0, 1), (1, 1)$ has order 2 — Cauchy delivers order-2 elements but, correctly, promises nothing of order 3 or 4 since $3 \nmid 4$ and 4 is not prime (and no element of order 4 exists, as V_4 is non-cyclic).

Method (Lagrange as a structural sieve — a worked checklist)**.** Given $|G| = n$, to extract structure:

1. Factor n and list its divisors — the menu of possible subgroup/element orders.
2. For each prime $p \mid n$: Cauchy guarantees an order-p element (so the group is *not* a counterexample to existence at primes).

3. Look for index-2 subgroups (automatically normal) or index = smallest prime (also normal) to find normal subgroups for quotients.

4. Use the product formula $|HK| = |H|\,|K|/|H \cap K|$ to bound $|HK|$; if it forces $|HK| = |G|$ then $HK = G$.

5. **Never** assert a subgroup of order d exists just because $d \mid n$ — check or cite Cauchy/Sylow.

Caution. **Index notation cuts both ways.** $[G : H] = |G|/|H|$ is the number of cosets, *not* a quotient group unless $H \trianglelefteq G$. A set of $[G : H]$ cosets always exists; the group structure on them (G/H) requires normality. Don't confuse "H has index 2" (always forces $H \trianglelefteq G$) with "$|H| = 2$" (says nothing about normality).

Exercises (from the text).

1. Which of the following are permissible orders for subgroups of a group of order 120: 1, 2, 5, 7, 9, 15, 60, 240? For each permissible order give the corresponding index.

2. Prove that the lattice of subgroups of S_3 in Section 2.5 is correct (i.e., prove that it contains all subgroups of S_3 and that their pairwise joins and intersections are correctly drawn).

3. Prove that the lattice of subgroups of Q_8 in Section 2.5 is correct.

4. Show that if $|G| = pq$ for some primes p and q (not necessarily distinct) then either G is abelian or $Z(G) = 1$. [See Exercise 36 in Section 1.]

5. Let H be a subgroup of G and fix some element $g \in G$. (a) Prove that gHg^{-1} is a subgroup of G of the same order as H. (b) Deduce that if $n \in \mathbb{Z}^+$ and H is the unique subgroup of G of order n then $H \trianglelefteq G$.

6. Let $H \leq G$ and let $g \in G$. Prove that if the right coset Hg equals some left coset of H in G then it equals the left coset gH and g must be in $N_G(H)$.

7. Let $H \leq G$ and define a relation $\sim$ on G by $a \sim b$ if and only if $b^{-1}a \in H$. Prove that $\sim$ is an equivalence relation and describe the equivalence class of each $a \in G$. Use this to prove Proposition 4.

8. Prove that if H and K are finite subgroups of G whose orders are relatively prime then $H \cap K = 1$.

9. This exercise outlines a proof of Cauchy's Theorem due to James McKay (*Another proof of Cauchy's group theorem*, Amer. Math. Monthly, 66(1959), p. 119). Let G be a finite group and let p be a prime dividing $|G|$. Let $\mathcal{S}$ denote the set of p-tuples of elements of G the product of whose coordinates is 1: $\mathcal{S} = \{(x_1, x_2, \ldots, x_p) \mid x_i \in G \text{ and } x_1 x_2 \cdots x_p = 1\}$. (a) Show that $\mathcal{S}$ has $|G|^{p-1}$ elements, hence has order divisible by p. Define the relation $\sim$ on $\mathcal{S}$ by letting $\alpha \sim \beta$ if β is a cyclic permutation of α. (b) Show that a cyclic permutation of an element of $\mathcal{S}$ is again an element of $\mathcal{S}$. (c) Prove that $\sim$ is an equivalence relation on $\mathcal{S}$. (d) Prove that an equivalence class contains a single element if and only if it is of the form $(x, x, \ldots, x)$ with $x^p = 1$. (e) Prove that every equivalence class has order 1 or p (this uses the fact that p is a prime). Deduce that $|G|^{p-1} = k + pd$, where k is the number of classes of size 1 and d is the number of classes of size p. (f) Since $\{(1, 1, \ldots, 1)\}$ is an equivalence class of size 1, conclude from (e) that there must be a nonidentity element x in G with $x^p = 1$, i.e., G contains an element of order p. [Show $p \mid k$ and so $k > 1$.]

10. Suppose H and K are subgroups of finite index in the (possibly infinite) group G with $[G : H] = m$ and $[G : K] = n$. Prove that $\mathrm{l.c.m.}(m, n) \leq [G : H \cap K] \leq mn$. Deduce that if m and n are relatively prime then $[G : H \cap K] = [G : H] \cdot [G : K]$.

11. Let $H \leq K \leq G$. Prove that $[G : H] = [G : K] \cdot [K : H]$ (do not assume G is finite).

12. Let $H \leq G$. Prove that the map $x \mapsto x^{-1}$ sends each left coset of H in G onto a right coset of H and gives a bijection between the set of left cosets and the set of right cosets of H in G (hence the number of left cosets of H in G equals the number of right cosets).

13. Fix any labelling of the vertices of a square and use this to identify D_8 as a subgroup of S_4. Prove that the elements of D_8 and $(1\,2\,3)$ do not commute in S_4.

14. Prove that S_4 does not have a normal subgroup of order 8 or a normal subgroup of order 3.

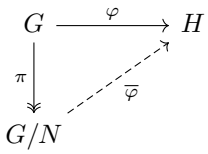
15. Let $G = S_n$, and for fixed $i \in \{1, 2, \ldots, n\}$ let G_i be the stabilizer of i. Prove that $G_i \cong S_{n-1}$.
16. Use Lagrange's Theorem in the multiplicative group $(\mathbb{Z}/p\mathbb{Z})^\times$ to prove Fermat's Little Theorem: if p is a prime then $a^p \equiv a \pmod{p}$ for all $a \in \mathbb{Z}$.
17. Let p be a prime and let n be a positive integer. Find the order of $\overline{p}$ in $(\mathbb{Z}/(p^n - 1)\mathbb{Z})^\times$ and deduce that $n \mid \varphi(p^n - 1)$ (here φ is Euler's function).
18. Let G be a finite group, let H be a subgroup of G and let $N \trianglelefteq G$. Prove that if $|H|$ and $[G : N]$ are relatively prime then $H \leq N$.
19. Prove that if N is a normal subgroup of the finite group G and $(|N|, [G : N]) = 1$ then N is the unique subgroup of G of order $|N|$.
20. If A is an abelian group with $A \trianglelefteq G$ and B is any subgroup of G prove that $A \cap B \trianglelefteq AB$.
21. Use Lagrange's Theorem in the multiplicative group $(\mathbb{Z}/n\mathbb{Z})^\times$ to prove Euler's Theorem: $a^{\varphi(n)} \equiv 1 \pmod{n}$ for every integer a relatively prime to n, where φ denotes Euler's function.
22. Determine the last two digits of $3^{3^{100}}$. [Determine $3^{100} \bmod \varphi(100)$ and use the previous exercise.]

Practice problems (additional).

1. Let $G = \mathbb{Z}_{12}$ (additive) and $H = \langle 4 \rangle = \{0, 4, 8\}$. List all distinct cosets of H in G, give $[G : H]$, and verify $[G : H] \cdot |H| = |G|$.
2. In S_3 let $H = \langle (1\,2) \rangle$. Compute all left cosets and all right cosets of H. Are the two partitions the same? Is $H \trianglelefteq S_3$?
3. Let $G = D_8$ (so $r^4 = s^2 = 1$, $sr = r^{-1}s$) and $H = \langle s \rangle$. Find $[G : H]$ and list a complete set of left coset representatives.
4. Suppose $|G| = 33$ and $x \in G$ with $x \neq 1$. Using Lagrange's theorem, determine all possible values of $|x|$.
5. Let G be a group of order p, p prime. Prove G is cyclic and that every nonidentity element is a generator.
6. Let $H, K \leq G$ be finite subgroups with $|H| = 15$ and $|K| = 8$. Prove $H \cap K = \{1\}$.
7. Let G be a finite group, $H \leq G$, and $x \in G$. Prove that $|xHx^{-1}| = |H|$, hence xHx^{-1} is again a subgroup of the same order.
8. Let $H \leq G$ with $[G : H] = 2$. Prove $H \trianglelefteq G$. (Compare a left coset with its complementary right coset.)
9. Let $G = \mathbb{Z}_{18}$ and $H = \langle 6 \rangle$. Identify the quotient group G/H up to isomorphism with a known group, giving its order and the order of $1 + H$.
10. Let G be a finite abelian group and $n = |G|$. Prove $x^n = 1$ for every $x \in G$.
11. Compute $[\mathbb{Z} : n\mathbb{Z}]$ for a positive integer n, and describe explicitly the cosets of $n\mathbb{Z}$ in $\mathbb{Z}$.
12. Let $H \leq K \leq G$ with all three groups finite. Prove the tower formula $[G : H] = [G : K] \cdot [K : H]$.
13. Let $\varphi \colon G \to G'$ be a homomorphism with $|G| = 20$ and $|G'| = 9$. Prove φ is trivial (i.e. $\varphi(g) = 1$ for all g).
14. In S_4, let $H = \langle (1\,2\,3\,4) \rangle$. Find $[S_4 : H]$ and exhibit a transversal (one representative from each left coset).
15. Let p be prime and $|G| = p^2$. List the possible orders of elements of G and explain why no element has order p^3.

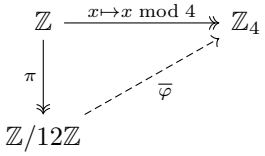
Additional exercises.

1. (Poincare's theorem) Let $H, K \leq G$ have finite index. Prove $[G : H \cap K] \leq [G : H] \cdot [G : K]$, with equality when $\gcd([G : H], [G : K]) = 1$.
2. Let G be a finite group, p the smallest prime dividing $|G|$, and $H \leq G$ with $[G : H] = p$. Prove $H \trianglelefteq G$.
3. Let $|G| = pq$ with $p < q$ primes. Prove that G has at most one subgroup of order q, and if it exists it is normal.



4. Let H, K be finite subgroups of G. Prove $|HK| = \dfrac{|H|\,|K|}{|H \cap K|}$, and deduce that HK is a subgroup whenever $HK = KH$.

5. Let G act on the set of left cosets G/H by left multiplication, giving a homomorphism $G \to \mathrm{Sym}(G/H)$. Show its kernel is contained in H, and use this to prove: if $|G|$ does not divide $[G : H]!$ then H contains a nontrivial normal subgroup of G.



6. Let G be a finite group in which every nonidentity element has order 2. Prove $|G|$ is a power of 2 and G is abelian.

Commutative-diagram exercises.

1. Let $N \trianglelefteq G$ and let $\pi\colon G \to G/N$ be the quotient map. Given a homomorphism $\varphi\colon G \to H$ with $N \subseteq \ker\varphi$, prove there is a unique $\overline{\varphi}$ making the diagram commute, and identify $\ker\overline{\varphi}$:

2. For $G = \mathbb{Z}$, $N = 12\mathbb{Z}$, complete the induced map $\overline{\varphi}\colon \mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}_4$ and prove it is a surjection with kernel $4\mathbb{Z}/12\mathbb{Z}$ (so it is NOT an isomorphism, since $|\mathbb{Z}/12\mathbb{Z}| = 12 \neq 4$):

   Determine $\ker(x \mapsto x \bmod 4)$ as a subgroup of $\mathbb{Z}$ and verify $12\mathbb{Z} \subseteq \ker$.

3. Let $\varphi\colon G \to \mathrm{im}\,\varphi$ be a surjective homomorphism with kernel $\ker\varphi$. Show the row below is a short exact sequence and label each arrow (inclusion vs. quotient):

$$1 \longrightarrow \ker\varphi \hookrightarrow G \xrightarrow{\varphi} \mathrm{im}\,\varphi \longrightarrow 1$$

   Verify exactness at each interior node for $G = \mathbb{Z}_6$, $\varphi(x) = x \bmod 3$.

4. Let $A, B \leq G$ with $A \cap B$ a subgroup. Fill in the inclusion arrows of the diamond and state which inclusion is an equality precisely when $A \subseteq B$:

   Taking $G = \mathbb{Z}_{12}$, $A = \langle 2\rangle$, $B = \langle 3\rangle$, compute $|A|$, $|B|$, $|A \cap B|$, $|AB|$ and confirm $|AB| = |A||B|/|A \cap B|$.

5. Let $N \trianglelefteq G$ and $H \leq G$. Using the second isomorphism theorem, label the induced isomorphism in the diagram and prove $[HN : N] = [H : H \cap N]$:

3.3 The Isomorphism Theorems

The first isomorphism theorem

Throughout, $\varphi : G \to H$ is a group homomorphism. Recall that its *kernel* $\ker\varphi = \{g \in G : \varphi(g) = 1_H\}$ is a normal subgroup of G and its *image* $\operatorname{im}\varphi = \{\varphi(g) : g \in G\}$ is a subgroup of H. We saw in 3.1 that for $N = \ker\varphi$ the fibers of φ are exactly the cosets of N: $\varphi(x) = \varphi(y) \iff xN = yN$. The present section turns this observation into a structural identification of the quotient G/N.

Theorem 3.3.1 (First Isomorphism Theorem)**.** *Let $\varphi : G \to H$ be a homomorphism and put $N = \ker\varphi$. Then the rule*

$$\overline{\varphi} : G/N \longrightarrow \operatorname{im}\varphi, \qquad \overline{\varphi}(gN) = \varphi(g),$$

is a well-defined isomorphism. Consequently

$$G/\ker\varphi \;\cong\; \operatorname{im}\varphi.$$

Proof. **Well-defined.** Suppose $g_1N = g_2N$. Then $g_2^{-1}g_1 \in N = \ker\varphi$, so $\varphi(g_2^{-1}g_1) = 1$, i.e. $\varphi(g_2)^{-1}\varphi(g_1) = 1$, hence $\varphi(g_1) = \varphi(g_2)$. Thus $\overline{\varphi}(g_1N) = \overline{\varphi}(g_2N)$: the value depends only on the coset, not on the chosen representative.

Homomorphism. For all $g_1, g_2 \in G$,

$$\overline{\varphi}\big((g_1N)(g_2N)\big) = \overline{\varphi}(g_1g_2\,N) = \varphi(g_1g_2) = \varphi(g_1)\varphi(g_2) = \overline{\varphi}(g_1N)\,\overline{\varphi}(g_2N).$$

(The first equality uses the definition of multiplication in G/N, which is legitimate precisely because $N \trianglelefteq G$.)

Injective. Compute the kernel of $\overline{\varphi}$. If $\overline{\varphi}(gN) = 1$ then $\varphi(g) = 1$, so $g \in \ker\varphi = N$, whence $gN = N$ is the identity coset. Thus $\ker\overline{\varphi} = \{N\}$ is trivial, so $\overline{\varphi}$ is injective.

Surjective. Every element of $\operatorname{im}\varphi$ has the form $\varphi(g)$ for some $g \in G$, and $\varphi(g) = \overline{\varphi}(gN)$ lies in the image of $\overline{\varphi}$. Hence $\overline{\varphi}$ maps onto $\operatorname{im}\varphi$.

Being a bijective homomorphism, $\overline{\varphi}$ is an isomorphism. □

The content of the theorem is exactly the factorization of φ through the natural projection $\pi : G \to G/N$, $\pi(g) = gN$. The triangle below commutes ($\overline{\varphi} \circ \pi = \varphi$), π is surjective, and the induced map $\overline{\varphi}$ is an isomorphism onto the image:

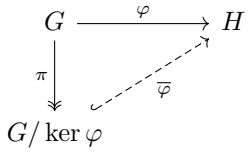


Diagram explanation. Objects: Three objects: the group G (upper-left), the group H (upper-right), and the quotient group $G/\ker\varphi$ (lower-left). $G/\ker\varphi$ is the set of cosets of the normal subgroup $\ker\varphi$ in G, itself a group under coset multiplication.

Arrows: (1) $\varphi : G \to H$, the given homomorphism. (2) $\pi : G \to G/\ker\varphi$, the natural projection $\pi(g) = g\ker\varphi$; it is surjective (double-head arrow) because every coset has a representative. (3) $\overline{\varphi} : G/\ker\varphi \to \operatorname{im}\varphi \subseteq H$, the induced map $\overline{\varphi}(g\ker\varphi) = \varphi(g)$; drawn dashed to signal it is *constructed* by the theorem, not given, and hooked because it is injective (an isomorphism onto $\operatorname{im}\varphi$).

What commutes: The triangle commutes: $\overline{\varphi} \circ \pi = \varphi$. In other words, going $G \xrightarrow{\pi} G/\ker\varphi \xrightarrow{\overline{\varphi}} \operatorname{im}\varphi$ gives the same result as going $G \xrightarrow{\varphi} \operatorname{im}\varphi$ directly.

Why it commutes: Take any $g \in G$. Along π then $\overline{\varphi}$: $g \mapsto g\ker\varphi \mapsto \varphi(g)$. Along φ directly: $g \mapsto \varphi(g)$. Both paths give $\varphi(g)$, so the triangle commutes. Well-definedness of $\overline{\varphi}$ is the key subtlety: if $g_1\ker\varphi = g_2\ker\varphi$ then $g_2^{-1}g_1 \in \ker\varphi$, so $\varphi(g_1) = \varphi(g_2)$, confirming the output depends only on the coset, not the representative.

Why this matters here: This diagram is the geometric content of the First Isomorphism Theorem. It says every homomorphism φ factors as surjection-onto-quotient followed by an isomorphism onto $\operatorname{im}\varphi$; the quotient $G/\ker\varphi$ is the universal way to make φ injective.

Concrete example: Let $\varphi : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$, $\varphi(a) = \overline{a}$. Then $\ker\varphi = 6\mathbb{Z}$, $\pi(a) = a + 6\mathbb{Z}$, and $\overline{\varphi}(a + 6\mathbb{Z}) = \overline{a}$. The triangle: $8 \mapsto 8 + 6\mathbb{Z} \mapsto \overline{8} = \overline{2}$, same as $\varphi(8) = \overline{2}$.

Common pitfall: The dashed arrow lands in $\operatorname{im}\varphi$, not all of H. Writing $G/\ker\varphi \cong H$ is wrong unless φ is surjective. Also, do not confuse $\overline{\varphi}$ (the induced isomorphism onto the image) with φ (the original map into the larger H).

Takeaway: The point of this diagram is that every homomorphism $\varphi : G \to H$ factors uniquely through the quotient by its own kernel, and the resulting induced map is an isomorphism onto the image.

Equivalently, φ splits as a surjection onto its image followed by an inclusion, which is the meaning of the short exact sequence

$$1 \longrightarrow \ker\varphi \hookrightarrow G \xrightarrow{\varphi} \operatorname{im}\varphi \longrightarrow 1.$$

Diagram explanation. Objects: Five nodes, left to right: the trivial group 1; the subgroup $\ker\varphi \leq G$; the group G; the subgroup $\operatorname{im}\varphi \leq H$; and a second trivial group 1. The trivial groups serve as left and right terminators forcing injectivity and surjectivity of the flanking maps.

Arrows: (1) $1 \to \ker\varphi$: the unique map from the trivial group (sends 1_1 to $1_{\ker\varphi}$). (2) $\ker\varphi \hookrightarrow G$: the inclusion (hook arrow), injective by definition. (3) $G \twoheadrightarrow \operatorname{im}\varphi$: the map φ with codomain restricted to $\operatorname{im}\varphi$, surjective by definition of image (double-head arrow). (4) $\operatorname{im}\varphi \to 1$: the unique map to the trivial group.

What commutes: The sequence is *exact*: at $\ker\varphi$, $\operatorname{im}(1 \to \ker\varphi) = \{1\} = \ker(\ker\varphi \hookrightarrow G)$, i.e. the inclusion is injective; at G, $\operatorname{im}(\ker\varphi \hookrightarrow G) = \ker\varphi = \ker(\varphi)$; at $\operatorname{im}\varphi$, $\operatorname{im}(\varphi) = \operatorname{im}\varphi = \ker(\operatorname{im}\varphi \to 1)$ (the whole group maps to zero), i.e. φ is surjective onto $\operatorname{im}\varphi$.

Why it commutes: Exactness at G is the substance: the image of the inclusion is $\ker\varphi$, and the kernel of φ (restricted to image) is exactly $\ker\varphi$. These coincide by definition of kernel. The other exactness conditions are tautological from injectivity and surjectivity.

Why this matters here: This sequence packages the First Isomorphism Theorem into a single line. The phrase "φ splits as surjection onto image followed by inclusion" becomes the two-arrow sequence; the theorem then identifies the quotient $G/\ker\varphi \cong \operatorname{im}\varphi$.

Concrete example: Take $\varphi : \mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$, $\varphi(a) = \overline{a}$. The sequence is $1 \to 4\mathbb{Z} \hookrightarrow \mathbb{Z} \twoheadrightarrow \mathbb{Z}/4\mathbb{Z} \to 1$. Exactness at $\mathbb{Z}$: $\ker\varphi = 4\mathbb{Z} = \operatorname{im}(\text{inclusion})$.

Common pitfall: The arrow from G is labelled φ but its codomain here is $\operatorname{im}\varphi$, not all of H. Writing the sequence as $1 \to \ker\varphi \to G \xrightarrow{\varphi} H \to 1$ is wrong unless φ is surjective onto H; always use $\operatorname{im}\varphi$ as the right-hand term.

Takeaway: The point of this diagram is that the short exact sequence $1 \to \ker\varphi \to G \to \operatorname{im}\varphi \to 1$ is exactly the First Isomorphism Theorem stated in the language of exactness: injectivity on the left, surjectivity on the right, and ker = im in the middle.

Exactness at $\ker\varphi$ says the inclusion is injective; exactness at G says $\operatorname{im}(\ker\varphi \hookrightarrow G) = \ker\varphi$; exactness at $\operatorname{im}\varphi$ says φ is onto its image.

Remark 3.3.1. Two reformulations worth memorizing. (1) *Counting:* if G is finite then $|\operatorname{im}\varphi| = |G/\ker\varphi| = [G : \ker\varphi] = |G|/|\ker\varphi|$; so $|\operatorname{im}\varphi|$ divides $|G|$, and also $|H|$ when H is finite. (2) *Size of fibers:* every nonempty fiber $\varphi^{-1}(\{h\})$ is a coset of $\ker\varphi$, hence has exactly $|\ker\varphi|$ elements.

Proposition 3.3.2 (Universal property of the quotient)**.** *Let $N \trianglelefteq G$ and let $\pi : G \to G/N$ be the natural projection. If $\psi : G \to K$ is any homomorphism with $N \subseteq \ker\psi$, then there is a* unique *homomorphism $\overline{\psi} : G/N \to K$ with $\overline{\psi} \circ \pi = \psi$, namely $\overline{\psi}(gN) = \psi(g)$. Moreover $\ker\overline{\psi} = \ker\psi/N$ and $\operatorname{im}\overline{\psi} = \operatorname{im}\psi$, so $\overline{\psi}$ is injective iff $N = \ker\psi$.*

Proof. **Existence/well-defined.** If $g_1N = g_2N$ then $g_2^{-1}g_1 \in N \subseteq \ker\psi$, so $\psi(g_1) = \psi(g_2)$; thus $\overline{\psi}(gN) = \psi(g)$ is unambiguous. It is a homomorphism by the same computation as before: $\overline{\psi}(g_1N\, g_2N) = \psi(g_1g_2) = \psi(g_1)\psi(g_2)$. By construction $\overline{\psi}(\pi(g)) = \overline{\psi}(gN) = \psi(g)$.

Uniqueness. If $\theta : G/N \to K$ also satisfies $\theta \circ \pi = \psi$, then for every g, $\theta(gN) = \theta(\pi(g)) = \psi(g) = \overline{\psi}(gN)$. Since the cosets gN exhaust G/N, $\theta = \overline{\psi}$.

Kernel/image. $gN \in \ker\overline{\psi} \iff \psi(g) = 1 \iff g \in \ker\psi$, so $\ker\overline{\psi} = \{gN : g \in \ker\psi\} = \ker\psi/N$ (this is a subgroup of G/N because $N \subseteq \ker\psi$). And $\operatorname{im}\overline{\psi} = \{\psi(g) : g \in G\} = \operatorname{im}\psi$. Injectivity is equivalent to $\ker\overline{\psi}$ trivial, i.e. $\ker\psi = N$. □

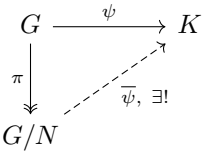

Diagram explanation. Objects: Three objects: the group G (upper-left); an arbitrary target group K (upper-right); and the quotient group G/N (lower-left), where $N \trianglelefteq G$ is a fixed normal subgroup not necessarily equal to $\ker\psi$.

Arrows: (1) $\psi : G \to K$, any homomorphism satisfying $N \subseteq \ker\psi$. (2) $\pi : G \to G/N$, the canonical surjection $\pi(g) = gN$ (double-head). (3) $\overline{\psi} : G/N \to K$, the unique induced homomorphism $\overline{\psi}(gN) = \psi(g)$ (dashed, labelled $\exists!$ to emphasize both existence and uniqueness).

What commutes: $\overline{\psi} \circ \pi = \psi$: going $G \xrightarrow{\pi} G/N \xrightarrow{\overline{\psi}} K$ equals going $G \xrightarrow{\psi} K$ directly. Uniqueness: any $\theta : G/N \to K$ with $\theta \circ \pi = \psi$ must satisfy $\theta(gN) = \psi(g) = \overline{\psi}(gN)$ for all g, so $\theta = \overline{\psi}$.

Why it commutes: For any $g \in G$: via π then $\overline{\psi}$, $g \mapsto gN \mapsto \psi(g)$; via ψ directly, $g \mapsto \psi(g)$. Both give $\psi(g)$. Well-definedness requires $N \subseteq \ker\psi$: if $g_1N = g_2N$ then $g_2^{-1}g_1 \in N \subseteq \ker\psi$, so $\psi(g_1) = \psi(g_2)$. Without this containment $\overline{\psi}$ would not be a function.

Why this matters here: This is the universal property of the quotient G/N: it converts any ψ that kills N into a unique factored map through G/N. The First Isomorphism Theorem is the special case $N = \ker\psi$, making $\overline{\psi}$ an isomorphism onto $\operatorname{im}\psi$.

Concrete example: Let $G = \mathbb{Z}$, $N = 6\mathbb{Z}$, $K = \mathbb{Z}/2\mathbb{Z}$, $\psi(a) = \overline{a} \bmod 2$. Since $6\mathbb{Z} \subseteq 2\mathbb{Z} = \ker\psi$, the induced $\overline{\psi} : \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ sends $a + 6\mathbb{Z} \mapsto a \bmod 2$. Check: $\overline{\psi}(4 + 6\mathbb{Z}) = 0$, same as $\psi(4) = 0$.

Common pitfall: The condition $N \subseteq \ker\psi$ is essential and must be verified before constructing $\overline{\psi}$. Assuming any $N \trianglelefteq G$ automatically gives an induced map to any target is wrong; the map is only well-defined when N is killed by ψ.

Takeaway: The point of this diagram is that G/N is the universal quotient through which any homomorphism killing N factors uniquely, a property that in the extremal case $N = \ker\psi$ immediately yields the First Isomorphism Theorem.

Remark 3.3.2. The First Isomorphism Theorem is the special case $K = \operatorname{im}\varphi$, $\psi = \varphi$ (codomain restricted to the image) and $N = \ker\varphi$: then $N = \ker\psi$, so the induced map is not only unique but an *isomorphism*. In this sense the universal property is the engine and the isomorphism theorem is its sharpest consequence.

Method (First Isomorphism Theorem strategy: identifying a quotient G/N)**.** *Trigger.* You are asked "what is G/N?" or asked to prove $G/N \cong Q$ for a known group Q, with $N \trianglelefteq G$.

1. **Build a surjection.** Produce a homomorphism $\varphi : G \to Q$ that is *onto*. (Often φ is the "obvious natural map": a determinant, a sign, a reduction mod n, a conjugation action, evaluation, etc.)
2. **Compute the kernel.** Show $\ker\varphi = N$ *exactly* — prove both $\ker\varphi \subseteq N$ and $N \subseteq \ker\varphi$.
3. *Conclude.* The theorem gives $G/N = G/\ker\varphi \cong \operatorname{im}\varphi = Q$, the last equality because φ is onto.

Counting shortcut (finite case). If you only need $|G/N|$, surjectivity plus $|G/N| = |G|/|N|$ suffices; to *name* the group you usually still need the explicit map. **Reverse use.** Given a target Q and a desired kernel N, you may instead build Q as G/N first, then exhibit the isomorphism — but the forward direction (find a surjection with kernel N) is almost always faster.

Caution. The map $gN \mapsto \varphi(g)$ lands in $\operatorname{im}\varphi$, *not necessarily in all of* H. The induced map $G/\ker\varphi \to H$ is an isomorphism only when φ is surjective. Writing "$G/\ker\varphi \cong H$" for a non-surjective φ is the single most common error. Always check onto, or write $\operatorname{im}\varphi$.

Caution. "$\ker\varphi = N$" requires *both* inclusions. A map can certainly kill every element of N (so $N \subseteq \ker\varphi$) while killing more (so $\ker\varphi \supsetneq N$); then $G/N \ncong \operatorname{im}\varphi$ in general. For example $\varphi : \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ reduction mod 2 kills $2\mathbb{Z}$ (and in particular $4\mathbb{Z} \subseteq \ker\varphi$), but $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z}$ because $\ker\varphi = 2\mathbb{Z} \supsetneq 4\mathbb{Z}$: one must verify $\ker\varphi$ equals the intended $N = 4\mathbb{Z}$, not merely contains it.

Worked Example 3.3.3 ($\mathrm{GL}_n(F)/\mathrm{SL}_n(F) \cong F^\times$ via the determinant)**.** Let F be a field and $n \geq 1$. Show $\mathrm{GL}_n(F)/\mathrm{SL}_n(F) \cong F^\times$ (the multiplicative group of nonzero scalars).

Recognition. First Isomorphism Theorem strategy: the determinant gives the canonical surjection $\mathrm{GL}_n(F) \to F^\times$, and $\mathrm{SL}_n(F)$ is by definition its kernel.

Solution. **Map.** Define $\det : \mathrm{GL}_n(F) \to F^\times$. This is a homomorphism because $\det(AB) = \det A \det B$, and it lands in $F^\times$ since invertible matrices have nonzero determinant.

Surjective. For any $c \in F^\times$, the diagonal matrix $D = \mathrm{diag}(c, 1, \ldots, 1)$ is invertible with $\det D = c$. So det is onto.

Kernel. By definition $\mathrm{SL}_n(F) = \{A : \det A = 1\} = \ker \det$.

Conclude. The theorem gives $\mathrm{GL}_n(F)/\mathrm{SL}_n(F) = \mathrm{GL}_n(F)/\ker\det \cong \mathrm{im}\det = F^\times$.

Check. Take $F = \mathbb{Z}/5\mathbb{Z}$ (a field, 5 prime) and $n = 2$. Then $F^\times$ has order 4. Indeed $|\mathrm{GL}_2(\mathbb{Z}/5\mathbb{Z})| = (5^2-1)(5^2-5) = 24 \cdot 20 = 480$ and $|\mathrm{SL}_2(\mathbb{Z}/5\mathbb{Z})| = 480/(5-1) = 480/4 = 120$, so the quotient has order $480/120 = 4 = |F^\times|$. Consistent.

Worked Example 3.3.4 ($S_n/A_n \cong \mathbb{Z}/2\mathbb{Z}$ via the sign)**.** For $n \geq 2$, show $S_n/A_n \cong \mathbb{Z}/2\mathbb{Z}$.

Recognition. First Isomorphism Theorem strategy: sgn is the natural surjection onto $\{\pm 1\}$, and A_n is by definition its kernel.

Solution. **Map.** The sign homomorphism $\mathrm{sgn} : S_n \to \{\pm 1\}$ satisfies $\mathrm{sgn}(\sigma\tau) = \mathrm{sgn}(\sigma)\,\mathrm{sgn}(\tau)$. Identify $\{\pm 1\}$ (multiplicative) with $\mathbb{Z}/2\mathbb{Z}$ (additive) via $+1 \mapsto 0,\ -1 \mapsto 1$; this is a group isomorphism.

Surjective. For $n \geq 2$ the transposition $(1\,2)$ is odd, $\mathrm{sgn}(1\,2) = -1$, and the identity is even, $\mathrm{sgn}(e) = +1$. So both values ± 1 are attained; sgn is onto.

Kernel. By definition $A_n = \{\sigma : \mathrm{sgn}\,\sigma = +1\} = \ker(\mathrm{sgn})$.

Conclude. $S_n/A_n = S_n/\ker(\mathrm{sgn}) \cong \mathrm{im}(\mathrm{sgn}) = \{\pm 1\} \cong \mathbb{Z}/2\mathbb{Z}$.

Check. For finite n, $|S_n/A_n| = n!/(n!/2) = 2 = |\mathbb{Z}/2\mathbb{Z}|$, and there is only one group of order 2, so the identification is forced even before naming the map. (Recall a k-cycle is a product of $k-1$ transpositions, hence even iff k is odd, which is why sgn is the right invariant.) Consistent.

Worked Example 3.3.5 ($\mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/n\mathbb{Z}$ via reduction mod n)**.** Fix $n \geq 1$. Recover the familiar $\mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/n\mathbb{Z}$ from the theorem.

Recognition. First Isomorphism Theorem strategy: reduction mod n is a surjection $\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ whose kernel is exactly $n\mathbb{Z}$.

Solution. **Map.** Let $\varphi : \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$, $\varphi(a) = a \bmod n = \overline{a}$. Then $\varphi(a+b) = \overline{a+b} = \overline{a} + \overline{b} = \varphi(a) + \varphi(b)$, a homomorphism of additive groups.

Surjective. The residues $\overline{0}, \overline{1}, \ldots, \overline{n-1}$ are all hit by $0, 1, \ldots, n-1$, so $\mathrm{im}\,\varphi = \mathbb{Z}/n\mathbb{Z}$.

Kernel. $\varphi(a) = \overline{0} \iff n \mid a \iff a \in n\mathbb{Z}$. Hence $\ker\varphi = n\mathbb{Z}$.

Conclude. $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/\ker\varphi \cong \mathrm{im}\,\varphi = \mathbb{Z}/n\mathbb{Z}$. The induced isomorphism is $\overline{\varphi}(a + n\mathbb{Z}) = \overline{a}$, sending the coset $a + n\mathbb{Z}$ to the residue class of a.

Check. $n = 6$: the coset $8 + 6\mathbb{Z} = 2 + 6\mathbb{Z}$ maps to $\overline{8} = \overline{2}$. Well-defined, since $8 \equiv 2 \pmod 6$. The quotient has 6 cosets, matching $|\mathbb{Z}/6\mathbb{Z}| = 6$. Consistent.

Worked Example 3.3.6 ($G/Z(G) \cong \mathrm{Inn}(G)$)**.** For any group G, show $G/Z(G) \cong \mathrm{Inn}(G)$, the group of inner automorphisms.

Recognition. First Isomorphism Theorem strategy: conjugation defines a homomorphism $G \to \mathrm{Aut}(G)$ landing onto $\mathrm{Inn}(G)$, with kernel the center $Z(G)$.

Solution. **Map.** For $g \in G$ let $\psi_g : G \to G$, $\psi_g(x) = gxg^{-1}$. Each $\psi_g \in \mathrm{Aut}(G)$, and define $\Psi : G \to \mathrm{Aut}(G)$, $\Psi(g) = \psi_g$. It is a homomorphism: for all x,

$$(\psi_g \circ \psi_h)(x) = g(hxh^{-1})g^{-1} = (gh)x(gh)^{-1} = \psi_{gh}(x),$$

so $\Psi(g)\Psi(h) = \psi_{gh} = \Psi(gh)$.

Image. By definition $\mathrm{Inn}(G) = \{\psi_g : g \in G\} = \mathrm{im}\,\Psi$, so Ψ is onto $\mathrm{Inn}(G)$ (restrict the codomain to $\mathrm{Inn}(G)$, automatically surjective).

Kernel. $g \in \ker\Psi \iff \psi_g = \mathrm{id}_G \iff gxg^{-1} = x\ \forall x \iff gx = xg\ \forall x \iff g \in Z(G)$. Hence $\ker\Psi = Z(G)$.

Conclude. $G/Z(G) = G/\ker\Psi \cong \operatorname{im}\Psi = \operatorname{Inn}(G)$.

Check. $G = D_8$ (with $r^4 = s^2 = 1,\ sr = r^{-1}s$): here $Z(D_8) = \{1, r^2\}$ has order 2, so $|G/Z(G)| = 8/2 = 4$, forcing $|\operatorname{Inn}(D_8)| = 4$ — indeed $\operatorname{Inn}(D_8) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. For an abelian G, $Z(G) = G$, so $G/Z(G)$ is trivial and $\operatorname{Inn}(G) = \{\mathrm{id}\}$: abelian groups have no nontrivial inner automorphisms. Both consistent.

Worked Example 3.3.7 ($\mathbb{C}^\times/\{|z| = 1\} \cong \mathbb{R}_{>0}$ via the modulus)**.** Let $\mathbb{C}^\times$ be the nonzero complex numbers under multiplication and let $S^1 = \{z \in \mathbb{C} : |z| = 1\}$ be the unit circle. Show $\mathbb{C}^\times/S^1 \cong \mathbb{R}_{>0}$, the positive reals under multiplication.

Recognition. First Isomorphism Theorem strategy: the modulus is a multiplicative surjection $\mathbb{C}^\times \to \mathbb{R}_{>0}$ whose kernel is exactly the unit circle.

Solution. **Map.** Define $\mu : \mathbb{C}^\times \to \mathbb{R}_{>0}$, $\mu(z) = |z|$. Then $\mu(zw) = |zw| = |z||w| = \mu(z)\mu(w)$, and $|z| > 0$ for $z \neq 0$, so μ is a homomorphism into $\mathbb{R}_{>0}$.

Surjective. For $r \in \mathbb{R}_{>0}$, the real number r itself is a nonzero complex number with $\mu(r) = |r| = r$. So μ is onto.

Kernel. $\mu(z) = 1 \iff |z| = 1 \iff z \in S^1$. Hence $\ker\mu = S^1$, which is therefore a normal subgroup of $\mathbb{C}^\times$ (as a kernel; also automatic since $\mathbb{C}^\times$ is abelian).

Conclude. $\mathbb{C}^\times/S^1 = \mathbb{C}^\times/\ker\mu \cong \operatorname{im}\mu = \mathbb{R}_{>0}$.

Check. The coset of z is determined by $|z|$ alone; e.g. $2i$ and 2 lie in the same coset because $|2i| = |2| = 2$, and indeed $2i = 2 \cdot i$ with $i \in S^1$. Geometrically the cosets are the circles centered at the origin, parametrized by their radius in $\mathbb{R}_{>0}$. Consistent.

Worked Example 3.3.8 (Building a surjection with a prescribed kernel)**.** Inside $G = \mathbb{Z} \times \mathbb{Z}$, identify the quotient G/N where $N = \langle(1,1)\rangle = \{(k,k) : k \in \mathbb{Z}\}$.

Recognition. Reverse use of the strategy: we are handed N and must *construct* a surjection $\varphi : \mathbb{Z} \times \mathbb{Z} \to Q$ with $\ker\varphi = N$, then read off Q.

Solution. **Construct the map.** The elements of N satisfy "second coordinate = first coordinate," i.e. $a - b = 0$. This suggests $\varphi : \mathbb{Z} \times \mathbb{Z} \to \mathbb{Z}$, $\varphi(a,b) = a - b$. It is a homomorphism:

$$\varphi\big((a,b) + (c,d)\big) = \varphi(a+c,\, b+d) = (a+c) - (b+d) = (a-b) + (c-d) = \varphi(a,b) + \varphi(c,d).$$

Surjective. For any $m \in \mathbb{Z}$, $\varphi(m,0) = m - 0 = m$, so $\operatorname{im}\varphi = \mathbb{Z}$.

Kernel. $\varphi(a,b) = 0 \iff a - b = 0 \iff a = b \iff (a,b) = (b,b) \in N$. So $\ker\varphi = N = \langle(1,1)\rangle$, exactly as required.

Conclude. $G/N = (\mathbb{Z} \times \mathbb{Z})/\langle(1,1)\rangle \cong \operatorname{im}\varphi = \mathbb{Z}$. The induced isomorphism sends the coset $(a,b) + N$ to the integer $a - b$.

Check. $(3,5)$ and $(0,2)$ differ by $(3,3) \in N$, so they are in the same coset; and indeed $\varphi(3,5) = -2 = \varphi(0,2)$. The map is constant on cosets and distinguishes different ones, confirming the bijection $G/N \leftrightarrow \mathbb{Z}$. Consistent.

Remark 3.3.3 (The exact-sequence picture, revisited). Each example above is one instance of a single short exact sequence $1 \to N \to G \xrightarrow{\varphi} Q \to 1$. Reading the four maps in order:

$$1 \longrightarrow \mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F) \xrightarrow{\det} F^\times \longrightarrow 1$$

Diagram explanation. Objects: Five nodes: trivial group 1; the special linear group $\mathrm{SL}_n(F) = \{A \in \mathrm{GL}_n(F) : \det A = 1\}$ (the kernel); the general linear group $\mathrm{GL}_n(F)$ of invertible $n \times n$ matrices over the field F; the multiplicative group $F^\times$ of nonzero scalars (the image); and a trivial group 1 on the right.

Arrows: (1) $1 \to \mathrm{SL}_n(F)$: trivial inclusion. (2) $\mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F)$: inclusion of matrices (hook arrow, injective). (3) $\det : \mathrm{GL}_n(F) \twoheadrightarrow F^\times$: the determinant map $A \mapsto \det A$, a group homomorphism since $\det(AB) = \det A \det B$, surjective because $\mathrm{diag}(c, 1, \ldots, 1)$ has determinant c for any $c \in F^\times$. (4) $F^\times \to 1$: trivial map.

What commutes: Exactness: at $\mathrm{SL}_n(F)$, $\operatorname{im}(1 \to \mathrm{SL}_n(F)) = \{I\} = \ker(\mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F))$ (inclusion is injective); at $\mathrm{GL}_n(F)$, $\operatorname{im}(\mathrm{SL}_n(F) \hookrightarrow \mathrm{GL}_n(F)) = \mathrm{SL}_n(F) = \ker\det$ (matrices of determinant 1 are exactly those killed by det); at $F^\times$, $\operatorname{im}(\det) = F^\times = \ker(F^\times \to 1)$.

Why it commutes: Exactness at $\mathrm{GL}_n(F)$ is the key claim: $\ker\det = \mathrm{SL}_n(F)$ is true by definition. The surjectivity of det was shown in the worked example ($\mathrm{diag}(c, 1, \ldots, 1)$ has any prescribed nonzero determinant).

Why this matters here: This sequence summarizes the worked example $\mathrm{GL}_n(F)/\mathrm{SL}_n(F) \cong F^\times$ in a single line. Reading it: $\mathrm{SL}_n(F)$ is the kernel, det is the surjection, $F^\times$ is the quotient — this is the standard short exact sequence for the determinant.

Concrete example: $n = 1$, $F = \mathbb{R}$: $\mathrm{SL}_1(\mathbb{R}) = \{1\}$, $\mathrm{GL}_1(\mathbb{R}) = \mathbb{R}^\times$, det = id, sequence becomes $1 \to \{1\} \to \mathbb{R}^\times \xrightarrow{\mathrm{id}} \mathbb{R}^\times \to 1$, trivially exact. For $n = 2$, $F = \mathbb{Z}/5\mathbb{Z}$: kernel has $|\mathrm{GL}_2(\mathbb{Z}/5\mathbb{Z})|/(|\mathbb{Z}/5\mathbb{Z}| - 1) = 480/4 = 120$ elements, consistent with $|\mathrm{SL}_2(\mathbb{Z}/5\mathbb{Z})| = 120$.

Common pitfall: Students may read the hook arrow as an isomorphism. $\mathrm{SL}_n(F)$ is a proper subgroup of $\mathrm{GL}_n(F)$ (for $n \geq 1$ and $|F| > 2$; over $\mathbb{F}_2$ the two groups coincide); the sequence says only that the inclusion is injective (exact on the left), not that it is surjective.

Takeaway: The point of this diagram is that the short exact sequence $1 \to \mathrm{SL}_n(F) \to \mathrm{GL}_n(F) \xrightarrow{\det} F^\times \to 1$ encodes in one line that $\mathrm{SL}_n(F)$ is the entire kernel of det and det is surjective onto $F^\times$.

$$1 \longrightarrow A_n \hookrightarrow S_n \xrightarrow{\text{sgn}} \mathbb{Z}/2\mathbb{Z} \longrightarrow 1$$

Diagram explanation. Objects: Five nodes: trivial group 1; the alternating group $A_n = \ker(\text{sgn})$, consisting of all even permutations (a normal subgroup of S_n of index 2); the symmetric group S_n of all permutations of $\{1, \ldots, n\}$; the group $\mathbb{Z}/2\mathbb{Z} = \{0, 1\}$ under addition (or equivalently $\{\pm 1\}$ under multiplication, the target of the sign); and trivial 1.

Arrows: (1) $1 \to A_n$: trivial map. (2) $A_n \hookrightarrow S_n$: inclusion (injective). (3) $\text{sgn} : S_n \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$: the sign homomorphism $\sigma \mapsto \text{sgn}(\sigma)$, surjective for $n \geq 2$ because a transposition is odd and the identity is even. (4) $\mathbb{Z}/2\mathbb{Z} \to 1$: trivial map.

What commutes: Exactness: at A_n, inclusion is injective ($\ker(\iota) = \{e\}$); at S_n, $\mathrm{im}(A_n \hookrightarrow S_n) = A_n = \ker(\text{sgn})$ (exactly the even permutations are killed); at $\mathbb{Z}/2\mathbb{Z}$, $\mathrm{im}(\text{sgn}) = \mathbb{Z}/2\mathbb{Z} = \ker(\mathbb{Z}/2\mathbb{Z} \to 1)$ (surjectivity of sgn).

Why it commutes: Exactness at S_n uses the definition $A_n = \ker(\text{sgn})$ and injectivity of the inclusion. Surjectivity uses the fact that for $n \geq 2$ there is a transposition (odd) and the identity (even), so both values of sgn are realized.

Why this matters here: This sequence packages the result $S_n/A_n \cong \mathbb{Z}/2\mathbb{Z}$ (the second worked example of this section) into short exact sequence notation, illustrating the general template $1 \to N \to G \xrightarrow{\varphi} Q \to 1$ where $N = \ker\varphi$ and φ is onto.

Concrete example: $n = 3$: $|S_3| = 6$, $|A_3| = 3$ (the rotations of a triangle: $e, (123), (132)$). The sequence $1 \to A_3 \hookrightarrow S_3 \xrightarrow{\text{sgn}} \mathbb{Z}/2\mathbb{Z} \to 1$ is exact: $\ker(\text{sgn})$ contains exactly the three even permutations, which are A_3.

Common pitfall: Confusing A_n (even permutations, kernel of sgn) with the image of sgn (which is $\mathbb{Z}/2\mathbb{Z}$). The hook arrow shows A_n is the kernel, at the *left*; the double-head arrow shows $\mathbb{Z}/2\mathbb{Z}$ is the image, at the *right*.

Takeaway: The point of this diagram is that the short exact sequence $1 \to A_n \to S_n \xrightarrow{\text{sgn}} \mathbb{Z}/2\mathbb{Z} \to 1$ is a compact record that A_n is the full kernel of the sign and that the sign is surjective, so $S_n/A_n \cong \mathbb{Z}/2\mathbb{Z}$.

$$1 \longrightarrow Z(G) \hookrightarrow G \xrightarrow{\Psi} \mathrm{Inn}(G) \longrightarrow 1$$

Diagram explanation. Objects: Five nodes: trivial group 1; the center $Z(G) = \{z \in G : zg = gz \ \forall g \in G\}$ (a normal subgroup of G, the kernel of conjugation); the group G; the inner automorphism group $\mathrm{Inn}(G) = \{\psi_g : g \in G\}$ where $\psi_g(x) = gxg^{-1}$; and trivial 1.

Arrows: (1) $1 \to Z(G)$: trivial. (2) $Z(G) \hookrightarrow G$: inclusion (injective). (3) $\Psi : G \twoheadrightarrow \mathrm{Inn}(G)$: the conjugation homomorphism $\Psi(g) = \psi_g$, surjective by definition (every inner automorphism is some ψ_g). (4) $\mathrm{Inn}(G) \to 1$: trivial.

What commutes: Exactness: at $Z(G)$, inclusion is injective; at G, $\mathrm{im}(Z(G) \hookrightarrow G) = Z(G) = \ker\Psi$ (since $\Psi(g) = \mathrm{id} \iff gxg^{-1} = x \ \forall x \iff g \in Z(G)$); at $\mathrm{Inn}(G)$, $\mathrm{im}(\Psi) = \mathrm{Inn}(G)$ (surjective by construction).

Why it commutes: Exactness at G is the computation $\ker \Psi = Z(G)$ done in the worked example: g is in the kernel of conjugation iff $\psi_g = \mathrm{id}_G$ iff g commutes with every element of G. The surjectivity of Ψ onto $\mathrm{Inn}(G)$ is built into the definition of $\mathrm{Inn}(G)$.

Why this matters here: This packages the result $G/Z(G) \cong \mathrm{Inn}(G)$ as a short exact sequence, completing the trio of examples. It also highlights: when G is abelian, $Z(G) = G$, so the sequence collapses to $1 \to G \to G \to 1 \to 1$, reflecting $\mathrm{Inn}(G) = \{1\}$.

Concrete example: $G = S_3$: $Z(S_3) = \{e\}$ (the center of S_3 is trivial), so the sequence is $1 \to \{e\} \hookrightarrow S_3 \xrightarrow{\Psi} \mathrm{Inn}(S_3) \to 1$, giving $\mathrm{Inn}(S_3) \cong S_3/\{e\} \cong S_3$. Indeed all automorphisms of S_n for $n \neq 6$ are inner, so $\mathrm{Inn}(S_3) = \mathrm{Aut}(S_3) \cong S_3$.

Common pitfall: Conflating $\mathrm{Aut}(G)$ and $\mathrm{Inn}(G)$. The sequence ends at $\mathrm{Inn}(G)$, not $\mathrm{Aut}(G)$; outer automorphisms (elements of $\mathrm{Aut}(G) \setminus \mathrm{Inn}(G)$) are invisible here. Ψ is a map into $\mathrm{Aut}(G)$ but surjects only onto the inner subgroup $\mathrm{Inn}(G)$.

Takeaway: The point of this diagram is that the short exact sequence $1 \to Z(G) \to G \xrightarrow{\Psi} \mathrm{Inn}(G) \to 1$ encodes the isomorphism $G/Z(G) \cong \mathrm{Inn}(G)$, making the center the precise measure of how far conjugation falls short of being faithful.

In every case the middle quotient G/N is forced to be the group on the right by the First Isomorphism Theorem; the sequence is just shorthand for "$N = \ker$ and φ is onto."

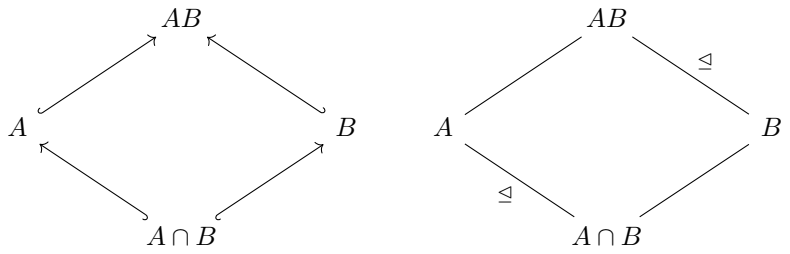
The second, third, and fourth isomorphism theorems

The First Isomorphism Theorem (§3.3) says every homomorphism factors through its kernel: if $\varphi\colon G \to H$ is a homomorphism then $G/\ker\varphi \cong \mathrm{im}\,\varphi$. The three remaining isomorphism theorems are all *consequences* of the first; each is obtained by writing down a cleverly chosen surjection and computing its kernel. We treat them in order, then close with the lattice (Fourth) theorem, which organizes the whole subgroup structure of a quotient.

Throughout, recall the workhorse fact (D&F §3.1): a subgroup $N \leq G$ is normal iff it is the kernel of some homomorphism, and the canonical projection $\pi\colon G \to G/N$, $\pi(g) = gN$, is a surjective homomorphism with $\ker\pi = N$.

The second (diamond) isomorphism theorem

Theorem 3.3.9 (Second Isomorphism Theorem)**.** *Let G be a group, let $A \leq G$ and $B \leq G$, and suppose $A \leq N_G(B)$ (i.e. A normalizes B). Then:*



(1) $AB \leq G$;

(2) $B \trianglelefteq AB$;

(3) $A \cap B \trianglelefteq A$; and

(4) $AB/B \cong A/(A \cap B)$.

The picture is a "diamond" of subgroups: AB on top, A and B in the middle, and $A \cap B$ at the bottom. The theorem says the two slanted edges $A \cap B \leq A$ and $B \leq AB$ carry isomorphic quotients.

On the right, the two edges marked $\trianglelefteq$ are the normal ones, and the two quotients AB/B and $A/(A \cap B)$ along those edges are isomorphic.

Proof. The hypothesis $A \le N_G(B)$ means $aBa^{-1} = B$ for all $a \in A$; also $B \le N_G(B)$ trivially. Hence both A and B lie in the subgroup $N_G(B)$, so the product set AB lies inside $N_G(B)$.

(1) AB is a subgroup. In general $AB \le G$ iff $AB = BA$ (D&F Prop. 3.2.14). Since A normalizes B, for $a \in A$ we have $aB = (aBa^{-1})a = Ba$, so $AB = \bigcup_{a\in A} aB = \bigcup_{a\in A} Ba = BA$. Thus $AB = BA$ and $AB \le G$. (Equivalently: $AB \le N_G(B)$ since $B \trianglelefteq N_G(B)$ and any subgroup-times-normal-subgroup product is a subgroup.)

(2) Inside $N_G(B)$ the subgroup B is normal, and $AB \le N_G(B)$, so $B \trianglelefteq AB$. Concretely, for $ab \in AB$ we have $(ab)B(ab)^{-1} = a(bBb^{-1})a^{-1} = aBa^{-1} = B$.

(3),(4) Define $\varphi\colon A \to AB/B$ by $\varphi(a) = aB$, the restriction to A of the canonical projection $\pi\colon AB \to AB/B$. It is a homomorphism (restriction of one). It is *surjective*: a typical coset is $(ab)B = a(bB) = aB = \varphi(a)$ since $bB = B$. Its kernel is $\ker\varphi = \{a \in A : aB = B\} = \{a \in A : a \in B\} = A \cap B$. Being a kernel, $A \cap B \trianglelefteq A$, proving (3). The First Isomorphism Theorem applied to φ gives $A/(A \cap B) = A/\ker\varphi \cong \operatorname{im}\varphi = AB/B$, proving (4). □

The proof is exactly the diagram below: φ is the horizontal restriction, π is the projection from A, and the induced map $\overline{\varphi}$ closes the triangle.

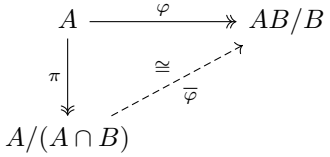


Diagram explanation. Objects: Three groups appear. A is a subgroup of G (top left). AB/B is the quotient of the product subgroup AB by B (top right); its elements are cosets $abB = aB$. $A/(A \cap B)$ is the quotient of A by its normal subgroup $A \cap B$ (bottom left); its elements are cosets $a(A \cap B)$.

Arrows: $\varphi\colon A \to AB/B$ sends $a \mapsto aB$; it is the restriction to A of the canonical projection $\pi_{AB}\colon AB \to AB/B$, hence a homomorphism. $\pi\colon A \twoheadrightarrow A/(A\cap B)$ is the canonical surjective projection, sending $a \mapsto a(A\cap B)$. $\overline{\varphi}\colon A/(A \cap B) \to AB/B$ is the map induced by φ through the First Isomorphism Theorem; it sends $a(A \cap B) \mapsto aB$ and is an isomorphism.

What commutes: The triangle commutes: $\overline{\varphi} \circ \pi = \varphi$, i.e. applying π then $\overline{\varphi}$ equals applying φ directly.

Why it commutes: Take $a \in A$. Along φ: $a \mapsto aB$. Along π then $\overline{\varphi}$: $a \mapsto a(A \cap B) \mapsto aB$. Both give aB. Well-definedness of $\overline{\varphi}$: if $a(A \cap B) = a'(A \cap B)$ then $a^{-1}a' \in A \cap B \le B$, so $aB = a'B$; thus the output aB does not depend on the coset representative chosen.

Why this matters here: This is the diagrammatic proof of the Second Isomorphism Theorem. The surjectivity of φ (every aB is hit) and the computation $\ker\varphi = A \cap B$ together force the First Iso Theorem to yield the dashed isomorphism $A/(A \cap B) \cong AB/B$, which is conclusion (4) of the theorem. The diagram collects all three maps into one picture.

Concrete example: In $G = S_4$, $A = \langle(123)\rangle$, $B = V$: $\varphi(a) = aV$ sends each 3-cycle to its V-coset; $\ker\varphi = A \cap V = \{e\}$, so $\overline{\varphi}$ is an isomorphism $A/\{e\} \cong AV/V$, i.e. $\mathbb{Z}/3 \cong A_4/V$.

Common pitfall: Students confuse $\overline{\varphi}$ (the induced map on the quotient) with φ (the original map on A). The dashed arrow does not exist until you verify $A \cap B = \ker\varphi$; do not draw it first and check later.

Takeaway: The point of this diagram is that the Second Isomorphism Theorem is just the First Isomorphism Theorem applied to the restriction $\varphi\colon A \to AB/B$, with $A \cap B$ playing the role of the kernel.

Remark 3.3.4. If $B \trianglelefteq G$ the hypothesis $A \le N_G(B)$ is automatic, because then $N_G(B) = G$. (Normality of A is not enough: $A_3 \trianglelefteq S_3$ does not normalize $B = \langle(1\,2)\rangle$, and B is not normal in $A_3B = S_3$; when $A \trianglelefteq G$, apply the theorem with the roles of A and B exchanged, getting $AB/A \cong B/(A \cap B)$.) In most textbook applications one of A, B is normal in G, so people often quote the theorem as "$A \le G$, $B \trianglelefteq G$ $\implies$ $AB/B \cong A/(A \cap B)$." The full hypothesis only needs $A \le N_G(B)$.

Method (Recognizing and applying the Diamond Theorem)**.** *Trigger.* You have two subgroups A, B of one group G, you want the order or structure of the *join* $AB = \langle A, B\rangle$ (when AB is a subgroup), or you see a quotient of the form AB/B and want to replace it by the smaller $A/(A \cap B)$.

Recipe.

1. Check the hypothesis: is $A \leq N_G(B)$? (Easiest sufficient condition: $B \trianglelefteq G$.)
2. Conclude $AB \leq G$ and $B \trianglelefteq AB$, $A \cap B \trianglelefteq A$.
3. Write the isomorphism $AB/B \cong A/(A \cap B)$.
4. For *orders* (finite case): from the isomorphism, $|AB/B| = |A/(A \cap B)|$, i.e. $\dfrac{|AB|}{|B|} = \dfrac{|A|}{|A \cap B|}$, giving the product formula $|AB| = \dfrac{|A|\,|B|}{|A \cap B|}$.

Worked Example 3.3.10 (A concrete diamond in $\mathbb{Z}/24\mathbb{Z}$)**.** In $G = \mathbb{Z}/24\mathbb{Z}$ let $A = \langle 4 \rangle$ and $B = \langle 6 \rangle$. Identify AB, $A \cap B$, and verify the Diamond Theorem.

Recognition. Second Isomorphism Theorem: G abelian so every subgroup is normal, hypothesis is free; we want the join and meet of two cyclic subgroups and to confirm $AB/B \cong A/(A \cap B)$.

Solution. Write the group additively, $G = \mathbb{Z}/24$. Here $A = \langle 4 \rangle = \{0, 4, 8, 12, 16, 20\}$, so $|A| = 6$; and $B = \langle 6 \rangle = \{0, 6, 12, 18\}$, so $|B| = 4$. The join is $A + B = \langle 4, 6 \rangle = \langle \gcd(4, 6) \rangle = \langle 2 \rangle = \{0, 2, 4, \ldots, 22\}$, $|A + B| = 12$. The meet is $A \cap B = \langle \operatorname{lcm}(4, 6) \rangle = \langle 12 \rangle = \{0, 12\}$, $|A \cap B| = 2$. Now check the isomorphism by orders:

$$|(A + B)/B| = \tfrac{12}{4} = 3, \qquad |A/(A \cap B)| = \tfrac{6}{2} = 3.$$

Both are cyclic of order 3 (every group of order 3 is $\cong \mathbb{Z}/3$), so indeed $(A + B)/B \cong A/(A \cap B) \cong \mathbb{Z}/3$. *Check (product formula).* $|A + B| = \dfrac{|A|\,|B|}{|A \cap B|} = \dfrac{6 \cdot 4}{2} = 12$, matching $|\langle 2 \rangle| = 12$. Good.

Worked Example 3.3.11 (Diamond in S_4 with a normal B)**.** In $G = S_4$ take $B = V = \{e, (12)(34), (13)(24), (14)(23)\}$ (the Klein four normal subgroup, $V \trianglelefteq S_4$) and $A = \langle (123) \rangle$, cyclic of order 3. Compute AB and verify the theorem.

Recognition. Diamond Theorem with $B \trianglelefteq G$, so the hypothesis $A \leq N_G(B) = G$ is automatic; we want $|AB|$ and the isomorphism type of AB/B.

Solution. Since $V \trianglelefteq S_4$, AV is a subgroup. Orders: $|A| = 3$, $|V| = 4$, and $A \cap V = \{e\}$ because the only element of $A = \{e, (123), (132)\}$ that could lie in V is e (the others are 3-cycles, V contains only double transpositions and e). Hence

$$|AV| = \frac{|A|\,|V|}{|A \cap V|} = \frac{3 \cdot 4}{1} = 12.$$

The unique subgroup of order 12 in S_4 is A_4, so $AV = A_4$. The theorem gives $AV/V \cong A/(A \cap V) = A/\{e\} \cong A \cong \mathbb{Z}/3$. *Check.* Indeed A_4/V has order $12/4 = 3$, so $A_4/V \cong \mathbb{Z}/3$, consistent. Sanity on normality: $V \trianglelefteq AV = A_4$ (yes, $V \trianglelefteq A_4$) and $A \cap V = \{e\} \trianglelefteq A$ (trivially). Good.

Worked Example 3.3.12 (When you must check $A \leq N_G(B)$: D_8)**.** In $G = D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$ let $B = \langle s \rangle = \{1, s\}$ and $A = \langle r^2 \rangle = \{1, r^2\}$. Does the Diamond Theorem apply, and what is AB?

Recognition. Second Iso: B is not normal in G (and normality of $A = Z(D_8)$ does not help), so we must verify the hypothesis $A \leq N_G(B)$ rather than assume it.

Solution. Check A normalizes B: $r^2 s r^{-2} = r^2(sr^{-2}) = r^2(r^2 s) = r^4 s = s \in B$ (using $sr^{-1} = rs$ so $sr^{-2} = r^2 s$). Thus $r^2 \in N_G(B)$, and since $A = \langle r^2 \rangle$ we get $A \leq N_G(B)$: the hypothesis holds. (Note r^2 is central in D_8, which forces this.) Now $A \cap B = \{1\}$ since $A = \{1, r^2\}$, $B = \{1, s\}$ share only 1. So

$$|AB| = \frac{|A|\,|B|}{|A \cap B|} = \frac{2 \cdot 2}{1} = 4,$$

and $AB = \{1, r^2, s, r^2 s\}$. This is a subgroup ($\cong V_4$, the Klein four-group, since all non-identity elements have order 2 and it is abelian). The theorem gives $B \trianglelefteq AB$ and $AB/B \cong A/(A \cap B) \cong \mathbb{Z}/2$. *Check.* $|AB/B| = 4/2 = 2 = |A/(A \cap B)|$. *Pitfall avoided:* $B = \langle s \rangle$ is *not* normal in all of D_8 (e.g. $rsr^{-1} = r^2 s \notin B$), but it *is* normal in the smaller group AB – which is exactly conclusion (2). Good.

Worked Example 3.3.13 (Diamond formula recovers a counting identity)**.** Let G be any group with subgroups A, B where $B \trianglelefteq G$, $|A| = 15$, $|B| = 10$, and $A \cap B$ has order 5. Find $|AB|$ and $|AB/B|$.

Recognition. Diamond Theorem in its order form: $B \trianglelefteq G$ supplies the hypothesis, and we use $|AB| = |A||B|/|A \cap B|$ plus $AB/B \cong A/(A \cap B)$.

Solution. $|AB| = \dfrac{15 \cdot 10}{5} = 30$. Then $|AB/B| = \dfrac{|AB|}{|B|} = \dfrac{30}{10} = 3$, and independently $|A/(A \cap B)| = \dfrac{15}{5} = 3$; the two agree, as the isomorphism demands. So $AB/B \cong A/(A \cap B)$ is a group of order 3, hence $\cong \mathbb{Z}/3$.
Check. $|A \cap B| = 5$ divides both $|A| = 15$ and $|B| = 10$ (Lagrange), so the data are consistent. Good.

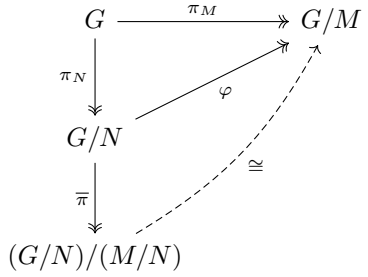
Caution. $AB = \{ab : a \in A, b \in B\}$ is **not always a subgroup**. It is a subgroup precisely when $AB = BA$; the Diamond Theorem's hypothesis $A \leq N_G(B)$ is what guarantees this. Never write "AB/B" without first knowing AB is a subgroup and B is normal in it. Also, $A \cap B \trianglelefteq A$ does *not* say $A \cap B \trianglelefteq G$; the normality is only inside A.

The third isomorphism theorem

Theorem 3.3.14 (Third Isomorphism Theorem)**.** *Let G be a group with normal subgroups $N \trianglelefteq G$ and $M \trianglelefteq G$ satisfying $N \leq M$. Then $N \trianglelefteq M$, the quotient M/N is a normal subgroup of G/N, and*

$$(G/N)\big/(M/N) \;\cong\; G/M.$$

"You can cancel the N."



Proof. Since $N \trianglelefteq G$ and $N \leq M \leq G$, also $N \trianglelefteq M$ (normality passes to any intermediate subgroup containing N). Both M/N and G/N are quotients by N; because $M \trianglelefteq G$, the image M/N is normal in G/N (this is part of the Fourth Iso Theorem, proved below, but also direct: for $gN \in G/N$ and $mN \in M/N$, $(gN)(mN)(gN)^{-1} = (gmg^{-1})N \in M/N$ since $gmg^{-1} \in M$).

Now build the natural surjection. Define $\varphi\colon G/N \to G/M$ by $\varphi(gN) = gM$. This is well defined: if $gN = g'N$ then $g^{-1}g' \in N \leq M$, so $gM = g'M$. It is a homomorphism, $\varphi((gN)(hN)) = \varphi(ghN) = ghM = (gM)(hM)$, and surjective (every gM is hit). Its kernel is

$$\ker\varphi = \{gN : gM = M\} = \{gN : g \in M\} = M/N.$$

By the First Isomorphism Theorem, $(G/N)/(M/N) = (G/N)/\ker\varphi \cong \operatorname{im}\varphi = G/M$. □

The map φ is exactly the statement "a coarser quotient factors a finer one": the two canonical projections $\pi_N\colon G \to G/N$ and $\pi_M\colon G \to G/M$ are related by $\pi_M = \varphi \circ \pi_N$.

The triangle $G \to G/N \to G/M$ commutes ($\pi_M = \varphi\,\pi_N$); collapsing the kernel M/N of φ via the First Iso Theorem produces the dashed isomorphism $(G/N)/(M/N) \cong G/M$.

Diagram explanation. Objects: Four groups. G is the ambient group (top left). G/M is the coarser quotient by the larger normal subgroup M (top right). G/N is the finer quotient by the smaller normal subgroup $N \leq M$ (middle left). $(G/N)/(M/N)$ is the iterated quotient of G/N by the image $M/N \trianglelefteq G/N$ (bottom left); the Third Isomorphism Theorem asserts it is isomorphic to G/M.

Arrows: $\pi_N\colon G \twoheadrightarrow G/N$, $g \mapsto gN$, the canonical projection mod N. $\pi_M\colon G \twoheadrightarrow G/M$, $g \mapsto gM$, the canonical projection mod M. $\varphi\colon G/N \twoheadrightarrow G/M$, $gN \mapsto gM$; this is the "coarsening" map. Well-defined: if $gN = g'N$

then $g^{-1}g' \in N \leq M$, so $gM = g'M$. $\overline{\pi}\colon G/N \twoheadrightarrow (G/N)/(M/N)$ is the canonical projection of G/N onto its quotient by M/N; it sends $gN \mapsto gN \cdot (M/N)$. The dashed arrow $(G/N)/(M/N) \xrightarrow{\cong} G/M$ is the isomorphism produced by the First Isomorphism Theorem applied to φ (since $\ker \varphi = M/N$).

What commutes: Upper triangle: $\varphi \circ \pi_N = \pi_M$ (both send $g \mapsto gM$). Full diagram: $\cong \circ \overline{\pi} = \varphi$, so all paths from G to G/M agree.

Why it commutes: Take $g \in G$. Path π_M: $g \mapsto gM$. Path π_N then φ: $g \mapsto gN \mapsto gM$. Equal because $N \leq M$ forces $gN \mapsto gM$ to be well-defined. The iterated quotient path adds $\overline{\pi}$ (to $(G/N)/(M/N)$) then the isomorphism (back to G/M); by the First Iso Theorem this also yields gM.

Why this matters here: The diagram captures the entire content of the Third Isomorphism Theorem in one picture. The upper triangle says a coarser quotient factors a finer one; the lower part records that the "extra" identification (collapsing M/N inside G/N) produces exactly G/M. The dashed isomorphism is the punchline: $(G/N)/(M/N) \cong G/M$.

Concrete example: $G = \mathbb{Z}$, $N = 12\mathbb{Z}$, $M = 6\mathbb{Z}$. Then $\pi_N(n) = n + 12\mathbb{Z}$, $\pi_M(n) = n + 6\mathbb{Z}$, $\varphi(n + 12\mathbb{Z}) = n + 6\mathbb{Z}$. The isomorphism $(\mathbb{Z}/12\mathbb{Z})/(6\mathbb{Z}/12\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$ sends $(n + 12\mathbb{Z}) + (6\mathbb{Z}/12\mathbb{Z}) \mapsto n + 6\mathbb{Z}$.

Common pitfall: φ is well-defined only because $N \leq M$; if $M \leq N$ (the chain is reversed), then $g^{-1}g' \in N$ does not imply $g^{-1}g' \in M$, and φ fails. Also, M/N must be recognized as a subgroup of G/N (needs $N \leq M$) before writing the iterated quotient.

Takeaway: The point of this diagram is that quotienting G in two stages (first mod N, then mod M/N) gives the same result as quotienting G in one step mod M, making $(G/N)/(M/N) \cong G/M$ visually self-evident from the commutativity.

Method (Recognizing and applying the Third Theorem)**.** *Trigger.* You see an iterated quotient $(G/N)/(M/N)$, or you want to "simplify" a quotient of a quotient, or you have a chain $N \leq M \leq G$ of normal subgroups and want the relationship among G/N, G/M, M/N.

Recipe.

1. Verify $N \trianglelefteq G$, $M \trianglelefteq G$, and $N \leq M$. (Then automatically $N \trianglelefteq M$ and $M/N \trianglelefteq G/N$.)
2. Cancel: $(G/N)/(M/N) \cong G/M$.
3. For orders (finite): $\big|(G/N)/(M/N)\big| = \dfrac{|G|/|N|}{|M|/|N|} = \dfrac{|G|}{|M|} = |G/M|$ – the $|N|$'s cancel, mirroring the theorem.

Worked Example 3.3.15 (Third iso in $\mathbb{Z}/12\mathbb{Z}$ (cancel a cyclic quotient))**.** Take $G = \mathbb{Z}/12\mathbb{Z}$, $M = \langle 2 \rangle = \{0, 2, 4, 6, 8, 10\}$ (order 6), and $N = \langle 4 \rangle = \{0, 4, 8\}$ (order 3). Note $N \leq M$. Verify $(G/N)/(M/N) \cong G/M$.

Recognition. Third Iso Theorem: a chain $N \leq M \leq G$ with G abelian (so all normal); we cancel N.

Solution. All subgroups of an abelian group are normal, so $N \trianglelefteq G$, $M \trianglelefteq G$, and $N = \langle 4 \rangle \leq \langle 2 \rangle = M$ since $4 = 2 \cdot 2 \in \langle 2 \rangle$. Orders: $|G/N| = 12/3 = 4$, so $G/N = (\mathbb{Z}/12)/\langle 4 \rangle \cong \mathbb{Z}/4$ (generated by $1 + N$). Inside it, $M/N = \langle 2 \rangle/\langle 4 \rangle$ has order $|M|/|N| = 6/3 = 2$, the subgroup $\{N, 2 + N\} \cong \mathbb{Z}/2$. Then

$$(G/N)/(M/N) \cong \mathbb{Z}/2$$

(an order-4 group modulo an order-2 subgroup, $4/2 = 2$). On the other side, $G/M = (\mathbb{Z}/12)/\langle 2 \rangle \cong \mathbb{Z}/2$ (order $12/6 = 2$). Both are $\mathbb{Z}/2$, so $(G/N)/(M/N) \cong G/M$. *Check.* Orders $4/2 = 2$ and $12/6 = 2$ agree. Good.

Worked Example 3.3.16 (Third iso with $G = \mathbb{Z}$ (the integers))**.** Let $G = \mathbb{Z}$, $M = 6\mathbb{Z}$, $N = 12\mathbb{Z}$; then $N = 12\mathbb{Z} \leq 6\mathbb{Z} = M$ since $12\mathbb{Z} \subseteq 6\mathbb{Z}$. Identify $(\mathbb{Z}/12\mathbb{Z})/(6\mathbb{Z}/12\mathbb{Z})$.

Recognition. Third Iso: $\mathbb{Z}$ abelian, chain $12\mathbb{Z} \leq 6\mathbb{Z} \leq \mathbb{Z}$; cancel $N = 12\mathbb{Z}$.

Solution. Here $G/N = \mathbb{Z}/12\mathbb{Z}$ and $M/N = 6\mathbb{Z}/12\mathbb{Z} = \{0 + 12\mathbb{Z},\ 6 + 12\mathbb{Z}\}$, a subgroup of order 2. The theorem gives

$$(\mathbb{Z}/12\mathbb{Z})/(6\mathbb{Z}/12\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}.$$

Indeed $G/M = \mathbb{Z}/6\mathbb{Z}$. *Check.* $|G/N|/|M/N| = 12/2 = 6 = |\mathbb{Z}/6\mathbb{Z}|$. *Reading:* collapsing $\mathbb{Z}$ mod 12 and then further collapsing the residue-6 class is the same as collapsing $\mathbb{Z}$ mod 6 in one shot. Good.

Worked Example 3.3.17 (Third iso in a non-abelian chain: S_4)**.** In $G = S_4$ take $M = A_4 \trianglelefteq S_4$ and $N = V \trianglelefteq S_4$ (Klein four), with $V \leq A_4$. Compute $(S_4/V)/(A_4/V)$.

Recognition. Third Iso: $V \trianglelefteq S_4$, $A_4 \trianglelefteq S_4$, and $V \leq A_4$; cancel $N = V$.

Solution. Orders: $|S_4/V| = 24/4 = 6$, $|A_4/V| = 12/4 = 3$. So A_4/V is a normal subgroup of order 3 inside the order-6 group S_4/V (in fact $S_4/V \cong S_3$ and A_4/V is its $\langle(123)\rangle \cong \mathbb{Z}/3$). The theorem gives

$$(S_4/V)/(A_4/V) \cong S_4/A_4.$$

Now S_4/A_4 has order $24/12 = 2$, so $S_4/A_4 \cong \mathbb{Z}/2$. *Check via orders inside $S_4/V \cong S_3$:* $S_3/A_3 \cong \mathbb{Z}/2$, order $6/3 = 2$, matching. Good. (This is the familiar sign map: $S_4/A_4 \cong \{\pm 1\}$.)

Worked Example 3.3.18 (Choosing the right N to simplify)**.** Let $G = \mathbb{Z}/36\mathbb{Z}$, $M = \langle 3\rangle$ (order 12), $N = \langle 9\rangle$ (order 4), so $N \leq M$ as $9 \in \langle 3\rangle$. Find $(G/N)/(M/N)$ two ways.

Recognition. Third Iso Theorem; abelian, chain $\langle 9\rangle \leq \langle 3\rangle \leq \mathbb{Z}/36$.

Solution. Way 1 (cancel): $(G/N)/(M/N) \cong G/M = (\mathbb{Z}/36)/\langle 3\rangle \cong \mathbb{Z}/3$ (order $36/12 = 3$). *Way 2 (compute the tower):* $G/N = (\mathbb{Z}/36)/\langle 9\rangle$ has order $36/4 = 9$, and is cyclic $\cong \mathbb{Z}/9$; the image $M/N = \langle 3\rangle/\langle 9\rangle$ has order $12/4 = 3$, the unique subgroup of order 3 in $\mathbb{Z}/9$. Then $(\mathbb{Z}/9)/(\mathbb{Z}/3) \cong \mathbb{Z}/3$, order $9/3 = 3$. Both routes give $\mathbb{Z}/3$. *Check.* $36/12 = 3$ and $9/3 = 3$ agree. Good.

Caution. The Third Theorem requires **both** M and N normal in G **and** $N \leq M$. The notation $(G/N)/(M/N)$ only makes sense once you know M/N is a subgroup of G/N (needs $N \leq M$) and is normal there (needs $M \trianglelefteq G$). Do not "cancel N" in $(G/N)/(M/N)$ unless $N \leq M$; if instead $M \leq N$ the expression is malformed.

The fourth (lattice) isomorphism theorem

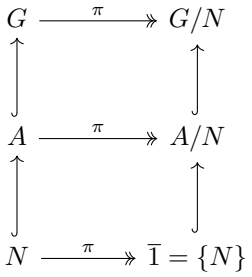
Theorem 3.3.19 (Fourth/Lattice Isomorphism Theorem)**.** *Let $N \trianglelefteq G$, and let $\pi\colon G \to G/N$ be the canonical projection. There is a bijection*

$$\{\, A : N \leq A \leq G \,\} \longleftrightarrow \{\, \overline{A} : \overline{A} \leq G/N \,\}$$

between the set of subgroups of G containing N *and the set of* all *subgroups of G/N, given by $A \mapsto A/N = \pi(A)$ with inverse $\overline{A} \mapsto \pi^{-1}(\overline{A})$. This bijection satisfies, for all $N \leq A, B \leq G$:*

(1) $A \leq B \iff A/N \leq B/N$ (preserves inclusion);

(2) if $A \leq B$ then $[B : A] = [B/N : A/N]$ (preserves index);



(3) $\overline{\langle A, B\rangle} = \langle A/N, B/N\rangle$ and $\overline{A \cap B} = (A/N) \cap (B/N)$ (preserves joins and meets);

(4) $A \trianglelefteq G \iff A/N \trianglelefteq G/N$ (preserves normality).

In short: the subgroup lattice of G/N is isomorphic to the sublattice of subgroups of G lying above N, "index and normality preserved."

Proof sketch. Standard preimage/image facts for the surjection π. If $N \leq A \leq G$ then $\pi(A) = A/N$ is a subgroup of G/N; if $\overline{A} \leq G/N$ then $\pi^{-1}(\overline{A}) \leq G$ and it contains $\pi^{-1}(\overline{1}) = N$. These are mutually inverse: $\pi(\pi^{-1}(\overline{A})) = \overline{A}$ since π is onto, and $\pi^{-1}(\pi(A)) = AN = A$ because $A \supseteq N$ (this last equality is exactly where "A contains N" is used). Inclusion-preservation (1) is immediate for image and preimage. For (2), cosets of A in B correspond bijectively to cosets of A/N in B/N via π (well defined since $N \leq A$). Joins and meets (3) follow from π and π^{-1} being lattice maps. For (4): $A \trianglelefteq G$ iff $gAg^{-1} = A$ for all g, and applying π (resp. π^{-1}) translates this exactly into $(gN)(A/N)(gN)^{-1} = A/N$ for all gN, i.e. $A/N \trianglelefteq G/N$; the Third Iso Theorem then realizes $G/A \cong (G/N)/(A/N)$. □

The bijection is captured by the correspondence square: every subgroup "upstairs" between N and G maps down to a subgroup of the quotient, and conversely.

Each horizontal π is surjective; the left column $N \leq A \leq G$ corresponds rung by rung to the right column $\{N\} \leq A/N \leq G/N$. Subgroups of G *below* N are invisible to the correspondence (they all collapse).

Diagram explanation. Objects: Six groups arranged in a 3×2 grid. Left column (upstairs): $N \leq A \leq G$, a chain of three subgroups of G with N normal in G. Right column (downstairs): $\overline{1} = \{N\} \leq A/N \leq G/N$, the corresponding chain of subgroups of the quotient G/N. Each right-column entry is the image of the entry beside it under π.

Arrows: Each horizontal $\pi\colon G \twoheadrightarrow G/N$ (and its restrictions to A and N) is the canonical surjective projection $g \mapsto gN$. Each vertical hook $\hookrightarrow$ is a subgroup inclusion. The three horizontal π-arrows are all the same map (just restricted to successively smaller domains); the commutativity of each square says "include first, then project" equals "project first, then include."

What commutes: Each small square commutes: $\pi|_A \circ (\text{inclusion of } N) = (\text{inclusion of } \{N\} \text{ in } A/N) \circ \pi|_N$, and similarly for the top square with $A \hookrightarrow G$. In plain terms: projecting any element of N (or A) and then including into G/N gives the same coset as including into G and then projecting.

Why it commutes: Chase $n \in N$. Include in A (still n), project: $n \mapsto nN = N = \overline{1}$. Or: project $n \mapsto nN = \overline{1}$, include in A/N: still $\overline{1}$. Equal. The same trivial chase works for the top square with any $a \in A$. The key is that π is defined globally on G and the inclusions are literal set inclusions, so order of operations is irrelevant.

Why this matters here: This 3×2 grid is the visual certificate of the Fourth (Lattice) Isomorphism Theorem. It shows that the subgroup lattice of G between N and G maps bijectively (rung by rung) to the full subgroup lattice of G/N, with inclusions, indices, and normality all preserved. Every property one wants to read from G/N's lattice can be read from the upstairs lattice of G above N.

Concrete example: $G = \mathbb{Z}/12\mathbb{Z}$, $N = \langle 6\rangle$, $A = \langle 3\rangle$. Upstairs: $\langle 6\rangle \leq \langle 3\rangle \leq \mathbb{Z}/12$. Downstairs: $\{0\} \leq \langle \overline{3}\rangle \leq \mathbb{Z}/6$. The horizontal π's send $\langle 3\rangle \mapsto \langle 3\rangle/\langle 6\rangle = \langle \overline{3}\rangle \cong \mathbb{Z}/2$.

Common pitfall: The correspondence only covers subgroups of G *containing* N. A subgroup $H \leq G$ with $H \cap N = \{e\}$ (so H does not contain N) has no matching subgroup of G/N; writing H/N is undefined. Students frequently forget this restriction and try to "push" every subgroup of G down to G/N.

Takeaway: The point of this diagram is that the canonical projection π creates a perfect rung-by-rung copy of the upper portion of G's subgroup lattice inside G/N, making it possible to read off all subgroups, indices, and normal subgroups of G/N from the original group G.

Method (Recognizing and applying the Lattice Theorem)**.** *Trigger.* You want to list *all* subgroups (or all normal subgroups) of a quotient G/N; or you want to count subgroups of G containing N; or you want the index of one such subgroup in another; or you must decide normality of a subgroup of G/N.

Recipe.

1. Find every subgroup A of G with $N \leq A \leq G$ (the "upstairs" lattice).
2. Its image A/N is the matching subgroup of G/N; this list is *all* of them.
3. Read off index ($[B : A] = [B/N : A/N]$) and normality ($A \trianglelefteq G \iff A/N \trianglelefteq G/N$) directly upstairs.
4. Conversely, to find $\pi^{-1}(\overline{A})$, take all $g \in G$ with $gN \in \overline{A}$.

Worked Example 3.3.20 (Lattice for G/N with $G = \mathbb{Z}/12\mathbb{Z}$, $N = \langle 6\rangle$)**.** Let $G = \mathbb{Z}/12\mathbb{Z}$ and $N = \langle 6\rangle = \{0, 6\}$, $|N| = 2$, so $|G/N| = 6$ and $G/N \cong \mathbb{Z}/6\mathbb{Z}$. List all subgroups of G/N via the correspondence.

Recognition. Fourth Iso Theorem: subgroups of $G/N \leftrightarrow$ subgroups of $\mathbb{Z}/12$ containing $\langle 6\rangle$.

Solution. Subgroups of $\mathbb{Z}/12$ are the $\langle d\rangle$ for $d \mid 12$: $\langle 1\rangle = \mathbb{Z}/12$, $\langle 2\rangle$, $\langle 3\rangle$, $\langle 4\rangle$, $\langle 6\rangle$, $\langle 12\rangle = \langle 0\rangle = \{0\}$. Those *containing* $N = \langle 6\rangle$ are exactly the ones with $6 \in \langle d\rangle$, i.e. $d \mid 6$: $\langle 1\rangle, \langle 2\rangle, \langle 3\rangle, \langle 6\rangle$. (The subgroups $\langle 4\rangle$ and $\{0\}$ do *not* contain 6, so they drop out.) These four correspond to the four subgroups of $G/N \cong \mathbb{Z}/6$:

$$\langle 1\rangle = \mathbb{Z}/12 \;\to\; \mathbb{Z}/6, \quad \langle 2\rangle \;\to\; \langle 2\rangle \cong \mathbb{Z}/3, \quad \langle 3\rangle \;\to\; \langle 3\rangle \cong \mathbb{Z}/2, \quad \langle 6\rangle = N \;\to\; \{0\}.$$

Check (count). $\mathbb{Z}/6$ has divisors $1, 2, 3, 6$ of 6, hence exactly 4 subgroups – matching the 4 upstairs. *Index check:* $[\langle 1\rangle : \langle 2\rangle] = 12/6 = 2$ upstairs equals $[\mathbb{Z}/6 : \mathbb{Z}/3] = 6/3 = 2$ downstairs. Good.

The correspondence is best seen as two side-by-side diamonds: the subgroups of $\mathbb{Z}/12$ *containing* $N = \langle 6\rangle$ (left) sit rung-for-rung opposite *all* the subgroups of $G/N \cong \mathbb{Z}/6$ (right), with faint ties joining matched pairs.

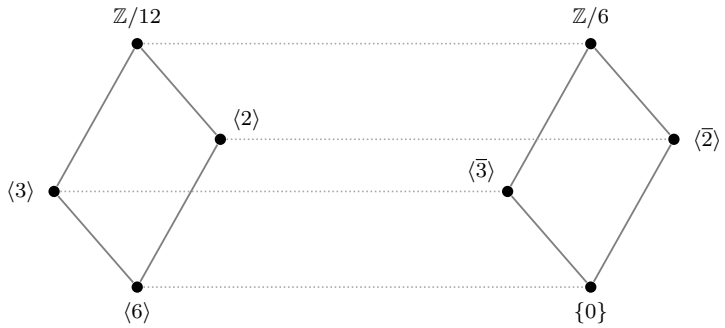


Diagram explanation. Objects: Two diamond lattices placed side by side. Left diamond: the four subgroups of $\mathbb{Z}/12\mathbb{Z}$ that contain $N = \langle 6\rangle$, namely $\langle 6\rangle$ (bottom), $\langle 3\rangle$ (left), $\langle 2\rangle$ (right), and $\mathbb{Z}/12$ (top). Right diamond: all four subgroups of $G/N \cong \mathbb{Z}/6$, namely $\{0\}$ (bottom), $\langle \overline{3}\rangle \cong \mathbb{Z}/2$ (left), $\langle \overline{2}\rangle \cong \mathbb{Z}/3$ (right), and $\mathbb{Z}/6$ (top). The horizontal ties connect matched pairs.

Arrows: The slanted edges within each diamond are subgroup inclusions (upward = larger subgroup). Horizontal tie-lines are the bijection $A \mapsto A/N$ of the Fourth Isomorphism Theorem (left to right) and its inverse $\overline{A} \mapsto \pi^{-1}(\overline{A})$ (right to left). Each tie connects A on the left to A/N on the right, realized as the image of A under the canonical projection $\pi\colon \mathbb{Z}/12 \to \mathbb{Z}/6$.

What commutes: Preservation of inclusion: if $A \le B$ upstairs (left edge), then $A/N \le B/N$ downstairs (right edge), so the tie-lines respect the heights of the rungs. Preservation of index: the index $[B : A]$ on the left equals $[B/N : A/N]$ on the right; e.g. $[\langle 2\rangle : \langle 6\rangle] = 3$ left equals $[\langle \overline{2}\rangle : \{0\}] = 3$ right.

Why it commutes: For the inclusion: if $a \in A \le B$, then $a + N \in A/N \le B/N$, immediate. For the index: cosets of A in B biject with cosets of A/N in B/N via π (since $N \le A$), giving equal indices.

Why this matters here: This picture makes the Fourth Isomorphism Theorem concrete: the student can verify by inspection that the two diamonds are identical in shape (isomorphic as lattices), that heights are preserved (no rung-crossings in the ties), and that the index along each left edge equals the index along the corresponding right edge. The picture replaces a proof with a visual check.

Concrete example: The diagram itself is the example: $G = \mathbb{Z}/12$, $N = \langle 6\rangle$, $G/N \cong \mathbb{Z}/6$. The tie $\langle 3\rangle \leftrightarrow \langle \overline{3}\rangle$ records that $\pi(\langle 3\rangle) = \langle 3\rangle/\langle 6\rangle$, which is the unique subgroup of order 2 in $\mathbb{Z}/6$, namely $\langle \overline{3}\rangle$.

Common pitfall: Students sometimes try to include $\langle 4\rangle$ or $\{0\}$ in the left diamond, forgetting the "contains $N = \langle 6\rangle$" restriction. Neither 4 nor 0 generates a subgroup containing 6, so they are invisible upstairs and have no tie-line. Attempting to draw ties for them would extend the left diamond below $\langle 6\rangle$, which is outside the correspondence.

Takeaway: The point of this diagram is that the Fourth Isomorphism Theorem is not just an abstract bijection but a true lattice isomorphism: the two diamonds are copies of each other, with every inclusion, index, and normality relation intact across the tie-lines.

The bijection $A \mapsto A/N$ preserves inclusion and index: matched rungs have the same shape and the index along each left edge equals the index along the tied right edge.

Worked Example 3.3.21 (Normal-subgroup lattice of S_4/V)**.** Let $G = S_4$, $N = V$ (Klein four, $V \trianglelefteq S_4$, $|V| = 4$), so $|G/N| = 6$ and $S_4/V \cong S_3$. Use the correspondence to find all *normal* subgroups of S_4/V.

Recognition. Fourth Iso Theorem, normality clause: normal subgroups of $S_4/V \leftrightarrow$ normal subgroups of S_4 containing V.

Solution. The normal subgroups of S_4 are $\{e\}$, V, A_4, S_4. Those containing V are V, A_4, S_4. Under π they correspond to:

$$V \to \{e\} \text{ (order 1)}, \quad A_4 \to A_4/V \text{ (order 3)}, \quad S_4 \to S_4/V \text{ (order 6)}.$$

So $S_4/V \cong S_3$ has exactly three normal subgroups, of orders $1, 3, 6$ – precisely the known normal subgroups $\{e\} \trianglelefteq A_3 \trianglelefteq S_3$ of S_3. *Check.* S_3's only proper nontrivial normal subgroup is A_3 (order 3), matching A_4/V. The order-2 subgroups $\langle(12)\rangle$-type of S_3 are *not* normal; correspondingly, each pulls back to a subgroup of order $2 \cdot 4 = 8$ in S_4 (index $24/8 = 3$) that is *not* normal in S_4, so it never appears in the normal-subgroup list. Good.

Worked Example 3.3.22 (Index preservation in $\mathbb{Z}/12\mathbb{Z}$)**.** With $G = \mathbb{Z}/12\mathbb{Z}$, $N = \langle 6\rangle$ as above, verify $[\langle 2\rangle : \langle 6\rangle] = [(\langle 2\rangle/N) : \{0\}]$ and $[G : \langle 3\rangle] = [(G/N) : (\langle 3\rangle/N)]$.

Recognition. Fourth Iso Theorem, index clause $[B : A] = [B/N : A/N]$.

Solution. Upstairs: $\langle 2\rangle = \{0, 2, 4, 6, 8, 10\}$ has order 6, $\langle 6\rangle = N$ has order 2, so $[\langle 2\rangle : \langle 6\rangle] = 6/2 = 3$. Downstairs $\langle 2\rangle/N$ has order $6/2 = 3$ and $N/N = \{0\}$ has order 1, so the index is $3/1 = 3$. Match. Next, $|G| = 12$, $|\langle 3\rangle| = |\{0, 3, 6, 9\}| = 4$, so $[G : \langle 3\rangle] = 12/4 = 3$; downstairs $|G/N| = 6$, $|\langle 3\rangle/N| = 4/2 = 2$, index $6/2 = 3$. Match. *Check.* Both indices equal 3 as the theorem guarantees. Good.

Worked Example 3.3.23 (Pulling back: π^{-1} of a subgroup)**.** Let $G = \mathbb{Z}$, $N = 12\mathbb{Z}$, so $G/N = \mathbb{Z}/12\mathbb{Z}$. Take $\overline{A} = \langle 4\rangle = \{0, 4, 8\} \leq \mathbb{Z}/12$. Compute $\pi^{-1}(\overline{A})$ and confirm it contains N.

Recognition. Fourth Iso Theorem: the inverse correspondence $\overline{A} \mapsto \pi^{-1}(\overline{A})$ lands among subgroups of $\mathbb{Z}$ containing $12\mathbb{Z}$.

Solution. $\pi^{-1}(\overline{A}) = \{n \in \mathbb{Z} : n + 12\mathbb{Z} \in \{0, 4, 8\} + 12\mathbb{Z}\} = \{n : n \equiv 0, 4, \text{ or } 8 \pmod{12}\} = 4\mathbb{Z}$. Indeed $4\mathbb{Z} \supseteq 12\mathbb{Z} = N$ (since $12 \in 4\mathbb{Z}$), as required. And $\pi(4\mathbb{Z}) = 4\mathbb{Z}/12\mathbb{Z} = \{0, 4, 8\} = \overline{A}$, confirming the round trip. *Index check:* $[\mathbb{Z} : 4\mathbb{Z}] = 4$ upstairs and $[\mathbb{Z}/12 : \langle 4\rangle] = 12/3 = 4$ downstairs. *Normality:* both are abelian so all subgroups normal, consistent with clause (4). Good.

Caution. The lattice correspondence sees **only** the subgroups of G that contain N. Subgroups not containing N (e.g. a subgroup meeting N trivially) are *not* in the correspondence; do not try to read them off the lattice of G/N. Also, $\pi^{-1}(\pi(A)) = AN$ in general – it equals A only when $N \leq A$. Forgetting the "contains N" restriction is the most common error.

Which theorem fits? A decision method

Method (Choosing the right isomorphism theorem)**.**

- **One homomorphism / one quotient, want $G/\ker \cong$ im:** First Iso Theorem.
- **Two subgroups A, B of one group; want the join AB, the product formula, or to rewrite AB/B:** Second (Diamond) Theorem. Verify $A \leq N_G(B)$.
- **A quotient of a quotient $(G/N)/(M/N)$, or a chain $N \leq M \leq G$ of normals; want to "cancel":** Third Theorem. Result G/M.
- **Want *all* subgroups / normal subgroups / indices of G/N, or to pull subgroups of G/N back to G:** Fourth (Lattice) Theorem. Work upstairs among subgroups containing N.

Tell-tale shapes: "AB" or "$A \cap B$" ⇒ Second; double slash "$/\!/$" i.e. $(\cdot/N)/(\cdot/N)$ ⇒ Third; "list every subgroup of a quotient" ⇒ Fourth.

Exercises (from the text).

1. Let F be a finite field of order q and let n be a positive integer. Prove that $[\mathrm{GL}_n(F) : \mathrm{SL}_n(F)] = q - 1$. [See Exercise 35, Section 1.]

2. Prove all parts of the Lattice Isomorphism Theorem (Theorem 20).

3. Prove that if H is a normal subgroup of G of prime index p then for all $K \leq G$ either

   (a) $K \leq H$ or

   (b) $G = HK$ and $[K : K \cap H] = p$.

4. Let C be a normal subgroup of the group A and let D be a normal subgroup of the group B. Prove that $(C \times D) \trianglelefteq (A \times B)$ and $(A \times B)/(C \times D) \cong (A/C) \times (B/D)$.

5. Let $QD_{16} = \langle \sigma, \tau \rangle$ be the quasidihedral group of order 16 described in Exercise 11 of Section 2.5. Prove that $\langle \sigma^4 \rangle$ is normal in QD_{16} and use the Lattice Isomorphism Theorem to draw the lattice of subgroups of $QD_{16}/\langle \sigma^4 \rangle$. Which group of order 8 has the same lattice as this quotient? Use generators and relations for $QD_{16}/\langle \sigma^4 \rangle$ to decide the isomorphism type of this group.

6. Let $M = \langle v, u \rangle$ be the modular group of order 16 described in Exercise 14 of Section 2.5. Prove that $\langle v^4 \rangle$ is normal in M and use the Lattice Isomorphism Theorem to draw the lattice of subgroups of $M/\langle v^4 \rangle$. Which group of order 8 has the same lattice as this quotient? Use generators and relations for $M/\langle v^4 \rangle$ to decide the isomorphism type of this group.

7. Let M and N be normal subgroups of G such that $G = MN$. Prove that $G/(M \cap N) \cong (G/M) \times (G/N)$. [Draw the lattice.]

8. Let p be a prime and let G be the group of p-power roots of 1 in $\mathbb{C}$ (cf. Exercise 18, Section 2.4). Prove that the map $z \mapsto z^p$ is a surjective homomorphism. Deduce that G is isomorphic to a proper quotient of itself.

9. Let p be a prime and let G be a group of order $p^a m$, where p does not divide m. Assume P is a subgroup of G of order p^a and N is a normal subgroup of G of order $p^b n$, where p does not divide n. Prove that $|P \cap N| = p^b$ and $|PN/N| = p^{a-b}$. (The subgroup P of G is called a *Sylow p-subgroup* of G. This exercise shows that the intersection of any Sylow p-subgroup of G with a normal subgroup N is a Sylow p-subgroup of N.)

10. Generalize the preceding exercise as follows. A subgroup H of a finite group G is called a *Hall subgroup* of G if its index in G is relatively prime to its order: $([G : H], |H|) = 1$. Prove that if H is a Hall subgroup of G and $N \trianglelefteq G$, then $H \cap N$ is a Hall subgroup of N and HN/N is a Hall subgroup of G/N.

Practice problems (additional).

1. Let $G = \mathbb{Z}$ and $H = 12\mathbb{Z}$, $K = 3\mathbb{Z}$. Verify $H \leq K$, both $\trianglelefteq G$, and confirm the Third Isomorphism Theorem by computing $|(G/H)/(K/H)|$ and $|G/K|$ directly and checking they agree.

2. In $G = \mathbb{Z}/24\mathbb{Z}$ let $H = \langle 8 \rangle$ and $K = \langle 4 \rangle$. List the elements of H and K, check $H \leq K \leq G$, and identify $(G/H)/(K/H)$ as a familiar group.

3. Let $\varphi : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ be reduction mod 6 and let $N = 2\mathbb{Z}$. Compute $\operatorname{im}\varphi$, $\ker\varphi$, and $\varphi(N)$; then state which quotient φ induces an isomorphism onto.

4. Let $\varphi : \mathbb{R} \to \mathbb{C}^\times$ be $\varphi(x) = e^{2\pi i x}$. Show φ is a homomorphism, compute $\ker\varphi$ and $\operatorname{im}\varphi$, and use the First Isomorphism Theorem to identify $\mathbb{R}/\mathbb{Z}$.

5. Let $G = \mathrm{GL}_2(\mathbb{R})$ and let $\varphi = \det : G \to \mathbb{R}^\times$. Identify $\ker\varphi$, prove it is normal, and state the isomorphism the First Isomorphism Theorem gives for $G/\mathrm{SL}_2(\mathbb{R})$.

6. In D_8 (with $r^4 = s^2 = 1$, $sr = r^{-1}s$) let $Z = \langle r^2 \rangle$. Show $Z \trianglelefteq D_8$, list the four cosets of Z, write the multiplication table of D_8/Z, and identify the quotient up to isomorphism.

7. Let $G = Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ and $N = \{\pm 1\}$. Show $N \trianglelefteq G$, list the cosets of N, and identify G/N.

8. Let $A = \langle (1\,2)(3\,4) \rangle$ and $B = \langle (1\,3)(2\,4) \rangle$ inside $V = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\} \leq A_4$. Compute $A \cap B$, AB, $|AB|$, and verify the Second Isomorphism Theorem count $|AB| = \dfrac{|A|\,|B|}{|A \cap B|}$.

9. Let $G = \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $A = \mathbb{Z}/4\mathbb{Z} \times \{0\}$, $B = \{0\} \times \mathbb{Z}/2\mathbb{Z}$, viewed additively. Treating $B \trianglelefteq G$, compute $A \cap B$, $A + B$, and verify $(A + B)/B \cong A/(A \cap B)$ by identifying both sides.

10. Let $\varphi : \mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ send $1 \mapsto 1$. Compute $\ker\varphi$ and $\operatorname{im}\varphi$, verify $\ker\varphi \trianglelefteq \mathbb{Z}/12\mathbb{Z}$, and confirm $\mathbb{Z}/12\mathbb{Z}/\ker\varphi \cong \operatorname{im}\varphi$ by comparing orders.

11. Let $N = \langle r \rangle \trianglelefteq D_8$. Use the Fourth (Lattice) Isomorphism Theorem to list all subgroups of D_8/N and the corresponding subgroups of D_8 containing N.

12. Let $G = \mathbb{Z}/30\mathbb{Z}$ and $N = \langle 6 \rangle = \{0, 6, 12, 18, 24\}$. List the subgroups of G/N via the lattice correspondence, naming the subgroup of G that each one pulls back to.

13. Compute the sign of each permutation and give a composition series step for S_4: write sgn of $(1\,2\,3)$, $(1\,2\,3\,4)$, and $(1\,2)(3\,4)$, then verify the chain $S_4 \rhd A_4 \rhd V \rhd \langle (1\,2)(3\,4) \rangle \rhd 1$ has each term normal in the previous one.

14. For the series in the previous problem, compute each factor group S_4/A_4, A_4/V, $V/\langle (1\,2)(3\,4) \rangle$, $\langle (1\,2)(3\,4) \rangle/1$ and confirm that S_4 is solvable by checking all factors are abelian.

15. Let $\pi : G \to G/N$ be the natural projection. If $[G : N] = 15$ and $H \leq G$ with $N \leq H$ and $[G : H] = 5$, compute $[(G/N) : (H/N)]$ and $|H/N|$, justifying each step by the Third/Fourth Isomorphism Theorems.

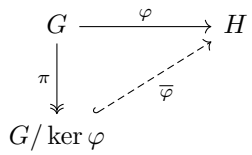
16. Let $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ and $N = \langle (1, 1, 0) \rangle$. Compute $|G/N|$, list its elements as cosets, and identify G/N up to isomorphism.

Additional exercises.

1. Let $H, K \trianglelefteq G$ with $H \leq K$. Prove directly from the definition of cosets that the map $\overline{\varphi} : G/H \to G/K$, $gH \mapsto gK$, is a well-defined surjective homomorphism with kernel K/H, recovering the Third Isomorphism Theorem.

2. Let G be a group, $H \leq G$, and $N \trianglelefteq G$. Prove the Second Isomorphism Theorem in full: show $HN \leq G$, $N \trianglelefteq HN$, $H \cap N \trianglelefteq H$, and that $HN/N \cong H/(H \cap N)$.

3. Let $\varphi : G \to G'$ be a surjective homomorphism with kernel K. Prove that there is an inclusion-preserving bijection between subgroups of G containing K and subgroups of G', and that this bijection sends normal subgroups to normal subgroups (the Lattice Isomorphism Theorem).



4. Let $G = S_3 \times \mathbb{Z}/2\mathbb{Z}$. Find all normal subgroups of G and, for each, identify the quotient G/N up to isomorphism. Use the isomorphism theorems to justify your identifications.

5. Let $N \trianglelefteq G$ with G/N abelian. Prove that the commutator subgroup $G' = [G, G]$ satisfies $G' \leq N$. Deduce that G/G' is the largest abelian quotient (the abelianization), and compute G' and G/G' for $G = D_8$.

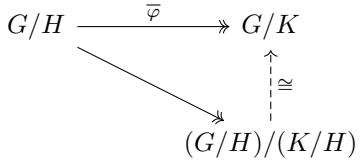
6. Suppose G has a composition series with factors all isomorphic to $\mathbb{Z}/p\mathbb{Z}$ for a fixed prime p. Prove $|G| = p^n$ where n is the length, and conversely exhibit such a series for $G = \mathbb{Z}/p^n\mathbb{Z}$.

Commutative-diagram exercises.

1. Let $\varphi : G \to H$ be a homomorphism and $\pi : G \to G/\ker\varphi$ the natural projection. Fill in the unique induced map and prove the triangle commutes:

   Show $\overline{\varphi}(g \ker\varphi) = \varphi(g)$ is well-defined and that $\overline{\varphi}$ is an isomorphism onto $\operatorname{im}\varphi$.

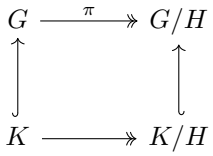
2. For $\varphi : G \to H$ a homomorphism, complete the short exact sequence by naming the two outer maps and proving exactness at G and at $\operatorname{im}\varphi$:



$$1 \longrightarrow \ker\varphi \hookrightarrow G \xrightarrow{\varphi} \operatorname{im}\varphi \longrightarrow 1$$

Then specialize to $\varphi = \det : \mathrm{GL}_2(\mathbb{R}) \to \mathbb{R}^\times$ and write the resulting sequence explicitly.

3. Let $H \leq G$ and $N \trianglelefteq G$. Label every arrow as an inclusion (hook) or quotient and prove the diamond exhibits the Second Isomorphism Theorem, i.e. that the quotients along the two parallel edges $N \leq HN$ and $H \cap N \leq H$ are isomorphic, $HN/N \cong H/(H \cap N)$:



4. With $H \leq K$ both normal in G, the Third Isomorphism Theorem says the composite of projections factors as below. Supply the dashed map and prove the triangle commutes:

Identify $\overline{\varphi}$, its kernel, and the isomorphism realizing $(G/H)/(K/H) \cong G/K$.

5. Take $G = \mathbb{Z}/12\mathbb{Z}$, $K = \langle 2 \rangle$, $H = \langle 6 \rangle$, so $H \leq K \trianglelefteq G$. Draw the lattice-correspondence diagram of the subgroups of G containing H versus the subgroups of G/H, labeling each horizontal arrow with the quotient map, and verify that $(G/H)/(K/H) \cong G/K$ by computing the orders of all three quotients:

3.4 Composition Series and the Hölder Program

Composition series, Jordan–Hölder, and solvable groups

This section organizes a finite group into "smallest reasonable pieces" and records (via the Jordan–Hölder theorem below) that the multiset of those pieces is an invariant of the group. The pieces are simple groups, and the assembly data is a chain of subgroups, each normal in the next. Two large results are quoted (their proofs are beyond the scope of this section): the Jordan–Hölder theorem and the simplicity of A_n for $n \geq 5$.

Definition 3.4.1 (Subnormal series)**.** A *subnormal series* for a group G is a chain of subgroups

$$1 = N_0 \trianglelefteq N_1 \trianglelefteq N_2 \trianglelefteq \cdots \trianglelefteq N_{k-1} \trianglelefteq N_k = G,$$

where each $N_i \trianglelefteq N_{i+1}$ (each term normal in the *next*, not necessarily in G). The quotients N_{i+1}/N_i are the *factors* of the series, and k is its *length*. We always allow ourselves to delete a repeated term $N_i = N_{i+1}$ (equivalently, drop trivial factors).

Remark 3.4.1. "Subnormal" is genuinely weaker than "normal." In D_8 the chain $1 \trianglelefteq \langle s \rangle \trianglelefteq \langle s, r^2 \rangle \trianglelefteq D_8$ is subnormal, but $\langle s \rangle$ is *not* normal in D_8 (since $rsr^{-1} = sr^2 \notin \langle s \rangle$). Each step is normal only in the *immediately* larger group: $\langle s \rangle \trianglelefteq \langle s, r^2 \rangle$ because $[\langle s, r^2 \rangle : \langle s \rangle] = 2$.

Definition 3.4.2 (Composition series)**.** A subnormal series

$$1 = N_0 \trianglelefteq N_1 \trianglelefteq \cdots \trianglelefteq N_k = G$$

is a *composition series* if every factor N_{i+1}/N_i is a *simple* group (no proper nontrivial normal subgroups; see the definition below). The factors N_{i+1}/N_i are then called the *composition factors* of G.

Theorem 3.4.3 (Existence)**.** *Every nontrivial finite group has a composition series.*

Proof. Induct on $|G|$. If G is simple, then $1 \trianglelefteq G$ is a composition series. Otherwise pick a *maximal* proper normal subgroup $M \lhd G$ (one exists since G is finite and $1 \lhd G$ is a proper normal subgroup, so the nonempty finite set of proper normal subgroups has a maximal element). By the Lattice Isomorphism (Correspondence) Theorem the normal subgroups of G/M correspond to normal subgroups of G between M and G; maximality of M says there are none strictly between, so G/M is simple. Since $|M| < |G|$, by induction M has a composition series $1 = N_0 \trianglelefteq \cdots \trianglelefteq N_r = M$; appending G gives $1 = N_0 \trianglelefteq \cdots \trianglelefteq N_r = M \trianglelefteq G$ with all factors simple. □

Definition 3.4.4 (Simple group)**.** A group $G \neq 1$ is *simple* if its only normal subgroups are 1 and G.

Proposition 3.4.5 (Abelian simple groups)**.** *An abelian group is simple if and only if it is $\mathbb{Z}/p\mathbb{Z}$ (cyclic of prime order p).*

Proof. In an abelian group every subgroup is normal, so simplicity means: the only subgroups are 1 and G. If $G = \mathbb{Z}/p\mathbb{Z}$ with p prime, Lagrange forces every subgroup to have order 1 or p, so G is simple. Conversely, if abelian G is simple, take $1 \neq x \in G$; then $\langle x \rangle$ is a nontrivial subgroup, hence $\langle x \rangle = G$, so G is cyclic. If G were infinite cyclic ($\cong \mathbb{Z}$) it would contain $2\mathbb{Z} \neq 1, G$; if $|G| = n$ were composite with $1 < d < n$ a divisor, the unique subgroup of order d would be proper nontrivial. So $|G| = p$ is prime, $G \cong \mathbb{Z}/p\mathbb{Z}$. □

Theorem 3.4.6 (Simplicity of A_n; stated)**.** *The alternating group A_n is simple for every $n \geq 5$. In particular A_5 (order 60) is a nonabelian simple group, the smallest one.*

Sketch. For $n \geq 5$ one shows A_n is generated by 3-cycles, that all 3-cycles are conjugate in A_n (using $n \geq 5$ to find an *even* conjugating permutation), and that any nontrivial normal subgroup $N \trianglelefteq A_n$ must contain a 3-cycle. From the last point and conjugacy, N contains every 3-cycle, hence $N = A_n$. The crux is the third step: analyzing the cycle type of a non-identity $\sigma \in N$ and forming a suitable commutator $\sigma\tau\sigma^{-1}\tau^{-1} \in N$ that simplifies to a 3-cycle. (Full details: D&F Section 4.6. We use only the *statement*.) For $n = 4$ this fails: $V = \{1, (12)(34), (13)(24), (14)(23)\} \trianglelefteq A_4$ is a proper nontrivial normal subgroup, so A_4 is *not* simple. □

Theorem 3.4.7 (Jordan–Hölder; stated)**.** *Let $G \neq 1$ be a finite group. Then:*

(1) *G has a composition series; and*

(2) *the composition factors are* unique*: if*

$$1 = N_0 \trianglelefteq N_1 \trianglelefteq \cdots \trianglelefteq N_r = G \quad \textit{and} \quad 1 = M_0 \trianglelefteq M_1 \trianglelefteq \cdots \trianglelefteq M_s = G$$

are two composition series, then $r = s$ and there is a permutation π of $\{1, \ldots, r\}$ with

$$N_i/N_{i-1} \;\cong\; M_{\pi(i)}/M_{\pi(i)-1} \qquad (1 \leq i \leq r).$$

That is, the length *and the* multiset of factors *(up to isomorphism) are invariants of G.*

Sketch. Part (1) is the existence theorem above. Part (2) is proved by induction on $|G|$ using the *Schreier refinement* idea: any two subnormal series of G have refinements that are *equivalent* (same multiset of nontrivial factors), which follows from the *Zassenhaus (butterfly) lemma*. A composition series admits no proper refinement (its factors are already simple), so the two given series are already equivalent. Concretely the induction compares the top factors G/N_{r-1} and G/M_{s-1}: if $N_{r-1} = M_{s-1}$ apply the inductive hypothesis to that subgroup; otherwise $N_{r-1}M_{s-1} = G$ and one matches the two top factors across the diamond $N_{r-1}/(N_{r-1} \cap M_{s-1}) \cong G/M_{s-1}$ and $M_{s-1}/(N_{r-1} \cap M_{s-1}) \cong G/N_{r-1}$ (Second Isomorphism Theorem), then induct on the common subgroup $N_{r-1} \cap M_{s-1}$. (D&F outline a full proof in the exercises of their Section 3.4; see Exercises 6, 9 and 10 at the end of this section.) □

Remark 3.4.2 (A composition series is NOT a factorization). Jordan–Hölder records the factors but *not* how they are assembled. $\mathbb{Z}/4\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ have the *same* composition factors $(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z})$ yet are non-isomorphic; likewise $\mathbb{Z}/6\mathbb{Z}$ and S_3 both have factors $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}$. The extension problem "which G have a given factor multiset" is exactly the hard half of the Hölder program below.

Method (Building a composition series and reading off its factors)**.** *Trigger.* You are asked for a composition series / composition factors of a specific finite group, or to verify a given chain is a composition series.

Recipe.

1. Top-down: find a maximal normal subgroup $M \lhd G$ (so G/M is simple). Repeat inside M. Each chosen step gives one simple factor G/M.
2. Bottom-up (often easier for small groups): start at 1, climb by prime-index normal steps. A step $N_i \trianglelefteq N_{i+1}$ of *prime index* p has factor $N_{i+1}/N_i \cong \mathbb{Z}/p\mathbb{Z}$ automatically (order p is simple). For abelian groups every step is automatically normal; in general a subgroup of index 2 is always normal, but a prime index $p \geq 3$ does *not* by itself force normality.
3. Factor of each step = quotient N_{i+1}/N_i; identify it by its order. Order p prime $\Rightarrow \mathbb{Z}/p\mathbb{Z}$. A nonabelian simple step (e.g. A_5) is read off as that group.
4. *Check.* (Jordan–Hölder sanity): $\prod_i |N_{i+1}/N_i| = |G|$, and every factor is simple. The multiset of factors must not depend on which maximal steps you chose.

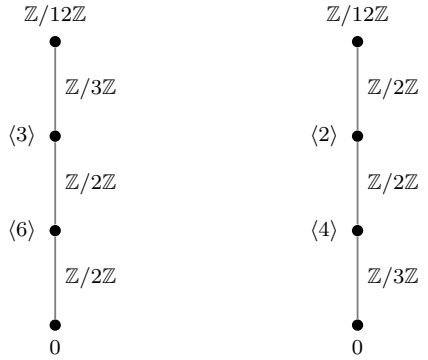
Worked Example 3.4.8 (Composition series of $\mathbb{Z}/12\mathbb{Z}$)**.** Give a composition series of $\mathbb{Z}/12\mathbb{Z}$ and list its composition factors.

Recognition. Bottom-up via prime-index steps: $12 = 2 \cdot 2 \cdot 3$, so build a chain whose successive indices are these primes.

Solution. Work additively in $\mathbb{Z}/12\mathbb{Z} = \{0, 1, \ldots, 11\}$. The subgroups are exactly the $\langle d \rangle$ for $d \mid 12$, with $\langle d \rangle$ of order $12/\gcd(d, 12)$; here $\langle 6 \rangle$ has order 2 and $\langle 3 \rangle$ has order 4. One chain:

$$0 \trianglelefteq \langle 6 \rangle \trianglelefteq \langle 3 \rangle \trianglelefteq \mathbb{Z}/12\mathbb{Z},$$

with $|\langle 6 \rangle| = 2$, $|\langle 3 \rangle| = 4$ (note $6 = 2 \cdot 3 \in \langle 3 \rangle$, so $\langle 6 \rangle \leq \langle 3 \rangle$). All subgroups of an abelian group are normal, so this is subnormal. Factors and their orders:



$$\langle 6 \rangle / 0 \cong \mathbb{Z}/2\mathbb{Z}, \quad \langle 3 \rangle / \langle 6 \rangle \text{ has order } 4/2 = 2 \cong \mathbb{Z}/2\mathbb{Z}, \quad \mathbb{Z}/12\mathbb{Z} / \langle 3 \rangle \text{ has order } 12/4 = 3 \cong \mathbb{Z}/3\mathbb{Z}.$$

Each factor is of prime order, hence simple. So this is a composition series, with factors

$$\boxed{\mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/3\mathbb{Z}}.$$

Check. $2 \cdot 2 \cdot 3 = 12 = |\mathbb{Z}/12\mathbb{Z}|$. A *different* chain $0 \trianglelefteq \langle 4 \rangle \trianglelefteq \langle 2 \rangle \trianglelefteq \mathbb{Z}/12\mathbb{Z}$ (with $|\langle 4 \rangle| = 3$, $|\langle 2 \rangle| = 6$) has indices $3, 2, 2$, giving factors $\mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$ — the same multiset, as Jordan–Hölder requires.

Both chains are vertical towers, each rung labeled by its composition factor; the two *differ in the order* of the factors but produce the *same multiset* $\{\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}\}$ — exactly the Jordan–Hölder invariance.

Orders climb $1, 2, 4, 12$ on the left and $1, 3, 6, 12$ on the right; the edge labels are the successive quotients, and both towers list $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}$.

Worked Example 3.4.9 (Composition series of D_8)**.** Give a composition series of the dihedral group $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$ (order 8) and list its factors.

Recognition. $|D_8| = 8 = 2^3$ is a 2-group; every step will have index 2, hence factor $\mathbb{Z}/2\mathbb{Z}$. A subgroup of index 2 is automatically normal, so any chain $1 \trianglelefteq H_1 \trianglelefteq H_2 \trianglelefteq D_8$ with successive indices 2 is a composition series.

Solution. Take $Z = \langle r^2 \rangle$ (the center, order 2) and $\langle r \rangle$ (the rotation subgroup, order 4, index 2 hence normal):

$$1 \ \trianglelefteq\ \langle r^2 \rangle \ \trianglelefteq\ \langle r \rangle \ \trianglelefteq\ D_8.$$

Indices: $[\langle r^2 \rangle : 1] = 2$, $[\langle r \rangle : \langle r^2 \rangle] = 4/2 = 2$, $[D_8 : \langle r \rangle] = 8/4 = 2$. Each step has index 2, so each smaller subgroup is normal in the next and each factor is $\cong \mathbb{Z}/2\mathbb{Z}$. Factors: $\boxed{\mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z}}$. *Check.* $2^3 = 8 = |D_8|$. A different composition series uses the subnormal (not normal in D_8!) chain $1 \trianglelefteq \langle s \rangle \trianglelefteq \langle s, r^2 \rangle \trianglelefteq D_8$: indices $2, 2, 2$, again factors $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$. Same multiset.

Caution. Composition factors do *not* pin down the group. D_8, $\mathbb{Z}/8\mathbb{Z}$, $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z}^3$, and Q_8 are five *non-isomorphic* groups of order 8, and all have composition factors $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$. Equal factor multiset $\neq$ isomorphic group.

Definition 3.4.10 (Solvable group)**.** A finite group G is *solvable* if it has a subnormal series

$$1 = N_0 \trianglelefteq N_1 \trianglelefteq \cdots \trianglelefteq N_k = G$$

all of whose factors N_{i+1}/N_i are *abelian*. Equivalently (for finite G) every composition factor is abelian, hence (composition factors are simple) every composition factor is $\cong \mathbb{Z}/p\mathbb{Z}$ for some prime p.

Remark 3.4.3 (Equivalent tests for finite G). For a finite group the following are equivalent: (i) G is solvable; (ii) G has a subnormal series with abelian factors; (iii) every composition factor of G is cyclic of prime order; (iv) the derived series $G \supseteq G' \supseteq G'' \supseteq \cdots$ reaches 1, where $G' = [G, G]$ is the commutator subgroup and $G^{(n+1)} = [G^{(n)}, G^{(n)}]$. We use (i)–(iii) below; (iv) is the "derived series" formulation.

Proposition 3.4.11 (Nonabelian simple ⇒ not solvable)**.** *If G is a nonabelian simple group then G is not solvable. In particular A_5 is not solvable.*

Proof. A nonabelian simple group G has exactly one composition series, $1 \trianglelefteq G$, whose only factor is $G/1 \cong G$ — nonabelian. By Jordan–Hölder these are the composition factors, and at least one (the only one) is nonabelian, so by the test (iii) above G is not solvable. □

Method (Testing solvability)**.** *Trigger.* "Is G solvable?" or "find a solvable/composition series."
Recipe.

1. Try to build a subnormal series with *abelian* factors (prime-order factors are automatically abelian). If you succeed, G is solvable.
2. Shortcut to "yes": G abelian ⇒ solvable; $|G| = p^a$ a prime power ⇒ solvable; $|G| = pq$, $p^2q, \ldots$ small orders are solvable (Sylow/Burnside).
3. Shortcut to "no": if G has *any* composition factor that is nonabelian simple (e.g. G contains a subnormal copy of A_5 as a factor, or G is itself nonabelian simple), then G is NOT solvable.
4. *Check.* Multiply factor orders to recover $|G|$; confirm each factor is $\mathbb{Z}/p\mathbb{Z}$ (solvable) or spot a nonabelian simple factor (not solvable).

Worked Example 3.4.12 (S_3 is solvable)**.** Show S_3 (order 6) is solvable and give a composition series.

Recognition. $A_3 \trianglelefteq S_3$ with index 2, and A_3 has prime order 3: both factors will be prime-order, hence abelian.

Solution. Use

$$1 \ \trianglelefteq\ A_3 \ \trianglelefteq\ S_3, \qquad A_3 = \langle (123) \rangle \cong \mathbb{Z}/3\mathbb{Z}.$$

Here $A_3 \trianglelefteq S_3$ (index 2), and $1 \trianglelefteq A_3$ trivially. Factors: $A_3/1 \cong \mathbb{Z}/3\mathbb{Z}$ and $S_3/A_3 \cong \mathbb{Z}/2\mathbb{Z}$. Both abelian (indeed simple of prime order), so S_3 is solvable; this is also its composition series, factors $\boxed{\mathbb{Z}/3\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z}}$. *Check.* $3 \cdot 2 = 6 = |S_3|$. (Derived-series view: $S_3' = A_3$, $A_3' = 1$, so the derived series $S_3 \supset A_3 \supset 1$ reaches 1 — consistent.)

Worked Example 3.4.13 (S_4 is solvable)**.** Show S_4 (order 24) is solvable by exhibiting a subnormal series with abelian factors.

Recognition. $S_4 \supset A_4 \supset V \supset \langle (12)(34) \rangle \supset 1$, where $V = \{1, (12)(34), (13)(24), (14)(23)\}$ is the Klein four-group. Indices $2, 3, 2, 2$ are prime, so all factors are prime-order abelian.

Solution. Take

$$1 \ \trianglelefteq\ \langle (12)(34) \rangle \ \trianglelefteq\ V \ \trianglelefteq\ A_4 \ \trianglelefteq\ S_4.$$

Normality and indices:

- $V \trianglelefteq A_4$ and $V \trianglelefteq S_4$ (V is the union of 1 and all three $(2,2)$-cycles, a full conjugacy-class-closed set; $|V| = 4$).
- $\langle (12)(34) \rangle \trianglelefteq V$: V is abelian (Klein four), so every subgroup is normal; $[V : \langle (12)(34) \rangle] = 4/2 = 2$.
- Indices up the chain: $[\langle (12)(34) \rangle : 1] = 2$, $[V : \langle (12)(34) \rangle] = 2$, $[A_4 : V] = 12/4 = 3$, $[S_4 : A_4] = 24/12 = 2$.

Factors: $\mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/3\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z}$, all of prime order, hence abelian and simple. So S_4 is solvable, and this is in fact a composition series. Factors $\boxed{\mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/3\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z}}$. *Check.* $2 \cdot 2 \cdot 3 \cdot 2 = 24 = |S_4|$. ■

Worked Example 3.4.14 (S_5 is NOT solvable)**.** Show S_5 (order 120) is not solvable.

Recognition. $A_5 \trianglelefteq S_5$ with A_5 nonabelian simple (stated theorem). A nonabelian simple composition factor blocks solvability.

Solution. The chain $1 \trianglelefteq A_5 \trianglelefteq S_5$ has $A_5 \trianglelefteq S_5$ of index 2. Since A_5 is *simple*, its only composition series is $1 \trianglelefteq A_5$, so a composition series of S_5 is

$$1 \ \trianglelefteq\ A_5 \ \trianglelefteq\ S_5,$$

with factors $A_5/1 \cong A_5$ and $S_5/A_5 \cong \mathbb{Z}/2\mathbb{Z}$. By Jordan–Hölder these (up to order and isomorphism) are *the* composition factors of S_5. The factor A_5 is nonabelian — for instance (123) and (124) lie in A_5 but do not commute, since $(123)(124) = (13)(24)$ while $(124)(123) = (14)(23)$ — hence A_5 is not of prime order. By the solvability test, S_5 is *not* solvable. *Check.* $|A_5| \cdot |\mathbb{Z}/2\mathbb{Z}| = 60 \cdot 2 = 120 = |S_5|$, and exactly one factor (A_5) is nonabelian simple. More generally S_n and A_n are not solvable for all $n \geq 5$, since A_n is then a nonabelian simple composition factor.

Worked Example 3.4.15 (Read the composition factors off a chain)**.** A finite group G has the subnormal series

$$1 \ \trianglelefteq\ \langle 12 \rangle \ \trianglelefteq\ \langle 4 \rangle \ \trianglelefteq\ \mathbb{Z}/60\mathbb{Z} =: G,$$

where $G = \mathbb{Z}/60\mathbb{Z}$ and the displayed terms have orders $1, 5, 15, 60$. List the composition factors and decide solvability.

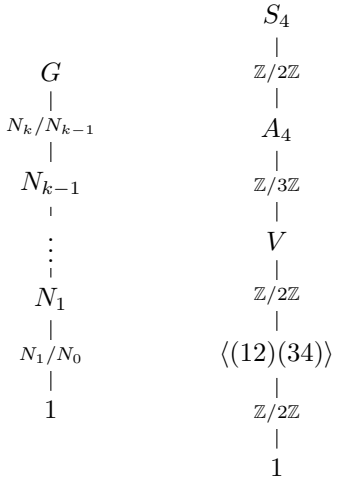
Recognition. Read each factor as the quotient of consecutive orders; a prime-order quotient is $\mathbb{Z}/p\mathbb{Z}$. Then apply the solvability test (all prime-order $\Rightarrow$ solvable).

Solution. Work additively in $\mathbb{Z}/60\mathbb{Z}$. Here $\langle 12 \rangle = \{0, 12, 24, 36, 48\}$ has order 5, and $\langle 4 \rangle$ has order 15 (with $12 = 3 \cdot 4 \in \langle 4 \rangle$, so $\langle 12 \rangle \leq \langle 4 \rangle$); all subgroups are normal since $\mathbb{Z}/60\mathbb{Z}$ is abelian. The successive orders are $1, 5, 15, 60$, so the factor orders are

$$5/1 = 5, \qquad 15/5 = 3, \qquad 60/15 = 4.$$

A factor of order 5 is $\mathbb{Z}/5\mathbb{Z}$ and of order 3 is $\mathbb{Z}/3\mathbb{Z}$ (prime, simple). The top factor has order 4, which is *not* prime — but a composition factor must be *simple*, and there is no simple group of order 4 ($\mathbb{Z}/4\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ are both non-simple). Hence the displayed chain is *not* a composition series as written: the top

step must be refined. Inserting the intermediate subgroup $\langle 2\rangle$ of order 30 between $\langle 4\rangle$ and $\mathbb{Z}/60\mathbb{Z}$ splits the order-4 gap into two order-2 steps ($[\langle 2\rangle : \langle 4\rangle] = 30/15 = 2$, $[\mathbb{Z}/60\mathbb{Z} : \langle 2\rangle] = 60/30 = 2$), giving genuine factors



$$\boxed{\mathbb{Z}/5\mathbb{Z},\ \mathbb{Z}/3\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z},\ \mathbb{Z}/2\mathbb{Z}}.$$

All factors are prime-order abelian, so G is solvable. *Check.* $5 \cdot 3 \cdot 2 \cdot 2 = 60 = |G|$. ■The lesson: every gap in a *composition* series must be a *simple* group; for an abelian (more generally, a solvable) group this means *prime* order, so a non-prime gap signals a missing refinement.

Caution. A factor of prime power order need not be simple. In a composition series each *factor* (quotient) must be *simple*; it has *prime* order exactly when it is abelian, as always happens for a solvable group, but a factor may also be nonabelian simple (e.g. A_5 in the composition series $1 \trianglelefteq A_5 \trianglelefteq S_5$). If you write a chain whose successive indices include a 4, 6, 8, or 9, it is a subnormal series but *not* a composition series (no simple group has any of these orders) — refine it until every factor is simple.

The subnormal series as a vertical chain, and two diagrams

A subnormal/composition series is best pictured as a vertical tower, each rung normal in the one above, labeled by its factor:

Each edge label is the composition factor of that step. Reading the right-hand tower top-to-bottom recovers the factor multiset $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$ of S_4 from the previous worked example.

Diagram explanation. Objects: Both diagrams contain groups arranged vertically. The left diagram is generic: G is a finite group at the top, $N_{k-1}, \ldots, N_1$ are successive normal subgroups, and 1 is the trivial group at the bottom. The right diagram is concrete: S_4 (order 24) at the top, then A_4 (alternating group, order 12), then the Klein four-group V (order 4), then $\langle(12)(34)\rangle$ (order 2), then 1.

Arrows: Each vertical dash (drawn with `dash`) represents a normal inclusion $N_i \trianglelefteq N_{i+1}$. It is an *inclusion map* $\iota : N_i \hookrightarrow N_{i+1}$, shown schematically as an undirected edge rather than an arrow to emphasize the *subnormal* (not necessarily globally normal) containment. The label on each edge is the *composition factor* N_{i+1}/N_i — the quotient group of that step.

What commutes: These are not square diagrams, so there is no commutativity condition in the usual sense. Instead, the key relation is that consecutive labels multiply to give the full group order: $|\mathbb{Z}/2\mathbb{Z}| \cdot |\mathbb{Z}/3\mathbb{Z}| \cdot |\mathbb{Z}/2\mathbb{Z}| \cdot |\mathbb{Z}/2\mathbb{Z}| = 24 = |S_4|$. Each label records the isomorphism type of the quotient N_{i+1}/N_i.

Why it commutes: The label N_{i+1}/N_i is well-defined because $N_i \trianglelefteq N_{i+1}$ (the subnormal condition), so the quotient group is an honest group. Well-definedness of the quotient requires N_i to be normal *in* N_{i+1}, not necessarily in all of G. In S_4: $\langle(12)(34)\rangle \trianglelefteq V$ because V is abelian; $V \trianglelefteq A_4$ because V is a union of full conjugacy classes in A_4; $A_4 \trianglelefteq S_4$ because $[S_4 : A_4] = 2$.

Why this matters here: This diagram records visually what a composition series *is*: a tower of groups, each normal in the one above, with each quotient (edge label) being a simple group. The right tower is the concrete

demonstration that the composition series $1 \trianglelefteq \langle(12)(34)\rangle \trianglelefteq V \trianglelefteq A_4 \trianglelefteq S_4$ found earlier is not just an algebraic list but a geometric chain of containments, and the factor multiset can be read directly off the edge labels.

Concrete example: For $\mathbb{Z}/8\mathbb{Z}$: the tower $1 \trianglelefteq \langle 4\rangle \trianglelefteq \langle 2\rangle \trianglelefteq \mathbb{Z}/8\mathbb{Z}$ has edge labels $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$. Each step has index 2, factor $\mathbb{Z}/2\mathbb{Z}$, and $2 \cdot 2 \cdot 2 = 8$. The tower diagram makes the factor multiset $\{\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}\}$ instantly visible.

Common pitfall: Students sometimes read the edge labels as claiming $N_i \cong N_{i+1}/N_i$ or that G is a *direct* product of the factors. Neither is true: the factors are the successive *quotients*, and the group G is an iterated extension — possibly non-split — of those factors. D_8 and $\mathbb{Z}/8\mathbb{Z}$ and Q_8 all have the same tower labels $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$ yet are non-isomorphic; the tower encodes factors, not the assembly.

Takeaway: The point of this diagram is that a composition series is a vertical tower whose edge labels are exactly the simple composition factors, giving a canonical group-theoretic "atomic decomposition" that Jordan–Hölder guarantees is unique up to reordering.

The single nontrivial step of a maximal normal subgroup gives a simple top factor, which is exactly a short exact sequence with simple quotient:

$$1 \longrightarrow M \hookrightarrow G \xrightarrow{\pi} G/M \longrightarrow 1 \qquad (G/M \text{ simple, by maximality of } M \lhd G).$$

Diagram explanation. Objects: Four objects appear. 1 is the trivial group (far left). M is a maximal proper normal subgroup of G. G is the ambient finite group. G/M is the quotient group, which is simple because M is maximal normal in G.

Arrows: Reading left to right: the leftmost arrow $1 \to M$ is the inclusion of the trivial group into M (the kernel of the next map). The arrow $M \hookrightarrow G$ (hook) is the inclusion map ι, which is injective. The arrow $G \twoheadrightarrow G/M$ (two heads, labeled π) is the canonical quotient/projection map $\pi(g) = gM$, which is surjective. The final arrow $G/M \to 1$ sends everything to 1. Together these four arrows form a *short exact sequence*.

What commutes: Exactness conditions at each interior node: $\mathrm{im}(1 \to M) = \ker(\iota) = \{1\}$ (the inclusion ι is injective, i.e. $\ker \iota = 1$); $\mathrm{im}(\iota) = M = \ker(\pi)$ (the image of the inclusion is exactly the kernel of the quotient map, since $\pi(g) = 1_{G/M} \iff gM = M \iff g \in M$); and $\mathrm{im}(\pi) = G/M = \ker(G/M \to 1)$ (the projection is surjective).

Why it commutes: Well-definedness of π: since $M \trianglelefteq G$, the coset multiplication $(aM)(bM) = (ab)M$ is independent of coset representatives. For a different representative am ($m \in M$), we get $(am)M = aM$ because $m \in M$, so π is well-defined on cosets. The exactness $\ker \pi = \mathrm{im}\, \iota = M$ holds by definition of the quotient map. The simplicity of G/M follows from the Lattice Isomorphism Theorem: normal subgroups of G/M correspond to normal subgroups of G containing M, and maximality of M ensures there are none strictly between M and G.

Why this matters here: This diagram encodes the single peeling step in the top-down construction of a composition series: given G, choose a maximal normal M and record the simple quotient G/M. The short exact sequence makes the roles of the maps explicit — M is the "kernel part" and G/M is the "simple top factor" — and shows the step produces a simple quotient by definition of maximality. Iterating this argument (applying it inside M, then inside M's maximal normal subgroup, etc.) builds the full composition series.

Concrete example: Take $G = S_4$, $M = A_4$. Then $[S_4 : A_4] = 2$, so $A_4 \trianglelefteq S_4$ and $S_4/A_4 \cong \mathbb{Z}/2\mathbb{Z}$, which is simple. The short exact sequence is $1 \to A_4 \to S_4 \xrightarrow{\mathrm{sgn}} \mathbb{Z}/2\mathbb{Z} \to 1$, where π is the sign homomorphism ($\ker \pi = A_4$, image $= \mathbb{Z}/2\mathbb{Z}$).

Common pitfall: Students sometimes think the short exact sequence $1 \to M \to G \to G/M \to 1$ means $G \cong M \times (G/M)$. This would require the sequence to *split*, which need not happen. For example, $1 \to \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 1$ does not split: $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. The diagram records the quotient structure, not a direct product.

Takeaway: The point of this diagram is that peeling a maximal normal subgroup M off G produces exactly a short exact sequence with a simple quotient G/M, and iterating this peeling process is precisely how a composition series is built top-down.

Iterating this — peeling off one simple quotient at a time — is precisely the top-down construction of a composition series in the Existence theorem.

Remark 3.4.4 (The Hölder program). Jordan–Hölder reduces the classification of all finite groups to two problems, jointly called the *Hölder program*:

(A) Classify the finite simple groups — the possible composition factors. This was completed (the Classification of Finite Simple Groups, ca. 2004): every finite simple group is cyclic of prime order, alternating A_n ($n \geq 5$), one of 16 infinite families of *Lie type*, or one of 26 *sporadic* groups (the largest being the Monster).

(B) The extension problem — given a multiset of simple composition factors, determine all groups G having exactly those factors (i.e. classify the ways to build G as iterated extensions). This is genuinely hard and largely open in general; the order-8 list $(\mathbb{Z}/8\mathbb{Z}, \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}^3, D_8, Q_8$, all with factors $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z})$ already shows one factor multiset can yield many groups.

Solvable groups are the case where (A) trivializes (all factors are $\mathbb{Z}/p\mathbb{Z}$); the entire content sits in (B).

Exercises (from the text).

1. Prove that if G is an abelian simple group then $G \cong \mathbb{Z}/p\mathbb{Z}$ for some prime p (do not assume G is a finite group).
2. Exhibit all 3 composition series for Q_8 and all 7 composition series for D_8. List the composition factors in each case.
3. Find a composition series for the quasidihedral group of order 16 (cf. Exercise 11, Section 2.5). Deduce that QD_{16} is solvable.
4. Use Cauchy's Theorem and induction to show that a finite abelian group has a subgroup of order n for each positive divisor n of its order.
5. Prove that subgroups and quotient groups of a solvable group are solvable.
6. Prove part (1) of the Jordan–Hölder Theorem by induction on $|G|$.
7. If G is a finite group and $H \trianglelefteq G$ prove that there is a composition series of G, one of whose terms is H.
8. Let G be a finite group. Prove that the following are equivalent: (i) G is solvable (ii) G has a chain of subgroups $1 = H_0 \trianglelefteq H_1 \trianglelefteq H_2 \trianglelefteq \ldots \trianglelefteq H_s = G$ such that H_{i+1}/H_i is cyclic, $0 \leq i \leq s-1$ (iii) all composition factors of G are of prime order (iv) G has a chain of subgroups $1 = N_0 \leq N_1 \leq N_2 \leq \cdots \leq N_s = G$ such that each N_i is a normal subgroup of G and N_{i+1}/N_i is abelian, $0 \leq i \leq s-1$. [For (iv), prove that a minimal normal subgroup M of G is necessarily abelian and then use induction. To see that M is abelian, let $N \trianglelefteq M$ be of prime index (by (iii)) and show that $x^{-1}y^{-1}xy \in N$ for all $x, y \in M$ (cf. Exercise 40, Section 1). Apply the same argument to gNg^{-1} to show that $x^{-1}y^{-1}xy$ lies in the intersection of all G-conjugates of N, and use the minimality of M to conclude that $x^{-1}y^{-1}xy = 1$.]
9. Prove the following special case of part (2) of the Jordan–Hölder Theorem: assume the finite group G has two composition series $1 = N_0 \trianglelefteq N_1 \trianglelefteq \ldots \trianglelefteq N_r = G$ and $1 = M_0 \trianglelefteq M_1 \trianglelefteq M_2 = G$. Show that $r = 2$ and that the list of composition factors is the same. [Use the Second Isomorphism Theorem.]
10. Prove part (2) of the Jordan–Hölder Theorem by induction on $\min\{r, s\}$. [Apply the inductive hypothesis to $H = N_{r-1} \cap M_{s-1}$ and use the preceding exercise.]
11. Prove that if H is a nontrivial normal subgroup of the solvable group G then there is a nontrivial subgroup A of H with $A \trianglelefteq G$ and A abelian.
12. Prove (without using the Feit–Thompson Theorem) that the following are equivalent: (i) every group of odd order is solvable (ii) the only simple groups of odd order are those of prime order.

Practice problems (additional).

1. Exhibit a composition series for $\mathbb{Z}/60\mathbb{Z}$ and verify that the successive quotients are simple. How many distinct composition series does $\mathbb{Z}/60\mathbb{Z}$ have (i.e. how many distinct chains, two chains being the same only if they consist of the same subgroups in the same order)?

2. Find all composition factors of the dihedral group D_{16} (order 16). Is the list of factors the same as for $\mathbb{Z}/16\mathbb{Z}$? Explain in light of the Jordan–Hölder theorem.

3. Write down a composition series for S_4. Identify each composition factor as a specific simple group, and confirm the product of the factor orders equals 24.

4. Show that A_4 has no subgroup of order 6. Show that the chain $1 \lhd \langle (1\,2)(3\,4) \rangle \lhd V \lhd A_4$ (where V is the Klein four-group) is a composition series, and name its factors. Explain why the shorter chain $1 \lhd V \lhd A_4$ is *not* a composition series.

5. Prove that every group of order p^n (p prime) is solvable by exhibiting a composition series all of whose factors are isomorphic to $\mathbb{Z}/p\mathbb{Z}$.

6. Let G be a finite group with a composition series $1 = N_0 \lhd N_1 \lhd \cdots \lhd N_k = G$. Prove that $|G| = \prod_{i=1}^{k} |N_i/N_{i-1}|$.

7. Show that $\mathbb{Z}$ (the infinite cyclic group) has no composition series.

8. Determine whether each of the following is solvable, giving a normal series with abelian factors when it is: (a) D_{2n} for every n; (b) S_3; (c) S_5; (d) the quaternion group Q_8.

9. Compute $\operatorname{sgn}(\sigma)$ for $\sigma = (1\,2\,3\,4\,5)(6\,7)$ in S_7, and state whether $\sigma \in A_7$.

10. Let G be solvable and $H \leq G$. Prove that H is solvable.

11. Let $N \trianglelefteq G$. Prove that G is solvable if and only if both N and G/N are solvable.

12. Show that the commutator subgroup $G' = \langle [x,y] \mid x, y \in G \rangle$ is normal in G and that G/G' is abelian. Conclude that G' is the smallest normal subgroup with abelian quotient.

13. For $G = S_4$, compute the derived series $G \supseteq G^{(1)} \supseteq G^{(2)} \supseteq \cdots$ explicitly, identifying each term, and use it to confirm S_4 is solvable.

14. Prove that a finite abelian group is solvable, and that its composition length equals the total number of prime factors of $|G|$ counted with multiplicity.

15. Let G be a group of order $p^2 q$ with p, q distinct primes. Without invoking Sylow theory beyond counting, argue that G is solvable. (You may assume the result that every group of order $p^a q^b$ is solvable.)

Additional exercises.

1. Prove the Jordan–Hölder theorem in the special case $|G| = p^3$ (p prime): show directly that any two composition series of such a G have the same length and isomorphic factors (all isomorphic to $\mathbb{Z}/p\mathbb{Z}$).

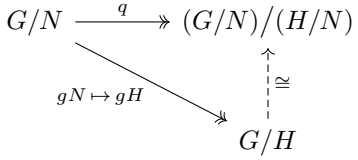
2. Let G be a nontrivial finite solvable group. Prove that G contains a nontrivial abelian normal subgroup. (Hint: consider the last nontrivial term of the derived series.)

3. Show that A_5 is simple by proving it has no nontrivial proper normal subgroup, and deduce that A_5 is not solvable. Conclude S_5 is not solvable.

4. Let G be a finite group such that every composition factor of G is cyclic of prime order. Prove that G is solvable, and conversely.

5. Suppose G has normal subgroups H and K with $G = HK$ and $H \cap K = 1$. Prove that if H and K are both solvable then G is solvable, and that the composition factors of G are exactly those of H together with those of K.

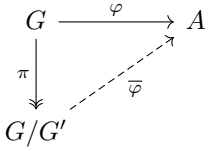
6. Let $\varphi : G \to H$ be a surjective homomorphism of finite groups. Prove that if G is solvable then H is solvable, and exhibit by example that the converse fails.



Commutative-diagram exercises.

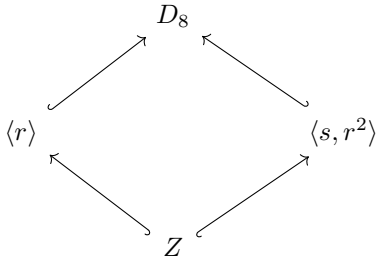
1. For a composition series $1 = N_0 \lhd N_1 \lhd N_2 = G$ with simple factors, complete and justify the short exact sequence

$$1 \longrightarrow N_1 \hookrightarrow G \xrightarrow{\pi} G/N_1 \longrightarrow 1$$



explaining why N_1 and G/N_1 are simple. Take $G = S_3$, $N_1 = A_3$, and label the maps concretely.

2. Let $N \trianglelefteq G$ and $H \trianglelefteq G$ with $N \leq H$. Using the lattice (third isomorphism) correspondence, justify the induced surjection in



and prove the dashed map is an isomorphism.

3. Let $\varphi : G \to A$ be a homomorphism into an abelian group A. Prove that φ factors uniquely through the abelianization, i.e. fill in the unique dashed map in

and show $\overline{\varphi}(gG') = \varphi(g)$ is well defined.

4. For $G = D_8$ (order 8) with center $Z = \langle r^2 \rangle$, build the diamond

Compute all four quotients along the edges, verify each is $\mathbb{Z}/2\mathbb{Z}$, and use this to read off a composition series for D_8.

5. Let $1 \lhd N_1 \lhd N_2 \lhd N_3 = G$ be a composition series. Arrange the three short exact sequences

$$1 \longrightarrow N_1 \hookrightarrow N_2 \twoheadrightarrow N_2/N_1 \longrightarrow 1$$

(and the analogous ones for $N_2 \lhd N_3$) and prove that the simple groups N_i/N_{i-1} are, up to reordering and isomorphism, independent of the chosen series. State which theorem you are invoking.

3.5 Transpositions and the Alternating Group

The sign homomorphism and the alternating group

This section makes precise the notion of an *even* or *odd* permutation. We first show every permutation is built from transpositions, then prove the parity of the number of transpositions used is an invariant of the permutation (not of the factorization). This invariant is packaged as a homomorphism $\operatorname{sgn}\colon S_n \to \{\pm 1\}$ whose kernel is the alternating group A_n.

Theorem 3.5.1 (Transpositions generate S_n)**.** *For $n \geq 2$, every element of S_n is a product of transpositions; that is, the transpositions $(a\ b)$ generate S_n. More precisely, a k-cycle is a product of $k-1$ transpositions:*

$$(a_1\ a_2\ \cdots\ a_k) = (a_1\ a_k)(a_1\ a_{k-1}) \cdots (a_1\ a_3)(a_1\ a_2).$$

Proof. First check the displayed factorization. Permutations compose right-to-left, so apply the right factor $(a_1\ a_2)$ first. Track where each symbol goes under the product $(a_1\ a_k)(a_1\ a_{k-1})\cdots(a_1\ a_2)$.

For a_i with $2 \le i \le k-1$: only the two transpositions $(a_1\ a_i)$ and $(a_1\ a_{i+1})$ move a_i. Reading right-to-left, the first transposition touching a_i is $(a_1\ a_i)$, which sends $a_i \mapsto a_1$; then $(a_1\ a_{i+1})$ sends $a_1 \mapsto a_{i+1}$; no later transposition contains a_{i+1}, so a_{i+1} is not moved again. Hence $a_i \mapsto a_{i+1}$, as required for the cycle. For a_1: the rightmost transposition $(a_1\ a_2)$ sends $a_1 \mapsto a_2$, and no later factor contains a_2, so $a_1 \mapsto a_2$. For a_k: only the leftmost factor $(a_1\ a_k)$ contains a_k; reading right-to-left a_k is untouched until that last factor sends $a_k \mapsto a_1$. So $a_k \mapsto a_1$. This is exactly the k-cycle, and it uses $k-1$ transpositions.

Since every permutation is a product of disjoint cycles (Section 1.3), and each cycle is a product of transpositions by the above, every permutation is a product of transpositions. (A fixed point, i.e. a 1-cycle, contributes 0 transpositions, consistent with $k-1=0$.) The identity is the empty product, or $(a\ b)(a\ b)$. □

Method (Writing a permutation as a product of transpositions)**.** *Trigger.* You are asked for a transposition factorization, or you need the parity of σ.

Recipe.

1. Write σ in disjoint cycle notation.
2. Replace each k-cycle $(a_1\, a_2\, \cdots\, a_k)$ by the $k-1$ transpositions $(a_1\ a_k)(a_1\ a_{k-1})\cdots(a_1\ a_2)$.
3. Concatenate. The total number of transpositions is $\sum(k_i - 1)$ over the cycles.

Worked Example 3.5.2 (Transposition factorization of a 5-cycle)**.** Write $\sigma = (1\ 3\ 5\ 2\ 4) \in S_5$ as a product of transpositions.

Recognition. A k-cycle equals $k-1$ transpositions via the standard "pivot on the first entry" formula.

Solution. Here $k=5$, pivot $a_1 = 1$:

$$(1\ 3\ 5\ 2\ 4) = (1\ 4)(1\ 2)(1\ 5)(1\ 3).$$

Check. Compose right-to-left on each symbol. $1 \xrightarrow{(1\ 3)} 3$, untouched after, so $1 \mapsto 3$. $3 \xrightarrow{(1\ 3)} 1 \xrightarrow{(1\ 5)} 5$, so $3 \mapsto 5$. $5 \xrightarrow{(1\ 5)} 1 \xrightarrow{(1\ 2)} 2$, so $5 \mapsto 2$. $2 \xrightarrow{(1\ 2)} 1 \xrightarrow{(1\ 4)} 4$, so $2 \mapsto 4$. $4 \xrightarrow{(1\ 4)} 1$, so $4 \mapsto 1$. This is $(1\ 3\ 5\ 2\ 4)$. Used $4 = k-1$ transpositions.

Worked Example 3.5.3 (A product of disjoint cycles)**.** Factor $\tau = (1\ 2\ 3)(4\ 5\ 6\ 7) \in S_7$ into transpositions and count them.

Recognition. Factor each disjoint cycle separately; a 3-cycle uses 2, a 4-cycle uses 3.

Solution.

$$(1\ 2\ 3) = (1\ 3)(1\ 2), \qquad (4\ 5\ 6\ 7) = (4\ 7)(4\ 6)(4\ 5).$$

So $\tau = (1\ 3)(1\ 2)(4\ 7)(4\ 6)(4\ 5)$, a product of $2+3=5$ transpositions. *Check.* $(1\ 3)(1\ 2)$: $1 \mapsto 2,\ 2 \mapsto 3,\ 3 \mapsto 1$, correct; $(4\ 7)(4\ 6)(4\ 5)$: $4 \mapsto 5,\ 5 \mapsto 6,\ 6 \mapsto 7,\ 7 \mapsto 4$, correct.

Worked Example 3.5.4 (Non-canonical factorizations have the same parity)**.** Show $(1\ 2\ 3)$ can be written with both 2 and 4 transpositions, but never with 3.

Recognition. Factorizations are not unique, but the *parity* of the count is forced (next theorem).

Solution. Canonical: $(1\ 2\ 3) = (1\ 3)(1\ 2)$, two transpositions. Insert a redundant pair $(1\ 2)(1\ 2) = 1$ at the front: $(1\ 2\ 3) = (1\ 2)(1\ 2)(1\ 3)(1\ 2)$, four transpositions. Both counts are even. By the parity theorem below, no factorization of $(1\ 2\ 3)$ has an odd number of factors; in particular none has 3. *Check.* $(1\ 2)(1\ 2) = 1$ so the second product collapses to the first.

Worked Example 3.5.5 (Factoring a single transposition and the identity)**.** Write the transposition $(2\ 5) \in S_5$ and the identity $e \in S_5$ as products of transpositions, and record the transposition counts.

Recognition. A transposition is already a 1-fold product (count 1); the identity is the empty product (count 0), or any even product such as $(a\ b)(a\ b)$.

Solution. The transposition $(2\ 5)$ is itself a single transposition, count 1 (odd). The identity $e = (1\ 5)(1\ 5)$, a product of 2 transpositions, count 2 (even); the empty product also represents e with count 0. *Check.* $(2\ 5)$ is a 2-cycle, so $k-1=1$ transposition, matching. And $(1\ 5)(1\ 5)$: $1 \mapsto 5 \mapsto 1$ and $5 \mapsto 1 \mapsto 5$, fixing everything, so it equals e; both 0 and 2 are even, consistent with the parity theorem below.

Caution. A k-cycle is a product of $k-1$ transpositions, *not* k. So a 3-cycle is *even* (two transpositions), a 4-cycle is *odd*, a 2-cycle (transposition) is odd. The off-by-one error "k-cycle $= k$ transpositions" flips every parity you compute.

Theorem 3.5.6 (Parity is well defined; the sign homomorphism)**.** *For $n \geq 2$ there is a (surjective) homomorphism*

$$\operatorname{sgn}\colon S_n \longrightarrow \{\pm 1\}$$

onto the multiplicative group $\{\pm 1\}$ with the property that $\operatorname{sgn}(\tau) = -1$ for every transposition τ. Consequently, if a permutation σ is written as a product of m transpositions, then $\operatorname{sgn}(\sigma) = (-1)^m$, so the parity of m depends only on σ. We call σ even *if $\operatorname{sgn}(\sigma) = +1$ and* odd *if $\operatorname{sgn}(\sigma) = -1$.*

Proof. Let the polynomial in independent variables $x_1, \ldots, x_n$ be

$$\Delta = \prod_{1 \leq i < j \leq n} (x_i - x_j).$$

For $\sigma \in S_n$ define $\sigma \cdot \Delta = \prod_{i<j}(x_{\sigma(i)} - x_{\sigma(j)})$. Each factor $x_i - x_j$ of Δ appears in $\sigma \cdot \Delta$ as $\pm(x_a - x_b)$ for a unique unordered pair $\{a, b\}$, so $\sigma \cdot \Delta = \pm\Delta$. Define $\operatorname{sgn}(\sigma) \in \{\pm 1\}$ by $\sigma \cdot \Delta = \operatorname{sgn}(\sigma)\,\Delta$.

Homomorphism. The action satisfies $(\sigma\tau)\cdot\Delta = \sigma\cdot(\tau\cdot\Delta) = \sigma\cdot(\operatorname{sgn}(\tau)\Delta) = \operatorname{sgn}(\tau)(\sigma\cdot\Delta) = \operatorname{sgn}(\tau)\operatorname{sgn}(\sigma)\Delta = \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau)\Delta$. Comparing with $(\sigma\tau)\cdot\Delta = \operatorname{sgn}(\sigma\tau)\Delta$ gives $\operatorname{sgn}(\sigma\tau) = \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau)$.

A transposition has sign -1. Take $\tau = (a\ b)$ with $a < b$. Swapping a, b in Δ negates the factor $(x_a - x_b)$. The factors $(x_i - x_a)$ and $(x_i - x_b)$ for $i \notin \{a, b\}$ are interchanged in pairs, contributing no net sign, and likewise the remaining factors are fixed; a careful count (D&F) shows exactly an odd number of sign flips in total, so $\tau \cdot \Delta = -\Delta$, i.e. $\operatorname{sgn}(\tau) = -1$.

Surjective and the parity statement. sgn takes the value -1 (any transposition) and $+1$ (the identity), so it is onto. If $\sigma = \tau_1 \cdots \tau_m$ with each τ_i a transposition, then $\operatorname{sgn}(\sigma) = \prod_i \operatorname{sgn}(\tau_i) = (-1)^m$. Since the left side depends only on σ, so does the parity of m. □

Definition 3.5.7 (Alternating group)**.** The *alternating group* A_n is the set of even permutations in S_n:

$$A_n = \ker(\operatorname{sgn}) = \{\sigma \in S_n : \operatorname{sgn}(\sigma) = +1\}.$$

Theorem 3.5.8 (Structure of A_n)**.** *For $n \geq 2$, $A_n \trianglelefteq S_n$, the quotient $S_n/A_n \cong \{\pm 1\}$ has order 2, and*

$$[S_n : A_n] = 2, \qquad |A_n| = \frac{n!}{2}.$$

Proof. $A_n = \ker(\operatorname{sgn})$ is the kernel of a homomorphism, hence a normal subgroup of S_n. By the First Isomorphism Theorem $S_n/\ker(\operatorname{sgn}) \cong \operatorname{im}(\operatorname{sgn}) = \{\pm 1\}$, which has order 2, so $[S_n : A_n] = |S_n/A_n| = 2$. Then $|A_n| = |S_n|/2 = n!/2$. □

The structure is summarized by the short exact sequence

$$1 \longrightarrow A_n \hookrightarrow S_n \xrightarrow{\ \operatorname{sgn}\ } \{\pm 1\} \longrightarrow 1,$$

Diagram explanation. Objects: Five nodes. The trivial group 1 appears at each end (boundary terms). A_n is the alternating group, a normal subgroup of S_n of index 2. S_n is the full symmetric group on n letters. $\{\pm 1\}$ is the multiplicative group of order 2.

Arrows: Left $1 \to A_n$: inclusion of the trivial group (sends the single element to the identity of A_n; records that 1 is a subgroup of A_n). $A_n \hookrightarrow S_n$: the inclusion map (hook arrow), injective, sends each even permutation to itself inside S_n. $S_n \twoheadrightarrow \{\pm 1\}$: the surjective sign homomorphism $\operatorname{sgn}(\sigma)$, which assigns $+1$ to even and -1 to odd permutations. Right $\{\pm 1\} \to 1$: collapse of everything to the trivial group.

What commutes: This is a short exact sequence; commutativity of composites is not the primary content. Instead, exactness at each internal node: at A_n, $\operatorname{im}(1 \to A_n) = 1 = \ker(A_n \to S_n)$ (inclusion is injective); at S_n, $\operatorname{im}(A_n \to S_n) = A_n = \ker(\operatorname{sgn})$ (the kernel of sgn is exactly A_n); at $\{\pm 1\}$, $\operatorname{im}(\operatorname{sgn}) = \{\pm 1\} = \ker(\{\pm 1\} \to 1)$ (sgn is surjective).

Why it commutes: The central exactness $\ker(\text{sgn}) = A_n$ is the content of the parity theorem: any even permutation has sgn $= +1$, which is precisely the definition of $A_n = \ker(\text{sgn})$. Surjectivity holds because a single transposition achieves sgn $= -1$ and the identity achieves $+1$.

Why this matters here: This diagram summarizes the entire Section 3.5 narrative in one line: A_n is not merely "the even permutations" but the kernel of an explicit group homomorphism, which forces it to be normal and forces the quotient to be $\{\pm 1\}$. The short exact sequence is the standard algebraic packaging of "A_n is normal with cyclic-of-order-2 quotient."

Concrete example: For $n = 3$: $1 \to A_3 \cong \mathbb{Z}/3 \to S_3 \xrightarrow{\text{sgn}} \{\pm 1\} \to 1$. $A_3 = \{e, (1\,2\,3), (1\,3\,2)\}$; sgn sends the three odd elements $(1\,2), (1\,3), (2\,3)$ to -1 and the rest to $+1$, and the kernel is exactly A_3.

Common pitfall: Students sometimes read exactness at S_n as saying $A_n = S_n$ or that sgn is injective. Exactness at S_n only says $\ker(\text{sgn}) = \text{im}(A_n \to S_n) = A_n$; sgn itself is far from injective (its kernel has order $n!/2$).

Takeaway: The point of this diagram is that A_n is characterized as the kernel of the sign homomorphism, making its normality in S_n and the isomorphism $S_n/A_n \cong \{\pm 1\}$ immediate consequences of the First Isomorphism Theorem.

and the induced isomorphism out of the quotient is the dashed map below:

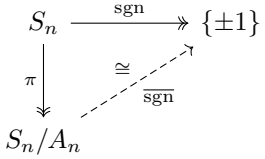


Diagram explanation. Objects: Three nodes. S_n is the full symmetric group (upper-left). $\{\pm 1\}$ is the two-element multiplicative group (upper-right). S_n/A_n is the quotient group whose elements are the two cosets A_n (even permutations) and $(1\,2)A_n$ (odd permutations) (lower-left). It is an abstract group of order 2, not yet identified with $\{\pm 1\}$.

Arrows: $\text{sgn}\colon S_n \to \{\pm 1\}$ (top, solid, double-headed): the sign homomorphism, surjective. $\pi\colon S_n \twoheadrightarrow S_n/A_n$ (left, double-headed): the canonical surjective quotient map $\sigma \mapsto \sigma A_n$, well-defined since $A_n \trianglelefteq S_n$. $\overline{\text{sgn}}\colon S_n/A_n \to \{\pm 1\}$ (diagonal, dashed): the induced map $\sigma A_n \mapsto \text{sgn}(\sigma)$, asserted to be an isomorphism.

What commutes: $\text{sgn} = \overline{\text{sgn}} \circ \pi$: both paths from S_n to $\{\pm 1\}$ agree. Explicitly, going $S_n \xrightarrow{\pi} S_n/A_n \xrightarrow{\overline{\text{sgn}}} \{\pm 1\}$ sends $\sigma \mapsto \sigma A_n \mapsto \text{sgn}(\sigma)$, which equals the direct map $\text{sgn}(\sigma)$.

Why it commutes: Well-definedness of $\overline{\text{sgn}}$ is the key point: if $\sigma A_n = \tau A_n$ then $\tau^{-1}\sigma \in A_n$, so $\text{sgn}(\tau^{-1}\sigma) = +1$, giving $\text{sgn}(\sigma) = \text{sgn}(\tau)$. Hence the output depends only on the coset, not the representative. Once well-defined, $\overline{\text{sgn}}(\sigma A_n) = \text{sgn}(\sigma)$ by design, so the triangle commutes.

Why this matters here: This is the First Isomorphism Theorem applied to sgn: every surjective homomorphism $\phi\colon G \to H$ factors uniquely through $G/\ker\phi$ via an isomorphism. Here $\ker(\text{sgn}) = A_n$, so $\overline{\text{sgn}}$ is that canonical isomorphism. The diagram records that S_n/A_n and $\{\pm 1\}$ are not just abstractly isomorphic but concretely identified via the sign.

Concrete example: $n = 3$: $S_3/A_3 \cong \{\pm 1\}$. Take $\sigma = (1\,2)$ (odd). Then $\pi(\sigma) = (1\,2)A_3$, the coset of odd permutations, and $\overline{\text{sgn}}((1\,2)A_3) = -1 = \text{sgn}((1\,2))$. Take $\sigma = (1\,2\,3)$ (even): $\overline{\text{sgn}}(A_3) = +1 = \text{sgn}((1\,2\,3))$. Both paths agree.

Common pitfall: The dashed arrow $\overline{\text{sgn}}$ is NOT the same map as sgn; it has a different domain (S_n/A_n, not S_n). Students sometimes write $\overline{\text{sgn}}(\sigma)$ when they mean $\overline{\text{sgn}}(\sigma A_n)$. Also, one must check well-definedness before calling $\overline{\text{sgn}}$ a map at all — the diagram only *commutes* after that check.

Takeaway: The point of this diagram is that the sign homomorphism factors through the quotient S_n/A_n via a canonical isomorphism, making $S_n/A_n \cong \{\pm 1\}$ not just a size coincidence but a structural identity encoded by sgn.

Method (Computing parity from cycle structure)**.** *Trigger.* You need $\text{sgn}(\sigma)$ or to decide whether $\sigma \in A_n$.

Recipe. Write σ as disjoint cycles of lengths $k_1, \ldots, k_r$ (include or ignore fixed points; they contribute 0). Then

$$\operatorname{sgn}(\sigma) = (-1)^{\sum_i (k_i - 1)} = \prod_i (-1)^{k_i - 1}.$$

Equivalently: a k-cycle is *even iff k is odd*. So count the cycles of *even* length; σ is odd iff that count is odd.

Worked Example 3.5.9 (Sign of a k-cycle)**.** Compute sgn of a 6-cycle and of a 7-cycle.

Recognition. A k-cycle is $k-1$ transpositions, so $\operatorname{sgn} = (-1)^{k-1}$; even iff k odd.

Solution. 6-cycle: $\operatorname{sgn} = (-1)^{6-1} = (-1)^5 = -1$, odd. 7-cycle: $\operatorname{sgn} = (-1)^{7-1} = (-1)^6 = +1$, even. *Check.* A 7-cycle = 6 transpositions, an even count, so even. A 6-cycle = 5 transpositions, odd. Consistent.

Worked Example 3.5.10 (Sign of a product of disjoint cycles)**.** Find $\operatorname{sgn}(\sigma)$ for $\sigma = (1\ 2\ 3)(4\ 5)(6\ 7\ 8\ 9) \in S_9$.

Recognition. Multiplicativity of sgn on disjoint cycles: multiply $(-1)^{k_i - 1}$.

Solution. Lengths $3, 2, 4$. Transposition counts $2, 1, 3$; total 6. $\operatorname{sgn}(\sigma) = (-1)^6 = +1$, so σ is *even*, $\sigma \in A_9$. *Check via even-length cycles:* the even-length cycles are $(4\ 5)$ and $(6\ 7\ 8\ 9)$, two of them; 2 is even, so σ is even. Agrees.

Worked Example 3.5.11 (Multiplicativity directly)**.** Verify $\operatorname{sgn}(\sigma\tau) = \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau)$ for $\sigma = (1\ 2\ 3)$, $\tau = (2\ 3\ 4)$ in S_4.

Recognition. sgn is a homomorphism; check by computing the product permutation independently.

Solution. $\operatorname{sgn}(\sigma) = (-1)^2 = +1$, $\operatorname{sgn}(\tau) = (-1)^2 = +1$, so the predicted sign is $(+1)(+1) = +1$. Now compute $\sigma\tau$ (apply τ first): $1 \xrightarrow{\tau} 1 \xrightarrow{\sigma} 2$; $2 \xrightarrow{\tau} 3 \xrightarrow{\sigma} 1$; $3 \xrightarrow{\tau} 4 \xrightarrow{\sigma} 4$; $4 \xrightarrow{\tau} 2 \xrightarrow{\sigma} 3$. So $\sigma\tau = (1\ 2)(3\ 4)$, with $\operatorname{sgn} = (-1)^2 = +1$. *Check.* Predicted $+1$ matches computed $+1$.

Worked Example 3.5.12 (An odd permutation)**.** Is $\sigma = (1\ 4)(2\ 5\ 3)(6\ 7\ 8\ 9\ 10) \in S_{10}$ even or odd?

Recognition. Count $\sum(k_i - 1)$ and read parity.

Solution. Lengths $2, 3, 5$; transposition counts $1, 2, 4$; total 7. $\operatorname{sgn}(\sigma) = (-1)^7 = -1$, *odd. Check via even-length cycles:* only $(1\ 4)$ has even length; one such cycle, an odd count, so σ is odd. Agrees.

Worked Example 3.5.13 (Sign and the determinant connection)**.** Show sgn agrees with the sign appearing in the Leibniz formula for det on a small case: compute sgn of the permutation $\sigma = (1\ 3\ 2) \in S_3$ and confirm it equals $+1$.

Recognition. A 3-cycle is two transpositions, hence even.

Solution. $(1\ 3\ 2) = (1\ 2)(1\ 3)$, two transpositions, $\operatorname{sgn} = (-1)^2 = +1$. *Check.* The three even permutations of S_3 are $e, (1\ 2\ 3), (1\ 3\ 2)$, forming $A_3 = \langle (1\ 2\ 3) \rangle \cong \mathbb{Z}/3\mathbb{Z}$; $(1\ 3\ 2)$ is in this list, so it is even. Also $|A_3| = 3!/2 = 3$, consistent.

Proposition 3.5.14 (A_4 has no subgroup of order 6)**.** *The group A_4 (order 12) has no subgroup of order 6. In particular the converse of Lagrange's theorem fails: a divisor $d \mid |G|$ need not be the order of a subgroup.*

Proof. Suppose $H \leq A_4$ with $|H| = 6$. Then $[A_4 : H] = 12/6 = 2$, so $H \trianglelefteq A_4$ (any index-2 subgroup is normal). The elements of A_4 are: the identity, the three double transpositions $(1\ 2)(3\ 4), (1\ 3)(2\ 4), (1\ 4)(2\ 3)$ (order 2), and the eight 3-cycles (order 3). A group of order 6 contains an element of order 3 (e.g. by Cauchy, or because the only groups of order 6 are $\mathbb{Z}/6\mathbb{Z}$ and S_3, both of which do), so H contains some 3-cycle g.

Since $H \trianglelefteq A_4$, H is a union of A_4-conjugacy classes. A normal subgroup containing one 3-cycle contains its inverse and all A_4-conjugates of both. The eight 3-cycles form two A_4-conjugacy classes of size 4 (the class of $(1\ 2\ 3)$ is $\{(1\ 2\ 3), (1\ 3\ 4), (1\ 4\ 2), (2\ 4\ 3)\}$), and inverting the elements of one class gives the other; so the A_4-conjugates of g and of g^{-1} together are all eight 3-cycles. Then $|H| \geq 1 + 8 = 9 > 6$, a contradiction.

(Alternatively and cleanly: if $|H| = 6$ then $[A_4 : H] = 2$, so $g^2 \in H$ for every $g \in A_4$. But each 3-cycle g has order 3, so $g = g^4 = (g^2)^2 \in H$; thus H contains all eight 3-cycles, giving $|H| \geq 9$, impossible.) $\square$

Remark 3.5.1. The clean argument is worth isolating: in any group G with $H \leq G$ of index 2, the quotient G/H has order 2, so $x^2 \in H$ for all $x \in G$. Applied to $G = A_4$, every 3-cycle g satisfies $g = (g^2)^2 \in H$, so all 3-cycles lie in H; with the identity that is at least 9 elements, exceeding 6.

Worked Example 3.5.15 (Verifying the index-2 squaring trick)**.** Inside A_4, let $g = (1\ 2\ 3)$. Show $g = (g^2)^2$ and identify g^2.

Recognition. Index-2 subgroups contain all squares; for order-3 elements squaring is invertible, so g itself is a square of a square.

Solution. $g = (1\ 2\ 3)$, $g^2 = (1\ 3\ 2)$ (since $g^3 = e$). Then $(g^2)^2 = g^4 = g^3 \cdot g = g = (1\ 2\ 3)$. *Check.* Compute $(1\ 3\ 2)(1\ 3\ 2)$ directly: $1 \mapsto 3 \mapsto 2$, $3 \mapsto 2 \mapsto 1$, $2 \mapsto 1 \mapsto 3$, giving $(1\ 2\ 3) = g$. Confirmed, so any index-2 H would contain g.

Remark 3.5.2 (The whole alternating group as a kernel). The sign map realizes A_n as the kernel of the simplest nontrivial homomorphism out of S_n. The diagram

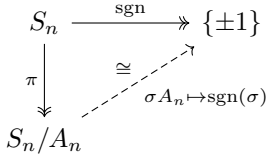

Diagram explanation. Objects: Three nodes, identical to the earlier factorization triangle. S_n is the symmetric group (upper-left). $\{\pm 1\}$ is the sign group (upper-right). S_n/A_n is the two-element quotient group whose two cosets are the even permutations (the class A_n) and the odd permutations (the class $(1\,2)A_n$) (lower-left).

Arrows: $\mathrm{sgn}\colon S_n \twoheadrightarrow \{\pm 1\}$ (top): the surjective sign homomorphism; both arrowheads indicate surjectivity. $\pi\colon S_n \twoheadrightarrow S_n/A_n$ (left): the canonical projection $\sigma \mapsto \sigma A_n$, also surjective. The dashed diagonal $S_n/A_n \xrightarrow{\sim} \{\pm 1\}$: the induced isomorphism with the explicit formula $\sigma A_n \mapsto \mathrm{sgn}(\sigma)$ written on the arrow.

What commutes: $\mathrm{sgn} = (\sigma A_n \mapsto \mathrm{sgn}(\sigma)) \circ \pi$. Explicitly: $\sigma \mapsto \sigma A_n \mapsto \mathrm{sgn}(\sigma)$, which equals $\mathrm{sgn}(\sigma)$ directly. The labelled formula on the dashed arrow makes the commutativity a definition rather than a claim.

Why it commutes: Well-definedness: if $\sigma A_n = \tau A_n$ then $\sigma^{-1}\tau \in A_n = \ker(\mathrm{sgn})$, so $\mathrm{sgn}(\tau) = \mathrm{sgn}(\sigma)$. Thus $\mathrm{sgn}(\sigma)$ depends only on the coset σA_n, making the formula $\sigma A_n \mapsto \mathrm{sgn}(\sigma)$ a genuine map. With that, the triangle commutes by the definition of the induced map. Uniqueness: any map $\phi\colon S_n/A_n \to \{\pm 1\}$ with $\phi \circ \pi = \mathrm{sgn}$ must satisfy $\phi(\sigma A_n) = \mathrm{sgn}(\sigma)$, forcing ϕ to equal the displayed formula.

Why this matters here: This remark makes explicit the universal property of the quotient group: S_n/A_n is the "most efficient" group through which sgn factors. The label on the dashed arrow also highlights that the cosets—not individual permutations—are the inputs, reinforcing that S_n/A_n organizes permutations by parity.

Concrete example: $n = 4$: $S_4/A_4 \cong \{\pm 1\}$. The coset A_4 (twelve even permutations) maps to $+1$; the coset $(1\,2)A_4$ (twelve odd permutations) maps to -1. Any odd permutation, say $(1\,2\,3\,4)$, belongs to $(1\,2)A_4$, so $(1\,2\,3\,4) \cdot A_4 \mapsto -1 = \mathrm{sgn}((1\,2\,3\,4))$.

Common pitfall: The explicit formula $\sigma A_n \mapsto \mathrm{sgn}(\sigma)$ may tempt a student to write $\sigma \mapsto \mathrm{sgn}(\sigma)$ and think the domain is S_n again. The input to the dashed map is the *coset* σA_n, an element of S_n/A_n; the formula merely describes it by a coset representative, which requires well-definedness.

Takeaway: The point of this diagram is that the coset partition of S_n by A_n captures exactly the even/odd distinction, and the map $\sigma A_n \mapsto \mathrm{sgn}(\sigma)$ induced by the sign homomorphism is the unique isomorphism $S_n/A_n \to \{\pm 1\}$; it reads off which coset a permutation belongs to.

shows the universal property: sgn factors through S_n/A_n via a unique isomorphism, because $A_n = \ker(\mathrm{sgn})$. The two cosets of A_n are precisely the even and the odd permutations.

Caution. Disjoint cycles *commute*, so sgn of a product of disjoint cycles is the product of their signs — but do not apply this to *non*-disjoint cycles by "adding lengths." For overlapping cycles, first multiply them out into disjoint form (or just use $\mathrm{sgn}(\alpha\beta) = \mathrm{sgn}(\alpha)\,\mathrm{sgn}(\beta)$, which always holds), then read the parity.

Exercises (from the text).

1. In Exercises 1 and 2 of Section 1.3 you were asked to find the cycle decomposition of some permutations. Write each of these permutations as a product of transpositions. Determine which of these is an even permutation and which is an odd permutation.

2. Prove that σ^2 is an even permutation for every permutation σ.
3. Prove that S_n is generated by $\{(i \;\; i{+}1) \mid 1 \le i \le n-1\}$. [Consider conjugates, viz. $(2\ 3)(1\ 2)(2\ 3)^{-1}$.]
4. Show that $S_n = \langle (1\ 2),\ (1\ 2\ 3\ \ldots\ n)\rangle$ for all $n \ge 2$.
5. Show that if p is prime, $S_p = \langle \sigma, \tau\rangle$ where σ is any transposition and τ is any p-cycle.
6. Show that $\langle (1\ 3),\ (1\ 2\ 3\ 4)\rangle$ is a proper subgroup of S_4. What is the isomorphism type of this subgroup?
7. Prove that the group of rigid motions of a tetrahedron is isomorphic to A_4. [Recall Exercise 20 in Section 1.7.]
8. Prove the lattice of subgroups of A_4 given in the text is correct. [By the preceding exercise and the comments following Lagrange's Theorem, A_4 has no subgroup of order 6.]
9. Prove that the (unique) subgroup of order 4 in A_4 is normal and isomorphic to V_4.
10. Find a composition series for A_4. Deduce that A_4 is solvable.
11. Prove that S_4 has no subgroup isomorphic to Q_8.
12. Prove that A_n contains a subgroup isomorphic to S_{n-2} for each $n \ge 3$.
13. Prove that every element of order 2 in A_n is the square of an element of order 4 in S_n.
14. Prove that if $n \ge 5$ then the subgroup generated by 3-cycles in S_n is A_n (i.e., A_n is the smallest subgroup of S_n containing all 3-cycles).
15. Prove that if x and y are distinct 3-cycles in S_4 with $x \ne y^{-1}$, then the subgroup of S_4 generated by x and y is A_4.
16. Let x and y be distinct 3-cycles in S_5 with $x \ne y^{-1}$. (a) Prove that if x and y fix a common element of $\{1, \ldots, 5\}$, then $\langle x, y\rangle \cong A_4$. (b) Prove that if x and y do not fix a common element of $\{1, \ldots, 5\}$, then $\langle x, y\rangle = A_5$.
17. If x and y are 3-cycles in S_n, prove that $\langle x, y\rangle$ is isomorphic to $\mathbb{Z}/3\mathbb{Z}$, A_4, A_5, or $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$.

Practice problems (additional).

1. Write each permutation in S_7 as a product of transpositions and determine its sign: (a) $(1\,2\,3\,4\,5\,6\,7)$; (b) $(1\,3\,5)(2\,4)$; (c) $(1\,2)(3\,4)(5\,6)$; (d) $(1\,4\,7\,2)(3\,6)$.
2. Compute the sign of an m-cycle in S_n (for $m \le n$) and prove your formula by exhibiting the m-cycle as a product of $m-1$ transpositions.
3. Let $\sigma = (1\,2\,3)(4\,5)$ and $\tau = (1\,5\,2\,4)$ in S_5. Compute $\operatorname{sgn}(\sigma)$, $\operatorname{sgn}(\tau)$, and $\operatorname{sgn}(\sigma\tau)$, and verify $\operatorname{sgn}(\sigma\tau) = \operatorname{sgn}(\sigma)\operatorname{sgn}(\tau)$ by computing $\sigma\tau$ directly (recall right-to-left composition).
4. List all 12 elements of A_4 in cycle notation, grouping them by cycle type, and confirm that each is even.
5. Show that A_n is generated by the 3-cycles for $n \ge 3$. (Hint: a product of two transpositions is either the identity, a 3-cycle, or a product of two disjoint transpositions; handle each case.)
6. Find the order of every element of A_4 and use this to prove that A_4 has no subgroup of order 6. Conclude that the converse of Lagrange's theorem fails.
7. Prove that for $n \ge 2$ the map $\operatorname{sgn}\colon S_n \to \{\pm 1\}$ is a homomorphism with $\ker(\operatorname{sgn}) = A_n$, and deduce $[S_n : A_n] = 2$ and $|A_n| = n!/2$.
8. Determine which of the following permutations lie in A_6: (a) $(1\,2\,3\,4\,5\,6)$; (b) $(1\,2)(3\,4\,5)$; (c) $(1\,2\,3)(4\,5\,6)$; (d) $(1\,2\,3\,4)(5\,6)$.
9. Let $H = \langle (1\,2\,3), (1\,2)(3\,4)\rangle \le S_4$. Show $H = A_4$.
10. Prove that any two transpositions in S_n are conjugate, and more generally that two permutations of S_n are conjugate iff they have the same cycle type.

11. Show that the number of even permutations in S_n equals the number of odd permutations for $n \geq 2$ by exhibiting an explicit bijection $A_n \to S_n \setminus A_n$.

12. Let $\sigma \in S_n$ have cycle type with cycles of lengths $\ell_1, \dots, \ell_k$ (including fixed points as 1-cycles, so that $\ell_1 + \cdots + \ell_k = n$). Prove $\operatorname{sgn}(\sigma) = (-1)^{n-k}$.

13. Compute the number of 3-cycles in S_5 and the number of elements of cycle type $(2,2)$ in S_5. Verify these counts are consistent with $|A_5| = 60$ by also counting the 5-cycles and the identity.

14. Determine whether the permutation $\sigma = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 3 & 1 & 5 & 6 & 2 & 4 \end{pmatrix}$ is even or odd by writing it in disjoint-cycle form and counting transpositions.

15. For $n \geq 3$, show that A_n is generated by the particular 3-cycles $(1\,2\,3), (1\,2\,4), \dots, (1\,2\,n)$.

Additional exercises.

1. Prove that A_n is a normal subgroup of S_n for all $n \geq 2$, and identify the quotient S_n/A_n up to isomorphism.

2. Show that for $n \geq 3$ the commutator subgroup of S_n is contained in A_n, and that in fact $[S_n, S_n] = A_n$. (Hint: every 3-cycle is a commutator, e.g. $(1\,3\,2) = [(1\,2), (2\,3)]$ where $[a,b] = aba^{-1}b^{-1}$; verify this and relabel.)

3. Prove that A_5 is simple as follows. First show every nonidentity element of A_5 is a 3-cycle, a $(2,2)$-element, or a 5-cycle; compute the conjugacy class sizes in A_5 (the classes have sizes $1, 15, 20, 12, 12$, the 5-cycles splitting into two classes of size 12); then show no union of conjugacy classes containing the identity has order properly dividing 60 except $\{1\}$ and A_5.

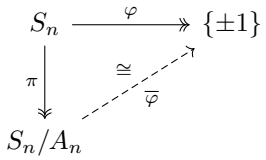
4. Let $N \trianglelefteq A_n$ for $n \geq 5$. Show that if N contains a single 3-cycle then $N = A_n$, using that all 3-cycles are conjugate in A_n when $n \geq 5$ together with the Exercise (in the first list) that 3-cycles generate A_n.

5. Prove that S_4 has the composition series

$$1 \trianglelefteq \langle (1\,2)(3\,4) \rangle \trianglelefteq V \trianglelefteq A_4 \trianglelefteq S_4,$$

where $V = \{1, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\}$ is the Klein four-group, and identify each composition factor. Verify that the factor orders multiply to $|S_4| = 24$.

6. Show that V in the previous exercise is the unique (hence normal) subgroup of A_4 of order 4, and that $A_4/V \cong \mathbb{Z}/3\mathbb{Z}$. Draw the conclusion that A_4 is solvable but not simple.



Commutative-diagram exercises.

1. Let $\pi\colon S_n \to S_n/A_n$ be the canonical projection. Show that the short exact sequence

$$1 \longrightarrow A_n \hookrightarrow S_n \xrightarrow{\operatorname{sgn}} \{\pm 1\} \longrightarrow 1$$

is exact, and exhibit a splitting $\{\pm 1\} \to S_n$ realizing S_n as a semidirect-style factorization $S_n = A_n \rtimes \langle (1\,2) \rangle$ (i.e. produce a section of sgn).

2. Let $\varphi\colon S_n \to \{\pm 1\}$ be the sign homomorphism. Use the first isomorphism theorem to fill in the dashed arrow making the diagram commute, and identify the induced map $\overline{\varphi}$ explicitly:

3. In A_4 with normal subgroup V (Klein four-group), draw the lattice-correspondence diagram relating subgroups of A_4 containing V to subgroups of $A_4/V \cong \mathbb{Z}/3\mathbb{Z}$. State which subgroups of A_4 correspond to the two subgroups of $\mathbb{Z}/3\mathbb{Z}$ and complete:

$$\begin{array}{ccccc} V & \hookrightarrow & A_4 & \xrightarrow{q} & A_4/V \\ \| & & \| & & \downarrow \cong \\ V & \hookrightarrow & A_4 & \twoheadrightarrow & \mathbb{Z}/3\mathbb{Z} \end{array}$$

4. Let $V \trianglelefteq A_4 \trianglelefteq S_4$ as above. Using the third isomorphism theorem, justify the isomorphism $(S_4/V)/(A_4/V) \cong S_4/A_4$ by completing the commutative diagram of quotient maps:

$$\begin{array}{ccc} S_4 & \twoheadrightarrow & S_4/V \\ \downarrow & & \vdots \\ S_4/A_4 & \xrightarrow[\cong]{} & (S_4/V)/(A_4/V) \end{array}$$

   Identify each quotient as a concrete small group: $S_4/A_4 \cong \mathbb{Z}/2\mathbb{Z}$, $A_4/V \cong \mathbb{Z}/3\mathbb{Z}$, and hence $(S_4/V)/(A_4/V) \cong \mathbb{Z}/2\mathbb{Z}$.

5. Realize the subnormal series $1 \trianglelefteq V \trianglelefteq A_4 \trianglelefteq S_4$ as a tower of quotient maps and identify each successive quotient. Complete the diagram, labeling each vertical inclusion and the quotient factor on each level:

$$\begin{array}{ccc} S_4 & \xrightarrow{p_1} & S_4/A_4 \\ \uparrow & & \\ A_4 & \xrightarrow{p_2} & A_4/V \\ \uparrow & & \\ V & \xrightarrow{p_3} & V/1 \end{array}$$

   Here $\ker p_1 = A_4$ with $S_4/A_4 \cong \mathbb{Z}/2\mathbb{Z}$, $\ker p_2 = V$ with $A_4/V \cong \mathbb{Z}/3\mathbb{Z}$, and $\ker p_3 = 1$ with $V/1 \cong V \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. (Note V is not simple, so to obtain a genuine composition series one refines $1 \trianglelefteq V$ by inserting $\langle (1\,2)(3\,4) \rangle$, giving simple factors $\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}$.)

3.6 Graded Problem Bank

Easy

DF 3.1.6 Define $\varphi : \mathbb{R}^\times \to \{\pm 1\}$ by $\varphi(x) = x/|x|$. Describe the fibers of φ and prove it is a homomorphism.

DF 3.1.7 Define $\pi : \mathbb{R}^2 \to \mathbb{R}$ by $\pi((x, y)) = x + y$. Prove π is a surjective homomorphism and describe its kernel and fibers geometrically.

DF 3.1.8 Let $\varphi : \mathbb{R}^\times \to \mathbb{R}^\times$ send x to $|x|$. Prove φ is a homomorphism, find its image, and describe the kernel and fibers geometrically.

DF 3.1.9 Define $\varphi : \mathbb{C}^\times \to \mathbb{R}^\times$ by $\varphi(a + bi) = a^2 + b^2$. Prove φ is a homomorphism, find its image, and describe the kernel and fibers as subsets of the plane.

DF 3.1.10 Let $\varphi : \mathbb{Z}/8\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ by $\varphi(\overline{a}) = \overline{a}$. Show this is a well-defined surjective homomorphism and describe its fibers and kernel explicitly.

DF 3.1.4 Prove that in the quotient group G/N, $(gN)^a = g^aN$ for all $a \in \mathbb{Z}$.

DF 3.1.12 For $G = (\mathbb{R}, +)$, $H = S^1$, and $\varphi : r \mapsto e^{2\pi ir}$, mark the kernel on the real line and describe the fibers above -1, i, and $e^{4\pi i/3}$.

DF 3.1.13 Repeat the preceding for $\varphi : r \mapsto e^{4\pi ir}$.

DF 3.1.20 Let $G = \mathbb{Z}/24\mathbb{Z}$ and $\overline{G} = G/\langle\overline{12}\rangle$. Show $\overline{G} = \{\widetilde{0}, \ldots, \widetilde{11}\}$, find the order of each element, and prove $\overline{G} \cong \mathbb{Z}/12\mathbb{Z}$.

DF 3.2.1 Which of $1, 2, 5, 7, 9, 15, 60, 240$ are permissible orders for subgroups of a group of order 120? Give the index for each permissible order.

DF 3.2.16 Use Lagrange's Theorem in $(\mathbb{Z}/p\mathbb{Z})^\times$ to prove Fermat's Little Theorem: if p is prime then $a^p \equiv a \pmod{p}$ for all $a \in \mathbb{Z}$.

DF 3.2.21 Use Lagrange's Theorem in $(\mathbb{Z}/n\mathbb{Z})^\times$ to prove Euler's Theorem: $a^{\varphi(n)} \equiv 1 \pmod{n}$ for $\gcd(a, n) = 1$.

DF 3.2.22 Determine the last two digits of $3^{3^{100}}$.

DF 3.5.2 Prove that σ^2 is an even permutation for every permutation σ.

DF 3.5.4 Show that $S_n = \langle(1\,2), (1\,2\,3\,\ldots\,n)\rangle$ for all $n \geq 2$.

Artin 4.3 Let $a, b \in G$. Prove that ab and ba have the same order.

Artin 8.3 Does every group whose order is a power of a prime p contain an element of order p?

Artin 8.4 Does a group of order 35 contain an element of order 5? of order 7?

Artin 8.5 A finite group contains an element of order 10 and an element of order 6. What can be said about $|G|$?

Artin 8.6 Let $\varphi : G \to G'$ be a homomorphism with $|G| = 18$, $|G'| = 15$, and φ nontrivial. What is the order of the kernel?

Artin 8.10 Prove that every subgroup of index 2 is normal, and show by example that a subgroup of index 3 need not be normal.

Artin 9.1 For which integers n does 2 have a multiplicative inverse in $\mathbb{Z}/n\mathbb{Z}$?

Artin 9.2 What are the possible values of a^2 modulo 4? modulo 8?

Artin 9.3 Prove that every integer a is congruent to the sum of its decimal digits modulo 9.

Artin 9.4 Solve the congruence $2x \equiv 5$ modulo 9 and modulo 6.

Artin 10.1 Describe how to tell from the cycle decomposition whether a permutation is odd or even.

Artin 10.3 For cyclic G, G' of orders $12, 6$ generated by x, y and $\varphi(x^i) = y^i$, exhibit the correspondence of the Correspondence Theorem explicitly.

Artin 10.4 With corresponding subgroups H, H' under the Correspondence Theorem, prove $[G : H] = [G' : H']$.

Artin 11.1 Let x have order r in G and y have order s in G'. What is the order of (x, y) in $G \times G'$?

Artin 12.4 Let $H = \{\pm 1, \pm i\} \leq G = \mathbb{C}^\times$. Describe the cosets of H in G explicitly. Is G/H isomorphic to G?

Fraleigh 10.1 Find all cosets of the subgroup $4\mathbb{Z}$ of $\mathbb{Z}$.

Fraleigh 10.2 Find all cosets of the subgroup $4\mathbb{Z}$ of $2\mathbb{Z}$.

Fraleigh 10.3 Find all cosets of the subgroup $\langle 3\rangle$ in $\mathbb{Z}/18\mathbb{Z}$.

Fraleigh 10.4 Find all cosets of the subgroup $\langle 6\rangle$ in $\mathbb{Z}/18\mathbb{Z}$.

Fraleigh 10.5 Find all cosets of the subgroup $\langle 18\rangle$ of $\mathbb{Z}/36\mathbb{Z}$.

Fraleigh 10.6 Find all left cosets of $\langle\mu\rho\rangle$ in D_4.

Fraleigh 10.7 Find the right cosets of $\langle\mu\rho\rangle$ in D_4; are they the same as the left cosets?

Fraleigh 10.8 Are the left and right cosets the same for $\{\iota, \rho^4, \mu, \mu\rho^4\} \leq D_8$? Display them or exhibit a left coset that is no right coset.

Fraleigh 10.9 Find all left cosets of $\langle \rho^2 \rangle \leq D_4$.

Fraleigh 10.10 Find the right cosets of $\langle \rho^2 \rangle \leq D_4$; if left and right agree, identify the group of order 4 the coset blocks form.

Fraleigh 10.11 Find the index of $\langle \rho^2 \rangle$ in D_6.

Fraleigh 10.12 Find the index of $\langle 3 \rangle$ in $\mathbb{Z}/24\mathbb{Z}$.

Fraleigh 10.13 Find the index of $12\mathbb{Z}$ in $\mathbb{Z}$.

Fraleigh 10.14 Find the index of $12\mathbb{Z}$ in $3\mathbb{Z}$.

Fraleigh 10.15 Let $\sigma = (1\,2\,5\,4)(2\,3)$ in S_5. Find the index of $\langle \sigma \rangle$ in S_5.

Fraleigh 10.16 Let $\mu = (1\,2\,4\,5)(3\,6)$ in S_6. Find the index of $\langle \mu \rangle$ in S_6.

Fraleigh 12.1 Find the order of the factor group $\mathbb{Z}/6\mathbb{Z}/\langle 3 \rangle$.

Fraleigh 12.2 Find the order of $(\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/12\mathbb{Z})/(\langle 2 \rangle \times \langle 2 \rangle)$.

Fraleigh 12.3 Find the order of $(\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z})/\langle (2,1) \rangle$.

Fraleigh 12.4 Find the order of $(\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z})/(\{0\} \times \mathbb{Z}/5\mathbb{Z})$.

Fraleigh 12.5 Find the order of $(\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z})/\langle (1,1) \rangle$.

Fraleigh 12.6 Find the order of $(\mathbb{Z}/50\mathbb{Z} \times \mathbb{Z}/75\mathbb{Z})/\langle (15,15) \rangle$.

Fraleigh 12.7 Find the order of $(\mathbb{Z}/26\mathbb{Z} \times \mathbb{Z}/15\mathbb{Z})/\langle (1,1) \rangle$.

Fraleigh 12.8 Find the order of $(\mathbb{Z}/8\mathbb{Z} \times S_3)/\langle (2, (1\,2\,3)) \rangle$.

Fraleigh 12.9 Find the order of $5 + \langle 4 \rangle$ in $\mathbb{Z}/12\mathbb{Z}/\langle 4 \rangle$.

Fraleigh 12.10 Find the order of $26 + \langle 12 \rangle$ in $\mathbb{Z}/60\mathbb{Z}/\langle 12 \rangle$.

Fraleigh 12.11 Find the order of $(2,1) + \langle (1,1) \rangle$ in $(\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z})/\langle (1,1) \rangle$.

Fraleigh 12.12 Find the order of $(3,1) + \langle (1,1) \rangle$ in $(\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z})/\langle (1,1) \rangle$.

Fraleigh 12.13 Find the order of $(2,3) + \langle (0,3) \rangle$ in $(\mathbb{Z}/10\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z})/\langle (0,3) \rangle$.

Fraleigh 12.14 Find the order of $(2,5) + \langle (1,2) \rangle$ in $(\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z})/\langle (1,2) \rangle$.

Fraleigh 12.15 Find the order of $(2,0) + \langle (4,4) \rangle$ in $(\mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/8\mathbb{Z})/\langle (4,4) \rangle$.

Fraleigh 12.16 Compute $i_\rho[H]$ for the subgroup $H = \{\iota, \mu\}$ of D_3.

Fraleigh 16.1 For $\varphi : \mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$ with $\varphi(1) = 2$, find the kernel K, list the cosets in $\mathbb{Z}/12\mathbb{Z}/K$, and give the correspondence with $\mathbb{Z}/3\mathbb{Z}$.

Fraleigh 16.2 For $\varphi : \mathbb{Z}/18\mathbb{Z} \to \mathbb{Z}/12\mathbb{Z}$ with $\varphi(1) = 10$, find the kernel, list the cosets in $\mathbb{Z}/18\mathbb{Z}/K$, find $\varphi[\mathbb{Z}/18\mathbb{Z}]$, and give the correspondence.

Medium

DF 3.1.1 Let $\varphi : G \to H$ be a homomorphism and $E \leq H$. Prove $\varphi^{-1}(E) \leq G$, that $E \trianglelefteq H$ implies $\varphi^{-1}(E) \trianglelefteq G$, and deduce $\ker \varphi \trianglelefteq G$.

DF 3.1.3 Let A be abelian and $B \leq A$. Prove A/B is abelian, and give a nonabelian G with proper $N \trianglelefteq G$ such that G/N is abelian.

DF 3.1.5 Prove the order of gN in G/N is the least $n > 0$ with $g^n \in N$ (infinite if none), and give an example where it is strictly smaller than the order of g.

DF 3.1.11 For $G = \{\left(\begin{smallmatrix} a & b \\ 0 & c \end{smallmatrix}\right) : ac \neq 0\} \leq \mathrm{GL}_2(F)$, prove $\left(\begin{smallmatrix} a & b \\ 0 & c \end{smallmatrix}\right) \mapsto a$ and $\mapsto (a, c)$ are surjective homomorphisms (describe fibers/kernels), and that $\{\left(\begin{smallmatrix} 1 & b \\ 0 & 1 \end{smallmatrix}\right)\} \cong (F, +)$.

DF 3.1.14 For $\mathbb{Q}/\mathbb{Z}$: every coset has a unique representative in $[0, 1)$; every element has finite order but orders are unbounded; it is the torsion subgroup of $\mathbb{R}/\mathbb{Z}$; and $\mathbb{Q}/\mathbb{Z} \cong$ the group of roots of unity in $\mathbb{C}^\times$.

DF 3.1.16 Let $N \trianglelefteq G$ and $\overline{G} = G/N$. Prove that if $G = \langle S \rangle$ then $\overline{G} = \langle \overline{S} \rangle$ (in particular for $S = \{x, y\}$).

DF 3.1.21 (a) Prove $H, K \trianglelefteq G$ implies $H \cap K \trianglelefteq G$. (b) Prove the intersection of an arbitrary nonempty family of normal subgroups is normal.

DF 3.1.22 Prove that the join of any nonempty collection of normal subgroups of G is normal.

DF 3.1.23 Prove that if $N \trianglelefteq G$ and $H \leq G$ then $N \cap H \trianglelefteq H$.

DF 3.1.24 (a) Prove $N \leq G$ is normal iff $gNg^{-1} \subseteq N$ for all g. (b) Exhibit $N \leq \mathrm{GL}_2(\mathbb{Q})$ and a diagonal g with $gNg^{-1} \subsetneq N$, so $g \notin N_G(N)$.

DF 3.1.27 Let $N \leq G$ be finite. Show $gNg^{-1} \subseteq N$ iff $gNg^{-1} = N$, and deduce $N_G(N) = \{g : gNg^{-1} \subseteq N\}$.

DF 3.1.31 Let $N \leq G$, $g \in G$. Prove $gN = Ng$ iff $g \in N_G(N)$.

DF 3.1.32 Prove that if $H \leq G$ and $N \trianglelefteq H$ then $H \leq N_G(N)$; deduce $N_G(N)$ is the largest subgroup of G in which N is normal.

DF 3.1.33 Prove every subgroup of Q_8 is normal and find the isomorphism type of each quotient.

DF 3.1.34 Find all normal subgroups of D_8 and the isomorphism type of each quotient.

DF 3.1.36 Prove $\mathrm{SL}_n(F) \trianglelefteq \mathrm{GL}_n(F)$ and describe the quotient.

DF 3.1.37 Prove that if $G/Z(G)$ is cyclic then G is abelian.

DF 3.1.38 Show $\{(a, 1) : a \in A\} \trianglelefteq A \times B$ and the quotient is isomorphic to B.

DF 3.1.39 For abelian A and diagonal $D = \{(a, a)\} \leq A \times A$, prove $D \trianglelefteq A \times A$ and $(A \times A)/D \cong A$.

DF 3.1.40 For $A = S_3$ and diagonal $D \leq A \times A$, prove D is not normal in $A \times A$.

DF 3.1.41 For $N \trianglelefteq G$, $\overline{G} = G/N$, prove $\overline{x}, \overline{y}$ commute iff $[x, y] = x^{-1}y^{-1}xy \in N$.

DF 3.1.43 Assume $H, K \trianglelefteq G$ with $H \cap K = 1$. Prove $xy = yx$ for all $x \in H$, $y \in K$.

DF 3.2.4 Show that if $|G| = pq$ for primes p, q (not necessarily distinct) then G is abelian or $Z(G) = 1$.

DF 3.2.5 Let $H \leq G$, $g \in G$. Prove $gHg^{-1} \leq G$ with $|gHg^{-1}| = |H|$, and deduce a unique subgroup of a given order is normal.

DF 3.2.6 Prove that if a right coset Hg equals some left coset of H then it equals gH and $g \in N_G(H)$.

DF 3.2.7 For $H \leq G$, define $a \sim b$ iff $b^{-1}a \in H$; prove $\sim$ is an equivalence relation, describe its classes, and prove Proposition 4.

DF 3.2.8 Prove that finite subgroups $H, K \leq G$ of relatively prime orders satisfy $H \cap K = 1$.

DF 3.2.11 Let $H \leq K \leq G$. Prove $[G : H] = [G : K] \cdot [K : H]$ without assuming G finite.

DF 3.2.12 Prove $x \mapsto x^{-1}$ sends each left coset of H onto a right coset and gives a bijection between left and right cosets.

DF 3.2.15 For $G = S_n$ and the stabilizer G_i of i, prove $G_i \cong S_{n-1}$.

DF 3.2.17 Find the order of $\overline{p}$ in $(\mathbb{Z}/(p^n - 1)\mathbb{Z})^\times$ and deduce $n \mid \varphi(p^n - 1)$.

DF 3.2.18 Let G finite, $H \leq G$, $N \trianglelefteq G$. Prove that if $|H|$ and $[G : N]$ are coprime then $H \leq N$.

DF 3.2.19 Prove that if $N \trianglelefteq G$ finite with $(|N|, [G : N]) = 1$ then N is the unique subgroup of G of order $|N|$.

DF 3.2.20 If A abelian with $A \trianglelefteq G$ and $B \leq G$, prove $A \cap B \trianglelefteq AB$.

DF 3.3.1 For a finite field F of order q, prove $[\mathrm{GL}_n(F) : \mathrm{SL}_n(F)] = q - 1$.

DF 3.3.3 Prove that if $H \trianglelefteq G$ of prime index p then for $K \leq G$, either $K \leq H$ or $G = HK$ with $[K : K \cap H] = p$.

DF 3.3.4 For $C \trianglelefteq A$ and $D \trianglelefteq B$, prove $(C \times D) \trianglelefteq (A \times B)$ and $(A \times B)/(C \times D) \cong (A/C) \times (B/D)$.

DF 3.3.7 For $M, N \trianglelefteq G$ with $G = MN$, prove $G/(M \cap N) \cong (G/M) \times (G/N)$.

DF 3.3.8 For prime p and G the group of p-power roots of 1 in $\mathbb{C}$, prove $z \mapsto z^p$ is a surjective homomorphism, so G is isomorphic to a proper quotient of itself.

DF 3.5.1 Write the permutations from Section 1.3 Exercises 1–2 as products of transpositions and determine parity.

DF 3.5.3 Prove S_n is generated by $\{(i\ \ i{+}1) : 1 \leq i \leq n-1\}$.

DF 3.5.5 Show that if p is prime then $S_p = \langle \sigma, \tau \rangle$ for any transposition σ and any p-cycle τ.

DF 3.5.6 Show $\langle (1\,3), (1\,2\,3\,4) \rangle$ is a proper subgroup of S_4 and find its isomorphism type.

DF 3.5.9 Prove the subgroup of order 4 in A_4 is normal and isomorphic to V_4.

DF 3.5.11 Prove A_n contains a subgroup isomorphic to S_{n-2} for each $n \geq 3$.

DF 3.5.12 Prove every element of order 2 in A_n is the square of an element of order 4 in S_n.

Artin 7.1 Prove the relation $a \sim b$ if $b = gag^{-1}$ for some $g \in G$ is an equivalence relation on G.

Artin 7.3 Viewing an equivalence relation as a subset $R \subseteq S \times S$, is the intersection $R \cap R'$ of two equivalence relations an equivalence relation? the union?

Artin 7.6 How many different equivalence relations can be defined on a set of five elements?

Artin 8.1 Let $H = \langle (1\,2\,3) \rangle \leq A_4$. Exhibit the left and the right cosets of H explicitly.

Artin 8.2 In $\mathbb{R}^m$ let W be the solution set of a homogeneous system $AX = 0$. Show the solutions of $AX = B$ form either the empty set or a coset of W.

Artin 8.7 A group G of order 22 contains $x \neq 1$ and y not a power of x. Prove $\langle x, y \rangle = G$.

Artin 8.8 Let $|G| = 25$. Prove G has a subgroup of order 5, and that if it has only one such subgroup then G is cyclic.

Artin 8.12 Let $S \subseteq G$ contain 1 and have the left cosets aS partition G. Prove S is a subgroup of G.

Artin 9.5 Determine the integers n for which $2x - y \equiv 1$, $4x + 3y \equiv 2 \pmod{n}$ has a solution.

Artin 9.7 Determine the order of each of the matrices $A = \left[\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right]$ and $B = \left[\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right]$ when the matrix entries are read modulo 3.

Artin 10.2 (a) Prove $xH \cap yK$ is empty or a coset of $H \cap K$. (b) If H, K have finite index in G then so does $H \cap K$.

Artin 10.5 For the homomorphism $S_4 \to S_3$ of Example 2.5.13, determine the six subgroups of S_4 containing K.

Artin 11.2 State what Proposition 2.11.4 gives for $K = \langle y \rangle$ and $H = \langle x \rangle$ in S_3.

Artin 11.3 Prove that the product of two infinite cyclic groups is not infinite cyclic.

Artin 11.5 Prove the center of $G_1 \times G_2$ is $Z_1 \times Z_2$.

Artin 11.6 Let G have normal subgroups of orders 3 and 5. Prove G contains an element of order 15.

Artin 11.9 Prove that HK is a subgroup of G if and only if $HK = KH$.

Artin 12.1 Show that if $H \leq G$ is not normal, there are left cosets aH, bH whose product is not a coset.

Artin 12.2 In $\mathrm{GL}_3(\mathbb{R})$, with H the set of matrices $\left(\begin{smallmatrix} 1 & * & * \\ 0 & 1 & * \\ 0 & 0 & 1 \end{smallmatrix}\right)$ and K its subset of matrices $\left(\begin{smallmatrix} 1 & 0 & * \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{smallmatrix}\right)$ (each $*$ an arbitrary real number), show $K \trianglelefteq H$, identify H/K, and find $Z(H)$.

Artin 12.3 Let $\mathcal{P}$ partition G with AB contained in a single block for all blocks A, B, and let N be the block containing 1. Prove $N \trianglelefteq G$ and $\mathcal{P}$ is its set of cosets.

Artin 12.5 For G the group of upper triangular $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ with $a, d \neq 0$, decide for each of $b = 0$, $d = 1$, $a = d$ whether S is a (normal) subgroup and identify G/S when normal.

Artin M.2 (a) Prove every group of even order contains an element of order 2. (b) Prove every group of order 21 contains an element of order 3.

Fraleigh 10.28 Prove that the relation $\sim_R$ used to define right cosets is an equivalence relation.

Fraleigh 10.29 For $H \leq G$ and $g \in G$, define a one-to-one map of H onto Hg and prove it is a bijection.

Fraleigh 10.30 Prove that if $g^{-1}hg \in H$ for all $g \in G$, $h \in H$, then $gH = Hg$ for all g.

Fraleigh 10.31 Prove the converse of the preceding: if the left- and right-coset partitions agree, then $g^{-1}hg \in H$ for all g, h.

Fraleigh 10.32 Prove or give a counterexample: if $aH = bH$ then $Ha = Hb$.

Fraleigh 10.33 Prove or give a counterexample: if $Ha = Hb$ then $b \in Ha$.

Fraleigh 10.34 Prove or give a counterexample: if $aH = bH$ then $Ha^{-1} = Hb^{-1}$.

Fraleigh 10.35 Prove or give a counterexample: if $aH = bH$ then $a^2H = b^2H$.

Fraleigh 10.37 Exhibit a bijection from left cosets of H onto right cosets, valid for any group G.

Fraleigh 10.41 Show that if H has index 2 in a finite group G, then every left coset of H is also a right coset.

Fraleigh 10.42 Show that if G has finite order n, then $a^n = e$ for all $a \in G$.

Fraleigh 10.43 Show that every left coset of $\mathbb{Z} \leq (\mathbb{R}, +)$ contains exactly one x with $0 \leq x < 1$.

Fraleigh 10.44 Show that sin is constant on each left coset of $\langle 2\pi \rangle \leq (\mathbb{R}, +)$, hence induces a well-defined function on cosets.

Fraleigh 10.46 For S_A and $c \in A$: (a) show $S_{c,c} = \{\sigma : \sigma(c) = c\} \leq S_A$; (b) decide whether $S_{c,d} = \{\sigma : \sigma(c) = d\}$ is a subgroup; (c) describe $S_{c,d}$ in terms of $S_{c,c}$.

Fraleigh 12.24 For $\pi_1 : G_1 \times G_2 \to G_1$, $\pi_1(a, b) = a$, prove it is a homomorphism, find $\ker \pi_1$, and prove $(G_1 \times G_2)/\ker \pi_1 \cong G_1$.

Fraleigh 12.25 For $\varphi : G_1 \times G_2 \to G_1 \times G_2$, $\varphi(a, b) = (a, e_2)$, prove it is a homomorphism, find $\ker \varphi$, and prove $(G_1 \times G_2)/\ker \varphi \cong G_1$.

Fraleigh 12.26 Complete the proof of Theorem 12.7: if left-coset multiplication $(aH)(bH) = (ab)H$ is well defined, then $Ha \subseteq aH$.

Fraleigh 12.28 Show that conjugacy of subgroups, $K = i_g[H]$ for some inner automorphism, is an equivalence relation.

Fraleigh 12.30 Find all subgroups of D_3 conjugate to $H = \{\iota, \mu\}$.

Fraleigh 12.32 For $N \trianglelefteq G$ with $m = [G : N]$, show $a^m \in N$ for every $a \in G$.

Fraleigh 12.33 Show that an intersection of normal subgroups of G is again normal.

Fraleigh 12.36 Show that if a finite group G has exactly one subgroup H of a given order, then $H \trianglelefteq G$.

Fraleigh 12.37 Show that if $H \leq G$ and $N \trianglelefteq G$ then $H \cap N \trianglelefteq H$, and give an example where $H \cap N$ is not normal in G.

Fraleigh 16.7 For positive n, h, $N = \langle n \rangle$, $H = \langle h \rangle \leq \mathbb{Z}$, use the Second Isomorphism Theorem to derive $nh = \gcd(n, h) \cdot \operatorname{lcm}(n, h)$.

Hard

DF 3.1.2 Let $\varphi : G \to H$ with kernel K, and $a, b \in \varphi(G)$ with fibers X, Y. Fix $u \in X$. Prove that if $XY = Z$ in G/K and $w \in Z$, then some $v \in Y$ has $uv = w$.

DF 3.1.15 Prove that a quotient of a divisible abelian group by any proper subgroup is divisible, and deduce $\mathbb{Q}/\mathbb{Z}$ is divisible.

DF 3.1.17 For $D_{16} = \langle r, s \mid r^8 = s^2 = 1,\ rs = sr^{-1}\rangle$ and $\overline{G} = G/\langle r^4\rangle$: show $|\overline{G}| = 8$; list elements as $\overline{s}^a\overline{r}^b$ with orders; reduce $\overline{rs}, \overline{sr^{-2}s}, \overline{s^{-1}r^{-1}sr}$; show $\overline{H} = \langle \overline{s}, \overline{r^2}\rangle \trianglelefteq \overline{G}$ is Klein and identify the preimage; find $Z(\overline{G})$ and $\overline{G}/Z(\overline{G})$.

DF 3.1.18 For the quasidihedral $G = \langle \sigma, \tau \mid \sigma^8 = \tau^2 = 1,\ \sigma\tau = \tau\sigma^3\rangle$ and $\overline{G} = G/\langle\sigma^4\rangle$: show $|\overline{G}| = 8$, list elements as $\overline{\tau}^a\overline{\sigma}^b$ with orders, write $\overline{\sigma\tau}$, $\overline{\tau\sigma^{-2}\tau}$, $\overline{\tau^{-1}\sigma^{-1}\tau\sigma}$ in this form, and prove $\overline{G} \cong D_8$.

DF 3.1.19 For the modular $G = \langle u, v \mid u^2 = v^8 = 1,\ vu = uv^5\rangle$ and $\overline{G} = G/\langle v^4\rangle$: show $|\overline{G}| = 8$, list elements as $\overline{u}^a\overline{v}^b$ with orders, write $\overline{vu}$, $\overline{uv^{-2}u}$, $\overline{u^{-1}v^{-1}uv}$ in this form, and prove $\overline{G}$ is abelian $\cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$.

DF 3.1.1b For $G = \mathbb{Z}_4 \times \mathbb{Z}_4 = \langle x, y \mid x^4 = y^4 = 1,\ xy = yx\rangle$ and the quotient $\overline{G} = G/\langle x^2y^2\rangle$ of order 8: list elements as $\overline{x}^a\overline{y}^b$ with orders and prove $\overline{G} \cong \mathbb{Z}_4 \times \mathbb{Z}_2$.

DF 3.1.25 (a) Prove the conjugate of ab is the product of the conjugates and conjugation preserves order. (b) The conjugate of a^{-1} is the inverse of the conjugate. (c) For $N = \langle S\rangle$, $N \trianglelefteq G$ iff $gSg^{-1} \subseteq N$ for all g. (d) For cyclic $N = \langle x\rangle$, normal iff $gxg^{-1} = x^k$. (e) The subgroup generated by all elements of order n is normal.

DF 3.1.26 Let $N = \langle S\rangle$ be a finite subgroup. Prove g normalizes N iff $gSg^{-1} \subseteq N$.

DF 3.1.28 Let $N = \langle S\rangle$ be finite with $G = \langle T\rangle$. Prove $N \trianglelefteq G$ iff $tSt^{-1} \subseteq N$ for all $t \in T$.

DF 3.1.29 For $D_{2n} = \langle r, s \mid r^n = s^2 = 1,\ rs = sr^{-1}\rangle$ and $k \mid n$, prove $\langle r^k\rangle \trianglelefteq D_{2n}$ and $D_{2n}/\langle r^k\rangle \cong D_{2k}$.

DF 3.1.42 Prove $N = \langle x^{-1}y^{-1}xy : x, y \in G\rangle$ is normal and G/N is abelian.

DF 3.1.44 Let $\mathcal{P} = \{A_i\}$ partition G and be a group under the quotient operation $A_iA_j =$ block of a_ia_j. Prove the block containing 1 is normal and $\mathcal{P}$ is its set of cosets.

DF 3.2.2 Prove the lattice of subgroups of S_3 is correct (all subgroups, joins, intersections).

DF 3.2.3 Prove the lattice of subgroups of Q_8 is correct.

DF 3.2.9 McKay's proof of Cauchy's Theorem via cyclic permutations of p-tuples with product 1: establish (a)–(f) to produce an element of order p.

DF 3.2.10 For H, K of finite indices m, n in G, prove $\operatorname{lcm}(m, n) \le [G : H \cap K] \le mn$ and deduce equality mn when $\gcd(m, n) = 1$.

DF 3.2.13 Identify D_8 as a subgroup of S_4 via a vertex labelling and prove its elements do not commute with (1 2 3).

DF 3.2.14 Prove S_4 has no normal subgroup of order 8 and no normal subgroup of order 3.

DF 3.3.2 Prove all parts of the Lattice Isomorphism Theorem (Theorem 20).

DF 3.3.5 For $QD_{16} = \langle \sigma, \tau\rangle$, prove $\langle\sigma^4\rangle \trianglelefteq QD_{16}$, draw the lattice of $QD_{16}/\langle\sigma^4\rangle$ via the Lattice Isomorphism Theorem, and identify its isomorphism type.

DF 3.3.6 For the modular $M = \langle v, u\rangle$ of order 16, prove $\langle v^4\rangle \trianglelefteq M$, draw the lattice of $M/\langle v^4\rangle$, and identify its isomorphism type.

DF 3.3.9 For a prime p and $|G| = p^am$ with $p \nmid m$, P of order p^a, $N \trianglelefteq G$ of order p^bn with $p \nmid n$, prove $|P \cap N| = p^b$ and $|PN/N| = p^{a-b}$.

DF 3.3.10 Prove that if H is a Hall subgroup of G and $N \trianglelefteq G$, then $H \cap N$ is a Hall subgroup of N and HN/N is a Hall subgroup of G/N.

DF 3.4.1 Prove that an abelian simple group is $\cong \mathbb{Z}/p\mathbb{Z}$ for some prime p (not assuming G finite).

DF 3.4.2 Exhibit all 3 composition series for Q_8 and all 7 for D_8, listing the composition factors.

DF 3.4.3 Find a composition series for the quasidihedral group of order 16 and deduce QD_{16} is solvable.

DF 3.4.4 Use Cauchy's Theorem and induction to show a finite abelian group has a subgroup of order n for each $n \mid |G|$.

DF 3.4.5 Prove that subgroups and quotient groups of a solvable group are solvable.

DF 3.4.6 Prove part (1) of the Jordan–Hölder Theorem by induction on $|G|$.

DF 3.4.7 Prove that if G is finite and $H \trianglelefteq G$, there is a composition series of G with H as a term.

DF 3.4.8 Prove the equivalence of (i) solvable, (ii) a chain with cyclic factors, (iii) all composition factors of prime order, (iv) a chain of G-normal subgroups with abelian factors.

DF 3.4.9 Prove the special case of Jordan–Hölder part (2) for series of lengths r and 2, showing $r = 2$ and matching factors.

DF 3.4.10 Prove part (2) of the Jordan–Hölder Theorem by induction on $\min\{r, s\}$.

DF 3.4.11 Prove that a nontrivial $H \trianglelefteq G$ in a solvable G contains a nontrivial abelian $A \trianglelefteq G$.

DF 3.4.12 Prove (without Feit–Thompson) that "every group of odd order is solvable" is equivalent to "the only simple groups of odd order have prime order."

DF 3.5.7 Prove that the group of rigid motions of a tetrahedron is isomorphic to A_4.

DF 3.5.8 Prove the lattice of subgroups of A_4 in the text is correct (A_4 has no subgroup of order 6).

DF 3.5.10 Find a composition series for A_4 and deduce A_4 is solvable.

DF 3.5.11b Prove S_4 has no subgroup isomorphic to Q_8.

DF 3.5.13 Prove that for $n \geq 5$ the subgroup of S_n generated by 3-cycles is A_n.

DF 3.5.14 Prove that distinct 3-cycles x, y in S_4 with $x \neq y^{-1}$ generate A_4.

DF 3.5.15 For distinct 3-cycles x, y in S_5 with $x \neq y^{-1}$: (a) if they fix a common point, $\langle x, y\rangle \cong A_4$; (b) if not, $\langle x, y\rangle = A_5$.

DF 3.5.16 Prove that for 3-cycles x, y in S_n, $\langle x, y\rangle$ is isomorphic to $\mathbb{Z}/3\mathbb{Z}$, A_4, A_5, or $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$.

Artin 9.6 Prove the Chinese Remainder Theorem: for $\gcd(a, b) = 1$ there is x with $x \equiv u \pmod{a}$ and $x \equiv v \pmod{b}$.

Artin M.3 Classify groups of order 6 by the cases: an element of order 6; an element of order 3 but none of order 6; all elements of order 1 or 2.

Artin M.9 (double cosets) For $H, K \leq G$ and $g \in G$, the set HgK is a double coset. Do the double cosets partition G?

Artin M.10 Let $H \leq G$. Show that the double cosets HgH ($g \in G$) coincide with the left cosets gH if and only if H is normal.

Fraleigh 10.36 Let $|G| = pq$ for primes p, q. Show every proper subgroup of G is cyclic.

Fraleigh 10.38 Using Lagrange, show that for odd n an abelian group of order $2n$ has precisely one element of order 2.

Fraleigh 10.39 Show that a group with at least two elements and no proper nontrivial subgroups is finite of prime order.

Fraleigh 10.40 Prove Theorem 10.11: for $K \leq H \leq G$ with finite indices, $[G : K] = [G : H]\,[H : K]$.

Fraleigh 10.45 For $H, K \leq G$ define $a \sim b$ iff $a = hbk$. Prove $\sim$ is an equivalence relation and describe the class of a (the double cosets).

Fraleigh 12.27 Prove the torsion subgroup T of an abelian group G is normal and G/T is torsion free.

Fraleigh 12.31 (Evaluation homomorphism) For $\varphi_c : F \to \mathbb{R}$, $\varphi_c(f) = f(c)$: prove it is a homomorphism, find its kernel, identify the coset of $f \equiv 1$, and identify $F/\ker \varphi_c$.

Fraleigh 12.34 Show that for any subset S of G there is a smallest normal subgroup containing S.

Fraleigh 12.35 Show the commutator subgroup C (smallest normal subgroup containing all commutators) gives an abelian quotient G/C.

Fraleigh 12.38 For G with at least one subgroup of fixed finite order s, show the intersection of all order-s subgroups is normal.

Chapter 4

Group Actions

4.1 Group Actions and Permutation Representations

Group actions, orbits, and stabilizers

We isolate the central idea of Chapter 4: a group G can *act* on a set A, meaning each group element permutes the points of A in a way compatible with the group law. The two axioms below say exactly that "do g_2 then do g_1" equals "do g_1g_2", and that the identity does nothing.

Definition 4.1.1 (Group action)**.** A (left) *action* of a group G on a set A is a map

$$G \times A \to A, \qquad (g, a) \mapsto g \cdot a,$$

satisfying the two axioms:

(1) $g_1 \cdot (g_2 \cdot a) = (g_1 g_2) \cdot a$ for all $g_1, g_2 \in G$ and $a \in A$;

(2) $1 \cdot a = a$ for all $a \in A$, where 1 is the identity of G.

We say G *acts on* A, and A is a G-set.

Remark 4.1.1. Each fixed $g \in G$ gives a map $\sigma_g : A \to A$, $\sigma_g(a) = g \cdot a$. Axioms (1)–(2) force σ_g to be a bijection: $\sigma_g \circ \sigma_{g^{-1}} = \sigma_{gg^{-1}} = \sigma_1 = \mathrm{id}_A$ and likewise $\sigma_{g^{-1}} \circ \sigma_g = \mathrm{id}_A$, so σ_g has two-sided inverse $\sigma_{g^{-1}}$. Thus every group element acts as a *permutation* of A. This is the bridge to the next definition.

Definition 4.1.2 (Permutation representation; kernel; faithful action)**.** Given an action of G on A, the *permutation representation* associated to it is the map

$$\rho : G \to \mathrm{Sym}(A), \qquad \rho(g) = \sigma_g \ \ (\text{i.e. } \sigma_g(a) = g \cdot a).$$

By the axioms ρ is a homomorphism. Its *kernel* is

$$\ker \rho = \{g \in G : \ g \cdot a = a \text{ for all } a \in A\},$$

the elements acting trivially on *every* point. The action is *faithful* if $\ker \rho = 1$, equivalently ρ is injective and so $G \cong \rho(G) \leq \mathrm{Sym}(A)$.

Proposition 4.1.3 (Actions $\iff$ permutation representations)**.** *For a group G and a set A there is a bijection between actions of G on A and homomorphisms $\rho : G \to \mathrm{Sym}(A)$, sending an action to the map ρ with $\rho(g)(a) = g \cdot a$, with inverse $\rho \mapsto (g \cdot a := \rho(g)(a))$.*

Proof. Start from an action. Axiom (2) gives $\rho(1)(a) = 1 \cdot a = a$, so $\rho(1) = \mathrm{id}_A$. Axiom (1) gives

$$\rho(g_1g_2)(a) = (g_1g_2) \cdot a = g_1 \cdot (g_2 \cdot a) = \rho(g_1)\big(\rho(g_2)(a)\big) = \big(\rho(g_1) \circ \rho(g_2)\big)(a),$$

so $\rho(g_1g_2) = \rho(g_1)\rho(g_2)$ in $\mathrm{Sym}(A)$; each $\rho(g)$ is a bijection by the previous remark, so ρ is a well-defined homomorphism $G \to \mathrm{Sym}(A)$.

Conversely, given a homomorphism $\rho : G \to \mathrm{Sym}(A)$, define $g \cdot a := \rho(g)(a)$. Then $1 \cdot a = \rho(1)(a) = \mathrm{id}_A(a) = a$, and $g_1 \cdot (g_2 \cdot a) = \rho(g_1)(\rho(g_2)(a)) = (\rho(g_1)\rho(g_2))(a) = \rho(g_1g_2)(a) = (g_1g_2) \cdot a$. The two constructions are mutually inverse by direct substitution. □

$$G \xrightarrow{\ \rho\ } \mathrm{Sym}(A) \qquad 1 \longrightarrow \ker\rho \hookrightarrow G \xrightarrow{\ \rho\ } \mathrm{Sym}(A)$$

Diagram explanation. Objects: Left diagram: G is the acting group; $\mathrm{Sym}(A)$ is the symmetric group on A, i.e. the group of all bijections $A \to A$. Right diagram: 1 is the trivial subgroup (the starting zero of the sequence); $\ker\rho \leq G$ is the normal subgroup of elements acting trivially on every point; G is the full acting group; $\mathrm{Sym}(A)$ is again the codomain.

Arrows: In both diagrams the map $\rho : G \to \mathrm{Sym}(A)$ sends g to its permutation σ_g (defined by $\sigma_g(a) = g \cdot a$). The unlabelled arrow $1 \to \ker\rho$ is the inclusion of the trivial group. The hooked arrow $\ker\rho \hookrightarrow G$ is the subgroup inclusion. Together they display $\ker\rho$ as the kernel inside G before ρ lands in $\mathrm{Sym}(A)$.

What commutes: The right diagram is an exact sequence at each interior node: $\mathrm{im}(1 \to \ker\rho) = \{1\} = \ker(\ker\rho \hookrightarrow G)$ (trivially), and $\mathrm{im}(\ker\rho \hookrightarrow G) = \ker\rho = \ker(\rho : G \to \mathrm{Sym}(A))$ (by definition of kernel).

Why it commutes: The exactness at G holds because $\rho(g) = \mathrm{id}_A$ iff $g \cdot a = a$ for every a, which is exactly the definition of $g \in \ker\rho$; so the image of the inclusion equals the kernel of ρ by definition.

Why this matters here: Immediately after proving that every action gives a homomorphism ρ, the author records in one picture both the fact that ρ exists (left) and the structure of its kernel (right). The diagrams package the entire Proposition: actions biject with homomorphisms, and the failure of faithfulness is measured by $\ker\rho$.

Concrete example: Conjugation on $G = S_3$: $\rho : S_3 \to \mathrm{Sym}(S_3)$ with $\ker\rho = Z(S_3) = \{1\}$, so the sequence $1 \to 1 \hookrightarrow S_3 \xrightarrow{\rho} \mathrm{Sym}(S_3)$ is exact and ρ is injective (faithful).

Common pitfall: Students sometimes write $\ker\rho = \{g : g \cdot a = a \text{ for some } a\}$, confusing the kernel (fixes *all* points simultaneously) with a pointwise stabilizer (fixes *one* point). The kernel is $\bigcap_{a \in A} G_a$, not a single G_a.

Takeaway: The point of this diagram is that every group action is secretly a homomorphism into a symmetric group, and the kernel of that homomorphism is exactly the subgroup of elements that act as the identity everywhere.

Method (Showing a formula defines an action / computing the kernel)**.** *Trigger.* A candidate rule $(g, a) \mapsto g \cdot a$, and you must verify it is an action or decide if it is faithful.

1. **Identity axiom:** check $1 \cdot a = a$ for all a.
2. **Compatibility axiom:** compute $g_1 \cdot (g_2 \cdot a)$ and $(g_1g_2) \cdot a$ *separately*, then confirm they agree. (Watch the order: a "g on the right" formula like $a \cdot g$ usually needs g^{-1} to be a *left* action.)
3. **Kernel:** solve $g \cdot a = a$ *for all* $a \in A$ simultaneously. The g satisfying every equation form $\ker\rho \trianglelefteq G$.
4. **Faithful?** Yes iff $\ker\rho = 1$.

Worked Example 4.1.4 (Left multiplication of G on itself is faithful)**.** Problem. Let G be any group, $A = G$, and $g \cdot a := ga$ (group product). Verify this is an action and compute its kernel.

Recognition. This is the defining setup of a group action: a candidate rule on $A = G$ to be tested against the two axioms, then the kernel solved over *all* a.

Solution. (2): $1 \cdot a = 1a = a$. (1): $g_1 \cdot (g_2 \cdot a) = g_1(g_2a) = (g_1g_2)a = (g_1g_2) \cdot a$ by associativity. So it is an action. Kernel: $g \cdot a = a$ for all a means $ga = a$ for all a; right-cancel a to get $g = 1$. Thus $\ker\rho = 1$, the action is *faithful*. *Check.* $\rho : G \hookrightarrow \mathrm{Sym}(G)$ is injective, which is Cayley's theorem: every group embeds in a symmetric group. For $G = \mathbb{Z}/3\mathbb{Z} = \{0, 1, 2\}$, $\rho(1)$ sends $0 \mapsto 1 \mapsto 2 \mapsto 0$, the 3-cycle $(0\,1\,2)$, indeed a nontrivial permutation, confirming faithfulness.

Worked Example 4.1.5 (Conjugation is an action)**.** Problem. Let $A = G$ and $g \cdot a := gag^{-1}$. Show this is an action and find its kernel.

Recognition. Same axiom-checking trigger, but with a twist: the rule wraps a in $g(\cdot)g^{-1}$, so axiom (1) must be checked carefully because two g's appear.

Solution. (2): $1 \cdot a = 1a1^{-1} = a$. (1): $g_1 \cdot (g_2 \cdot a) = g_1(g_2 a g_2^{-1})g_1^{-1} = (g_1 g_2)a(g_2^{-1}g_1^{-1}) = (g_1 g_2)a(g_1 g_2)^{-1} = (g_1 g_2) \cdot a$, using $(g_1 g_2)^{-1} = g_2^{-1}g_1^{-1}$. So it is an action. Kernel: $gag^{-1} = a$ for all $a \iff ga = ag$ for all $a \iff g \in Z(G)$. Thus $\ker \rho = Z(G)$. *Check.* The action is faithful iff $Z(G) = 1$. For $G = S_3$ (centerless) it is faithful; for $G = \mathbb{Z}/4\mathbb{Z}$ (abelian) every $\sigma_g = \mathrm{id}$, so $\ker \rho = G$, the most unfaithful possible.

Worked Example 4.1.6 (A formula that is NOT an action)**.** Problem. On $A = \mathbb{Z}$ let $g \cdot a := g + 2a$ for $g \in \mathbb{Z}$ (additive group). Is this an action?

Recognition. A candidate rule; run it through the two axioms looking for a *failure*.

Solution. (2): $0 \cdot a = 0 + 2a = 2a \neq a$ (for $a \neq 0$). Axiom (2) already fails, so this is *not* an action. (Axiom (1) also fails: $g_1 \cdot (g_2 \cdot a) = g_1 + 2(g_2 + 2a) = g_1 + 2g_2 + 4a$ but $(g_1 + g_2) \cdot a = g_1 + g_2 + 2a$.) *Check.* A genuine left action of $\mathbb{Z}$ on $\mathbb{Z}$ is $g \cdot a := g + a$; there $0 \cdot a = a$ and $g_1 \cdot (g_2 \cdot a) = g_1 + g_2 + a = (g_1 + g_2) \cdot a$. The doubled version breaks both axioms, confirming the diagnosis.

Orbits, the induced equivalence relation, and stabilizers

Theorem 4.1.7 (The action partitions A into orbits)**.** *Let G act on A. Define $a \sim b$ iff $b = g \cdot a$ for some $g \in G$. Then $\sim$ is an equivalence relation on A. Its equivalence classes are called the* orbits*; the orbit of a is*

$$\mathrm{orb}(a) = \{g \cdot a : \ g \in G\}.$$

Hence the orbits partition A.

Proof. **Reflexive:** $a = 1 \cdot a$, so $a \sim a$. **Symmetric:** if $b = g \cdot a$ then $g^{-1} \cdot b = g^{-1} \cdot (g \cdot a) = (g^{-1}g) \cdot a = 1 \cdot a = a$, so $b \sim a$. **Transitive:** if $b = g \cdot a$ and $c = h \cdot b$ then $c = h \cdot (g \cdot a) = (hg) \cdot a$, so $a \sim c$. An equivalence relation partitions A into its classes, and the class of a is exactly $\{b : a \sim b\} = \{g \cdot a : g \in G\} = \mathrm{orb}(a)$. □

Definition 4.1.8 (Transitive action; stabilizer)**.** An action is *transitive* if there is a single orbit, i.e. $\mathrm{orb}(a) = A$ for some (hence every) a. The *stabilizer* of $a \in A$ is

$$G_a = \mathrm{Stab}(a) = \{g \in G : \ g \cdot a = a\}.$$

Proposition 4.1.9 (The stabilizer is a subgroup)**.** *For each $a \in A$, $G_a \leq G$. Moreover* $\ker \rho = \bigcap_{a \in A} G_a$*, and points in the same orbit have conjugate stabilizers: $G_{g \cdot a} = g\, G_a\, g^{-1}$.*

Proof. $1 \cdot a = a$ gives $1 \in G_a$, so $G_a \neq \varnothing$. If $g, h \in G_a$ then $(gh) \cdot a = g \cdot (h \cdot a) = g \cdot a = a$, so $gh \in G_a$. If $g \in G_a$ then $a = 1 \cdot a = (g^{-1}g) \cdot a = g^{-1} \cdot (g \cdot a) = g^{-1} \cdot a$, so $g^{-1} \in G_a$. Thus $G_a \leq G$. An element fixes *all* points iff it lies in every G_a, giving $\ker \rho = \bigcap_a G_a$. Finally $x \in G_{g \cdot a} \iff x \cdot (g \cdot a) = g \cdot a \iff (g^{-1}xg) \cdot a = a \iff g^{-1}xg \in G_a \iff x \in gG_ag^{-1}$. □

Theorem 4.1.10 (Orbit–Stabilizer)**.** *Let G act on A and fix $a \in A$. The map*

$$\Phi : \ G/G_a \longrightarrow \mathrm{orb}(a), \qquad gG_a \longmapsto g \cdot a,$$

on the set of left cosets of G_a is a well-defined bijection. Consequently

$$\big|\mathrm{orb}(a)\big| = [G : G_a].$$

If G is finite, $\big|\mathrm{orb}(a)\big| = \dfrac{|G|}{|G_a|}$*, so every orbit size divides $|G|$.*

Proof. **Well-defined and injective (one calculation):** for $g, h \in G$,

$$gG_a = hG_a \iff h^{-1}g \in G_a \iff (h^{-1}g) \cdot a = a \iff g \cdot a = h \cdot a,$$

where the last step applies $h \cdot (-)$, a bijection, to both sides. Reading $\Rightarrow$ shows Φ is well-defined (the value $g \cdot a$ does not depend on the coset representative); reading $\Leftarrow$ shows Φ is injective. **Surjective:** every element of $\mathrm{orb}(a)$ has the form $g \cdot a = \Phi(gG_a)$ by definition of the orbit. Hence Φ is a bijection, so $|\mathrm{orb}(a)| = |G/G_a| = [G : G_a]$. When G is finite, Lagrange gives $[G : G_a] = |G|/|G_a|$, which divides $|G|$. $\square$

$$G/G_a \xrightarrow{\ \sim\ } \mathrm{orb}(a) \qquad\qquad \begin{array}{ccc} G & \xrightarrow{\ \pi\ } & G/G_a \\ & {\scriptstyle g \mapsto g\cdot a}\searrow & \downarrow{\scriptstyle \Phi} \\ & & \mathrm{orb}(a) \end{array}$$

Diagram explanation. Objects: Left diagram: G/G_a is the set of left cosets of the stabilizer G_a in G (a G-set, not necessarily a group unless $G_a \trianglelefteq G$); $\mathrm{orb}(a)$ is the orbit of a in A. Right diagram: G is the full acting group; G/G_a is the coset space; $\mathrm{orb}(a)$ is the orbit.

Arrows: Left diagram: the arrow labelled $\sim$ is the bijection $\Phi : G/G_a \to \mathrm{orb}(a)$ sending $gG_a \mapsto g \cdot a$. Right diagram: $\pi : G \to G/G_a$ is the canonical quotient map $g \mapsto gG_a$; the diagonal arrow $G \to \mathrm{orb}(a)$ is the orbit map $g \mapsto g \cdot a$; $\Phi : G/G_a \to \mathrm{orb}(a)$ is the induced bijection.

What commutes: The triangle says $\Phi \circ \pi =$ (orbit map): for any $g \in G$, $\Phi(\pi(g)) = \Phi(gG_a) = g \cdot a$, which is exactly the orbit map. So both paths from G to $\mathrm{orb}(a)$ agree.

Why it commutes: Well-definedness of Φ: if $gG_a = hG_a$ then $h^{-1}g \in G_a$, so $(h^{-1}g) \cdot a = a$, giving $g \cdot a = h \cdot a$. Thus Φ does not depend on the coset representative. The equality $\Phi \circ \pi =$ (orbit map) then holds by definition of Φ.

Why this matters here: The Orbit–Stabilizer theorem's heart is this triangle: it says the orbit map $G \to \mathrm{orb}(a)$, which need *not* be injective on G (it is injective iff $G_a = 1$), becomes a bijection once we collapse each coset gG_a to a single point. The left bijection records the counting consequence $|\mathrm{orb}(a)| = [G : G_a]$.

Concrete example: $G = S_4$ acting on $\{1, 2, 3, 4\}$, $a = 1$: $G_1 = \mathrm{Stab}(1) \cong S_3$ (order 6), $\mathrm{orb}(1) = \{1, 2, 3, 4\}$ (size 4). Then $\Phi : S_4/G_1 \to \{1, 2, 3, 4\}$ sends each coset $\sigma G_1 \mapsto \sigma(1)$, a bijection of four elements; and $4 \cdot 6 = 24 = |S_4|$.

Common pitfall: Φ is a bijection of *sets*, not a group isomorphism; G/G_a is generally not a group (unless $G_a \trianglelefteq G$). Do not write $G/G_a \cong \mathrm{orb}(a)$ as groups. Also, well-definedness of Φ requires checking that different coset representatives give the same orbit element – this step is the content of the proof and must not be skipped.

Takeaway: The point of this diagram is that the orbit of a is in bijection with the coset space G/G_a, so every orbit size is an index and hence divides $|G|$ when G is finite.

Remark 4.1.2. The second triangle is the action's "first isomorphism theorem" shape: the orbit map $g \mapsto g \cdot a$ factors through the quotient G/G_a, and the induced map Φ is a bijection onto the image $\mathrm{orb}(a)$. Collapsing G by the stabilizer exactly recovers the orbit.

Method (Counting with Orbit–Stabilizer)**.** *Trigger.* You want $|\mathrm{orb}(a)|$, or $|G|$, or $|G_a|$, and you can compute two of these three quantities; or you must show some orbit/index relationship.

1. Pick a convenient point $a \in A$.
2. Compute $\mathrm{orb}(a)$ directly (apply enough group elements until the orbit closes up) and read off $|\mathrm{orb}(a)|$.
3. Compute $G_a = \{g : g \cdot a = a\}$ and read off $|G_a|$.
4. Use $|\mathrm{orb}(a)| \cdot |G_a| = |G|$ to get the missing third number, or to *check* the two you computed.
5. For an unknown $|G|$: $|G| = |\mathrm{orb}(a)| \cdot |G_a|$ when the action is understood geometrically (e.g. symmetries of a figure acting on its vertices/faces).

Worked Example 4.1.11 (S_n on $\{1,\dots,n\}$: transitive, $\mathrm{Stab}(n) \cong S_{n-1}$)**.** Problem. Let $G = \mathrm{Sym}(\{1,\dots,n\}) = S_n$ act by $\sigma \cdot i = \sigma(i)$. Show it is transitive, find $\mathrm{Stab}(n)$, and confirm Orbit–Stabilizer.

Recognition. Transitivity asks for one orbit; the stabilizer is the natural-action recognition trigger, and Orbit–Stabilizer ties $|S_n|$ to $|S_{n-1}|$.

Solution. Transitive: for any i, the transposition $(i\,n)$ sends $n \mapsto i$, so $i \in \mathrm{orb}(n)$; thus $\mathrm{orb}(n) = \{1,\dots,n\}$ and $|\,\mathrm{orb}(n)| = n$. *Stabilizer:* $\mathrm{Stab}(n) = \{\sigma : \sigma(n) = n\}$, the permutations fixing n and permuting $\{1,\dots,n-1\}$ freely. The restriction map $\sigma \mapsto \sigma|_{\{1,\dots,n-1\}}$ is an isomorphism $\mathrm{Stab}(n) \cong S_{n-1}$, so $|\,\mathrm{Stab}(n)| = (n-1)!$. *Check.* $|\,\mathrm{orb}(n)| \cdot |\,\mathrm{Stab}(n)| = n \cdot (n-1)! = n! = |S_n|$. Consistent. For $n = 4$: orbit size 4, stabilizer order $3! = 6$, and $4 \cdot 6 = 24 = |S_4|$.

Worked Example 4.1.12 (D_8 on the 4 vertices of a square; representation into S_4)**.** Problem. Let $G = D_8 = \langle r, s\rangle$ ($r^4 = s^2 = 1$, $sr = r^{-1}s$) act on the square's vertices labelled $1,2,3,4$ counterclockwise. Compute $\rho(r), \rho(s)$ as elements of S_4, find $\mathrm{orb}(1)$ and $\mathrm{Stab}(1)$, and verify Orbit–Stabilizer.

Recognition. A concrete symmetry group acting on vertices: build the permutation representation $\rho : D_8 \to S_4$, then run the counting recipe.

Solution. The rotation r by $90°$ sends $1 \to 2 \to 3 \to 4 \to 1$, so $\rho(r) = (1\,2\,3\,4)$. Let s be the reflection fixing the diagonal through vertices 1 and 3; it swaps $2, 4$ and fixes $1, 3$, so $\rho(s) = (2\,4)$. *Orbit:* r, r^2, r^3 carry 1 to $2, 3, 4$, so $\mathrm{orb}(1) = \{1,2,3,4\}$, $|\,\mathrm{orb}(1)| = 4$ (the action is transitive). *Stabilizer:* $g \in \mathrm{Stab}(1)$ fixes vertex 1. The rotations fixing 1: only 1. The reflections fixing 1 are those whose axis passes through 1, namely s (axis 1–3). So $\mathrm{Stab}(1) = \{1, s\}$, order 2. *Check.* $|\,\mathrm{orb}(1)| \cdot |\,\mathrm{Stab}(1)| = 4 \cdot 2 = 8 = |D_8|$. Consistent. (As a sanity check ρ is faithful: a symmetry fixing all four vertices is the identity, so $\ker\rho = 1$ and $D_8 \hookrightarrow S_4$.)

Worked Example 4.1.13 (Orbit–Stabilizer to count $|G|$: rotations of a cube on its faces)**.** Problem. Let G be the group of rotational symmetries of a cube acting on its 6 faces. Use Orbit–Stabilizer to compute $|G|$.

Recognition. Unknown group order, but a geometric action whose orbit and one stabilizer are easy to see: this is the "$|G| = |\,\mathrm{orb}\,| \cdot |\,\mathrm{Stab}\,|$" recipe.

Solution. Orbit: any face can be rotated to any other face, so the action is transitive and $|\,\mathrm{orb}(\text{face})| = 6$. *Stabilizer:* rotations fixing a chosen (say top) face are exactly the rotations about the vertical axis through that face's center: by $0°, 90°, 180°, 270°$. So $|\,\mathrm{Stab}(\text{face})| = 4$. **Compute:** $|G| = |\,\mathrm{orb}\,| \cdot |\,\mathrm{Stab}\,| = 6 \cdot 4 = 24$. *Check.* This matches the known fact that the rotation group of the cube has order 24 (and is isomorphic to S_4 via its action on the 4 space diagonals). Counting instead via vertices: 8 vertices, stabilizer of a vertex has order 3 (the three rotations by $0°, 120°, 240°$ about the body diagonal), and $8 \cdot 3 = 24$. The two routes agree.

Worked Example 4.1.14 (Action of G on left cosets G/H)**.** Problem. Let $H \le G$ and let G act on the set $A = G/H$ of left cosets by $g \cdot (xH) := (gx)H$. Verify it is an action, show it is transitive, compute $\mathrm{Stab}(H)$ (stabilizer of the coset $1H$), and identify $\ker\rho$.

Recognition. The standard "left multiplication on cosets" action; recognize it as the source of every transitive action, then apply the stabilizer/kernel machinery.

Solution. Well-defined: if $xH = x'H$ then $x' = xh$, so $(gx')H = (gxh)H = (gx)H$; the rule does not depend on the representative. *Axioms:* $1 \cdot (xH) = xH$, and $g_1 \cdot (g_2 \cdot xH) = g_1 \cdot (g_2x)H = (g_1g_2x)H = (g_1g_2) \cdot xH$. *Transitive:* given cosets xH, yH, the element $g = yx^{-1}$ sends $xH \mapsto (yx^{-1}x)H = yH$; one orbit. *Stabilizer of* $1H$*:* $g \cdot (1H) = 1H \iff gH = H \iff g \in H$, so $\mathrm{Stab}(1H) = H$. *Kernel:* $\ker\rho = \bigcap_{x\in G} \mathrm{Stab}(xH) = \bigcap_{x\in G} xHx^{-1}$, the largest normal subgroup of G contained in H (the *core* of H), using $\mathrm{Stab}(xH) = xHx^{-1}$ from the conjugacy of stabilizers in the same orbit. *Check.* Orbit–Stabilizer reads $|\,\mathrm{orb}(1H)| = [G : H] = |G/H|$, which is correct since the orbit is all of $A = G/H$. For $G = S_3$, $H = \langle(1\,2)\rangle$ of order 2: $|G/H| = 3$, $\rho : S_3 \to S_3$, and $\ker\rho$ is the core of H, which is 1 (so S_3 acts faithfully on its 3 cosets, recovering $S_3 \cong S_3$).

Worked Example 4.1.15 (A non-transitive action with several orbits)**.** Problem. Let $G = \langle r\rangle = \langle(1\,2\,3)\rangle \cong \mathbb{Z}/3\mathbb{Z} \le S_5$ act on $A = \{1,2,3,4,5\}$ by $\sigma \cdot i = \sigma(i)$, where $r = (1\,2\,3)$ fixes 4 and 5. List the orbits, the stabilizers, and check Orbit–Stabilizer on each.

Recognition. Several points, an obviously non-transitive action: the trigger to *enumerate* orbits as equivalence classes and verify the counting theorem orbit-by-orbit.

Solution. Orbits: applying $1, r, r^2$ to each point:

$$\mathrm{orb}(1) = \{1,2,3\} = \mathrm{orb}(2) = \mathrm{orb}(3), \quad \mathrm{orb}(4) = \{4\}, \quad \mathrm{orb}(5) = \{5\}.$$

So there are three orbits: $\{1,2,3\}, \{4\}, \{5\}$; the action is *not* transitive. *Stabilizers:* $\mathrm{Stab}(1) = \{g \in G : g(1) = 1\}$. Since $r(1) = 2 \neq 1$ and $r^2(1) = 3 \neq 1$, only $g = 1$ fixes 1, so $\mathrm{Stab}(1) = \{1\}$, order 1. Similarly $\mathrm{Stab}(2) = \mathrm{Stab}(3) = \{1\}$. Every element fixes 4, so $\mathrm{Stab}(4) = G$, order 3; likewise $\mathrm{Stab}(5) = G$. *Check (per orbit).* $|\mathrm{orb}(1)| \cdot |\mathrm{Stab}(1)| = 3 \cdot 1 = 3 = |G|$. $|\mathrm{orb}(4)| \cdot |\mathrm{Stab}(4)| = 1 \cdot 3 = 3 = |G|$. Same for 5. All consistent. As a partition check, $3 + 1 + 1 = 5 = |A|$, so the orbits exhaust A disjointly.

Caution. **Orbit vs. stabilizer live in different worlds.** The orbit $\mathrm{orb}(a) \subseteq A$ is a set of *points*; the stabilizer $G_a \leq G$ is a set of *group elements*. Orbit–Stabilizer relates their sizes via the *index* $[G : G_a]$, not by any direct inclusion. Writing "$\mathrm{orb}(a) = G/G_a$" is only a bijection of sets, never an equality.

Caution. **The stabilizer is a subgroup of G, but the orbit is not a subgroup of anything.** Students sometimes "check $\mathrm{orb}(a)$ is a subgroup" — it usually is not even contained in G. Only G_a (and $\ker \rho = \bigcap_a G_a$) are subgroups.

Caution. **Left vs. right.** For axiom (1) you need $g_1 \cdot (g_2 \cdot a) = (g_1 g_2) \cdot a$. A rule like $a \cdot g := ag$ (right multiplication, written on the right) gives $(a \cdot g_1) \cdot g_2 = a g_1 g_2$, which corresponds to $(g_1 g_2)$ acting as "g_1 then g_2" — the *wrong* order for a left action. To convert a right action to a left action, use $g \cdot a := ag^{-1}$, so that $g_1 \cdot (g_2 \cdot a) = a g_2^{-1} g_1^{-1} = a(g_1 g_2)^{-1} = (g_1 g_2) \cdot a$.

Remark 4.1.3 (Same-orbit stabilizers are conjugate — diagram). The relation $G_{g \cdot a} = g G_a g^{-1}$ says conjugation by g carries the stabilizer of a to the stabilizer of $g \cdot a$:

$$G_a \xrightarrow[\sim]{x \mapsto gxg^{-1}} G_{g \cdot a}$$

Diagram explanation. Objects: $G_a = \mathrm{Stab}(a) \leq G$ is the stabilizer subgroup of the point $a \in A$; $G_{g \cdot a} = \mathrm{Stab}(g \cdot a) \leq G$ is the stabilizer of the point $g \cdot a$ in the same orbit. Both are subgroups of G.

Arrows: The single arrow is conjugation by g: the map $x \mapsto gxg^{-1}$, a group isomorphism $G_a \xrightarrow{\sim} G_{g \cdot a}$. It carries a stabilizer element of a to a stabilizer element of $g \cdot a$.

What commutes: There is no commutativity condition here (only one arrow, so no two paths to compare). The content is instead that the map is a well-defined *isomorphism*: if $x \in G_a$ (i.e. $x \cdot a = a$) then $gxg^{-1} \in G_{g \cdot a}$ (i.e. $(gxg^{-1}) \cdot (g \cdot a) = g \cdot a$).

Why it commutes: Verify the target: $(gxg^{-1}) \cdot (g \cdot a) = g \cdot (x \cdot (g^{-1} \cdot g \cdot a)) = g \cdot (x \cdot a) = g \cdot a$, since $x \cdot a = a$. The inverse map is conjugation by g^{-1}, confirming it is an isomorphism. This is a direct element-chase using the action axioms.

Why this matters here: The diagram makes the abstract statement $G_{g \cdot a} = g G_a g^{-1}$ visible: points in the same orbit have *conjugate* stabilizers, hence isomorphic ones. Combined with Orbit–Stabilizer ($|\mathrm{orb}(a)| = |G|/|G_a|$), this forces every orbit element to have a stabilizer of the same size, making the formula $|\mathrm{orb}(a)| = |G|/|G_a|$ truly well-defined independent of which point in the orbit you choose.

Concrete example: $G = D_8$ acting on vertices of a square, $a = 1$, $g = r$ (rotation by 90°), $g \cdot a = 2$. Then $G_1 = \{1, s\}$ (the reflection fixing vertex 1) and $G_2 = \{1, r^2 s\}$ (the reflection fixing vertex 2); conjugation by r sends $s \mapsto rsr^{-1} = r^2 s$, confirming $r G_1 r^{-1} = G_2$.

Common pitfall: The diagram does not say $G_a = G_{g \cdot a}$ as sets; it says they are isomorphic via an *inner* automorphism of G. Students sometimes read the $\sim$ label as equality and conclude incorrectly that distinct points have identical stabilizers.

Takeaway: The point of this diagram is that conjugation by g witnesses the isomorphism between stabilizers of points in the same orbit, so all stabilizers in one orbit are conjugate subgroups of G and in particular have the same order.

In particular all stabilizers along one orbit are isomorphic, so $|G_a|$ is constant on each orbit — consistent with Orbit–Stabilizer forcing $|\mathrm{orb}(a)| = |G|/|G_a|$ to be the same for every a in that orbit.

Exercises (from the text).

1. Let G act on the set A. Prove that if $a, b \in A$ and $b = g \cdot a$ for some $g \in G$, then $G_b = gG_ag^{-1}$ (G_a is the stabilizer of a). Deduce that if G acts transitively on A then the kernel of the action is $\bigcap_{g \in G} gG_ag^{-1}$.

2. Let G be a permutation group on the set A (i.e., $G \leq S_A$), let $\sigma \in G$ and let $a \in A$. Prove that $\sigma G_a \sigma^{-1} = G_{\sigma(a)}$. Deduce that if G acts transitively on A then $\bigcap_{\sigma \in G} \sigma G_a \sigma^{-1} = 1$.

3. Assume that G is an abelian, transitive subgroup of S_A. Show that $\sigma(a) \neq a$ for all $\sigma \in G - \{1\}$ and all $a \in A$. Deduce that $|G| = |A|$. [Use the preceding exercise.]

4. Let S_3 act on the set Ω of ordered pairs $\{(i, j) \mid 1 \leq i, j \leq 3\}$ by $\sigma((i, j)) = (\sigma(i), \sigma(j))$. Find the orbits of S_3 on Ω. For each $\sigma \in S_3$ list the cycle decomposition of σ under this action (i.e., find its cycle decomposition when σ is considered as an element of S_9 – first fix a labelling of these nine ordered pairs). For each orbit $\mathcal{O}$ of S_3 acting on these nine points pick some $a \in \mathcal{O}$ and find the stabilizer of a in S_3.

5. For each of parts (a) and (b) repeat the preceding exercise but with S_3 acting on the specified set:

   (a) the set of 27 triples $\{(i, j, k) \mid 1 \leq i, j, k \leq 3\}$

   (b) the set $\mathcal{P}(\{1, 2, 3\}) - \{\emptyset\}$ of all 7 nonempty subsets of $\{1, 2, 3\}$.

6. As in Exercise 12 of Section 2.2 let R be the set of all polynomials with integer coefficients in the independent variables x_1, x_2, x_3, x_4 and let S_4 act on R by permuting the indices of the four variables:

$$\sigma \cdot p(x_1, x_2, x_3, x_4) = p(x_{\sigma(1)}, x_{\sigma(2)}, x_{\sigma(3)}, x_{\sigma(4)})$$

   for all $\sigma \in S_4$.

   (a) Find the polynomials in the orbit of S_4 on R containing $x_1 + x_2$ (recall from Exercise 12 in Section 2.2 that the stabilizer of this polynomial has order 4).

   (b) Find the polynomials in the orbit of S_4 on R containing $x_1x_2 + x_3x_4$ (recall from Exercise 12 in Section 2.2 that the stabilizer of this polynomial has order 8).

   (c) Find the polynomials in the orbit of S_4 on R containing $(x_1 + x_2)(x_3 + x_4)$.

7. Let G be a transitive permutation group on the finite set A. A *block* is a nonempty subset B of A such that for all $\sigma \in G$ either $\sigma(B) = B$ or $\sigma(B) \cap B = \emptyset$ (here $\sigma(B)$ is the set $\{\sigma(b) \mid b \in B\}$).

   (a) Prove that if B is a block containing the element a of A, then the set G_B defined by $G_B = \{\sigma \in G \mid \sigma(B) = B\}$ is a subgroup of G containing G_a.

   (b) Show that if B is a block and $\sigma_1(B), \sigma_2(B), \ldots, \sigma_n(B)$ are all the distinct images of B under the elements of G, then these form a partition of A.

   (c) A (transitive) group G on a set A is said to be *primitive* if the only blocks in A are the trivial ones: the sets of size 1 and A itself. Show that S_4 is primitive on $A = \{1, 2, 3, 4\}$. Show that D_8 is not primitive as a permutation group on the four vertices of a square.

   (d) Prove that the transitive group G is primitive on A if and only if for each $a \in A$, the only subgroups of G containing G_a are G_a and G (i.e., G_a is a *maximal* subgroup of G, cf. Exercise 16, Section 2.4). [Use part (a).]

8. A transitive permutation group G on a set A is called *doubly transitive* if for any (hence all) $a \in A$ the subgroup G_a is transitive on the set $A - \{a\}$.

   (a) Prove that S_n is doubly transitive on $\{1, 2, \ldots, n\}$ for all $n \geq 2$.

   (b) Prove that a doubly transitive group is primitive. Deduce that D_8 is not doubly transitive in its action on the 4 vertices of a square.

9. Assume G acts transitively on the finite set A and let H be a normal subgroup of G. Let $\mathcal{O}_1, \mathcal{O}_2, \ldots, \mathcal{O}_r$ be the distinct orbits of H on A.

(a) Prove that G permutes the sets $\mathcal{O}_1, \mathcal{O}_2, \ldots, \mathcal{O}_r$ (i.e., for each $g \in G$ and each $i \in \{1, \ldots, r\}$ there is a j such that $g\mathcal{O}_i = \mathcal{O}_j$, where $g\mathcal{O} = \{g \cdot a \mid a \in \mathcal{O}\}$) (i.e., in the notation of Exercise 7 the sets $\mathcal{O}_1, \ldots, \mathcal{O}_r$ are blocks). Prove that G is transitive on $\{\mathcal{O}_1, \ldots, \mathcal{O}_r\}$. Deduce that all orbits of H on A have the same cardinality.

(b) Prove that if $a \in \mathcal{O}_1$ then $|\mathcal{O}_1| = |H : H \cap G_a|$ and prove that $r = |G : HG_a|$. [Draw the sublattice describing the Second Isomorphism Theorem for the subgroups H and G_a of G. Note that $H \cap G_a = H_a$.]

10. Let H and K be subgroups of the group G. For each $x \in G$ define the HK *double coset* of x in G to be the set

$$HxK = \{hxk \mid h \in H,\ k \in K\}.$$

(a) Prove that HxK is the union of the left cosets $x_1K, \ldots, x_nK$ where $\{x_1K, \ldots, x_nK\}$ is the orbit containing xK of H acting by left multiplication on the set of left cosets of K.

(b) Prove that HxK is a union of right cosets of H.

(c) Show that HxK and HyK are either the same set or are disjoint for all $x, y \in G$. Show that the set of HK double cosets partitions G.

(d) Prove that $|HxK| = |K| \cdot |H : H \cap xKx^{-1}|$.

(e) Prove that $|HxK| = |H| \cdot |K : K \cap x^{-1}Hx|$.

Practice problems.

1. Let G act on the set A. Show that the relation $a \sim b$ iff $b = g \cdot a$ for some $g \in G$ is an equivalence relation on A, and that its classes are exactly the orbits $\mathrm{orb}(a)$.

2. Let $G = D_8 = \langle r, s \rangle$ act on the four vertices $\{1, 2, 3, 4\}$ of a square (labeled cyclically), with r the rotation $(1\,2\,3\,4)$ and s the reflection $(2\,4)$. Write down the permutation representation $\rho : G \to S_4$ explicitly (give the image of r and of s), and compute $\mathrm{Stab}_G(1)$ and the orbit $\mathrm{orb}(1)$. Verify $|\,\mathrm{orb}(1)| \cdot |\,\mathrm{Stab}_G(1)| = |G|$.

3. Let G act on A and fix $a \in A$. Prove that for all $g \in G$, $\mathrm{Stab}_G(g \cdot a) = g\,\mathrm{Stab}_G(a)\,g^{-1}$. Conclude that points in the same orbit have conjugate stabilizers.

4. Let G act on itself by left multiplication, $g \cdot x = gx$. Show this action is faithful and transitive, and that the induced map $G \to \mathrm{Sym}(G)$ is the (left regular) representation. Deduce Cayley's theorem: every group of order n embeds in S_n.

5. Let G act on itself by conjugation, $g \cdot x = gxg^{-1}$. Identify the orbits, the stabilizer $\mathrm{Stab}_G(x)$, and the kernel of the corresponding permutation representation $G \to \mathrm{Sym}(G)$.

6. Let G be a group of order 30 act on a set A with $|A| = 8$. Prove that every orbit has size dividing 30, hence size in $\{1, 2, 3, 5, 6\}$ (the divisors of 30 that are ≤ 8), and that the orbit sizes sum to 8. List all possible multisets of orbit sizes, and conclude that at least one orbit has size 1 (a fixed point) unless the orbit sizes can be chosen from $\{2, 3, 5, 6\}$ summing to 8 – determine exactly which multisets force a fixed point.

7. For $G = Q_8$ acting on itself by conjugation, compute the class equation $|G| = |Z(G)| + \sum[G : C_G(x_i)]$ explicitly, naming a representative x_i for each noncentral class. (Here $Z(Q_8) = \{\pm 1\}$ and the noncentral classes are $\{i, -i\}, \{j, -j\}, \{k, -k\}$, giving $8 = 2 + 2 + 2 + 2$.)

8. Let $G = S_4$. Using that conjugacy classes correspond to cycle types, write the class equation of S_4. Verify the class sizes sum to 24 and each divides 24. (The class sizes are $1, 6, 3, 8, 6$.)

9. Let G act transitively on a finite set A with $|A| > 1$. Prove there exists $g \in G$ that fixes no point of A (Jordan). Suggestion: the number of fixed points averaged over G equals the number of orbits, which is 1; since the identity fixes all $|A| > 1$ points, some element must fix none.

10. Let p be prime and let G be a group of order p^n act on a finite set A. Prove $|A| \equiv |A^G| \pmod{p}$, where $A^G = \{a \in A : g \cdot a = a\ \forall g\}$ is the fixed-point set. Deduce that if $p \mid |A|$ then $p \mid |A^G|$ (so $|A^G| \geq p$ as soon as $A^G \neq \varnothing$), that A^G is nonempty whenever $p \nmid |A|$, and that a nontrivial p-group has nontrivial center.

11. Compute $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$ for p prime and show $|\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})| = p-1$. More generally show $\mathrm{Aut}(\mathbb{Z}/n\mathbb{Z}) \cong (\mathbb{Z}/n\mathbb{Z})^\times$ and compute its order via Euler's φ.

12. Let G have order p^2 with p prime. Using the class equation, prove G is abelian, hence $G \cong \mathbb{Z}/p^2\mathbb{Z}$ or $G \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$.

13. Let $G = S_3$ act on the set A of its three 2-element subsets $\{1,2\},\{1,3\},\{2,3\}$. Build the permutation representation $\rho : S_3 \to \mathrm{Sym}(A) \cong S_3$, determine $\ker\rho$, and decide whether ρ is faithful.

14. Let G act on A and B. Define the diagonal action of G on $A \times B$ by $g \cdot (a,b) = (g\cdot a,\, g\cdot b)$. Verify this is an action, and for $G = \mathbb{Z}/4\mathbb{Z}$ acting on $A = B = \mathbb{Z}/4\mathbb{Z}$ by addition (translation), find all orbits on $A \times B$ and their sizes.

15. Let G act on the left cosets $A = G/H$ of a subgroup $H \le G$ by $g \cdot (xH) = (gx)H$. Show this action is transitive, compute $\mathrm{Stab}_G(H)$, and show ker of the representation $G \to \mathrm{Sym}(G/H)$ equals $\bigcap_{x\in G} xHx^{-1}$ (the core of H).

16. Let G be a finite group and $H \le G$ with $[G:H] = p$ the smallest prime dividing $|G|$. Using the action of G on G/H and the resulting map $G \to S_p$, prove $H \trianglelefteq G$.

Additional exercises.

1. (Cauchy via actions) Let p divide $|G|$. Let $\mathbb{Z}/p\mathbb{Z}$ act on $X = \{(x_1,\dots,x_p) \in G^p : x_1x_2\cdots x_p = 1\}$ by cyclic rotation of coordinates. Show $|X| = |G|^{p-1}$, that $\mathbb{Z}/p\mathbb{Z}$ acts on X, and apply $|X| \equiv |X^{\mathbb{Z}/p\mathbb{Z}}| \pmod p$ to produce an element of order p.

2. Let G act 2-transitively on A (for any two ordered pairs of distinct points there is g carrying one to the other). Prove that for $a \in A$, the stabilizer $\mathrm{Stab}_G(a)$ acts transitively on $A \setminus \{a\}$, and that $|G| = |A|(|A|-1)\,|\mathrm{Stab}_G(a,b)|$ for distinct a,b, where $\mathrm{Stab}_G(a,b)$ is the pointwise stabilizer of $\{a,b\}$.

3. Let G be a finite group acting transitively on A with $|A| = n \ge 2$. Show that the number of orbits of G on $A \times A$ (the rank of the action) equals the number of $\mathrm{Stab}_G(a)$-orbits on A, and is at least 2.

4. Let G act on A and let $N = \ker(G \to \mathrm{Sym}(A))$ be the kernel. Prove $N = \bigcap_{a\in A}\mathrm{Stab}_G(a)$, that $N \trianglelefteq G$, and that the induced action of G/N on A is faithful with the same orbits.

5. (Counting necklaces) Using Burnside's lemma, the number of orbits equals $|G|^{-1}\sum_g |\mathrm{Fix}(g)|$ where $\mathrm{Fix}(g) = \{a : g\cdot a = a\}$. Let $\mathbb{Z}/6\mathbb{Z}$ act by rotation on the 2^6 colorings of 6 beads with 2 colors. Compute the number of distinct necklaces.

6. Let G be a finite simple group acting nontrivially on a set A with $|A| = n$. Prove G embeds in S_n, and hence A_5 has no faithful action on a set with fewer than 5 points. Conclude $|G| \mid n!$.

Commutative-diagram exercises.

1. An action of G on A is the same data as a homomorphism $\rho : G \to \mathrm{Sym}(A)$. State the two action axioms and verify they are equivalent to ρ being a homomorphism filling

$$G \xrightarrow{\ \rho\ } \mathrm{Sym}(A)$$

   i.e. $\rho(gh) = \rho(g)\rho(h)$ and $\rho(1) = \mathrm{id}_A$.

2. Let G act transitively on A and fix $a \in A$. Prove the orbit-stabilizer map is a well-defined G-set bijection making

$$G/\mathrm{Stab}_G(a) \xrightarrow[\sim]{g\,\mathrm{Stab}_G(a) \mapsto g\cdot a} A$$

   commute with the G-actions (left multiplication on cosets, the given action on A). Deduce $|A| = [G : \mathrm{Stab}_G(a)]$.

3. Let G act on itself by conjugation. Show this is the homomorphism $\psi : G \to \mathrm{Aut}(G)$, $g \mapsto (x \mapsto gxg^{-1})$, with image $\mathrm{Inn}(G)$, and that $\ker\psi = Z(G)$, giving the exact sequence

$$1 \longrightarrow Z(G) \hookrightarrow G \xrightarrow{\ \psi\ } \mathrm{Aut}(G) \twoheadrightarrow \mathrm{Aut}(G)/\mathrm{Inn}(G) \longrightarrow 1$$

Identify the cokernel-side quotient $\mathrm{Aut}(G)/\mathrm{Inn}(G)$ as $\mathrm{Out}(G)$.

4. Let $H \le G$ and consider the action of G on G/H. Show the permutation representation factors as

$$\begin{array}{ccc} G & \xrightarrow{\ \pi\ } & G/K \\ & {\scriptstyle\rho}\searrow & \downarrow \\ & & \mathrm{Sym}(G/H) \end{array}$$

where $K = \ker\rho = \bigcap_{x\in G} xHx^{-1}$ is the core of H, π is the quotient map, and the vertical arrow is the induced faithful action. Conclude G/K embeds in $S_{[G:H]}$.

5. Let G act on sets A and B. A map $f : A \to B$ is G-equivariant if $f(g\cdot a) = g\cdot f(a)$ for all g, a, i.e. for each g the square

$$\begin{array}{ccc} A & \xrightarrow{\ f\ } & B \\ {\scriptstyle g\cdot}\downarrow & & \downarrow{\scriptstyle g\cdot} \\ A & \xrightarrow[\ f\ ]{} & B \end{array}$$

commutes. Prove that an equivariant f sends orbits to orbits and that if f is a bijection it carries $\mathrm{Stab}_G(a)$ isomorphically onto $\mathrm{Stab}_G(f(a))$.

4.2 Cayley's Theorem and Actions by Left Multiplication

The left regular action and Cayley's theorem

We isolate the simplest action a group has on itself — left multiplication — and extract from it Cayley's theorem and, more flexibly, the action on cosets of a subgroup. The coset action is the single most useful counting tool in this chapter: it manufactures a homomorphism $G \to S_m$ out of nothing but a subgroup of index m, and its kernel is canonically described.

Definition 4.2.1 (Left regular action)**.** Let G be a group. The *left regular action* of G on the set $A = G$ is

$$g \cdot x = gx \qquad (g \in G,\ x \in G),$$

the product taken in G. This is a (left) group action: $1\cdot x = 1x = x$, and $g\cdot(h\cdot x) = g(hx) = (gh)x = (gh)\cdot x$ by associativity.

Remark 4.2.1. Do not confuse the action with the group operation conceptually: G acts *on the set* of its own elements. The permutation attached to g is left-translation $\lambda_g\colon x \mapsto gx$, which is a bijection of the set G (with inverse $\lambda_{g^{-1}}$), but λ_g is essentially never a group homomorphism $G \to G$.

Theorem 4.2.2 (Cayley)**.** *Let G be a group. The left regular action affords an* injective *homomorphism*

$$\lambda\colon G \longrightarrow \mathrm{Sym}(G), \qquad \lambda(g) = \lambda_g, \quad \lambda_g(x) = gx.$$

Hence G is isomorphic to a subgroup of $\mathrm{Sym}(G)$*. If $|G| = n < \infty$, then* $\mathrm{Sym}(G) \cong S_n$ *and so G embeds in S_n.*

$$G \xhookrightarrow{\ \lambda\ } \mathrm{Sym}(G) \xrightarrow{\ \sim\ } S_n$$

Diagram explanation. Objects: Three objects in a horizontal chain. G is the abstract group being embedded. $\mathrm{Sym}(G)$ is the symmetric group on the underlying set of G, i.e. the group of all bijections $G \to G$; it is a group under composition. S_n is the symmetric group on $\{1,\dots,n\}$ for $n = |G|$; once a bijection $G \xrightarrow{\sim} \{1,\dots,n\}$ is fixed, $\mathrm{Sym}(G) \cong S_n$ concretely.

Arrows: The first arrow $\lambda\colon G \hookrightarrow \mathrm{Sym}(G)$ is the *left regular representation*: $\lambda(g) = \lambda_g$ where $\lambda_g(x) = gx$ for every $x \in G$. The hook indicates it is injective (proved below via $\ker\lambda = \{1\}$). The second arrow

$\mathrm{Sym}(G) \xrightarrow{\sim} S_n$ is the *isomorphism* induced by any fixed labelling of the elements of G as $x_1, \ldots, x_n$; it sends a bijection $\sigma\colon G \to G$ to the permutation of indices $i \mapsto j$ where $\sigma(x_i) = x_j$.

What commutes: There is no square here; the diagram is a straight chain of two maps. The implicit equality is $G \cong \lambda(G) \leq \mathrm{Sym}(G) \cong S_n$: following the two arrows in sequence gives an injective group homomorphism $G \hookrightarrow S_n$.

Why it commutes: Start with $g \in G$. Along the left arrow, g maps to the left-translation $\lambda_g \in \mathrm{Sym}(G)$. Along the right isomorphism, λ_g maps to the permutation of $\{1, \ldots, n\}$ it induces via the labelling. The composite is a group homomorphism because λ is a homomorphism (by the action axioms) and the labelling isomorphism is a homomorphism; injective because $\ker \lambda = \{1\}$ (if $\lambda_g = \mathrm{id}$ then $g \cdot 1 = 1$ forces $g = 1$).

Why this matters here: This is the punchline of Cayley's theorem: every abstract group is concretely realized inside a symmetric group. The diagram makes visible both the embedding λ and the specific identification $\mathrm{Sym}(G) \cong S_n$ that lets one say "G embeds in S_n." Without the diagram, the two steps — defining λ and identifying $\mathrm{Sym}(G)$ with S_n — could blur together.

Concrete example: For $G = \mathbb{Z}/4\mathbb{Z}$, label $x_i = i - 1$. $\lambda_1(x) = x + 1 \pmod 4$ gives the permutation $1 \mapsto 2 \mapsto 3 \mapsto 4 \mapsto 1$, i.e. the 4-cycle $(1\,2\,3\,4) \in S_4$. The chain $\mathbb{Z}/4\mathbb{Z} \hookrightarrow \mathrm{Sym}(\mathbb{Z}/4\mathbb{Z}) \cong S_4$ sends $1 \mapsto \lambda_1 \mapsto (1\,2\,3\,4)$.

Common pitfall: Students sometimes think $\lambda(g) = \lambda_g$ is a map $G \to G$ (a group endomorphism). It is not: λ_g is a *permutation of the set* G, so λ maps into $\mathrm{Sym}(G)$, not into G. Also, the isomorphism $\mathrm{Sym}(G) \cong S_n$ depends on a choice of labelling; the embedding $G \hookrightarrow S_n$ changes by conjugation when the labelling changes, but injectivity does not.

Takeaway: The point of this diagram is that the left regular action provides a canonical injective group homomorphism $G \to \mathrm{Sym}(G)$, hence (once the elements of G are labelled $1, \ldots, n$) an embedding $G \hookrightarrow S_n$, realizing any abstract group of order n as a concrete subgroup of the symmetric group S_n.

Proof. By the general permutation-representation theorem (§4.1), every action of G on a set A gives a homomorphism $\rho\colon G \to \mathrm{Sym}(A)$ with kernel

$$\ker \rho = \{\, g \in G : g \cdot a = a \text{ for all } a \in A \,\}.$$

Apply this to $A = G$ with $g \cdot x = gx$. Then $g \in \ker \lambda$ iff $gx = x$ for all $x \in G$. Taking $x = 1$ gives $g \cdot 1 = g = 1$. Thus $\ker \lambda = \{1\}$ and λ is injective, so $G \cong \lambda(G) \leq \mathrm{Sym}(G)$. If $|G| = n$, a bijection $G \to \{1, \ldots, n\}$ induces $\mathrm{Sym}(G) \cong S_n$, and composing gives an embedding $G \hookrightarrow S_n$. □

Remark 4.2.2 (Image of Cayley's embedding). Each nonidentity λ_g is a *fixed-point-free* permutation of G: if $gx = x$ then $g = 1$. Consequently every nonidentity λ_g is a product of cycles all of the same length $|g|$, and there are exactly $n/|g|$ of them. (This is the cycle structure of the regular representation.)

Method (Using Cayley's theorem / the regular representation)**.** *Trigger.* You want to realize an abstract group concretely inside a symmetric group, or you need a permutation whose cycle type encodes element orders.

Recipe.

1. Fix an ordering/labelling $x_1, \ldots, x_n$ of the elements of G.
2. For each generator g, compute $\lambda_g(x_i) = gx_i$ and read off the permutation of indices.
3. Write λ_g in cycle notation. Sanity check: λ_g moves *every* point unless $g = 1$ (fixed-point free), and its cycles all have length $|g|$, giving $n/|g|$ cycles.
4. The map $g \mapsto \lambda_g$ is the embedding $G \hookrightarrow S_n$.

Worked Example 4.2.3 (Cayley for $\mathbb{Z}/4\mathbb{Z}$)**.** Realize $\mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}$ (addition mod 4) as a subgroup of S_4 via its left regular representation.

Recognition. Cayley's theorem (Thm. 4.2.2): the left regular action gives $\lambda\colon G \hookrightarrow S_n$. Here "multiply" means "add mod 4."

Solution. Label the points $1{:}0,\ 2{:}1,\ 3{:}2,\ 4{:}3$ (point i is the element $i-1$). For $g=1$, $\lambda_1(x)=x+1$:

$$0\mapsto 1\mapsto 2\mapsto 3\mapsto 0,\quad \text{i.e. labels } 1\mapsto 2\mapsto 3\mapsto 4\mapsto 1,$$

so $\lambda_1=(1\,2\,3\,4)$. Then

$$\lambda_2=\lambda_1^2=(1\,3)(2\,4),\qquad \lambda_3=\lambda_1^3=(1\,4\,3\,2),\qquad \lambda_0=\mathrm{id}\,.$$

Thus $\mathbb{Z}/4\mathbb{Z}\cong\langle(1\,2\,3\,4)\rangle\le S_4$.

Check. $|1|=4$ so λ_1 should be a single 4-cycle: it is. $|2|=2$ so λ_2 should be $4/2=2$ transpositions: $(1\,3)(2\,4)$. Fixed-point-free for all nonidentity elements. Good.

Worked Example 4.2.4 (Cayley for V_4 into S_4)**.** Embed the Klein four-group $V_4=\{1,a,b,c\}$ with $a^2=b^2=c^2=1$, $ab=c$, into S_4.

Recognition. Cayley's theorem: left regular representation of V_4, an order-4 group, lands in S_4.

Solution. Label $1{:}1,\ 2{:}a,\ 3{:}b,\ 4{:}c$. Compute $\lambda_a(x)=ax$:

$$a\cdot 1=a,\quad a\cdot a=1,\quad a\cdot b=ab=c,\quad a\cdot c=ac=a(ab)=a^2b=b,$$

so labels $1\mapsto 2,\ 2\mapsto 1,\ 3\mapsto 4,\ 4\mapsto 3$, giving $\lambda_a=(1\,2)(3\,4)$. Similarly $\lambda_b(x)=bx$:

$$b\cdot 1=b,\qquad b\cdot a=ba=ab=c,\qquad b\cdot b=1,\qquad b\cdot c=bc=b(ab)=(ba)b=(ab)b=ab^2=a.$$

So $1\mapsto 3,\ 2\mapsto 4,\ 3\mapsto 1,\ 4\mapsto 2$, giving $\lambda_b=(1\,3)(2\,4)$. And $\lambda_c=\lambda_a\lambda_b$ corresponds to $c=ab$:

$$\lambda_c=(1\,4)(2\,3).$$

Thus $V_4\cong\{\mathrm{id},(1\,2)(3\,4),(1\,3)(2\,4),(1\,4)(2\,3)\}\le S_4$, the standard copy.

Check. Every nonidentity element has order 2, so each λ is $4/2=2$ transpositions: confirmed. The three images plus identity form exactly the normal Klein four-subgroup of S_4. Closure: $(1\,2)(3\,4)\cdot(1\,3)(2\,4)=(1\,4)(2\,3)$, matching $ab=c$. Good.

Worked Example 4.2.5 (Cayley for S_3 into S_6)**.** Describe the cycle type of λ_g for the regular representation $S_3\hookrightarrow S_6$ as g ranges over S_3.

Recognition. Cayley plus the cycle-structure remark: nonidentity λ_g is fixed-point free with all cycles of length $|g|$.

Solution. Here $n=6$. By element orders in S_3:

- $g=1$: $\lambda_g=\mathrm{id}$.
- g a transposition ($|g|=2$, three such g): λ_g is $6/2=3$ transpositions, type 2^3.
- g a 3-cycle ($|g|=3$, two such g): λ_g is $6/3=2$ three-cycles, type 3^2.

So the image consists of id, three permutations of type 2^3, and two of type 3^2.

Check. The element count matches $|S_3|=6=1+3+2$. For a transposition g, λ_g has type 2^3 with sign $(-1)^3=-1$, so λ_g is an odd permutation of S_6; for a 3-cycle g, λ_g has type 3^2 with sign $(+1)^2=+1$, an even permutation. Consistent with S_3 having a sign map. Good.

Worked Example 4.2.6 (Order 6 with no 6-cycle image? (cyclic vs. noncyclic))**.** For which groups G of order 6 does the regular representation contain a 6-cycle?

Recognition. Cayley plus cycle structure: λ_g is a single n-cycle iff $|g|=n=|G|$, i.e. iff g generates G.

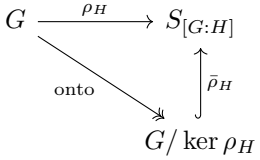
Solution. A nonidentity λ_g is one 6-cycle iff $|g|=6$, i.e. g generates G, i.e. G is cyclic. For $G=\mathbb{Z}/6\mathbb{Z}$ the generator 1 gives $\lambda_1=(1\,2\,3\,4\,5\,6)$, a 6-cycle. For $G=S_3$ there is no element of order 6 (orders are $1,2,3$), so *no* λ_g is a 6-cycle: the regular representation of S_3 contains only types 2^3 and 3^2 (and id).

Check. $\mathbb{Z}/6\mathbb{Z}$ has $\phi(6)=2$ generators, giving two 6-cycles $(1\,2\,3\,4\,5\,6)$ and its inverse; consistent with $\mathbb{Z}/6\mathbb{Z}$ cyclic. S_3 noncyclic, no 6-cycle. Good.

Caution. Cayley says $G\le S_n$ for $n=|G|$, but n is usually *far* from optimal. E.g. $\mathbb{Z}/6\mathbb{Z}\hookrightarrow S_6$ via the regular action, yet $\mathbb{Z}/6\mathbb{Z}$ also embeds in S_5 (as $(1\,2)(3\,4\,5)$). Cayley gives *an* embedding, not the smallest one. Do not claim "the least n with $G\le S_n$ is $|G|$."

The action on cosets and the core

Theorem 4.2.7 (Coset action; kernel is the core)**.** *Let G be a group, $H \leq G$, and let $A = \{\, gH : g \in G \,\}$ be the set of left cosets of H, so $|A| = [G : H]$. Then G acts on A by left multiplication,*



$$g \cdot (xH) = (gx)H,$$

and this affords a homomorphism

$$\rho_H \colon G \longrightarrow \mathrm{Sym}(A) \cong S_{[G:H]}.$$

Moreover:

1. *the action is transitive;*
2. *the stabilizer of the coset $1H = H$ is exactly H;*
3. $\ker \rho_H = \bigcap_{x \in G} xHx^{-1}$*, and this is the* largest normal subgroup of G contained in H*. It is called the* core *of H in G, written* $\mathrm{core}_G(H)$*.*

$$\ker \rho_H = \mathrm{core}_G(H) = \bigcap_{x \in G} xHx^{-1}.$$

Diagram explanation. Objects: Three objects arranged in a triangle. G is the ambient group (upper-left). $S_{[G:H]} = S_m$ where $m = [G : H]$ is the symmetric group on m letters, which receives the coset-action permutations (upper-right). $G/\ker \rho_H$ is the quotient of G by the core $K = \ker \rho_H = \mathrm{core}_G(H)$, a normal subgroup; it is the group of cosets gK (lower-right). The displayed equation identifies K explicitly as the intersection $\bigcap_{x \in G} xHx^{-1}$ of all conjugates of H.

Arrows: $\rho_H \colon G \to S_m$ is the *coset permutation representation*: $\rho_H(g)$ is the permutation of left cosets xH given by $\rho_H(g)(xH) = (gx)H$. The diagonal surjection $G \twoheadrightarrow G/K$ is the canonical quotient map $g \mapsto gK$, which is surjective by construction (marked "onto"). $\bar{\rho}_H \colon G/K \hookrightarrow S_m$ is the *induced* (or factor) map $gK \mapsto \rho_H(g)$; the hook signals it is injective (its kernel is trivial because $K = \ker \rho_H$ by construction).

What commutes: The triangle commutes: $\bar{\rho}_H \circ \pi = \rho_H$, where $\pi \colon G \twoheadrightarrow G/K$ is the quotient map. Explicitly: following the top-right arrow gives $g \mapsto \rho_H(g)$; following the diagonal then the right arrow gives $g \mapsto gK \mapsto \bar{\rho}_H(gK) = \rho_H(g)$. Both paths agree.

Why it commutes: Well-definedness of $\bar{\rho}_H$: if $gK = g'K$ then $g' = gk$ for some $k \in K = \ker \rho_H$, so $\rho_H(g') = \rho_H(g)\rho_H(k) = \rho_H(g) \cdot \mathrm{id} = \rho_H(g)$. Thus $\bar{\rho}_H(gK)$ is independent of the coset representative, and $\bar{\rho}_H \circ \pi = \rho_H$ holds by this very definition. This is exactly the universal property of the quotient: a homomorphism out of G whose kernel contains K factors uniquely through G/K.

Why this matters here: The diagram encodes the First Isomorphism Theorem applied to ρ_H, and makes the coset action's structure transparent: the quotient G/K embeds faithfully in S_m, so $|G/K| = [G : K]$ divides $m! = ([G : H])!$. This divisibility (Corollary 4.2.8) is the key tool for proving normality and non-simplicity conclusions from small-index subgroups.

Concrete example: Take $G = S_3$, $H = \langle (1\,2) \rangle$, $m = 3$. The kernel is $K = \ker \rho_H = \{1\}$ (computed in the worked example), so $G/K \cong S_3$ embeds injectively in S_3, actually as an isomorphism. The triangle collapses to $S_3 \xrightarrow{\sim} G/\{1\} \hookrightarrow S_3$. For contrast, if $G = D_8$ and H is the Klein four-subgroup of index 2, then $K = H$ and the triangle yields $D_8/H \cong \mathbb{Z}/2\mathbb{Z} \hookrightarrow S_2$.

Common pitfall: Students forget to verify well-definedness of $\bar{\rho}_H$ before claiming the triangle commutes. The induced map is only defined on cosets gK (not on individual elements) because K is specifically $\ker \rho_H$; if K were merely a subgroup not contained in $\ker \rho_H$, the formula $\bar{\rho}_H(gK) = \rho_H(g)$ would depend on the representative and would fail to be a function. Another common error: reading the hook on $\bar{\rho}_H$ as meaning $G/K \cong S_m$; it only means G/K embeds in S_m, not that the embedding is surjective.

Takeaway: The point of this diagram is that the coset action ρ_H factors through the quotient $G/\operatorname{core}_G(H)$, which then embeds faithfully in S_m, giving the divisibility $[G : \operatorname{core}_G(H)] \mid ([G : H])!$ and the mechanism behind every "small-index subgroup" normality or non-simplicity argument.

Proof. Well-defined action. If $xH = x'H$ then $x' = xh$ for some $h \in H$, so $(gx')H = (gxh)H = (gx)hH = (gx)H$; thus $g \cdot (xH)$ depends only on the coset. The action axioms hold by associativity exactly as for the regular action.

(1) Transitivity. Given cosets xH, yH, the element $g = yx^{-1}$ satisfies $g \cdot (xH) = (yx^{-1}x)H = yH$.

(2) Stabilizer of H. $g \cdot H = H$ iff $gH = H$ iff $g \in H$. So $\operatorname{Stab}(H) = H$.

(3) Kernel. By the general formula, $\ker \rho_H = \bigcap_{xH \in A} \operatorname{Stab}(xH)$. Now $g \cdot (xH) = xH$ iff $(gx)H = xH$ iff $x^{-1}gx \in H$ iff $g \in xHx^{-1}$. Hence $\operatorname{Stab}(xH) = xHx^{-1}$ and

$$\ker \rho_H = \bigcap_{x \in G} xHx^{-1} =: K.$$

K is normal (it is a kernel). $K \leq H$ (take $x = 1$). Finally, if $N \trianglelefteq G$ and $N \leq H$, then for every x, $N = xNx^{-1} \leq xHx^{-1}$, so $N \leq \bigcap_x xHx^{-1} = K$. Thus K is the largest normal subgroup of G contained in H. □

Corollary 4.2.8 (Index–order divisibility)**.** *With $K = \ker \rho_H = \operatorname{core}_G(H)$, the induced map $\bar{\rho}_H \colon G/K \hookrightarrow S_{[G:H]}$ is injective, so*

$$[G : K] = |G/K| \quad \textit{divides} \quad [G : H]!\,.$$

Proof. First Isomorphism Theorem: $G/K \cong \operatorname{im} \rho_H \leq S_{[G:H]}$, of order $[G : H]!$. Lagrange in $S_{[G:H]}$ gives the divisibility. □

Corollary 4.2.9 (Smallest-prime index forces normality)**.** *Let G be a finite group and $H \leq G$ with $[G : H] = p$, where p is the* smallest *prime dividing $|G|$. Then $H \trianglelefteq G$.*

Proof. Let $K = \operatorname{core}_G(H)$ and put $k = [H : K]$. By Cor. 4.2.8, $[G : K] \mid p!$. Also $[G : K] = [G : H] \cdot [H : K] = p\,k$, so $pk \mid p!$, giving $k \mid (p-1)!$. But $k = [H : K]$ divides $|G|$ (since $K \leq H \leq G$), and every prime divisor of $|G|$ is $\geq p$. A prime $q \mid k$ would satisfy $q \mid (p-1)!$, forcing $q \leq p - 1 < p$, contradicting minimality of p unless k has no prime divisors, i.e. $k = 1$. Hence $K = H$, so $H = \operatorname{core}_G(H) \trianglelefteq G$. □

Remark 4.2.3. Taking $p = 2$ recovers the familiar fact: *every subgroup of index* 2 *is normal.* Indeed 2 is the smallest prime dividing any even order.

Method (Coset (permutation) representation and the core)**.** *Trigger.* A subgroup H of small index $m = [G : H]$ appears; you want a homomorphism $G \to S_m$, a normal subgroup inside H, or a normality/non-simplicity conclusion.

Recipe.

1. List the m left cosets $g_1H, \ldots, g_mH$ (with $g_1 = 1$). This is the set A.
2. For each generator g, compute $g \cdot (g_iH) = (gg_i)H$ and identify which coset it equals; record the permutation $\rho_H(g) \in S_m$.
3. $\ker \rho_H = \bigcap_x xHx^{-1} = \operatorname{core}_G(H)$ is the largest normal subgroup inside H. In practice intersect the conjugates, or read it off as $\bigcap_i \operatorname{Stab}(g_iH)$.
4. *Conclusions.* $[G : \ker \rho_H] \mid m!$ (Cor. 4.2.8); if m is the least prime dividing $|G|$ then $H \trianglelefteq G$ (Cor. 4.2.9); if $m > 1$ and $|G| \nmid m!$ then ρ_H has nontrivial kernel, contained in $H \neq G$, so G has a proper nontrivial normal subgroup (not simple).

Worked Example 4.2.10 (Coset action of S_3 on $S_3/\langle(1\,2)\rangle$)**.** Let $G = S_3$ and $H = \langle(1\,2)\rangle = \{1, (1\,2)\}$, so $[G : H] = 3$. Compute $\rho_H \colon S_3 \to S_3$ explicitly and find $\ker \rho_H$.

Recognition. Coset action (Thm. 4.2.7): left multiplication on the 3 cosets of H gives $\rho_H \colon G \to S_3$ with kernel the core of H.

Solution. The three left cosets are

$$c_1 = H = \{1, (1\,2)\}, \quad c_2 = (1\,3)H = \{(1\,3), (1\,3)(1\,2)\} = \{(1\,3), (1\,2\,3)\},$$

$$c_3 = (2\,3)H = \{(2\,3), (2\,3)(1\,2)\} = \{(2\,3), (1\,3\,2)\}.$$

(Recall right-to-left composition: for $(1\,3)(1\,2)$, apply $(1\,2)$ first: $1 \mapsto 2 \mapsto 2$, $2 \mapsto 1 \mapsto 3$, $3 \mapsto 3 \mapsto 1$, giving $(1\,2\,3)$.)

Now compute $\rho_H(g)$ on $\{c_1, c_2, c_3\}$.

$g = (1\,2\,3)$*:* $gc_1 = (1\,2\,3)H$. Since $(1\,2\,3) \in c_2$, $(1\,2\,3)H = c_2$. $gc_2 = (1\,2\,3)(1\,3)H$; here $(1\,2\,3)(1\,3) = (2\,3)$ (apply $(1\,3)$ first then $(1\,2\,3)$: $1 \mapsto 3 \mapsto 1$, $2 \mapsto 2 \mapsto 3$, $3 \mapsto 1 \mapsto 2$, that is $(2\,3)$), so $gc_2 = (2\,3)H = c_3$. $gc_3 = (1\,2\,3)(2\,3)H$; here $(1\,2\,3)(2\,3) = (1\,2)$ (apply $(2\,3)$ then $(1\,2\,3)$: $1 \mapsto 1 \mapsto 2$, $2 \mapsto 3 \mapsto 1$, $3 \mapsto 2 \mapsto 3$, that is $(1\,2)$), and $(1\,2) \in H$, so $gc_3 = c_1$. Thus $\rho_H((1\,2\,3)) = (c_1\,c_2\,c_3)$, a 3-cycle.

$g = (1\,2)$*:* $gc_1 = (1\,2)H = c_1$ (fixes c_1). $gc_2 = (1\,2)(1\,3)H$; here $(1\,2)(1\,3) = (1\,3\,2) \in c_3$, so $gc_2 = c_3$. $gc_3 = (1\,2)(2\,3)H$; here $(1\,2)(2\,3) = (1\,2\,3)$ (apply $(2\,3)$ then $(1\,2)$: $1 \mapsto 1 \mapsto 2$, $2 \mapsto 3 \mapsto 3$, $3 \mapsto 2 \mapsto 1$, that is $(1\,2\,3)) \in c_2$, so $gc_3 = c_2$. Thus $\rho_H((1\,2)) = (c_2\,c_3)$, a transposition.

Hence ρ_H is an *isomorphism* $S_3 \xrightarrow{\sim} \mathrm{Sym}(\{c_1, c_2, c_3\}) \cong S_3$. Therefore $\ker \rho_H = \{1\} = \mathrm{core}_G(H)$.

Check. Independently, $\mathrm{core}_G(H) = \bigcap_x xHx^{-1}$. The conjugates of $H = \langle(1\,2)\rangle$ are $\langle(1\,2)\rangle, \langle(1\,3)\rangle, \langle(2\,3)\rangle$, whose intersection is $\{1\}$. Matches $\ker \rho_H = 1$. Also $[G : \ker] = 6 \mid 3! = 6$: tight. Good.

Worked Example 4.2.11 (Kernel = core: $H = \langle s\rangle$ in D_8 acting on $G/\langle s\rangle$)**.** Let $G = D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s\rangle$ and $H = \langle s\rangle = \{1, s\}$, $[G : H] = 4$. Find $\mathrm{core}_G(H) = \ker \rho_H$.

Recognition. Coset action: kernel is the largest normal subgroup inside H, computable as $\bigcap_x xHx^{-1}$.

Solution. Since $|H| = 2$, any normal subgroup inside H is $\{1\}$ or H itself. Is $H = \langle s\rangle \trianglelefteq G$? Conjugate: $rsr^{-1} = r(sr^{-1}) = r(rs) = r^2 s$ (using $sr^{-1} = rs$, from $sr = r^{-1}s \Rightarrow sr^{-1} = rs$). So $rsr^{-1} = r^2 s \notin \{1, s\} = H$. Thus $H \not\trianglelefteq G$, and the only normal subgroup contained in H is $\{1\}$.

Therefore $\mathrm{core}_G(H) = \ker \rho_H = \{1\}$, i.e. the coset action $\rho_H \colon D_8 \hookrightarrow S_4$ is *faithful*.

Check. Confirm via the conjugate intersection: $sHs^{-1} = H$ but $rHr^{-1} = \{1, r^2 s\}$, and $H \cap rHr^{-1} = \{1\}$ already. So $\bigcap_x xHx^{-1} = \{1\}$. Consistent. Note $|G| = 8 \mid 4! = 24$, so a faithful map into S_4 is possible; indeed $D_8 \leq S_4$ as symmetries of the square. Good.

Worked Example 4.2.12 (Nontrivial core)**.** Let $G = D_8$ and $H = \langle r^2, s\rangle = \{1, r^2, s, r^2 s\}$ (a Klein four-subgroup), $[G : H] = 2$. Find $\ker \rho_H$ and $\mathrm{core}_G(H)$.

Recognition. Coset action; kernel = core. Index 2 is the smallest prime dividing 8, so Cor. 4.2.9 predicts $H \trianglelefteq G$, forcing $\mathrm{core}_G(H) = H$.

Solution. $[G : H] = 2$, so by Cor. 4.2.9 (or the index-2 remark) $H \trianglelefteq G$. The largest normal subgroup of G inside H is then H itself, so

$$\ker \rho_H = \mathrm{core}_G(H) = H = \{1, r^2, s, r^2 s\}.$$

The map $\rho_H \colon G \to S_2$ has image of order $[G : H] = 2$ and kernel H.

Check. $[G : \ker \rho_H] = [G : H] = 2 \mid 2! = 2$. And $G/H \cong \rho_H(G) \leq S_2$ has order 2: matches. Verify normality directly: $rsr^{-1} = r^2 s \in H$ and $r(r^2)r^{-1} = r^2 \in H$, so indeed $H \trianglelefteq G$. Good.

Worked Example 4.2.13 (Index = smallest prime $\Rightarrow$ normal: subgroup of index 3 in a group of order 33)**.** Let $|G| = 33 = 3 \cdot 11$ and suppose $H \leq G$ with $[G : H] = 3$. Show $H \trianglelefteq G$.

Recognition. Cor. 4.2.9: the smallest prime dividing $|G| = 33$ is 3, and $[G : H] = 3$.

Solution. The primes dividing 33 are 3 and 11; the smallest is $p = 3 = [G : H]$. By Cor. 4.2.9, $H \trianglelefteq G$.

We re-derive it concretely. Let $K = \mathrm{core}_G(H) \trianglelefteq G$. Then $[G : K] \mid 3! = 6$ and $|G/K| = [G : K]$ divides $|G| = 33$. So $[G : K] \mid \gcd(6, 33) = 3$. Since $K \leq H$ gives $[G : K] \geq [G : H] = 3$, we get $[G : K] = 3 = [G : H]$, hence $K = H$. Therefore $H = K \trianglelefteq G$.

Check. $\gcd(6, 33) = 3$; $[G : K] \in \{1, 3\}$ but ≥ 3, so $= 3$. $K \leq H$ with equal index $\Rightarrow K = H$. The logic used only $3 = [G : H] =$ least prime. Good.

Worked Example 4.2.14 (Forcing non-simplicity from a small-index subgroup)**.** Suppose $|G| = 24$ and G has a subgroup H with $[G : H] = 3$. Show G is not simple.

Recognition. Coset action $\rho_H\colon G \to S_3$ with $\ker\rho_H = \mathrm{core}_G(H)$; use the order obstruction $[G:\ker] \mid 3!$ (Cor. 4.2.8).

Solution. $\rho_H\colon G \to S_3$ has $|G/\ker\rho_H| \mid 3! = 6$. If $\ker\rho_H = \{1\}$ then $G \hookrightarrow S_3$, so $24 = |G| \mid 6$, false. Hence $\ker\rho_H \neq \{1\}$. Also $\ker\rho_H \leq H \subsetneq G$, so $\ker\rho_H \neq G$. Thus $\ker\rho_H$ is a proper nontrivial normal subgroup of G: G is not simple.

Check. The obstruction is $24 \nmid 6$. More precisely $[G:\ker] \mid \gcd(6,24) = 6$, but $[G:\ker] \geq 3$ and divides 24, so $[G:\ker] \in \{3,6\}$; either way ker has order 8 or 4, a genuine normal subgroup. Good.

Worked Example 4.2.15 (A group of order n with no n-cycle in its regular representation)**.** Show that for $G = Q_8$ (quaternion group, order 8), the regular representation $Q_8 \hookrightarrow S_8$ contains *no* 8-cycle, and in fact every nonidentity image is fixed-point free.

Recognition. Cycle-structure remark for Cayley: nonidentity λ_g is fixed-point free with all cycles of length $|g|$; an n-cycle requires an element of order n.

Solution. Element orders in $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ are: $|1| = 1$, $|-1| = 2$, and $|\pm i| = |\pm j| = |\pm k| = 4$. The maximal order is $4 < 8$, so no λ_g is an 8-cycle (that would need $|g| = 8$). Concretely the regular representation has:

- $g = -1$ ($|g| = 2$): λ_g has type 2^4 ($8/2 = 4$ transpositions);
- $g \in \{\pm i, \pm j, \pm k\}$ ($|g| = 4$): λ_g has type 4^2 ($8/4 = 2$ four-cycles).

Every nonidentity image is fixed-point free, so none has a fixed point (no 1 in the cycle type).

Check. Counts: 6 elements of order 4 give type 4^2, 1 element of order 2 gives 2^4, 1 identity. Total $6 + 1 + 1 = 8 = |Q_8|$. No element of order 8 exists, so no 8-cycle; consistent with Q_8 not being cyclic. Good.

Caution. The core is built from *conjugates* xHx^{-1}, not from H alone. A common error is to take $\ker\rho_H = H$ "because the stabilizer of H is H." The stabilizer of the basepoint $1H$ is H, but the kernel is the intersection of the stabilizers of *all* cosets, $\bigcap_x xHx^{-1}$, which can be much smaller. Equality $\ker\rho_H = H$ holds iff $H \trianglelefteq G$.

Caution. Cor. 4.2.9 needs p to be the *smallest* prime dividing $|G|$, not just any prime. In A_4 ($|A_4| = 12$) the subgroup of index 3 (order 4, the Klein four V) *is* normal — here 3 is not the least prime, yet it happens to work — but a subgroup of index 3 is *not* guaranteed normal in general when 3 is not the smallest prime. The theorem only *guarantees* normality at the least prime; e.g. A_4 has subgroups of index 4 (order 3) that are not normal, and 4 is not a prime dividing 12.

Exercises (from the text).

Let G be a group and let H be a subgroup of G.

1. Let $G = \{1, a, b, c\}$ be the Klein 4-group whose group table is written out in Section 2.5.

   (a) Label $1, a, b, c$ with the integers $1, 2, 4, 3$, respectively, and prove that under the left regular representation of G into S_4 the nonidentity elements are mapped as follows:

   $$a \mapsto (1\ 2)(3\ 4) \qquad b \mapsto (1\ 4)(2\ 3) \qquad c \mapsto (1\ 3)(2\ 4).$$

   (b) Relabel $1, a, b, c$ as $1, 2, 3, 4$, respectively, and compute the image of each element of G under the left regular representation of G into S_4. Show that the image of G in S_4 under this labelling is the same subgroup as the image of G in part (a) (even though the nonidentity elements individually map to different permutations under the two different labellings).

2. List the elements of S_3 as $1, (1\ 2), (2\ 3), (1\ 3), (1\ 2\ 3), (1\ 3\ 2)$ and label these with the integers $1, 2, 3, 4, 5, 6$ respectively. Exhibit the image of each element of S_3 under the left regular representation of S_3 into S_6.

3. Let r and s be the usual generators for the dihedral group of order 8.

   (a) List the elements of D_8 as $1, r, r^2, r^3, s, sr, sr^2, sr^3$ and label these with the integers $1, 2, \ldots, 8$ respectively. Exhibit the image of each element of D_8 under the left regular representation of D_8 into S_8.

(b) Relabel this same list of elements of D_8 with the integers $1, 3, 5, 7, 2, 4, 6, 8$ respectively and recompute the image of each element of D_8 under the left regular representation with respect to this new labelling. Show that the two subgroups of S_8 obtained in parts (a) and (b) are different.

4. Use the left regular representation of Q_8 to produce two elements of S_8 which generate a subgroup of S_8 isomorphic to the quaternion group Q_8.

5. Let r and s be the usual generators for the dihedral group of order 8 and let $H = \langle s \rangle$. List the left cosets of H in D_8 as $1H, rH, r^2H$ and r^3H.

   (a) Label these cosets with the integers $1, 2, 3, 4$, respectively. Exhibit the image of each element of D_8 under the representation π_H of D_8 into S_4 obtained from the action of D_8 by left multiplication on the set of 4 left cosets of H in D_8. Deduce that this representation is faithful (i.e., the elements of S_4 obtained form a subgroup isomorphic to D_8).

   (b) Repeat part (a) with the list of cosets relabelled by the integers $1, 3, 2, 4$, respectively. Show that the permutations obtained from this labelling form a subgroup of S_4 that is different from the subgroup obtained in part (a).

   (c) Let $K = \langle sr \rangle$, list the cosets of K in D_8 as $1K, rK, r^2K$ and r^3K, and label these with the integers $1, 2, 3, 4$. Prove that, with respect to this labelling, the image of D_8 under the representation π_K obtained from left multiplication on the cosets of K is the same subgroup of S_4 as in part (a) (even though the subgroups H and K are different and some of the elements of D_8 map to different permutations under the two homomorphisms).

6. Let r and s be the usual generators for the dihedral group of order 8 and let $N = \langle r^2 \rangle$. List the left cosets of N in D_8 as $1N, rN, sN$ and srN. Label these cosets with the integers $1, 2, 3, 4$ respectively. Exhibit the image of each element of D_8 under the representation π_N of D_8 into S_4 obtained from the action of D_8 by left multiplication on the set of 4 left cosets of N in D_8. Deduce that this representation is not faithful and prove that $\pi_N(D_8)$ is isomorphic to the Klein 4-group.

7. Let Q_8 be the quaternion group of order 8.

   (a) Prove that Q_8 is isomorphic to a subgroup of S_8.

   (b) Prove that Q_8 is not isomorphic to a subgroup of S_n for any $n \leq 7$. [If Q_8 acts on any set A of order ≤ 7 show that the stabilizer of any point $a \in A$ must contain the subgroup $\langle -1 \rangle$.]

8. Prove that if H has finite index n then there is a normal subgroup K of G with $K \leq H$ and $|G : K| \leq n!$.

9. Prove that if p is a prime and G is a group of order p^α for some $\alpha \in \mathbb{Z}^+$, then every subgroup of index p is normal in G. Deduce that every group of order p^2 has a normal subgroup of order p.

10. Prove that every non-abelian group of order 6 has a nonnormal subgroup of order 2. Use this to classify groups of order 6. [Produce an injective homomorphism into S_3.]

11. Let G be a finite group and let $\pi : G \to S_G$ be the left regular representation. Prove that if x is an element of G of order n and $|G| = mn$, then $\pi(x)$ is a product of m n-cycles. Deduce that $\pi(x)$ is an odd permutation if and only if $|x|$ is even and $|G|/|x|$ is odd.

12. Let G and π be as in the preceding exercise. Prove that if $\pi(G)$ contains an odd permutation then G has a subgroup of index 2. [Use Exercise 3 in Section 3.3.]

13. Prove that if $|G| = 2k$ where k is odd then G has a subgroup of index 2. [Use Cauchy's Theorem to produce an element of order 2 and then use the preceding two exercises.]

14. Let G be a finite group of composite order n with the property that G has a subgroup of order k for each positive integer k dividing n. Prove that G is not simple.

Practice problems.

1. Let G be a group acting on itself by left multiplication, $g \cdot x = gx$. Verify directly that this is a group action and that the induced homomorphism $\rho\colon G \to \mathrm{Sym}(G)$ has $\ker \rho = 1$.

2. For $G = \mathbb{Z}_4 = \{0, 1, 2, 3\}$ under addition, write down the permutation $\rho(1) \in \mathrm{Sym}(G)$ in cycle notation (label the points $0, 1, 2, 3$). Confirm $\rho(1)$ is a 4-cycle and that $\rho(2) = \rho(1)^2$ is a product of two transpositions.

3. Let $G = D_8 = \langle r, s \rangle$ with $r^4 = s^2 = 1$, $sr = r^{-1}s$. Using the left regular representation $\rho\colon D_8 \hookrightarrow \mathrm{Sym}(D_8) \cong S_8$, determine the cycle type of $\rho(r)$ and of $\rho(s)$. (Each should be a product of cycles all of the same length equal to the order of the element.)

4. Prove that in the left regular representation, every nonidentity element $g \in G$ acts as a product of $|G|/|g|$ disjoint cycles, each of length $|g|$. Deduce that $\rho(g)$ has no fixed points for $g \neq 1$.

5. Use the previous problem to show: if $|G| = 2m$ with m odd, then G has a subgroup of index 2. (Hint: find an element of order 2 whose image under the regular representation is an odd permutation, then consider $\ker(\mathrm{sgn} \circ \rho)$.)

6. Let $H \leq G$ with $[G : H] = n$. Describe the action of G on the left cosets G/H by left multiplication and write the induced map $\pi_H\colon G \to \mathrm{Sym}(G/H) \cong S_n$. Show that $\ker \pi_H = \bigcap_{g \in G} gHg^{-1}$ and that this kernel is the largest normal subgroup of G contained in H.

7. Prove that if G is a finite group, $H \leq G$, and $[G : H] = p$ is the smallest prime dividing $|G|$, then $H \trianglelefteq G$. (Apply the action on G/H and bound $[G : \ker \pi_H]$.)

8. Let G be a group of order n and let p be the smallest prime dividing n. Using the previous result, show that any subgroup of index p is normal. Then conclude that every subgroup of index 2 is normal.

9. Let $G = Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$. Take $H = \langle i \rangle$. List the left cosets G/H, write the permutation $\pi_H(j) \in \mathrm{Sym}(G/H) \cong S_2$, and identify $\ker \pi_H$.

10. Let G act on G/H by left multiplication where $H \leq G$ and $[G : H] = n$. Prove the action is transitive and that the stabilizer of the coset $1H$ is exactly H. Identify the resulting bijection $G/H \to \mathrm{Orb}(1H)$ explicitly.

11. Suppose $|G| = 12$ and G has a subgroup H with $[G : H] = 3$. Show $\ker \pi_H$ is a nontrivial normal subgroup of G, and conclude G is not simple.

12. Let G be a finite simple group containing a subgroup H of index $n > 1$. Prove that $|G|$ divides $n!$. (Use π_H and that G simple forces $\ker \pi_H = 1$.)

13. Use the previous problem to show there is no simple group of order $112 = 2^4 \cdot 7$ possessing a subgroup of index 4. More generally, show a simple group of order $|G|$ has no proper subgroup of index n with $|G| \nmid n!$.

14. Let $\rho\colon G \to \mathrm{Sym}(G)$ be the left regular representation. Show that the image $\rho(G)$ is a transitive subgroup of $\mathrm{Sym}(G)$ acting on the $|G|$ points, and that $\rho(G)$ acts on G with trivial point stabilizers (a regular/sharply transitive action).

15. Let G be a group of order $33 = 3 \cdot 11$. Let H be a subgroup of order 11 (assume one exists). Show $[G : H] = 3$ is the smallest prime dividing $|G|$, hence $H \trianglelefteq G$, and use this to argue $G \cong \mathbb{Z}_{33}$ is cyclic.

16. Let $H, K \leq G$ with $H \leq K \leq G$. Compare the actions of G on G/H and G/K by exhibiting a G-equivariant surjection $\sigma\colon G/H \to G/K$, $gH \mapsto gK$. Verify G-equivariance: $\sigma(g' \cdot gH) = g' \cdot \sigma(gH)$ for all $g' \in G$.

Additional exercises.

1. Let G be a finite group of order n. Prove that G embeds in S_n, and that if G has no subgroup of index 2 then the regular representation embeds G in A_n. Show that the converse fails: the regular representation of V_4 already lies in A_4, although V_4 has subgroups of index 2. (Use the cycle-type description of the regular representation to compute $\mathrm{sgn} \circ \rho$, and show that whenever $\mathrm{sgn} \circ \rho\colon G \to \{\pm 1\}$ is nontrivial its kernel is a subgroup of index 2.)

2. Show that the left regular representation $\rho\colon G \to \mathrm{Sym}(G)$ and the right regular representation $\lambda\colon G \to \mathrm{Sym}(G)$, $\lambda(g)\colon x \mapsto xg^{-1}$, have images that centralize each other inside $\mathrm{Sym}(G)$; that is, $\rho(g)$ and $\lambda(h)$ commute for all $g, h \in G$. Identify $\rho(G) \cap \lambda(G)$ with $Z(G)$ via these embeddings.

3. Let G be a finite group, p the smallest prime dividing $|G|$, and $H \leq G$ with $[G:H] = p$ (do not assume H is normal). Consider the coset action $\pi_H \colon G \to \mathrm{Sym}(G/H) \cong S_p$. Prove that $[G : \ker \pi_H]$ divides p and is greater than 1, hence equals p; deduce $\ker \pi_H = H$ and conclude $H \trianglelefteq G$.

4. Let G be a group with a subgroup H of finite index n. Prove (Poincare) that H contains a normal subgroup $N \trianglelefteq G$ with $[G:N] \leq n!$. For $G = S_n$ acting on G/H where H is the point stabilizer S_{n-1} of index n, determine the core of H and decide for which n that core is trivial and $[G:N] = n!$ holds exactly.

5. Let G be a group in which every proper subgroup has finite index. Must G be finite? Either prove it, or analyze what the coset actions $G \to \mathrm{Sym}(G/H)$ tell you when $[G:H] = n < \infty$ for every proper H.

6. Let p be a prime and G a group of order p^2. Using the action of G on the left cosets of a subgroup of order p, prove that every subgroup of order p is normal in G, and conclude G is abelian.

Commutative-diagram exercises.

1. For the action of G on G/H by left multiplication ($[G:H] = n$), fill in and justify the factorization

$$\begin{array}{ccc} G & \xrightarrow{\pi_H} & \mathrm{Sym}(G/H) \\ & \searrow^{q} & \uparrow{\scriptstyle \bar{\pi}_H} \\ & & G/K \end{array}$$

   where $K = \ker \pi_H$ and q is the quotient map. Identify K as $\bigcap_{g \in G} gHg^{-1}$ and explain why the injection $G/K \hookrightarrow \mathrm{Sym}(G/H)$ exists.

2. Let $H \leq G$ with stabilizer of the base coset equal to H. Show the orbit-stabilizer map is a G-equivariant bijection by verifying the diagram

$$G/H \xrightarrow[gH \mapsto g\cdot(1H)]{\sim} \mathrm{Orb}(1H)$$

   commutes with the left-multiplication actions on both sides; i.e. that translating by g' before and after the map agree.

3. Let G be finite, $|G| = n$, and let ρ be the left regular representation. Show the composite below is a homomorphism, compute its image, and state the condition for it to be surjective onto $\{\pm 1\}$:

$$G \xrightarrow{\rho} \mathrm{Sym}(G) \xrightarrow{\mathrm{sgn}} \{\pm 1\}$$

   When $\mathrm{sgn} \circ \rho$ is surjective, identify its kernel and the resulting short exact sequence

$$1 \longrightarrow \ker(\mathrm{sgn} \circ \rho) \hookrightarrow G \xrightarrow{\mathrm{sgn} \circ \rho} \{\pm 1\} \longrightarrow 1.$$

4. For $N \trianglelefteq G$, the quotient map and the coset action fit together. Show the triangle

$$\begin{array}{ccc} G & \xrightarrow{\pi_N} & \mathrm{Sym}(G/N) \\ {\scriptstyle q}\downarrow & \nearrow_{\lambda} & \\ G/N & & \end{array}$$

   commutes, where $q \colon G \to G/N$ is the quotient and λ is the (left regular) action of G/N on itself. Conclude $\pi_N = \lambda \circ q$ and identify $\ker \pi_N = N$.

5. Let $H \leq K \leq G$ with $[G:H], [G:K]$ finite. Show the natural projection $\sigma \colon G/H \to G/K$, $gH \mapsto gK$, is G-equivariant by proving the square

$$\begin{array}{ccc} G/H & \xrightarrow{g'\cdot -} & G/H \\ {\scriptstyle \sigma}\downarrow & & \downarrow{\scriptstyle \sigma} \\ G/K & \xrightarrow[g'\cdot -]{} & G/K \end{array}$$

   commutes for every $g' \in G$. State what this says about the corresponding permutation representations π_H and π_K.

4.3 Conjugation and the Class Equation

The conjugation action and the class equation

We now study one of the most important actions a group has on itself: *conjugation*. The orbits of this action are the conjugacy classes, and counting them yields the class equation – a single numerical identity that drives a remarkable amount of structure theory for finite groups (most famously for p-groups).

Definition 4.3.1 (Conjugation action)**.** Let G be a group. The map

$$G \times G \longrightarrow G, \qquad g \cdot x = gxg^{-1}$$

is a (left) group action of G on itself, called the *conjugation action*. The element gxg^{-1} is the *conjugate* of x by g. Two elements $x, y \in G$ are *conjugate* if $y = gxg^{-1}$ for some $g \in G$. More generally, G acts by conjugation on the set $\mathcal{S}$ of all subsets of G via $g \cdot S = gSg^{-1} = \{\, gsg^{-1} : s \in S \,\}$; two subsets are conjugate when they lie in the same orbit.

That this is an action is a direct check: $1 \cdot x = 1x1^{-1} = x$, and

$$g_1 \cdot (g_2 \cdot x) = g_1(g_2 x g_2^{-1})g_1^{-1} = (g_1 g_2)x(g_1 g_2)^{-1} = (g_1 g_2) \cdot x.$$

The associated permutation representation is the map sending g to the inner automorphism $\psi_g(x) = gxg^{-1}$:

$$\begin{array}{ccc} G & \xrightarrow{\ \psi\ } & \mathrm{Sym}(G) \\ g & \longmapsto & \psi_g. \end{array}$$

Diagram explanation. Objects: Two objects: the group G (on the left) and the symmetric group $\mathrm{Sym}(G)$ (on the right), which is the group of all bijections $G \to G$ under composition. The secondary row records the element-level action: a generic group element $g \in G$ and the inner automorphism $\psi_g \in \mathrm{Sym}(G)$ defined by $\psi_g(x) = gxg^{-1}$.

Arrows: The single arrow $\psi\colon G \to \mathrm{Sym}(G)$ is the *permutation representation* of the conjugation action. It is a group homomorphism (not merely a set map) sending each g to the function "conjugate by g." The mapsto arrow $g \mapsto \psi_g$ spells out the formula.

What commutes: There is only one arrow, so no path-equality to check; instead the key property is that ψ is a *homomorphism*: $\psi(g_1 g_2) = \psi_{g_1 g_2} = \psi_{g_1} \circ \psi_{g_2} = \psi(g_1) \circ \psi(g_2)$.

Why it commutes: Chase: $\psi_{g_1 g_2}(x) = (g_1 g_2)x(g_1 g_2)^{-1} = g_1(g_2 x g_2^{-1})g_1^{-1} = \psi_{g_1}(\psi_{g_2}(x))$. The associativity of G is the only ingredient needed.

Why this matters here: Every group action is equivalent to a homomorphism into a symmetric group; this diagram makes that correspondence explicit for conjugation. It also sets up the identification $\operatorname{im}\psi = \mathrm{Inn}(G) \leq \mathrm{Aut}(G) \leq \mathrm{Sym}(G)$ and $\ker\psi = Z(G)$, facts invoked throughout the section.

Concrete example: For $G = S_3$ and $g = (1\,2\,3)$, the map ψ_g sends each transposition $(a\,b)$ to the transposition $(\tau(a)\,\tau(b))$ where $\tau = g$; concretely $\psi_g((1\,2)) = (2\,3)$, a non-trivial element of $\mathrm{Aut}(S_3)$.

Common pitfall: Students often read ψ as a map of *sets* and forget it is a group homomorphism. The content is precisely that conjugation respects the group operation, which is what lets the image land in $\mathrm{Aut}(G)$ rather than merely in $\mathrm{Sym}(G)$.

Takeaway: The point of this diagram is that the conjugation action of G on itself is encoded by a single group homomorphism $\psi\colon G \to \mathrm{Sym}(G)$, whose kernel is $Z(G)$ and whose image is the group of inner automorphisms.

Each ψ_g is not merely a permutation of the set G but an *automorphism* of G (it preserves the product: $\psi_g(xy) = gxyg^{-1} = (gxg^{-1})(gyg^{-1}) = \psi_g(x)\psi_g(y)$), so the image lands in $\mathrm{Aut}(G) \leq \mathrm{Sym}(G)$ and we get $\psi\colon G \to \mathrm{Aut}(G)$ with image $\mathrm{Inn}(G)$. Its kernel is exactly the center $Z(G)$.

Definition 4.3.2 (Conjugacy class)**.** The orbit of x under the conjugation action,

$$\mathcal{K}_x \;=\; \{\, gxg^{-1} : g \in G \,\},$$

is the *conjugacy class* of x. The conjugacy classes partition G into disjoint pieces (they are the equivalence classes of the relation "is conjugate to").

The size of a conjugacy class

The stabilizer of x under conjugation is precisely the set of elements that commute with x.

Proposition 4.3.3 (Class size = index of the centralizer)**.** *For $x \in G$, the stabilizer of x under the conjugation action is the centralizer*

$$G_x \;=\; \{\, g \in G : gxg^{-1} = x \,\} \;=\; \{\, g \in G : gx = xg \,\} \;=\; C_G(x).$$

Consequently, by the orbit–stabilizer theorem, the number of conjugates of x equals

$$\big|\mathcal{K}_x\big| \;=\; [G : C_G(x)].$$

In particular $|\mathcal{K}_x|$ divides $|G|$ when G is finite, and $|\mathcal{K}_x| = 1$ iff $x \in Z(G)$.

Proof. g fixes x under conjugation $\iff gxg^{-1} = x \iff gx = xg \iff g \in C_G(x)$; that is the definition of the centralizer. Orbit–stabilizer gives the bijection

$$G/C_G(x) \xrightarrow[gC_G(x) \mapsto gxg^{-1}]{\sim} \mathcal{K}_x,$$

Diagram explanation. Objects: Two objects: the left coset space $G/C_G(x)$ (the set of left cosets of the centralizer of x in G; this is a set, not a group in general) and the conjugacy class $\mathcal{K}_x = \{gxg^{-1} : g \in G\} \subseteq G$ (also a set, one orbit of the conjugation action).

Arrows: The single arrow is the bijection $\varphi\colon G/C_G(x) \to \mathcal{K}_x$ sending a coset $gC_G(x)$ to the conjugate gxg^{-1}. It is an instance of the orbit-stabilizer theorem, which produces a canonical bijection from coset space to orbit whenever a group acts on a set.

What commutes: There is one arrow, so well-definedness is the key claim: if $gC_G(x) = hC_G(x)$ then $gxg^{-1} = hxh^{-1}$. (No two-path commutativity to check.)

Why it commutes: Well-definedness: $gC_G(x) = hC_G(x)$ means $h^{-1}g \in C_G(x)$, i.e., $h^{-1}g$ commutes with x, i.e., $(h^{-1}g)x(h^{-1}g)^{-1} = x$. Rearranging: $gxg^{-1} = hxh^{-1}$. So the coset representative chosen does not affect the output; φ is well-defined and is a bijection because φ is surjective by definition of $\mathcal{K}_x$ and injective by reversing the argument.

Why this matters here: This bijection converts the abstract orbit into a countable coset space, giving the formula $|\mathcal{K}_x| = [G : C_G(x)]$, the central computational tool for finding conjugacy class sizes throughout the section and in the class equation.

Concrete example: In S_3 with $x = (1\,2\,3)$: $C_{S_3}(x) = \langle (1\,2\,3) \rangle$ has order 3, so $G/C_G(x)$ has two cosets $\{e, (1\,2\,3), (1\,3\,2)\}$ and $\{(1\,2), \ldots\}$, mapped to $(1\,2\,3)$ and $(1\,3\,2)$ respectively, matching $|\mathcal{K}_x| = 2$.

Common pitfall: The map sends a *coset* to a conjugate, not a group element to a conjugate. Writing $g \mapsto gxg^{-1}$ (without the coset) gives a well-defined map $G \to \mathcal{K}_x$, but in general not an injective one: two elements in the same coset give the same conjugate, while two elements in different cosets give different conjugates – which is precisely the content of the bijection.

Takeaway: The point of this diagram is that orbit-stabilizer converts an orbit (hard to count directly) into a coset space (easy to count), yielding $|\mathcal{K}_x| = [G : C_G(x)]$ as a clean index formula.

so $|\mathcal{K}_x| = [G : C_G(x)]$. Since this is an index, it divides $|G|$ for finite G. Finally $|\mathcal{K}_x| = 1$ means $gxg^{-1} = x$ for all g, i.e. x commutes with everything, i.e. $x \in Z(G)$. □

Method (Computing one conjugacy class)**.** *Trigger.* You are asked for the conjugacy class of a specific x, or for $|\mathcal{K}_x|$.

1. Find $C_G(x) = \{g : gx = xg\}$ – list which elements commute with x. It always contains $\langle x \rangle$ and $Z(G)$.
2. Compute $|C_G(x)|$ and then $|\mathcal{K}_x| = [G : C_G(x)] = |G|/|C_G(x)|$.
3. Produce the conjugates by conjugating x by a transversal of $C_G(x)$ (one g per coset). Stop when you have collected $|\mathcal{K}_x|$ distinct elements.

4. *Check.* Class size divides $|G|$; the class is a single element iff x is central.

Caution. Do not confuse the *centralizer* $C_G(x)$ (the stabilizer, which governs class *size*) with the *normalizer* $N_G(H)$ (used for subgroup conjugation). For elements use $C_G(x)$; for subgroups use $N_G(H)$.

Worked Example 4.3.4 (Class of a reflection in D_8)**.** In $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s\rangle$, find the conjugacy class of the reflection s.

Recognition. Conjugation action; the class of s has size $[D_8 : C_{D_8}(s)]$, so first pin down which elements commute with s.

Solution. $|D_8| = 8$. The centralizer of s contains $\langle s\rangle = \{1, s\}$ and the center $Z(D_8) = \{1, r^2\}$, so $\{1, s, r^2, r^2s\} \le C_{D_8}(s)$, giving $|C_{D_8}(s)| \ge 4$. Now $rs = sr^{-1} = sr^3 \ne sr$, so $r \notin C_{D_8}(s)$; thus $C_{D_8}(s) \ne D_8$ and $|C_{D_8}(s)| = 4$. Hence

$$|\mathcal{K}_s| = [D_8 : C_{D_8}(s)] = 8/4 = 2.$$

Conjugating by r: using $sr^{-1} = rs$ we get $rsr^{-1} = r(sr^{-1}) = r(rs) = r^2s$. So $\mathcal{K}_s = \{s, r^2s\}$. *Check.* $2 \mid 8$. The four reflections split into two classes $\{s, r^2s\}$ and $\{rs, r^3s\}$, each of size 2 – consistent.

Worked Example 4.3.5 (A central element forms a singleton class)**.** In $Q_8 = \{\pm1, \pm i, \pm j, \pm k\}$, find the class of -1.

Recognition. Singletons come from the center: $|\mathcal{K}_x| = 1 \iff x \in Z(G)$.

Solution. -1 commutes with every element of Q_8 (it is the unique element of order 2 and lies in $Z(Q_8)$). So $C_{Q_8}(-1) = Q_8$ and $|\mathcal{K}_{-1}| = 8/8 = 1$, i.e. $\mathcal{K}_{-1} = \{-1\}$. *Check.* Singleton class $\iff$ central; indeed $Z(Q_8) = \{1, -1\}$.

Worked Example 4.3.6 (Class of i in Q_8)**.** Find the conjugacy class of i in Q_8.

Recognition. $|\mathcal{K}_i| = [Q_8 : C_{Q_8}(i)]$; compute the centralizer first.

Solution. $C_{Q_8}(i) \supseteq \langle i\rangle = \{1, -1, i, -i\}$, of order 4. Does j commute with i? $ji = -k$ while $ij = k$, so $ji \ne ij$ and $j \notin C_{Q_8}(i)$. Thus $C_{Q_8}(i) = \{\pm1, \pm i\}$, order 4, and $|\mathcal{K}_i| = 8/4 = 2$. Conjugate i by j (with $j^{-1} = -j$): $jij^{-1} = (ji)(-j) = (-k)(-j) = kj$, and $kj = -i$, so $jij^{-1} = -i$. Hence $\mathcal{K}_i = \{i, -i\}$. *Check.* $2 \mid 8$; and $i, -i$ are exactly the two noncentral powers of i – consistent.

Worked Example 4.3.7 (Class of a 3-cycle vs. the centralizer in S_3)**.** Find the conjugacy class of $(1\,2\,3)$ in S_3.

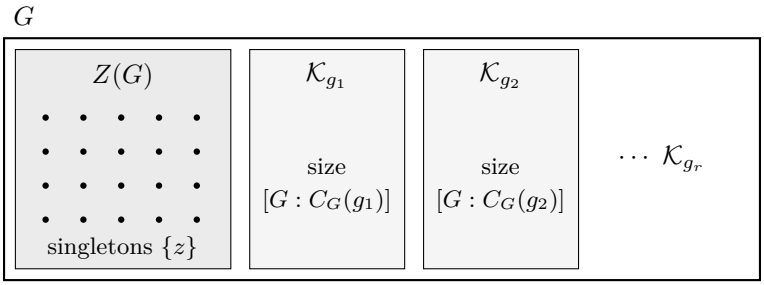
Recognition. In S_n conjugation preserves cycle type; class size $= [S_3 : C_{S_3}((1\,2\,3))]$.

Solution. $|S_3| = 6$. The element $(1\,2\,3)$ commutes with the cyclic group it generates, $\langle(1\,2\,3)\rangle = \{e, (1\,2\,3), (1\,3\,2)\}$, of order 3. No transposition commutes with it (e.g. $(1\,2)(1\,2\,3)(1\,2) = (2\,1\,3) = (1\,3\,2) \ne (1\,2\,3)$), so $C_{S_3}((1\,2\,3)) = \langle(1\,2\,3)\rangle$, order 3. Thus $|\mathcal{K}| = 6/3 = 2$, and $\mathcal{K}_{(1\,2\,3)} = \{(1\,2\,3), (1\,3\,2)\}$ – both 3-cycles. *Check.* There are exactly two 3-cycles in S_3; class size $2 \mid 6$. Good.

The class equation

Partitioning G into conjugacy classes and isolating the singletons (the central elements) gives the central counting identity of the chapter.

Theorem 4.3.8 (The Class Equation)**.** *Let G be a finite group and let $g_1, \ldots, g_r$ be representatives of the distinct conjugacy classes of G that are* not *contained in $Z(G)$. Then*



$$\boxed{|G| \;=\; |Z(G)| \;+\; \sum_{i=1}^{r} [G : C_G(g_i)].}$$

Proof. The conjugacy classes partition G, so $|G|$ is the sum of the sizes of the distinct classes. A class is a singleton exactly when its representative is central (Proposition 4.3.3); the singleton classes are the $|Z(G)|$

one-element sets $\{z\}$ for $z \in Z(G)$, contributing $|Z(G)|$ in total. Every remaining class has size > 1, with representative $g_i \notin Z(G)$ and size $[G : C_G(g_i)]$. Summing,

$$|G| = \underbrace{\sum_{z \in Z(G)} 1}_{=|Z(G)|} + \sum_{i=1}^{r} [G : C_G(g_i)] = |Z(G)| + \sum_{i=1}^{r} [G : C_G(g_i)]. \qquad \square$$

Pictorially, G is partitioned into a central block of singletons plus the larger non-central classes:

Each grey block is one orbit; the central block holds the $|Z(G)|$ orbits of size 1. Reading off the total width recovers the class equation.

Method (Writing the class equation of a finite group)**.** *Trigger.* "find the class equation of G" or "how many conjugacy classes does G have."

1. Compute $|Z(G)|$; each central element is its own class (a 1).
2. For each non-central element, find its class size $[G : C_G(g)]$; group elements into classes so you never double-count.
3. Write $|G| = |Z(G)| +$ (non-central class sizes); every summand divides $|G|$, and the central part is $|Z(G)|$ copies of 1.
4. *Check.* The right side sums to $|G|$, and the count of summands equals the number of conjugacy classes.

Worked Example 4.3.9 (Class equation of S_3)**.** Write the class equation of S_3.

Recognition. Class equation = sum of class sizes; in S_n classes are cycle types, so list them.

Solution. $|S_3| = 6$. Cycle types: identity e (1 element), transpositions $(1\,2), (1\,3), (2\,3)$ (3 elements), 3-cycles $(1\,2\,3), (1\,3\,2)$ (2 elements). $Z(S_3) = \{e\}$ so $|Z(S_3)| = 1$. Thus

$$6 \;=\; 1 + 2 + 3.$$

Check. $1 + 2 + 3 = 6$; each summand $(1, 2, 3)$ divides 6; three conjugacy classes. Centralizer check: $|\mathcal{K}_{(1\,2)}| = 3 \implies |C_{S_3}((1\,2))| = 2 = |\langle (1\,2) \rangle|$. Consistent.

Worked Example 4.3.10 (Class equation of D_8)**.** Write the class equation of $D_8 = \langle r, s \rangle$, $|D_8| = 8$.

Recognition. Group elements into conjugacy classes; central elements are singletons, the rest have size $[D_8 : C_{D_8}(g)]$.

Solution. Center: $Z(D_8) = \{1, r^2\}$, two singletons. Rotations: r and r^3 are conjugate ($srs^{-1} = r^{-1} = r^3$), forming $\{r, r^3\}$ of size 2. Reflections split into $\{s, r^2 s\}$ and $\{rs, r^3 s\}$, each size 2 (from the previous worked example and its analogue). Therefore

$$8 \;=\; \underbrace{1+1}_{Z(D_8)} + \underbrace{2}_{\{r,r^3\}} + \underbrace{2}_{\{s,r^2 s\}} + \underbrace{2}_{\{rs,r^3 s\}}.$$

Check. $1 + 1 + 2 + 2 + 2 = 8$; all summands divide 8; five conjugacy classes; $|Z| = 2$. Good.

Worked Example 4.3.11 (Class equation of Q_8)**.** Write the class equation of Q_8, $|Q_8| = 8$.

Recognition. Same recipe; note Q_8 has the *same* class equation as D_8 though the groups differ.

Solution. $Z(Q_8) = \{1, -1\}$, two singletons. The remaining six elements fall into $\{i, -i\}$, $\{j, -j\}$, $\{k, -k\}$, each a class of size 2 (e.g. $jij^{-1} = -i$ from before). Thus

$$8 \;=\; 1 + 1 + 2 + 2 + 2.$$

Check. $1 + 1 + 2 + 2 + 2 = 8$; five classes. So the class equation does *not* distinguish D_8 from Q_8 – a useful reminder that it is a coarse invariant.

Worked Example 4.3.12 (Class equation of A_4)**.** Write the class equation of A_4, $|A_4| = 12$.

Recognition. In S_n a class may *split* when restricted to A_n; check whether the cycle-type class stays whole by testing if some odd permutation centralizes a representative.

Solution. Elements of A_4: e (1); three double-transpositions $(1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)$; eight 3-cycles. The double-transpositions form one class of size 3 (they are all conjugate in A_4). The eight 3-cycles split into *two* A_4-classes of size 4: for $g = (1\,2\,3)$, $|C_{A_4}(g)| = 3$ (only powers of g centralize it inside A_4), so $|\mathcal{K}_g| = 12/3 = 4$; conjugating by even permutations cannot reach $(1\,3\,2)$, which heads the other class. Hence

$$12 \;=\; 1 + 3 + 4 + 4.$$

Check. $1 + 3 + 4 + 4 = 12$; $Z(A_4) = \{e\}$ so $|Z| = 1$; four classes. (Contrast: in S_4 all eight 3-cycles are one class – splitting is genuine.)

Conjugacy in S_n: same cycle type

Theorem 4.3.13 (Conjugacy classes of S_n)**.** *Two elements of S_n are conjugate* if and only if *they have the same cycle type. Concretely, if $\sigma = (a_1\, a_2 \cdots a_k)(b_1\, b_2 \cdots)\cdots$ in disjoint-cycle form and $\tau \in S_n$, then*

$$\tau\sigma\tau^{-1} \;=\; (\tau(a_1)\,\tau(a_2) \cdots \tau(a_k))(\tau(b_1)\,\tau(b_2) \cdots)\cdots .$$

Thus the conjugacy classes of S_n are indexed by the partitions of n.

Proof. Formula. For a k-cycle $(a_1 \cdots a_k)$ and any τ, evaluate $\tau\sigma\tau^{-1}$ at $\tau(a_j)$: $\tau\sigma\tau^{-1}(\tau(a_j)) = \tau\sigma(a_j) = \tau(a_{j+1})$ (indices mod k), so $\tau\sigma\tau^{-1} = (\tau(a_1) \cdots \tau(a_k))$, a k-cycle. Applying this to each disjoint cycle of σ (and noting τ keeps the cycles disjoint, being a bijection) shows $\tau\sigma\tau^{-1}$ has the same cycle type as σ. *Converse.* If σ, σ' have the same cycle type, align their cycles and let τ be the bijection sending the entries of σ to the correspondingly-placed entries of σ'; then $\tau\sigma\tau^{-1} = \sigma'$ by the formula. Hence "same cycle type" is exactly conjugacy, and cycle types are partitions of n. □

Theorem 4.3.14 (Counting a cycle-type class)**.** *If a cycle type has m_k cycles of length k (so $\sum_k k\, m_k = n$, counting fixed points as 1-cycles), the number of permutations of that type, equivalently the size of the conjugacy class, is*

$$\frac{n!}{\displaystyle\prod_{k \geq 1} k^{\,m_k}\, m_k!}.$$

Proof. Fill the cycle skeleton with the n symbols in one of $n!$ orders. Each cycle of length k has k cyclic rotations giving the same permutation, accounting for $\prod_k k^{m_k}$; and the m_k cycles of equal length k can be permuted among themselves without changing the permutation, accounting for $\prod_k m_k!$. Dividing removes the overcount. □

Method (Conjugacy in S_n)**.** *Trigger.* "are these two permutations conjugate in S_n?" or "how many elements / classes of a given type?"

1. Write each permutation in disjoint cycles (include fixed points to read the full type).
2. Conjugate by *relabeling*: $\tau\sigma\tau^{-1}$ just applies τ to each entry – so two are conjugate iff same multiset of cycle lengths.

3. Count a class by $n!/\prod_k k^{m_k} m_k!$. Sum over all partitions of n to recover $n!$.

4. *Check.* Class sizes are integers dividing $n!$ and sum to $n!$; the number of classes equals $p(n)$, the number of partitions.

Worked Example 4.3.15 (Conjugacy classes of S_4 by cycle type)**.** List all conjugacy classes of S_4 with their sizes, and verify they sum to 24.

Recognition. In S_n classes = partitions of n; size given by $n!/\prod k^{m_k} m_k!$.

Solution. Partitions of 4 and counts ($n = 4$, $n! = 24$):

$$\begin{aligned}
&\text{type } 1^4 \ (e): && \frac{24}{1^4 \cdot 4!} = 1, && \\
&\text{type } 2\,1^2 \ (a\,b): && \frac{24}{2^1 1! \cdot 1^2 2!} = \frac{24}{2 \cdot 2} = 6, && \text{transpositions} \\
&\text{type } 2^2 \ (a\,b)(c\,d): && \frac{24}{2^2 2!} = \frac{24}{8} = 3, && \text{double transpositions} \\
&\text{type } 3\,1 \ (a\,b\,c): && \frac{24}{3^1 1! \cdot 1 \cdot 1!} = \frac{24}{3} = 8, && \text{3-cycles} \\
&\text{type } 4 \ (a\,b\,c\,d): && \frac{24}{4^1 1!} = 6, && \text{4-cycles.}
\end{aligned}$$

So the class equation of S_4 is

$$24 \;=\; 1 + 6 + 3 + 8 + 6.$$

Check. $1 + 6 + 3 + 8 + 6 = 24$; five classes $= p(4) = 5$; $Z(S_4) = \{e\}$, so the lone singleton is the identity – consistent. (The even classes $1 + 3 + 8 = 12 = |A_4|$ also check out.)

Worked Example 4.3.16 (Are these conjugate in S_5?)**.** Decide whether $\sigma = (1\,2\,3)(4\,5)$ and $\tau = (1\,4)(2\,5\,3)$ are conjugate in S_5, and if so exhibit a conjugator.

Recognition. Conjugate in $S_n \iff$ same cycle type; build the conjugator by aligning cycles.

Solution. Both have type $3 + 2$ (a 3-cycle and a disjoint 2-cycle): σ acts as a 3-cycle on $\{1, 2, 3\}$ and a 2-cycle on $\{4, 5\}$; $\tau = (2\,5\,3)(1\,4)$ acts as a 3-cycle on $\{2, 5, 3\}$ and a 2-cycle on $\{1, 4\}$. Same type $\implies$ conjugate. To build ρ with $\rho\sigma\rho^{-1} = \tau$, map σ's cycles onto τ's entry-by-entry: $1 \mapsto 2$, $2 \mapsto 5$, $3 \mapsto 3$, $4 \mapsto 1$, $5 \mapsto 4$, i.e. $\rho = (1\,2\,5\,4)$. *Check.* $\rho\sigma\rho^{-1} = (\rho(1)\,\rho(2)\,\rho(3))(\rho(4)\,\rho(5)) = (2\,5\,3)(1\,4) = \tau$. Correct.

Worked Example 4.3.17 (Counting 5-cycles in S_5)**.** How many 5-cycles are in S_5, and what is the centralizer of one?

Recognition. Size of a cycle-type class $= n!/\prod k^{m_k} m_k!$; centralizer order $= |G|/|\text{class}|$.

Solution. Type 5: $m_5 = 1$, all others 0, so count $= 5!/(5^1 \cdot 1!) = 120/5 = 24$. By orbit–stabilizer, $|C_{S_5}(\sigma)| = |S_5|/|\mathcal{K}_\sigma| = 120/24 = 5$, so the centralizer is exactly $\langle\sigma\rangle$ (a 5-cycle commutes only with its own powers). *Check.* $24 \mid 120$; $|C| = 5 = |\langle\sigma\rangle|$. A 5-cycle has order 5, so $\langle\sigma\rangle$ has order 5 – matches.

Worked Example 4.3.18 (Counting double transpositions in S_6)**.** Count the elements of type $2^2 1^2$ in S_6.

Recognition. $n!/\prod k^{m_k} m_k!$ with $m_2 = 2$, $m_1 = 2$.

Solution. $n = 6$, $n! = 720$. Here $m_2 = 2,\ m_1 = 2$:

$$\frac{720}{(2^2 \cdot 2!)\,(1^2 \cdot 2!)} = \frac{720}{(4 \cdot 2)(1 \cdot 2)} = \frac{720}{16} = 45.$$

Check. $45 \mid 720$ ($720/45 = 16$), so the centralizer of such an element has order 16 – a 2-group, plausible. Counting directly: choose the two moved pairs, $\binom{6}{2}\binom{4}{2}/2! = 15 \cdot 6/2 = 45$. Matches.

Applications of the class equation

The first application is the cornerstone fact that finite p-groups have nontrivial center.

Theorem 4.3.19 (p-groups have nontrivial center)**.** *If p is a prime and $|G| = p^a$ with $a \geq 1$, then $Z(G) \neq 1$; that is, $p \mid |Z(G)|$.*

Proof. Write the class equation $|G| = |Z(G)| + \sum_{i=1}^{r}[G : C_G(g_i)]$ over non-central representatives g_i. For each such g_i we have $C_G(g_i) \neq G$ (else g_i would be central), so $[G : C_G(g_i)] > 1$. As an index it divides $|G| = p^a$, hence $[G : C_G(g_i)] = p^{b_i}$ with $b_i \geq 1$, so $p \mid [G : C_G(g_i)]$. Therefore p divides $|G|$ and the entire sum $\sum_i [G : C_G(g_i)]$, and rearranging the class equation gives

$$|Z(G)| = |G| - \sum_{i=1}^{r}[G : C_G(g_i)] \equiv 0 \pmod{p}.$$

Since $1 \in Z(G)$ gives $|Z(G)| \geq 1$ and $p \mid |Z(G)|$, we get $|Z(G)| \geq p > 1$. □

Corollary 4.3.20 (Groups of order p^2 are abelian)**.** *If $|G| = p^2$ for a prime p, then G is abelian (so $G \cong \mathbb{Z}/p^2\mathbb{Z}$ or $G \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$).*

Proof. By Theorem 4.3.19, $Z(G) \neq 1$, so $|Z(G)| \in \{p, p^2\}$. If $|Z(G)| = p^2$ then $G = Z(G)$ is abelian and we are done. Suppose instead $|Z(G)| = p$. Then $|G/Z(G)| = p^2/p = p$, so $G/Z(G)$ is cyclic. But it is a standard lemma that *if $G/Z(G)$ is cyclic then G is abelian*: write $G/Z(G) = \langle xZ(G)\rangle$; every $g \in G$ is $g = x^m z$ for some integer m and $z \in Z(G)$, and two such elements $x^m z$, $x^n w$ commute because powers of x commute with each other and z, w are central. So G is abelian, which forces $Z(G) = G$ and contradicts $|Z(G)| = p < p^2$. Hence the case $|Z(G)| = p$ is impossible, $|Z(G)| = p^2$, and G is abelian. The classification into $\mathbb{Z}/p^2\mathbb{Z}$ and $\mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$ follows from the structure of finite abelian groups. □

Method (Using the class equation modulo p)**.** *Trigger.* $|G|$ is a prime power p^a (or you need to show some central element exists).

1. Write $|G| = |Z(G)| + \sum[G : C_G(g_i)]$ over non-central classes.
2. Each non-central index $[G : C_G(g_i)]$ is a power p^{b_i}, $b_i \geq 1$, hence $\equiv 0 \pmod{p}$.
3. Reduce mod p: $0 \equiv |Z(G)| + 0$, so $p \mid |Z(G)|$, forcing $Z(G) \neq 1$.
4. *Check.* Consistency – the central summand $|Z(G)|$ plus a multiple of p equals p^a, also a multiple of p.

Worked Example 4.3.21 ($Z(G) \neq 1$ for $|G| = 27$)**.** Show every group of order 27 has nontrivial center.

Recognition. $27 = 3^3$ is a p-group; apply the class-equation-mod-p argument.

Solution. Class equation: $27 = |Z(G)| + \sum_i [G : C_G(g_i)]$ with each non-central index a power 3^{b_i}, $b_i \geq 1$, so each is divisible by 3. Reducing mod 3: $0 \equiv |Z(G)| + 0 \pmod{3}$, so $3 \mid |Z(G)|$. As $|Z(G)| \geq 1$, we get $|Z(G)| \in \{3, 9, 27\}$, in particular $Z(G) \neq 1$. *Check.* Possible class equations include $27 = 27$ (abelian) and $27 = 3 + 3 + 3 + 3 + 3 + 3 + 3 + 3 + 3$ (i.e. $|Z| = 3$ together with eight non-central classes of size 3). Each summand divides 27 and the centre is a multiple of 3. Consistent.

Worked Example 4.3.22 (Order p^2 is abelian: $|G| = 25$)**.** Prove any group of order 25 is abelian.

Recognition. $25 = 5^2$; use $Z(G) \neq 1$ and the $G/Z(G)$-cyclic lemma.

Solution. By Theorem 4.3.19, $Z(G) \neq 1$, so $|Z(G)| \in \{5, 25\}$. If $|Z(G)| = 5$ then $|G/Z(G)| = 5$, hence $G/Z(G)$ is cyclic of prime order, which forces G abelian and thus $Z(G) = G$ – contradicting $|Z(G)| = 5$. So $|Z(G)| = 25$ and G is abelian; concretely $G \cong \mathbb{Z}/25\mathbb{Z}$ or $\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$. *Check.* Both candidate groups are indeed abelian, and there is no nonabelian group of order 25. Consistent with the theorem.

Worked Example 4.3.23 (A nonabelian group of order p^3)**.** Verify the center-of-p-group theorem is sharp at p^3 by examining D_8.

Recognition. At p^3 the center can be exactly p; check D_8 ($p = 2$, $a = 3$).

Solution. $|D_8| = 8 = 2^3$. Its class equation $8 = 1 + 1 + 2 + 2 + 2$ has central part $|Z(D_8)| = 2 = p$, the smallest allowed. So $Z(D_8) \neq 1$ (as the theorem guarantees) but D_8 is nonabelian, showing the corollary "$p^2 \implies$ abelian" cannot be pushed to p^3. *Check.* $2 \mid |Z(D_8)|$ holds; $|Z| = 2 < 8$ so nonabelian – exactly the boundary case.

Conjugate subgroups and the normalizer

Conjugation also acts on subgroups, and the count of conjugates is governed by the normalizer rather than the centralizer.

Proposition 4.3.24 (Number of conjugates of a subgroup)**.** *Let $H \leq G$. Under the conjugation action of G on its subsets, the stabilizer of H is the normalizer $N_G(H) = \{g \in G : gHg^{-1} = H\}$. Hence the number of distinct conjugate subgroups gHg^{-1} equals*

$$\left|\{\, gHg^{-1} : g \in G \,\}\right| \;=\; [G : N_G(H)].$$

In particular this number divides $|G|$, and it equals 1 iff $H \trianglelefteq G$.

Proof. g stabilizes H under conjugation $\iff gHg^{-1} = H \iff g \in N_G(H)$, by definition of the normalizer. Orbit–stabilizer applied to this action on subsets gives the bijection

$$G/N_G(H) \xrightarrow[gN_G(H) \mapsto gHg^{-1}]{\sim} \{\, gHg^{-1} : g \in G \,\},$$

Diagram explanation. Objects: Two objects: the coset space $G/N_G(H)$ (left cosets of the normalizer $N_G(H)$ in G; again a set, not a group in general) and the set $\{gHg^{-1} : g \in G\}$ of all distinct conjugates of the subgroup $H \leq G$ (the orbit of H under the conjugation action of G on its power set).

Arrows: The bijection $\Phi\colon G/N_G(H) \to \{gHg^{-1} : g \in G\}$ sends a coset $gN_G(H)$ to the conjugate subgroup gHg^{-1}. This is the orbit-stabilizer bijection applied to the action of G by conjugation on the set of subsets of G, with stabilizer of H equal to $N_G(H)$.

What commutes: Well-definedness is the key: if $gN_G(H) = g'N_G(H)$, then $gHg^{-1} = g'Hg'^{-1}$.

Why it commutes: Well-definedness: $gN_G(H) = g'N_G(H)$ means $g^{-1}g' \in N_G(H)$, i.e., $(g^{-1}g')H(g^{-1}g')^{-1} = H$. Conjugating by g on both sides: $g'Hg'^{-1} = gHg^{-1}$. So the coset representative does not affect the conjugate subgroup produced. Injectivity and surjectivity follow as in the element case. If one mistakenly uses $C_G(H)$ instead of $N_G(H)$, the map $gC_G(H) \mapsto gHg^{-1}$ is still well defined (every element of $C_G(H) \leq N_G(H)$ sends H to itself, even fixing it pointwise), but it is no longer injective when $C_G(H) \neq N_G(H)$: the $[N_G(H) : C_G(H)]$ cosets of $C_G(H)$ lying in $N_G(H)$ all go to H.

Why this matters here: This bijection is the subgroup analogue of the element bijection from the class-size proposition. It shows the number of conjugate subgroups equals the index $[G : N_G(H)]$, giving a divisibility condition ($|G|$ finite) and a normality criterion ($H \trianglelefteq G$ iff there is exactly one conjugate iff $N_G(H) = G$).

Concrete example: In D_8 with $H = \langle s \rangle$: $N_{D_8}(H) = \{1, s, r^2, r^2s\}$ has order 4, so $[D_8 : N_{D_8}(H)] = 2$, matching the count of two conjugate subgroups $\langle s \rangle$ and $\langle r^2s \rangle$.

Common pitfall: Students confuse the normalizer $N_G(H)$ (which controls how many conjugate *subgroups* there are) with the centralizer $C_G(H)$ (which controls elements that fix H pointwise). The number of conjugates is $[G : N_G(H)]$, not $[G : C_G(H)]$: since $[G : C_G(H)] = [G : N_G(H)]\,[N_G(H) : C_G(H)]$, for finite G using the centralizer overcounts by the factor $[N_G(H) : C_G(H)]$ (the answers agree only when $C_G(H) = N_G(H)$).

Takeaway: The point of this diagram is that the orbit-stabilizer theorem for the conjugation action on subsets converts the count of conjugate subgroups into the computable index $[G : N_G(H)]$, encoding normality as the condition that this index equals 1.

so the number of conjugates is $[G : N_G(H)]$. It divides $|G|$, and it is 1 exactly when $N_G(H) = G$, i.e. when H is normal. □

Caution. For *subgroup* conjugacy use the *normalizer* $N_G(H)$, not the centralizer. Always $H \leq N_G(H)$ and $C_G(H) \leq N_G(H)$, but the number of conjugates is $[G : N_G(H)]$. Using $C_G(H)$ here is a common error.

Method (Counting conjugates of a subgroup)**.** *Trigger.* "how many subgroups are conjugate to H" or "is H normal."

1. Compute $N_G(H) = \{g : gHg^{-1} = H\}$; note $H \leq N_G(H) \leq G$.
2. Number of conjugates $= [G : N_G(H)] = |G|/|N_G(H)|$.

3. $H \trianglelefteq G \iff$ this index is $1 \iff N_G(H) = G$.

4. *Check.* The count divides $|G|$; if you also have the count by direct listing, it must match.

Worked Example 4.3.25 (Conjugates of $\langle s \rangle$ in D_8)**.** Count the subgroups of D_8 conjugate to $H = \langle s \rangle = \{1, s\}$.

Recognition. Number of conjugates $= [D_8 : N_{D_8}(H)]$; find the normalizer.

Solution. $N_{D_8}(H) \supseteq H = \{1, s\}$ and contains $Z(D_8) = \{1, r^2\}$ since central elements normalize everything; so $\{1, s, r^2, r^2 s\} \leq N_{D_8}(H)$, order ≥ 4. Is $r \in N$? $r\langle s \rangle r^{-1} = \langle rsr^{-1} \rangle = \langle r^2 s \rangle \neq \langle s \rangle$, so $r \notin N$, giving $N_{D_8}(H) = \{1, s, r^2, r^2 s\}$, order 4. Hence the number of conjugates is $8/4 = 2$, namely $\langle s \rangle$ and $\langle r^2 s \rangle$. *Check.* $2 \mid 8$; $\langle s \rangle$ is not normal (the count exceeds 1), and indeed conjugating gives $\langle r^2 s \rangle$. Consistent.

Worked Example 4.3.26 (Conjugates of $\langle (1\,2) \rangle$ in S_3)**.** Count the subgroups of S_3 conjugate to $H = \langle (1\,2) \rangle$.

Recognition. $[S_3 : N_{S_3}(H)]$; find which elements normalize H.

Solution. $N_{S_3}(H) \supseteq H = \{e, (1\,2)\}$, order 2. A 3-cycle conjugates $(1\,2)$ to a different transposition (e.g. $(1\,2\,3)(1\,2)(1\,3\,2) = (2\,3)$), so no 3-cycle normalizes H; thus $N_{S_3}(H) = H$, order 2, and the number of conjugates is $6/2 = 3$: namely $\langle (1\,2) \rangle, \langle (1\,3) \rangle, \langle (2\,3) \rangle$. *Check.* $3 \mid 6$; there are exactly three order-2 subgroups in S_3 and they are all conjugate – matches.

Worked Example 4.3.27 (A normal subgroup has one conjugate)**.** Count the conjugates of $A_3 = \langle (1\,2\,3) \rangle$ in S_3.

Recognition. Number of conjugates $= 1 \iff H \trianglelefteq G \iff N_G(H) = G$.

Solution. A_3 has index 2 in S_3, hence is normal, so $N_{S_3}(A_3) = S_3$ and the number of conjugates is $6/6 = 1$. Directly: conjugating a 3-cycle gives a 3-cycle, so $gA_3g^{-1} = A_3$ for all g. *Check.* index-2 subgroups are always normal; count 1 as expected.

Worked Example 4.3.28 (Conjugates of a Sylow 2-subgroup of S_4)**.** Count the subgroups of S_4 conjugate to a Sylow 2-subgroup P ($|P| = 8$), and identify $N_{S_4}(P)$.

Recognition. $[S_4 : N_{S_4}(P)]$ gives the count; for a Sylow subgroup the count is also the Sylow number n_2.

Solution. $|S_4| = 24 = 2^3 \cdot 3$, so $|P| = 8$ and $[S_4 : P] = 3$. Since $P \leq N_{S_4}(P) \leq S_4$, the order $|N_{S_4}(P)|$ is a multiple of 8 dividing 24, so it is 8 or 24. P is not normal in S_4 (e.g. S_4 has more than one Sylow 2-subgroup), so $|N_{S_4}(P)| \neq 24$; thus $N_{S_4}(P) = P$, order 8, and the number of conjugates is $24/8 = 3$. *Check.* $3 \mid 24$; $n_2 = 3 \equiv 1 \pmod 2$ and $3 \mid 3$, consistent with Sylow's theorem. So S_4 has exactly three Sylow 2-subgroups, all conjugate.

Worked Example 4.3.29 (Conjugates of $\langle i \rangle$ in Q_8)**.** Count the conjugates of $H = \langle i \rangle = \{1, -1, i, -i\}$ in Q_8.

Recognition. $[Q_8 : N_{Q_8}(H)]$; index-2 subgroups are normal.

Solution. $|H| = 4$ and $[Q_8 : H] = 8/4 = 2$, so H has index 2 and is therefore normal: $N_{Q_8}(H) = Q_8$. The number of conjugates is $8/8 = 1$. *Check.* Every index-2 subgroup is normal, so a single conjugate – and indeed $\langle i \rangle, \langle j \rangle, \langle k \rangle$ are three *distinct* normal subgroups, each its own sole conjugate. Consistent.

Remark 4.3.1. Proposition 4.3.24 is the engine behind Sylow's theorems: applying it to a Sylow p-subgroup P shows the number of Sylow p-subgroups is $[G : N_G(P)]$, which combined with a counting argument yields $n_p \equiv 1 \pmod p$ and $n_p \mid |G|$. Conjugation – of elements and of subgroups – is thus the common thread running from the class equation through the structure of p-groups to the Sylow theory of the next section.

Exercises (from the text).

1. Suppose G has a left action on a set A, denoted by $g \cdot a$ for all $g \in G$ and $a \in A$. Denote the corresponding right action on A by $a \cdot g$. Prove that the (equivalence) relations $\sim$ and $\sim'$ defined by

$$a \sim b \quad \text{if and only if} \quad a = g \cdot b \quad \text{for some } g \in G$$

and

$$a \sim' b \quad \text{if and only if} \quad a = b \cdot g \quad \text{for some } g \in G$$

are the same relation (i.e., $a \sim b$ if and only if $a \sim' b$).

2. Find all the conjugacy classes and their sizes in the following groups: (a) D_8 (b) Q_8 (c) A_4.

3. Find all the conjugacy classes and their sizes in the following groups: (a) $\mathbb{Z}_2 \times S_3$ (b) $S_3 \times S_3$ (c) $\mathbb{Z}_3 \times A_4$.

4. Prove that if $S \subseteq G$ and $g \in G$ then $gN_G(S)g^{-1} = N_G(gSg^{-1})$ and $gC_G(S)g^{-1} = C_G(gSg^{-1})$.

5. If the center of G is of index n, prove that every conjugacy class has at most n elements.

6. Assume G is a non-abelian group of order 15. Prove that $Z(G) = 1$. Use the fact that $\langle g \rangle \leq C_G(g)$ for all $g \in G$ to show that there is at most one possible class equation for G. [Use Exercise 36, Section 3.1.]

7. For $n = 3, 4, 5$ and 7 make tables of the partitions of n and give representatives for the corresponding conjugacy classes of S_n.

8. Prove that $Z(S_n) = 1$ for all $n \geq 3$.

9. Show that $|C_{S_n}((1\,2)(3\,4))| = 8 \cdot (n-4)!$ for all $n \geq 4$. Determine the elements in this centralizer.

10. Let σ be the 5-cycle $(1\,2\,3\,4\,5)$ in S_5. In each of (a) to (c) find an explicit element $\tau \in S_5$ which accomplishes the specified conjugation: (a) $\tau\sigma\tau^{-1} = \sigma^2$ (b) $\tau\sigma\tau^{-1} = \sigma^{-1}$ (c) $\tau\sigma\tau^{-1} = \sigma^{-2}$.

11. In each of (a) – (d) determine whether σ_1 and σ_2 are conjugate. If they are, give an explicit permutation τ such that $\tau\sigma_1\tau^{-1} = \sigma_2$. (a) $\sigma_1 = (1\,2)(3\,4\,5)$ and $\sigma_2 = (1\,2\,3)(4\,5)$ (b) $\sigma_1 = (1\,5)(3\,7\,2)(10\,6\,8\,11)$ and $\sigma_2 = (3\,7\,5\,10)(4\,9)(13\,11\,2)$ (c) $\sigma_1 = (1\,5)(3\,7\,2)(10\,6\,8\,11)$ and $\sigma_2 = \sigma_1^3$ (d) $\sigma_1 = (1\,3)(2\,4\,6)$ and $\sigma_2 = (3\,5)(2\,4)(5\,6)$.

12. Find a representative for each conjugacy class of elements of order 4 in S_8 and in S_{12}.

13. Find all finite groups which have exactly two conjugacy classes.

14. In Exercise 1 of Section 2 two labellings of the elements $\{1, a, b, c\}$ of the Klein 4-group V were chosen to give two versions of the left regular representation of V into S_4. Let π_1 be the version of regular representation obtained in part (a) of that exercise and let π_2 be the version obtained via the labelling in part (b). Let $\tau = (2\,4)$. Show that $\tau \circ \pi_1(g) \circ \tau^{-1} = \pi_2(g)$ for each $g \in V$ (i.e., conjugation by τ sends the image of π_1 to the image of π_2 elementwise).

15. Find an element of S_8 which conjugates the subgroup of S_8 obtained in part (a) of Exercise 3, Section 2 to the subgroup of S_8 obtained in part (b) of that same exercise (both of these subgroups are isomorphic to D_8).

16. Find an element of S_4 which conjugates the subgroup of S_4 obtained in part (a) of Exercise 5, Section 2 to the subgroup of S_4 obtained in part (b) of that same exercise (both of these subgroups are isomorphic to D_8).

17. Let A be a nonempty set and let X be any subset of S_A. Let

$$F(X) = \{a \in A \mid \sigma(a) = a \text{ for all } \sigma \in X\} \qquad \text{— the } \textit{fixed set} \text{ of } X.$$

Let $M(X) = A - F(X)$ be the elements which are *moved* by some element of X. Let $D = \{\sigma \in S_A \mid |M(\sigma)| < \infty\}$. Prove that D is a normal subgroup of S_A.

18. Let A be a set, let H be a subgroup of S_A and let $F(H)$ be the fixed points of H on A as defined in the preceding exercise. Prove that if $\tau \in N_{S_A}(H)$ then τ stabilizes the set $F(H)$ and its complement $A - F(H)$.

19. Assume H is a normal subgroup of G, $\mathcal{K}$ is a conjugacy class of G contained in H and $x \in \mathcal{K}$. Prove that $\mathcal{K}$ is a union of k conjugacy classes of equal size in H, where $k = [G : HC_G(x)]$. Deduce that a conjugacy class in S_n which consists of even permutations is either a single conjugacy class under the action of A_n or is a union of two classes of the same size in A_n. [Let $A = C_G(x)$ and $B = H$ so $A \cap B = C_H(x)$. Draw the lattice diagram associated to the Second Isomorphism Theorem and interpret the appropriate indices. See also Exercise 9, Section 1.]

20. Let $\sigma \in A_n$. Show that all elements in the conjugacy class of σ in S_n (i.e., all elements of the same cycle type as σ) are conjugate in A_n if and only if σ commutes with an odd permutation. [Use the preceding exercise.]

21. Let $\mathcal{K}$ be a conjugacy class in S_n and assume that $\mathcal{K} \subseteq A_n$. Show $\sigma \in S_n$ does *not* commute with any odd permutation if and only if the cycle type of σ consists of distinct odd integers. Deduce that $\mathcal{K}$ consists of two conjugacy classes in A_n if and only if the cycle type of an element of $\mathcal{K}$ consists of distinct odd integers. [Assume first that $\sigma \in \mathcal{K}$ does not commute with any odd permutation. Observe that σ commutes with each individual cycle in its cycle decomposition — use this to show that all its cycles must be of odd length. If two cycles have the same odd length, k, find a product of k transpositions which interchanges them and commutes with σ. Conversely, if the cycle type of σ consists of distinct integers, prove that σ commutes *only* with the group generated by the cycles in its cycle decomposition.]

22. Show that if n is odd then the set of all n-cycles consists of two conjugacy classes of equal size in A_n.

23. Recall (cf. Exercise 16, Section 2.4) that a proper subgroup M of G is called *maximal* if whenever $M \leq H \leq G$, either $H = M$ or $H = G$. Prove that if M is a maximal subgroup of G then either $N_G(M) = M$ or $N_G(M) = G$. Deduce that if M is a maximal subgroup of G that is not normal in G then the number of nonidentity elements of G that are contained in conjugates of M is at most $(|M|-1)[G:M]$.

24. Assume H is a proper subgroup of the finite group G. Prove $G \neq \bigcup_{g \in G} gHg^{-1}$, i.e., G is not the union of the conjugates of any proper subgroup. [Put H in a maximal subgroup and use the preceding exercise.]

25. Let $G = GL_2(\mathbb{C})$ and let $H = \{\begin{pmatrix} a & b \\ 0 & c \end{pmatrix} \mid a, b, c \in \mathbb{C},\ ac \neq 0\}$. Prove that every element of G is conjugate to some element of the subgroup H and deduce that G is the union of conjugates of H. [Show that every element of $GL_2(\mathbb{C})$ has an eigenvector.]

26. Let G be a transitive permutation group on the finite set A with $|A| > 1$. Show that there is some $\sigma \in G$ such that $\sigma(a) \neq a$ for all $a \in A$ (such an element σ is called *fixed point free*).

27. Let $g_1, g_2, \ldots, g_r$ be representatives of the conjugacy classes of the finite group G and assume these elements pairwise commute. Prove that G is abelian.

28. Let p and q be primes with $p < q$. Prove that a non-abelian group G of order pq has a nonnormal subgroup of index q, so that there exists an injective homomorphism into S_q. Deduce that G is isomorphic to a subgroup of the normalizer in S_q of the cyclic group generated by the q-cycle $(1\,2 \ldots q)$.

29. Let p be a prime and let G be a group of order p^a. Prove that G has a subgroup of order p^b, for every b with $0 \leq b \leq a$. [Use Theorem 4.3.19 and induction on a.]

30. If G is a group of odd order, prove for any nonidentity element $x \in G$ that x and x^{-1} are not conjugate in G.

31. Using the usual generators and relations for the dihedral group D_{2n} (cf. Section 1.2) show that for $n = 2k$ an even integer the conjugacy classes in D_{2n} are the following: $\{1\}$, $\{r^k\}$, $\{r^{\pm 1}\}$, $\{r^{\pm 2}\}$, …, $\{r^{\pm(k-1)}\}$, $\{sr^{2b} \mid b = 1, \ldots, k\}$ and $\{sr^{2b-1} \mid b = 1, \ldots, k\}$. Give the class equation for D_{2n}.

32. For $n = 2k+1$ an odd integer show that the conjugacy classes in D_{2n} are $\{1\}$, $\{r^{\pm 1}\}$, $\{r^{\pm 2}\}$, …, $\{r^{\pm k}\}$, $\{sr^b \mid b = 1, \ldots, n\}$. Give the class equation for D_{2n}.

33. This exercise gives a formula for the size of each conjugacy class in S_n. Let σ be a permutation in S_n and let $m_1, m_2, \ldots, m_s$ be the *distinct* integers which appear in the cycle type of σ (including 1-cycles). For each $i \in \{1, 2, \ldots, s\}$ assume σ has k_i cycles of length m_i. (So $\sum_i k_i m_i = n$.) Prove that the number of conjugates of σ is
$$\frac{n!}{(k_1!\, m_1^{k_1})(k_2!\, m_2^{k_2}) \cdots (k_s!\, m_s^{k_s})}.$$
[See Exercises 16 and 17 in Section 1.3 where this formula was given in some special cases.]

34. Prove that if p is a prime and P is a subgroup of S_p of order p then $|N_{S_p}(P)| = p(p-1)$. [Argue that every conjugate of P contains exactly $p-1$ p-cycles and use the formula for the number of p-cycles to compute the index of $N_{S_p}(P)$ in S_p.]

35. Let p be a prime. Find a formula for the number of conjugacy classes of elements of order p in S_n (using the greatest integer function).

36. Let $\pi : G \to S_G$ be the left regular representation afforded by the action of G on itself by left multiplication. For each $g \in G$ denote the permutation $\pi(g)$ by σ_g, so that $\sigma_g(x) = gx$ for all $x \in G$. Let $\lambda : G \to S_G$ be the permutation representation afforded by the corresponding right action of G on itself, and for each $h \in G$ denote the permutation $\lambda(h)$ by τ_h. Thus $\tau_h(x) = xh^{-1}$ for all $x \in G$ (λ is called the *right regular representation* of G). (a) Prove that σ_g and τ_h commute for all $g, h \in G$. (Thus the centralizer in S_G of $\pi(G)$ contains the subgroup $\lambda(G)$, which is isomorphic to G.) (b) Prove that $\sigma_g = \tau_g$ if and only if g is an element of order 1 or 2 in the center of G. (c) Prove that $\sigma_g = \tau_h$ if and only if g and h lie in the center of G and $g = h^{-1}$. Deduce that $\lambda(G) \cap \pi(G) = Z(\lambda(G)) = Z(\pi(G))$.

Practice problems.

1. Find all conjugacy classes of D_8 (order 8, with $r^4 = s^2 = 1$, $sr = r^{-1}s$). List the class sizes and verify they partition $|D_8| = 8$. Use the data to write the class equation of D_8.

2. In S_4 list a representative of each conjugacy class (by cycle type), give the size of each class, and confirm the sizes sum to 24. Identify $Z(S_4)$.

3. For each cycle type in S_5 compute the order of the centralizer $C_{S_5}(\sigma)$ of a representative σ, using $|C_{S_5}(\sigma)| = 120/(\text{class size})$. (Recall the class of a permutation with a_i cycles of length i has size $n!/\prod_i i^{a_i}\, a_i!$.)

4. Let G be a group of order p^2 for a prime p. Use the class equation to prove $Z(G) \neq 1$, then deduce G is abelian. Conclude $G \cong \mathbb{Z}/p^2\mathbb{Z}$ or $G \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$.

5. Show that a group of order p^n (p prime, $n \geq 1$) has a nontrivial center. Then show every group of order p^n has a normal subgroup of order p^k for each $0 \leq k \leq n$.

6. Let $G = Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$. Compute all conjugacy classes, the class equation, and $Z(Q_8)$. Compare the class equation of Q_8 with that of D_8 from Problem 1.

7. Suppose $|G| = p\,m$ where p is the smallest prime dividing $|G|$ and $H \leq G$ with $[G : H] = p$. Prove $H \trianglelefteq G$. (Hint: let G act on the left cosets G/H and analyze the kernel of the induced map $G \to \mathrm{Sym}(G/H)$.)

8. Let $\sigma = (1\,2\,3)(4\,5) \in S_5$ and $\tau = (1\,4\,2)(3\,5) \in S_5$. Exhibit an explicit $\pi \in S_5$ with $\pi\sigma\pi^{-1} = \tau$, and confirm by direct computation.

9. Determine $C_{S_6}(\sigma)$ explicitly (as a set of generators) for $\sigma = (1\,2)(3\,4)(5\,6) \in S_6$, and compute $|C_{S_6}(\sigma)|$. Verify your count against the class-size formula.

10. Let G act on itself by conjugation. Show the orbits are exactly the conjugacy classes and that the stabilizer of $x \in G$ is $C_G(x)$. Deduce $|\text{class of } x| = [G : C_G(x)]$ and that this index divides $|G|$.

11. Prove that two elements of S_n are conjugate in S_n iff they have the same cycle type. Use this to count the number of conjugacy classes of S_5 (i.e. the number of partitions of 5) and list each class size.

12. Let G be a finite group and $H \trianglelefteq G$ with $|H| = p$, p prime. Prove that $H \leq Z(G)$ provided p is the smallest prime dividing $|G|$. (Hint: G acts on H by conjugation, giving $G \to \mathrm{Aut}(H) \cong (\mathbb{Z}/p\mathbb{Z})^{\times}$.)

13. Show that if $G/Z(G)$ is cyclic then G is abelian. Use this to prove no group of order p^3 (p prime) has center of order p^2.

14. Let $\sigma \in S_n$ be an n-cycle. Compute $|C_{S_n}(\sigma)|$ and describe $C_{S_n}(\sigma)$ explicitly. How many n-cycles are there in S_n?

15. A group G of order 60 has class equation $60 = 1 + 15 + 20 + 12 + 12$. Show G is simple, i.e. has no nontrivial proper normal subgroup. (Any normal subgroup is a union of classes including $\{1\}$ whose total order divides 60.)

Additional exercises.

1. Let G be a finite group in which every conjugacy class has size at most 2. Prove that $[G,G]$ (the subgroup generated by all commutators) has order at most 2, and that $G/Z(G)$ has exponent 2.

2. Let p be a prime and G a group of order p^n with $n \geq 1$. Prove that the number of conjugacy classes of size 1 (i.e. $|Z(G)|$) is divisible by p, and use the class equation to show G cannot have exactly p^{n-1} classes of size p. Then show $|Z(G)| \neq p^{n-1}$, and determine whether a nonabelian G can have $|Z(G)| = p^{n-2}$.

3. Show that if $|G| = p^a m$ with $\gcd(p,m) = 1$ and G has a single conjugacy class of size coprime to p other than $\{1\}$, derive what this forces about $|Z(G)|$. Then prove more generally: if $x \in G$ has $[G : C_G(x)]$ a power of p for every $x \notin Z(G)$, then a Sylow p-subgroup is normal.

4. Let G be a nonabelian group of order p^3. Prove $|Z(G)| = p$, that $Z(G) = [G,G]$, and that $G/Z(G) \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$. Conclude the class equation is $p^3 = p + \underbrace{(p^2-1)}_{\text{number of size-}p\text{ classes}} \cdot p$, i.e. $p^3 = p + (p^2-1)p$.

5. Let G act on a finite set A. Prove Burnside's counting lemma: the number of orbits equals $\frac{1}{|G|}\sum_{g \in G} |\operatorname{Fix}(g)|$, where $\operatorname{Fix}(g) = \{a \in A : g \cdot a = a\}$. Apply it to count the orbits of D_8 acting on the 4 vertices of a square.

6. Suppose G is a finite group with exactly three conjugacy classes. Prove $|G| \in \{3, 6\}$ and identify the groups (up to isomorphism) realizing each.

Commutative-diagram exercises.

1. Let G act on a finite set A, giving the permutation representation $\rho\colon G \to \operatorname{Sym}(A)$. For a fixed $a \in A$ let $G_a = \operatorname{Stab}_G(a)$. Prove the orbit map

$$G/G_a \xrightarrow[gG_a \mapsto g\cdot a]{\sim} \operatorname{orb}(a)$$

is a well-defined bijection of G-sets, and deduce $|\operatorname{orb}(a)| = [G : G_a]$. State precisely what "$G$-set map" means here.

2. Conjugation gives an action of G on itself. Show the induced map fits in

$$1 \longrightarrow Z(G) \hookrightarrow G \xrightarrow{\ \psi\ } \operatorname{Aut}(G)$$

where $\psi(g)$ is conjugation by g. Prove this row is exact, identify $\operatorname{im}\psi = \operatorname{Inn}(G)$, and conclude $G/Z(G) \cong \operatorname{Inn}(G)$.

3. For $G = S_4$ acting on itself by conjugation, the representation is $\rho\colon S_4 \to \operatorname{Sym}(S_4)$. Restricting to the orbit of a transposition $t = (1\,2)$ yields

$$S_4/C_{S_4}(t) \xrightarrow[gC \mapsto gtg^{-1}]{\sim} \operatorname{orb}(t)$$

Compute $C_{S_4}(t)$, the order of $S_4/C_{S_4}(t)$, and list $\operatorname{orb}(t)$; verify the bijection on two specific cosets.

4. Let $H \leq G$ with $[G : H] = n$, and let G act on the left cosets G/H. This gives

$$G \xrightarrow{\ \pi\ } \operatorname{Sym}(G/H)$$

Show $\ker\pi = \bigcap_{g \in G} gHg^{-1}$, the largest normal subgroup of G contained in H (the *core* of H). Deduce that if $|G| \nmid n!$ then H contains a nontrivial normal subgroup of G.

5. Let G be a finite group with $N \trianglelefteq G$ and form the conjugation action of G on N. Show it induces a homomorphism into $\operatorname{Aut}(N)$ making

$$1 \longrightarrow C_G(N) \hookrightarrow G \xrightarrow{\ \varphi\ } \operatorname{Aut}(N)$$

exact, where $C_G(N) = \{g \in G : gn = ng\ \forall n \in N\}$. Conclude $G/C_G(N)$ embeds in $\operatorname{Aut}(N)$, and apply this with $N = G$ to recover the fact that $G/Z(G)$ is isomorphic to a subgroup of $\operatorname{Aut}(G)$.

4.4 Automorphisms

Automorphisms: $\mathrm{Aut}(G)$, inner automorphisms, characteristic subgroups

An *automorphism* of G is an isomorphism $\varphi\colon G \to G$. Under composition the set of all automorphisms forms a group, the principal object of this section.

Definition 4.4.1 (Automorphism group)**.** For a group G, let

$$\mathrm{Aut}(G) = \{\varphi\colon G \to G \mid \varphi \text{ is an isomorphism}\}.$$

Under composition of functions $\mathrm{Aut}(G)$ is a group: composition of isomorphisms is an isomorphism, composition is associative, the identity map id_G is the unit, and every isomorphism has an inverse isomorphism. Thus $\mathrm{Aut}(G) \leq \mathrm{Sym}(G)$, the symmetric group on the underlying set of G.

Remark 4.4.1. $\mathrm{Aut}(G)$ records the symmetries of G *as a group*, not merely as a set: an automorphism must preserve the multiplication, so it permutes elements of each order among themselves and fixes e. If $|G| = n$ then $\mathrm{Aut}(G) \leq S_n$, so $|\mathrm{Aut}(G)|$ divides $n!$, but in practice it is far smaller because of these constraints.

Method (Computing $\mathrm{Aut}(G)$ by hand)**.** *Trigger.* "find all automorphisms of this concrete (small or generated) group."

1. An automorphism is determined by where it sends a *generating set*; so list generators and where each can go.
2. A generator of order k must map to an element of order k (automorphisms preserve order). This bounds the possibilities.
3. Each candidate assignment that *respects the defining relations* extends to a homomorphism; injectivity/surjectivity on a finite group then make it an automorphism.
4. Count the survivors; identify the group structure on $\mathrm{Aut}(G)$ (orders of the automorphisms, whether they commute) and match it to a known group.

Worked Example 4.4.2 (Order forces the count for $\mathbb{Z}_n$)**.** Show every automorphism of $\mathbb{Z}_n = \langle x \rangle$ is $x \mapsto x^a$ with $\gcd(a, n) = 1$, hence $|\mathrm{Aut}(\mathbb{Z}_n)| = \varphi(n)$.

Recognition. An automorphism is determined by the image of the single generator x, and that image must again generate, i.e. have order n.

Solution. A homomorphism $\mathbb{Z}_n \to \mathbb{Z}_n$ is determined by $\varphi(x)$; if $\varphi(x) = x^a$ then $\varphi(x^k) = x^{ak}$. This is well defined for every a, but φ is an automorphism iff $\varphi(x)$ generates $\mathbb{Z}_n$, i.e. iff $|x^a| = n$, i.e. iff $\gcd(a, n) = 1$. Distinct $a \in \{0, 1, \ldots, n-1\}$ with $\gcd(a, n) = 1$ give distinct automorphisms, so $|\mathrm{Aut}(\mathbb{Z}_n)| = \varphi(n)$. *Check ($n = 8$).* The valid a are $1, 3, 5, 7$, four of them, and $\varphi(8) = 4$. The map $x \mapsto x^3$ has $x \mapsto x^3 \mapsto x^9 = x$, so it is its own inverse, order 2. ■

Worked Example 4.4.3 ($\mathrm{Aut}(S_3)$ has order 6)**.** Compute $|\mathrm{Aut}(S_3)|$.

Recognition. S_3 is generated by transpositions; an automorphism must permute the three transpositions, and order considerations pin down the count.

Solution. S_3 has three transpositions $(1\,2), (1\,3), (2\,3)$ (the order-2 elements) and two 3-cycles (the order-3 elements). An automorphism permutes the transpositions, giving at most $3! = 6$ possibilities. Since $S_3 = \langle (1\,2), (2\,3) \rangle$ and any permutation of the transpositions can be realized by conjugation, all 6 occur. Thus $|\mathrm{Aut}(S_3)| = 6$. Moreover every automorphism is inner (next), so $\mathrm{Aut}(S_3) \cong S_3/Z(S_3) = S_3/1 \cong S_3$. *Check.* $|\mathrm{Aut}(S_3)| = 6$ divides $|S_3|! = 720$, and $6 = |S_3|$ matches $\mathrm{Inn}(S_3) \cong S_3/Z(S_3)$. ■

Inner automorphisms and $\mathrm{Inn}(G) \cong G/Z(G)$

Conjugation gives a canonical supply of automorphisms.

Definition 4.4.4 (Inner automorphism)**.** For $g \in G$ define the *conjugation map*

$$\psi_g \colon G \to G, \qquad \psi_g(x) = gxg^{-1}.$$

Each ψ_g is an automorphism (it is a bijection with inverse $\psi_{g^{-1}}$ and $\psi_g(xy) = gxyg^{-1} = (gxg^{-1})(gyg^{-1}) = \psi_g(x)\psi_g(y)$). The set $\mathrm{Inn}(G) = \{\psi_g \mid g \in G\}$ is the group of *inner automorphisms*.

Theorem 4.4.5 ($\mathrm{Inn}(G) \cong G/Z(G)$)**.** *The map $\psi \colon G \to \mathrm{Aut}(G)$, $g \mapsto \psi_g$, is a homomorphism with image $\mathrm{Inn}(G)$ and kernel $Z(G)$. Hence $\mathrm{Inn}(G) \lhd \mathrm{Aut}(G)$ and*

$$\mathrm{Inn}(G) \cong G/Z(G).$$

Proof. Homomorphism. For $g, h \in G$ and all x, $\psi_{gh}(x) = (gh)x(gh)^{-1} = g(hxh^{-1})g^{-1} = \psi_g(\psi_h(x)) = (\psi_g \circ \psi_h)(x)$, so $\psi_{gh} = \psi_g \circ \psi_h$.

Image. By definition $\operatorname{im}\psi = \mathrm{Inn}(G)$, so $\mathrm{Inn}(G) \leq \mathrm{Aut}(G)$.

Kernel. $g \in \ker\psi$ iff $\psi_g = \mathrm{id}_G$ iff $gxg^{-1} = x$ for all x iff $gx = xg$ for all x iff $g \in Z(G)$. Thus $\ker\psi = Z(G)$.

By the First Isomorphism Theorem $G/Z(G) \cong \operatorname{im}\psi = \mathrm{Inn}(G)$.

Normality of $\mathrm{Inn}(G)$ *in* $\mathrm{Aut}(G)$. For $\sigma \in \mathrm{Aut}(G)$ and $g \in G$, a direct computation gives, for all x,

$$(\sigma \circ \psi_g \circ \sigma^{-1})(x) = \sigma\big(g\,\sigma^{-1}(x)\,g^{-1}\big) = \sigma(g)\,x\,\sigma(g)^{-1} = \psi_{\sigma(g)}(x),$$

so $\sigma\psi_g\sigma^{-1} = \psi_{\sigma(g)} \in \mathrm{Inn}(G)$. Hence $\mathrm{Inn}(G) \lhd \mathrm{Aut}(G)$. □

The map ψ and the exact sequence it produces are displayed below; the image is exactly $\mathrm{Inn}(G)$ and the kernel is $Z(G)$.

$$1 \longrightarrow Z(G) \hookrightarrow G \xrightarrow{\ \psi\ } \mathrm{Aut}(G) \qquad\qquad G/Z(G) \xrightarrow[gZ(G)\mapsto\psi_g]{\sim} \mathrm{Inn}(G)$$

Diagram explanation. Objects: Left diagram: the trivial group 1, the center $Z(G)$ (a normal subgroup of G), the group G itself, and the automorphism group $\mathrm{Aut}(G)$. Right diagram: the quotient group $G/Z(G)$ (cosets of the center) and the subgroup $\mathrm{Inn}(G) \leq \mathrm{Aut}(G)$ of inner automorphisms.

Arrows: Left diagram: $1 \to Z(G)$ is the zero map (inclusion of the trivial group); $Z(G) \hookrightarrow G$ is the inclusion (the hooked arrow signals it is injective); $G \xrightarrow{\psi} \mathrm{Aut}(G)$ sends each g to the conjugation map $\psi_g(x) = gxg^{-1}$. Right diagram: the single arrow sends the coset $gZ(G)$ to the inner automorphism ψ_g; it is the map induced by ψ on the quotient, and it carries the label $\sim$ (isomorphism).

What commutes: The left diagram records a left-exact sequence: the composition $Z(G) \hookrightarrow G \xrightarrow{\psi} \mathrm{Aut}(G)$ is the zero map because every central element z satisfies $\psi_z = \mathrm{id}$ (conjugation by a central element is trivial); thus $\operatorname{im}(Z(G) \hookrightarrow G) \subseteq \ker\psi$, and the proof shows equality: $\ker\psi = Z(G)$. The right diagram is a single arrow with no triangle to commute, but the isomorphism asserts that $\psi_g = \psi_h$ iff $gZ(G) = hZ(G)$, i.e. the coset is exactly the fiber of ψ.

Why it commutes: Chase a central element $z \in Z(G)$ through the left sequence: z maps to itself in G, then $\psi(z) = \psi_z$ where $\psi_z(x) = zxz^{-1} = x$ for all x (since z is central), so $\psi_z = \mathrm{id}$, the identity of $\mathrm{Aut}(G)$. For the right map, well-definedness on cosets: if $g' = gz$ with $z \in Z(G)$, then $\psi_{g'}(x) = g'x(g')^{-1} = gzxz^{-1}g^{-1} = gxg^{-1} = \psi_g(x)$, so different coset representatives give the same inner automorphism.

Why this matters here: These two diagrams encode the full content of the theorem $\mathrm{Inn}(G) \cong G/Z(G)$: the left sequence shows $Z(G)$ is exactly the obstruction to ψ being injective, and the right isomorphism is the First Isomorphism Theorem conclusion, packaging both the surjectivity onto $\mathrm{Inn}(G)$ and the identification of the kernel.

Concrete example: Take $G = D_8$. Then $Z(D_8) = \{1, r^2\}$, so $\ker\psi = \{1, r^2\}$. The coset $rZ(D_8) = \{r, r^3\}$ maps to ψ_r (not the identity, since $\psi_r(s) = r^2 s \neq s$). The quotient $D_8/Z(D_8) \cong V_4$ via the right isomorphism gives $\mathrm{Inn}(D_8) \cong V_4$, with four distinct inner automorphisms.

Common pitfall: Students sometimes read the left sequence as $1 \to Z(G) \to G \to \mathrm{Aut}(G) \to 1$ (a short exact sequence), implying G surjects onto $\mathrm{Aut}(G)$. The diagram deliberately omits a final 1: ψ is almost never surjective (outer automorphisms exist), so the sequence is only left-exact here. The right isomorphism lands in $\mathrm{Inn}(G)$, not $\mathrm{Aut}(G)$.

Takeaway: The point of this diagram is that the kernel of the conjugation map is exactly the center, so $G/Z(G)$ measures precisely how many distinct inner automorphisms G produces.

Remark 4.4.2. The quotient $\mathrm{Aut}(G)/\mathrm{Inn}(G)$ is the *outer automorphism group* $\mathrm{Out}(G)$. When every automorphism is inner (e.g. $G = S_n$ for $n \neq 6$, and the case S_3 above), $\mathrm{Out}(G) = 1$ and $\mathrm{Aut}(G) \cong G/Z(G)$.

Method (Using $\mathrm{Inn}(G) \cong G/Z(G)$)**.** *Trigger.* You want $\mathrm{Inn}(G)$, or you want a lower bound on $\mathrm{Aut}(G)$, or you must show two conjugation maps are equal/distinct.

1. Compute $Z(G)$.
2. Then $\mathrm{Inn}(G) \cong G/Z(G)$ as groups; in particular $|\mathrm{Inn}(G)| = [G : Z(G)]$.
3. $\psi_g = \psi_h$ *iff* $gh^{-1} \in Z(G)$; so inner automorphisms are parametrized by cosets of $Z(G)$.
4. Since $\mathrm{Inn}(G) \lhd \mathrm{Aut}(G)$, $|\mathrm{Inn}(G)|$ divides $|\mathrm{Aut}(G)|$ — a quick consistency check.

Worked Example 4.4.6 ($\mathrm{Inn}(D_8) \cong D_8/Z(D_8) \cong V_4$)**.** With $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$, compute $\mathrm{Inn}(D_8)$.

Recognition. Apply $\mathrm{Inn}(G) \cong G/Z(G)$; first find the center of D_8.

Solution. $Z(D_8) = \{1, r^2\}$: the element r^2 is central since $sr^2 = r^{-2}s = r^2 s$ and it commutes with r; no reflection is central (e.g. $rs \neq sr$), and r, r^3 are not central because $sr = r^3 s \neq rs$. So $|Z(D_8)| = 2$ and $|\mathrm{Inn}(D_8)| = [D_8 : Z(D_8)] = 8/2 = 4$. The quotient $D_8/\langle r^2 \rangle$ has order 4 and is non-cyclic (the images of r and s each square to the identity coset), so $D_8/Z(D_8) \cong V_4$. Hence $\mathrm{Inn}(D_8) \cong V_4$. *Check.* Representatives $1, r, s, rs$ of the four cosets give four distinct conjugation maps; for instance, using $sr^{-1} = rs$ (equivalently $sr = r^{-1}s$),

$$\psi_r(s) = r\, s\, r^{-1} = r\,(sr^{-1}) = r\,(rs) = r^2 s \neq s,$$

so $\psi_r \neq \mathrm{id}$, confirming $r \notin Z(D_8)$. ■

Worked Example 4.4.7 ($\mathrm{Inn}(Q_8) \cong V_4$)**.** For the quaternion group $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, compute $\mathrm{Inn}(Q_8)$.

Recognition. Use $\mathrm{Inn}(G) \cong G/Z(G)$ once $Z(Q_8)$ is known.

Solution. $Z(Q_8) = \{\pm 1\}$ (these commute with everything; i, j, k do not, e.g. $ij = k$ but $ji = -k$). So $|Z(Q_8)| = 2$ and $|\mathrm{Inn}(Q_8)| = 8/2 = 4$. The quotient $Q_8/\{\pm 1\}$ has order 4 with every nonidentity coset of order 2 (e.g. $\overline{i}^2 = \overline{i^2} = \overline{-1} = \overline{1}$), hence $Q_8/Z(Q_8) \cong V_4$. Thus $\mathrm{Inn}(Q_8) \cong V_4$. *Check.* With $i^{-1} = -i$ (since $i^2 = -1$), and using $ij = k$, $ki = j$,

$$\psi_i(j) = i\, j\, i^{-1} = i\, j\, (-i) = k\,(-i) = -(ki) = -j \neq j,$$

confirming $i \notin Z(Q_8)$. ■

Worked Example 4.4.8 (Distinguishing inner automorphisms by cosets)**.** In D_8 decide whether ψ_r and ψ_{r^3} are the same automorphism.

Recognition. Two conjugations coincide iff the elements differ by a central factor: $\psi_g = \psi_h \iff gh^{-1} \in Z(G)$.

Solution. $r(r^3)^{-1} = r \cdot r = r^2 \in Z(D_8)$, so $\psi_r = \psi_{r^3}$. By contrast $r \cdot 1^{-1} = r \notin Z(D_8)$, so $\psi_r \neq \psi_1 = \mathrm{id}$. *Check.* Cosets of $Z(D_8) = \{1, r^2\}$ are $\{1, r^2\}, \{r, r^3\}, \{s, r^2 s\}, \{rs, r^3 s\}$; r and r^3 share a coset, matching $\psi_r = \psi_{r^3}$, and there are 4 cosets, matching $|\mathrm{Inn}(D_8)| = 4$. ■

Worked Example 4.4.9 ($Z(G) = 1 \Rightarrow \mathrm{Inn}(G) \cong G$)**.** Show that if G is centerless then G embeds in $\mathrm{Aut}(G)$.

Recognition. $\ker \psi = Z(G) = 1$ makes ψ injective.

Solution. With $Z(G) = 1$ the homomorphism $\psi\colon G \to \mathrm{Aut}(G)$ has trivial kernel, hence is injective, so $G \cong \mathrm{Inn}(G) \leq \mathrm{Aut}(G)$. For $G = S_3$ this gives $S_3 \cong \mathrm{Inn}(S_3)$, and we saw $|\mathrm{Aut}(S_3)| = 6$, so in fact $\mathrm{Aut}(S_3) = \mathrm{Inn}(S_3) \cong S_3$. *Check.* $\mathrm{Inn}(G) \cong G/Z(G) = G/1 = G$, consistent. ■

Caution. $\mathrm{Inn}(G) \cong G/Z(G)$, *not* G in general. Forgetting the center collapses distinct group elements to the same automorphism: in D_8, r and r^3 give the same conjugation. Also $\mathrm{Inn}(G)$ can be much smaller than $\mathrm{Aut}(G)$ — abelian groups have $\mathrm{Inn}(G) = 1$ but often large $\mathrm{Aut}(G)$.

Characteristic subgroups

A subgroup that is preserved by *every* automorphism, not merely the inner ones.

Definition 4.4.10 (Characteristic subgroup)**.** A subgroup $H \leq G$ is *characteristic in* G, written H char G, if $\sigma(H) = H$ for every $\sigma \in \mathrm{Aut}(G)$.

Proposition 4.4.11 (char $\implies$ normal, and transitivity)**.** *Let $H \leq G$.*

1. *If H char G then $H \trianglelefteq G$.*
2. *If K char H and $H \trianglelefteq G$ then $K \trianglelefteq G$.*
3. *If K char H and H char G then K char G.*

Proof. (1) Normality means stability under inner automorphisms; characteristic means stability under all automorphisms, which include the inner ones. So $\sigma(H) = H$ for every σ, in particular for $\sigma = \psi_g$, giving $gHg^{-1} = H$, i.e. $H \trianglelefteq G$.

(2) Let $g \in G$. Conjugation ψ_g restricts to an automorphism of H because $H \trianglelefteq G$ (so $gHg^{-1} = H$). Since K char H, the automorphism $\psi_g|_H$ fixes K: $gKg^{-1} = \psi_g(K) = K$. As g was arbitrary, $K \trianglelefteq G$.

(3) Let $\sigma \in \mathrm{Aut}(G)$. Since H char G, $\sigma(H) = H$, so $\sigma|_H$ is an automorphism of H. Since K char H, $\sigma|_H(K) = K$, i.e. $\sigma(K) = K$. Hence K char G. □

Caution. "Normal in normal" need *not* be normal: $K \trianglelefteq H \trianglelefteq G$ does *not* imply $K \trianglelefteq G$. The hypothesis "K *characteristic* in H" in part (2) is what saves the argument. Concretely, in D_8 one has $\langle s\rangle \trianglelefteq \langle s, r^2\rangle \trianglelefteq D_8$ but $\langle s\rangle \not\trianglelefteq D_8$.

Method (Proving H char G)**.** *Trigger.* "show H is preserved by every automorphism," or you need "$K \trianglelefteq G$" where $K \trianglelefteq H \trianglelefteq G$.

1. Best route: describe H by a property that automorphisms must preserve (order of elements, being the center, being generated by all commutators, the unique subgroup of a given order, etc.).
2. Then any $\sigma \in \mathrm{Aut}(G)$ sends that distinguished set to itself, so $\sigma(H) = H$.
3. Remember char $\implies$ normal, and char is transitive — use these to upgrade normality.

Worked Example 4.4.12 ($Z(G)$ is characteristic)**.** Prove $Z(G)$ char G.

Recognition. The center is defined by a property ("commutes with everything") that automorphisms preserve.

Solution. Let $\sigma \in \mathrm{Aut}(G)$ and $z \in Z(G)$. For any $x \in G$ write $x = \sigma(y)$ (surjective), then $\sigma(z)x = \sigma(z)\sigma(y) = \sigma(zy) = \sigma(yz) = \sigma(y)\sigma(z) = x\sigma(z)$, so $\sigma(z) \in Z(G)$. Thus $\sigma(Z(G)) \leq Z(G)$; applying the same to σ^{-1} gives the reverse inclusion, so $\sigma(Z(G)) = Z(G)$. Hence $Z(G)$ char G, and in particular $Z(G) \trianglelefteq G$. *Check.* For $G = D_8$, $Z(D_8) = \langle r^2\rangle$ is the unique subgroup of order 2 inside $\langle r\rangle$ central in D_8; any automorphism, preserving "central element of order 2," fixes it. ■

Worked Example 4.4.13 (The commutator subgroup G' is characteristic)**.** Prove $G' = \langle [x, y] \mid x, y \in G\rangle$ char G, where $[x, y] = x^{-1}y^{-1}xy$.

Recognition. G' is generated by all commutators; automorphisms send commutators to commutators.

Solution. For $\sigma \in \mathrm{Aut}(G)$, $\sigma([x, y]) = \sigma(x^{-1}y^{-1}xy) = \sigma(x)^{-1}\sigma(y)^{-1}\sigma(x)\sigma(y) = [\sigma(x), \sigma(y)]$, again a commutator. So σ maps the generating set of G' into G', whence $\sigma(G') \leq G'$; the same for σ^{-1} gives equality. Thus G' char G, and in particular $G' \trianglelefteq G$ — recovering that G/G' is the abelianization. *Check.* For $G = D_8$, $G' = \langle r^2\rangle$; any $\sigma \in \mathrm{Aut}(D_8)$ preserves $\langle r^2\rangle$, consistent with G' char D_8. ■

Worked Example 4.4.14 (Unique subgroup of given order is characteristic)**.** If H is the *unique* subgroup of G of its order, show H char G.

Recognition. Automorphisms preserve order, so $\sigma(H)$ is another subgroup of the same order — but there is only one.

Solution. For $\sigma \in \mathrm{Aut}(G)$, $\sigma(H)$ is a subgroup with $|\sigma(H)| = |H|$ (bijection). By uniqueness $\sigma(H) = H$. Hence H char G. *Check.* In $\mathbb{Z}_{12}$ the unique subgroup of order 3 is characteristic; indeed every automorphism $x \mapsto x^a$ with $\gcd(a, 12) = 1$ fixes the order-3 subgroup $\langle x^4 \rangle$. ■

Worked Example 4.4.15 (A non-characteristic normal subgroup)**.** Exhibit $H \trianglelefteq G$ that is *not* characteristic.

Recognition. Normal means stable under inner automorphisms only; an outer automorphism can move H.

Solution. Take $G = V_4 = \{1, a, b, c\}$. Every subgroup of the abelian group V_4 is normal, so $\langle a \rangle \trianglelefteq V_4$. But V_4 has automorphisms permuting a, b, c arbitrarily (next subsection, $\mathrm{Aut}(V_4) \cong S_3$); the automorphism swapping $a \leftrightarrow b$ sends $\langle a \rangle$ to $\langle b \rangle \neq \langle a \rangle$. So $\langle a \rangle$ is normal but not characteristic. *Check.* A characteristic subgroup must be *fixed* by all 6 automorphisms; only 1 and V_4 qualify here, so the three order-2 subgroups are normal but not characteristic. ■

$\mathrm{Aut}(\mathbb{Z}_n) \cong (\mathbb{Z}/n\mathbb{Z})^\times$

Theorem 4.4.16. *For each $n \geq 1$, $\mathrm{Aut}(\mathbb{Z}_n) \cong (\mathbb{Z}/n\mathbb{Z})^\times$, the multiplicative group of units modulo n. In particular $|\mathrm{Aut}(\mathbb{Z}_n)| = \varphi(n)$, and $\mathrm{Aut}(\mathbb{Z}_n)$ is abelian.*

Proof. Write $\mathbb{Z}_n = \langle x \rangle$ additively, x of order n. As computed above, each $\sigma \in \mathrm{Aut}(\mathbb{Z}_n)$ has the form $\sigma = \sigma_a \colon x \mapsto ax$ for a unique $a \in (\mathbb{Z}/n\mathbb{Z})^\times$ (i.e. $\gcd(a, n) = 1$), and conversely each such a gives an automorphism. Define

$$\Phi \colon \mathrm{Aut}(\mathbb{Z}_n) \to (\mathbb{Z}/n\mathbb{Z})^\times, \qquad \Phi(\sigma_a) = a.$$

It is a bijection by the above. It is a homomorphism: $(\sigma_a \circ \sigma_b)(x) = \sigma_a(bx) = a(bx) = (ab)x = \sigma_{ab}(x)$, so $\sigma_a \circ \sigma_b = \sigma_{ab}$ and $\Phi(\sigma_a \sigma_b) = ab = \Phi(\sigma_a)\Phi(\sigma_b)$. Hence Φ is an isomorphism. □

$$\mathrm{Aut}(\mathbb{Z}_n) \xrightarrow[\sigma_a \mapsto a]{\sim} (\mathbb{Z}/n\mathbb{Z})^\times$$

Diagram explanation. Objects: The automorphism group $\mathrm{Aut}(\mathbb{Z}_n)$ (the group of all group-isomorphisms $\mathbb{Z}_n \to \mathbb{Z}_n$ under composition) and the multiplicative group of units $(\mathbb{Z}/n\mathbb{Z})^\times = (\mathbb{Z}/n\mathbb{Z})^\times$ (residues $a \in \{0, \ldots, n-1\}$ with $\gcd(a, n) = 1$, under multiplication mod n).

Arrows: A single arrow, labelled $\sim$ (isomorphism) and $\sigma_a \mapsto a$; it sends the automorphism $\sigma_a \colon x \mapsto ax$ to the unit $a \in (\mathbb{Z}/n\mathbb{Z})^\times$. It is the map Φ defined in the proof, converting a function on $\mathbb{Z}_n$ into an integer mod n.

What commutes: There is only one arrow (no path to compare), but the isomorphism encodes a bijective correspondence: $\Phi(\sigma_a \circ \sigma_b) = \Phi(\sigma_{ab}) = ab = \Phi(\sigma_a) \cdot \Phi(\sigma_b)$, so Φ is a group homomorphism. The composition law in $\mathrm{Aut}(\mathbb{Z}_n)$ (function composition) corresponds exactly to multiplication in $(\mathbb{Z}/n\mathbb{Z})^\times$.

Why it commutes: Chase a product: $(\sigma_a \circ \sigma_b)(x) = \sigma_a(bx) = a(bx) = (ab)x = \sigma_{ab}(x)$, so $\sigma_a \circ \sigma_b = \sigma_{ab}$. Applying Φ gives $\Phi(\sigma_a \sigma_b) = ab = \Phi(\sigma_a)\Phi(\sigma_b)$. Well-definedness of Φ is immediate: each automorphism determines a unique a (the image of the generator x).

Why this matters here: The diagram summarizes the theorem $\mathrm{Aut}(\mathbb{Z}_n) \cong (\mathbb{Z}/n\mathbb{Z})^\times$ in one line. It converts an abstract function group into a concrete number-theoretic object, making the order $|\mathrm{Aut}(\mathbb{Z}_n)| = \varphi(n)$ and the abelian structure ($(\mathbb{Z}/n\mathbb{Z})^\times$ is abelian) immediately visible. Every subsequent computation of $\mathrm{Aut}(\mathbb{Z}_n)$ reduces to factoring n and reading off $(\mathbb{Z}/n\mathbb{Z})^\times$ via CRT.

Concrete example: $n = 5$: $(\mathbb{Z}/5\mathbb{Z})^\times = \{1, 2, 3, 4\}$ is cyclic of order 4 (generator 2, since $2, 4, 8 \equiv 3, 16 \equiv 1$). Correspondingly, $\sigma_2 \colon x \mapsto 2x$ has order 4 in $\mathrm{Aut}(\mathbb{Z}_5)$, and the four automorphisms $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ correspond to $1, 2, 3, 4 \in (\mathbb{Z}/5\mathbb{Z})^\times$.

Common pitfall: The map $\sigma_a \mapsto a$ is an isomorphism of groups, but students sometimes confuse the group operations: $\mathrm{Aut}(\mathbb{Z}_n)$ uses *composition* and $(\mathbb{Z}/n\mathbb{Z})^\times$ uses *multiplication*. The diagram records that these match; do not add or compose residues additively on the right side. Also, for $n \geq 2$, $a = 0$ is never a unit, so the trivial homomorphism $x \mapsto 0$ is not an automorphism and does not appear.

Takeaway: The point of this diagram is that every automorphism of the cyclic group $\mathbb{Z}_n$ is exactly "multiply by a unit," giving a canonical isomorphism with the multiplicative group $(\mathbb{Z}/n\mathbb{Z})^\times$.

Method (Computing $\mathrm{Aut}(\mathbb{Z}_n)$)**.** *Trigger.* Cyclic group; "find/describe its automorphism group."

1. $\mathrm{Aut}(\mathbb{Z}_n) \cong (\mathbb{Z}/n\mathbb{Z})^\times$, an abelian group of order $\varphi(n)$.
2. To get its *structure*, use the CRT factorization $(\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_p (\mathbb{Z}/p^k\mathbb{Z})^\times$ over prime powers $p^k \,\|\, n$, with $(\mathbb{Z}/p^k\mathbb{Z})^\times$ cyclic of order $p^{k-1}(p-1)$ for odd p, and $(\mathbb{Z}/2\mathbb{Z})^\times \cong 1$, $(\mathbb{Z}/4\mathbb{Z})^\times \cong \mathbb{Z}_2$, $(\mathbb{Z}/2^k\mathbb{Z})^\times \cong \mathbb{Z}_2 \times \mathbb{Z}_{2^{k-2}}$ $(k \geq 3)$.

Worked Example 4.4.17 ($\mathrm{Aut}(\mathbb{Z}_{15}) \cong \mathbb{Z}_2 \times \mathbb{Z}_4$)**.** Identify $\mathrm{Aut}(\mathbb{Z}_{15})$ concretely.

Recognition. Cyclic group: $\mathrm{Aut}(\mathbb{Z}_{15}) \cong (\mathbb{Z}/15\mathbb{Z})^\times$; factor with CRT.

Solution. $|\mathrm{Aut}(\mathbb{Z}_{15})| = \varphi(15) = \varphi(3)\varphi(5) = 2 \cdot 4 = 8$. By CRT $(\mathbb{Z}/15\mathbb{Z})^\times \cong (\mathbb{Z}/3\mathbb{Z})^\times \times (\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}_2 \times \mathbb{Z}_4$. The units mod 15 are $\{1, 2, 4, 7, 8, 11, 13, 14\}$ (the 8 residues coprime to 15). *Check.* $|2|$ in $(\mathbb{Z}/15\mathbb{Z})^\times$: $2, 4, 8, 16 \equiv 1$, so $|2| = 4$; and $|14|$: $14 \equiv -1$, $14^2 \equiv 1$, so $|14| = 2$. With an order-4 and an order-2 element and no element of order 8 (every unit squares to 1 or 4, and $4^2 \equiv 1$, so $u^4 \equiv 1$ for all units u), the group is $\mathbb{Z}_2 \times \mathbb{Z}_4$, not $\mathbb{Z}_8$. ■

Worked Example 4.4.18 ($\mathrm{Aut}(\mathbb{Z}_{12}) \cong V_4$)**.** Find $\mathrm{Aut}(\mathbb{Z}_{12})$.

Recognition. $\mathrm{Aut}(\mathbb{Z}_{12}) \cong (\mathbb{Z}/12\mathbb{Z})^\times$; compute orders of units.

Solution. $\varphi(12) = 4$, units $\{1, 5, 7, 11\}$. Each nonidentity unit squares to 1: $5^2 = 25 \equiv 1$, $7^2 = 49 \equiv 1$, $11^2 = 121 \equiv 1 \pmod{12}$. A group of order 4 with every nonidentity element of order 2 is V_4. So $\mathrm{Aut}(\mathbb{Z}_{12}) \cong V_4$. *Check.* $(\mathbb{Z}/12\mathbb{Z})^\times \cong (\mathbb{Z}/4\mathbb{Z})^\times \times (\mathbb{Z}/3\mathbb{Z})^\times \cong \mathbb{Z}_2 \times \mathbb{Z}_2 = V_4$. ■

Worked Example 4.4.19 ($\mathrm{Aut}(\mathbb{Z}_9)$ is cyclic of order 6)**.** Show $\mathrm{Aut}(\mathbb{Z}_9) \cong \mathbb{Z}_6$.

Recognition. Odd prime power: $(\mathbb{Z}/p^k\mathbb{Z})^\times$ is cyclic of order $p^{k-1}(p-1)$.

Solution. $|\mathrm{Aut}(\mathbb{Z}_9)| = \varphi(9) = 9 - 3 = 6$. For odd prime powers $(\mathbb{Z}/p^k\mathbb{Z})^\times$ is cyclic, so $\mathrm{Aut}(\mathbb{Z}_9) \cong \mathbb{Z}_6$. A generator: 2 is a primitive root mod 9 since $2, 4, 8, 16 \equiv 7, 32 \equiv 5, 64 \equiv 1$ cycles through $2, 4, 8, 7, 5, 1$ — six distinct units — so $|2| = 6$. *Check.* The six powers of 2 are exactly the six units $\{1, 2, 4, 5, 7, 8\}$ coprime to 9. ■

Worked Example 4.4.20 ($\mathrm{Aut}(\mathbb{Z}_8) \cong V_4$, a non-cyclic prime-power case)**.** Compute $\mathrm{Aut}(\mathbb{Z}_8)$.

Recognition. 2-power modulus ≥ 8: $(\mathbb{Z}/2^k\mathbb{Z})^\times$ is *not* cyclic.

Solution. $\varphi(8) = 4$, units $\{1, 3, 5, 7\}$. Squares: $3^2 = 9 \equiv 1$, $5^2 = 25 \equiv 1$, $7^2 = 49 \equiv 1 \pmod 8$. All nonidentity units have order 2, so $(\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$, hence $\mathrm{Aut}(\mathbb{Z}_8) \cong V_4$. *Check.* Matches the formula $(\mathbb{Z}/2^3\mathbb{Z})^\times \cong \mathbb{Z}_2 \times \mathbb{Z}_{2^{3-2}} = \mathbb{Z}_2 \times \mathbb{Z}_2$. This is the smallest n for which $\mathrm{Aut}(\mathbb{Z}_n)$ is noncyclic. ■

$\mathrm{Aut}(V_4) \cong S_3$

Theorem 4.4.21. $\mathrm{Aut}(V_4) \cong S_3$*; equivalently* $|\mathrm{Aut}(V_4)| = 6$.

Proof. Write $V_4 = \{1, a, b, c\}$ with $a^2 = b^2 = c^2 = 1$ and $ab = c$, $bc = a$, $ca = b$ (so $c = ab$). The three nonidentity elements a, b, c all have order 2, and any two of them generate V_4 with the third as their product. An automorphism σ fixes 1 and permutes $\{a, b, c\}$ (it preserves order 2), so σ is determined by its action on $\{a, b, c\}$, giving a homomorphism

$$\Theta\colon \mathrm{Aut}(V_4) \to \mathrm{Sym}(\{a, b, c\}) \cong S_3, \qquad \sigma \mapsto \sigma|_{\{a,b,c\}}.$$

Θ is injective: σ is determined on the generators a, b (hence on $c = ab$). Θ is surjective: any permutation π of $\{a, b, c\}$ defines a bijection of V_4 (fix 1), and it respects the multiplication because the product of any two distinct nonidentity elements is the third, a relation symmetric in a, b, c — so π is an automorphism. Therefore Θ is an isomorphism and $\mathrm{Aut}(V_4) \cong S_3$. □

$$\mathrm{Aut}(V_4) \xrightarrow[\sim]{\Theta} \mathrm{Sym}(\{a, b, c\}) \xrightarrow{\sim} S_3$$

Diagram explanation. Objects: Three groups in a chain. $\mathrm{Aut}(V_4)$ is the automorphism group of the Klein four-group $V_4 = \{1, a, b, c\}$. $\mathrm{Sym}(\{a, b, c\})$ is the symmetric group on the three-element set of nonidentity elements of V_4. S_3 is the symmetric group on three letters; the two rightmost objects are equal as abstract groups (the second arrow is just the canonical identification between these two presentations of the same group).

Arrows: The left arrow Θ sends an automorphism $\sigma \in \mathrm{Aut}(V_4)$ to its restriction $\sigma|_{\{a,b,c\}}$, a permutation of the three nonidentity elements. It is the map defined in the proof. Both arrows are labelled $\sim$ (isomorphisms). The right arrow is the identity/relabelling map $\mathrm{Sym}(\{a, b, c\}) \xrightarrow{\sim} S_3$ (writing $a = 1, b = 2, c = 3$).

What commutes: This is a composition of two isomorphisms, so the composite $\mathrm{Aut}(V_4) \to S_3$ is also an isomorphism. The formal equality is $(\text{right}) \circ \Theta = \mathrm{Aut}(V_4) \xrightarrow{\sim} S_3$; concretely, tracing a specific automorphism through both arrows lands on the same permutation whichever way one reads the chain.

Why it commutes: Θ is well-defined because every $\sigma \in \mathrm{Aut}(V_4)$ permutes the set of order-2 elements $\{a, b, c\}$ (automorphisms preserve element order, and all three have order 2). Injectivity: σ is determined by its images on a, b (the generators), hence by $\sigma|_{\{a,b,c\}}$. Surjectivity: any permutation π of $\{a, b, c\}$ extends to an automorphism of V_4 (fix 1, use the fact that the product of any two distinct nonidentity elements is the third — a relation symmetric in a, b, c), so no coset relations are violated.

Why this matters here: The diagram delivers the punchline $\mathrm{Aut}(V_4) \cong S_3$ visibly: the structure of the automorphism group is read off from the symmetry of the nonidentity part of V_4. It also sets up the GL-viewpoint in the remark: permutations of the three nonzero vectors of $\mathbb{F}_2^2$ are the same data as $\mathrm{GL}_2(\mathbb{F}_2)$.

Concrete example: The cyclic permutation $a \mapsto b \mapsto c \mapsto a$ in $\mathrm{Sym}(\{a, b, c\})$ corresponds to the automorphism σ of V_4 with $\sigma(a) = b,\ \sigma(b) = c,\ \sigma(c) = a$; one checks $\sigma(ab) = \sigma(c) = a = bc = \sigma(b)\sigma(a)$ (using $ab = c,\ bc = a$ in V_4). This automorphism has order 3 in $\mathrm{Aut}(V_4)$, matching the 3-cycle in S_3.

Common pitfall: Students sometimes assume Θ needs a separate well-definedness check for cosets or quotients. There are no quotients here: Θ is a restriction of a function, not an induced map on a quotient. The only thing to verify is that restriction to $\{a, b, c\}$ stays within $\mathrm{Sym}(\{a, b, c\})$, which follows from order-preservation.

Takeaway: The point of this diagram is that automorphisms of V_4 are exactly permutations of its three nonidentity elements, making $\mathrm{Aut}(V_4)$ isomorphic to S_3 with no extra structure to check.

Remark 4.4.3. $V_4 \cong \mathbb{Z}_2 \times \mathbb{Z}_2$ is a 2-dimensional vector space over $\mathbb{F}_2$, and automorphisms of it as a group coincide with $\mathbb{F}_2$-linear automorphisms, so $\mathrm{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_2) \cong \mathrm{GL}_2(\mathbb{F}_2)$. Counting ordered bases: the first basis vector is any of the 3 nonzero vectors, the second any of the 2 remaining nonzero non-multiples (over $\mathbb{F}_2$ "non-multiple" just means "different and nonzero"), giving $3 \cdot 2 = 6$. Thus $|\mathrm{GL}_2(\mathbb{F}_2)| = 6$ and $\mathrm{GL}_2(\mathbb{F}_2) \cong S_3$, matching the theorem.

Method (Automorphisms of an elementary abelian group)**.** *Trigger.* $G \cong (\mathbb{Z}_p)^k$ (elementary abelian p-group).

1. View G as a vector space $\mathbb{F}_p^k$; group automorphisms = linear automorphisms.
2. So $\mathrm{Aut}\big((\mathbb{Z}_p)^k\big) \cong \mathrm{GL}_k(\mathbb{F}_p)$, of order $(p^k - 1)(p^k - p) \cdots (p^k - p^{k-1})$ (count ordered bases).
3. For $k = 2, p = 2$ this gives 6, i.e. S_3.

Worked Example 4.4.22 ($\mathrm{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_2)$ from $\mathrm{GL}_2(\mathbb{F}_2)$)**.** Recompute $|\mathrm{Aut}(V_4)|$ via $\mathrm{GL}_2(\mathbb{F}_2)$ and exhibit a generating automorphism of order 3.

Recognition. Elementary abelian: $\mathrm{Aut} \cong \mathrm{GL}_2(\mathbb{F}_2)$, count ordered bases.

Solution. $|\mathrm{GL}_2(\mathbb{F}_2)| = (2^2 - 1)(2^2 - 2) = 3 \cdot 2 = 6$. The cyclic permutation $a \mapsto b \mapsto c \mapsto a$ is an automorphism of order 3 (it is the linear map $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ on basis a, b with $c = a + b$); a transposition $a \leftrightarrow b$ (fixing c) has order 2. Together they generate a group isomorphic to S_3. *Check.* $6 = |S_3|$, an order-3 and an order-2 element generating non-abelianly (the transposition conjugates the 3-cycle to its inverse) $\implies S_3$, not $\mathbb{Z}_6$. ■

Worked Example 4.4.23 ($\mathrm{Aut}(\mathbb{Z}_3 \times \mathbb{Z}_3) \cong \mathrm{GL}_2(\mathbb{F}_3)$)**.** Compute $|\mathrm{Aut}(\mathbb{Z}_3 \times \mathbb{Z}_3)|$.

Recognition. Elementary abelian $p = 3, k = 2$: order of $\mathrm{GL}_2(\mathbb{F}_3)$.

Solution. $|\mathrm{Aut}(\mathbb{Z}_3 \times \mathbb{Z}_3)| = |\mathrm{GL}_2(\mathbb{F}_3)| = (3^2 - 1)(3^2 - 3) = 8 \cdot 6 = 48$. *Check.* $48 = |\mathrm{GL}_2(\mathbb{F}_3)|$ also factors as $2 \cdot |\mathrm{SL}_2(\mathbb{F}_3)| = 2 \cdot 24$; and it equals $(p^2 - 1)(p^2 - p)$ with $p = 3$. ■

Automorphism groups of a few small groups

Worked Example 4.4.24 ($\mathrm{Aut}(Q_8) \cong S_4$)**.** State and verify the order of $\mathrm{Aut}(Q_8)$.

Recognition. An automorphism permutes the elements $\{\pm i, \pm j, \pm k\}$ subject to the quaternion relations; counting valid images bounds $|\mathrm{Aut}(Q_8)|$.

Solution. An automorphism σ fixes ± 1 (the only elements of order $1, 2$) and permutes the six order-4 elements $\pm i, \pm j, \pm k$. It is determined by $(\sigma(i), \sigma(j))$: $\sigma(i)$ can be any of the 6 order-4 elements, and $\sigma(j)$ any order-4 element not in $\{\pm\sigma(i)\}$, i.e. 4 choices; then $\sigma(k) = \sigma(i)\sigma(j)$ is forced. This gives $6 \cdot 4 = 24$ candidates, and each respects the relations ($i^2 = j^2 = -1,\ ij = k$), so $|\mathrm{Aut}(Q_8)| = 24$. The group is $\mathrm{Aut}(Q_8) \cong S_4$. *Check.* $\mathrm{Inn}(Q_8) \cong Q_8/Z(Q_8) \cong V_4$ has order 4, and $4 \mid 24$; indeed $\mathrm{Out}(Q_8) \cong S_4/V_4 \cong S_3$, of order 6. ■

Worked Example 4.4.25 ($\mathrm{Aut}(\mathbb{Z}_2) = 1$ and $\mathrm{Aut}(\mathbb{Z}) = \mathbb{Z}_2$)**.** Contrast the automorphism groups of $\mathbb{Z}_2$ and of $\mathbb{Z}$.

Recognition. Count generators / order-preserving images of a generator.

Solution. $\mathbb{Z}_2 = \{0, 1\}$ has only the identity automorphism (the nonidentity element must go to a nonidentity element of the same order, but there is only one), so $\mathrm{Aut}(\mathbb{Z}_2) = 1$. For the infinite cyclic $\mathbb{Z} = \langle 1 \rangle$, an automorphism sends the generator 1 to a generator, and the only generators are ± 1; thus $\mathrm{Aut}(\mathbb{Z}) = \{\pm \mathrm{id}\} \cong \mathbb{Z}_2$. *Check.* $\mathrm{Aut}(\mathbb{Z}_2) \cong (\mathbb{Z}/2\mathbb{Z})^\times = 1$ and $\mathrm{Aut}(\mathbb{Z}) \cong \{\pm 1\} \cong \mathbb{Z}_2$. ■

Worked Example 4.4.26 ($\mathrm{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_4)$ has order 8)**.** Compute $|\mathrm{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_4)|$ (a non-elementary, non-cyclic abelian group).

Recognition. Track where a generator of order 4 and an order-2 element can go; count consistent images.

Solution. Write $G = \langle x \rangle \times \langle y \rangle$ with $|x| = 2,\ |y| = 4$. An automorphism is determined by $(\sigma(y), \sigma(x))$. $\sigma(y)$ must have order 4: the order-4 elements of G are $(0,1), (0,3), (1,1), (1,3)$, i.e. 4 choices. $\sigma(x)$ must have order 2 and, together with $\sigma(y)$, generate G; the order-2 elements are $(1,0), (0,2), (1,2)$, and we must avoid the unique square $2\sigma(y)$ of $\sigma(y)$ to keep a generating pair, leaving 2 valid choices. Total $4 \cdot 2 = 8$, so $|\mathrm{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_4)| = 8$. *Check.* This 8 is consistent with the known structure $\mathrm{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_4) \cong D_8$; in particular $8 \mid |G|! = 8!$ and exceeds $|\mathrm{Inn}| = 1$ (the group is abelian), as it must. ■

Caution. $\mathrm{Aut}(G_1 \times G_2) \neq \mathrm{Aut}(G_1) \times \mathrm{Aut}(G_2)$ in general. The factorization $\mathrm{Aut}(A \times B) \cong \mathrm{Aut}(A) \times \mathrm{Aut}(B)$ holds when $|A|$ and $|B|$ are coprime (no "cross" homomorphisms); for non-coprime orders it may fail, though not always (e.g. $\mathrm{Aut}(S_3 \times \mathbb{Z}_3) \cong \mathrm{Aut}(S_3) \times \mathrm{Aut}(\mathbb{Z}_3)$). For $\mathbb{Z}_2 \times \mathbb{Z}_4$ (both even) it fails: $|\mathrm{Aut}| = 8$, not $|\mathrm{Aut}(\mathbb{Z}_2)| \cdot |\mathrm{Aut}(\mathbb{Z}_4)| = 1 \cdot 2 = 2$.

Corollary 4.4.27 (Abelian groups have only outer automorphisms)**.** *If G is abelian then* $\mathrm{Inn}(G) = 1$ *(every conjugation is trivial), so* $\mathrm{Aut}(G) = \mathrm{Out}(G)$*. Thus all nontrivial automorphisms of an abelian group are outer.*

Proof. $Z(G) = G$ when G is abelian, so $\mathrm{Inn}(G) \cong G/Z(G) = G/G = 1$. Hence $\mathrm{Out}(G) = \mathrm{Aut}(G)/\mathrm{Inn}(G) = \mathrm{Aut}(G)$. □

Exercises (from the text).

1. Let G be a group. If $\sigma \in \mathrm{Aut}(G)$ and φ_g is conjugation by g prove $\sigma\varphi_g\sigma^{-1} = \varphi_{\sigma(g)}$. Deduce that $\mathrm{Inn}(G) \trianglelefteq \mathrm{Aut}(G)$. (The group $\mathrm{Aut}(G)/\mathrm{Inn}(G)$ is called the *outer automorphism group* of G.)
2. Prove that if G is an abelian group of order pq, where p and q are distinct primes, then G is cyclic. [Use Cauchy's Theorem to produce elements of order p and q and consider the order of their product.]
3. Prove that under any automorphism of D_8, r has at most 2 possible images and s has at most 4 possible images (r and s are the usual generators — cf. Section 1.2). Deduce that $|\mathrm{Aut}(D_8)| \leq 8$.
4. Use arguments similar to those in the preceding exercise to show $|\mathrm{Aut}(Q_8)| \leq 24$.
5. Use the fact that $D_8 \trianglelefteq D_{16}$ to prove that $\mathrm{Aut}(D_8) \cong D_8$.
6. Prove that characteristic subgroups are normal. Give an example of a normal subgroup that is not characteristic.

7. If H is the unique subgroup of a given order in a group G prove H is characteristic in G.

8. Let G be a group with subgroups H and K with $H \leq K$.

   (a) Prove that if H is characteristic in K and K is normal in G then H is normal in G.

   (b) Prove that if H is characteristic in K and K is characteristic in G then H is characteristic in G. Use this to prove that the Klein 4-group V_4 contained in A_4 is characteristic in S_4.

   (c) Give an example to show that if H is normal in K and K is characteristic in G then H need not be normal in G.

9. If r, s are the usual generators for the dihedral group D_{2n}, use the preceding two exercises to deduce that every subgroup of $\langle r \rangle$ is normal in D_{2n}.

10. Let G be a group, let A be an abelian normal subgroup of G, and write $\bar{G} = G/A$. Show that $\bar{G}$ acts (on the left) by conjugation on A by $\bar{g} \cdot a = gag^{-1}$, where g is any representative of the coset $\bar{g}$ (in particular, show that this action is well defined). Give an explicit example to show that this action is not well defined if A is non-abelian.

11. If p is a prime and P is a subgroup of S_p of order p, prove $N_{S_p}(P)/C_{S_p}(P) \cong \mathrm{Aut}(P)$. [Use Exercise 34, Section 3.]

12. Let G be a group of order 3825. Prove that if H is a normal subgroup of order 17 in G then $H \leq Z(G)$.

13. Let G be a group of order 203. Prove that if H is a normal subgroup of order 7 in G then $H \leq Z(G)$. Deduce that G is abelian in this case.

14. Let G be a group of order 1575. Prove that if H is a normal subgroup of order 9 in G then $H \leq Z(G)$.

15. Prove that each of the following (multiplicative) groups is cyclic: $(\mathbb{Z}/5\mathbb{Z})^\times$, $(\mathbb{Z}/9\mathbb{Z})^\times$ and $(\mathbb{Z}/18\mathbb{Z})^\times$.

16. Prove that $(\mathbb{Z}/24\mathbb{Z})^\times$ is an elementary abelian group of order 8. (We shall see later that $(\mathbb{Z}/n\mathbb{Z})^\times$ is an elementary abelian group if and only if $n \mid 24$.)

17. Let $G = \langle x \rangle$ be a cyclic group of order n. For $n = 2, 3, 4, 5, 6$ write out the elements of $\mathrm{Aut}(G)$ explicitly (by Proposition 16 above we know $\mathrm{Aut}(G) \cong (\mathbb{Z}/n\mathbb{Z})^\times$, so for each element $a \in (\mathbb{Z}/n\mathbb{Z})^\times$, write out explicitly what the automorphism ψ_a does to the elements $\{1, x, x^2, \ldots, x^{n-1}\}$ of G).

18. This exercise shows that for $n \neq 6$ every automorphism of S_n is inner. Fix an integer $n \geq 2$ with $n \neq 6$.

   (a) Prove that the automorphism group of a group G permutes the conjugacy classes of G, i.e., for each $\sigma \in \mathrm{Aut}(G)$ and each conjugacy class $\mathcal{K}$ of G the set $\sigma(\mathcal{K})$ is also a conjugacy class of G.

   (b) Let $\mathcal{K}$ be the conjugacy class of transpositions in S_n and let $\mathcal{K}'$ be the conjugacy class of any element of order 2 in S_n that is not a transposition. Prove that $|\mathcal{K}| \neq |\mathcal{K}'|$. Deduce that any automorphism of S_n sends transpositions to transpositions. [See Exercise 33 in Section 3.]

   (c) Prove that for each $\sigma \in \mathrm{Aut}(S_n)$

   $$\sigma : (1\ 2) \mapsto (a\ b_2), \quad \sigma : (1\ 3) \mapsto (a\ b_3), \quad \ldots, \quad \sigma : (1\ n) \mapsto (a\ b_n)$$

   for some distinct integers $a, b_2, b_3, \ldots, b_n \in \{1, 2, \ldots, n\}$.

   (d) Show that (1 2), (1 3), ..., (1 n) generate S_n and deduce that any automorphism of S_n is uniquely determined by its action on these elements. Use (c) to show that S_n has at most $n!$ automorphisms and conclude that $\mathrm{Aut}(S_n) = \mathrm{Inn}(S_n)$ for $n \neq 6$.

19. This exercise shows that $|\mathrm{Aut}(S_6) : \mathrm{Inn}(S_6)| \leq 2$ (Exercise 10 in Section 6.3 shows that equality holds by exhibiting an automorphism of S_6 that is not inner).

   (a) Let $\mathcal{K}$ be the conjugacy class of transpositions in S_6 and let $\mathcal{K}'$ be the conjugacy class of any element of order 2 in S_6 that is not a transposition. Prove that $|\mathcal{K}| \neq |\mathcal{K}'|$ unless $\mathcal{K}'$ is the conjugacy class of products of three disjoint transpositions. Deduce that $\mathrm{Aut}(S_6)$ has a subgroup of index at most 2 which sends transpositions to transpositions.

(b) Prove that $|\operatorname{Aut}(S_6) : \operatorname{Inn}(S_6)| \leq 2$. [Follow the same steps as in (c) and (d) of the preceding exercise to show that any automorphism that sends transpositions to transpositions is inner.]

20. The next exercise introduces a subgroup, $J(P)$, which (like the center of P) is defined for an arbitrary finite group P (although in most applications P is a group whose order is a power of a prime). This subgroup was defined by J. Thompson in 1964 and it now plays a pivotal role in the study of finite groups, in particular, in the classification of finite simple groups. For any finite group P let $d(P)$ be the minimum number of generators of P (so, for example, $d(P) = 1$ if and only if P is a nontrivial cyclic group and $d(Q_8) = 2$). Let $m(P)$ be the maximum of the integers $d(A)$ as A runs over all abelian subgroups of P (so, for example, $m(Q_8) = 1$ and $m(D_8) = 2$). Define

$$J(P) = \langle A : A \text{ is an abelian subgroup of } P \text{ with } d(A) = m(P) \rangle.$$

($J(P)$ is called the *Thompson subgroup* of P.)

(a) Prove that $J(P)$ is a characteristic subgroup of P.

(b) For each of the following groups P list all abelian subgroups A of P that satisfy $d(A) = m(P)$: Q_8, D_8, D_{16} and QD_{16} (where QD_{16} is the quasidihedral group of order 16 defined in Exercise 11 of Section 2.5). [Use the lattices of subgroups for these groups in Section 2.5.]

(c) Show that $J(Q_8) = Q_8$, $J(D_8) = D_8$, $J(D_{16}) = D_{16}$ and $J(QD_{16})$ is a dihedral subgroup of order 8 in QD_{16}.

(d) Prove that if $Q \leq P$ and $J(P)$ is a subgroup of Q, then $J(P) = J(Q)$. Deduce that if P is a subgroup (not necessarily normal) of the finite group G and $J(P)$ is contained in some subgroup Q of P such that $Q \trianglelefteq G$, then $J(P) \trianglelefteq G$.

Practice problems.

1. Let $G = \mathbb{Z}_{24}$ (additive). Show $\operatorname{Aut}(G) \cong (\mathbb{Z}/24\mathbb{Z})^\times$, list its elements, and determine $|\operatorname{Aut}(G)|$ and its isomorphism type as a product of cyclic groups.
2. For each $n \in \{5, 8, 10, 12, 15\}$ compute $|\operatorname{Aut}(\mathbb{Z}/n\mathbb{Z})|$ and decide whether $\operatorname{Aut}(\mathbb{Z}/n\mathbb{Z})$ is cyclic.
3. Let $V = \mathbb{Z}_2 \times \mathbb{Z}_2$ be the Klein four-group. Prove $\operatorname{Aut}(V) \cong S_3$ by exhibiting the action of each automorphism as a permutation of the three nonidentity elements.
4. Let $\varphi \in \operatorname{Aut}(G)$ and let $x \in G$. Prove $|\varphi(x)| = |x|$. Use this to show no automorphism of $\mathbb{Z}_8$ sends a generator to an element of order 4.
5. Compute $\operatorname{Aut}(\mathbb{Z}_2 \times \mathbb{Z}_4)$. Determine its order and exhibit an automorphism of order 2 that is not inner (recall $\mathbb{Z}_2 \times \mathbb{Z}_4$ is abelian, so $\operatorname{Inn} = 1$).
6. Let G be a group with $\operatorname{Inn}(G) \cong G/Z(G)$. For $G = D_8$ (order 8) compute $Z(G)$, $\operatorname{Inn}(G)$, and then $\operatorname{Aut}(D_8)$, identifying its order.
7. Let p be prime. Show every nonidentity element of $\mathbb{Z}/p\mathbb{Z}$ is a generator and deduce $\operatorname{Aut}(\mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/(p-1)\mathbb{Z}$.
8. Prove that if H char G (characteristic: $\varphi(H) = H$ for all $\varphi \in \operatorname{Aut}(G)$) and K char H, then K char G.
9. Show that $Z(G)$ and the commutator subgroup $[G, G]$ are characteristic in G.
10. Let $\sigma \in \operatorname{Aut}(\mathbb{Z}_p \times \mathbb{Z}_p)$ for p prime. Identify $\operatorname{Aut}(\mathbb{Z}_p \times \mathbb{Z}_p)$ with $\mathrm{GL}_2(\mathbb{Z}/p\mathbb{Z})$ and compute its order for $p = 3$.
11. In $G = Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, show $Z(G) = \{\pm 1\}$ and prove $\operatorname{Inn}(Q_8) \cong V$ (Klein four). State $|\operatorname{Inn}(Q_8)|$.
12. Let G be cyclic of order n with generator x. Prove the map $\sigma_a : x \mapsto x^a$ is an automorphism iff $\gcd(a, n) = 1$, and that $\sigma_a \sigma_b = \sigma_{ab}$. Conclude $\operatorname{Aut}(G) \cong (\mathbb{Z}/n\mathbb{Z})^\times$.
13. Let $H \trianglelefteq G$. Show conjugation gives a homomorphism $G \to \operatorname{Aut}(H)$, and that its kernel is $C_G(H)$. Apply this with $G = S_3$ and $H = \langle (1\,2\,3) \rangle$ to compute the image in $\operatorname{Aut}(H)$.

14. Show that for $n \geq 3$, $n \neq 6$, every automorphism of S_n is inner, so $\mathrm{Aut}(S_n) \cong S_n$. (You may cite the bound $|\mathrm{Aut}(S_n)| \leq n!$ for $n \neq 6$ from Exercise 18(d) above; then it suffices to prove $Z(S_n) = 1$ for $n \geq 3$, since this gives $|\mathrm{Inn}(S_n)| = n!$.)

15. Let $G = \mathbb{Z}_p \times \mathbb{Z}_{p^2}$ for p prime. Determine which elements have order p, and use this to bound $|\mathrm{Aut}(G)|$ from above by counting ordered images of a generating set.

Additional exercises.

1. Prove that $\mathrm{Aut}(\mathbb{Z}_2^n) \cong \mathrm{GL}_n(\mathbb{Z}/2\mathbb{Z})$ and compute $|\mathrm{GL}_n(\mathbb{Z}/2\mathbb{Z})|$ in closed form as a product over $k = 0, \ldots, n-1$. Evaluate it for $n = 3$.

2. Show that a group G is complete (trivial center and every automorphism inner) iff the natural map $G \to \mathrm{Aut}(G)$ is an isomorphism. Prove S_3 is complete.

3. Let p be an odd prime. Prove $\mathrm{Aut}(\mathbb{Z}_{p^n})$ is cyclic of order $p^{n-1}(p-1)$, and show $\mathrm{Aut}(\mathbb{Z}_{2^n}) \cong \mathbb{Z}_2 \times \mathbb{Z}_{2^{n-2}}$ for $n \geq 3$ (so it is *not* cyclic).

4. Suppose $|G| = pq$ with $p < q$ primes and $p \nmid q-1$, and let Q be the Sylow q-subgroup (normal, since its index p is the smallest prime dividing $|G|$). Using the conjugation homomorphism $G \to \mathrm{Aut}(Q) \cong \mathbb{Z}/(q-1)\mathbb{Z}$ argue that the Sylow q-subgroup is central, hence G is cyclic.

5. Let φ be an automorphism of a finite group G that fixes only the identity and satisfies $\varphi^2 = \mathrm{id}$. Prove G is abelian of odd order. (Hint: show $g \mapsto g^{-1}\varphi(g)$ is a bijection.)

6. Constructing an explicit outer automorphism of S_6 is hard; instead prove that any automorphism of S_n ($n \geq 2$) sending transpositions to transpositions is inner, and that for $n \neq 6$ every automorphism does so.

Commutative-diagram exercises.

1. Let G act on itself by conjugation. Show this is the homomorphism ψ in

$$1 \longrightarrow Z(G) \hookrightarrow G \xrightarrow{\ \psi\ } \mathrm{Aut}(G)$$

   with $\operatorname{im}\psi = \mathrm{Inn}(G)$ and $\ker\psi = Z(G)$. Verify exactness at G and conclude $G/Z(G) \cong \mathrm{Inn}(G)$.

2. Let G act on a set A via $\rho\colon G \to \mathrm{Sym}(A)$, and fix $a \in A$. Prove the orbit-stabilizer bijection makes

$$G/G_a \xrightarrow[gG_a \mapsto g\cdot a]{\sim} \mathrm{orb}(a)$$

   a well-defined G-equivariant bijection, where $G_a = \mathrm{Stab}_G(a)$.

3. Let $H \trianglelefteq G$ and let $c\colon G \to \mathrm{Aut}(H)$ be conjugation. Show the diagram

$$\begin{array}{ccc} G & \xrightarrow{\ c\ } & \mathrm{Aut}(H) \\ \downarrow & \nearrow_{\bar{c}} & \\ G/C_G(H) & & \end{array}$$

   commutes and $\bar{c}$ is injective, identifying $G/C_G(H)$ with a subgroup of $\mathrm{Aut}(H)$.

4. For G acting on the cosets of $H \leq G$ by left multiplication, describe the homomorphism π in

$$G \xrightarrow{\ \pi\ } \mathrm{Sym}(G/H)$$

   and show $\ker\pi = \bigcap_{g \in G} gHg^{-1}$ is the largest normal subgroup of G contained in H. State the consequence when $[G : H] = p$ is the smallest prime dividing $|G|$.

5. Let $1 \to N \to G \to Q \to 1$ be exact with N abelian. Show the conjugation action of G on N factors through Q, giving $\bar{\rho}$ in

$$\begin{array}{ccc} G & \xrightarrow{\ \rho\ } & \mathrm{Aut}(N) \\ {\scriptstyle q}\big\downarrow & \nearrow_{\bar{\rho}} & \\ Q & & \end{array}$$

and explain why N abelian is exactly what is needed for this factorization.

4.5 The Sylow Theorems

Sylow p-subgroups and Sylow's theorems

Throughout this section G is a finite group and p is a prime. Write

$$|G| = p^a m, \qquad p \nmid m, \qquad a \geq 0.$$

So p^a is the exact power of p dividing $|G|$. The entire theory rests on Lagrange's theorem (the order of a subgroup divides $|G|$) and on counting fixed points of p-group actions. We first isolate the relevant vocabulary.

Definition 4.5.1 (p-group, p-subgroup)**.** A group is a *p-group* if every element has order a power of p. A finite group is a p-group if and only if its order is a power of p (this equivalence uses Cauchy's theorem, which follows from Sylow's theorem below). A subgroup of G that is a p-group is a *p-subgroup* of G.

Definition 4.5.2 (Sylow p-subgroup)**.** With $|G| = p^a m$ and $p \nmid m$, a subgroup $P \leq G$ is a *Sylow p-subgroup* if $|P| = p^a$, i.e. P is a p-subgroup of the maximal possible order. The set of all Sylow p-subgroups is denoted $\mathrm{Syl}_p(G)$, and

$$n_p = n_p(G) = \left|\mathrm{Syl}_p(G)\right|$$

is the *number* of Sylow p-subgroups.

Remark 4.5.1. A Sylow p-subgroup is exactly a p-subgroup whose index in G is coprime to p: if $|P| = p^a$ then $[G : P] = m$ with $p \nmid m$, and conversely a p-subgroup of p-free index must have order p^a. Sylow's first theorem asserts these are never vacuous.

The three Sylow theorems

We state the package as D&F does, then sketch the proofs. The engine is a single idea: let a p-group act on a finite set; the number of points fixed is congruent mod p to the size of the set. We record this lemma first.

Lemma 4.5.3 (Fixed-point congruence)**.** *Let P be a finite p-group acting on a finite set Ω, and let $\Omega_0 = \{\, \omega \in \Omega : g \cdot \omega = \omega \text{ for all } g \in P \,\}$ be the set of fixed points. Then*

$$|\Omega| \equiv |\Omega_0| \pmod{p}.$$

Proof. Decompose Ω into P-orbits. By the orbit–stabilizer theorem each orbit has size $[P : P_\omega]$, a power of p (since $|P| = p^k$). An orbit has size 1 exactly when its point is fixed; every other orbit has size divisible by p. Summing, $|\Omega| = |\Omega_0| + \sum(\text{orbit sizes divisible by } p)$, so $|\Omega| \equiv |\Omega_0| \pmod{p}$. □

Theorem 4.5.4 (Sylow's Theorem)**.** *Let G be a finite group with $|G| = p^a m$, $p \nmid m$.*

(1) (Existence.) *G has a Sylow p-subgroup; that is, $n_p \geq 1$. More generally G has a subgroup of order p^b for every $0 \leq b \leq a$.*

(2) (Conjugacy and domination.) *If P is a Sylow p-subgroup and Q is any p-subgroup of G, then there exists $g \in G$ with $Q \leq gPg^{-1}$. In particular, any two Sylow p-subgroups are conjugate in G, and every p-subgroup is contained in some Sylow p-subgroup.*

(3) (Counting.) *The number of Sylow p-subgroups satisfies*

$$n_p \equiv 1 \pmod{p}, \qquad n_p \mid m, \qquad n_p = [G : N_G(P)]$$

for any Sylow p-subgroup P.

Proof sketch. **(1) Existence.** Induct on $|G|$ (Wielandt's count, or D&F's approach). If G has a proper subgroup H with $p \nmid [G : H]$ then $p^a \mid |H|$, and a Sylow p-subgroup of H (by induction) is one of G. Otherwise $p \mid [G : H]$ for every proper H, so the class equation $|G| = |Z(G)| + \sum[G : C_G(x_i)]$ forces $p \mid |Z(G)|$; by Cauchy $Z(G)$ has an element of order p, generating $N \lhd G$ with $|N| = p$. By induction G/N has a Sylow p-subgroup $\overline{P}$ of order p^{a-1}; its preimage in G has order p^a. The "every p^b" refinement follows by inducting inside P using that a p-group has normal subgroups of every order dividing $|P|$.

(2)+(3) The conjugation action. Fix one Sylow p-subgroup P (exists by (1)) and let $\mathcal{S} = \{\, gPg^{-1} : g \in G \,\}$ be the G-conjugates of P. Then $|\mathcal{S}| = [G : N_G(P)]$ by orbit–stabilizer for the conjugation action of G on subgroups (the stabilizer of P is $N_G(P)$). Since $P \leq N_G(P)$, $[G : N_G(P)] \mid m$, so $|\mathcal{S}| \mid m$ and in particular $p \nmid |\mathcal{S}|$.

Now restrict the conjugation action to any p-subgroup $Q \leq G$ acting on $\mathcal{S}$. By Lemma 4.5.3, $|\mathcal{S}| \equiv |\mathcal{S}_0| \pmod{p}$ where $\mathcal{S}_0$ is the set of Q-fixed points. A point $R = gPg^{-1} \in \mathcal{S}$ is Q-fixed iff $Q \leq N_G(R)$; one shows $Q \leq N_G(R) \implies Q \leq R$ (because QR is then a p-group containing the Sylow p-subgroup R, forcing $QR = R$). Taking $Q = P$: P fixes itself and no other point (if $P \leq N_G(R)$ then $P \leq R$, so $P = R$), whence $|\mathcal{S}_0| = 1$ and $|\mathcal{S}| \equiv 1 \not\equiv 0$, consistent with $p \nmid |\mathcal{S}|$.

For a general p-subgroup Q: if Q fixed no point of $\mathcal{S}$, then $|\mathcal{S}_0| = 0$, so $p \mid |\mathcal{S}|$ — contradiction. Hence some $R = gPg^{-1}$ is Q-fixed, giving $Q \leq R = gPg^{-1}$. This is (2). Applying it to a second Sylow p-subgroup Q (same order as P) forces $Q = gPg^{-1}$: all Sylow p-subgroups are conjugate, so $\mathrm{Syl}_p(G) = \mathcal{S}$ and $n_p = |\mathcal{S}| = [G : N_G(P)] \mid m$. Finally take $Q = P$ acting on $\mathcal{S} = \mathrm{Syl}_p(G)$: the only fixed point is P itself (if P normalizes another Sylow R then $P \leq R$, so $P = R$), whence $|\mathcal{S}_0| = 1$ and $n_p \equiv 1 \pmod{p}$. □

Corollary 4.5.5 (Normality criterion)**.** *A Sylow p-subgroup P is normal in G if and only if $n_p = 1$ (equivalently $N_G(P) = G$). More generally $P \trianglelefteq G$ iff P is the unique Sylow p-subgroup.*

Proof. By Theorem 4.5.4(2) all Sylow p-subgroups are conjugate, so $P \trianglelefteq G$ ($\iff gPg^{-1} = P$ for all g) is equivalent to P having no distinct conjugate, i.e. $n_p = 1$. The reformulation $n_p = [G : N_G(P)] = 1 \iff N_G(P) = G \iff P \trianglelefteq G$ is immediate. □

The conjugation action that powers the proof is the central diagram of the section.

$$G \xrightarrow{\ \rho\ } \mathrm{Sym}\big(\mathrm{Syl}_p(G)\big) \qquad \rho(g)\colon P \longmapsto gPg^{-1}.$$

Diagram explanation. Objects: Two groups: G is the finite group of order $p^a m$ whose Sylow structure we are studying; $\mathrm{Sym}(\mathrm{Syl}_p(G))$ is the symmetric group on the (finite) set $\mathrm{Syl}_p(G)$ of all Sylow p-subgroups of G. The set $\mathrm{Syl}_p(G)$ has n_p elements, so $\mathrm{Sym}(\mathrm{Syl}_p(G)) \cong S_{n_p}$.

Arrows: The single arrow $\rho\colon G \to \mathrm{Sym}(\mathrm{Syl}_p(G))$ is the conjugation action homomorphism. Its formula is $\rho(g)(P) = gPg^{-1}$. It is well-defined because conjugation sends a subgroup of order p^a to another subgroup of the same order, so $gPg^{-1} \in \mathrm{Syl}_p(G)$ whenever $P \in \mathrm{Syl}_p(G)$. It is a homomorphism because $\rho(gh)(P) = ghP(gh)^{-1} = g(hPh^{-1})g^{-1} = \rho(g)(\rho(h)(P))$.

What commutes: This is a one-arrow diagram, so there is no commutativity condition. The key structural fact is instead that $\ker\rho = \bigcap_{P \in \mathrm{Syl}_p(G)} N_G(P)$ (those g that normalize *every* Sylow p-subgroup) and $\mathrm{im}\,\rho$ is a transitive subgroup of S_{n_p} by Theorem 4.5.4(2).

Why it commutes: Homomorphism verification: for any $g, h \in G$ and $P \in \mathrm{Syl}_p(G)$, following g then h gives $\rho(h)(\rho(g)(P)) = h(gPg^{-1})h^{-1} = (hg)P(hg)^{-1} = \rho(hg)(P)$, confirming ρ respects the group operation. The action is well-defined on all of $\mathrm{Syl}_p(G)$ because every conjugate of a Sylow p-subgroup is again a Sylow p-subgroup of the same order.

Why this matters here: This diagram is the engine of all three Sylow theorems. Transitivity of ρ (proved via the fixed-point congruence argument) is exactly Sylow (2): every Sylow p-subgroup is a conjugate of P.

Applying orbit–stabilizer to this action gives $n_p = [G : N_G(P)]$, the key formula in Sylow (3). The arrow records precisely the data needed to count and compare all Sylow p-subgroups simultaneously.

Concrete example: Take $G = S_4$, $p = 3$. Then $\mathrm{Syl}_3(S_4)$ has $n_3 = 4$ elements (the four subgroups $\langle(123)\rangle, \langle(124)\rangle, \langle(134)\rangle, \langle(234)\rangle$), so $\rho\colon S_4 \to S_4$ (i.e. S_4 acting on a 4-element set). Conjugating (123) by the transposition (12) gives (213) = (132), moving its subgroup to $\langle(132)\rangle = \langle(123)\rangle$; conjugating by (14) gives (423) = (234), moving to a different Sylow.

Common pitfall: Students sometimes think ρ maps G into $\mathrm{Aut}(P)$ rather than into $\mathrm{Sym}(\mathrm{Syl}_p(G))$: ρ permutes the *set of subgroups* $\mathrm{Syl}_p(G)$, not the elements inside a single P. Also, ρ need not be injective; its kernel (elements normalizing every Sylow p-subgroup) can be nontrivial.

Takeaway: The point of this diagram is that the conjugation action of G on its own Sylow p-subgroups is a single homomorphism whose transitivity and orbit-stabilizer structure encode all three Sylow theorems at once.

The action is *transitive* (Theorem 4.5.4(2)), so there is a single orbit, and orbit–stabilizer collapses to one bijection:

$$G/N_G(P) \xrightarrow[gN_G(P) \mapsto gPg^{-1}]{\sim} \mathrm{Syl}_p(G) \qquad \Longrightarrow \qquad n_p = [G : N_G(P)].$$

Diagram explanation. Objects: $G/N_G(P)$ is the set of left cosets of the normalizer $N_G(P)$ in G (not necessarily a group, since $N_G(P)$ need not be normal in G); it has $[G : N_G(P)]$ elements. $\mathrm{Syl}_p(G)$ is the finite set of all Sylow p-subgroups of G, which has n_p elements.

Arrows: The arrow labeled $\sim$ is the bijection $gN_G(P) \mapsto gPg^{-1}$. This is the orbit–stabilizer bijection for the conjugation action ρ of G on $\mathrm{Syl}_p(G)$: the orbit of P under conjugation is exactly $\mathrm{Syl}_p(G)$ (by Sylow (2), transitivity), and the stabilizer of P is $N_G(P)$ (those g with $gPg^{-1} = P$). Well-definedness: if $gN_G(P) = hN_G(P)$, then $h^{-1}g \in N_G(P)$, so $h^{-1}gP(h^{-1}g)^{-1} = P$, giving $gPg^{-1} = hPh^{-1}$. Hence the map does not depend on the choice of coset representative.

What commutes: Since this is a bijection between two sets (not a square), there is no commutativity path to state. The essential equality encoded is $n_p = \left|\mathrm{Syl}_p(G)\right| = \left|G/N_G(P)\right| = [G : N_G(P)]$.

Why it commutes: The bijection follows from the general orbit–stabilizer theorem: for any G-set X and $x \in X$, the map $G/\operatorname{Stab}(x) \to \mathrm{Orb}(x)$, $g\operatorname{Stab}(x) \mapsto g \cdot x$, is a well-defined bijection. Here $X = \mathrm{Syl}_p(G)$, $x = P$, $\mathrm{Orb}(P) = \mathrm{Syl}_p(G)$ (transitivity), $\mathrm{Stab}(P) = N_G(P)$.

Why this matters here: This diagram collapses the abstract orbit–stabilizer theorem into the concrete formula $n_p = [G : N_G(P)]$, which is part (3) of Sylow's theorem. Combined with $P \leq N_G(P)$, it forces $n_p \mid m$; and the congruence $n_p \equiv 1 \pmod p$ is derived separately by having P act on $\mathrm{Syl}_p(G)$.

Concrete example: In $G = S_3$ with $p = 3$: $\mathrm{Syl}_3(S_3) = \{\langle(123)\rangle\}$, $N_{S_3}(\langle(123)\rangle) = S_3$ (the 3-Sylow is normal), so $G/N_G(P) = \{e\}$, and the bijection sends the single coset eS_3 to the single Sylow subgroup, giving $n_3 = 1$. In S_4 with $p = 3$: $N_{S_4}(P) \cong S_3$ (order 6), $[S_4 : N_{S_4}(P)] = 4 = n_3$.

Common pitfall: The map is defined on *cosets* of $N_G(P)$, not on elements of G; a student who writes $g \mapsto gPg^{-1}$ without quotienting must check well-definedness on cosets, i.e. that a different representative of the same coset gives the same conjugate. Also, the domain $G/N_G(P)$ is a set of cosets, not a quotient group (unless $N_G(P) \trianglelefteq G$).

Takeaway: The point of this diagram is that transitivity of the conjugation action makes the number of Sylow p-subgroups exactly the index of the normalizer, turning a counting question into a purely arithmetical one.

Method (Reading off n_p from the constraints)**.** *Trigger.* You know $|G| = p^a m$ ($p \nmid m$) and want the possible values of n_p, usually to find a normal Sylow subgroup or to rule out simplicity.

Recipe.

1. Factor $|G| = p^a m$ for the prime p of interest.
2. List the positive divisors d of m (these are the candidates from $n_p \mid m$).
3. Keep only those d with $d \equiv 1 \pmod p$. The surviving list is the complete set of *a priori* possibilities for n_p.

4. If 1 is the only survivor, then $n_p = 1$: the Sylow p-subgroup is normal (Corollary 4.5.5).

5. If more than one survives, combine with counting of elements (next method) or with information about $N_G(P)$.

Worked examples: computing n_p and Sylow subgroups

Worked Example 4.5.6 (Sylow subgroups of S_4 and A_4)**.** Find n_2, n_3 for S_4 ($|S_4| = 24$) and n_2, n_3 for A_4 ($|A_4| = 12$); exhibit the Sylow subgroups.

Recognition. This is direct application of Theorem 4.5.4(3): the congruence-and-divisor constraints pin down n_p, and we confirm by listing actual subgroups.

Solution. S_4**,** $|S_4| = 24 = 2^3 \cdot 3$**.** $p = 3$*:* $m = 8$, divisors $1, 2, 4, 8$; those $\equiv 1 \pmod 3$ are $1, 4$. The 3-Sylows have order 3, generated by 3-cycles; the number of 3-cycles is 8, each subgroup $\langle (abc) \rangle$ contains two of them, so there are $8/2 = 4$ such subgroups. Hence $n_3 = 4$ (consistent: $4 \equiv 1 \pmod 3$). $p = 2$*:* $m = 3$, divisors $1, 3$; both are $\equiv 1 \pmod 2$. A Sylow 2-subgroup has order 8; in S_4 it is a dihedral group D_8, e.g. the symmetries of a square on $\{1, 2, 3, 4\}$: $\langle (1234), (13) \rangle$. There are exactly 3 such (one per pairing of the 4 points into "diagonals"), so $n_2 = 3$.

A_4**,** $|A_4| = 12 = 2^2 \cdot 3$**.** $p = 3$*:* $m = 4$, divisors $1, 2, 4$ with $\equiv 1 \pmod 3$ giving $1, 4$. The eight 3-cycles again form 4 subgroups of order 3, so $n_3 = 4$. $p = 2$*:* $m = 3$, candidates $1, 3$. The unique Sylow 2-subgroup is the Klein four-group $V = \{ e, (12)(34), (13)(24), (14)(23) \}$, which is normal in A_4; hence $n_2 = 1$.

Check. For A_4: $n_2 = 1$ matches the well-known fact $V \trianglelefteq A_4$, and the absence of a subgroup of order 6 is consistent with $n_3 = 4 \neq 1$ (no normal Sylow 3). For S_4: $n_3 = 4 = [S_4 : N_{S_4}(P_3)]$ gives $|N_{S_4}(P_3)| = 6$, indeed S_3 stabilizing a point. All congruences hold.

Worked Example 4.5.7 (Every group of order 15 is cyclic)**.** Show that a group G with $|G| = 15$ is isomorphic to $\mathbb{Z}/15\mathbb{Z}$.

Recognition. Order $15 = 3 \cdot 5$ has both Sylow numbers forced to 1 by the congruence/divisor constraints (Method box), so both Sylow subgroups are normal — the recognition cue for an internal direct product.

Solution. $|G| = 15 = 3 \cdot 5$. $p = 5$*:* $m = 3$, divisors $1, 3$; need $\equiv 1 \pmod 5$. Only 1 qualifies, so $n_5 = 1$. Let P be the (unique, hence normal) Sylow 5-subgroup, $|P| = 5$. $p = 3$*:* $m = 5$, divisors $1, 5$; need $\equiv 1 \pmod 3$. Since $5 \equiv 2$, only 1 qualifies, so $n_3 = 1$. Let Q be the normal Sylow 3-subgroup, $|Q| = 3$. Now $P \trianglelefteq G$, $Q \trianglelefteq G$, $P \cap Q = 1$ (orders coprime), and $|PQ| = |P||Q|/|P \cap Q| = 15 = |G|$, so $G = PQ$. With both factors normal and trivial intersection, $G \cong P \times Q \cong \mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. Since $\gcd(5, 3) = 1$, this is cyclic: $G \cong \mathbb{Z}/15\mathbb{Z}$. *Check.* A generator: if $|x| = 5$, $|y| = 3$ then $xy = yx$ (they lie in normal subgroups intersecting trivially, so commutators vanish: $xyx^{-1}y^{-1} \in P \cap Q = 1$), and $|xy| = 15$.

Worked Example 4.5.8 (Groups of order pq with $p < q$ and $p \nmid q - 1$ are cyclic)**.** Let $|G| = pq$ with primes $p < q$ and suppose $p \nmid q - 1$. Prove G is cyclic.

Recognition. This generalizes the order-15 case: the divisor/congruence test plus the extra hypothesis $p \nmid q - 1$ kills the only obstruction to $n_p = 1$.

Solution. Sylow q. $m = p$, divisors $1, p$; need $\equiv 1 \pmod q$. Since $1 \leq p < q$ we have $p \not\equiv 1 \pmod q$ (as $0 < p < q$ and $p \neq 1$), so $n_q = 1$. Let Q be the normal Sylow q-subgroup, $|Q| = q$. *Sylow p.* $m = q$, divisors $1, q$; need $\equiv 1 \pmod p$. So $n_p \in \{1, q\}$, and $n_p = q$ is possible only if $q \equiv 1 \pmod p$, i.e. $p \mid q - 1$. The hypothesis $p \nmid q - 1$ rules this out, forcing $n_p = 1$. Let P be the normal Sylow p-subgroup. As in the previous example $P, Q \trianglelefteq G$, $P \cap Q = 1$, $|PQ| = pq$, so $G \cong P \times Q \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/q\mathbb{Z} \cong \mathbb{Z}/pq\mathbb{Z}$ (coprime orders), which is cyclic. *Check.* The hypothesis is sharp: when $p \mid q - 1$ there *is* a nonabelian group of order pq (a semidirect product $\mathbb{Z}/q \rtimes \mathbb{Z}/p$), e.g. $|G| = 21 = 3 \cdot 7$ with $3 \mid 6$ admits a nonabelian group; here our hypothesis fails, correctly.

Worked Example 4.5.9 (No simple group of order 56)**.** Show that a group G of order 56 is not simple.

Recognition. Counting argument (next method): the candidates for n_7 are few; if $n_7 \neq 1$ the Sylow 7-subgroups consume so many elements that the Sylow 2-subgroup must be unique.

Solution. $|G| = 56 = 2^3 \cdot 7$. $p = 7$*:* $m = 8$, divisors $1, 2, 4, 8$ with $\equiv 1 \pmod 7$: only 1 and 8. So $n_7 \in \{1, 8\}$. *Case $n_7 = 1$:* the Sylow 7-subgroup is normal, so G is not simple. Done. *Case $n_7 = 8$:* each Sylow 7-subgroup

has order 7 (prime), so distinct ones meet only in the identity. They contribute $8 \cdot (7-1) = 48$ elements of order 7. That leaves $56 - 48 = 8$ elements of order $\neq 7$. A Sylow 2-subgroup has order 8 and consists entirely of those remaining 8 elements (it contains the identity and elements of 2-power order). Thus there is room for exactly *one* Sylow 2-subgroup, forcing $n_2 = 1$: the Sylow 2-subgroup is normal, and again G is not simple. In either case G has a nontrivial proper normal subgroup, so G is not simple. *Check.* $8 \equiv 1 \pmod 7$ and $8 \mid 8$: a valid value. The element count is exact: $48 + 8 = 56$. The argument used only that 7-Sylows have prime order (clean intersections).

Worked Example 4.5.10 (No simple group of order 36)**.** Show a group G of order 36 is not simple.

Recognition. Here the p-Sylows intersect nontrivially, so we use the *action on cosets*: a small index forces a normal kernel.

Solution. $|G| = 36 = 2^2 \cdot 3^2$. $p = 3$*:* $m = 4$, divisors $1, 2, 4$ with $\equiv 1 \pmod 3$: only 1 and 4. So $n_3 \in \{1, 4\}$. If $n_3 = 1$, the Sylow 3-subgroup is normal — not simple, done. Suppose $n_3 = 4$. Let $P \in \mathrm{Syl}_3(G)$, $|P| = 9$, and let G act by left multiplication on the $4 = [G : N_G(P)]$ cosets of $N_G(P)$ (equivalently on $\mathrm{Syl}_3(G)$ by conjugation). This is a homomorphism

$$\varphi \colon G \longrightarrow \mathrm{Sym}\big(\mathrm{Syl}_3(G)\big) \cong S_4.$$

Diagram explanation. Objects: G is the specific group of order 36 under analysis. $\mathrm{Sym}(\mathrm{Syl}_3(G))$ is the symmetric group on the set $\mathrm{Syl}_3(G)$, which under the assumption $n_3 = 4$ has 4 elements; hence $\mathrm{Sym}(\mathrm{Syl}_3(G)) \cong S_4$, a group of order 24.

Arrows: The arrow $\varphi \colon G \to \mathrm{Sym}(\mathrm{Syl}_3(G)) \cong S_4$ is the conjugation-action homomorphism: $\varphi(g)$ sends each $P \in \mathrm{Syl}_3(G)$ to gPg^{-1}. Well-definedness: conjugation by g maps $\mathrm{Syl}_3(G)$ to itself because gPg^{-1} has the same order as P, so it is still a Sylow 3-subgroup. φ is a homomorphism by the same calculation as ρ above: $\varphi(gh) = \varphi(g) \circ \varphi(h)$.

What commutes: This is again a one-arrow diagram; the structural content is the first isomorphism theorem: $G/\ker\varphi \cong \operatorname{im}\varphi \leq S_4$, so $|G/\ker\varphi| \mid |S_4| = 24$. Since $|G| = 36 \nmid 24$, $\ker\varphi \neq 1$, and since the action is transitive $\ker\varphi \neq G$.

Why it commutes: Chasing the first isomorphism theorem: any element $g \in \ker\varphi$ satisfies $gPg^{-1} = P$ for every $P \in \mathrm{Syl}_3(G)$, i.e. g normalizes every Sylow 3-subgroup. This is precisely the intersection $\bigcap_P N_G(P)$. The order constraint $36 > 24$ forces this kernel to be nontrivial; the transitivity of the action forces it to be proper.

Why this matters here: This diagram encodes the *coset-action trick*: when an element count ($n_3 = 4$) and an order comparison ($|G| > |S_{n_3}|$) together prevent injectivity, the kernel $K = \ker\varphi$ is automatically a nontrivial proper normal subgroup, proving G is not simple. This technique bypasses the need for an element-count overflow.

Concrete example: The same argument applied verbatim to any group G of order 36 with $n_3 = 4$: $\varphi \colon G \to S_4$, $\ker\varphi \neq 1$ since $36 > 24$; $|G/K| \mid 12$ (from $\gcd(24, 36) = 12$), so $|K| \geq 3$. For contrast, if $|G| = 24$ and $n_3 = 4$, the same map $\varphi \colon G \to S_4$ could be injective ($24 \mid 24$), so the argument fails — you would need additional information to find a normal subgroup.

Common pitfall: Students may think $\mathrm{Sym}(\mathrm{Syl}_3(G)) \cong S_4$ forces G to embed in S_4, but that is only true if φ is injective. Here we explicitly use *non*-injectivity ($36 > 24$) to get a nontrivial kernel. The diagram records φ's existence; the order comparison is the extra arithmetic step.

Takeaway: The point of this diagram is that when the group order exceeds the order of the target symmetric group the kernel of the conjugation-action homomorphism is automatically a nontrivial proper normal subgroup, so G cannot be simple.

The kernel $K = \ker\varphi$ is normal in G. Now $|G| = 36 > 24 = |S_4|$, so φ cannot be injective: $K \neq 1$. Also $K \neq G$, since the action is transitive (hence nontrivial) by Theorem 4.5.4(2). Thus $1 \neq K \trianglelefteq G$ is a proper normal subgroup and G is not simple. *Check.* $\operatorname{im}\varphi \cong G/K$ embeds in S_4, so $|G/K| \mid 24$; combined with $|G/K| \mid 36$ this gives $|G/K| \mid \gcd(24, 36) = 12$, hence $|K| \geq 3$, confirming K is a genuine nontrivial normal subgroup.

Method (Counting elements to force a normal Sylow (n_p non-simplicity recipe)). *Trigger.* You want to prove G (of known order $p^a m \cdots$) is *not simple*, or that some Sylow subgroup is normal. *Recipe.*

1. For each prime, list the legal n_p via the Method box ($n_p \mid m$, $n_p \equiv 1 \pmod p$). If any prime forces $n_p = 1$, that Sylow subgroup is normal — stop.
2. Otherwise take a prime q whose Sylow subgroups have *prime* order q (so distinct ones meet trivially). If $n_q > 1$ they occupy $n_q(q-1)$ nonidentity elements. Add up the forced element counts for several primes; if they exceed $|G| - 1$ you get a contradiction, pinning some n_p to 1.
3. If element-counting is inconclusive (Sylows overlap), use the *coset action*: act on the $[G : N_G(P)] = n_p$ Sylow p-subgroups, giving $\varphi\colon G \to S_{n_p}$. If $|G| \nmid n_p!$ the kernel is a nontrivial proper normal subgroup.

Worked Example 4.5.11 (Counting n_p purely from the congruences). Determine all possible values of n_2, n_3, n_5 for a group of order $|G| = 60$, and use one to show such a group, if simple, must have $n_5 = 6$.

Recognition. Pure constraint solving (Method box) followed by the counting argument; this is the opening move in classifying simple groups of order 60 (which is A_5).

Solution. $|G| = 60 = 2^2 \cdot 3 \cdot 5$. $p = 5$*:* $m = 12$, divisors $1, 2, 3, 4, 6, 12$; those $\equiv 1 \pmod 5$ are 1 and 6. So $n_5 \in \{1, 6\}$. $p = 3$*:* $m = 20$, divisors $1, 2, 4, 5, 10, 20$; those $\equiv 1 \pmod 3$ are $1, 4, 10$. So $n_3 \in \{1, 4, 10\}$. $p = 2$*:* $m = 15$, divisors $1, 3, 5, 15$; those $\equiv 1 \pmod 2$ are all of $1, 3, 5, 15$ (every odd number is $\equiv 1 \pmod 2$). So $n_2 \in \{1, 3, 5, 15\}$. Now suppose G is simple. Then no Sylow subgroup is normal, so $n_5 \neq 1$, forcing $n_5 = 6$. (Likewise $n_3 \neq 1$ and $n_2 \neq 1$.) *Check.* $6 \equiv 1 \pmod 5$ and $6 \mid 12$: valid. With $n_5 = 6$ we have $[G : N_G(P_5)] = 6$, so G embeds in S_6 via the action on $\mathrm{Syl}_5(G)$; since G is simple the map is injective and lands in A_6 — the first step toward $G \cong A_5$. The values match the known data for A_5: $n_5 = 6, n_3 = 10, n_2 = 5$.

Worked Example 4.5.12 (Order *pqr* flavor: a group of order 30 has a normal Sylow). Show a group G of order 30 has a normal Sylow 3-subgroup or a normal Sylow 5-subgroup (in fact both).

Recognition. Element counting across two primes of prime-order Sylows; if neither were normal the nonidentity elements would overflow $|G|$.

Solution. $|G| = 30 = 2 \cdot 3 \cdot 5$. $p = 5$*:* $m = 6$, divisors $1, 2, 3, 6$ with $\equiv 1 \pmod 5$: $1, 6$. So $n_5 \in \{1, 6\}$. $p = 3$*:* $m = 10$, divisors $1, 2, 5, 10$ with $\equiv 1 \pmod 3$: $1, 10$. So $n_3 \in \{1, 10\}$. Suppose for contradiction both $n_5 \neq 1$ and $n_3 \neq 1$, i.e. $n_5 = 6$, $n_3 = 10$. Sylow 5-subgroups have prime order 5, distinct ones meeting trivially, contributing $6 \cdot 4 = 24$ elements of order 5. Sylow 3-subgroups have prime order 3, contributing $10 \cdot 2 = 20$ elements of order 3. But $24 + 20 = 44 > 30 = |G|$, impossible. Hence $n_5 = 1$ or $n_3 = 1$: a normal Sylow exists. *Check.* Strengthening: once (say) $n_5 = 1$, $P_5 \trianglelefteq G$ and G/P_5 has order 6; one shows the Sylow 3 is normal too, so G has a normal subgroup of order 15 (cyclic by the order-15 example), and G is not simple. The element overflow $44 > 30$ is the load-bearing inequality.

Caution. $n_p \equiv 1 \pmod p$ does *not* say n_p is odd or prime — it is congruent to 1 modulo p specifically. For $p = 2$ the congruence $n_2 \equiv 1 \pmod 2$ only says n_2 is odd, which is weak; lean on $n_2 \mid m$ instead. Always intersect *both* conditions.

Caution. The clean "distinct Sylows meet trivially" element count is valid *only* when the Sylow p-subgroups have prime order p (i.e. $a = 1$). If $|P| = p^a$ with $a \geq 2$, two distinct Sylow p-subgroups can share a subgroup of order p^{a-1}, so $n_p(p^a - 1)$ overcounts. Use the coset/conjugation action instead (as in the order-36 example).

Caution. $n_p = [G : N_G(P)]$, *not* $[G : P]$. These agree only when $N_G(P) = P$ (i.e. P is self-normalizing). Confusing them gives wrong counts; e.g. in S_4, $[S_4 : P_2] = 3 = n_2$ because the Sylow 2 is self-normalizing, but for the Sylow 3, $[S_4 : P_3] = 8 \neq 4 = n_3$ since $N_{S_4}(P_3) = S_3$ has order $6 > 3$.

Remark 4.5.2 (Why conjugacy makes normality a counting question). Theorem 4.5.4(2) says G permutes $\mathrm{Syl}_p(G)$ transitively by conjugation, so "P is normal" (the orbit of P is a single point) is equivalent to "$n_p = 1$". This is why the entire non-simplicity industry reduces to arithmetic: bound n_p by the two congruences, and a forced $n_p = 1$ instantly produces a normal subgroup. The orbit picture

$$G/N_G(P) \xrightarrow[gN_G(P) \mapsto gPg^{-1}]{\sim} \mathrm{Syl}_p(G)$$

makes the dictionary $n_p = 1 \iff N_G(P) = G \iff P \trianglelefteq G$ visible at a glance.

Diagram explanation. Objects: $G/N_G(P)$ is the set of left cosets of the normalizer $N_G(P)$ in G, with $[G : N_G(P)] = n_p$ elements by the orbit–stabilizer theorem applied to the conjugation action. $\mathrm{Syl}_p(G)$ is the set of all Sylow p-subgroups of G, with cardinality n_p.

Arrows: The bijection $gN_G(P) \mapsto gPg^{-1}$ is the same orbit–stabilizer map as the earlier diagram, now placed in the remark to summarize the normality equivalence. Well-definedness: if $gN_G(P) = hN_G(P)$ then $h^{-1}g \in N_G(P)$, so $h^{-1}g$ fixes P under conjugation, giving $gPg^{-1} = hPh^{-1}$. The bijection is therefore independent of the coset representative.

What commutes: No commutativity path (single arrow between two sets). The equality encoded is $n_p = \left|G/N_G(P)\right| = 1 \iff G/N_G(P)$ is a single coset $\iff N_G(P) = G \iff P \trianglelefteq G$.

Why it commutes: The chain of equivalences $n_p = 1 \iff N_G(P) = G \iff P \trianglelefteq G$ follows immediately from the bijection: the domain has size 1 iff $[G : N_G(P)] = 1$ iff $N_G(P) = G$; and $N_G(P) = G$ means every $g \in G$ satisfies $gPg^{-1} = P$, exactly the definition of P being normal in G.

Why this matters here: This diagram closes the remark by distilling the entire Sylow (2)–(3) package into one picture: the bijection between cosets of the normalizer and the set of Sylow subgroups makes visible why $n_p = 1$ is simultaneously an arithmetic condition (n_p divides m and is 1), a subgroup condition ($N_G(P) = G$), and a normality condition ($P \trianglelefteq G$). This is the dictionary that drives all non-simplicity arguments.

Concrete example: In $G = A_4$, $p = 2$: $P = V$ (the Klein four-group), $N_{A_4}(V) = A_4$ (since $V \trianglelefteq A_4$), so $G/N_G(P)$ consists of a single coset $\{A_4\}$, and the bijection maps it to the single element $\mathrm{Syl}_2(A_4) = \{V\}$, giving $n_2 = 1$. In S_4 with $p = 3$: $N_{S_4}(P)$ has order 6, so $G/N_G(P)$ has 4 cosets mapping bijectively to the 4 Sylow 3-subgroups, giving $n_3 = 4 \neq 1$, confirming no Sylow 3-subgroup is normal in S_4.

Common pitfall: The equivalence $n_p = 1 \iff P \trianglelefteq G$ requires that all Sylow p-subgroups are conjugate (Sylow (2)); without this, $n_p = 1$ would mean P is the only Sylow subgroup, but would not immediately imply normality (though it does, since gPg^{-1} is always a Sylow subgroup and there is only one). The subtle point is that Sylow (2) is used implicitly here.

Takeaway: The point of this diagram is that the orbit–stabilizer bijection makes the normality of a Sylow p-subgroup purely a matter of counting — $P \trianglelefteq G$ if and only if the number of its conjugates is exactly one.

Exercises (from the text).

1. Prove that if $P \in \mathrm{Syl}_p(G)$ and H is a subgroup of G containing P then $P \in \mathrm{Syl}_p(H)$. Give an example to show that, in general, a Sylow p-subgroup of a subgroup H of G need not be a Sylow p-subgroup of G.
2. Prove that if H is a subgroup of G and $Q \in \mathrm{Syl}_p(H)$ then $gQg^{-1} \in \mathrm{Syl}_p(gHg^{-1})$ for all $g \in G$.
3. Use Sylow's Theorem to prove Cauchy's Theorem. (Note that we only used Cauchy's Theorem for abelian groups — Proposition 3.21 — in the proof of Sylow's Theorem so this line of reasoning is not circular.)
4. Exhibit all Sylow 2-subgroups and Sylow 3-subgroups of D_{12} and $S_3 \times S_3$.
5. Show that a Sylow p-subgroup of D_{2n} is cyclic and normal for every odd prime p.
6. Exhibit all Sylow 3-subgroups of A_4 and all Sylow 3-subgroups of S_4.
7. Exhibit all Sylow 2-subgroups of S_4 and find elements of S_4 which conjugate one of these into each of the others.
8. Exhibit two distinct Sylow 2-subgroups of S_5 and an element of S_5 that conjugates one into the other.
9. Exhibit all Sylow 3-subgroups of $\mathrm{SL}_2(\mathbb{F}_3)$ (cf. Exercise 9, Section 2.1).
10. Prove that the subgroup of $\mathrm{SL}_2(\mathbb{F}_3)$ generated by $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ and $\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ is the unique Sylow 2-subgroup of $\mathrm{SL}_2(\mathbb{F}_3)$ (cf. Exercise 10, Section 2.4).
11. Show that the center of $\mathrm{SL}_2(\mathbb{F}_3)$ is the group of order 2 consisting of $\pm I$, where I is the identity matrix. Prove that $\mathrm{SL}_2(\mathbb{F}_3)/Z(\mathrm{SL}_2(\mathbb{F}_3)) \cong A_4$. [Use facts about groups of order 12.]
12. Let $2n = 2^a k$ where k is odd. Prove that the number of Sylow 2-subgroups of D_{2n} is k. [Prove that if $P \in \mathrm{Syl}_2(D_{2n})$ then $N_{D_{2n}}(P) = P$.]

13. Prove that a group of order 56 has a normal Sylow p-subgroup for some prime p dividing its order.

14. Prove that a group of order 312 has a normal Sylow p-subgroup for some prime p dividing its order.

15. Prove that a group of order 351 has a normal Sylow p-subgroup for some prime p dividing its order.

16. Let $|G| = pqr$, where p, q and r are primes with $p < q < r$. Prove that G has a normal Sylow subgroup for either p, q or r.

17. Prove that if $|G| = 105$ then G has a normal Sylow 5-subgroup and a normal Sylow 7-subgroup.

18. Prove that a group of order 200 has a normal Sylow 5-subgroup.

19. Prove that if $|G| = 6545$ then G is not simple.

20. Prove that if $|G| = 1365$ then G is not simple.

21. Prove that if $|G| = 2907$ then G is not simple.

22. Prove that if $|G| = 132$ then G is not simple.

23. Prove that if $|G| = 462$ then G is not simple.

24. Prove that if G is a group of order 231 then $Z(G)$ contains a Sylow 11-subgroup of G and a Sylow 7-subgroup is normal in G.

25. Prove that if G is a group of order 385 then $Z(G)$ contains a Sylow 7-subgroup of G and a Sylow 11-subgroup is normal in G.

26. Let G be a group of order 105. Prove that if a Sylow 3-subgroup of G is normal then G is abelian.

27. Let G be a group of order 315 which has a normal Sylow 3-subgroup. Prove that $Z(G)$ contains a Sylow 3-subgroup of G and deduce that G is abelian.

28. Let G be a group of order 1575. Prove that if a Sylow 3-subgroup of G is normal then a Sylow 5-subgroup and a Sylow 7-subgroup are normal. In this situation prove that G is abelian.

29. If G is a non-abelian simple group of order < 100, prove that $G \cong A_5$. [Eliminate all orders but 60.]

30. How many elements of order 7 must there be in a simple group of order 168?

31. For $p = 2$, 3 and 5 find $n_p(A_5)$ and $n_p(S_5)$. [Note that $A_4 \leq A_5$.]

32. Let P be a Sylow p-subgroup of H and let H be a subgroup of K. If $P \trianglelefteq H$ and $H \trianglelefteq K$, prove that P is normal in K. Deduce that if $P \in \mathrm{Syl}_p(G)$ and $H = N_G(P)$, then $N_G(H) = H$ (in words: normalizers of Sylow p-subgroups are self-normalizing).

33. Let P be a normal Sylow p-subgroup of G and let H be any subgroup of G. Prove that $P \cap H$ is the unique Sylow p-subgroup of H.

34. Let $P \in \mathrm{Syl}_p(G)$ and assume $N \trianglelefteq G$. Use the conjugacy part of Sylow's Theorem to prove that $P \cap N$ is a Sylow p-subgroup of N. Deduce that PN/N is a Sylow p-subgroup of G/N (note that this may also be done by the Second Isomorphism Theorem — cf. Exercise 9, Section 3.3).

35. Let $P \in \mathrm{Syl}_p(G)$ and let $H \leq G$. Prove that $gPg^{-1} \cap H$ is a Sylow p-subgroup of H for some $g \in G$. Give an explicit example showing that $hPh^{-1} \cap H$ is not always a Sylow p-subgroup of H for any $h \in H$ (in particular, we cannot always take $g = 1$ in the first part of this problem, as we could when H was normal in G).

36. Prove that if N is a normal subgroup of G then $n_p(G/N) \leq n_p(G)$.

37. Let R be a normal p-subgroup of G (not necessarily a Sylow subgroup).

    (a) Prove that R is contained in every Sylow p-subgroup of G.

    (b) If S is another normal p-subgroup of G, prove that RS is also a normal p-subgroup of G.

(c) The subgroup $O_p(G)$ is defined to be the group generated by all normal p-subgroups of G. Prove that $O_p(G)$ is the unique largest normal p-subgroup of G and $O_p(G)$ equals the intersection of all Sylow p-subgroups of G.

(d) Let $\overline{G} = G/O_p(G)$. Prove that $O_p(\overline{G}) = \overline{1}$ (i.e., $\overline{G}$ has no nontrivial normal p-subgroup).

38. Use the method of proof in Sylow's Theorem to show that if n_p is not congruent to 1 (mod p^2) then there are distinct Sylow p-subgroups P and Q of G such that $[P : P \cap Q] = [Q : P \cap Q] = p$.

39. Show that the subgroup of strictly upper triangular matrices in $\mathrm{GL}_n(\mathbb{F}_p)$ (cf. Exercise 17, Section 2.1) is a Sylow p-subgroup of this finite group. [Use the order formula in Section 1.4 to find the order of a Sylow p-subgroup of $\mathrm{GL}_n(\mathbb{F}_p)$.]

40. Prove that the number of Sylow p-subgroups of $\mathrm{GL}_2(\mathbb{F}_p)$ is $p+1$. [Exhibit two distinct Sylow p-subgroups.]

41. Prove that $\mathrm{SL}_2(\mathbb{F}_4) \cong A_5$ (cf. Exercise 9, Section 2.1 for the definition of $\mathrm{SL}_2(\mathbb{F}_4)$).

42. Prove that the group of rigid motions in $\mathbb{R}^3$ of an icosahedron is isomorphic to A_5. [Recall that the order of this group is 60: Exercise 13, Section 1.2.]

43. Prove that the group of rigid motions in $\mathbb{R}^3$ of a dodecahedron is isomorphic to A_5. (As with the cube and the tetrahedron, the icosahedron and the dodecahedron are dual solids.) [Recall that the order of this group is 60: Exercise 12, Section 1.2.]

44. Let p be the smallest prime dividing the order of the finite group G. If $P \in \mathrm{Syl}_p(G)$ and P is cyclic prove that $N_G(P) = C_G(P)$.

45. Find generators for a Sylow p-subgroup of S_{2p}, where p is an odd prime. Show that this is an abelian group of order p^2.

46. Find generators for a Sylow p-subgroup of S_{p^2}, where p is a prime. Show that this is a non-abelian group of order p^{p+1}.

47. Write and execute a computer program which (i) gives each odd number $n < 10{,}000$ that is not a power of a prime and that has some prime divisor p such that n_p is not forced to be 1 for all groups of order n by the congruence condition of Sylow's Theorem, and (ii) gives for each n in (i) the factorization of n into prime powers and gives the list of all permissible values of n_p for all primes p dividing n (i.e., those values not ruled out by Part 3 of Sylow's Theorem).

48. Carry out the same process as in the preceding exercise for all even numbers less than 1000. Explain the relative lengths of the lists versus the number of integers tested.

49. Prove that if $|G| = 2^n m$ where m is odd and G has a cyclic Sylow 2-subgroup then G has a normal subgroup of order m. [Use induction and Exercises 11 and 12 in Section 2.]

50. Prove that if U and W are normal subsets of a Sylow p-subgroup P of G then U is conjugate to W in G if and only if U is conjugate to W in $N_G(P)$. Deduce that two elements in the center of P are conjugate in G if and only if they are conjugate in $N_G(P)$. (A subset U of P is normal in P if $N_P(U) = P$.)

51. Let P be a Sylow p-subgroup of G and let M be any subgroup of G which contains $N_G(P)$. Prove that $[G : M] \equiv 1 \pmod{p}$.

52. Suppose G is a finite simple group in which every proper subgroup is abelian. If M and N are distinct maximal subgroups of G prove $M \cap N = 1$. [See Exercise 23 in Section 3.]

53. Use the preceding exercise to prove that if G is any non-abelian group in which every proper subgroup is abelian then G is not simple. [Let G be a counterexample to this assertion and use Exercise 24 in Section 3 to show that G has more than one conjugacy class of maximal subgroups. Use the method of Exercise 23 in Section 3 to count the elements which lie in all conjugates of M and N, where M and N are nonconjugate maximal subgroups of G; show that this gives more than $|G|$ elements.]

54. Prove the following classification: if G is a finite group of order $p_1 p_2 \cdots p_r$ where the p_i's are distinct primes such that p_i does not divide $p_j - 1$ for all i and j, then G is cyclic. [By induction, every proper

subgroup of G is cyclic, so G is not simple by the preceding exercise. If N is a nontrivial proper normal subgroup, N is cyclic and G/N acts as automorphisms of N. Use Proposition 16 to show that $N \leq Z(G)$ and use induction to show $G/Z(G)$ is cyclic, hence G is abelian by Exercise 36 of Section 3.1.]

55. Prove the converse to the preceding exercise: if $n \geq 2$ is an integer such that every group of order n is cyclic, then $n = p_1 p_2 \cdots p_r$ is a product of distinct primes and p_i does not divide $p_j - 1$ for all i, j. [If n is not of this form, construct noncyclic groups of order n using direct products of noncyclic groups of order p^2 and pq, where $p \mid q - 1$.]

56. If G is a finite group in which every proper subgroup is abelian, show that G is solvable.

Practice problems.

1. Verify Sylow's theorems concretely for $G = S_4$ (order $24 = 2^3 \cdot 3$): show $n_2 \in \{1, 3\}$ and $n_3 \in \{1, 4\}$, and find the actual values by exhibiting a Sylow 2-subgroup (order 8) and a Sylow 3-subgroup (order 3).

2. Let $|G| = p^a m$ with $p \nmid m$. State the three divisibility/congruence constraints Sylow's theorems impose on $n_p = |\operatorname{Syl}_p(G)|$, and use them to prove that a group of order 15 is cyclic.

3. Prove that every group of order p^2 (with p prime) is abelian. (Use that a p-group has nontrivial center and the $G/Z(G)$ cyclic argument.)

4. Show that a group of order 20 has a normal Sylow 5-subgroup. Generalize: if $|G| = pq^k$ with $p > q$ primes and $p \nmid (q^j - 1)$ for all relevant j, discuss what you can conclude.

5. Find n_3 and n_5 for a group of order 30, list the possibilities, and prove that G has a normal Sylow 3-subgroup or a normal Sylow 5-subgroup (and hence a normal subgroup of order 15).

6. Prove there is no simple group of order 56. (Hint: count elements of order 7 when $n_7 = 8$, then deduce $n_2 = 1$.)

7. Let $P \in \operatorname{Syl}_p(G)$. Prove $N_G(N_G(P)) = N_G(P)$.

8. Let $P \in \operatorname{Syl}_p(G)$ and suppose $P \trianglelefteq G$. Prove P is the unique Sylow p-subgroup of G, and conversely. Conclude P is characteristic in G.

9. Let $|G| = p^a m$ and $P \in \operatorname{Syl}_p(G)$. Let P act by left multiplication on the set of left cosets of P; show that the fixed cosets are exactly the gP with $g \in N_G(P)$, so that $m = [G : P] \equiv [N_G(P) : P] \pmod{p}$, and combine this with $[G : P] = n_p \, [N_G(P) : P]$ to deduce $n_p \equiv 1 \pmod{p}$. Compare with the direct proof via the conjugation action of P on $\operatorname{Syl}_p(G)$.

10. Suppose $|G| = p^a m$ and $H \leq G$ is a p-subgroup. Prove H is contained in some Sylow p-subgroup of G. (This is the containment half of Sylow II.)

11. Let G be a group of order $p^a m$ with $n_p = 1$, and let P be its unique Sylow p-subgroup. If $\varphi \in \operatorname{Aut}(G)$, prove $\varphi(P) = P$.

12. Prove that a group of order pq with $p < q$ primes and $p \mid (q - 1)$ has exactly one nonabelian isomorphism type, and that otherwise the only group of order pq is cyclic.

13. Let $P \in \operatorname{Syl}_p(G)$ and $H \trianglelefteq G$. Prove that $P \cap H \in \operatorname{Syl}_p(H)$ and that $PH/H \in \operatorname{Syl}_p(G/H)$.

14. Show that a group of order $p^2 q$ (p, q distinct primes) is never simple. Handle the cases $p < q$ and $p > q$ separately by bounding n_p and n_q.

15. Let G act on $\operatorname{Syl}_p(G)$ by conjugation. Describe the orbits and the stabilizer of $P \in \operatorname{Syl}_p(G)$, and use the orbit-stabilizer theorem to write $n_p = [G : N_G(P)]$.

16. Prove that if G has a unique Sylow p-subgroup for every prime p dividing $|G|$, then G is the (internal) direct product of those Sylow subgroups.

Additional exercises.

1. (Frattini argument) Let $H \trianglelefteq G$ and $P \in \operatorname{Syl}_p(H)$. Prove $G = N_G(P)H$. Deduce that if G/H is a p-group and $P \in \operatorname{Syl}_p(H)$, then $[G : N_G(P)]$ is prime to p.

2. Prove that no group of order p^2q^2 with $p < q$ and $q \not\equiv 1 \pmod{p}$, $p^2 \not\equiv 1 \pmod{q}$ is simple, and in fact such a group has a normal Sylow q-subgroup.

3. Prove that a group of order 48 has a normal subgroup of order 8 or 16. (Consider the action on $\mathrm{Syl}_2(G)$ and the kernel of the induced map $G \to S_{n_2}$.)

4. Let G be simple of order 60. Prove $G \cong A_5$. (Show $n_2 = 5$, build a transitive action on 5 points giving an injection $G \hookrightarrow S_5$ with image in A_5, then compare orders.)

5. Let $P \in \mathrm{Syl}_p(G)$ be a central Sylow subgroup (i.e. $P \le Z(G)$). Prove that P has a normal complement in G (Burnside normal p-complement, special case).

6. Suppose $|G| = p^a m$ with $a \ge 2$ and $n_p > 1$. Show that the Sylow p-subgroups need not contain $n_p(p^a - 1)$ distinct nonidentity elements (distinct ones may intersect nontrivially), but that distinct Sylow p-subgroups P, Q with $|P \cap Q| = p^{a-1}$ force $N_G(P \cap Q)$ to contain at least two Sylow subgroups; use this to sharpen nonsimplicity arguments when Sylow subgroups intersect nontrivially.

Commutative-diagram exercises.

1. Let G act on $\mathrm{Syl}_p(G)$ by conjugation, giving a homomorphism $\rho\colon G \to \mathrm{Sym}(\mathrm{Syl}_p(G))$. For $P \in \mathrm{Syl}_p(G)$ identify the stabilizer and complete the orbit-stabilizer isomorphism in the diagram

$$G/N_G(P) \xrightarrow[gN_G(P) \mapsto gPg^{-1}]{\sim} \mathrm{Orb}(P).$$

   Explain why ρ is transitive (Sylow II) and hence $\operatorname{im}\rho$ acts transitively on $\mathrm{Syl}_p(G)$.

2. For the left-multiplication action of G on the cosets G/P (where $P \in \mathrm{Syl}_p(G)$), the permutation representation $\rho\colon G \to \mathrm{Sym}(G/P)$ has kernel the largest normal subgroup of G contained in P. Fill in and justify the factorization

$$\begin{array}{ccc} G & \xrightarrow{\ \rho\ } & \mathrm{Sym}(G/P) \\ \downarrow & \nearrow & \\ G/\ker\rho & & \end{array}$$

   and use $[G : P] = m$ to bound $|G/\ker\rho|$, deducing nonsimplicity when $m > 1$ and $|G| \nmid m!$.

3. Let $P \trianglelefteq G$ be the unique Sylow p-subgroup. Show the conjugation action gives a homomorphism $\psi\colon G \to \mathrm{Aut}(P)$ and identify $\ker\psi = C_G(P)$. Complete the exact sequence

$$1 \longrightarrow C_G(P) \longhookrightarrow G \xrightarrow{\ \psi\ } \mathrm{Aut}(P)$$

   and explain when ψ is surjective for G of order pq ($q < p$, $q \mid p - 1$).

4. (Frattini diagram) Let $H \trianglelefteq G$ and $P \in \mathrm{Syl}_p(H)$. Using $G = N_G(P)H$, complete the isomorphism in

$$N_G(P)/(N_G(P) \cap H) \xrightarrow{\ \sim\ } G/H$$

   by the second isomorphism theorem, and explain how this transfers a p-group quotient structure from G/H to $N_G(P)$.

5. Let G be simple of order 60 with $n_2 = 5$. The conjugation action on $\mathrm{Syl}_2(G)$ gives $\rho\colon G \to S_5$. Show ρ is injective and lands in A_5 by completing

$$\begin{array}{ccc} G & \xhookrightarrow{\ \rho\ } & S_5 \\ & {\scriptstyle \mathrm{sgn}\circ\rho}\searrow & \downarrow{\scriptstyle \mathrm{sgn}} \\ & & \{\pm 1\} \end{array}$$

   arguing $\mathrm{sgn}\circ\rho$ is trivial because G is simple, hence $\operatorname{im}\rho \le A_5$.

4.6 The Simplicity of A_n

Simplicity of A_5 and A_n $(n \geq 5)$

A nontrivial group G is *simple* if its only normal subgroups are $\{1\}$ and G. The abelian simple groups are exactly the $\mathbb{Z}/p\mathbb{Z}$ (p prime). The first nonabelian simple group is A_5, of order 60. This section proves A_5 is simple by a counting argument on its conjugacy classes, then states the general fact that A_n is simple for every $n \geq 5$.

The engine of every such argument is the following observation: a normal subgroup is a *union of conjugacy classes*. Indeed if $N \trianglelefteq G$ and $x \in N$, then $gxg^{-1} \in N$ for all $g \in G$, so the entire class of x lies in N. Conversely N is closed under conjugation. Hence:

$$N \trianglelefteq G \quad \Longleftrightarrow \quad N \text{ is a subgroup that is a union of conjugacy classes of } G.$$

Since $1 \in N$ always, $|N|$ must be a sum of class sizes *one of which is the class* $\{1\}$, and $|N|$ must divide $|G|$ by Lagrange. If no such sum (other than 1 and $|G|$) divides $|G|$, then G is simple.

Definition 4.6.1 (Simple group)**.** A group $G \neq \{1\}$ is *simple* if its only normal subgroups are $\{1\}$ and G.

Conjugacy in A_n: the splitting criterion

In S_n, two permutations are conjugate iff they have the same cycle type. Inside A_n a single S_n-class can either stay one A_n-class or split into two equal halves. The deciding mechanism: the S_n-class of σ has size $|S_n|/|C_{S_n}(\sigma)|$, and its A_n-class has size $|A_n|/|C_{A_n}(\sigma)|$. Since $|S_n| = 2|A_n|$,

$$\frac{|S_n\text{-class}|}{|A_n\text{-class}|} = \frac{|S_n|}{|A_n|} \cdot \frac{|C_{A_n}(\sigma)|}{|C_{S_n}(\sigma)|} = 2 \cdot \frac{|C_{A_n}(\sigma)|}{|C_{S_n}(\sigma)|}.$$

Now $C_{A_n}(\sigma) = C_{S_n}(\sigma) \cap A_n$ has index 1 or 2 in $C_{S_n}(\sigma)$, so the ratio is 1 (no split) or 2 (split).

Proposition 4.6.2 (Splitting criterion in A_n)**.** *Let $\sigma \in A_n$ with S_n-conjugacy class K. Then:*

(a) If $C_{S_n}(\sigma) \not\subseteq A_n$ (i.e. some *odd permutation commutes with σ), then K is a single A_n-class.*

(b) If $C_{S_n}(\sigma) \subseteq A_n$ (i.e. every *permutation commuting with σ is even), then K splits into two A_n-classes of equal size $|K|/2$.*

Concretely, K splits iff the cycle type of σ consists of distinct odd-length cycles *(each part odd, no part repeated, fixed points counting as* 1*-cycles).*

Proof. The S_n-class K is one orbit under conjugation by S_n; the A_n-classes inside it are the orbits under conjugation by A_n. Pick $\sigma \in K$. By the orbit-stabilizer relation, A_n acts transitively on K iff $A_n \cdot C_{S_n}(\sigma) = S_n$, i.e. iff $C_{S_n}(\sigma) \not\subseteq A_n$; in that case K is a single A_n-class. If instead $C_{S_n}(\sigma) \subseteq A_n$, then $A_n\, C_{S_n}(\sigma) = A_n$ has index 2 in S_n, giving two A_n-orbits; since $C_{A_n}(\sigma) = C_{S_n}(\sigma)$, their common size is

$$[A_n : C_{A_n}(\sigma)] = [A_n : C_{S_n}(\sigma)] = \tfrac{1}{2}[S_n : C_{S_n}(\sigma)] = \tfrac{1}{2}|K|.$$

For the concrete criterion: $C_{S_n}(\sigma)$ is generated by the individual cycles of σ together with permutations swapping cycles of equal length. A cycle of length ℓ is itself an ℓ-cycle, which is odd as a permutation exactly when ℓ is even. A swap of two cycles of the same length ℓ (matching their entries in order) is a product of ℓ transpositions, hence odd when ℓ is odd. So $C_{S_n}(\sigma) \subseteq A_n$ forces every cycle to have odd length and no two cycles to share a length, i.e. distinct odd parts; conversely with distinct odd parts the centralizer is the abelian group generated by the cycles, all even, so $C_{S_n}(\sigma) \subseteq A_n$. □

Method (Counting conjugacy classes of A_n)**.** *Trigger.* You need the class sizes of A_n (e.g. to test simplicity). *Recipe.*

1. List the cycle types appearing in A_n (even permutations only: an ℓ-cycle is even iff ℓ is odd, so a permutation is even iff total length minus number of cycles is even).

2. For each type compute the S_n-class size $\dfrac{n!}{\prod_i \ell_i \cdot \prod_\ell m_\ell!}$ where m_ℓ is the number of ℓ-cycles.

3. Apply Proposition 4.6.2: the type *splits* into two halves iff its parts are *distinct and all odd*; otherwise it stays one class.

4. Sanity check: the class sizes sum to $|A_n| = n!/2$, and every class size divides $|A_n|$.

A_5 is simple

Theorem 4.6.3 (Simplicity of A_5)**.** *A_5 is a simple group of order 60.*

Proof. We use the conjugacy classes of A_5. The even permutations on 5 symbols have cycle types 1^5 (identity), $2^2 1$ (double transpositions), $3\,1^2$ (3-cycles), and 5 (5-cycles). We compute each S_5-class size and apply Proposition 4.6.2.

Identity: one element, class size 1.

Double transpositions $(ab)(cd)$: number $= \frac{1}{2}\binom{5}{2}\binom{3}{2} = \frac{1}{2}\cdot 10 \cdot 3 = 15$. Type $2^2 1$ has a repeated part (two 2-cycles), so by Proposition 4.6.2 it does *not* split: one A_5-class of size 15.

3-cycles (abc): number $= \dfrac{5\cdot 4\cdot 3}{3} = 20$. Type $3\,1^2$ has a repeated part (two fixed points, i.e. two 1-cycles), so it does *not* split: one A_5-class of size 20.

5-cycles $(abcde)$: number $= \dfrac{5!}{5} = 24$. Type 5 has distinct odd parts (a single 5-cycle, all parts odd, none repeated), so by Proposition 4.6.2 it *splits* into two A_5-classes of size 12 each.

Thus the conjugacy classes of A_5 have sizes

$$1, \quad 15, \quad 20, \quad 12, \quad 12, \qquad 1+15+20+12+12 = 60 = |A_5|. \ \blacksquare$$

Now suppose $N \trianglelefteq A_5$. Then N is a union of these classes including $\{1\}$, so $|N|$ is a sum of a subcollection of $\{1, 15, 20, 12, 12\}$ that includes the summand 1. Moreover $|N|$ must divide 60. The possible sums including 1 are:

$$1,\ 1+12=13,\ 1+12+12=25,\ 1+15=16,\ 1+20=21,\ 1+15+12=28,$$
$$1+20+12=33,\ 1+15+20=36,\ 1+15+12+12=40,\ 1+20+12+12=45,$$
$$1+15+20+12=48,\ 1+15+20+12+12=60.$$

Of these, the only divisors of 60 are 1 and 60. (Check the rest: $13, 16, 21, 25, 28, 33, 36, 40, 45, 48$ are none of $1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, 60$.) Hence $N = \{1\}$ or $N = A_5$, and A_5 is simple. □

Caution. The two classes of 5-cycles are *genuinely distinct in A_5*: e.g. $(1\,2\,3\,4\,5)$ and $(1\,3\,5\,2\,4) = (1\,2\,3\,4\,5)^2$ are not conjugate by any even permutation, though they are conjugate in S_5 (by the odd permutation $(2\,3\,5\,4)$, which checks: $(2\,3\,5\,4)(1\,2\,3\,4\,5)(2\,3\,5\,4)^{-1} = (1\,3\,5\,2\,4)$). Forgetting the split and lumping the 5-cycles into a single class of 24 is simply wrong: the A_5-class of a 5-cycle has size 12, not 24. Always apply the splitting criterion before reading off class sizes.

Method (Proving a specific group is simple by class sizes)**.** *Trigger.* A finite group G whose conjugacy-class sizes you can list.
Recipe.

1. Compute all class sizes; verify they sum to $|G|$.

2. A normal subgroup has order = (a sub-sum of class sizes that *includes the class* $\{1\}$) and that order must divide $|G|$ (Lagrange).

3. Enumerate sub-sums containing 1; check which divide $|G|$.

4. If only 1 and $|G|$ survive, G is simple.

Why it works: $N \trianglelefteq G \implies N$ is a union of classes; $1 \in N$; $|N| \mid |G|$.

Worked Example 4.6.4 (The conjugacy classes of A_5 and their sizes)**.** List the conjugacy classes of A_5 with sizes, and confirm the 5-cycles split into two classes of 12.

Recognition. Two even permutations are A_5-conjugate iff they are S_5-conjugate (same cycle type), *provided* the type does not satisfy the splitting criterion; a type with distinct odd parts splits into two halves (Proposition 4.6.2).

Solution. Even cycle types on 5 points: 1^5, 2^21, $3\,1^2$, 5.

- 1^5: identity, size 1.
- 2^21: $\frac{1}{2}\binom{5}{2}\binom{3}{2} = \frac{1}{2}(10)(3) = 15$. Repeated part $\Rightarrow$ no split: size 15.
- $3\,1^2$: $\frac{5\cdot4\cdot3}{3} = 20$. Repeated 1-cycles $\Rightarrow$ no split: size 20.
- 5: $\frac{120}{5} = 24$. Distinct odd parts $\Rightarrow$ splits into $12 + 12$.

Splitting check via centralizers: for $\sigma = (1\,2\,3\,4\,5)$, $|C_{S_5}(\sigma)| = 120/24 = 5$, generated by σ itself, which is even, so $C_{S_5}(\sigma) = \langle\sigma\rangle \subseteq A_5$. By Proposition 4.6.2(b) the class splits, each half of size $\frac{1}{2}\cdot 24 = 12$.

Check. $1 + 15 + 20 + 12 + 12 = 60 = |A_5|$. ■ Each size divides 60? $1, 12, 15, 20 \mid 60$. ■

Worked Example 4.6.5 (No proper normal subgroup from the class sizes)**.** Using sizes $1, 15, 20, 12, 12$, show A_5 has no normal subgroup of order strictly between 1 and 60.

Recognition. A normal subgroup's order is a sum of class sizes that includes the summand 1, and the order must divide $|G|$.

Solution. Any $N \trianglelefteq A_5$ satisfies $|N| = 1 +$ (a sub-sum of $\{15, 20, 12, 12\}$) and $|N| \mid 60$. The proper-nontrivial candidate orders dividing 60 are

$$2, 3, 4, 5, 6, 10, 12, 15, 20, 30.$$

Now the smallest nonidentity class is 12, so any $N \neq \{1\}$ has $|N| \geq 1 + 12 = 13$. That already kills $2, 3, 4, 5, 6, 10, 12$. For the remaining candidates we must realize $|N| - 1$ as a sub-sum of $\{15, 20, 12, 12\}$:

$$15 \text{ needs the sub-sum } 14: \text{ impossible.} \qquad 20 \text{ needs } 19: \text{ impossible.}$$

$$30 \text{ needs } 29: \text{ impossible. The nonzero sub-sums of } \{15, 20, 12, 12\} \text{ are}$$
$$12,\ 15,\ 20,\ 24,\ 27,\ 32,\ 35,\ 39,\ 44,\ 47,\ 59.$$

No candidate is realizable, so $N = \{1\}$ or A_5.

Check. The realizable sums containing 1 are $1, 13, 16, 21, 25, 28, 33, 36, 40, 45, 48, 60$; intersect with divisors of 60 to get $\{1, 60\}$. ■

Worked Example 4.6.6 (A normal subgroup of A_5 containing a 3-cycle is everything)**.** Show that if $N \trianglelefteq A_5$ contains one 3-cycle, then $N = A_5$ — an alternate route to simplicity.

Recognition. All 3-cycles are conjugate in A_n for $n \geq 5$ (the 3-cycle type does not split when $n \geq 5$, as it has ≥ 2 fixed points), so a normal subgroup containing one contains all; and 3-cycles generate A_n.

Solution. In A_5, the type $3\,1^2$ has two fixed points (a repeated part), so by Proposition 4.6.2 it forms a single class of 20 elements. If $N \trianglelefteq A_5$ contains a 3-cycle, normality forces N to contain the whole class: all 20 three-cycles. Hence $|N| \geq 1 + 20 = 21$. Combined with $|N| \mid 60$, the only divisor of 60 that is ≥ 21 and realizable is $|N| = 60$ (the divisor 30 would require $29 = 20 + 9$, i.e. a sub-sum 9 of $\{15, 12, 12\}$ after using $1 + 20$, which is impossible). Therefore $N = A_5$.

Alternatively, 3-cycles generate A_5 (Lemma 4.6.8), so $N \supseteq \langle\text{3-cycles}\rangle = A_5$ directly.

Check. A_5 contains 20 three-cycles; e.g. $(1\,2\,3), (1\,3\,2), (1\,2\,4), \ldots$; $\frac{5\cdot4\cdot3}{3} = 20$. ■

Worked Example 4.6.7 (The Klein four candidate is not normal)**.** The double transpositions plus identity, $\{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\}$, form a subgroup $V \cong V_4$ of A_5. Show V is *not* normal in A_5, consistent with simplicity.

Recognition. $N \trianglelefteq A_5 \implies N$ is a union of full conjugacy classes; the double-transposition class has size 15, so no 4-element subset of it can be a union of classes.

Solution. V has order 4. For V to be normal it would have to be a union of conjugacy classes containing $\{e\}$. The only nonidentity elements of V are double transpositions, which all lie in the single A_5-class of size 15. A union of classes containing any double transposition must contain all 15 of them, but V contains only 3. Hence V is not a union of classes, so $V \not\trianglelefteq A_5$. (Concretely, conjugating $(1\,2)(3\,4)$ by $(1\,2\,5) \in A_5$ gives $(2\,5)(3\,4) \notin V$.)

Check. $(1\,2\,5)(1\,2)(3\,4)(1\,2\,5)^{-1}$ relabels each point by $1 \mapsto 2, 2 \mapsto 5, 5 \mapsto 1$ (and fixes $3, 4$), so $(1\,2) \mapsto (2\,5)$ and $(3\,4) \mapsto (3\,4)$, giving $(2\,5)(3\,4) \notin V$. ■

3-cycles generate A_n

Lemma 4.6.8 (3-cycles generate A_n)**.** *For $n \geq 3$, $A_n = \langle\, 3\text{-cycles} \,\rangle$.*

Proof. Every element of A_n is a product of an even number of transpositions. It suffices to show a product of two transpositions is a product of 3-cycles. Two cases for $(a\,b)(c\,d)$:

- Share a point: $(a\,b)(a\,c) = (a\,c\,b)$, already a 3-cycle.
- Disjoint: insert $(b\,c)(b\,c) = 1$ to get

$$(a\,b)(c\,d) = (a\,b)\,(b\,c)\cdot(b\,c)\,(c\,d) = (a\,b\,c)\,(b\,c\,d),$$

  using $(a\,b)(b\,c) = (a\,b\,c)$ and $(b\,c)(c\,d) = (b\,c\,d)$ — a product of two 3-cycles.

Since A_n is generated by such pairs, it is generated by 3-cycles. □

Method (Reducing an even permutation to 3-cycles)**.** *Trigger.* You must express something in A_n via 3-cycles, or show a subgroup containing all 3-cycles is A_n.
Recipe.

1. Write the permutation as a product of transpositions (even count, since it's in A_n).
2. Pair the transpositions. For a pair sharing a point use $(a\,b)(a\,c) = (a\,c\,b)$.
3. For a disjoint pair $(a\,b)(c\,d)$, insert $(b\,c)(b\,c) = 1$ to split into two overlapping pairs $= (a\,b\,c)(b\,c\,d)$.

Sanity check. Verify the resulting product on a couple of points (evaluating right-to-left).

Worked Example 4.6.9 (Writing a specific even permutation as 3-cycles)**.** Express $(1\,2)(3\,4) \in A_4$ as a product of 3-cycles.

Recognition. Disjoint transposition pair; insert $(2\,3)(2\,3) = 1$ and use $(a\,b)(b\,c) = (a\,b\,c)$ (Lemma 4.6.8).

Solution. Apply the disjoint case of Lemma 4.6.8 with $a = 1, b = 2, c = 3, d = 4$:

$$(1\,2)(3\,4) = (1\,2)\,(2\,3)\cdot(2\,3)\,(3\,4) = (1\,2\,3)\,(2\,3\,4).$$

Check. Evaluate $(1\,2\,3)(2\,3\,4)$ right-to-left:

$$1 \xrightarrow{(2\,3\,4)} 1 \xrightarrow{(1\,2\,3)} 2, \quad 2 \xrightarrow{(2\,3\,4)} 3 \xrightarrow{(1\,2\,3)} 1, \quad 3 \xrightarrow{(2\,3\,4)} 4 \xrightarrow{(1\,2\,3)} 4, \quad 4 \xrightarrow{(2\,3\,4)} 2 \xrightarrow{(1\,2\,3)} 3.$$

So $1 \mapsto 2$, $2 \mapsto 1$, $3 \mapsto 4$, $4 \mapsto 3$, i.e. $(1\,2)(3\,4)$. ■ Thus $(1\,2)(3\,4) = (1\,2\,3)(2\,3\,4)$.

Caution. Cycle products must be evaluated *right-to-left* (our convention), and orientation matters: $(a\,b)(b\,c) = (a\,b\,c)$ while $(a\,b)(a\,c) = (a\,c\,b)$. When you derive a factorization symbolically, always re-verify by tracking each point through the final product. For instance $(1\,2)(3\,4) = (1\,2\,3)(2\,3\,4)$, confirmed point-by-point above.

A_n is simple for all $n \geq 5$

Theorem 4.6.10 (Simplicity of A_n, $n \geq 5$)**.** *For every $n \geq 5$, the alternating group A_n is simple.*

Sketch. We outline the standard two-step argument; the base case $n = 5$ is Theorem 4.6.3.

Step 1 (a normal subgroup containing a 3-cycle is everything). For $n \geq 5$ all 3-cycles are conjugate in A_n: given $(a\,b\,c)$ and $(d\,e\,f)$, choose $\tau \in S_n$ with $\tau(a\,b\,c)\tau^{-1} = (d\,e\,f)$; if τ is odd, multiply it by a transposition $(x\,y)$ disjoint from $\{d, e, f\}$ (available since $n \geq 5$), which fixes $(d\,e\,f)$ and flips parity, yielding an even conjugator. Hence if $N \trianglelefteq A_n$ contains one 3-cycle it contains all of them, so by Lemma 4.6.8 $N \supseteq \langle 3\text{-cycles}\rangle = A_n$, i.e. $N = A_n$.

Step 2 (every nontrivial $N \trianglelefteq A_n$ contains a 3-cycle). Let $N \trianglelefteq A_n$ with $N \neq \{1\}$ and pick $1 \neq \sigma \in N$ with a maximal number of fixed points. One shows σ must be a 3-cycle by the *commutator trick*: if not, then σ moves at least 4 points (one analyzes its cycle structure into the cases "σ has a cycle of length ≥ 3" and "σ is a product of disjoint 2-cycles"). In each case choose a suitable 3-cycle τ and form

$$\sigma' \;=\; \sigma\,(\tau\sigma\tau^{-1})^{-1} \;=\; \sigma\,\tau\sigma^{-1}\tau^{-1} \in N$$

(which lies in N since $\tau\sigma^{-1}\tau^{-1} \in N$ by normality and $\sigma \in N$). A direct count shows $\sigma' \neq 1$ but σ' fixes *more* points than σ, contradicting maximality — unless σ was already a 3-cycle. Hence N contains a 3-cycle.

Combining Steps 1 and 2: any $N \trianglelefteq A_n$ with $N \neq \{1\}$ contains a 3-cycle (Step 2), hence equals A_n (Step 1). Therefore A_n is simple. □

Remark 4.6.1. The hypothesis $n \geq 5$ is essential. A_4 is *not* simple: its subgroup

$$V = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\} \cong V_4$$

has order $4 \mid 12$ and is closed under A_4-conjugation (the three double transpositions form a single A_4-class of size 3, and $3 + 1 = 4 = |V|$), so $V \trianglelefteq A_4$. The argument above fails at $n = 4$ precisely because in Step 1 there is no transposition disjoint from a given 3-cycle's support, and the double transpositions close up into a proper normal subgroup.

Method (Showing every nontrivial $N \trianglelefteq A_n$ contains a 3-cycle (commutator trick))**.** *Trigger.* Proving A_n ($n \geq 5$) simple, Step 2.
Recipe.

1. Pick $1 \neq \sigma \in N$ moving the fewest points.
2. Choose a 3-cycle τ overlapping the support of σ cleverly; form $\sigma' = \sigma\,\tau\sigma^{-1}\tau^{-1} \in N$ (in N by normality).
3. Show $\sigma' \neq 1$ yet σ' fixes strictly more points than σ.
4. Minimality forces σ to already be a 3-cycle.

Check. A 3-cycle on $n \geq 5$ points fixes $n - 3 \geq 2$ points; the trick can only terminate at one.

Worked Example 4.6.11 (All 3-cycles are conjugate in A_5)**.** Find an *even* permutation conjugating $(1\,2\,3)$ to $(1\,2\,4)$ in A_5.

Recognition. In A_n ($n \geq 5$) all 3-cycles are conjugate; if the natural conjugator is odd, fix it up with a transposition disjoint from the target's support (Step 1 of Theorem 4.6.10).

Solution. A transposition τ with $\tau(1\,2\,3)\tau^{-1} = (\tau 1\,\tau 2\,\tau 3)$ equal to $(1\,2\,4)$: take $\tau = (3\,4)$, since $(3\,4)(1\,2\,3)(3\,4) = (1\,2\,4)$. But $(3\,4)$ is odd. Multiply by a transposition disjoint from $\{1, 2, 4\}$, namely $(3\,5)$: set $g = (3\,5)(3\,4)$. Then g is even, and since $(3\,5)$ fixes $(1\,2\,4)$ pointwise,

$$g(1\,2\,3)g^{-1} = (3\,5)\big[(3\,4)(1\,2\,3)(3\,4)\big](3\,5)^{-1} = (3\,5)(1\,2\,4)(3\,5) = (1\,2\,4).$$

And $g = (3\,5)(3\,4) = (3\,4\,5)$, a 3-cycle, certainly even.

Check. $(3\,4\,5)(1\,2\,3)(3\,4\,5)^{-1}$ relabels via $3 \mapsto 4, 4 \mapsto 5, 5 \mapsto 3$, so $(1\,2\,3) \mapsto (1\,2\,4)$. ■ g even (3-cycle). ■

Worked Example 4.6.12 (The commutator trick lands on a 3-cycle ($n = 5$, one case)). Let $\sigma = (1\,2\,3\,4\,5) \in A_5$ and $\tau = (1\,2\,3)$. Compute the commutator $\sigma' = \sigma\,\tau\sigma^{-1}\tau^{-1}$ and observe it is a 3-cycle (more fixed points than σ).

Recognition. The commutator $\sigma\tau\sigma^{-1}\tau^{-1}$ of an element with a chosen 3-cycle lands in any $N \trianglelefteq A_n$ containing σ, and (with a good τ) fixes more points (Step 2 method).

Solution. $\sigma = (1\,2\,3\,4\,5)$, $\sigma^{-1} = (1\,5\,4\,3\,2)$, $\tau = (1\,2\,3)$, $\tau^{-1} = (1\,3\,2)$. Compute $\sigma\tau\sigma^{-1} = (\sigma 1\,\sigma 2\,\sigma 3) = (2\,3\,4)$. Then

$$\sigma' = (\sigma\tau\sigma^{-1})\,\tau^{-1} = (2\,3\,4)(1\,3\,2).$$

Evaluate right-to-left: $1 \xrightarrow{(1\,3\,2)} 3 \xrightarrow{(2\,3\,4)} 4$ so $1 \mapsto 4$; $3 \xrightarrow{(1\,3\,2)} 2 \xrightarrow{(2\,3\,4)} 3$ so $3 \mapsto 3$ (fixed); $2 \xrightarrow{(1\,3\,2)} 1 \xrightarrow{(2\,3\,4)} 1$ so $2 \mapsto 1$; $4 \xrightarrow{(1\,3\,2)} 4 \xrightarrow{(2\,3\,4)} 2$ so $4 \mapsto 2$; $5 \mapsto 5$. Result: $1 \mapsto 4, 4 \mapsto 2, 2 \mapsto 1$, i.e. $(1\,4\,2)$, a 3-cycle.

Check. $\sigma' = (1\,4\,2)$ fixes 3 and 5 (two fixed points) versus σ which fixes none — strictly more fixed points, as the trick predicts. ■ And σ' is a 3-cycle, so any $N \trianglelefteq A_5$ containing σ contains a 3-cycle, hence all of A_5. ■

Worked Example 4.6.13 ($|A_5| = 60$ is the smallest order of a nonabelian simple group). Verify $|A_5| = 60$ and sketch, via Sylow counting, why a simple group of order 60 must be A_5 and why no nonabelian simple group has smaller order.

Recognition. Sylow obstruction: a nonabelian simple group cannot have a normal Sylow p-subgroup ($n_p \equiv 1 \pmod p$, $n_p \mid m$); for composite orders below 60 these constraints, with element counting, the action on the Sylow subgroups, or the nontrivial center of a p-group, rule out every nonabelian simple group, though they do not always produce a normal Sylow subgroup (S_4 has $n_2 = 3$, $n_3 = 4$).

Solution. $|A_5| = 5!/2 = 60 = 2^2 \cdot 3 \cdot 5$. Suppose G is simple of order 60. By Sylow, $n_5 \mid 12$ and $n_5 \equiv 1 \pmod 5$, so $n_5 \in \{1, 6\}$; simplicity forbids $n_5 = 1$ (that would be a normal Sylow 5-subgroup), so $n_5 = 6$, giving $6 \cdot 4 = 24$ elements of order 5. Likewise $n_3 \mid 20$ and $n_3 \equiv 1 \pmod 3$, so $n_3 \in \{1, 4, 10\}$, with $n_3 = 1$ forbidden. If $n_3 = 10$ that is $10 \cdot 2 = 20$ elements of order 3; then $24 + 20 + 1 = 45$ elements are accounted for, leaving 15 for 2-power order, and a closer count (with $n_2 \mid 15$, n_2 odd, so $n_2 \in \{1, 3, 5, 15\}$) forces $n_2 = 5$; the action of G on its 5 Sylow 2-subgroups embeds $G \hookrightarrow S_5$ with image A_5. (The case $n_3 = 4$ is handled similarly by a Sylow normalizer count.) Thus the only simple group of order 60 is A_5.

Check. 24 (order 5) + 20 (order 3) + 1 = 45 ≤ 60, leaving 15 for 2-power order. ■ $|A_5| = 60$, and every group of composite order below 60 has a nontrivial proper normal subgroup by similar arguments (not always a normal Sylow subgroup, e.g. S_4), so A_5 is the smallest nonabelian simple group. ■

Remark 4.6.2 (The class equation, summarized). The class equation of A_5 is

$$60 = |A_5| = |Z(A_5)| + \sum_{\text{noncentral classes}} [A_5 : C_{A_5}(x_i)] = 1 + 15 + 20 + 12 + 12.$$

Since $Z(A_5) = \{1\}$ (the center is normal, hence trivial or all of A_5; as A_5 is nonabelian it is trivial), the leading term is 1. Simplicity is exactly the statement that no submultiset of $\{15, 20, 12, 12\}$ adjoined to 1 gives a proper divisor of 60.

Exercises (from the text).

1. Prove that A_n does not have a proper subgroup of index $< n$ for all $n \geq 5$.
2. Find all normal subgroups of S_n for all $n \geq 5$.
3. Prove that A_n is the only proper subgroup of index $< n$ in S_n for all $n \geq 5$.
4. Prove that A_n is generated by the set of all 3-cycles for each $n \geq 3$.
5. Prove that if there exists a chain of subgroups $G_1 \leq G_2 \leq \cdots \leq G$ such that $G = \bigcup_{i=1}^{\infty} G_i$ and each G_i is simple then G is simple.
6. Let Ω be an infinite set and let D be the subgroup of S_Ω consisting of permutations which move only a finite number of elements of Ω (described in Exercise 17 in Section 3) and let A be the set of all elements $\sigma \in D$ such that σ acts as an even permutation on the (finite) set of points it moves. Prove that A is an infinite simple group. [Show that every pair of elements of D lie in a finite simple subgroup of D.]

7. Under the notation of the preceding, exercise prove that if $H \trianglelefteq S_\Omega$ and $H \neq 1$ then $A \leq H$, i.e., A is the unique (nontrivial) minimal normal subgroup of S_Ω.

8. Under the notation of the preceding two exercises prove that $|D| = |A| = |\Omega|$. Deduce that

$$\text{if } S_\Omega \cong S_\Delta \text{ then } |\Omega| = |\Delta|.$$

[Use the fact that D is generated by transpositions. You may assume that countable unions and finite direct products of sets of cardinality $|\Omega|$ also have cardinality $|\Omega|$.]

Practice problems.

1. Verify directly that the four conjugates of the 3-cycle $(1\,2\,3)$ under elements of A_4 are exactly $(1\,2\,3), (1\,3\,4), (1\,4\,2), (2\,4\,3)$, and that the remaining four 3-cycles form the conjugacy class of $(1\,3\,2)$ in A_4. Conclude that the 3-cycles in A_4 split into two A_4-classes of size 4.

2. Compute the class equation of A_4. Use it together with the divisors of 12 to prove that A_4 has no subgroup of order 6.

3. Exhibit explicitly the conjugacy classes of A_5 by listing a representative of each, giving its cycle type and the size of its A_5-class. (Classes: id, size 1; 3-cycles, size 20; double transpositions, size 15; and the two classes of 5-cycles, each of size 12.) Verify that the four nontrivial class sizes are 20, 15, 12, 12.

4. Using the class equation $60 = 1 + 15 + 20 + 12 + 12$ for A_5, prove that A_5 is simple by checking that no union of classes containing $\{\mathrm{id}\}$, other than $\{\mathrm{id}\}$ and A_5 itself, has order dividing 60.

5. Let $H \trianglelefteq A_5$. Show that H is a union of conjugacy classes of A_5 and use the previous problem to conclude $H = 1$ or $H = A_5$.

6. Show that for $n \geq 5$ every two 3-cycles are conjugate in A_n. (Reduce to showing $(1\,2\,3)$ is conjugate to $(a\,b\,c)$ by an even permutation.)

7. Prove that A_n is generated by 3-cycles for all $n \geq 3$ by writing a product of two transpositions as a product of 3-cycles in the two cases (disjoint / sharing one point).

8. Let $N \trianglelefteq A_n$ with $n \geq 5$, and suppose N contains a 3-cycle. Prove $N = A_n$. (Combine the previous two problems.)

9. Compute $|C_{A_5}((1\,2\,3))|$ and $|C_{A_5}((1\,2\,3\,4\,5))|$ via orbit-stabilizer applied to the conjugation action, and check your answers against the class sizes 20 and 12.

10. Determine $\mathrm{Aut}(A_5)$ up to its order. Using $A_5 \trianglelefteq S_5$ and that conjugation by S_5 induces automorphisms, show $S_5 \hookrightarrow \mathrm{Aut}(A_5)$; granting $|\mathrm{Aut}(A_5)| = 120$, conclude $\mathrm{Aut}(A_5) \cong S_5$.

11. Show that S_n has exactly three normal subgroups for $n \geq 5$, namely $1,\ A_n,\ S_n$. (Use simplicity of A_n and the fact $[S_n : A_n] = 2$.)

12. Let G act on itself by conjugation. For $G = A_5$, compute the number of orbits (conjugacy classes) and verify the orbit sizes sum to 60.

13. Count the Sylow 5-subgroups of A_5: show $n_5 \equiv 1 \pmod 5$ and $n_5 \mid 12$, then use the number of 5-cycles to pin down $n_5 = 6$. Deduce $|N_{A_5}(P)| = 10$ for a Sylow 5-subgroup P.

14. Count the Sylow 2-subgroups and Sylow 3-subgroups of A_5. Show $n_3 = 10$ and $n_2 = 5$, and identify $N_{A_5}(P)$ in each case: $|N_{A_5}(P)| = 6$ when P is a Sylow 3-subgroup and $|N_{A_5}(P)| = 12$ when P is a Sylow 2-subgroup.

15. Prove that A_5 has no subgroup of order 15, 20, or 30. (For 30, such a subgroup would be normal of index 2, contradicting simplicity.)

16. Show that A_6 has an outer automorphism: exhibit two conjugacy classes of subgroups isomorphic to A_5 in A_6 (point stabilizers vs. a transitive A_5), which no inner automorphism can interchange; then let A_6 act on the six left cosets of a transitive A_5 and show that the resulting automorphism of A_6 carries this A_5 to a point stabilizer, so it is not inner.

Additional exercises.

1. Prove the general simplicity theorem: A_n is simple for all $n \geq 5$. Use induction on n, the fact that A_n is generated by 3-cycles, and that a normal subgroup containing one 3-cycle contains all of them.
2. Let G be a simple group of order 60. Prove $G \cong A_5$. (Show G has a subgroup of index 5 by Sylow counting, get $G \hookrightarrow S_5$, and identify the image with A_5.)
3. Show that A_5 is the unique nonabelian simple group of order at most 100. (Rule out the other orders by Sylow and counting arguments.)
4. Prove that $A_6 \cong \mathrm{PSL}_2(\mathbb{F}_9)$ has order 360 and is simple, and exhibit its class equation $360 = 1 + 40 + 45 + 40 + 90 + 72 + 72$. Verify the orbit sizes are exactly the indices of the corresponding centralizers.
5. Let $n \geq 5$. Prove that the only normal subgroups of $A_n \times A_n$ are 1, $A_n \times 1$, $1 \times A_n$, $A_n \times A_n$, and the diagonal-type subgroups arise only when an isomorphism between factors is present. (Use simplicity of each factor.)
6. Show that the commutator subgroup of S_n is A_n for all $n \geq 2$, and that the commutator subgroup of A_n is A_n itself for $n \geq 5$ (i.e. A_n is perfect).

Commutative-diagram exercises.

1. The conjugation action of A_5 on itself gives a homomorphism with image $\mathrm{Inn}(A_5)$. Fill in and justify each arrow of

$$1 \longrightarrow Z(A_5) \hookrightarrow A_5 \xrightarrow{\text{conj}} \mathrm{Aut}(A_5) \twoheadrightarrow \mathrm{Out}(A_5) \longrightarrow 1$$

   Show $Z(A_5) = 1$, identify $\mathrm{Inn}(A_5)$ with A_5, and determine $\mathrm{Out}(A_5)$.

2. For the conjugation action of A_5 on the set A of its six Sylow 5-subgroups, write the permutation representation and the orbit-stabilizer isomorphism:

$$A_5 \xrightarrow{\rho} \mathrm{Sym}(A) \qquad A_5/N_{A_5}(P) \xrightarrow[\sim]{gN \mapsto g\cdot P} \mathrm{orb}(P)$$

   Show ρ is injective (so $A_5 \hookrightarrow S_6$), compute $|\mathrm{orb}(P)|$, and conclude $\mathrm{im}\,\rho \leq A_6$.

3. Let $G = A_5$ act on the 5 points by the natural action. Identify the point stabilizer and complete

$$\mathrm{Stab}_{A_5}(1) \hookrightarrow A_5 \xrightarrow{\rho} \mathrm{Sym}(\{1, \ldots, 5\})$$

   explaining why $\ker \rho = 1$ and why $\mathrm{Stab}_{A_5}(1) \cong A_4$.

4. Realize the exceptional isomorphism via the action of A_5 on the six pairs of antipodal vertices of an icosahedron, giving a map $A_5 \to \mathrm{Sym}(6)$. Draw the factorization

$$\begin{array}{ccc} A_5 & \xrightarrow{\rho} & \mathrm{Sym}(6) \\ & \searrow^{\sim} & \uparrow \\ & & A_6 \cap \mathrm{im}\,\rho \end{array}$$

   and explain which arrow is the claimed isomorphism onto its image.

5. For the conjugation map $c_g \colon x \mapsto gxg^{-1}$ on A_5, show naturality, $c_g \circ c_h = c_{ghg^{-1}} \circ c_g$ for all $g, h \in A_5$. By contrast, the square

$$\begin{array}{ccc} A_5 & \xrightarrow{c_h} & A_5 \\ {\scriptstyle c_g}\downarrow & & \downarrow{\scriptstyle c_g} \\ A_5 & \xrightarrow[c_h]{} & A_5 \end{array}$$

   need NOT commute in general; determine the exact condition on g, h under which it does, and relate it to $C_{A_5}(h)$.

4.7 Symmetry: Isometries of the Plane

Isometries of the plane: classification and composition

A *symmetry* of a plane figure F is a rigid motion of the plane carrying F to itself, and the symmetries of F form a group. Before classifying them we recall the four flavours one sees in nature and ornament. A figure has *bilateral symmetry* when it is fixed by a reflection (a letter A, an isoceles triangle); *rotational symmetry* when it is fixed by a nontrivial rotation about a center (a pinwheel, a regular n-gon); *translational symmetry* when a translation slides it onto itself (an infinite frieze, supposed to extend indefinitely); and *glide symmetry* when it is fixed by a reflection followed by a translation parallel to the mirror line (a row of left-right alternating footprints). The symmetry group of F is a subgroup of the full isometry group of the plane, so to understand symmetry we first pin down every isometry there is.

Definition 4.7.1 (Isometry)**.** An *isometry* of $\mathbb{R}^n$ is a distance-preserving map $f\colon \mathbb{R}^n \to \mathbb{R}^n$, i.e. $|f(u)-f(v)| = |u-v|$ for all $u, v \in \mathbb{R}^n$. The set of all isometries of $\mathbb{R}^n$ is a group under composition, denoted M_n (write M for M_2). An isometry carries a figure to a congruent figure.

Two basic families of isometries generate everything. The *translation* t_a by a vector a is $t_a(x) = x + a$; it is an isometry because $|(x+a)-(y+a)| = |x-y|$, but it is not linear unless $a = 0$ (it moves the origin). An *orthogonal operator* $\varphi \in \mathrm{O}(n)$ – a linear map preserving the dot product – is an isometry that fixes the origin, since $|\varphi(u)-\varphi(v)| = |\varphi(u-v)| = |u-v|$. The content of the next theorem is that these two families are all there is.

Theorem 4.7.2 (Every isometry is $t_a\varphi$)**.** *Let f be an isometry of $\mathbb{R}^n$ and put $a = f(0)$. Then $f = t_a\varphi$ for a unique orthogonal operator $\varphi \in \mathrm{O}(n)$. In particular every isometry that fixes the origin is an orthogonal linear operator.*

Proof. Set $\varphi = t_{-a}f$, so that $t_a\varphi = f$. As a composition of the isometries t_{-a} and f, the map φ is an isometry, and $\varphi(0) = t_{-a}(f(0)) = t_{-a}(a) = 0$, so φ fixes the origin. An isometry fixing the origin preserves dot products: from $|u-v|^2 = |\varphi(u)-\varphi(v)|^2$ and $\varphi(0)=0$ one expands and cancels $\langle u,u\rangle, \langle v,v\rangle$ to get $\langle \varphi(u), \varphi(v)\rangle = \langle u, v\rangle$. A dot-product-preserving map is forced to be linear (if $w = u+v$ then $\varphi(w)$ and $\varphi(u)+\varphi(v)$ have equal pairwise dot products, hence are equal, and similarly $\varphi(cv) = c\varphi(v)$), so φ is an orthogonal linear operator. Uniqueness: any decomposition $f = t_a\varphi$ has $\varphi(0) = 0$, so $a = f(0)$ is forced and then $\varphi = t_{-a}f$. □

Remark 4.7.1. On $\mathbb{R}^2$ the orthogonal operators are exactly the rotations ρ_θ about the origin and the reflections $\rho_\theta r$ about lines through the origin, where r is reflection in the x-axis. Thus by Theorem 4.7.2 every plane isometry is $m = t_v\rho_\theta$ (when $\det\varphi = +1$) or $m = t_v\rho_\theta r$ (when $\det\varphi = -1$), for a uniquely determined vector v and angle θ. The map $\pi\colon M \to \mathrm{O}(2)$ dropping the translation part, $\pi(t_v\varphi) = \varphi$, is a surjective homomorphism with kernel the translation subgroup $T = \{t_v\}$, so $T \trianglelefteq M$ and $M/T \cong \mathrm{O}(2)$.

The composition rules

To compute products of isometries written in the symbols t_v, ρ_θ, r, one slides translations past linear operators using $\varphi t_a = t_{\varphi(a)}\varphi$ (because $\varphi t_a(x) = \varphi(x)+\varphi(a) = t_{\varphi(a)}\varphi(x)$). Specialized to the three generators these give the multiplication table of M.

Proposition 4.7.3 (Generator relations in M)**.** *The generators t_v, ρ_θ, r of the plane isometry group satisfy*

$$t_v t_w = t_{v+w}, \qquad \rho_\alpha\rho_\beta = \rho_{\alpha+\beta}, \qquad r^2 = 1,$$

$$\rho_\theta\, t_v = t_{v'}\,\rho_\theta \quad (v' = \rho_\theta(v)), \qquad r\, t_v = t_{v'}\, r \quad (v' = r(v)), \qquad r\,\rho_\theta = \rho_{-\theta}\, r.$$

Proof. The first row is immediate: $t_v t_w(x) = x + w + v$; rotations about a fixed center add their angles; and r is its own inverse. For the second row, apply $\varphi t_a = t_{\varphi(a)}\varphi$ with $\varphi = \rho_\theta$ and with $\varphi = r$. Finally $r\rho_\theta = \rho_{-\theta}r$ follows from the matrices: $r = \left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$ conjugates the rotation matrix $\left(\begin{smallmatrix}c & -s\\ s & c\end{smallmatrix}\right)$ $(c = \cos\theta,\ s = \sin\theta)$ to $\left(\begin{smallmatrix}c & s\\ -s & c\end{smallmatrix}\right)$, which is $\rho_{-\theta}$. □

Method (Reducing a product to normal form $t_v\rho_\theta$ or $t_v\rho_\theta r$)**.** *Trigger.* You must compose isometries and name the result's type.

1. Write each factor as $t_v\rho_\theta$ or $t_v\rho_\theta r$.
2. Move all translations to the *left* using $\rho_\theta t_v = t_{\rho_\theta(v)}\rho_\theta$ and $rt_v = t_{r(v)}r$; collect rotations with $\rho_\alpha\rho_\beta = \rho_{\alpha+\beta}$ and use $r\rho_\theta = \rho_{-\theta}r$, $r^2 = 1$ to leave at most one r on the right.
3. Read off the result: $t_v\rho_\theta$ (orientation-preserving) or $t_v\rho_\theta r$ (orientation-reversing).
4. *Check.* Orientation = det of the linear part = $(+1)$ for ρ_θ, (-1) for $\rho_\theta r$; it must equal the product of the input orientations.

The four types, by orientation and fixed points

Theorem 4.7.4 (Geometric classification of plane isometries)**.** *Every isometry of the plane is exactly one of:*

(a) orientation-preserving *(*$\det = +1$*):*

- *(i) a* translation t_v *(the case $\theta = 0$), with no fixed point unless $v = 0$;*
- *(ii) a* rotation *through a nonzero angle θ about some point p (a unique fixed point);*

(b) orientation-reversing *(*$\det = -1$*):*

- *(i) a* reflection *in a line ℓ (the fixed-point set is the whole line ℓ);*
- *(ii) a* glide reflection*: reflection in a line ℓ followed by translation by a nonzero vector parallel to ℓ (no fixed point).*

Proof. By Theorem 4.7.2 write $m = t_a\rho_\theta$ or $m = t_a\rho_\theta r$.

Orientation-preserving. If $\theta = 0$ then $m = t_a$ is a translation. If $\theta \neq 0$ we claim $m = t_a\rho_\theta$ is a rotation through θ about a suitable point p. Conjugating by the translation t_p moves the center to the origin: $m' = t_{-p}\, m\, t_p$, and using $\rho_\theta t_p = t_{\rho_\theta(p)}\rho_\theta$ we get $m' = t_b\,\rho_\theta$ with $b = a + \rho_\theta(p) - p = a - (I - \rho_\theta)p$. We want $b = 0$, i.e. $(I - \rho_\theta)p = a$. The matrix $I - \rho_\theta = \left(\begin{smallmatrix} 1-c & s \\ -s & 1-c \end{smallmatrix}\right)$ has determinant $2 - 2\cos\theta$, which is nonzero because $\theta \neq 0$; hence $p = (I - \rho_\theta)^{-1}a$ exists uniquely and $m' = \rho_\theta$, so m is rotation through θ about p. This p is the unique fixed point.

Orientation-reversing. Here $m = t_a\rho_\theta r$, and $\rho_\theta r$ is reflection in some line ℓ_0 through the origin. Rotate coordinates so ℓ_0 is the x-axis; then $\rho_\theta r$ becomes the standard reflection r and $m = t_a r$. Writing $a = (a_1, a_2)$, the line ℓ: $\{x_2 = a_2/2\}$ is parallel to the x-axis, and $m = t_{a_1 e_1} \circ$ (reflection in ℓ). If $a_1 \neq 0$ this is a glide reflection along ℓ; if $a_1 = 0$ it is the reflection in ℓ. □

Remark 4.7.2. The classification fits a simple decision table on orientation and fixed points:

	has a fixed point	no fixed point
$\det = +1$ (preserves)	rotation (one point)	translation
$\det = -1$ (reverses)	reflection (a whole line)	glide reflection

Two corollaries fall out for free. The composition of two reflections in nonparallel lines fixes their intersection point and preserves orientation, hence is a *rotation* about that point; in parallel lines it is a *translation* orthogonal to them. And the composition of two rotations is a rotation (or, exceptionally, a translation), since it preserves orientation.

Worked Example 4.7.5 (Two reflections compose to a rotation)**.** With r = reflection in the x-axis and $\rho_{2\alpha}r$ = reflection in the line through 0 at angle α, compute the product $(\rho_{2\alpha}r)(r)$ and name it.

Recognition. Product of two orientation-reversing maps is orientation-preserving (Theorem 4.7.4); use $r^2 = 1$ from Proposition 4.7.3.

Solution. $(\rho_{2\alpha}r)(r) = \rho_{2\alpha}\, r^2 = \rho_{2\alpha}$. Both mirrors pass through the origin, so the result fixes 0; it is the rotation through 2α about the origin. *Check.* $\det = (-1)(-1) = +1$, orientation-preserving; the angle 2α is twice the angle between the two mirror lines – the standard "two reflections make a rotation" fact.

Worked Example 4.7.6 (A rotation not about the origin)**.** Let $m = t_a\rho_\theta$ with $a = (2, 0)$ and $\theta = \frac{\pi}{2}$. Identify m and find its center.

Recognition. Orientation-preserving with $\theta \neq 0$, so a rotation; solve $(I - \rho_\theta)p = a$ (Theorem 4.7.4).

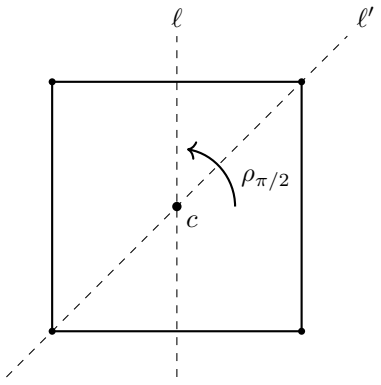
Solution. $\rho_{\pi/2} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, so $I - \rho_{\pi/2} = \left(\begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix}\right)$, with determinant 2. Solve $\left(\begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix}\right)p = \left(\begin{smallmatrix} 2 \\ 0 \end{smallmatrix}\right)$: from $p_1 + p_2 = 2$ and $-p_1 + p_2 = 0$ we get $p_1 = p_2 = 1$, so $p = (1, 1)$. Hence m is rotation through $\pi/2$ about $(1, 1)$. *Check.* $m(p) = \rho_{\pi/2}(1, 1) + (2, 0) = (-1, 1) + (2, 0) = (1, 1) = p$, so p is indeed fixed, and a 90° orientation-preserving isometry with a fixed point is a rotation about it.

Worked Example 4.7.7 (Identifying a glide reflection)**.** Let $m = t_a r$ with $a = (3, 4)$, r = reflection in the x-axis. Decide whether m is a reflection or a glide, and give the line.

Recognition. Orientation-reversing; split a into components along and across the mirror $\{x_2 = a_2/2\}$ (Theorem 4.7.4).

Solution. r is reflection in the x-axis; with $a = (3, 4)$ the relevant mirror is ℓ: $\{x_2 = 2\}$ (the perpendicular component $a_2 = 4$ shifts the axis up by $a_2/2 = 2$), and the parallel component is $a_1 e_1 = (3, 0) \neq 0$. So m is a *glide reflection* along ℓ: $x_2 = 2$ by the vector $(3, 0)$. *Check.* $\det = -1$ (orientation-reversing); m has no fixed point because $m(x_1, x_2) = (x_1 + 3, -x_2 + 4)$ forces $x_1 = x_1 + 3$, impossible – consistent with "glide," not "reflection."

Worked Example 4.7.8 (Conjugating a rotation by a translation)**.** Show that $t_v\, \rho_{\theta,0}\, t_v^{-1}$ is rotation through θ about the point v, where $\rho_{\theta,0}$ is rotation through θ about the origin.



Recognition. Use the rule $\rho_\theta t_w = t_{\rho_\theta(w)}\rho_\theta$ (Proposition 4.7.3) and read off the normal form $t_b\rho_\theta$.

Solution. Compute $t_v\rho_\theta t_{-v} = t_v\, t_{\rho_\theta(-v)}\rho_\theta = t_{v-\rho_\theta(v)}\, \rho_\theta = t_b\rho_\theta$ with $b = (I - \rho_\theta)v$. By the rotation case of Theorem 4.7.4, this is rotation through θ about the point p solving $(I - \rho_\theta)p = b = (I - \rho_\theta)v$, i.e. $p = v$. *Check.* Geometrically, $t_v\rho_\theta t_{-v}$ means "translate v to the origin, rotate, translate back," which is exactly rotation about v. Orientation $+1$, single fixed point v – a rotation, as claimed.

Caution. Isometries do not commute, so order matters and translations do *not* pass freely through rotations: $\rho_\theta t_v = t_{\rho_\theta(v)}\rho_\theta$, with the vector rotated. Writing $\rho_\theta t_v = t_v\rho_\theta$ is the most common slip. Likewise $r\rho_\theta = \rho_{-\theta}r$, not $\rho_\theta r$.

A figure with its symmetry axis and center

The square below carries the dihedral symmetry group D_8: four rotations about its center c (multiples of 90°) and four reflections, in the two diagonals and the two edge-bisectors. Two mirror lines, ℓ and ℓ', and the rotation center c are marked; the reflection in ℓ and the quarter-turn about c generate all eight symmetries.

Reflection in ℓ is the orientation-reversing generator (its fixed-point set is the whole line ℓ), while the quarter-turn $\rho_{\pi/2}$ about c is the orientation-preserving generator (its only fixed point is c). Composing the two reflections in ℓ and ℓ', whose lines meet at c at angle $\pi/4$, gives the rotation through $\pi/2$ about c – the "two reflections make a rotation" principle in action, and the reason a square's symmetry group is generated by a single mirror together with a single quarter-turn.

4.8 Finite Groups of Orthogonal Operators on the Plane

Finite groups of orthogonal operators on the plane

The orthogonal group O(2) consists of the linear isometries of the plane fixing the origin. Its elements come in two kinds: the rotations ρ_θ about the origin and the reflections $\rho_\theta r$ about lines through the origin, where r is a fixed reference reflection. In a coordinate system whose horizontal axis is the line of r,

$$\rho_\theta = \begin{pmatrix} c & -s \\ s & c \end{pmatrix}, \qquad r = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \qquad c = \cos\theta,\ s = \sin\theta.$$

A matrix in O(2) has determinant $+1$ (a rotation) or -1 (a reflection). The goal of this section is to classify all *finite* subgroups of O(2): there are only two families, the cyclic groups C_n and the dihedral groups D_n.

The dihedral group and its presentation

Definition 4.8.1 (Dihedral group D_n)**.** Fix $\theta = 2\pi/n$, write $x = \rho_\theta$ for the rotation through θ and $y = r$ for the standard reflection. The *dihedral group* D_n is the subgroup of O(2) generated by x and y. Its $2n$ elements are the n rotations x^k and the n reflections $x^k y$ for $0 \le k \le n-1$. (This is Artin's notation: the group of order $2n$ that D&F write D_{2n} is D_n here, so the symmetry group of the square, written D_8 above, is D_4 below.)

The single rule needed to multiply in D_n is the commutation law between a rotation and a reflection. Reflecting, then rotating by θ, is the same as rotating by $-\theta$, then reflecting: in matrices,

$$y\,x\,y^{-1} = r\,\rho_\theta\,r^{-1} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\begin{pmatrix} c & -s \\ s & c \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} c & s \\ -s & c \end{pmatrix} = \rho_{-\theta} = x^{-1}.$$

Proposition 4.8.2 (Presentation of D_n)**.** *The dihedral group D_n has order $2n$. It is generated by two elements x and y satisfying*

$$x^n = 1, \qquad y^2 = 1, \qquad yx = x^{-1}y.$$

Using the first two relations, the third is equivalent to $xyxy = 1$ and also to $yx = x^{n-1}y$.

Proof. We have $x^n = \rho_\theta^n = \rho_{2\pi} = 1$ and $y^2 = r^2 = 1$. The matrix computation above gives $yxy^{-1} = x^{-1}$, i.e. $yx = x^{-1}y$. Multiplying $yx = x^{-1}y$ on the left by x and on the right by $y^{-1} = y$ rearranges it as $xyxy = 1$; and since $x^{-1} = x^{n-1}$, it is also $yx = x^{n-1}y$. The rule $yx = x^{-1}y$ lets every word in x, y be pushed into the normal form $x^k y^\varepsilon$ with $0 \le k < n$ and $\varepsilon \in \{0, 1\}$, so there are at most $2n$ elements; the n rotations x^k and n reflections $x^k y$ are visibly distinct (determinants $+1$ and -1 separate the two blocks, and within each block the matrices differ). Hence $|D_n| = 2n$. □

Remark 4.8.1. For $n \ge 3$ the elements of D_n are exactly the orthogonal operators carrying a regular n-gon centered at the origin to itself — its *symmetry group*. The small cases are degenerate: $D_1 = \{1, r\}$ has order 2 (a single reflection) and $D_2 = \{1, \rho_\pi, r, \rho_\pi r\}$ has order 4 and is isomorphic to the Klein four-group V_4. When $n = 3$ the relations $x^3 = y^2 = 1,\ yx = x^{-1}y$ are precisely those of S_3, so $D_3 \cong S_3$.

The classification theorem

A subgroup Γ of the additive group $\mathbb{R}$ is *discrete* if there is a small $\epsilon > 0$ such that every nonzero element of Γ has absolute value $\ge \epsilon$. The proof of the classification rests on the following description of such subgroups, the additive analogue of "every subgroup of $\mathbb{Z}$ is $\mathbb{Z}n$."

Lemma 4.8.3 (Discrete subgroups of $\mathbb{R}$)**.** *Let Γ be a discrete subgroup of $\mathbb{R}$. Then either $\Gamma = \{0\}$, or $\Gamma = \mathbb{Z}a$, the set of integer multiples of a positive real number a.*

Proof. If $a, b \in \Gamma$ are distinct then $a - b \in \Gamma$ and $|a - b| \ge \epsilon$, so distinct elements are separated by at least ϵ; hence any bounded interval contains only finitely many elements of Γ. Suppose $\Gamma \ne \{0\}$. Then Γ contains a positive element, and we may choose the *smallest* positive element a (the candidates below any fixed positive

member form a finite set). Since $a \in \Gamma$, $\mathbb{Z}a \subseteq \Gamma$. Conversely take $b \in \Gamma$ and write $b = ra$ with $r \in \mathbb{R}$; put $r = m + r_0$, $m \in \mathbb{Z}$, $0 \le r_0 < 1$. Then $b' = b - ma = r_0 a \in \Gamma$ with $0 \le b' < a$, and minimality of a forces $b' = 0$, so $b = ma \in \mathbb{Z}a$. Thus $\Gamma = \mathbb{Z}a$. □

Theorem 4.8.4 (Finite subgroups of O(2))**.** *Let G be a finite subgroup of the orthogonal group* O(2)*. Then there is an integer n such that G is one of:*

1. *C_n: the cyclic group of order n generated by the rotation ρ_θ, $\theta = 2\pi/n$;*
2. *D_n: the dihedral group of order $2n$ generated by ρ_θ and a reflection r in a line through the origin.*

Proof. Recall the elements of O(2) are the rotations ρ_α and the reflections $\rho_\alpha r$.

Case 1: every element of G is a rotation. Let $\Gamma = \{\alpha \in \mathbb{R} \mid \rho_\alpha \in G\}$. Since $\rho_\alpha \rho_\beta = \rho_{\alpha+\beta}$, Γ is a subgroup of $(\mathbb{R}, +)$, and it contains 2π. As G is finite, Γ is discrete. By Lemma 4.8.3, $\Gamma = \mathbb{Z}\alpha$ for some $\alpha > 0$. Since $2\pi \in \Gamma = \mathbb{Z}\alpha$, we have $2\pi = n\alpha$ for an integer n, i.e. $\alpha = 2\pi/n$. Then G consists of the rotations through integer multiples of $2\pi/n$, so $G = C_n$.

Case 2: G contains a reflection. Choose coordinates so the standard reflection r lies in G. Let H be the subgroup of rotations in G. By Case 1, $H = C_n$ is generated by ρ_θ with $\theta = 2\pi/n$. The $2n$ products ρ_θ^k and $\rho_\theta^k r$ $(0 \le k < n)$ all lie in G, so $D_n \subseteq G$. Conversely take any $g \in G$. If g is a rotation, then $g \in H \subseteq D_n$. If g is a reflection, write $g = \rho_\alpha r$; since $r \in G$, the product $gr = \rho_\alpha \in G$ is a rotation, hence a power of ρ_θ, so $g = \rho_\theta^k r \in D_n$. Therefore $G = D_n$. □

Method (Identifying a finite plane symmetry group)**.** *Trigger.* "name the symmetry group of this figure / this finite group of plane isometries."

1. Decide whether any element *reverses orientation* (a reflection, $\det = -1$). If none, the group is rotations only.
2. Find the smallest rotation angle present, $2\pi/n$. The rotations form C_n.
3. No reflection ⇒ the whole group is C_n. At least one reflection ⇒ the group is D_n (order $2n$), generated by that rotation and one reflection.
4. Sanity check the order: $|C_n| = n$, $|D_n| = 2n$.

Corollary 4.8.5 ($D_3 \cong S_3$)**.** *The dihedral group D_3 and the symmetric group S_3 are isomorphic.*

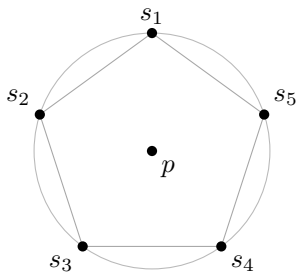
Proof. By Proposition 4.8.2 the group D_3 has the presentation $x^3 = y^2 = 1,\ yx = x^{-1}y$, the same relations as the standard presentation of S_3 on a 3-cycle x and a transposition y; both groups have order 6, so the relation-respecting map $x \mapsto (1\,2\,3),\ y \mapsto (1\,2)$ is an isomorphism. □

The fixed point theorem

So far the operators fixed the origin. A general isometry of the plane may move every point. The next theorem shows a finite group of isometries always has a common fixed point, which we may then take as the origin — reducing the symmetry group of a bounded figure to the orthogonal case above.

Theorem 4.8.6 (Fixed Point Theorem)**.** *Let G be a finite group of isometries of the plane. Then there is a point p fixed by every element of G: $g(p) = p$ for all $g \in G$.*

Proof. Pick any point s and form its *orbit* $S = \{g(s) \mid g \in G\} = \{s_1, \ldots, s_m\}$. Each $h \in G$ permutes S: if $s' = g(s) \in S$ then $h(s') = hg(s) \in S$ because $hg \in G$. Let p be the *centroid* of the orbit,



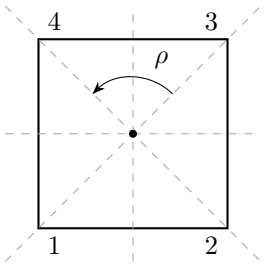
$$p = \frac{1}{m}\,(s_1 + s_2 + \cdots + s_m),$$

computed by vector addition in any coordinate system. Isometries carry centroids to centroids (Lemma 4.8.7); since each $g \in G$ merely permutes S, it sends the centroid of S to the centroid of S, i.e. $g(p) = p$. Thus p is fixed by every element of G. □

Lemma 4.8.7 (Isometries carry centroids to centroids)**.** *Let $S = \{s_1, \dots, s_m\}$ with centroid $p = \frac{1}{m}\sum_i s_i$, and let φ be an isometry. Then $\varphi(p)$ is the centroid of $\varphi(S) = \{\varphi(s_1), \dots, \varphi(s_m)\}$.*

Proof. Every isometry is a composition of a translation $t_a(v) = v + a$ and a linear orthogonal operator, so it suffices to check the two cases. *Translation:* with $s_i' = s_i + a$, $\frac{1}{m}\sum_i s_i' = \big(\frac{1}{m}\sum_i s_i\big) + a = p + a = t_a(p)$. *Linear operator φ:* by linearity $\varphi(p) = \varphi\big(\frac{1}{m}\sum_i s_i\big) = \frac{1}{m}\sum_i \varphi(s_i)$, the centroid of $\varphi(S)$. Composing the two cases proves the lemma for every isometry. □

The orbit and its centroid are shown below for the symmetries of a regular pentagon: the five images of a point lie on a circle about the fixed centroid p.



Corollary 4.8.8 (Symmetry groups of bounded plane figures)**.** *Let G be a finite subgroup of the group of all isometries of the plane (in particular, the symmetry group of a bounded plane figure, when that group is finite; a disk has the infinite symmetry group $\mathrm{O}(2)$). For suitable coordinates G is one of the groups C_n or D_n.*

Proof. By Theorem 4.8.6, G fixes a point p. Translate coordinates so that p is the origin. Every element of G then fixes the origin, so $G \subseteq \mathrm{O}(2)$. Being finite, G is C_n or D_n by Theorem 4.8.4. □

D_4 acting on a square

The square has the eight symmetries of D_4: four rotations $1, \rho, \rho^2, \rho^3$ through multiples of 90°, and four reflections — two in the diagonals and two in the horizontal/vertical midlines. The reflection axes are drawn below.

Numbering the vertices $1, 2, 3, 4$ counterclockwise, the rotation $x = \rho$ acts as the 4-cycle $(1\,2\,3\,4)$ and the reflection y in the vertical midline as $(1\,2)(3\,4)$; one checks $x^4 = y^2 = 1$ and $yx = x^{-1}y$, realizing D_4 as a group of permutations of the four vertices.

Worked Example 4.8.9 (Symmetries of a regular hexagon)**.** Name the full symmetry group of a regular hexagon centered at the origin and list its elements by type.

Recognition. The figure is bounded and has only finitely many symmetries, so its symmetry group is C_n or D_n (Corollary 4.8.8); a regular n-gon with $n \geq 3$ has both rotations and reflections, giving D_n.

Solution. A regular hexagon is carried to itself by rotation through $60° = 2\pi/6$, so the rotation subgroup is $C_6 = \{1, \rho, \rho^2, \dots, \rho^5\}$, where $\rho = \rho_{2\pi/6}$. It also has reflection symmetry, so by Theorem 4.8.4 the full group is D_6, of order 12. Its 12 elements are the 6 rotations ρ^k $(0 \leq k \leq 5)$ and the 6 reflections $\rho^k r$: three reflections in the lines through opposite vertices and three through midpoints of opposite edges. *Check.* $|D_6| = 2 \cdot 6 = 12$; six orientation-preserving ($\det = +1$) and six orientation-reversing ($\det = -1$) elements, matching the rotation/reflection split. ■

Worked Example 4.8.10 (A figure with only rotational symmetry)**.** A pinwheel is drawn by attaching four identical curved (chiral) blades to a central hub, each blade obtained from the previous by a 90° rotation. Determine its symmetry group.

Recognition. Look for orientation-reversing symmetry first (Method above). A chiral blade has no mirror line, so no reflection can be a symmetry; only rotations survive.

Solution. Rotation by $90° = 2\pi/4$ carries each blade onto the next, so $\rho_{2\pi/4}$ is a symmetry and the rotation subgroup is $C_4 = \{1, \rho, \rho^2, \rho^3\}$. A reflection would reverse the handedness of every blade, turning a left-curved blade into a right-curved one, which is *not* the original figure; hence no reflection is a symmetry. By Theorem 4.8.4 the symmetry group is therefore C_4, *not* D_4. *Check.* $|C_4| = 4$, all with $\det = +1$; the figure looks the same after $0°, 90°, 180°, 270°$ and different in a mirror, exactly the cyclic (chiral) case. ■

Worked Example 4.8.11 (Reading off the relation $yx = x^{-1}y$ on the square)**.** Using the vertex permutations $x = (1\,2\,3\,4)$ and $y = (1\,2)(3\,4)$ for D_4, verify $yx = x^{-1}y$.

Recognition. This is the dihedral commutation law from Proposition 4.8.2; compute both sides as permutations.

Solution. Compose right-to-left. Left side yx: apply x then y. Tracking $1 \overset{x}{\mapsto} 2 \overset{y}{\mapsto} 1$, $2 \overset{x}{\mapsto} 3 \overset{y}{\mapsto} 4$, $3 \overset{x}{\mapsto} 4 \overset{y}{\mapsto} 3$, $4 \overset{x}{\mapsto} 1 \overset{y}{\mapsto} 2$, so $yx = (2\,4)$. Right side $x^{-1}y$ with $x^{-1} = (1\,4\,3\,2)$: $1 \overset{y}{\mapsto} 2 \overset{x^{-1}}{\longmapsto} 1$, $2 \overset{y}{\mapsto} 1 \overset{x^{-1}}{\longmapsto} 4$, $3 \overset{y}{\mapsto} 4 \overset{x^{-1}}{\longmapsto} 3$, $4 \overset{y}{\mapsto} 3 \overset{x^{-1}}{\longmapsto} 2$, so $x^{-1}y = (2\,4)$. The two agree. *Check.* $yx = x^{-1}y$ holds, and $(2\,4)$ is a reflection ($\det = -1$ on the square), as it must be since it is a product of a reflection and a rotation. ■

Caution. The presence of n-fold rotational symmetry does *not* by itself make the group D_n. Only a figure that also admits a mirror line is dihedral; a chiral figure (like the pinwheel) with n-fold rotation has the smaller group C_n of order n, not D_n of order $2n$. Always test for an orientation-reversing symmetry before naming the group.

4.9 Discrete Groups, Lattices, and the Crystallographic Restriction

Discrete groups, translation lattices, and point groups

To do geometry with an infinite group of symmetries — the symmetries of a wallpaper pattern or a planar crystal, not just of a bounded figure — we must first rule out groups that crowd arbitrarily close to the identity. A group with arbitrarily small rotations or translations has no sensible geometry. The condition that forbids this is *discreteness*, and it has remarkable structural consequences: the translations form one of only three shapes, and the rotational symmetries are always finite.

Throughout, M denotes the group of isometries of the plane P, V the (additive) group of translation vectors, and t_v the translation by v. We write ρ_θ for the rotation through angle θ about the origin and $\mathrm{O}(2)$ for the orthogonal group.

Definition 4.9.1 (Discrete group of isometries)**.** A subgroup $G \leq M$ is *discrete* if there is a real number $\varepsilon > 0$ such that:

(i) if $t_a \in G$ is a translation by a nonzero vector a, then $|a| \geq \varepsilon$, and

(ii) if $g \in G$ is a rotation through a nonzero angle θ about some point of P, then $|\theta| \geq \varepsilon$.

Remark 4.9.1. The same ε governs both vectors and angles; we do not care about optimal bounds, only that one positive bound works for all nonzero translations and rotations at once. No condition is imposed on the orientation-reversing isometries: if m is a glide with glide vector w, then $m^2 = t_{2w}$ is a translation, so the bound on translation lengths already controls the glides.

Artin singles out three tools for dissecting a discrete G: its *translation group* $L \leq V$, its *point group* $\overline{G} \leq \mathrm{O}(2)$, and an operation of $\overline{G}$ on L. We take them in turn.

The translation group and its classification

Definition 4.9.2 (Translation group; discrete subgroup of V)**.** The *translation group* of $G \leq M$ is

$$L = \{\, v \in V \mid t_v \in G \,\}.$$

Since $t_v t_w = t_{v+w}$ and $t_v^{-1} = t_{-v}$, L is a subgroup of V. A subgroup $L \leq V$ (or $L \leq \mathbb{R}^n$) is itself called *discrete* if there is $\varepsilon > 0$ with $|v| \geq \varepsilon$ for every nonzero $v \in L$. The bound on translations in a discrete G makes its L a discrete subgroup of V.

Remark 4.9.2. Discreteness of L is equivalently a *separation* statement: distinct $a, b \in L$ satisfy $|b - a| \geq \varepsilon$, because $b - a \in L$ and $|b - a| \geq \varepsilon$ by hypothesis. So the points of a discrete L are uniformly spread out, never accumulating.

The engine behind everything is the existence of a shortest nonzero vector.

Lemma 4.9.3 (Minimal vector)**.** *Let $L \leq V$ be discrete.*

(a) Any bounded region of the plane contains only finitely many points of L.

(b) If $L \neq \{0\}$, it contains a nonzero vector of minimal length*.*

Proof. (a) The points of L are pairwise at distance $\geq \varepsilon$, so a square of side $< \varepsilon/2$ contains at most one point of L (any two would be within distance $< \varepsilon$). A bounded region lies inside some large rectangle, which is covered by finitely many such squares; hence it meets L in finitely many points.

(b) Pick any nonzero $a \in L$. The closed disk of radius $|a|$ about the origin is bounded, so by (a) it contains only finitely many points of L, among them a. Finitely many nonzero lengths occur, so a smallest one is attained; the corresponding vector is a nonzero vector of minimal length. □

To turn a candidate basis into a genuine description of L we need the *fundamental parallelogram*. For a basis $B = (u, w)$ of $\mathbb{R}^2$ let $\Pi'(B)$ denote the half-open parallelogram

$$\Pi'(B) = \{\, ru + sw \mid 0 \leq r < 1,\ 0 \leq s < 1 \,\},$$

that is, the parallelogram with vertices $0, u, w, u + w$ with the two far edges deleted.

Lemma 4.9.4 (Fundamental domain)**.** *Let $B = (u, w)$ be a basis of $\mathbb{R}^2$ and let $L = \mathbb{Z}u + \mathbb{Z}w$ be the lattice of integer combinations. Every $v \in \mathbb{R}^2$ is written* uniquely *as $v = x + v_0$ with $x \in L$ and $v_0 \in \Pi'(B)$.*

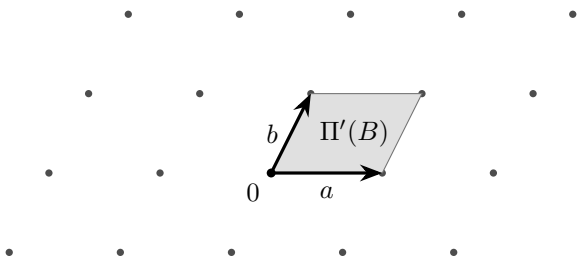
Proof. Since B is a basis, $v = ru + sw$ for unique reals r, s. Split off integer parts: $r = m + r_0$, $s = n + s_0$ with $m, n \in \mathbb{Z}$ and $0 \leq r_0, s_0 < 1$. Then $v = x + v_0$ with $x = mu + nw \in L$ and $v_0 = r_0 u + s_0 w \in \Pi'(B)$. Uniqueness: if $x + v_0 = x' + v_0'$ with $x, x' \in L$ and $v_0, v_0' \in \Pi'(B)$, then $v_0 - v_0' = x' - x \in L$ has integer coordinates in B, yet each coordinate lies strictly between -1 and 1; the only such integer is 0, so $v_0 = v_0'$ and $x = x'$. □

Theorem 4.9.5 (Classification of discrete subgroups of the plane)**.** *Every discrete subgroup $L \leq V$ (equivalently $L \leq \mathbb{R}^2$) is exactly one of:*

(a) the trivial group $L = \{0\}$;

(b) an infinite cyclic group $L = \mathbb{Z}a = \{\, ma \mid m \in \mathbb{Z} \,\}$ for some nonzero a; or

(c) a lattice *$L = \mathbb{Z}a + \mathbb{Z}b = \{\, ma + nb \mid m, n \in \mathbb{Z} \,\}$ for two linearly independent a, b.*



In case (c), (a, b) is called a lattice basis*.*

Proof. The trivial group is case (a). Assume $L \neq \{0\}$, and split on whether L spans a line.

Case 1: all of L lies on a line ℓ through the origin. Identify ℓ with $\mathbb{R}$; then $L \leq \mathbb{R}$ is discrete, so by Lemma 4.9.3 it has a shortest nonzero vector a. If some $v \in L$ were not an integer multiple of a, subtract the nearest multiple: $v - ma \in L$ would be nonzero with $|v - ma| < |a|$, contradicting minimality. Hence $L = \mathbb{Z}a$, case (b).

Case 2: L does not lie on a line. Then L contains independent vectors, so we may choose coordinates with $a = (1,0)^t$ a shortest nonzero vector of L on the horizontal axis ℓ (using Case 1 on $L \cap \ell = \mathbb{Z}a$). Among the vectors of L with positive second coordinate, choose $b = (b_1, b_2)^t$ with b_2 *as small as possible*; adding a multiple of a we may also take $0 \le b_1 < 1$. This b exists: such vectors with $0 \le b_1 < 1$ and b_2 bounded above by any fixed candidate lie in a bounded region, which meets L finitely often by Lemma 4.9.3(a).

Set $\widetilde{L} = \mathbb{Z}a + \mathbb{Z}b \subseteq L$; we show $\widetilde{L} = L$. By Lemma 4.9.4 applied to $B = (a, b)$, it suffices to show the only point of L in $\Pi'(B)$ is 0. Let $c = (c_1, c_2)^t \in L \cap \Pi'(B)$, so $0 \le c_2 < b_2$. Minimality of b_2 forces $c_2 = 0$, so c lies on ℓ, hence $c \in \mathbb{Z}a$; but $0 \le c_1 < 1$ leaves only $c = 0$. Therefore $L = \mathbb{Z}a + \mathbb{Z}b$ is a lattice, case (c). □

Worked Example 4.9.6 (Reading off the three types)**.** Problem. Classify each subgroup of $\mathbb{R}^2$: (i) $L_1 = \mathbb{Z}(2,0)$; (ii) $L_2 = \mathbb{Z}(1,0) + \mathbb{Z}(0,1)$; (iii) $L_3 = \{\,(x,y) \mid x, y \in \mathbb{Z},\ x + y \text{ even}\,\}$.

Recognition. Each is a subgroup of V; decide *trivial / line / lattice* by whether it lies on a line and, if a lattice, find a basis (Theorem 4.9.5).

Solution. (i) Every vector is a multiple of $(2,0)$, on the horizontal axis: type (b), infinite cyclic, $L_1 = \mathbb{Z}(2,0)$. (ii) $(1,0)$ and $(0,1)$ are independent and generate all integer points: type (c), the square lattice $\mathbb{Z}^2$. (iii) The condition $x + y$ even is a subgroup (sums of even-sum vectors have even sum). It contains the independent vectors $(1,1)$ and $(1,-1)$, and every even-sum integer vector is an integer combination of these: $(x,y) = \frac{x+y}{2}(1,1) + \frac{x-y}{2}(1,-1)$ with both coefficients integers since $x + y, x - y$ are even. Type (c), a lattice with basis $((1,1),(1,-1))$. *Check.* Each minimal nonzero length is positive — 2, 1, $\sqrt{2}$ respectively — so all three are genuinely discrete, and no list entry is omitted.

The point group is finite

The homomorphism $\pi : M \to \mathrm{O}(2)$ with kernel the translations T (it strips an isometry of its translational part) restricts to G.

Definition 4.9.7 (Point group)**.** The *point group* of $G \le M$ is $\overline{G} = \pi(G) \le \mathrm{O}(2)$. We bar symbols of $\overline{G}$: for $g \in G$, $\overline{g} = \pi(g)$ is an orthogonal operator. Thus $\overline{G}$ records the rotation angles and the reflection/glide slopes occurring in G, forgetting the translation part.

Proposition 4.9.8 (Discrete subgroups of O(2) are finite)**.** *A discrete subgroup $\overline{G} \le \mathrm{O}(2)$ is finite, hence cyclic or dihedral.*

Proof. Let $\Gamma = \{\,\theta \in \mathbb{R} \mid \rho_\theta \in \overline{G}\,\}$ be the set of rotation angles in $\overline{G}$. It is a subgroup of $\mathbb{R}$ (composing rotations adds angles) containing 2π, and it is discrete because $\overline{G}$ contains no arbitrarily small rotations. A discrete subgroup of $\mathbb{R}$ is infinite cyclic (the line case of Theorem 4.9.5): take the smallest positive angle θ_0, so $\Gamma = \mathbb{Z}\theta_0$; since $2\pi \in \Gamma$ we get $2\pi = n\theta_0$, i.e. $\theta_0 = 2\pi/n$ for some positive integer n. So the rotations in $\overline{G}$ form a cyclic group of order n. If $\overline{G}$ contains a reflection, it is dihedral D_n; otherwise it is cyclic C_n. Either way $|\overline{G}| < \infty$. □

Worked Example 4.9.9 (Why "discrete" is essential)**.** Problem. Show the full group SO(2) of all rotations about the origin is a subgroup of O(2) that is *not* discrete, and exhibit arbitrarily small rotations in it.

Recognition. Proposition 4.9.8 concludes finiteness only *under* discreteness; to see the hypothesis is needed, produce a non-discrete subgroup violating the conclusion.

Solution. $\mathrm{SO}(2) = \{\,\rho_\theta \mid \theta \in \mathbb{R}\,\}$ is closed under composition and inverses, so it is a subgroup. For any $\varepsilon > 0$ the rotation $\rho_{\varepsilon/2}$ is a nonzero rotation with angle $\varepsilon/2 < \varepsilon$, so no single ε bounds all nonzero angles from below:

$\mathrm{SO}(2)$ is not discrete. And it is infinite, so the finiteness conclusion genuinely fails. *Check.* The rotations $\rho_{2\pi/n}$ generate the finite cyclic group $C_n \leq \mathrm{SO}(2)$ for each n, and these C_n *are* discrete — discreteness, not membership in $\mathrm{O}(2)$, is exactly what forces finiteness.

The point group operates on the lattice

The third tool links the first two. Although $\overline{G}$ does not act on the plane P (no origin is fixed), it does act on the vector space V of translation vectors.

Proposition 4.9.10 ($\overline{G}$ preserves L)**.** *Let $G \leq M$, with translation group L and point group $\overline{G}$. For every $a \in L$ and every $\overline{g} \in \overline{G}$, we have $\overline{g}(a) \in L$. Equivalently, $\overline{G}$ lies in the group of symmetries of L regarded as a figure in V.*

Proof. Take $g \in G$ with image $\overline{g}$, and set $a' = \overline{g}(a)$. Write $g = t_b\varphi$ with $\varphi \in \mathrm{O}(2)$, so $\overline{g} = \varphi$ and $a' = \varphi(a)$. Conjugating the translation t_a (which is in G since $a \in L$) by g, and using $\varphi\, t_a\, \varphi^{-1} = t_{\varphi(a)}$,

$$g\, t_a\, g^{-1} = (t_b\varphi)\, t_a\, (\varphi^{-1} t_{-b}) = t_b\, t_{\varphi(a)}\, t_{-b} = t_{\varphi(a)} = t_{a'}.$$

Both g and t_a lie in G, so the conjugate $t_{a'} \in G$; therefore $a' \in L$. □

Remark 4.9.3. It is genuinely important that $\overline{G}$ acts on $L \subseteq V$, not that G acts on L: the elements of G are isometries of P, while L lives in V, and P is identified with V only after an origin is chosen. The clean statement is the one above — the orthogonal *point* group permutes the lattice.

This single fact is the gateway to crystallography. Because the point group must permute a lattice, its rotations cannot be arbitrary.

Theorem 4.9.11 (Crystallographic restriction)**.** *Let $L \leq V$ be a nontrivial discrete subgroup and let $H \leq \mathrm{O}(2)$ be a subgroup carrying L to itself. Then every rotation in H has order $1, 2, 3, 4,$ or 6; consequently H is one of C_n or D_n with $n \in \{1, 2, 3, 4, 6\}$. In particular five-fold rotational symmetry is impossible.*

Proof. Let $\rho \in H$ be a nontrivial rotation, through an angle θ with $0 < \theta \leq \pi$ (replace ρ by ρ^{-1} if necessary), and let $a \in L$ be a nonzero vector of minimal length (Lemma 4.9.3). Since H preserves L, $\rho(a) \in L$, hence $b = \rho(a) - a \in L$. By minimality $|b| \geq |a|$. But $|b| = |\rho(a) - a| = 2|a|\sin(\theta/2)$, and $2\sin(\theta/2) < 1$ exactly when $0 < \theta < \pi/3 = 2\pi/6$. So $|b| < |a|$ for $0 < \theta < 2\pi/6$, which is forbidden; hence $\theta \geq 2\pi/6$ for every nontrivial rotation in H. Thus H is discrete, hence finite by Proposition 4.9.8; its rotations form a cyclic group generated by $\rho_{2\pi/n}$, and $2\pi/n \geq 2\pi/6$ gives $n \leq 6$, so ρ has order at most 6. Order 5 ($\theta = 2\pi/5$) is also excluded: there $b' = \rho^2(a) + a$ satisfies $|b'| < |a|$ (a short computation with $\cos(4\pi/5) = -(1+\sqrt{5})/4 < -1/2$ gives $|b'|^2 = |a|^2(2 + 2\cos\frac{4\pi}{5}) < |a|^2$), again contradicting minimality. So only orders $1, 2, 3, 4, 6$ survive, and by Proposition 4.9.8 H is the corresponding C_n or D_n. □

Worked Example 4.9.12 (The point group operating on a lattice)**.** Problem. Let $L = \mathbb{Z}^2$ be the square lattice and let $\overline{g} = \rho_{\pi/2}$ be the quarter-turn. Verify $\overline{g}$ permutes L, find the order of $\overline{g}$ as a symmetry of L, and locate it on the crystallographic list.

Recognition. This is Proposition 4.9.10 made concrete (check $\overline{g}(a) \in L$ on a basis) followed by the order test of Theorem 4.9.11.

Solution. On the standard basis, $\rho_{\pi/2}(1,0) = (0,1)$ and $\rho_{\pi/2}(0,1) = (-1,0)$, both in $\mathbb{Z}^2$; since $\rho_{\pi/2}$ is linear it sends every integer combination to an integer combination, so $\overline{g}(L) = L$. As a symmetry $\overline{g}$ has order 4 (four quarter-turns return to the identity), and $4 \in \{1, 2, 3, 4, 6\}$, consistent with the restriction. The full symmetry group of $\mathbb{Z}^2$ in $\mathrm{O}(2)$ is D_4 (the quarter-turn together with a reflection). *Check.* Test the theorem's inequality with $a = (1,0)$: $b = \rho_{\pi/2}(a) - a = (-1,1)$ has $|b| = \sqrt{2} \geq 1 = |a|$, no contradiction, so order 4 is allowed. For $\theta = 2\pi/5$ this first test still passes ($2\sin 36^\circ \approx 1.18 \geq 1$); the lattice vector that is forced to be shorter than a is $\rho^2(a) + a$, of length $2\cos 72^\circ\, |a| \approx 0.618\, |a|$ (next example) — which is why no lattice has five-fold symmetry.

Worked Example 4.9.13 (No five-fold lattice symmetry, directly)**.** Problem. Suppose a nonzero discrete $L \leq V$ admits a rotation ρ of order 5 as a symmetry. Derive a contradiction using a minimal vector.

Recognition. The crystallographic restriction in action: assume the forbidden order and manufacture a shorter lattice vector (Theorem 4.9.11).

Solution. Let $a \in L$ be a shortest nonzero vector and $\theta = 2\pi/5$. Then $\rho(a), \rho^2(a) \in L$, so $b' = \rho^2(a) + a \in L$. Compute

$$|b'|^2 = |a|^2 + |a|^2 + 2|a|^2 \cos\tfrac{4\pi}{5} = 2|a|^2\big(1 + \cos\tfrac{4\pi}{5}\big).$$

Since $\cos\frac{4\pi}{5} = -\frac{1+\sqrt{5}}{4} \approx -0.809$, we get $|b'|^2 \approx 2|a|^2(0.191) \approx 0.382\,|a|^2 < |a|^2$. So b' is a nonzero lattice vector shorter than a — contradicting minimality. (It is nonzero: $\rho^2(a) = -a$ would force ρ^2 to be the half-turn, of order 2, incompatible with ρ of order 5.) *Check.* The same computation with $\theta = 2\pi/6$ gives $\cos\frac{2\pi}{3} = -\frac{1}{2}$, so $|b'|^2 = 2|a|^2(1 - \frac{1}{2}) = |a|^2$, exactly the borderline — order 6 is allowed, order 5 is not, precisely as the theorem predicts.

Remark 4.9.4 (Where this goes). When L is trivial, π is injective on G, so $G \cong \overline{G}$ is finite cyclic or dihedral — the symmetry groups of bounded figures. When L is infinite cyclic ($\mathbb{Z}a$), G is the symmetry group of a frieze pattern. When L is a full lattice, G is a *plane crystallographic group*; the crystallographic restriction cuts the possible point groups down to C_n, D_n with $n \in \{1, 2, 3, 4, 6\}$, and a finer analysis sorts these into the 17 wallpaper groups.

Caution. G does *not* act on its own translation lattice L. The elements of G are isometries of the plane P; L is a set of vectors in V. Only after fixing an origin (identifying P with V) does the question even make sense, and whether such an origin can be chosen so that G stabilizes L depends on the group. The clean, always-valid statement is Proposition 4.9.10: the *point* group $\overline{G} \leq \mathrm{O}(2)$ permutes L.

The crystallographic restriction

A two-dimensional lattice is the set of integer combinations of two independent vectors,

$$L = \mathbb{Z}a + \mathbb{Z}b = \{ma + nb \mid m, n \in \mathbb{Z}\},$$

the translation group of a planar crystal or wallpaper pattern. A rotation that maps the pattern to itself must in particular map L to itself. The remarkable fact, due to the rigidity of L, is that only a handful of rotation orders are compatible with a lattice: the orders $1, 2, 3, 4, 6$ and no others. In particular there is no lattice with 5-fold or 7-fold symmetry.

Definition 4.9.14 (Discrete subgroup and lattice)**.** A subgroup L of the additive group $\mathbb{R}^2$ of translation vectors is *discrete* if there is $\varepsilon > 0$ with $|v| \geq \varepsilon$ for every nonzero $v \in L$; equivalently, distinct points of L are separated by distance at least ε. A discrete subgroup spanned over $\mathbb{Z}$ by two independent vectors is a *lattice*. A nonzero $v \in L$ is a *minimal vector* if L contains no shorter nonzero vector.

Remark 4.9.5. Discreteness guarantees a minimal vector exists: a bounded disk meets L in only finitely many points (the ε-separation packs at most one lattice point per small square), so the finitely many nonzero points of L inside the disk of radius $|a|$ about the origin include one of least length. This is the only existence fact the main proof needs.

The point group acts on L. We first record the underlying fact: an orthogonal symmetry of the pattern permutes the translation lattice.

Proposition 4.9.15 (The point group preserves the lattice)**.** *Let $G \leq M$ be a discrete group of isometries of the plane with translation lattice L and point group $\overline{G} \leq \mathrm{O}(2)$. If $g \in G$ has image $\overline{g} \in \overline{G}$ and $a \in L$, then $\overline{g}(a) \in L$. Equivalently, every element of $\overline{G}$ maps L to itself, so $\overline{G}$ is a subgroup of the symmetry group of L.*

Proof. Write $g = t_b\varphi$ with $\varphi \in \mathrm{O}(2)$ the linear part, so $\overline{g} = \varphi$. Let $t_a \in G$ be the translation by a and put $a' = \varphi(a)$. A direct computation with the composition rule $t_c\psi = \psi\, t_{\psi^{-1}(c)}$ for isometries gives

$$g\, t_a\, g^{-1} = (t_b\varphi)\, t_a\, (\varphi^{-1}t_{-b}) = t_b\, t_{\varphi(a)}\, \varphi\varphi^{-1}\, t_{-b} = t_{a'},$$

the conjugate of a translation being the translation by the rotated vector. Since G is a group, $t_{a'} = g\, t_a\, g^{-1} \in G$, hence $a' = \varphi(a) \in L$. □

Theorem 4.9.16 (Crystallographic restriction)**.** *Let $L \subset \mathbb{R}^2$ be a lattice and let $H \leq \mathrm{O}(2)$ be a subgroup of the symmetry group of L. Then every rotation in H has order $1, 2, 3, 4,$ or 6; consequently H is one of the cyclic groups C_n or dihedral groups D_n with $n \in \{1, 2, 3, 4, 6\}$. In particular a rotation of order 5 (or of order 7, or any order outside this list) cannot be a symmetry of a lattice.*

Proof. Let $\rho \in H$ be a rotation through an angle θ with $0 < \theta \leq \pi$ (replacing ρ by ρ^{-1} if needed does not change its order). Let a be a minimal vector of L, of length $r = |a| > 0$. Since H preserves L, the vector $\rho(a)$ lies in L, and therefore so does

$$b = \rho(a) - a \in L.$$

Both a and $\rho(a)$ have length r, and the angle between them is θ, so $a, \rho(a), b$ form an isosceles triangle and

$$|b| = 2r \sin\left(\tfrac{\theta}{2}\right).$$

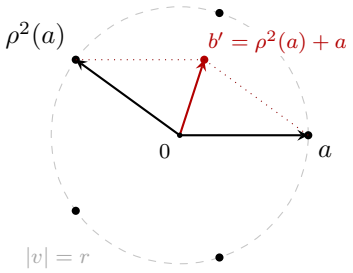
Because a is a *minimal* vector and $b \in L$ is nonzero (as $\theta \neq 0$), we need $|b| \geq r$, i.e.

$$2\sin\left(\tfrac{\theta}{2}\right) \geq 1, \qquad \text{so} \qquad \sin\left(\tfrac{\theta}{2}\right) \geq \tfrac{1}{2}, \qquad \tfrac{\theta}{2} \geq \tfrac{\pi}{6}, \qquad \theta \geq \tfrac{\pi}{3} = \tfrac{2\pi}{6}.$$

A rotation of order n has $\theta = 2\pi/n$ as its smallest positive angle, so $2\pi/n \geq 2\pi/6$ forces $n \leq 6$. Discreteness makes H finite, hence (being a finite subgroup of $\mathrm{O}(2)$) cyclic C_n or dihedral D_n.

It remains to exclude $n = 5$, the one survivor of $n \leq 6$ not already in the list. Suppose $\theta = 2\pi/5$. Apply the symmetry again: $\rho^2(a) \in L$, so

$$b' = \rho^2(a) + a \in L.$$



Now $\rho^2(a)$ has length r and makes angle $2\theta = 4\pi/5$ with a, so the parallelogram diagonal $b' = \rho^2(a) + a$ has length

$$|b'| = 2r\cos\left(\tfrac{2\theta}{2}\right) = 2r\cos\left(\tfrac{2\pi}{5}\right) = 2r\cos 72^\circ \approx 0.618\, r < r.$$

Thus b' is a nonzero lattice vector strictly shorter than the minimal vector a, a contradiction. Hence $\theta = 2\pi/5$ is impossible and $n = 5$ is ruled out, leaving exactly $n \in \{1, 2, 3, 4, 6\}$. □

Remark 4.9.6. The same length estimate kills every forbidden order at once. For order n the vector $\rho(a) - a$ has length $2r\sin(\pi/n)$, which is $\geq r$ only for $n \leq 6$; and among $n \leq 6$ the case $n = 5$ is removed by the auxiliary vector $\rho^2(a) + a$ of length $2r\cos(2\pi/5) < r$. Orders $7, 8, 9, \ldots$ already fail the first test, so no separate argument is needed for 7-fold symmetry.

The contradiction for 5-fold symmetry is best seen in a picture: rotating a minimal vector by 72° five times produces a regular pentagon of lattice points, and the "second-neighbour" combination $\rho^2(a) + a$ lands strictly inside the minimal circle.

The red lattice vector b' lies inside the dashed circle of radius r, so it is a nonzero lattice vector shorter than the supposed minimal vector a — impossible.

Method (Deciding whether a rotation order is lattice-compatible)**.** *Trigger.* "can an n-fold rotation be a symmetry of a 2D lattice / wallpaper pattern?"

1. Take a minimal lattice vector a of length r and rotate it: $\rho(a) - a$ is a lattice vector of length $2r\sin(\pi/n)$.

2. Demand $2r\sin(\pi/n) \geq r$, i.e. $\sin(\pi/n) \geq \frac{1}{2}$. This passes only for $n \leq 6$.

3. Among the survivors, test $n = 5$ separately: $\rho^2(a) + a$ has length $2r\cos(2\pi/5) < r$, a contradiction. So the admissible orders are exactly $1, 2, 3, 4, 6$.

Worked Example 4.9.17 (5-fold symmetry is impossible)**.** Show that no planar lattice has a rotational symmetry of order 5.

Recognition. Use the crystallographic restriction: build a lattice vector shorter than the minimal one.

Solution. Let ρ be rotation by $\theta = 2\pi/5 = 72^\circ$ and let a be a minimal vector, $|a| = r$. Then $\rho^2(a) \in L$ makes angle $4\pi/5 = 144^\circ$ with a, so

$$b' = \rho^2(a) + a \in L, \qquad |b'| = 2r\cos\Big(\tfrac{2\pi}{5}\Big) = 2r\cos 72^\circ \approx 0.618\, r < r.$$

This nonzero lattice vector is shorter than the minimal vector, a contradiction. Hence no 5-fold lattice symmetry exists. *Check.* The first test $2\sin(\pi/5) = 2\sin 36^\circ \approx 1.176 \geq 1$ does *not* exclude $n = 5$, which is exactly why the auxiliary vector $\rho^2(a) + a$ is needed. ■

Worked Example 4.9.18 (7-fold symmetry is impossible (the first test suffices))**.** Show that a lattice admits no rotational symmetry of order 7.

Recognition. Apply step 2 of the method: compare $|\rho(a) - a|$ to r.

Solution. With $\theta = 2\pi/7$ and a minimal vector a, the lattice vector $b = \rho(a) - a$ has length

$$|b| = 2r\sin\Big(\tfrac{\pi}{7}\Big) = 2r\sin\big(25.7^\circ\big) \approx 0.868\, r < r.$$

So b is a nonzero lattice vector shorter than the minimal a — impossible. Order 7 is excluded already by the first inequality; no second vector is required. *Check.* $\sin(\pi/7) \approx 0.4339 < \frac{1}{2}$, so $2\sin(\pi/7) < 1$, confirming the failure for every $n \geq 7$ since $\sin(\pi/n)$ decreases. ■

Worked Example 4.9.19 (6-fold symmetry is allowed — the hexagonal lattice)**.** Verify that the order $n = 6$ is compatible, and exhibit the lattice.

Recognition. Order 6 is on the admissible list; check the inequality is met with equality and name a realizing lattice.

Solution. For $n = 6$, $\theta = \pi/3 = 60^\circ$, and $|\rho(a) - a| = 2r\sin 30^\circ = 2r \cdot \frac{1}{2} = r$. The bound $|\rho(a) - a| \geq r$ holds with *equality*: $\rho(a) - a$ is itself a minimal vector, so no contradiction arises. The realizing lattice is the hexagonal (triangular) lattice $L = \mathbb{Z}a + \mathbb{Z}b$ with $|a| = |b| = r$ and angle 60° between a and b; its symmetry group is D_6, with a 6-fold rotation about each lattice point. *Check.* The six vectors $\rho^k(a)$, $k = 0, \ldots, 5$, are the six minimal vectors of the hexagonal lattice, all of length r, consistent with equality in the bound. ■

Worked Example 4.9.20 (Which $n \leq 6$ are realized, and by which lattice)**.** List, for each admissible order, a lattice realizing it.

Recognition. Match each $n \in \{1, 2, 3, 4, 6\}$ to a standard plane lattice.

Solution.

n	a lattice with an n-fold rotation
1	any lattice (trivial rotation only), generic oblique lattice
2	every lattice has $-\mathrm{id}$, the 180° rotation; oblique lattice
3	hexagonal lattice (also carries $C_3 \leq C_6$)
4	square lattice $\mathbb{Z}e_1 + \mathbb{Z}e_2$, symmetry D_4
6	hexagonal lattice, symmetry D_6

Order 5 is absent, as is every $n \geq 7$. *Check.* The orders present, $\{1, 2, 3, 4, 6\}$, are exactly the lattice-compatible set from the theorem; every plane lattice automatically has the order-2 symmetry $v \mapsto -v$, so C_2 always lies in the full symmetry group of the lattice (a subgroup H, such as C_1 or C_3, need not contain it). ■

Remark 4.9.7 (Quasicrystals). The restriction forbids *periodic* 5-fold symmetry, not 5-fold symmetry as such. Dropping the requirement that the pattern repeat by a lattice, one can build aperiodic tilings — the Penrose tiling is the famous example — whose diffraction patterns show sharp 10-fold (hence 5-fold) spots. Physical solids with exactly this aperiodic long-range order, *quasicrystals*, were discovered by Shechtman in 1982 and earned the 2011 Nobel Prize in Chemistry. They evade the theorem precisely because their translation group is *not* a lattice, so the minimal-vector argument has no minimal vector to exploit.

Caution. The bound $|\rho(a) - a| \geq |a|$ alone rules out only $n \geq 7$; it does *not* exclude $n = 5$, since $2\sin(\pi/5) \approx 1.18 \geq 1$. The order 5 must be killed by the *second* vector $\rho^2(a) + a$. Skipping that step is the common error in stating the proof. Note too that the theorem is special to dimension 2 (and 3): in higher dimensions lattices with 5-fold symmetry do exist, e.g. the root lattice underlying the 4-dimensional analogue.

4.10 Plane Crystallographic (Wallpaper) Groups

Plane crystallographic (wallpaper) groups

We continue the analysis of discrete groups of isometries $G \leq \mathrm{M}$ of the Euclidean plane, where M is the group of all isometries. Such a G comes with two pieces of data: its *translation group*

$$L = \{\, v \in V : \; t_v \in G \,\},$$

the set of translation vectors v for which the translation t_v lies in G, and its *point group* $\overline{G} \leq \mathrm{O}(2)$, the image of G under the homomorphism $\pi : \mathrm{M} \to \mathrm{O}(2)$ that forgets the translation part of an isometry. When L is the trivial group, G is cyclic or dihedral; when L is infinite cyclic, G is the symmetry group of a frieze pattern. The remaining case — when L is a full *lattice* — is the subject here.

Definition 4.10.1 (Plane crystallographic group)**.** A subgroup $G \leq \mathrm{M}$ is a *(two-dimensional) plane crystallographic group*, or *wallpaper group*, if it is discrete and its translation group L is a *lattice*: there are two linearly independent vectors $a, b \in V$ with

$$L = \mathbb{Z}a + \mathbb{Z}b = \{\, ma + nb : \; m, n \in \mathbb{Z} \,\}.$$

Equivalently, G has two independent translational symmetries and no points of accumulation. These are exactly the symmetry groups of doubly periodic plane figures — wallpaper patterns, and cross-sections of two-dimensional crystals such as graphite.

Remark 4.10.1. The point group $\overline{G}$ acts on the translation space V but *not* on the plane P itself (without a chosen origin, P and V are different objects). The key compatibility, due to the conjugation identity $g\, t_a\, g^{-1} = t_{\overline{g}(a)}$, is that $\overline{G}$ carries the lattice L to itself: if $a \in L$ and $\overline{g} \in \overline{G}$, then $\overline{g}(a) \in L$. Thus $\overline{G}$ is a subgroup of the symmetry group of the lattice L, regarded as a figure in V. This single fact forces a severe restriction.

Theorem 4.10.2 (Crystallographic restriction)**.** *Let L be a lattice in V, and let $H \leq \mathrm{O}(2)$ be a subgroup of the group of symmetries of L (so H carries L to itself). Then:*

(a) every rotation in H has order $1, 2, 3, 4$, or 6; and

(b) H is one of the groups C_n or D_n with $n \in \{1, 2, 3, 4, 6\}$.

In particular a rotation of order 5 is impossible: there is no wallpaper pattern with five-fold rotational symmetry.

Proof. We prove (a); part (b) follows from (a) together with the classification of finite subgroups of $\mathrm{O}(2)$ as C_n or D_n. Let $\rho_\theta \in H$ be a rotation through angle $\theta > 0$, and choose a nonzero $a \in L$ of *minimal length*. Since H carries L to itself, $\rho_\theta(a) \in L$, and hence

$$b = \rho_\theta(a) - a \in L.$$

By minimality $|a| \le |b|$. A short computation gives $|b|^2 = |a|^2(2 - 2\cos\theta)$, so $|b| \ge |a|$ forces $2 - 2\cos\theta \ge 1$, i.e. $\cos\theta \le \frac{1}{2}$, i.e. $\theta \ge 2\pi/6$. Thus the smallest rotation angle in H is at least $2\pi/6$, so a rotation has order at most 6.

It remains to exclude order 5, i.e. $\theta = 2\pi/5$. For that angle consider instead

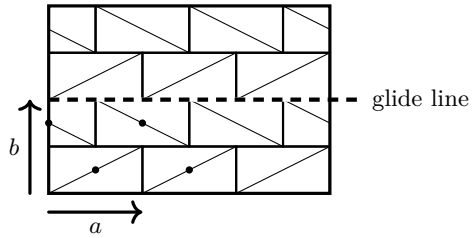
$$b' = \rho_\theta^2(a) + a \in L.$$

One computes $|b'|^2 = |a|^2\big(2 + 2\cos 2\theta\big) = |a|^2(2 + 2\cos(4\pi/5))$, and since $\cos(4\pi/5) = -\frac{1+\sqrt{5}}{4} < -\frac{1}{2}$ we get $|b'| < |a|$, contradicting minimality. So order 5 cannot occur, and every rotation in H has order $1, 2, 3, 4$, or 6. □

Remark 4.10.2. The point group records only the angles of rotation and the lines of reflection or glide; it does *not* determine G. Two complications arise. First, the lattice L and the point group $\overline{G}$ together still leave room for genuinely different groups G. Second, and more subtly, a reflection in the point group $\overline{G}$ need not be realized in G by an honest reflection: it may be present in G only through *glide reflections*. Recall a glide reflection is the composite $t_w\, r$ of a reflection r across a line ℓ with a translation t_w *along* ℓ; it has no fixed point, whereas an ordinary reflection fixes its whole axis.

Theorem 4.10.3 (Classification of plane crystallographic groups)**.** *Up to isomorphism (equivalently, up to an affine change of coordinates), there are exactly* 17 *plane crystallographic groups. They are distributed over the allowed point groups C_n, D_n ($n \in \{1, 2, 3, 4, 6\}$) as follows.*

point group	*order*	*# wallpaper types*	*which*
C_1	1	1	*p1*
C_2	2	1	*p2*
C_3	3	1	*p3*
C_4	4	1	*p4*
C_6	6	1	*p6*
D_1	2	3	*pm, pg, cm*
D_2	4	4	*pmm, pmg, pgg, cmm*
D_3	6	2	*p3m1, p31m*
D_4	8	2	*p4m, p4g*
D_6	12	1	*p6m*
total		17	



*The five cyclic point groups give one type each (*5 *in all); the dihedral point groups split into* 12 *types, the extra ones distinguished by whether a reflection in $\overline{G}$ is realized by a true reflection or only by a glide, by the shape (square, rectangular, rhombic, hexagonal) of the underlying lattice, and, for the pair p3m1, p31m (both on the hexagonal lattice, both with true reflections in three directions), by how the mirror lines sit relative to the lattice: in p3m1 every* 3*-fold rotation center lies on a mirror line, in p31m some do not.*

Remark 4.10.3. We do not reproduce the full case analysis; it proceeds point group by point group, in each case pinning down the position of a reflection or glide relative to the lattice. As a sample of the method we treat the point group $D_1 = \{1, r\}$ informally below and the brick pattern in detail. Artin carries out the analysis only for the point groups C_4 and D_4 (Propositions 6.6.3 and 6.6.4), as a model of the method; that the 17 types exhaust the possibilities is left as an exercise (Artin, Exercise 6.6.6).

Glide vs. ordinary reflection: the brick pattern

The cleanest illustration of why the point group alone is not enough is a *brick pattern*: a running bond in which every brick carries a diagonal stroke, rising to the right in alternate rows and falling to the right in the rows between. Its symmetry group has the same point group D_2 as a fully symmetric rectangular pattern, yet it contains *no reflection at all* — only glides. (The strokes matter: the plain running bond is *not* an

example, since reflection across the middle line of any row preserves it; its group is of type cmm, with a centered lattice.)

$c = \left(\frac{1}{2}, \frac{1}{2}\right)$ glide

Let the lattice be $L = \mathbb{Z}a + \mathbb{Z}b$ where a spans the length of one brick and b spans two rows. The pattern has a half-turn (ρ_π, order 2) about the center of each brick and about the midpoints of its short edges; these are all the same element ρ_π of the point group. There are no rotations of any other nontrivial angle. Crucially, although the pattern *looks* like it should have a mirror, no reflection actually fixes it: reflecting across a horizontal line through the middle of a row reverses the slant of the strokes in that row, reflecting across a mortar line sends the staggered rows out of register, and every vertical reflection reverses the slant of the strokes. What *does* fix it is the glide reflection across the dashed line, combining the reflection across the middle line of the row just below it with the half-period translation $c = (\frac{1}{2}, \frac{1}{2})$ measured in the basis (a, b). Hence

$$\overline{G} = D_2 = \{1,\ \rho_\pi,\ r,\ \rho_\pi r\}, \qquad \text{but } G \text{ contains no reflection — the } r \text{ in } \overline{G} \text{ is realized only by a glide.}$$

This is the type **pgg**; the type **pmm** has the *same* point group D_2 but realizes both reflections honestly.

Method (Determining the type of a wallpaper pattern)**.** *Trigger.* You are handed a doubly periodic pattern and must name its point group (and ultimately its type).

1. **Find the rotations.** Locate the centers of rotational symmetry and the smallest rotation angle. This gives n with the point group C_n or D_n; by Theorem 4.10.2, $n \in \{1, 2, 3, 4, 6\}$.
2. **Reflection or glide?** Look for mirror lines and glide lines. If the pattern has any reflection or glide symmetry, the point group is D_n; if it has none, it is C_n.
3. **Distinguish same-point-group types.** When $\overline{G} = D_n$, decide for each mirror direction in $\overline{G}$ whether it is realized by a true reflection (axis fixed) or only by a glide (no fixed line), and read off the lattice shape. This separates e.g. pm/pg/cm or pmm/pmg/pgg/cmm.

Worked Example 4.10.4 (The point group of the brick pattern is D_2, not C_2)**.** Problem. Determine the point group of the brick pattern above, and explain why it is D_2 even though the group contains no reflection.

Recognition. Apply the recipe: first the rotations fix n, then the presence of glide/reflection symmetry decides C_n vs. D_n.

Solution. Rotations: the only nontrivial rotational symmetry is the half-turn ρ_π about a brick center (or the midpoint of a short edge). No 90° or 120° rotation preserves the staggered rows, so $n = 2$. *Reflection or glide:* a horizontal reflection alone fails (it reverses the slant of the strokes or puts the offset rows out of register), but the glide across the dashed line — the reflection across the middle line of the row just below it, followed by the translation by $c = (\frac{1}{2}, \frac{1}{2})$ — does preserve the pattern. The point group is the *image* in O(2), and the linear part of a glide reflection is an honest reflection r. So $r \in \overline{G}$. *Check.* $\overline{G}$ contains $1, \rho_\pi, r$, hence also $\rho_\pi r$, giving $\overline{G} = D_2$ of order 4. Yet G itself has no element with reflection-type fixed line, so $G \neq D_2$ as an isometry group: the point group sees the mirror, the isometry group realizes it only as a glide. This is precisely why $\overline{G}$ and L do not determine G.

Worked Example 4.10.5 (Five-fold symmetry is impossible)**.** Problem. Show directly that no wallpaper pattern can have a rotation of order 5.

Recognition. This is exactly the content of part (a) of the crystallographic restriction (Theorem 4.10.2); reproduce the minimal-vector argument for $\theta = 2\pi/5$.

Solution. Suppose ρ_θ with $\theta = 2\pi/5$ were a symmetry, so $\rho_\theta \in \overline{G}$ carries L to itself. Pick $a \in L$ nonzero of minimal length and set $b' = \rho_\theta^2(a) + a$, which lies in L. Then

$$|b'|^2 = |a|^2\big(2 + 2\cos 2\theta\big) = |a|^2\big(2 + 2\cos \tfrac{4\pi}{5}\big).$$

Numerically $\cos \frac{4\pi}{5} \approx -0.809$, so $2 + 2\cos \frac{4\pi}{5} \approx 0.382$ and $|b'| \approx 0.618\,|a| < |a|$. *Check.* $b' \in L$ is a nonzero vector shorter than a, contradicting the minimality of a. Hence $\theta = 2\pi/5$ is impossible, and order 5 is excluded — consistent with the table allowing only $n \in \{1, 2, 3, 4, 6\}$.

Worked Example 4.10.6 (Counting the D_1 types: pm, pg, cm)**.** Problem. The point group $D_1 = \{1, r\}$ has a single mirror direction. Explain why it yields *three* distinct wallpaper types rather than one.

Recognition. Step 3 of the recipe: with $\overline{G}$ fixed at D_1, enumerate the ways the single reflection can sit relative to the lattice, plus the lattice shape.

Solution. With $\overline{G} = D_1$ the only structure to vary is how the mirror r of $\overline{G}$ is realized in G and what lattice supports it. There are three inequivalent possibilities:

(pm) r is realized by an *ordinary reflection* (its axis is fixed pointwise), on a rectangular lattice;

(pg) r is realized *only by a glide* (no fixed mirror line), on a rectangular lattice;

(cm) both a reflection and a glide occur, forced by a *rhombic* (centered) lattice.

Check. These three exhaust the cases: either there is a true mirror or not (pm vs. pg on the rectangular lattice), and the centered lattice gives the third, genuinely different, group cm. This matches the row $D_1 \to 3$ types in Theorem 4.10.3. The same reflection-vs-glide-plus-lattice bookkeeping, applied to D_2, produces its 4 types pmm, pmg, pgg, cmm.

Remark 4.10.4. Artin works out the cases C_4 and D_4 explicitly to model the method. After choosing the minimal vector a and setting $b = \rho_{\pi/2}(a)$, one shows the lattice L is *square* with basis (a, b) (Lemma 6.6.2); rescaling makes $L = \mathbb{Z}^2$. For $\overline{G} = C_4$ one finds $G = \{\, t_v\rho^i : \ v \in L,\ 0 \le i < 4 \,\}$ (Proposition 6.6.3), the single type p4. For $\overline{G} = D_4$ a short computation shows the reflection generator g with $\overline{g} = r$ must satisfy $u \in \{(0,0), c\}$ with $c = (\frac{1}{2}, \frac{1}{2})$: the case $u = (0,0)$ gives a true reflection (type p4m), and the case $u = c$ realizes the reflection only as a glide (type p4g), exactly the two D_4 types of the table (Proposition 6.6.4).

Caution. **Same point group does not mean same group.** The brick pattern and a mirror-symmetric rectangular pattern both have point group D_2, but they are different wallpaper types (pgg vs. pmm) because one realizes the reflection only as a glide. Never read off the wallpaper type from $\overline{G}$ alone — you must also examine how each mirror sits relative to the lattice, and the lattice's shape.

Caution. **The point group lives in** $\mathrm{O}(2)$**, the group** G **lives in** M**.** A glide reflection $t_w r \in G$ has *linear part* the reflection r, so it contributes r to $\overline{G}$ even though $t_w r$ itself fixes no line. Confusing an element of G with its image in $\overline{G}$ is the source of most errors in classifying these groups.

4.11 Finite Subgroups of the Rotation Group $\mathrm{SO}(3)$

Finite subgroups of $\mathrm{SO}(3)$: the Platonic symmetries

We classify the finite groups of rotations of $\mathbb{R}^3$. The answer is short and famous: besides the cyclic and dihedral families there are exactly three exceptional groups, the rotation groups of the regular polyhedra. The proof is a counting argument run on the *poles* of the group — the points where rotation axes pierce the unit sphere — and it leans on the orbit–stabilizer (counting) formula $|\operatorname{Orb}(p)| \cdot |\operatorname{Stab}(p)| = |G|$.

Theorem 4.11.1 (Classification of finite subgroups of $\mathrm{SO}(3)$)**.** *A finite subgroup G of* $\mathrm{SO}(3)$ *is one of:*

- *C_k, the cyclic group of rotations by multiples of $2\pi/k$ about a fixed line (k arbitrary);*

- D_k, *the dihedral group of the* $2k$ *rotations carrying a regular* k*-gon to itself;*
- T, *the* tetrahedral *group of the* 12 *rotational symmetries of a regular tetrahedron;*
- O, *the* octahedral *group of the* 24 *rotational symmetries of a cube (equivalently an octahedron);*
- I, *the* icosahedral *group of the* 60 *rotational symmetries of a regular icosahedron (equivalently a dodecahedron).*

Remark 4.11.1. The dihedral groups appear here as honest *rotation* groups. A reflection of a plane is realized in $\mathbb{R}^3$ by a rotation through angle π about an axis lying in that plane. So D_k is generated by a rotation x of angle $2\pi/k$ about the vertical axis together with a rotation y of angle π about a horizontal axis; with $c = \cos(2\pi/k)$ and $s = \sin(2\pi/k)$,

$$x = \begin{pmatrix} c & -s & 0 \\ s & c & 0 \\ 0 & 0 & 1 \end{pmatrix}, \qquad y = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

Poles and spins

Definition 4.11.2 (Pole)**.** Let $G \leq \mathrm{SO}(3)$ be finite of order $N > 1$. Every $g \neq 1$ in $\mathrm{SO}(3)$ is a rotation about a unique axis; that axis meets the unit sphere S^2 in two points. A *pole* of G is a point $p \in S^2$ fixed by some $g \in G$ with $g \neq 1$. Write P for the set of all poles of G.

Lemma 4.11.3 (P is a union of orbits)**.** *G permutes P: if $p \in P$ and $h \in G$ then $hp \in P$. Hence P is a union of G-orbits.*

Proof. Say p is fixed by $g \neq 1$, and put $q = hp$. Then $hgh^{-1} \neq 1$ (conjugate of a nonidentity element), and

$$(hgh^{-1})\, q = (hgh^{-1})\, hp = hg\, p = hp = q,$$

so q is fixed by the nonidentity element hgh^{-1}, i.e. q is a pole. □

For a pole p the stabilizer $\mathrm{Stab}(p) = G_p$ is the set of elements of G rotating about the axis through p. It is cyclic, generated by the rotation of smallest positive angle; write $r_p = |G_p|$. Since p is a pole, $r_p > 1$. The nonidentity elements of G fixing p are exactly the $r_p - 1$ nonidentity elements of G_p.

Theorem 4.11.4 (The pole-counting formula)**.** *Let $G \leq \mathrm{SO}(3)$ be finite of order $N > 1$, with pole-orbits $O_1, \ldots, O_k$. Write $r_i = r_p$ and $n_i = |O_i|$ for $p \in O_i$ (these depend only on the orbit), so that $r_i n_i = N$. Then*

$$\sum_{i=1}^{k} \Big(1 - \tfrac{1}{r_i}\Big) = 2 - \tfrac{2}{N}.$$

Proof. Count *spins*: pairs (g, p) with $g \neq 1$ and $gp = p$. Counting by group elements, each $g \neq 1$ is a nontrivial rotation, hence has exactly two poles, so there are $2(N-1)$ spins. Counting by poles, the pole p occurs in $r_p - 1$ spins. Equating,

$$\sum_{p \in P} (r_p - 1) = 2(N-1).$$

Now collect by orbits. By orbit–stabilizer $r_p\, n_p = N$ (where $n_p = |\,\mathrm{Orb}(p)|$); poles in the same orbit share the same r_p and n_p. Each orbit O_i contributes n_i equal terms $r_i - 1$, so the left side is $\sum_i n_i(r_i - 1) = 2N - 2$. Divide by N and use $n_i/N = 1/r_i$:

$$\sum_{i=1}^{k} \frac{n_i(r_i - 1)}{N} = \sum_{i=1}^{k} \Big(1 - \frac{1}{r_i}\Big) = 2 - \frac{2}{N}.$$ □

Method (Reading the constraint $\sum_i \big(1 - \frac{1}{r_i}\big) = 2 - \frac{2}{N}$)**.** *Trigger.* You must enumerate the finite subgroups of SO(3), or bound the number of pole-orbits.

1. The right side $2 - \frac{2}{N}$ lies in $[1, 2)$ for $N \geq 2$.
2. Each $r_i \geq 2$, so each term $1 - \frac{1}{r_i} \geq \frac{1}{2}$. Hence $k \leq 3$: four or more terms already sum to at least $2 > 2 - \frac{2}{N}$.
3. Tabulate by number of orbits ($k = 1, 2, 3$). The case $k = 3$ forces $\frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3} > 1$ with $2 \leq r_1 \leq r_2 \leq r_3$; its solutions are the infinite family $(2, 2, r)$, $r \geq 2$, and the three triples $(2, 3, 3), (2, 3, 4), (2, 3, 5)$.
4. Each surviving triple (r_1, r_2, r_3) pins down N and the orbit sizes $n_i = N/r_i$.

The case analysis

There can be at most three orbits. We run through $k = 1, 2, 3$.

One orbit. The formula reads $1 - \frac{1}{r_1} = 2 - \frac{2}{N}$. The left side is < 1 while the right is ≥ 1 (as $N \geq 2$): impossible.

Two orbits. Here $\left(1 - \frac{1}{r_1}\right) + \left(1 - \frac{1}{r_2}\right) = 2 - \frac{2}{N}$, i.e. $\frac{1}{r_1} + \frac{1}{r_2} = \frac{2}{N}$. Since $r_i \mid N$ and $r_i \leq N$, each $\frac{1}{r_i} \geq \frac{1}{N}$, with equality forced: $r_1 = r_2 = N$ and $n_1 = n_2 = 1$. Two poles, each fixed by all of G, so G rotates about the single line ℓ through them: $G = C_N$.

Three orbits. Now $\frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3} = 1 + \frac{2}{N} > 1$ with $2 \leq r_1 \leq r_2 \leq r_3$. If $r_1 \geq 3$ the left side is $\leq 3 \cdot \frac{1}{3} = 1$, contradiction; so $r_1 = 2$. Then $\frac{1}{r_2} + \frac{1}{r_3} = \frac{1}{2} + \frac{2}{N} > \frac{1}{2}$.

- If $r_2 = 2$ as well, $r_3 = k$ is arbitrary and $N = 2k$: the orbit data $(r_i) = (2, 2, k)$, $(n_i) = (k, k, 2)$. Half of G fixes the polar pair, the other half swaps it by a π-rotation about a perpendicular axis. This is the dihedral group D_k of a regular k-gon in the plane perpendicular to ℓ.
- If $r_2 = 3$: from $\frac{1}{3} + \frac{1}{r_3} > \frac{1}{2}$ we get $r_3 < 6$, and $r_3 \geq r_2 = 3$, so $r_3 \in \{3, 4, 5\}$. ($r_2 \geq 4$ already fails: $\frac{1}{4} + \frac{1}{4} = \frac{1}{2}$ leaves no room.)

The three triples with $r_1 = 2, r_2 = 3$ are

$$(2, 3, 3)\colon\ N = 12; \qquad (2, 3, 4)\colon\ N = 24; \qquad (2, 3, 5)\colon\ N = 60,$$

the tetrahedral, octahedral, and icosahedral groups T, O, I. This proves Theorem 4.11.1.

Remark 4.11.2. In each polyhedral case the three orbit sizes $n_i = N/r_i$ count, in order, the edge-centers, face-centers, and vertices of the associated regular solid (the larger r_i, the more rotations fix that pole, hence the fewer such poles). The poles with $r_i = 2$ sit above edge-midpoints; the vertex-poles carry the highest-order rotations.

Worked counting

Worked Example 4.11.5 (The tetrahedral group T: counting its 14 poles and 22 spins)**.** The rotation group T of a regular tetrahedron Δ has order 12. Verify the spin count directly, without the abstract formula.

Recognition. Poles sit above the centers of faces, the vertices, and the centers of edges; count spins two ways and check they agree with $2(N - 1)$.

Solution. Δ has 4 faces, 4 vertices, 6 edges, so

$$|P| = 4 + 4 + 6 = 14.$$

Each $g \neq 1$ (there are 11) has two poles, giving $2 \cdot 11 = 22$ spins. By pole-type: a face axis has stabilizer of order 3, contributing $r - 1 = 2$ spins per pole, over 4 faces; a vertex axis likewise $r = 3$, contributing 2 spins over 4 vertices; an edge axis has $r = 2$, contributing 1 spin over 6 edges. Total

$$2 \cdot 4 + 2 \cdot 4 + 1 \cdot 6 = 8 + 8 + 6 = 22.$$

Check. $22 = 2(N - 1) = 2(12 - 1)$. ■

Worked Example 4.11.6 (Reading off T from the triple $(2,3,3)$)**.** For $(r_1,r_2,r_3)=(2,3,3)$ compute N and the orbit sizes, and match them to the tetrahedron.

Recognition. Use $\frac{1}{r_1}+\frac{1}{r_2}+\frac{1}{r_3}=1+\frac{2}{N}$ to solve for N, then $n_i=N/r_i$.

Solution. $\frac{1}{2}+\frac{1}{3}+\frac{1}{3}=\frac{3+2+2}{6}=\frac{7}{6}=1+\frac{1}{6}$, so $\frac{2}{N}=\frac{1}{6}$ and $N=12$. The orbit sizes are

$$n_1=\tfrac{12}{2}=6,\qquad n_2=\tfrac{12}{3}=4,\qquad n_3=\tfrac{12}{3}=4,$$

i.e. 6 edge-centers, 4 face-centers, 4 vertices — exactly the tetrahedron's tallies. *Check.* $\left(1-\frac{1}{2}\right)+\left(1-\frac{1}{3}\right)+\left(1-\frac{1}{3}\right)=\frac{1}{2}+\frac{2}{3}+\frac{2}{3}=\frac{11}{6}=2-\frac{2}{12}$. ■

Worked Example 4.11.7 (The octahedral triple $(2,3,4)$ gives $N=24$)**.** Solve $(2,3,4)$ and identify the orbits with a cube.

Recognition. Same recipe: solve for N, then $n_i=N/r_i$; interpret on the cube.

Solution. $\frac{1}{2}+\frac{1}{3}+\frac{1}{4}=\frac{6+4+3}{12}=\frac{13}{12}=1+\frac{1}{12}$, so $\frac{2}{N}=\frac{1}{12}$ and $N=24$. Then

$$n_1=\tfrac{24}{2}=12,\qquad n_2=\tfrac{24}{3}=8,\qquad n_3=\tfrac{24}{4}=6.$$

On a cube these are the 12 edge-centers ($r=2$, half-turns), the 8 vertices ($r=3$, body-diagonal thirds-turns), and the 6 face-centers ($r=4$, quarter-turns). The dual octahedron swaps the roles of the 6 and the 8, giving the same group O. *Check.* $\left(1-\frac{1}{2}\right)+\left(1-\frac{1}{3}\right)+\left(1-\frac{1}{4}\right)=\frac{1}{2}+\frac{2}{3}+\frac{3}{4}=\frac{6+8+9}{12}=\frac{23}{12}=2-\frac{2}{24}$. ■

Worked Example 4.11.8 (The icosahedral triple $(2,3,5)$ gives $N=60$)**.** Solve $(2,3,5)$ and read off the orbit sizes; relate the vertex-orbit to a regular icosahedron.

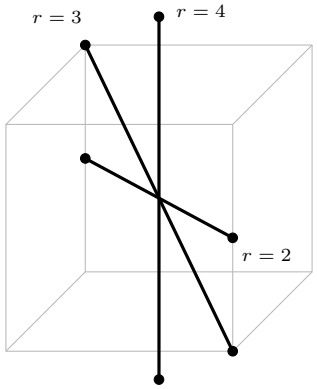
Recognition. Solve for N, then $n_i=N/r_i$; the order-5 orbit is the vertex set.

Solution. $\frac{1}{2}+\frac{1}{3}+\frac{1}{5}=\frac{15+10+6}{30}=\frac{31}{30}=1+\frac{1}{30}$, so $\frac{2}{N}=\frac{1}{30}$ and $N=60$. Then

$$n_1=\tfrac{60}{2}=30,\qquad n_2=\tfrac{60}{3}=20,\qquad n_3=\tfrac{60}{5}=12,$$

giving 30 edge-centers, 20 face-centers, and 12 vertices. Taking one vertex-pole p as "north pole," its stabilizer is cyclic of order 5; the remaining vertex-poles split into the south pole and two 5-element rings. The five congruent equilateral triangles meeting at p are faces of a regular icosahedron, so the order-5 orbit is its 12 vertices. *Check.* $\left(1-\frac{1}{2}\right)+\left(1-\frac{1}{3}\right)+\left(1-\frac{1}{5}\right)=\frac{1}{2}+\frac{2}{3}+\frac{4}{5}=\frac{15+20+24}{30}=\frac{59}{30}=2-\frac{2}{60}$. ■

Remark 4.11.3 (Summary of the polyhedral data). The three exceptional groups correspond to the only integer triples $2\le r_1\le r_2\le r_3$ with $\frac{1}{r_1}+\frac{1}{r_2}+\frac{1}{r_3}>1$ beyond the dihedral family:



(r_1,r_2,r_3)	N	$(n_1,n_2,n_3)=$ (edges, faces, vertices)	group
$(2,3,3)$	12	$(6,4,4)$	T
$(2,3,4)$	24	$(12,8,6)$	O
$(2,3,5)$	60	$(30,20,12)$	I

Caution. The poles in an orbit need *not* be the vertices of a regular polyhedron. For the cube, the 12 edge-centers form a single orbit but span a *truncated* figure (a cuboctahedron), not a Platonic solid. In the polyhedral cases the two orbits with $r_i\ge 3$ are the vertex sets of a regular polyhedron and of its dual; only the $r_1=2$ orbit of edge-centers can fail to be one. Likewise, "at most three orbits" counts *pole*-orbits, not group elements; a single orbit can be large ($n_i=N/r_i$).

Remark 4.11.4. With $r_1=2$ the integer constraint $\frac{1}{r_1}+\frac{1}{r_2}+\frac{1}{r_3}>1$ reads $\frac{1}{p}+\frac{1}{q}>\frac{1}{2}$ for $\{p,q\}=\{r_2,r_3\}$, which is exactly the condition that q regular p-gons fit around a vertex with angle sum less than 2π; this is why "only five regular polyhedra" and "only three exceptional rotation groups" come from the same combinatorial fact. The five solids have Schläfli symbols $\{3,3\},\{4,3\},\{3,4\},\{5,3\},\{3,5\}$ (p-gonal faces, q at each vertex); here they appear as the triples $(2,3,q)$ for $q=3,4,5$, a solid and its dual giving the same triple, while the remaining solutions $(2,2,k)$ are the dihedral family.

A picture of the axes

The diagram below shows a cube with its three kinds of rotation axes: through opposite *face* centers ($r = 4$, quarter-turns), opposite *vertices* along a body diagonal ($r = 3$, third-turns), and opposite *edge* midpoints ($r = 2$, half-turns). The pole of each axis is where it pierces the surrounding sphere.

The three axis types correspond to the three pole-orbits $(n_1, n_2, n_3) = (12, 8, 6)$ of the octahedral group O: 6 face-poles of order 4, 8 vertex-poles of order 3, and 12 edge-poles of order 2, matching the triple $(r_1, r_2, r_3) = (2, 3, 4)$ with $N = 24$.

4.12 Counting Orbits: the Cauchy–Frobenius Formula

Counting orbits: the Cauchy–Frobenius (Burnside) formula

A group action partitions the set it acts on into orbits, and the first quantitative question is: *how many orbits are there?* For symmetry-counting problems — how many genuinely different bead necklaces, or face-colorings of a cube, exist once we identify configurations that differ by a rotation — the orbits *are* the answer. Artin's Counting Formula (Proposition 6.9.2) relates the size of one orbit to a stabilizer; averaging that relation over the whole group turns the geometric question into a clean arithmetic one. Throughout, G is a finite group acting on a finite set S.

Theorem 4.12.1 (Counting Formula, Artin 6.9.2)**.** *Let G act on a finite set S and let $s \in S$. Writing* $\mathrm{Orb}(s)$ *for the orbit and* $\mathrm{Stab}(s) = \{\, g \in G : g \cdot s = s \,\}$ *for the stabilizer,*

$$|G| = |\mathrm{Stab}(s)| \cdot |\mathrm{Orb}(s)|, \qquad \textit{equivalently} \qquad |\mathrm{Orb}(s)| = [G : \mathrm{Stab}(s)].$$

In particular the size of every orbit divides $|G|$.

Proof. The stabilizer $H = \mathrm{Stab}(s)$ is a subgroup of G. Define $\varphi\colon G/H \to \mathrm{Orb}(s)$ on left cosets by $\varphi(gH) = g \cdot s$. This is well defined and injective: $g_1 H = g_2 H$ iff $g_2^{-1} g_1 \in H$ iff $g_2^{-1} g_1 \cdot s = s$ iff $g_1 \cdot s = g_2 \cdot s$. It is surjective by definition of the orbit. Hence $|\mathrm{Orb}(s)| = [G : H]$, and Lagrange's theorem $|G| = |H| \cdot [G : H]$ gives the product form. □

We record the partition consequence Artin uses repeatedly: if S splits into orbits $O_1, \dots, O_k$, then $|S| = |O_1| + \cdots + |O_k|$, each summand an index $[G : \mathrm{Stab}(s_i)]$. The Cauchy–Frobenius formula is the dual count: instead of summing orbit sizes over orbits, sum fixed-point counts over group elements.

Definition 4.12.2 (Fixed-point set)**.** For $g \in G$ acting on S, the *fixed-point set* is

$$\mathrm{Fix}(g) = \{\, s \in S : g \cdot s = s \,\} \subseteq S.$$

Its size $|\mathrm{Fix}(g)|$ counts the elements left in place by g.

Theorem 4.12.3 (Cauchy–Frobenius / Burnside Counting Formula)**.** *Let a finite group G act on a finite set S, and let N be the number of orbits. Then*

$$N = \frac{1}{|G|} \sum_{g \in G} |\mathrm{Fix}(g)|,$$

i.e. the number of orbits equals the average *number of fixed points of the elements of G.*

Proof. Count the set of incident pairs $P = \{ (g, s) \in G \times S : g \cdot s = s \}$ in two ways. Summing over group elements,

$$|P| = \sum_{g \in G} |\mathrm{Fix}(g)|.$$

Summing over points, $|P| = \sum_{s \in S} |\mathrm{Stab}(s)|$. Group the second sum by orbits. For s in a fixed orbit O, Theorem 4.12.1 gives $|\mathrm{Stab}(s)| = |G|/|\mathrm{Orb}(s)| = |G|/|O|$, and there are $|O|$ such points, so each orbit contributes $|O| \cdot (|G|/|O|) = |G|$. With N orbits,

$$\sum_{s \in S} |\mathrm{Stab}(s)| = \sum_{\text{orbits } O} |G| = N \cdot |G|.$$

Equating the two counts of $|P|$ gives $\sum_g |\mathrm{Fix}(g)| = N \cdot |G|$, and dividing by $|G|$ yields the formula. □

Remark 4.12.1. The proof is exactly Artin's orbit-stabilizer relation applied to the "elements" inside one orbit: every point of an orbit has a stabilizer of the same order $|G|/|O|$, and the $|O|$ stabilizers of an orbit pool to $|G|$ pairs. The double count is the whole idea — no characters, no representation theory. Despite the traditional name, the formula predates Burnside; it is due to Cauchy and Frobenius, which is why the neutral name is now preferred.

Method (Burnside enumeration recipe)**.** *Trigger.* You must count configurations *up to* a symmetry group G (rotations of a polygon/polyhedron, reflections, etc.): necklaces, colorings, labelings.

1. Identify S (all raw configurations, ignoring symmetry) and the acting group G.
2. For each $g \in G$ compute $|\mathrm{Fix}(g)|$: a coloring is fixed by g iff it is constant on every cycle of the permutation g induces on the slots. If there are c colors and g has $\mathrm{cyc}(g)$ cycles on the slots, then $|\mathrm{Fix}(g)| = c^{\mathrm{cyc}(g)}$.
3. Average: $N = \frac{1}{|G|} \sum_g |\mathrm{Fix}(g)|$. Group g's by conjugacy class to avoid repeating identical counts.

Worked enumerations

Worked Example 4.12.4 (Two-color bead necklaces on a square (rotations))**.** How many distinct ways are there to color the 4 corner beads of a square with 2 colors (black/white), where two colorings are the same if a rotation carries one to the other? Here $G = \mathbb{Z}/4\mathbb{Z} = \{ e, r, r^2, r^3 \}$ is the cyclic group of rotations by $0, 90, 180, 270$ degrees, acting on the $S = 2^4 = 16$ raw colorings.

Recognition. Counting colorings up to rotation is the signature Burnside situation (Theorem 4.12.3): average $|\mathrm{Fix}(g)|$, computing each fixed count from the cycle structure of g on the four bead positions.

Solution. Label positions $1, 2, 3, 4$ around the square. The rotation r acts as the 4-cycle $(1\,2\,3\,4)$; a coloring is r-fixed iff all four beads share a color.

g	cycles on positions	$\mathrm{cyc}(g)$	$\lvert\mathrm{Fix}(g)\rvert = 2^{\mathrm{cyc}(g)}$
e	$(1)(2)(3)(4)$	4	$2^4 = 16$
r	$(1\,2\,3\,4)$	1	$2^1 = 2$
r^2	$(1\,3)(2\,4)$	2	$2^2 = 4$
r^3	$(1\,4\,3\,2)$	1	$2^1 = 2$

Average over $|G| = 4$:

$$N = \frac{1}{4}\big(16 + 2 + 4 + 2\big) = \frac{24}{4} = 6.$$

Check. The six classes are easy to list by number of black beads up to rotation: 0 black (1 way), 1 black (1), 2 black adjacent (1), 2 black opposite (1), 3 black (1), 4 black (1) — total 6, matching.

Worked Example 4.12.5 (Necklaces with the full dihedral symmetry)**.** Same square of 4 beads and 2 colors, but now allow *reflections* too, so $G = D_8$ (the dihedral group of order 8: four rotations and four reflections). Count colorings up to this larger symmetry.

Recognition. Same formula; the new group elements (reflections) contribute their own fixed counts. We reuse the rotation data from the previous example and add the four reflections.

Solution. The four rotations contribute $16 + 2 + 4 + 2 = 24$ as before. The reflections of a square come in two geometric types acting on positions $1, 2, 3, 4$ (corners in order): *vertex axes* (through two opposite corners) fix those two corners and swap the other two, e.g. $(1)(3)(2\,4)$, so cyc = 3, $|\mathrm{Fix}| = 2^3 = 8$; there are 2 of these. *Edge axes* (through midpoints of opposite sides) swap corners in two pairs, e.g. $(1\,2)(3\,4)$, so cyc = 2, $|\mathrm{Fix}| = 2^2 = 4$; there are 2 of these.

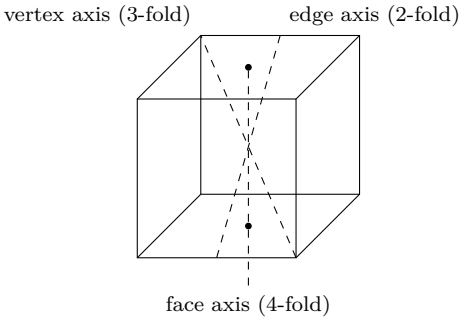
$$N = \frac{1}{8}\Big(\underbrace{16 + 2 + 4 + 2}_{\text{rotations}} + \underbrace{8 + 8}_{\text{vertex axes}} + \underbrace{4 + 4}_{\text{edge axes}}\Big) = \frac{1}{8}(24 + 16 + 8) = \frac{48}{8} = 6.$$

Check. Adding reflections cannot *increase* the orbit count (it can only merge orbits), and indeed $6 \le 6$ here: of the rotation-classes, 1 black, 3 black, and the two 2-black types each already coincide with their mirror images, so no further merging occurs and the count stays 6.

Worked Example 4.12.6 (Face colorings of a cube (Artin's octahedral group))**.** Artin's octahedral group O is the group of 24 rotations of a cube (Section 6.10). In how many ways can the 6 faces be painted with c colors, identifying colorings related by a rotation? Here $S = c^6$ and $G = O$, $|O| = 24$.

Recognition. Burnside over the rotation group of the cube. We need the cycle structure of each rotation *on the six faces*, organized by conjugacy class — the standard inventory of O.

Solution. The 24 rotations of the cube fall into five conjugacy classes; for each we read off the cycle type on the 6 faces and apply $|\mathrm{Fix}(g)| = c^{\mathrm{cyc}(g)}$:



class of g	$\#\,g$	face cycle type	$\lvert\mathrm{Fix}(g)\rvert$
identity	1	$1+1+1+1+1+1$	c^6
face axis, $\pm 90°$	6	$1+1+4$	c^3
face axis, $180°$	3	$1+1+2+2$	c^4
vertex axis, $\pm 120°$	8	$3+3$	c^2
edge axis, $180°$	6	$2+2+2$	c^3

Averaging,

$$N(c) = \frac{1}{24}\Big(c^6 + 6c^3 + 3c^4 + 8c^2 + 6c^3\Big) = \frac{c^6 + 3c^4 + 12c^3 + 8c^2}{24}.$$

For $c = 2$: $N(2) = (64 + 48 + 96 + 32)/24 = 240/24 = 10$. For $c = 3$: $N(3) = (729 + 243 + 324 + 72)/24 = 1368/24 = 57$. *Check.* The face axes give $6/2 = 3$ axes with $\pm 90°$ and $180°$ each: $6 + 3 = 9$ rotations, plus 8 vertex-axis and 6 edge-axis, plus the identity, totals $1 + 9 + 8 + 6 = 24 = |O|$, accounting for every rotation. The value $N(2) = 10$ is the classic "ten distinct two-color cubes" count.

The cube example is governed by the three rotation-axis types Artin emphasizes when applying the Counting Formula to polyhedra. The schematic below records the axes whose cycle structures fed the table.

Worked Example 4.12.7 (Pairs of faces of the cube: recovering Artin's 3 and 12)**.** Artin notes (Section 6.10) that O acts on the 15 unordered pairs of faces of a cube, splitting them into the 3 pairs of *opposite* faces and the 12 pairs of *adjacent* faces. Recover these orbit sizes with the Counting Formula, and verify the orbit count via Burnside.

Recognition. Two checks: (i) orbit sizes by Theorem 4.12.1; (ii) the number of orbits by Theorem 4.12.3. The action is on $S =$ the 15 unordered face-pairs.

Solution. (i) Orbit sizes. Fix a pair of opposite faces U. Its stabilizer is the set of rotations sending {top,bottom} to itself; Artin records $|\mathrm{Stab}(U)| = 8$ (rotations about the vertical axis together with the 180° flips). Then $|\mathrm{Orb}(U)| = |O|/|\mathrm{Stab}(U)| = 24/8 = 3$ — the three axis-directions. For a pair of adjacent faces U', the stabilizer consists of the identity and the half-turn about the axis through the midpoint of their common edge, so it has order 2, giving orbit size $24/2 = 12$. $3 + 12 = 15$ exhausts S. *(ii) Orbit count by Burnside.* We expect $N = 2$. Class by class on the 15 pairs: the identity fixes all 15; each of the 6 quarter-turns about a face axis fixes only the pair of faces on its axis; each of the 3 face half-turns fixes 3 pairs (the three pairs of opposite faces); the 8 vertex rotations fix none (they permute the faces in two 3-cycles); each of the 6 edge half-turns fixes the 3 pairs of faces it swaps. So

$$N = \frac{1}{24}\sum_{g\in O}|\mathrm{Fix}(g)| = \frac{1}{24}\big(15 + 6\cdot 1 + 3\cdot 3 + 8\cdot 0 + 6\cdot 3\big) = \frac{48}{24} = 2.$$

Check. Both methods agree with Artin: orbit sizes 3 and 12 (summing to 15), and $N = 2$ orbits. The stabilizer order 8 for an opposite-face pair is exactly the value Artin states in Section 6.10.

Caution. The fixed-point count $|\mathrm{Fix}(g)| = c^{\mathrm{cyc}(g)}$ uses the cycle decomposition of g *on the slots being colored* (faces, beads), *not* on the vertices or on abstract group elements. Using the wrong action's cycle type is the most common error; always fix in your mind which set S the group is permuting before counting cycles.

Caution. Burnside counts orbits of the *exact* group you average over. Including reflections (dihedral) versus rotations only (cyclic) generally gives different answers; the necklace examples above happened to agree, but for larger bead counts they diverge. Decide first whether mirror images count as "the same."

Remark 4.12.2. The two summation directions are worth keeping side by side. Partitioning S into orbits sums *orbit sizes*: $|S| = \sum_O [G : \mathrm{Stab}(s_O)]$, the count Artin uses for the dodecahedron's $12 = 1 + 1 + 5 + 5$ face partition under a cyclic stabilizer of order 5. Cauchy–Frobenius instead sums *fixed-point counts* over G to extract the *number* of orbits. Both rest on the single identity $|\mathrm{Orb}(s)| \cdot |\mathrm{Stab}(s)| = |G|$ of Theorem 4.12.1.

4.13 Graded Problem Bank

Easy

DF 4.1.4 Let S_3 act on the 9 ordered pairs $\{(i,j) \mid 1 \le i,j \le 3\}$ by $\sigma \cdot (i,j) = (\sigma(i), \sigma(j))$. Find the orbits, the cycle decomposition of each σ as an element of S_9, and a stabilizer for one point in each orbit.

DF 4.1.5 Repeat the preceding for S_3 acting on (a) the 27 triples $\{(i,j,k) \mid 1 \le i,j,k \le 3\}$ and (b) the 7 nonempty subsets of $\{1,2,3\}$.

DF 4.1.6 With S_4 permuting variable indices of integer polynomials in x_1, x_2, x_3, x_4, find the orbit of (a) $x_1 + x_2$, (b) $x_1x_2 + x_3x_4$, (c) $(x_1 + x_2)(x_3 + x_4)$.

DF 4.2.1 Label the Klein 4-group $\{1, a, b, c\}$ as $1, 2, 4, 3$ and verify that the left regular representation sends $a \mapsto (1\,2)(3\,4)$, $b \mapsto (1\,4)(2\,3)$, $c \mapsto (1\,3)(2\,4)$; then relabel $1, a, b, c$ as $1, 4, 2, 3$ and show the image in S_4 is the same subgroup.

DF 4.2.2 List S_3 as $1, (1\,2), (2\,3), (1\,3), (1\,2\,3), (1\,3\,2)$ labelled $1, \ldots, 6$ and exhibit the image of each element under the left regular representation $S_3 \to S_6$.

DF 4.2.3 For $D_8 = \langle r, s\rangle$ labelled $1, r, r^2, r^3, s, sr, sr^2, sr^3 \mapsto 1, \ldots, 8$, exhibit the image of each element under the left regular representation $D_8 \to S_8$; relabel by $1, 3, 5, 7, 2, 4, 6, 8$ and show the two resulting subgroups of S_8 differ.

DF 4.2.4 Use the left regular representation of Q_8 to produce two elements of S_8 generating a subgroup isomorphic to Q_8.

DF 4.2.5 For $D_8 = \langle r, s\rangle$ and $H = \langle s\rangle$, label the cosets $1H, rH, r^2H, r^3H$ as $1, 2, 3, 4$: (a) exhibit the image of each element of D_8 under $\pi_H : D_8 \to S_4$ from left multiplication on these cosets and deduce π_H is faithful; (b) relabel the cosets as $1, 3, 2, 4$ and show the resulting image is a different subgroup of S_4; (c) for $K = \langle sr\rangle$, with cosets $1K, rK, r^2K, r^3K$ labelled $1, 2, 3, 4$, show $\pi_K(D_8)$ is the same subgroup of S_4 as in (a).

DF 4.2.6 For D_8 and $N = \langle r^2\rangle$, exhibit $\pi_N : D_8 \to S_4$ on the cosets $1N, rN, sN, srN$; show it is not faithful and that $\pi_N(D_8) \cong V_4$.

DF 4.3.2 Find all conjugacy classes and their sizes in (a) D_8, (b) Q_8, (c) A_4.

DF 4.3.3 Find all conjugacy classes and their sizes in (a) $\mathbb{Z}_2 \times S_3$, (b) $S_3 \times S_3$, (c) $\mathbb{Z}_3 \times A_4$.

DF 4.3.7 For $n = 3, 4, 5, 7$ tabulate the partitions of n and give representatives for the corresponding conjugacy classes of S_n.

DF 4.3.10 For the 5-cycle $\sigma = (1\,2\,3\,4\,5)$ in S_5, find an explicit $\tau \in S_5$ with (a) $\tau\sigma\tau^{-1} = \sigma^2$, (b) $\tau\sigma\tau^{-1} = \sigma^{-1}$, (c) $\tau\sigma\tau^{-1} = \sigma^{-2}$.

DF 4.3.11 In each case decide whether σ_1, σ_2 are conjugate and if so give τ with $\tau\sigma_1\tau^{-1} = \sigma_2$: (a) $(1\,2)(3\,4\,5)$ and $(1\,2\,3)(4\,5)$; (b) $(1\,5)(3\,7\,2)(10\,6\,8\,11)$ and $(3\,7\,5\,10)(4\,9)(13\,11\,2)$; (c) $\sigma_1 = (1\,5)(3\,7\,2)(10\,6\,8\,11)$ and σ_1^3; (d) $(1\,3)(2\,4\,6)$ and $(3\,5)(2\,4)(5\,6)$.

DF 4.3.12 Find a representative for each conjugacy class of elements of order 4 in S_8 and in S_{12}.

DF 4.5.4 Exhibit all Sylow 2-subgroups and Sylow 3-subgroups of D_{12} and of $S_3 \times S_3$.

DF 4.5.6 Exhibit all Sylow 3-subgroups of A_4 and all Sylow 3-subgroups of S_4.

DF 4.5.7 Exhibit all Sylow 3-subgroups of S_4 and find elements of S_4 conjugating one into each of the others.

DF 4.5.8 Exhibit two distinct Sylow 2-subgroups of S_5 and an element of S_5 conjugating one into the other.

DF 4.5.9 Exhibit all Sylow 3-subgroups of $\mathrm{SL}_2(\mathbb{F}_3)$.

DF 4.5.31 How many elements of order 7 must there be in a simple group of order 168?

DF 4.5.32 For $p = 2, 3, 5$ find $n_p(A_5)$ and $n_p(S_5)$.

DF 4.6.4 Prove that A_n is generated by the set of all 3-cycles for each $n \geq 3$.

Artin 6.7.1 For $G = D_4$ acting on the square, find the stabilizer of a vertex and of an edge; for the action on the two diagonal lines, find the stabilizer of a diagonal.

Artin 6.9.1 Use the counting formula to determine the orders of the rotational symmetry groups of a cube and of a tetrahedron.

Artin 6.4.1 Write the product $x^2yx^{-1}y^{-1}x^3y^3$ in the form x^iy^j in the dihedral group D_n.

Artin 6.4.3a Compute the left cosets of $H = \{1, x^5\}$ in the dihedral group D_{10}.

Artin 6.10.1 Determine the orders of the orbits for left multiplication on the set of subsets of order 3 of D_3.

Artin 6.12.2 Describe the orbits of poles for the group of rotations of an octahedron.

Artin 6.12.3 Let O be the group of rotations of a cube and S the four diagonal lines joining opposite vertices; determine the stabilizer of one diagonal.

Artin 7.5.2 What is the centralizer of the element $(1\,2)$ in S_5?

Artin 7.5.3 Determine the orders of the elements of the symmetric group S_7.

Artin 7.7.5 Find Sylow 2-subgroups of the following groups: (a) D_{10}, (b) T, (c) O, (d) I.

Artin 7.2.2 A group of order 21 contains a conjugacy class $C(x)$ of order 3. What is the order of x in the group?

Artin 7.1.2 Let $H \leq G$. Describe the orbits for the operation of H on G by left multiplication.

Fraleigh 11.1 Describe all symmetries (isometries leaving the figure fixed) of: (a) a point in $\mathbb{R}$, (b) a point in $\mathbb{R}^2$, (c) a line segment in $\mathbb{R}$, (d) a line segment in $\mathbb{R}^2$, (e) some symmetries of a line segment in $\mathbb{R}^3$.

Fraleigh 11.4 Draw a plane figure whose group of symmetries in $\mathbb{R}^2$ has one element.

Fraleigh 11.5 Draw a plane figure whose group of symmetries in $\mathbb{R}^2$ has two elements.

Fraleigh 11.6 Draw a plane figure whose group of symmetries in $\mathbb{R}^2$ has three elements.

Fraleigh 11.7 Draw a plane figure whose group of symmetries in $\mathbb{R}^2$ is isomorphic to $\mathbb{Z}_4$.

Fraleigh 11.8 Draw a plane figure whose group of symmetries in $\mathbb{R}^2$ is isomorphic to the Klein 4-group V.

Fraleigh 11.9 For each of the four nonidentity plane-isometry types, give the possible orders of an isometry of that type.

Fraleigh 11.10 Which of the four nonidentity plane-isometry types can have a fixed point?

Fraleigh 11.11 Which plane-isometry types have exactly one fixed point?

Fraleigh 11.12 Which plane-isometry types have exactly two fixed points?

Fraleigh 11.13 Which plane-isometry types have an infinite number of fixed points?

Fraleigh 14.1 For the D_4-set X of Example 14.9, find the fixed sets X_σ for each $\sigma \in D_4$.

Fraleigh 14.2 For the same D_4-set, find the isotropy subgroup G_x for each $x \in X$.

Fraleigh 14.3 For the same D_4-set, find all the orbits in X under D_4.

Fraleigh 14.4 Find the center of D_8 (the dihedral group of order 16).

Fraleigh 14.5 Find the center of D_7.

Fraleigh 14.6 Make $X = S_3$ a $G = S_3$-set by conjugation $\sigma * \tau = \sigma\tau\sigma^{-1}$ and find all orbits.

Fraleigh 14.7 Let $G = D_4$ act by conjugation on the set X of its order-2 subgroups; find all orbits.

Fraleigh 14.8 Let $U = \{z \in \mathbb{C} \mid |z| = 1\}$ act on $X = \mathbb{C}$ by multiplication; find all orbits and X_G.

Fraleigh 14.9 Let $|G| = 3$ and $|X| = 6$; for each possible action of G on X list the orbit sizes (largest first).

Fraleigh 14.10 Let $|G| = 9$ and $|X| = 10$; for each possible action list the orbit sizes.

Fraleigh 14.11 Let $|G| = 8$ and $|X| = 10$; for each possible action list the orbit sizes.

Fraleigh 15.1 Find the number of orbits in $\{1, \ldots, 8\}$ under the cyclic subgroup $\langle(1\,3\,5\,6)\rangle$ of S_8.

Fraleigh 15.2 Find the number of orbits in $\{1, \ldots, 8\}$ under the subgroup of S_8 generated by $(1\,3)$ and $(2\,4\,7)$.

Fraleigh 15.3 Find the number of distinguishable tetrahedral dice made with $1, 2, 3, 4$ dots on the faces of a regular tetrahedron.

Fraleigh 15.4 How many distinguishable blocks if each of the 6 faces of a cube is painted a different color from 8 available colors?

Fraleigh 15.5 Repeat the cube-coloring count when colors may be repeated freely on faces.

Fraleigh 15.6 How many distinguishable colorings of the 8 corners of a cube with 4 colors (repeats allowed)?

Fraleigh 15.7a How many distinguishable ways to paint the 4 edges of a square of cardboard (which may be turned over) with 6 colors if no color is used more than once?

Fraleigh 15.7b Same as above but the same color may be used on any number of edges.

Fraleigh 15.8 Six equal wires soldered into the edges of a regular tetrahedron each get a 50- or 100-ohm resistor; how many essentially different wirings?

Fraleigh 15.9a A 2 ft rectangular prism with 1 ft square ends has its 6 faces painted from 6 colors with no repeats; how many distinguishable prisms?

Fraleigh 15.9b Same prism, but each color may be used on any number of faces.

Fraleigh 17.1 A Sylow 3-subgroup of a group of order 12 has what order?

Fraleigh 17.2 A Sylow 3-subgroup of a group of order 54 has what order?

Fraleigh 17.3 By Theorem 17.7 alone, a group of order 24 has how many Sylow 2-subgroups (give the permissible values)?

Fraleigh 17.4 By Theorem 17.7 alone, list the permissible numbers of Sylow 3- and Sylow 5-subgroups for a group of order $255 = 3 \cdot 5 \cdot 17$.

Fraleigh 17.5 Find all Sylow 3-subgroups of S_4 and show they are all conjugate.

Fraleigh 17.6 Find two Sylow 2-subgroups of S_4 and show they are conjugate.

Fraleigh 17.7 Determine for which $n \leq 20$ every group of order n is abelian.

Fraleigh 17.8 Determine for which $n \leq 20$ every group of order n is cyclic.

Medium

DF 4.1.1 If G acts on A and $b = g \cdot a$, prove $G_b = gG_ag^{-1}$; deduce that for a transitive action the kernel is $\bigcap_{g \in G} gG_ag^{-1}$.

DF 4.1.2 For a permutation group $G \leq S_A$, $\sigma \in G$, $a \in A$, prove $\sigma G_a \sigma^{-1} = G_{\sigma(a)}$; deduce that for a transitive action $\bigcap_{\sigma \in G} \sigma G_a \sigma^{-1} = 1$.

DF 4.1.3 If G is an abelian transitive subgroup of S_A, show $\sigma(a) \neq a$ for all $\sigma \in G - \{1\}$ and all a, and deduce $|G| = |A|$.

DF 4.2.7 Prove that if $H \leq G$ has finite index n then there is a normal $K \trianglelefteq G$ with $K \leq H$ and $[G : K] \leq n!$.

DF 4.2.8 Prove that if p is prime and $|G| = p^\alpha$ then every subgroup of index p is normal; deduce every group of order p^2 has a normal subgroup of order p.

DF 4.2.9 Prove every non-abelian group of order 6 has a nonnormal subgroup of order 2, and use this to classify groups of order 6.

DF 4.2.10 For the left regular representation $\pi : G \to S_G$ with $|x| = n$ and $|G| = mn$, prove $\pi(x)$ is a product of m n-cycles; deduce $\pi(x)$ is odd iff $|x|$ is even and $|G|/|x|$ is odd.

DF 4.2.11 If $\pi(G)$ contains an odd permutation (for π the left regular representation), prove G has a subgroup of index 2.

DF 4.2.12 Prove that if $|G| = 2k$ with k odd then G has a subgroup of index 2.

DF 4.3.1 For a left action of G on A and the corresponding right action, prove the equivalence relations $a \sim b$ ($a = g \cdot b$ some g) and $a \sim' b$ ($a = b \cdot g$ some g) coincide.

DF 4.3.4 Prove $gN_G(S)g^{-1} = N_G(gSg^{-1})$ and $gC_G(S)g^{-1} = C_G(gSg^{-1})$ for $S \subseteq G$.

DF 4.3.5 If the center of G has index n, prove every conjugacy class has at most n elements.

DF 4.3.8 Prove $Z(S_n) = 1$ for all $n \geq 3$.

DF 4.3.9 Show $|C_{S_n}((1\,2)(3\,4))| = 8 \cdot (n-4)!$ for all $n \geq 4$ and describe the centralizer.

DF 4.3.13 Find all finite groups with exactly two conjugacy classes.

DF 4.3.14 With π_1, π_2 the two regular representations of V_4 and $\tau = (2\,4)$, show $\tau \circ \pi_1(g) \circ \tau^{-1} = \pi_2(g)$ for each $g \in V_4$.

DF 4.3.15 Find an element of S_8 conjugating the D_8 image from Exercise 4.2.3(a) to the image from (b).

DF 4.3.16 Find an element of S_4 conjugating the D_8 image from Exercise 4.2.5(a) to the image from (b).

DF 4.3.18 If $H \leq S_A$ has fixed-point set $F(H)$ and $\tau \in N_{S_A}(H)$, prove τ stabilizes $F(H)$ and its complement.

DF 4.3.22 Show that if n is odd then the n-cycles form two conjugacy classes of equal size in A_n.

DF 4.3.26 If $g_1, \ldots, g_r$ represent the conjugacy classes of finite G and pairwise commute, prove G is abelian.

DF 4.3.28 Let G have order p^a; prove G has a subgroup of order p^b for each $0 \leq b \leq a$.

DF 4.3.29 If G has odd order, prove that for any $x \neq 1$, x and x^{-1} are not conjugate in G.

DF 4.3.31 For $n = 2k+1$ odd, determine the conjugacy classes of D_{2n} and give the class equation.

DF 4.3.32 Prove the formula $|C(\sigma)| = n! / \prod_i (k_i!\, m_i^{k_i})$ for the size of the conjugacy class of $\sigma \in S_n$ with k_i cycles of length m_i.

DF 4.4.1 If $\sigma \in \mathrm{Aut}(G)$ and φ_g is conjugation by g, prove $\sigma \varphi_g \sigma^{-1} = \varphi_{\sigma(g)}$ and deduce $\mathrm{Inn}(G) \trianglelefteq \mathrm{Aut}(G)$.

DF 4.4.2 Prove that an abelian group of order pq (p, q distinct primes) is cyclic.

DF 4.4.6 Prove characteristic subgroups are normal, and give a normal subgroup that is not characteristic.

DF 4.4.7 If H is the unique subgroup of its order in G, prove H is characteristic in G.

DF 4.4.8 Let $H \leq K \leq G$: (a) if H char K and $K \trianglelefteq G$ then $H \trianglelefteq G$; (b) if H char K and K char G then H char G, and use this to show that the Klein 4-group V_4 contained in A_4 is characteristic in S_4; (c) give an example where $H \trianglelefteq K$ char G but $H \not\trianglelefteq G$.

DF 4.4.9 Using [DF 4.4.7] and [DF 4.4.8](a) (every subgroup of the cyclic group $\langle r \rangle$ is characteristic in $\langle r \rangle$, and $\langle r \rangle \trianglelefteq D_{2n}$), deduce that every subgroup of $\langle r \rangle$ is normal in D_{2n}.

DF 4.4.10 For abelian normal $A \trianglelefteq G$ and $\bar{G} = G/A$, show $\bar{G}$ acts by conjugation on A via $\bar{g} \cdot a = gag^{-1}$ (well defined), and give an example showing this fails if A is non-abelian.

DF 4.4.15 Prove that each of $(\mathbb{Z}/5\mathbb{Z})^\times$, $(\mathbb{Z}/9\mathbb{Z})^\times$, $(\mathbb{Z}/18\mathbb{Z})^\times$ is cyclic.

DF 4.4.16 Prove that $(\mathbb{Z}/24\mathbb{Z})^\times$ is an elementary abelian group of order 8.

DF 4.4.17 For $G = \langle x \rangle$ cyclic of order n and $n = 2, 3, 4, 5, 6$, write out the elements of $\mathrm{Aut}(G)$ explicitly.

DF 4.5.1 Prove that if $P \in \mathrm{Syl}_p(G)$ and $P \leq H \leq G$ then $P \in \mathrm{Syl}_p(H)$, and give an example where a Sylow p-subgroup of H is not Sylow in G.

DF 4.5.2 Prove that if $H \leq G$ and $Q \in \mathrm{Syl}_p(H)$ then $gQg^{-1} \in \mathrm{Syl}_p(gHg^{-1})$.

DF 4.5.3 Use Sylow's Theorem to prove Cauchy's Theorem.

DF 4.5.5 Show a Sylow p-subgroup of D_{2n} is cyclic and normal for every odd prime p.

DF 4.5.10 Prove that $\left\langle \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right), \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right) \right\rangle$ is the unique Sylow 2-subgroup of $\mathrm{SL}_2(\mathbb{F}_3)$.

DF 4.5.13 Prove a group of order 56 has a normal Sylow p-subgroup for some prime p.

DF 4.5.14 Prove a group of order 312 has a normal Sylow p-subgroup for some prime p.

DF 4.5.15 Prove a group of order 351 has a normal Sylow p-subgroup for some prime p.

DF 4.5.17 Prove that if $|G| = 105$ then G has a normal Sylow 5- and a normal Sylow 7-subgroup.

DF 4.5.18 Prove a group of order 200 has a normal Sylow 5-subgroup.

DF 4.5.22 Prove that if $|G| = 132$ then G is not simple.

DF 4.5.23 Prove that if $|G| = 462$ then G is not simple.

DF 4.5.24 Prove that if $|G| = 231$ then $Z(G)$ contains a Sylow 11-subgroup and the Sylow 7-subgroup is normal.

DF 4.5.25 Prove that if $|G| = 385$ then $Z(G)$ contains a Sylow 7-subgroup and the Sylow 11-subgroup is normal.

DF 4.5.26 If $|G| = 105$ and a Sylow 3-subgroup is normal, prove G is abelian.

DF 4.5.30 If G is a non-abelian simple group of order < 100, prove $G \cong A_5$.

DF 4.5.33 If $P \in \mathrm{Syl}_p(H)$, $P \trianglelefteq H$, $H \trianglelefteq K$, prove $P \trianglelefteq K$; deduce that normalizers of Sylow p-subgroups are self-normalizing.

DF 4.5.34 If $P \trianglelefteq G$ is a Sylow p-subgroup and $H \leq G$, prove $P \cap H$ is the unique Sylow p-subgroup of H.

DF 4.5.35 For $P \in \mathrm{Syl}_p(G)$ and $N \trianglelefteq G$, prove $P \cap N \in \mathrm{Syl}_p(N)$ and $PN/N \in \mathrm{Syl}_p(G/N)$.

DF 4.5.37 Prove that if $N \trianglelefteq G$ then $n_p(G/N) \leq n_p(G)$.

DF 4.5.40 Prove the upper-triangular matrices with 1's on the diagonal form a Sylow p-subgroup of $\mathrm{GL}_n(\mathbb{F}_p)$.

DF 4.5.41 Prove the number of Sylow p-subgroups of $\mathrm{GL}_2(\mathbb{F}_p)$ is $p + 1$.

DF 4.5.46 Prove the group of rigid motions of an icosahedron is isomorphic to A_5.

DF 4.5.47 Prove the group of rigid motions of a dodecahedron is isomorphic to A_5.

DF 4.5.48 If p is the smallest prime dividing $|G|$, $P \in \mathrm{Syl}_p(G)$ and P cyclic, prove $N_G(P) = C_G(P)$.

Artin 6.3.2 Let m be an orientation-reversing isometry; prove algebraically that m^2 is a translation.

Artin 6.3.3 Prove a linear operator on $\mathbb{R}^2$ is a reflection iff its eigenvalues are 1 and -1 with orthogonal eigenvectors.

Artin 6.3.4 Prove that a conjugate of a glide reflection in M is a glide reflection, and the glide vectors have equal length.

Artin 6.4.2a List all subgroups of the dihedral group D_4 and decide which are normal.

Artin 6.4.2b List the proper normal subgroups N of D_{15} and identify the quotients D_{15}/N.

Artin 6.4.3b Prove $H = \{1, x^5\}$ is normal in D_{10} and that $D_{10}/H \cong D_5$.

Artin 6.5.1 If lines ℓ_1, ℓ_2 through the origin meet at angle π/n, prove the reflections r_1, r_2 generate a dihedral group D_n.

Artin 6.7.3 Decompose $U \times V$ (with $|U| = |V| = 3$) into orbits for the diagonal action of S_3 when (a) both actions are transitive, (b) the action on V has orbits $\{v_1\}$ and $\{v_2, v_3\}$.

Artin 6.7.7 For $G = \mathrm{GL}_n(\mathbb{R})$ acting on $\mathbb{R}^n$ by left multiplication, describe the orbits and the stabilizer of e_1.

Artin 6.7.8 Decompose the 2×2 complex matrices into orbits for (a) left multiplication and (b) conjugation by $\mathrm{GL}_2(\mathbb{C})$.

Artin 6.7.11 Prove the only subgroup of order 12 of S_4 is the alternating group A_4.

Artin 6.9.2 For the rotation group of a cube, determine the orbit decompositions of the vertices, edges, and faces under the stabilizers G_v, G_e, G_f.

Artin 6.10.2 If G acts transitively on a finite set S and $U \subseteq S$, prove the subsets gU cover S evenly.

Artin 6.10.3 For left multiplication of G on its subsets, if the sets gU partition G and H is the one containing 1, prove H is a subgroup.

Artin 6.11.3 If G acts on S and $H = \{g \mid gs = s \ \forall s \in S\}$, prove $H \trianglelefteq G$.

Artin 6.11.4 Decide whether the action of D_4 on the vertices of a square is faithful, and likewise on the diagonals.

Artin 6.11.5 A group acts faithfully on a 5-element set with orbits of sizes 3 and 2; determine the possible groups.

Artin 6.11.6 For $F = \mathbb{F}_3$, list the four 1-dimensional subspaces of F^2 and prove left multiplication gives a homomorphism $\mathrm{GL}_2(F) \to S_4$; find its kernel and image.

Artin 6.11.7 For each group find the least n with a faithful action on a set of order n: (a) D_4, (b) D_6, (c) Q_8.

Artin 6.12.5 Prove the icosahedral group has a subgroup of order 10.

Artin 7.2.16 For a surjection $\varphi : G \to G'$ with $C = C(x)$ and $C' = C(\varphi(x))$, prove φ maps C onto C' and $|C'|$ divides $|C|$.

Artin 7.2.17 Use the class equation to show a group of order pq (p, q prime) contains an element of order p.

Artin 7.2.9 Determine the class equation of (a) Q_8, (b) D_4, (c) D_5, (d) the upper-triangular subgroup of $\mathrm{GL}_2(\mathbb{F}_3)$.

Artin 7.3.2 Prove that if $Z = Z(G)$ and G/Z is cyclic then G is abelian (so $G = Z$).

Artin 7.4.3 Determine the centralizer of an element of order 2 in the icosahedral group I.

Artin 7.4.4a Determine the class equation of the tetrahedral group T.

Artin 7.4.6a Prove $T \cong A_4$ and $O \cong S_4$ by finding 4-element sets on which the groups act.

Artin 7.4.7 If $|G| = n$ acts nontrivially on a set of order r with $n > r!$, prove G has a proper normal subgroup.

Artin 7.5.1 (a) Prove the transpositions $(1\,2), (2\,3), \ldots, (n-1, n)$ generate S_n; (b) how many transpositions write the cycle $(1\,2\cdots n)$; (c) prove $(1\,2\cdots n)$ and $(1\,2)$ generate S_n.

Artin 7.5.4 Describe the centralizer $Z(\sigma)$ for $\sigma = (1\,5\,3)(2\,4\,6)$ in S_7 and compute $|Z(\sigma)|$ and $|C(\sigma)|$.

Artin 7.5.5 For permutations p, q prove that pq and qp have cycles of equal sizes.

Artin 7.5.6 Find all subgroups of S_4 of order 4 and decide which are normal.

Artin 7.5.7 Prove A_n is the only subgroup of S_n of index 2.

Artin 7.5.9 For a 3-cycle q in S_n, count the even permutations p with $pqp^{-1} = q$.

Artin 7.5.10 Verify the class equations of S_4 and S_5 and determine a centralizer in each class.

Artin 7.6.4 If $H \trianglelefteq G$ has prime order p equal to the smallest prime dividing $|G|$, prove $H \leq Z(G)$.

Artin 7.7.3 How many elements of order 5 might a group of order 20 contain?

Artin 7.7.4 Prove no simple group has order (a) pq or (b) p^2q for primes p, q.

Artin 7.7.6 Exhibit a subgroup of S_7 that is a non-abelian group of order 21.

Artin 7.7.9 Classify groups of order (a) 33, (b) 18, (c) 20, (d) 30.

Artin 7.7.10 Prove the only simple groups of order < 60 are the groups of prime order.

Artin 7.8.4 Prove a group of order $n = 2p$ (p prime) is either cyclic or dihedral.

Fraleigh 11.14 Argue geometrically that a plane isometry fixing three non-collinear points is the identity.

Fraleigh 11.15 Using the previous result, show algebraically that two plane isometries agreeing on three non-collinear points are equal.

Fraleigh 11.16 Do the rotations together with the identity form a subgroup of the plane isometry group? Justify.

Fraleigh 11.17 Do the translations together with the identity form a subgroup? Justify.

Fraleigh 11.18 Do the rotations about one fixed point P together with the identity form a subgroup? Justify.

Fraleigh 11.19 Does the reflection across one fixed line L together with the identity form a subgroup? Justify.

Fraleigh 11.20 Do the glide reflections together with the identity form a subgroup? Justify.

Fraleigh 11.21 Which of the four isometry types can be elements of a finite subgroup of the plane isometry group?

Fraleigh 11.40 For $\varphi : \mathbb{R} \to U$, $\varphi(\theta) = \cos\theta + i\sin\theta$ and $S = \varphi[\mathbb{Z}]$: (a) show a rotation mapping S to S is by an integer angle; (b) show reflection across the x-axis maps S to S; (c) identify the symmetry group of S.

Fraleigh 11.41 Show the rotations of a cube in space form a group isomorphic to S_4.

Fraleigh 14.19 Let $|G| = p^n$ and X a G-set; prove $|X| \equiv |X_G| \pmod{p}$.

Fraleigh 14.20 Prove Cauchy's Theorem: if p divides $|G|$ then G has an element of order p.

Fraleigh 14.24 Prove that a finite p-group $G \neq \{e\}$ has nontrivial center $Z(G)$.

Fraleigh 14.25 Prove that every group of order p^2 is abelian.

Fraleigh 14.20b Let X be a G-set and $Y \subseteq X$; prove $G_Y = \{g \mid gy = y \ \forall y \in Y\}$ is a subgroup of G.

Fraleigh 14.26 Up to isomorphism, how many transitive $\mathbb{Z}_4$-sets are there? Give an action table for each type.

Fraleigh 14.27 Repeat the previous count for $\mathbb{Z}_6$.

Fraleigh 14.28 Repeat the count for S_3.

Fraleigh 14.29 Prove that if $|G| = p^3$ then $|Z(G)|$ is p or p^3, and give an example of each.

Fraleigh 14.30 Prove a finite group G is a p-group iff $|G| = p^n$ for some $n \geq 0$.

Fraleigh 14.31 For G acting on its subgroups by conjugation, state and prove a normality criterion for $H \leq G$ in terms of (a) G_H, (b) the orbit of H.

Fraleigh 17.15 Let G be finite and let primes p and $q \neq p$ divide $|G|$. Prove that if G has precisely one Sylow p-subgroup it is normal, so G is not simple.

Fraleigh 17.16 Show every group of order 45 has a normal subgroup of order 9.

Fraleigh 17.24 If P is a normal p-subgroup of G, show P is contained in every Sylow p-subgroup.

Fraleigh 17.26 Prove every group of order $5 \cdot 7 \cdot 47$ is abelian and cyclic.

Fraleigh 17.28 Show every group of order 30 contains a subgroup of order 15.

Fraleigh 17.31 Use conjugation to prove the class equation $|G| = |Z(G)| + n_1 + \cdots + n_k$.

Fraleigh 17.33 Show that for every integer $1 < n < 15$, if every group of order n is cyclic then n is prime.

Hard

DF 4.1.7 Define a *block* for a transitive $G \leq \mathrm{Sym}(A)$ and prove: (a) if $a \in B$ then $G_B = \{\sigma \mid \sigma(B) = B\}$ is a subgroup containing G_a; (b) the distinct images of a block partition A; (c) S_4 is primitive on $\{1,2,3,4\}$ while D_8 is not primitive on the square's vertices; (d) G is primitive iff each G_a is maximal.

DF 4.1.8 Define *doubly transitive* and prove: (a) S_n is doubly transitive on $\{1,\ldots,n\}$ for $n \geq 2$; (b) a doubly transitive group is primitive, so D_8 is not doubly transitive on the square.

DF 4.1.9 For G transitive on finite A and $H \trianglelefteq G$ with H-orbits $\mathcal{O}_1, \ldots, \mathcal{O}_r$: (a) prove G permutes the $\mathcal{O}_i$ transitively, so all have equal size; (b) prove $|\mathcal{O}_1| = |H : H \cap G_a|$ and $r = |G : HG_a|$.

DF 4.1.10 For subgroups $H, K \leq G$ define the double coset HxK and prove: (a) it is a union of left cosets of K forming an H-orbit; (b) it is a union of right cosets of H; (c) double cosets partition G; (d) $|HxK| = |K| \cdot |H : H \cap xKx^{-1}|$; (e) $|HxK| = |H| \cdot |K : K \cap x^{-1}Hx|$.

DF 4.2.13 Prove that a finite group G of composite order n having a subgroup of order k for every $k \mid n$ is not simple.

DF 4.2.–Q8 Prove Q_8 embeds in S_8 but in no S_n with $n \leq 7$.

DF 4.3.6 If G is non-abelian of order 15, prove $Z(G) = 1$ and that there is at most one possible class equation for G.

DF 4.3.17 For $X \subseteq S_A$ with moved set $M(\sigma)$, prove $D = \{\sigma \in S_A \mid |M(\sigma)| < \infty\}$ is a normal subgroup of S_A.

DF 4.3.19 For $H \trianglelefteq G$ and a conjugacy class $\mathcal{K} \subseteq H$ with $x \in \mathcal{K}$, prove $\mathcal{K}$ splits into $k = [G : HC_G(x)]$ classes of equal size in H; deduce the S_n-versus-A_n splitting of even classes.

DF 4.3.20 Prove $\sigma \in A_n$ has its S_n-class remain a single A_n-class iff σ commutes with an odd permutation.

DF 4.3.21 Prove σ commutes with no odd permutation iff its cycle type consists of distinct odd integers; deduce the criterion for an S_n-class to split in A_n.

DF 4.3.23 Prove that if M is a maximal subgroup of G then $N_G(M) = M$ or G; deduce the bound $(|M| - 1)[G : M]$ on nonidentity elements in conjugates of a nonnormal maximal M.

DF 4.3.24 Prove a finite group G is not the union of the conjugates of any proper subgroup.

DF 4.3.25 For $G = \mathrm{GL}_2(\mathbb{C})$ and H the upper-triangular subgroup, prove every element of G is conjugate into H, so G is a union of conjugates of H.

DF 4.3.27 If G is transitive on finite A with $|A| > 1$, show some $\sigma \in G$ is fixed-point free.

DF 4.3.30 For primes $p < q$, prove a non-abelian group of order pq has a nonnormal subgroup of index q, hence embeds in S_q as a subgroup of $N_{S_q}(\langle(1\,2\cdots q)\rangle)$.

DF 4.3.33 For $n = 2k$ even, determine the conjugacy classes of D_{2n} and give the class equation.

DF 4.3.34 Prove that for a prime p and $P \leq S_p$ of order p, $|N_{S_p}(P)| = p(p-1)$.

DF 4.3.35 Find a formula (using the floor function) for the number of conjugacy classes of elements of order p in S_n.

DF 4.3.36 For the left and right regular representations π, λ with $\sigma_g = \pi(g)$, $\tau_h = \lambda(h)$ (so $\tau_h(x) = xh^{-1}$): (a) prove σ_g, τ_h commute; (b) $\sigma_g = \tau_g$ iff g has order 1 or 2 in $Z(G)$; (c) $\sigma_g = \tau_h$ iff $g, h \in Z(G)$ and $g = h^{-1}$, so $\lambda(G) \cap \pi(G) = Z(\lambda(G)) = Z(\pi(G))$.

DF 4.4.3 Prove that under any automorphism of D_8, r has at most 2 images and s at most 4; deduce $|\operatorname{Aut}(D_8)| \leq 8$.

DF 4.4.4 Show $|\operatorname{Aut}(Q_8)| \leq 24$ by similar arguments.

DF 4.4.5 Use $D_8 \trianglelefteq D_{16}$ to prove $\operatorname{Aut}(D_8) \cong D_8$.

DF 4.4.11 For p prime and $P \leq S_p$ of order p, prove $N_{S_p}(P)/C_{S_p}(P) \cong \operatorname{Aut}(P)$.

DF 4.4.12 Let $|G| = 3825$; prove that a normal subgroup of order 17 lies in $Z(G)$.

DF 4.4.13 Let $|G| = 203$; prove a normal subgroup of order 7 lies in $Z(G)$, and deduce G is abelian.

DF 4.4.14 Let $|G| = 1575$; prove a normal subgroup of order 9 lies in $Z(G)$.

DF 4.4.18 Prove that for $n \neq 6$ every automorphism of S_n is inner.

DF 4.4.19 Prove $|\operatorname{Aut}(S_6) : \operatorname{Inn}(S_6)| \leq 2$.

DF 4.4.20 For the Thompson subgroup $J(P)$: (a) prove $J(P)$ is characteristic; (b) list the relevant abelian subgroups for $Q_8, D_8, D_{16}, QD_{16}$; (c) compute J for each; (d) prove the normality-transfer property of $J(P)$.

DF 4.5.11 Prove $Z(\mathrm{SL}_2(\mathbb{F}_3)) = \{\pm I\}$ and $\mathrm{SL}_2(\mathbb{F}_3)/Z \cong A_4$.

DF 4.5.12 For $2n = 2^a k$ with k odd, prove the number of Sylow 2-subgroups of D_{2n} is k.

DF 4.5.16 For $|G| = pqr$ with primes $p < q < r$, prove G has a normal Sylow subgroup for p, q, or r.

DF 4.5.19 Prove that if $|G| = 6545$ then G is not simple.

DF 4.5.20 Prove that if $|G| = 1365$ then G is not simple.

DF 4.5.21 Prove that if $|G| = 2907$ then G is not simple.

DF 4.5.27 If $|G| = 315$ has a normal Sylow 3-subgroup, prove $Z(G)$ contains it and G is abelian.

DF 4.5.28 If $|G| = 1575$ has a normal Sylow 3-subgroup, prove the Sylow 5- and 7-subgroups are normal and G is abelian.

DF 4.5.29 If G is a non-abelian simple group of order < 100, prove $G \cong A_5$.

DF 4.5.36 For $P \in \mathrm{Syl}_p(G)$ and $H \leq G$, prove $gPg^{-1} \cap H \in \mathrm{Syl}_p(H)$ for some g, and give an example where no $h \in H$ works.

DF 4.5.38 For a normal p-subgroup $R \trianglelefteq G$: (a) R lies in every Sylow p-subgroup; (b) RS is a normal p-subgroup for another such S; (c) $O_p(G)$ is the unique largest normal p-subgroup and equals $\bigcap \mathrm{Syl}_p(G)$; (d) $O_p(G/O_p(G)) = 1$.

DF 4.5.39 Show that if $n_p \not\equiv 1 \pmod{p^2}$ then there exist distinct $P, Q \in \mathrm{Syl}_p(G)$ with $[P : P \cap Q] = [Q : P \cap Q] = p$.

DF 4.5.42 Prove $\mathrm{SL}_2(\mathbb{F}_4) \cong A_5$.

DF 4.5.49 Find generators for a Sylow p-subgroup of S_{2p} (p odd prime) and show it is abelian of order p^2.

DF 4.5.50 Find generators for a Sylow p-subgroup of S_{p^2} and show it is non-abelian of order p^{p+1}.

DF 4.5.54 Prove that if $|G| = 2^n m$ with m odd and the Sylow 2-subgroup is cyclic, then G has a normal subgroup of order m.

DF 4.5.55 Prove that normal subsets U, W of a Sylow p-subgroup P are conjugate in G iff conjugate in $N_G(P)$; deduce the corresponding statement for central elements.

DF 4.5.56 For $P \in \mathrm{Syl}_p(G)$ and $M \geq N_G(P)$, prove $[G : M] \equiv 1 \pmod{p}$.

DF 4.5.57 If G is finite simple with every proper subgroup abelian and M, N distinct maximal subgroups, prove $M \cap N = 1$.

DF 4.5.58 Prove that a non-abelian finite group in which every proper subgroup is abelian is not simple.

DF 4.5.59 Prove that if $|G| = p_1 \cdots p_r$ with distinct primes and $p_i \nmid (p_j - 1)$ for all i, j, then G is cyclic.

DF 4.5.60 Prove the converse: if $n \geq 2$ and every group of order n is cyclic, then $n = p_1 \cdots p_r$ with distinct primes and $p_i \nmid (p_j - 1)$.

DF 4.5.61 Prove that a finite group in which every proper subgroup is abelian is solvable.

DF 4.6.1 Prove A_n has no proper subgroup of index $< n$ for all $n \geq 5$.

DF 4.6.2 Find all normal subgroups of S_n for all $n \geq 5$.

DF 4.6.3 Prove A_n is the only proper subgroup of index $< n$ in S_n for all $n \geq 5$.

DF 4.6.5 Prove that if $G_1 \leq G_2 \leq \cdots$ with $G = \bigcup_i G_i$ and each G_i simple, then G is simple.

DF 4.6.6 For an infinite set Ω, let $D \leq S_\Omega$ be the finitely-moving permutations and A the even ones; prove A is an infinite simple group.

DF 4.6.7 For Ω infinite, prove that if $H \trianglelefteq S_\Omega$ and $H \neq 1$ then $A \leq H$, i.e. A is the unique minimal normal subgroup.

DF 4.6.8 For Ω infinite, prove $|D| = |A| = |\Omega|$ and deduce that $S_\Omega \cong S_\Delta$ implies $|\Omega| = |\Delta|$.

Artin 6.M.2 Prove $\mathrm{Aut}(G)$ is a group, that $g \mapsto$ (conjugation by g) is a homomorphism with determined kernel, and that the inner automorphisms form a normal subgroup of $\mathrm{Aut}(G)$.

Artin 6.M.3 Determine the automorphism groups of (a) C_4, (b) C_8, (c) $C_2 \times C_2$, (d) D_4, (e) Q_8.

Artin 6.M.4 For the n-dimensional hypercube symmetry group $G_n \leq O_n$: (a) use the counting formula and induction to find $|G_n|$; (b) describe G_n explicitly and the stabilizer of $(1, \ldots, 1)$, checking $G_2 \cong D_4$.

Artin 6.M.7 For finite G acting on finite S with $S_g = \{s \mid gs = s\}$ and G_s the stabilizer: prove $\sum_s |G_s| = \sum_g |S_g|$ and deduce Burnside's Formula $|G| \cdot (\text{orbits}) = \sum_g |S_g|$.

Artin 6.M.8 Of the $\binom{8}{4} = 70$ ways to color the edges of an octagon with four black and four white, use Burnside's Formula to count the D_8-equivalence classes.

Artin 7.3.3 For non-abelian G of order p^3: (a) possible orders of Z; (b) order of $Z(x)$ for $x \notin Z$; (c) possible class equations.

Artin 7.3.4 Classify the groups of order 8.

Artin 7.4.5 For the octahedral group O: (a) determine its class equation; (b) find its two nontrivial proper normal subgroups and show there are no others.

Artin 7.5.11 (a) Show the S_n-class of an even permutation p is one A_n-class or splits into two of equal order, decided by the centralizer; (b) determine the class equations of A_4 and A_5; (c) describe the splitting for odd-order permutations.

Artin 7.5.12 Determine the class equations of S_6 and A_6.

Artin 7.6.5 For a p-group G and proper $H < G$, prove $N(H) > H$ and that H lies in a normal subgroup of index p.

Artin 7.6.6 For a proper subgroup $H < G$ of a finite group G: (a) prove G is not the union of conjugates of H; (b) there is a conjugacy class disjoint from H.

Artin 7.7.8 Compute $|\mathrm{GL}_n(\mathbb{F}_p)|$, find a Sylow p-subgroup, and determine the number of Sylow p-subgroups.

Artin 7.8.5 For a non-abelian group G of order 28 with cyclic Sylow 2-subgroups: (a) find the numbers of Sylow 2- and 7-subgroups; (b) show there is at most one isomorphism class; (c) find the element orders and the class equation.

Artin 7.8.6 For a group of order 55: (a) show it is $\langle x, y \mid x^{11} = 1, y^5 = 1, yxy^{-1} = x^r \rangle$; (b) decide which r are possible; (c) prove there are two isomorphism classes.

Artin 7.M.9 Prove that for $x \neq 1$ in a group of odd order, x and x^{-1} are not conjugate.

Artin 7.M.10 If finite G acts transitively on a set of order ≥ 2, show G contains an element fixing no point.

Artin 7.M.12 (Class equation of SL_2.) For $A = \left(\begin{smallmatrix} a & -1 \\ 1 & 0 \end{smallmatrix}\right)$: (a) find the centralizers in $\mathrm{SL}_2(\mathbb{F}_5)$ for $a = 0, \ldots, 4$; (b) determine the class equation of $\mathrm{SL}_2(\mathbb{F}_5)$; (c) count solutions of $x^2 + axy + y^2 = 1$ in $\mathbb{F}_p$; (d) determine the class equation of $\mathrm{SL}_2(\mathbb{F}_p)$.

Fraleigh 17.17 For $P \in \mathrm{Syl}_p(G)$, prove $N[N[P]] = N[P]$.

Fraleigh 17.18 For $P \in \mathrm{Syl}_p(G)$ and any p-subgroup H, prove there is g with $gHg^{-1} \leq P$.

Fraleigh 17.19 Show every group of order $(35)^3$ has a normal subgroup of order 125.

Fraleigh 17.20 Show there are no simple groups of order $255 = 3 \cdot 5 \cdot 17$.

Fraleigh 17.21 Show there are no simple groups of order $p^r m$ where p is prime, $r \geq 1$, $m < p$, and $p^r m$ is not prime.

Fraleigh 17.22 Prove all simple groups of order at most 20 are cyclic.

Fraleigh 17.23 Show a finite group of order p^n has normal subgroups H_i with $|H_i| = p^i$ and $H_i < H_{i+1}$ for $0 \leq i < n$.

Fraleigh 17.25 Prove that for a prime $p \geq 3$ and $k \geq 1$, any group of order $2p^k$ is not simple.

Fraleigh 17.27 Prove no group of order 96 is simple.

Fraleigh 17.29 Prove no group of order 160 is simple.

Fraleigh 17.30 If for each $k \mid |G|$ the finite group G has at most one subgroup of order k, prove G is cyclic.

Chapter 5

Direct and Semidirect Products and Abelian Groups

5.1 Direct Products

External direct products

Definition 5.1.1 (External direct product)**.** Let $G_1, G_2, \ldots, G_n$ be groups (written multiplicatively, with identities 1_i). The *(external) direct product* $G_1 \times G_2 \times \cdots \times G_n$ is the set of all n-tuples

$$G_1 \times \cdots \times G_n = \{\, (g_1, \ldots, g_n) \mid g_i \in G_i \text{ for all } i \,\}$$

with *componentwise* multiplication

$$(g_1, \ldots, g_n) \cdot (h_1, \ldots, h_n) = (g_1 h_1,\, g_2 h_2,\, \ldots,\, g_n h_n).$$

The identity is $(1_1, \ldots, 1_n)$ and $(g_1, \ldots, g_n)^{-1} = (g_1^{-1}, \ldots, g_n^{-1})$. When every G_i is abelian and written additively, the same construction is called the *direct sum* and written $G_1 \oplus \cdots \oplus G_n$.

Proposition 5.1.2 (It is a group; its order)**.** *$G = G_1 \times \cdots \times G_n$ is a group, and if every G_i is finite then*

$$|G| = |G_1| \cdot |G_2| \cdots |G_n| = \prod_{i=1}^{n} |G_i|.$$

Proof. The operation is well defined since each $g_i h_i \in G_i$. Associativity holds coordinatewise: the i-th coordinate of either bracketing of $(g_i)(h_i)(k_i)$ is $g_i(h_i k_i) = (g_i h_i)k_i$ by associativity in G_i. The element $e = (1_1, \ldots, 1_n)$ satisfies $e \cdot (g_i) = (1_i g_i) = (g_i)$ and similarly on the right, so e is the identity. Finally (g_i^{-1}) inverts (g_i) coordinatewise, so every element has an inverse; hence G is a group. For the order: choosing $(g_1, \ldots, g_n)$ amounts to choosing each $g_i \in G_i$ independently, so by the multiplication principle there are $\prod_i |G_i|$ tuples. □

Method (Computing in a direct product)**.** *Trigger.* The group is presented as a product $G_1 \times \cdots \times G_n$, or you must count its elements.

1. Work *slot by slot*: multiply, invert, and reduce each coordinate inside its own G_i. Coordinates never interact.
2. For the order of the group, multiply the orders: $\prod_i |G_i|$.
3. Identity is the tuple of identities; inverse is the tuple of inverses.

Worked Example 5.1.3 (Multiplying in $\mathbb{Z}/4\mathbb{Z} \times S_3$)**.** Problem. In $\mathbb{Z}/4\mathbb{Z} \times S_3$ compute $(3, (1\,2)) \cdot (2, (1\,2\,3))$ and the order of the whole group.

Recognition. Componentwise operation: add mod 4 in the first slot, compose permutations in the second; the order of the group is the product of the orders.

Solution. First slot: $3+2 = 5 \equiv 1 \pmod 4$. Second slot: apply $(1\,2\,3)$ then $(1\,2)$ (D&F composes right-to-left). Track each point: $1 \xmapsto{(1\,2\,3)} 2 \xmapsto{(1\,2)} 1$, $2 \mapsto 3 \mapsto 3$, $3 \mapsto 1 \mapsto 2$, giving $(2\,3)$. So the product is $(1, (2\,3))$. Order of the group: $|\mathbb{Z}/4\mathbb{Z}| \cdot |S_3| = 4 \cdot 6 = 24$. *Check.* The first slot reduces correctly, $5 \bmod 4 = 1$; in the second slot $1 \mapsto 1$ is fixed while $2 \leftrightarrow 3$ are swapped, so the result is the transposition $(2\,3)$. Both coordinates land in their groups, and $24 = 4 \cdot 6$.

Order of an element

Proposition 5.1.4 (Order of a tuple)**.** *Let $g_i \in G_i$ have finite order $|g_i|$ for each i. Then in $G_1 \times \cdots \times G_n$,*

$$|(g_1, \ldots, g_n)| = \operatorname{lcm}\big(|g_1|,\, |g_2|,\, \ldots,\, |g_n|\big).$$

Proof. Since multiplication is componentwise, induction on m gives $(g_1, \ldots, g_n)^m = (g_1^m, \ldots, g_n^m)$. Thus $(g_1, \ldots, g_n)^m = (1_1, \ldots, 1_n) \iff g_i^m = 1_i$ for every $i \iff |g_i| \mid m$ for every i. The set of integers m divisible by every $|g_i|$ is exactly the set of multiples of $L := \operatorname{lcm}(|g_1|, \ldots, |g_n|)$ (a common multiple is divisible by the least common multiple). The order of the tuple is the smallest positive such m, namely L. □

Method (Order of $(g_1, \ldots, g_n)$)**.** *Trigger.* You are asked for the order of a specific tuple, or the largest possible order of an element.

1. Find each coordinate order $|g_i|$ separately (in $\mathbb{Z}/m\mathbb{Z}$, $|a| = m/\gcd(a, m)$).
2. Take the **lcm** of those numbers — *not* the product, and *not* the sum.
3. For the *largest element order* in $\mathbb{Z}/m_1\mathbb{Z} \times \cdots \times \mathbb{Z}/m_n\mathbb{Z}$, the exponent of the group is $\operatorname{lcm}(m_1, \ldots, m_n)$; an element of that order exists (take a generator in each slot), so the maximum equals $\operatorname{lcm}(m_1, \ldots, m_n)$.

Caution. The order of a tuple is the **lcm**, never the product, of the coordinate orders. In $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ the element $(1, 1)$ has order $\operatorname{lcm}(4, 6) = 12$, not $4 \cdot 6 = 24$ and not $4 + 6 = 10$. Using the product 24 is wrong on two counts: it equals the full group order $|\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}| = 24$, which no element can match here, and it exceeds the exponent $\operatorname{lcm}(4, 6) = 12$, which already bounds every element order.

Worked Example 5.1.5 (Order of an element of $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ (D&F))**.** Problem. Find the order of $(2, 3)$ and of $(1, 1)$ in $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$.

Recognition. Proposition 5.1.4: order = lcm of coordinate orders; in $\mathbb{Z}/m\mathbb{Z}$, $|a| = m/\gcd(a, m)$.

Solution. For $(2, 3)$: in $\mathbb{Z}/4\mathbb{Z}$, $|2| = 4/\gcd(2, 4) = 4/2 = 2$; in $\mathbb{Z}/6\mathbb{Z}$, $|3| = 6/\gcd(3, 6) = 6/3 = 2$. So $|(2, 3)| = \operatorname{lcm}(2, 2) = 2$. *Check.* $(2, 3) + (2, 3) = (4, 6) = (0, 0)$, and $(2, 3) \neq (0, 0)$, confirming order 2.
For $(1, 1)$: $|1| = 4$ in $\mathbb{Z}/4\mathbb{Z}$ and $|1| = 6$ in $\mathbb{Z}/6\mathbb{Z}$, so $|(1, 1)| = \operatorname{lcm}(4, 6) = 12$. *Check.* $12 \cdot (1, 1) = (12, 12) = (0, 0)$ since $4 \mid 12$ and $6 \mid 12$; and $6 \cdot (1, 1) = (6, 6) = (2, 0) \neq (0, 0)$, so the order is not 6. Indeed 12 is the exponent of the group.

Worked Example 5.1.6 (Order in $\mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/18\mathbb{Z}$)**.** Problem. Find $|(8, 15)|$ in $\mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/18\mathbb{Z}$.

Recognition. Coordinatewise orders via $m/\gcd(a, m)$, then lcm.

Solution. In $\mathbb{Z}/12\mathbb{Z}$: $\gcd(8, 12) = 4$, so $|8| = 12/4 = 3$. In $\mathbb{Z}/18\mathbb{Z}$: $\gcd(15, 18) = 3$, so $|15| = 18/3 = 6$. Hence $|(8, 15)| = \operatorname{lcm}(3, 6) = 6$. *Check.* $6 \cdot (8, 15) = (48, 90) = (0, 0)$ since $48 = 4 \cdot 12$ and $90 = 5 \cdot 18$; and $3 \cdot (8, 15) = (24, 45) = (0, 9) \neq (0, 0)$, so the order exceeds 3, consistent with 6.

Worked Example 5.1.7 (Order of a permutation/quaternion pair)**.** Problem. In $D_8 \times Q_8$ find the order of (r, i), where r is the rotation of order 4 in D_8 ($n = 4$) and $i \in Q_8$.

Recognition. Order of a tuple is the lcm of coordinate orders; read off $|r| = 4$ and $|i| = 4$.

Solution. In D_8 we have $r^4 = 1$ and $r, r^2, r^3 \neq 1$, so $|r| = 4$. In Q_8, $i^2 = -1$ and $i^4 = 1$ with $i, i^2, i^3 \neq 1$, so $|i| = 4$. Thus $|(r, i)| = \operatorname{lcm}(4, 4) = 4$. *Check.* $(r, i)^4 = (r^4, i^4) = (1, 1)$ and $(r, i)^2 = (r^2, i^2) = (r^2, -1) \neq (1, 1)$, so the order is exactly 4.

Worked Example 5.1.8 (Largest order of an element of $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$)**.** Problem. What is the largest order of any element of $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$?

Recognition. The maximum element order equals the exponent $\operatorname{lcm}(m_1, \ldots, m_n)$, attained by a tuple of generators.

Solution. Compute $\operatorname{lcm}(4, 6, 9)$. Prime factorizations: $4 = 2^2$, $6 = 2 \cdot 3$, $9 = 3^2$. Take the highest power of each prime: 2^2 from 4 and 3^2 from 9, giving $4 \cdot 9 = 36$. So the maximum order is 36, attained by $(1, 1, 1)$: indeed $|(1, 1, 1)| = \operatorname{lcm}(4, 6, 9) = 36$. *Check.* No element can have larger order, since $g^{36} = (g_1^{36}, g_2^{36}, g_3^{36}) = (0, 0, 0)$ for every g (as $4, 6, 9 \mid 36$), so 36 is the exponent and bounds all orders; and $(1, 1, 1)$ achieves it. Note $|\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}| = 4 \cdot 6 \cdot 9 = 216$, so the group is far from cyclic.

The Chinese remainder theorem for cyclic groups

Theorem 5.1.9 ($\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/mn\mathbb{Z}$ iff coprime)**.** *For $m, n \in \mathbb{Z}^+$,*

$$\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/mn\mathbb{Z} \quad \iff \quad \gcd(m, n) = 1.$$

More generally, $\mathbb{Z}/m_1\mathbb{Z} \times \cdots \times \mathbb{Z}/m_k\mathbb{Z} \cong \mathbb{Z}/m_1 \cdots m_k\mathbb{Z}$ iff the m_i are pairwise coprime. Equivalently, $\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$ is cyclic $\iff \gcd(m, n) = 1$.

Proof. Both groups have order mn, so it suffices to decide when $\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$ is cyclic, i.e. has an element of order mn. By Proposition 5.1.4 the maximum element order is the exponent $\operatorname{lcm}(m, n)$. Using $\operatorname{lcm}(m, n) \cdot \gcd(m, n) = mn$, we get $\operatorname{lcm}(m, n) = mn \iff \gcd(m, n) = 1$.

($\Leftarrow$) If $\gcd(m, n) = 1$ then $(1, 1)$ has order $\operatorname{lcm}(m, n) = mn$, so $\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} = \langle (1, 1) \rangle$ is cyclic of order mn, hence $\cong \mathbb{Z}/mn\mathbb{Z}$.

($\Rightarrow$) If $\mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/mn\mathbb{Z}$ it is cyclic of order mn, so it has an element of order mn; but every element has order dividing $\operatorname{lcm}(m, n)$, forcing $\operatorname{lcm}(m, n) = mn$, i.e. $\gcd(m, n) = 1$. The general statement follows by induction on k, since $\mathbb{Z}/m_1\mathbb{Z} \times \cdots \times \mathbb{Z}/m_k\mathbb{Z}$ is cyclic iff the orders of the standard generators combine to an element of order $m_1 \cdots m_k$, which happens iff the m_i are pairwise coprime. □

Method (Is $\mathbb{Z}/m_1\mathbb{Z} \times \cdots \times \mathbb{Z}/m_k\mathbb{Z}$ cyclic?)**.** *Trigger.* A product of cyclic groups; you must decide if it is cyclic, or identify it as some $\mathbb{Z}/N\mathbb{Z}$.

1. Compute $E = \operatorname{lcm}(m_1, \ldots, m_k)$ and $N = m_1 \cdots m_k$ (the group order).
2. Cyclic $\iff E = N \iff$ the m_i are *pairwise* coprime. If so, the group $\cong \mathbb{Z}/N\mathbb{Z}$ and $(1, \ldots, 1)$ is a generator.
3. If $E < N$ the group is *not* cyclic; the maximum element order is E.

Pairwise coprime is essential: $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ has $\operatorname{lcm} = 6 < 18$, not cyclic, even though $\gcd(2, 3) = 1$.

Worked Example 5.1.10 ($\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$ but $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \ncong \mathbb{Z}/4\mathbb{Z}$ (D&F))**.** Problem. Show $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$ while $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \ncong \mathbb{Z}/4\mathbb{Z}$.

Recognition. Theorem 5.1.9: cyclic $\iff$ coordinate moduli coprime; compare lcm with the group order.

Solution. For $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$: $\gcd(2, 3) = 1$, so $(1, 1)$ has order $\operatorname{lcm}(2, 3) = 6 = |\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}|$, making the group cyclic, hence $\cong \mathbb{Z}/6\mathbb{Z}$. *Check.* List multiples of $(1, 1)$: $(1, 1), (0, 2), (1, 0), (0, 1), (1, 2), (0, 0)$ — six distinct elements, so $(1, 1)$ generates.
For $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$: $\gcd(2, 2) = 2 \neq 1$, so $\operatorname{lcm}(2, 2) = 2 < 4$. Every nonidentity element $(1, 0), (0, 1), (1, 1)$ has order 2, so there is no element of order 4 and the group cannot be cyclic; thus $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \ncong \mathbb{Z}/4\mathbb{Z}$ (this is the Klein four-group V_4). *Check.* $\mathbb{Z}/4\mathbb{Z}$ has the element 1 of order 4, which V_4 lacks, so they are not isomorphic.

Worked Example 5.1.11 (Is $\mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z}$ cyclic?)**.** Problem. Decide whether $\mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z}$ is cyclic, and find its maximum element order.

Recognition. Cyclic $\iff$ moduli coprime; otherwise the max order is lcm, strictly below the group order.

Solution. $\gcd(6,10) = 2 \neq 1$, so by Theorem 5.1.9 the group is *not* cyclic. The group order is $6 \cdot 10 = 60$, but the maximum element order is $E = \operatorname{lcm}(6,10) = \dfrac{6 \cdot 10}{\gcd(6,10)} = \dfrac{60}{2} = 30$. *Check.* $(1,1)$ has order $\operatorname{lcm}(6,10) = 30 \neq 60$, so it is not a generator; since the exponent $30 < 60$, no element generates. (As a sanity decomposition, $\mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/30\mathbb{Z}$, which visibly is not cyclic because of the repeated factor 2.)

Worked Example 5.1.12 (Three-factor CRT: $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/60\mathbb{Z}$)**.** Problem. Show $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$ is cyclic and identify it.

Recognition. Pairwise-coprime moduli $\implies$ cyclic of order their product.

Solution. Check pairwise: $\gcd(3,4) = \gcd(3,5) = \gcd(4,5) = 1$. By Theorem 5.1.9 the product is cyclic of order $3 \cdot 4 \cdot 5 = 60$, so $\cong \mathbb{Z}/60\mathbb{Z}$, with generator $(1,1,1)$. *Check.* $|(1,1,1)| = \operatorname{lcm}(3,4,5) = 60 = |\text{group}|$, confirming $(1,1,1)$ generates and the group is $\mathbb{Z}/60\mathbb{Z}$.

Worked Example 5.1.13 (A non-pairwise-coprime trap)**.** Problem. Is $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ isomorphic to $\mathbb{Z}/24\mathbb{Z}$?

Recognition. Apply CRT: $\cong \mathbb{Z}/24\mathbb{Z}$ would require an element of order 24.

Solution. $\gcd(4,6) = 2 \neq 1$, so $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ is *not* cyclic; its maximum element order is $\operatorname{lcm}(4,6) = 12 < 24$. Hence $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \ncong \mathbb{Z}/24\mathbb{Z}$. *Check.* We already saw $(1,1)$ has order 12; since 12 is the exponent, no element reaches 24. (Refining: $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, invariant factors $2 \mid 12$.)

Worked Example 5.1.14 ($\mathbb{Z}\times\mathbb{Z}$ is not cyclic)**.** Problem. Prove the infinite group $\mathbb{Z}\times\mathbb{Z}$ (under coordinatewise addition) is not cyclic.

Recognition. A cyclic group is generated by one element; show a single element cannot reach both $(1,0)$ and $(0,1)$.

Solution. Suppose $\mathbb{Z}\times\mathbb{Z} = \langle (a,b) \rangle$ for some (a,b). Then every element is an integer multiple $k\,(a,b) = (ka, kb)$. To get $(1,0)$ we need $kb = 0$ with $ka = 1$; from $ka = 1$ we have $k \neq 0$, so $b = 0$. With $b = 0$ every element is $(ka, 0)$, whose second coordinate is always 0, so $(0,1)$ can never be reached. So no single element generates: $\mathbb{Z} \times \mathbb{Z}$ is not cyclic. *Check.* Equivalently, a cyclic group is generated by one element and (if infinite) is $\cong \mathbb{Z}$, which has rank 1; but $\mathbb{Z} \times \mathbb{Z}$ needs the two independent generators $(1,0), (0,1)$ (rank 2), so it cannot be $\cong \mathbb{Z}$. Concretely $\{(1,0),(0,1)\}$ cannot both be expressed as multiples of a common (a,b).

Projections, injections, and the universal property

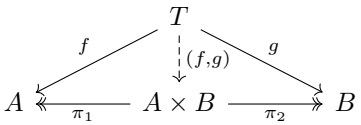
Definition 5.1.15 (Canonical projections and injections)**.** For $G = G_1 \times \cdots \times G_n$ define, for each i, the *i-th projection* $\pi_i : G \to G_i$ and the *i-th injection* $\iota_i : G_i \to G$ by

$$\pi_i(g_1, \ldots, g_n) = g_i, \qquad \iota_i(g) = (1_1, \ldots, 1_{i-1}, g, 1_{i+1}, \ldots, 1_n).$$

Each π_i is a surjective homomorphism with $\ker \pi_i = \{(g_1, \ldots, g_n) \mid g_i = 1_i\} \cong \prod_{j \neq i} G_j$, and each ι_i is an injective homomorphism. The images $\widehat{G}_i := \iota_i(G_i) \trianglelefteq G$ are normal, pairwise commuting, and generate G.

Proposition 5.1.16 (π_i, ι_i are homomorphisms)**.** *With notation as above, π_i and ι_i are group homomorphisms; π_i is onto and ι_i is one-to-one; and $\pi_i \circ \iota_i = \mathrm{id}_{G_i}$ while $\pi_j \circ \iota_i$ is the trivial map for $j \neq i$.*

Proof. $\pi_i\big((g_k)(h_k)\big) = \pi_i\big((g_k h_k)\big) = g_i h_i = \pi_i((g_k))\pi_i((h_k))$, so π_i is a homomorphism; it is onto since $\pi_i(\iota_i(g)) = g$. For ι_i, $\iota_i(gh)$ has gh in slot i and 1 elsewhere, which equals $\iota_i(g)\iota_i(h)$ because off-slot coordinates multiply $1 \cdot 1 = 1$; it is injective since $\iota_i(g) = \iota_i(g') \implies g = g'$ by reading slot i. The composite identities are immediate from the formulas: $\pi_i(\iota_i(g)) = g$ and $\pi_j(\iota_i(g)) = 1_j$ for $j \neq i$. □



Theorem 5.1.17 (Universal property of the direct product)**.** *Let $G_1, \ldots, G_n$ be groups and $G = G_1 \times \cdots \times G_n$ with projections π_i. For every group T and every family of homomorphisms $f_i : T \to G_i$ $(1 \le i \le n)$, there is a* unique *homomorphism $\varphi : T \to G$ with $\pi_i \circ \varphi = f_i$ for all i, namely*

$$\varphi(t) = \big(f_1(t),\, f_2(t),\, \ldots,\, f_n(t)\big).$$

Proof. Existence. Define $\varphi(t) = (f_1(t), \ldots, f_n(t))$. It is a homomorphism because each coordinate is: $\varphi(st) = (f_i(st)) = (f_i(s)f_i(t)) = (f_i(s))(f_i(t)) = \varphi(s)\varphi(t)$, using componentwise multiplication. And $\pi_i(\varphi(t)) = f_i(t)$, so $\pi_i \circ \varphi = f_i$.

Uniqueness. If $\psi : T \to G$ also satisfies $\pi_i \circ \psi = f_i$ for all i, then for each t the i-th coordinate of $\psi(t)$ is $\pi_i(\psi(t)) = f_i(t)$, which is exactly the i-th coordinate of $\varphi(t)$. As all coordinates agree, $\psi(t) = \varphi(t)$ for all t, so $\psi = \varphi$. □

For two factors the universal property is the commuting triangle: a map into $A \times B$ is the same data as a pair of maps, one into each factor.

The dashed arrow (f, g) is the unique homomorphism making both triangles commute: $\pi_1 \circ (f, g) = f$ and $\pi_2 \circ (f, g) = g$.

Diagram explanation. Objects: Four nodes. T is any group (the "test" source). A and B are the two factor groups. $A \times B$ is their external direct product, which sits in the middle of the bottom row.

Arrows: $f : T \to A$ and $g : T \to B$ are any two group homomorphisms (solid diagonal arrows). $\pi_1 : A \times B \to A$ and $\pi_2 : A \times B \to B$ are the canonical projections (solid horizontal arrows), defined by $\pi_1(a, b) = a$ and $\pi_2(a, b) = b$. The dashed vertical arrow $(f, g) : T \to A \times B$ is the *induced* homomorphism, defined by $(f, g)(t) = (f(t), g(t))$; it is dashed to signal that it is the map whose existence and uniqueness the universal property asserts.

What commutes: Two triangles must commute simultaneously: $\pi_1 \circ (f, g) = f$ (left triangle: $T \to A \times B \to A$ equals $T \to A$) and $\pi_2 \circ (f, g) = g$ (right triangle: $T \to A \times B \to B$ equals $T \to B$).

Why it commutes: Chase a generic $t \in T$. Along the left path: $(f, g)(t) = (f(t), g(t))$, then π_1 extracts the first coordinate, giving $f(t)$. Along the direct path $f(t)$ arrives at the same value. Right triangle: $\pi_2(f(t), g(t)) = g(t)$, matching $g(t)$ directly. Both equalities hold by definition of (f, g); no coset representative ambiguity arises because (f, g) maps group elements, not cosets.

Why this matters here: This diagram is the pay-off of the universal property theorem proved just above. It encodes the slogan "a map into $A \times B$ is *exactly* the same data as a pair of maps, one into each factor". The theorem proves existence and uniqueness of the dashed arrow; the diagram organizes all four maps and their two commutativity conditions at a glance, replacing two equations with one picture.

Concrete example: Take $T = \mathbb{Z}$, $f : \mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ the reduction mod 4, and $g : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ the reduction mod 6. Then $(f, g) : \mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ sends $k \mapsto (k \bmod 4,\ k \bmod 6)$. Check: $\pi_1((f, g)(5)) = \pi_1(1, 5) = 1 = 5 \bmod 4 = f(5)$, and $\pi_2((f, g)(5)) = 5 = 5 \bmod 6 = g(5)$. Both triangles commute for every k.

Common pitfall: Students sometimes think the dashed arrow (f, g) is determined only up to choice, or that it might not exist. The universal property guarantees *both* existence and uniqueness: there is exactly one homomorphism $T \to A \times B$ whose projections are f and g. Also, do not confuse this "into-product" property with a dual "out-of-product" property: a homomorphism $A \times B \to T$ *is* determined by its restrictions to A and B, but a given pair of homomorphisms $A \to T$, $B \to T$ extends to such a homomorphism only when their images commute elementwise in T.

Takeaway: The point of this diagram is that giving a single homomorphism into a direct product is equivalent to independently giving one homomorphism into each factor, with the projections recovering the factors automatically.

Method (Mapping into a product)**.** *Trigger.* You must build (or recognize the unique) homomorphism $T \to G_1 \times \cdots \times G_n$.

1. Specify the coordinate maps $f_i = \pi_i \circ \varphi : T \to G_i$ separately; each may be any homomorphism.
2. Assemble $\varphi = (f_1, \ldots, f_n)$. By Theorem 5.1.17 this is the only map with those projections.

3. Kernel: $\ker\varphi = \bigcap_i \ker f_i$, since $\varphi(t) = 1 \iff f_i(t) = 1$ for all i.

Caution. The universal property characterizes maps *into* a product via projections, not maps *out of* it. A homomorphism $A \times B \to T$ is determined by its restrictions to A and B, but a pair of homomorphisms $A \to T$, $B \to T$ need *not* come from any homomorphism $A \times B \to T$: it does exactly when the two images commute elementwise in T. (The "co-universal" picture with injections and coproducts works cleanly only for *abelian* groups.)

Worked Example 5.1.18 (Diagonal map and CRT, diagrammatically)**.** Problem. With $T = \mathbb{Z}$, $f : \mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ and $g : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ the reductions, identify the induced map $(f, g) : \mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ and its kernel.

Recognition. Theorem 5.1.17: paired maps assemble; the kernel is the intersection of kernels.

Solution. By the universal property $(f, g)(k) = (k \bmod 4,\ k \bmod 6)$, the unique homomorphism with $\pi_1 \circ (f, g) = f$ and $\pi_2 \circ (f, g) = g$. Its kernel is $\ker f \cap \ker g = 4\mathbb{Z} \cap 6\mathbb{Z} = \operatorname{lcm}(4, 6)\,\mathbb{Z} = 12\mathbb{Z}$. *Check.* $(f, g)(12) = (12 \bmod 4, 12 \bmod 6) = (0, 0)$, and $(f, g)(6) = (2, 0) \neq (0, 0)$, so the kernel is exactly $12\mathbb{Z}$. Thus $\mathbb{Z}/12\mathbb{Z}$ embeds as the cyclic subgroup $\langle(1, 1)\rangle$ of order 12 inside $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ — recovering that the max element order is 12, not 24, since $\gcd(4, 6) \neq 1$.

Worked Example 5.1.19 (Projection kernels and an internal/external bridge)**.** Problem. In $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ describe π_1, π_2, their kernels, and the injection images.

Recognition. Definition 5.1.15: $\ker\pi_i \cong \prod_{j \neq i} G_j$; injection images are normal and generate.

Solution. $\pi_1(a, b) = a \in \mathbb{Z}/2\mathbb{Z}$ with $\ker\pi_1 = \{(0, b) \mid b \in \mathbb{Z}/3\mathbb{Z}\} \cong \mathbb{Z}/3\mathbb{Z}$; $\pi_2(a, b) = b \in \mathbb{Z}/3\mathbb{Z}$ with $\ker\pi_2 = \{(a, 0) \mid a \in \mathbb{Z}/2\mathbb{Z}\} \cong \mathbb{Z}/2\mathbb{Z}$. The injection images are $\widehat{G}_1 = \iota_1(\mathbb{Z}/2\mathbb{Z}) = \{(0, 0), (1, 0)\} \cong \mathbb{Z}/2\mathbb{Z}$ and $\widehat{G}_2 = \iota_2(\mathbb{Z}/3\mathbb{Z}) = \{(0, 0), (0, 1), (0, 2)\} \cong \mathbb{Z}/3\mathbb{Z}$. *Check.* $\widehat{G}_1 \cap \widehat{G}_2 = \{(0, 0)\}$, the two subgroups commute (the group is abelian) and generate G since $|\widehat{G}_1|\,|\widehat{G}_2| = 2 \cdot 3 = 6 = |G|$. This realizes $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ as the internal direct product of $\widehat{G}_1$ and $\widehat{G}_2$, consistent with $\cong \mathbb{Z}/6\mathbb{Z}$.

Worked Example 5.1.20 (Using the universal property to detect a generator)**.** Problem. Construct a surjection $\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$ and use it to confirm $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/15\mathbb{Z}$.

Recognition. Pair the reductions via Theorem 5.1.17; surjectivity plus the first isomorphism theorem identifies the quotient.

Solution. Let $f : \mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$, $g : \mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$ be reduction maps and $\varphi = (f, g) : \mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$, $\varphi(k) = (k \bmod 3, k \bmod 5)$. Then $\ker\varphi = 3\mathbb{Z} \cap 5\mathbb{Z} = 15\mathbb{Z}$, so $\mathbb{Z}/15\mathbb{Z} \cong \operatorname{im}\varphi$. Since $\gcd(3, 5) = 1$, $(1, 1)$ has order $\operatorname{lcm}(3, 5) = 15 = |\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}|$, so φ is onto and $\operatorname{im}\varphi = \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$. Therefore $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/15\mathbb{Z} = \mathbb{Z}/15\mathbb{Z}$. *Check.* $|\operatorname{im}\varphi| = |\mathbb{Z}/15\mathbb{Z}| = 15 = |\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}|$, so the induced injective map is in fact an isomorphism.

Worked Example 5.1.21 (Failure of the dual property)**.** Problem. Give homomorphisms $\alpha, \beta : \mathbb{Z} \to T$ on the two factors of $\mathbb{Z} \times \mathbb{Z}$ that are not the restrictions of any single homomorphism $\mathbb{Z} \times \mathbb{Z} \to T$.

Recognition. Pitfall above: maps *out* of a product need the factor-images to commute; pick noncommuting targets.

Solution. Take $T = S_3$, and let $\alpha : \mathbb{Z} \to S_3$ send $1 \mapsto (1\,2)$ and $\beta : \mathbb{Z} \to S_3$ send $1 \mapsto (1\,3)$. There is no homomorphism $\Phi : \mathbb{Z} \times \mathbb{Z} \to S_3$ with $\Phi(k, 0) = \alpha(k)$ and $\Phi(0, \ell) = \beta(\ell)$ simultaneously, because $(1, 0)$ and $(0, 1)$ commute in $\mathbb{Z} \times \mathbb{Z}$ but their would-be images $(1\,2)$ and $(1\,3)$ do not commute in S_3: $(1\,2)(1\,3) = (1\,3\,2) \neq (1\,2\,3) = (1\,3)(1\,2)$. *Check.* Any homomorphism preserves commuting, so $\Phi(1, 0)$ and $\Phi(0, 1)$ must commute; since the prescribed values do not, no such Φ exists — confirming there is no universal property of products via restriction maps for nonabelian targets.

Exercises (from the text).

1. Show that the center of a direct product is the direct product of the centers:

$$Z(G_1 \times G_2 \times \cdots \times G_n) = Z(G_1) \times Z(G_2) \times \cdots \times Z(G_n).$$

Deduce that a direct product of groups is abelian if and only if each of the factors is abelian.

2. Let $G_1, G_2, \ldots, G_n$ be groups and let $G = G_1 \times \cdots \times G_n$. Let I be a proper, nonempty subset of $\{1, \ldots, n\}$ and let $J = \{1, \ldots, n\} - I$. Define G_I to be the set of elements of G that have the identity of G_j in position j for all $j \in J$.

   (a) Prove that G_I is isomorphic to the direct product of the groups G_i, $i \in I$.

   (b) Prove that G_I is a normal subgroup of G and $G/G_I \cong G_J$.

   (c) Prove that $G \cong G_I \times G_J$.

3. Under the notation of the preceding exercise let I and K be any disjoint nonempty subsets of $\{1, 2, \ldots, n\}$ and let G_I and G_K be the subgroups of G defined above. Prove that $xy = yx$ for all $x \in G_I$ and all $y \in G_K$.

4. Let A and B be finite groups and let p be a prime. Prove that any Sylow p-subgroup of $A \times B$ is of the form $P \times Q$, where $P \in \mathrm{Syl}_p(A)$ and $Q \in \mathrm{Syl}_p(B)$. Prove that $n_p(A \times B) = n_p(A)n_p(B)$. Generalize both of these results to a direct product of any finite number of finite groups (so that the number of Sylow p-subgroups of a direct product is the product of the numbers of Sylow p-subgroups of the factors).

5. Exhibit a nonnormal subgroup of $Q_8 \times Z_4$ (note that every subgroup of each factor is normal).

6. Show that all subgroups of $Q_8 \times E_{2^n}$ are normal.

7. Let $G_1, G_2, \ldots, G_n$ be groups and let π be a fixed element of S_n. Prove that the map

$$\varphi_\pi : G_1 \times G_2 \times \cdots \times G_n \to G_{\pi^{-1}(1)} \times G_{\pi^{-1}(2)} \times \cdots \times G_{\pi^{-1}(n)}$$

   defined by

$$\varphi_\pi(g_1, g_2, \ldots, g_n) = (g_{\pi^{-1}(1)}, g_{\pi^{-1}(2)}, \ldots, g_{\pi^{-1}(n)})$$

   is an isomorphism (so changing the order of the factors in a direct product does not change the isomorphism type).

8. Let $G_1 = G_2 = \cdots = G_n$ and let $G = G_1 \times \cdots \times G_n$. Under the notation of the preceding exercise show that $\varphi_\pi \in \mathrm{Aut}(G)$. Show that the map $\pi \mapsto \varphi_\pi$ is an injective homomorphism of S_n into $\mathrm{Aut}(G)$ (in particular, $\varphi_{\pi_1} \circ \varphi_{\pi_2} = \varphi_{\pi_1 \pi_2}$. It is at this point that the π^{-1}'s in the definition of φ_π are needed. The underlying reason for this is because if e_i is the n-tuple with 1 in position i and zeros elsewhere, $1 \leq i \leq n$, then S_n acts on $\{e_1, \ldots, e_n\}$ by $\pi \cdot e_i = e_{\pi(i)}$; this is a left group action. If the n-tuple $(g_1, \ldots, g_n)$ is represented by $g_1 e_1 + \cdots + g_n e_n$, then this left group action on $\{e_1, \ldots, e_n\}$ extends to a left group action on sums by

$$\pi \cdot (g_1 e_1 + g_2 e_2 + \cdots + g_n e_n) = g_1 e_{\pi(1)} + g_2 e_{\pi(2)} + \cdots + g_n e_{\pi(n)}.$$

   The coefficient of $e_{\pi(i)}$ on the right hand side is g_i, so the coefficient of e_i is $g_{\pi^{-1}(i)}$. Thus the right hand side may be rewritten as $g_{\pi^{-1}(1)} e_1 + g_{\pi^{-1}(2)} e_2 + \cdots + g_{\pi^{-1}(n)} e_n$, which is precisely the sum attached to the n-tuple $(g_{\pi^{-1}(1)}, g_{\pi^{-1}(2)}, \ldots, g_{\pi^{-1}(n)})$. In other words, any permutation of the "position vectors" $e_1, \ldots, e_n$ (which fixes their coefficients) is the same as the inverse permutation on the coefficients (fixing the e_i's). If one uses π's in place of π^{-1}'s in the definition of φ_π then the map $\pi \mapsto \varphi_\pi$ is not necessarily a homomorphism — it corresponds to a *right* group action.)

9. Let G_i be a field F for all i and use the preceding exercise to show that the set of $n \times n$ matrices with one 1 in each row and each column is a subgroup of $\mathrm{GL}_n(F)$ isomorphic to S_n (these matrices are called *permutation matrices* since they simply permute the standard basis $e_1, \ldots, e_n$ (as above) of the n-dimensional vector space $F \times F \times \cdots \times F$).

10. Let p be a prime. Let A and B be two cyclic groups of order p with generators x and y, respectively. Set $E = A \times B$ so that E is the elementary abelian group of order p^2: E_{p^2}. Prove that the distinct subgroups of E of order p are

$$\langle x \rangle, \quad \langle xy \rangle, \quad \langle xy^2 \rangle, \quad \ldots, \quad \langle xy^{p-1} \rangle, \quad \langle y \rangle$$

    (note that there are $p + 1$ of them).

11. Let p be a prime and let $n \in \mathbb{Z}^+$. Find a formula for the number of subgroups of order p in the elementary abelian group E_{p^n}.

12. Let A and B be groups. Assume $Z(A)$ contains a subgroup Z_1 and $Z(B)$ contains a subgroup Z_2 with $Z_1 \cong Z_2$. Let this isomorphism be given by the map $x_i \mapsto y_i$ for all $x_i \in Z_1$. A *central product* of A and B is a quotient

$$(A \times B)/Z \quad \text{where} \quad Z = \{(x_i, y_i^{-1}) \mid x_i \in Z_1\}$$

and is denoted by $A * B$ — it is not unique since it depends on Z_1, Z_2 and the isomorphism between them. (Think of $A * B$ as the direct product of A and B "collapsed" by identifying each element x_i in Z_1 with its corresponding element y_i in Z_2.)

   (a) Prove that the images of A and B in the quotient group $A*B$ are isomorphic to A and B, respectively, and that these images intersect in a central subgroup isomorphic to Z_1. Find $|A * B|$.

   (b) Let $Z_4 = \langle x \rangle$. Let $D_8 = \langle r, s \rangle$ and $Q_8 = \langle i, j \rangle$ be given by their usual generators and relations. Let Z_4D_8 be the central product of Z_4 and D_8 which identifies x^2 and r^2 (i.e., $Z_1 = \langle x^2 \rangle$, $Z_2 = \langle r^2 \rangle$ and the isomorphism is $x^2 \mapsto r^2$) and let Z_4Q_8 be the central product of Z_4 and Q_8 which identifies x^2 and -1. Prove that $Z_4D_8 \cong Z_4Q_8$.

13. Give presentations for the groups Z_4D_8 and Z_4Q_8 constructed in the preceding exercise.

14. Let $G = A_1 \times A_2 \times \cdots \times A_n$ and for each i let B_i be a normal subgroup of A_i. Prove that $B_1 \times B_2 \times \cdots \times B_n \trianglelefteq G$ and that

$$(A_1 \times A_2 \times \cdots \times A_n)/(B_1 \times B_2 \times \cdots \times B_n) \cong (A_1/B_1) \times (A_2/B_2) \times \cdots \times (A_n/B_n).$$

15. Let I be any nonempty index set and let $(G_i, \star_i)$ be a group for each $i \in I$. The *direct product* of the groups G_i, $i \in I$ is the set $G = \prod_{i \in I} G_i$ (the Cartesian product of the G_i's) with a binary operation defined as follows: if $\prod_{i \in I} a_i$ and $\prod_{i \in I} b_i$ are elements of G, then their product in G is given by

$$\left(\prod_{i \in I} a_i\right)\left(\prod_{i \in I} b_i\right) = \prod_{i \in I} (a_i \star_i b_i)$$

   (i.e., the group operation in the direct product is defined componentwise).

   (a) Show that this binary operation is well defined and associative.

   (b) Show that the element $\prod_{i \in I} 1_i$ satisfies the axiom for the identity of G, where 1_i is the identity of G_i for all i.

   (c) Show that the element $\prod_{i \in I} a_i^{-1}$ is the inverse of $\prod_{i \in I} a_i$, where the inverse of each component element a_i is taken in the group G_i. Conclude that the direct product is a group.

   (Note that if $I = \{1, 2, \ldots, n\}$, this definition of the direct product is the same as the n-tuple definition in the text.)

16. State and prove the generalization of Proposition 2 to arbitrary direct products.

17. Let I be any nonempty index set and let G_i be a group for each $i \in I$. The *restricted direct product* (or *direct sum*) of the groups G_i is the set of elements of the direct product which are the identity in all but finitely many components, that is, the set of all elements $\prod_{i \in I} a_i \in \prod_{i \in I} G_i$ such that $a_i = 1_i$ for all but a finite number of $i \in I$.

   (a) Prove that the restricted direct product is a subgroup of the direct product.

   (b) Prove that the restricted direct product is normal in the direct product.

   (c) Let $I = \mathbb{Z}^+$ and let p_i be the ith integer prime. Show that if $G_i = \mathbb{Z}/p_i\mathbb{Z}$ for all $i \in \mathbb{Z}^+$, then every element of the restricted direct product of the G_i's has finite order but $\prod_{i \in \mathbb{Z}^+} G_i$ has elements of infinite order. Show that in this example the restricted direct product is the torsion subgroup of the direct product (cf. Exercise 6, Section 2.1).

18. In each of (a) to (e) give an example of a group with the specified properties:

(a) an infinite group in which every element has order 1 or 2

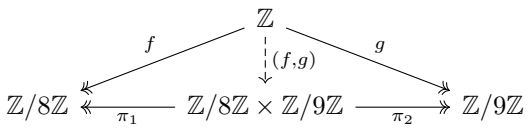
(b) an infinite group in which every element has finite order but for each positive integer n there is an element of order n

(c) a group with an element of infinite order and an element of order 2

(d) a group G such that every finite group is isomorphic to some subgroup of G

(e) a nontrivial group G such that $G \cong G \times G$.

Practice problems.



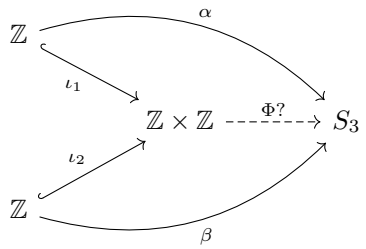
1. In $\mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ compute $|(6,2)|$ and $|(1,1)|$, and decide which is larger. Relate the larger value to the exponent of the group.
2. Find the order of $\big((1\,2\,3\,4),\,(1\,2\,3)\big)$ in $S_4 \times S_3$ (a 4-cycle paired with a 3-cycle).
3. What is the largest order of an element of $\mathbb{Z}/8\mathbb{Z} \times \mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/15\mathbb{Z}$? Exhibit one such element, and compare with $|\mathbb{Z}/8\mathbb{Z} \times \mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/15\mathbb{Z}|$.
4. Decide whether $\mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/15\mathbb{Z}$ is cyclic. If it is not, give its maximum element order and rewrite the group via the Chinese Remainder Theorem.
5. Show that $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/7\mathbb{Z}$ is cyclic, identify it as some $\mathbb{Z}/N\mathbb{Z}$, and give an explicit generator.
6. Count the elements of order 3 in $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$.
7. For $G = \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$ describe the projection π_1 and the injection ι_2. Give $\ker \pi_1$ and $\operatorname{im} \iota_2$ (up to isomorphism) and explain why the two injection images commute and generate G.
8. In a three-fold product $G_1 \times G_2 \times G_3$ write down the identity and the inverse of (g,h,k). Then, in $\mathbb{Z}/n\mathbb{Z} \times H$, compute $(a,b)(c,d)(a,b)^{-1}$ slot by slot, and explain why the two coordinates never interact.

Additional exercises.

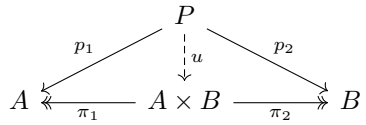
1. Let G_1, G_2 be groups. Prove directly that $G_1 \times \{1\} \trianglelefteq G_1 \times G_2$ and that $(G_1 \times G_2)/(G_1 \times \{1\}) \cong G_2$, by exhibiting $G_1 \times \{1\}$ as the kernel of the projection π_2 and applying the first isomorphism theorem.
2. Prove that the exponent of $\mathbb{Z}/m_1\mathbb{Z} \times \cdots \times \mathbb{Z}/m_k\mathbb{Z}$ equals $\operatorname{lcm}(m_1, \ldots, m_k)$ and that some element attains it. Deduce that the group is cyclic $\iff \operatorname{lcm}(m_1, \ldots, m_k) = m_1 \cdots m_k \iff$ the m_i are pairwise coprime.
3. Let A, B be groups, $a \in A$ of order m and $b \in B$ of order n. Show that $\langle (a,b) \rangle$ has order $\operatorname{lcm}(m,n)$, and that $\langle (a,b) \rangle = \langle a \rangle \times \langle b \rangle \iff \gcd(m,n) = 1$. (When $\gcd(m,n) > 1$, conclude $\langle (a,b) \rangle$ is a proper cyclic subgroup of $\langle a \rangle \times \langle b \rangle$.)
4. For finite groups G, H recall $|G \times H| = |G|\,|H|$. Fixing $p = 2$, verify that a Sylow 2-subgroup of $\mathbb{Z}/4\mathbb{Z} \times S_3$ has the form $P \times Q$ with $P \in \operatorname{Syl}_2(\mathbb{Z}/4\mathbb{Z})$, $Q \in \operatorname{Syl}_2(S_3)$, and compute $n_2(\mathbb{Z}/4\mathbb{Z} \times S_3) = n_2(\mathbb{Z}/4\mathbb{Z})\, n_2(S_3)$ as a concrete number.

Commutative-diagram exercises.

1. Use the universal property of the direct product to build the unique homomorphism $\varphi : \mathbb{Z} \to \mathbb{Z}/8\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$ from the two reduction maps, and compute $\ker \varphi$ and $\operatorname{im} \varphi$. Conclude that $\mathbb{Z}/72\mathbb{Z} \cong \mathbb{Z}/8\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$ (CRT).



2. **(Functoriality.)** For the reductions $f : \mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ and $g : \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$, describe the unique map $f \times g : \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ making both squares commute, and compute $\ker(f \times g) = \ker f \times \ker g$



explicitly (state its isomorphism type and order).

$$\begin{array}{ccccc} \mathbb{Z}/4\mathbb{Z} & \xleftarrow{\pi_1} & \mathbb{Z}/4\mathbb{Z}\times\mathbb{Z}/6\mathbb{Z} & \xrightarrow{\pi_2} & \mathbb{Z}/6\mathbb{Z} \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f\times g} & & \downarrow{\scriptstyle g} \\ \mathbb{Z}/2\mathbb{Z} & \xleftarrow[\pi_1']{} & \mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z} & \xrightarrow[\pi_2']{} & \mathbb{Z}/3\mathbb{Z} \end{array}$$

3. Show that the "co-universal" property *fails* for maps out of $\mathbb{Z}\times\mathbb{Z}$ into a nonabelian target. Taking $T = S_3$, exhibit homomorphisms $\alpha : \mathbb{Z} \to S_3$ with $\alpha(1) = (1\,2\,3)$ and $\beta : \mathbb{Z} \to S_3$ with $\beta(1) = (1\,2)$, and identify the precise obstruction that prevents any homomorphism $\Phi : \mathbb{Z}\times\mathbb{Z} \to S_3$ from restricting to α on the first factor and β on the second — even though the standard generators $(1,0)$ and $(0,1)$ commute in $\mathbb{Z}\times\mathbb{Z}$. State the general principle (which pairs α, β *do* extend to such a Φ).

4. Prove that the projections π_1, π_2 of $A\times B$ form the universal cone: if (P, p_1, p_2) satisfies the same universal property, then there is a unique isomorphism $u : P \to A\times B$ with $\pi_1 \circ u = p_1$ and $\pi_2 \circ u = p_2$. (Use the mediating maps $u : P \to A\times B$ and $v : A\times B \to P$ and the uniqueness clause to force $vu = \mathrm{id}_P$ and $uv = \mathrm{id}_{A\times B}$.)

5.2 The Fundamental Theorem of Finitely Generated Abelian Groups

The fundamental theorem of finitely generated abelian groups

This is the central classification theorem of Chapter 5: every finitely generated abelian group is, up to isomorphism, a direct sum of cyclic groups, and the decomposition is governed by a list of integers that is *unique*. D&F states the result in two equivalent packagings – the *invariant factor* form and the *elementary divisor* form – and the bridge between them is the Chinese Remainder Theorem.

Definition 5.2.1 (Free rank and finitely generated)**.** An abelian group G is *finitely generated* if there is a finite set $g_1, \ldots, g_s \in G$ with $G = \langle g_1, \ldots, g_s\rangle$. The group $\mathbb{Z}^r = \mathbb{Z}\times\cdots\times\mathbb{Z}$ (r copies) is the *free abelian group of rank r*; the integer r is its *free rank* (or *Betti number*).

Theorem 5.2.2 (Fundamental Theorem, invariant factor form)**.** *Let G be a finitely generated abelian group. Then*

$$G \cong \mathbb{Z}^r \times \mathbb{Z}/n_1\mathbb{Z} \times \mathbb{Z}/n_2\mathbb{Z} \times \cdots \times \mathbb{Z}/n_k\mathbb{Z}$$

for some integers $r \geq 0$ and $n_1, n_2, \ldots, n_k$ satisfying

$$n_i \geq 2 \quad \textit{for all } i, \qquad n_1 \mid n_2 \mid \cdots \mid n_k.$$

Moreover this expression is unique*: the free rank r and the list of* invariant factors *$n_1, \ldots, n_k$ are determined by G alone (any two such decompositions of isomorphic groups have the same r and the same list).*

Sketch. Existence. Pick a generating set of size s, giving a surjection $\mathbb{Z}^s \twoheadrightarrow G$. Its kernel K is a subgroup of the free abelian group $\mathbb{Z}^s$, hence (by the theory of finitely generated modules over the PID $\mathbb{Z}$, equivalently Smith normal form of an integer matrix) one may choose a basis $x_1, \dots, x_s$ of $\mathbb{Z}^s$ and integers $d_1 \mid d_2 \mid \cdots \mid d_t$ (the nonzero diagonal entries of the Smith normal form) so that $d_1 x_1, \dots, d_t x_t$ is a basis of K. Then

$$G \cong \mathbb{Z}^s/K \cong \mathbb{Z}/d_1\mathbb{Z} \times \cdots \times \mathbb{Z}/d_t\mathbb{Z} \times \mathbb{Z}^{s-t}.$$

Discarding the factors with $d_i = 1$ (which are trivial) and setting $r = s - t$ gives the stated form with n_i the surviving d_i, still satisfying $n_1 \mid \cdots \mid n_k$. The existence step is a short exact sequence: choosing the Smith bases makes $K \hookrightarrow \mathbb{Z}^s \twoheadrightarrow G$ diagonal.

$$\begin{array}{ccccccccc} 0 & \longrightarrow & K & \hookrightarrow & \mathbb{Z}^s & \twoheadrightarrow & G & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \sim} & & \\ 0 & \longrightarrow & \bigoplus_i d_i\mathbb{Z} & \hookrightarrow & \bigoplus_i \mathbb{Z} & \twoheadrightarrow & \bigoplus_i \mathbb{Z}/d_i\mathbb{Z} & \longrightarrow & 0 \end{array}$$

Diagram explanation. Objects: The top row contains three abelian groups: the kernel K (a subgroup of $\mathbb{Z}^s$, not yet identified concretely), the free abelian group $\mathbb{Z}^s$ (the group of s-tuples of integers), and the original finitely generated abelian group G (the quotient $\mathbb{Z}^s/K$). The bottom row contains their Smith-normal-form counterparts: $\bigoplus_i d_i\mathbb{Z}$ (the diagonal submodule of $\bigoplus_i \mathbb{Z}$, i.e. the subgroup of s-tuples whose i-th entry is a multiple of d_i), the standard free abelian group $\bigoplus_i \mathbb{Z} \cong \mathbb{Z}^s$ written in the Smith basis, and $\bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$ (a direct sum of cyclic groups, the explicit decomposition promised by the theorem). Each "0" is the trivial group serving as a bookend.

Arrows: The top horizontal arrows form the original exact sequence: the hooked arrow $K \hookrightarrow \mathbb{Z}^s$ is the set-theoretic inclusion of the kernel, and $\mathbb{Z}^s \twoheadrightarrow G$ is the canonical surjection $v \mapsto v + K$. The bottom horizontal arrows are the Smith-basis counterparts: $\bigoplus_i d_i\mathbb{Z} \hookrightarrow \bigoplus_i \mathbb{Z}$ is coordinatewise inclusion (multiples of d_i sit inside $\mathbb{Z}$), and $\bigoplus_i \mathbb{Z} \twoheadrightarrow \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$ is coordinatewise reduction mod d_i. The three vertical arrows are all isomorphisms: the left vertical identifies K with $\bigoplus_i d_i\mathbb{Z}$ via the Smith basis of K (it sends the i-th Smith basis vector $d_i x_i$ to the i-th standard multiple); the middle vertical is the change-of-basis isomorphism $\mathbb{Z}^s \xrightarrow{\sim} \bigoplus_i \mathbb{Z}$ sending Smith basis vector x_i to the i-th standard vector; the right vertical is the induced isomorphism $G \xrightarrow{\sim} \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$ that the diagram forces to exist.

What commutes: Two squares commute. Left square: inclusion-then-middle-vertical equals left-vertical-then-bottom-inclusion, i.e. $\phi_{\mathbb{Z}^s} \circ \iota_{\text{top}} = \iota_{\text{bot}} \circ \phi_K$. Right square: middle-vertical-then-bottom-quotient equals top-quotient-then-right-vertical, i.e. $\pi_{\text{bot}} \circ \phi_{\mathbb{Z}^s} = \phi_G \circ \pi_{\text{top}}$.

Why it commutes: Chase a generic element $v = \sum_i a_i x_i \in \mathbb{Z}^s$. Along top-then-right: $v \mapsto v + K \in G \mapsto (a_1 \bmod d_1, \dots, a_s \bmod d_s) \in \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$. Along middle-vertical-then-bottom: $v \mapsto (a_1, \dots, a_s) \in \bigoplus_i \mathbb{Z} \mapsto (a_1 \bmod d_1, \dots, a_s \bmod d_s)$. These agree. Well-definedness of the induced map $\phi_G \colon G \to \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$: if $v' = v + k$ for some $k \in K$, then $k = \sum_i b_i d_i x_i$, so the i-th coordinate of v' is $a_i + b_i d_i \equiv a_i \pmod{d_i}$. Different coset representatives give the same image precisely because $K = \operatorname{span}\{d_i x_i\}$ and the d_i are killed by reduction mod d_i.

Why this matters here: This diagram is the payoff of the existence step. The Smith normal form argument produces bases abstractly; the diagram makes the conclusion concrete: the mysterious short exact sequence $0 \to K \to \mathbb{Z}^s \to G \to 0$ is isomorphic (via three vertical isomorphisms) to the completely explicit diagonal sequence $0 \to \bigoplus d_i\mathbb{Z} \to \bigoplus \mathbb{Z} \to \bigoplus \mathbb{Z}/d_i\mathbb{Z} \to 0$. Reading off the right column yields $G \cong \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$, which is the invariant-factor decomposition the theorem claims.

Concrete example: Take $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ generated by two elements, so $s = 2$ and $K = \langle (2,0), (0,3) \rangle \subset \mathbb{Z}^2$. Smith normal form of the relation matrix $\begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}$ is *not* this diagonal matrix, since $2 \nmid 3$: it is $\begin{pmatrix} 1 & 0 \\ 0 & 6 \end{pmatrix}$ ($d_1 = \gcd(2,3) = 1$ and $d_1 d_2 = \det = 6$). Smith bases: $x_1 = (2,3)$, $x_2 = (1,2)$ is a basis of $\mathbb{Z}^2$ (determinant 1), and $1 \cdot x_1 = (2,3)$, $6x_2 = (6,12)$ is a basis of K, so the vertical maps are *not* identities. The bottom row reads $0 \to \mathbb{Z} \oplus 6\mathbb{Z} \to \mathbb{Z}^2 \to \mathbb{Z}/1\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \to 0$, and discarding $\mathbb{Z}/1\mathbb{Z} = 0$ gives $G \cong \mathbb{Z}/6\mathbb{Z}$, the single invariant factor 6 (as the CRT predicts, since $\gcd(2,3) = 1$).

Common pitfall: The right vertical isomorphism $G \xrightarrow{\sim} \bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$ is a map *from a quotient group* and requires the well-definedness check above – it is not automatic. A second pitfall: the factors with $d_i = 1$ contribute

trivial groups $\mathbb{Z}/1\mathbb{Z} = 0$ and must be discarded; including them gives the wrong invariant-factor list. Third: the diagram shows an *isomorphism* of exact sequences, not a splitting; do not read the horizontal arrows as splittings of G (unless $K = 0$).

Takeaway: The point of this diagram is that the Smith normal form bases produce three vertical isomorphisms that convert the abstract presentation $G = \mathbb{Z}^s/K$ into the explicit product $\bigoplus_i \mathbb{Z}/d_i\mathbb{Z}$, completing the existence half of the Fundamental Theorem.

Uniqueness. The free rank is recovered as $r = \dim_{\mathbb{Q}}(G \otimes_{\mathbb{Z}} \mathbb{Q})$, equivalently the rank of the maximal free quotient $G/(\text{torsion})$. For the torsion part one shows, prime by prime, that the numbers $\dim_{\mathbb{F}_p}\big((p^j G)[p]\big)$, $j \geq 0$ (where $A[p] = \{x \in A : px = 0\}$) determine, and are determined by, the multiset of invariant factors. Hence the list is an isomorphism invariant. □ □

Remark 5.2.1. G is *finite* $\iff$ $r = 0$. When $r = 0$ the order is $|G| = n_1 n_2 \cdots n_k$, and the largest invariant factor n_k equals the *exponent* of G (the lcm of all element orders). The factor $\mathbb{Z}^r$ is the *free part*; $\mathbb{Z}/n_1\mathbb{Z} \times \cdots \times \mathbb{Z}/n_k\mathbb{Z}$ is the *torsion part* (the torsion subgroup).

Theorem 5.2.3 (Fundamental Theorem, elementary divisor form)**.** *Let G be a finitely generated abelian group. Then*

$$G \cong \mathbb{Z}^r \times \mathbb{Z}/p_1^{a_1}\mathbb{Z} \times \mathbb{Z}/p_2^{a_2}\mathbb{Z} \times \cdots \times \mathbb{Z}/p_m^{a_m}\mathbb{Z},$$

where the p_i are primes (not necessarily distinct) and $a_i \geq 1$. The integer r and the multiset of prime powers $p_1^{a_1}, \ldots, p_m^{a_m}$ – the elementary divisors *of G – are uniquely determined by G.*

Sketch. Apply CRT (Theorem 5.1.9 / the ring isomorphism $\mathbb{Z}/ab\mathbb{Z} \cong \mathbb{Z}/a\mathbb{Z} \times \mathbb{Z}/b\mathbb{Z}$ when $\gcd(a, b) = 1$) to split each invariant factor $n_i = \prod_p p^{v_p(n_i)}$ into its prime-power pieces. This produces the elementary divisor form from the invariant factor form; uniqueness transfers because the two forms determine each other (see the conversion below). □ □

Proposition 5.2.4 (Equivalence via CRT)**.** *The two decompositions are equivalent and interconvertible:*

(a) ***Invariant → elementary.*** *Factor each invariant factor into prime powers; the resulting prime powers are the elementary divisors.*

(b) ***Elementary → invariant.*** *For each prime p occurring, list the p-power elementary divisors in one row with exponents* increasing *from left to right; align these rows flush-right; the product down each column (taking the p-power in that column, or 1 if absent) gives the invariant factors $n_1, \ldots, n_k$ from left to right, the rightmost column giving n_k. Equivalently: n_k is the product of the* largest *prime power for each prime, n_{k-1} the product of the next-largest, etc.*

Proof. Both directions are repeated application of $\mathbb{Z}/a\mathbb{Z} \times \mathbb{Z}/b\mathbb{Z} \cong \mathbb{Z}/ab\mathbb{Z}$ for $\gcd(a, b) = 1$ (CRT) and its converse. In (b), for fixed prime p the p-primary part is a fixed list of cyclic p-groups; distributing one such p-power into each invariant factor from the top down keeps the divisibility $n_1 \mid \cdots \mid n_k$ because within each prime the exponents are nonincreasing as we go from n_k to n_1. □ □

Method (Stating a group's two forms / converting between them)**.** *Trigger.* You are handed an abelian group as a product of cyclic groups, or asked for invariant factors / elementary divisors.

1. **To get elementary divisors:** split every cyclic factor $\mathbb{Z}/n\mathbb{Z}$ via CRT into $\mathbb{Z}/p^a\mathbb{Z}$ over the primes $p \mid n$. Collect all prime powers (with multiplicity).
2. **To get invariant factors:** group the elementary divisors by prime. For each prime p, write its powers in increasing order from left to right: $p^{e_1} \leq p^{e_2} \leq \cdots$ (pad shorter lists with 1's on the *left*). Form a table, one row per prime, right-justified. Multiply each column: rightmost column $\to n_k$ (largest), next $\to n_{k-1}$, ... The number of columns is $k = \max_p(\#\text{ of } p\text{-powers})$.
3. *Check.* $n_1 \mid n_2 \mid \cdots \mid n_k$, all $n_i \geq 2$, and $\prod n_i = \prod(\text{elem. divisors}) = |G_{\text{tors}}|$.

Method (Listing all abelian groups of order n)**.** *Trigger.* "How many / which abelian groups of order n?"

1. Factor $n = p_1^{a_1} p_2^{a_2} \cdots p_t^{a_t}$.

2. For each prime power $p_i^{a_i}$, the abelian groups of that order correspond bijectively to the *partitions* of the exponent a_i: a partition $a_i = b_1 + b_2 + \cdots$ gives $\mathbb{Z}/p_i^{b_1}\mathbb{Z} \times \mathbb{Z}/p_i^{b_2}\mathbb{Z} \times \cdots$.

3. Take all combinations (one partition per prime). The number of abelian groups of order n is $\prod_i P(a_i)$, where P is the partition function.

4. Each combination is the elementary divisor form; assemble invariant factors via the table method if requested.

The count depends only on the exponents a_i, not on the primes themselves.

Caution. The decomposition is unique only *after* imposing the side conditions. Invariant factors *require* $n_1 \mid n_2 \mid \cdots \mid n_k$ and each $n_i \geq 2$: $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ is a legal invariant-factor list ($2 \mid 6$) but $\mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ is not (wrong order), and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ is *not* in invariant-factor form because $2 \nmid 3$ – it equals the single invariant factor $\mathbb{Z}/6\mathbb{Z}$. Elementary divisors must be *prime powers*: $\mathbb{Z}/6\mathbb{Z}$ is not an elementary divisor; it splits as $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$.

Caution. $\mathbb{Z}/a\mathbb{Z} \times \mathbb{Z}/b\mathbb{Z} \cong \mathbb{Z}/ab\mathbb{Z}$ holds *iff* $\gcd(a, b) = 1$. So $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \ncong \mathbb{Z}/4\mathbb{Z}$ (the left has exponent 2, no element of order 4), but $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$. Always check coprimality before merging or splitting.

Worked Example 5.2.5 (All abelian groups of order 8)**.** List, up to isomorphism, every abelian group of order 8, in elementary divisor and invariant factor form.

Recognition. Order $8 = 2^3$ is a single prime power, so the groups correspond to the partitions of the exponent 3; this is the elementary-divisor method.

Solution. The partitions of 3 are $3 = 3$, $3 = 2 + 1$, $3 = 1 + 1 + 1$, so $P(3) = 3$ groups.

partition	elementary divisors	invariant factors
3	$\mathbb{Z}/8\mathbb{Z}$	$\mathbb{Z}/8\mathbb{Z}$
$2+1$	$\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$
$1+1+1$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$

For $2 + 1$: the 2-powers are $4, 2$; sorted decreasing $4 \geq 2$, only one prime so invariant factors are just these in increasing order $n_1 = 2 \mid n_2 = 4$. For $1 + 1 + 1$: powers $2, 2, 2$ give $n_1 = 2 \mid n_2 = 2 \mid n_3 = 2$.

Check. Orders multiply to 8 in each row (8; $4 \cdot 2$; $2 \cdot 2 \cdot 2$). The three are pairwise non-isomorphic by exponent / number of elements of order 2: $\mathbb{Z}/8\mathbb{Z}$ has one element of order 2; $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ has 3; $(\mathbb{Z}/2\mathbb{Z})^3$ has 7. So exactly 3 abelian groups of order 8.

Worked Example 5.2.6 (All abelian groups of order 360, both forms)**.** List all abelian groups of order 360 and give each in both forms.

Recognition. 360 is not a prime power; factor it, take partitions of each exponent, and combine. Then build invariant factors with the right-justified table.

Solution. $360 = 2^3 \cdot 3^2 \cdot 5$. Partitions: $P(3) = 3$ (for 2^3), $P(2) = 2$ (for 3^2), $P(1) = 1$ (for 5). Total $3 \cdot 2 \cdot 1 = 6$ groups.

The 2-part options: $\mathbb{Z}/8\mathbb{Z}$; $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$; $\mathbb{Z}/2\mathbb{Z}^3$. The 3-part options: $\mathbb{Z}/9\mathbb{Z}$; $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. The 5-part: $\mathbb{Z}/5\mathbb{Z}$ only.

To turn each combination into invariant factors, right-justify the prime rows and read columns. For example, take 2-part $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, 3-part $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, 5-part $\mathbb{Z}/5\mathbb{Z}$:

	col n_1	col n_2
$p = 2$	2	4
$p = 3$	3	3
$p = 5$	1	5
product	6	60

$\Rightarrow \qquad n_1 = 6 \mid n_2 = 60, \quad 6 \cdot 60 = 360.$

Doing this for all six:

elementary divisors	invariant factors
$\mathbb{Z}/8\mathbb{Z}, \mathbb{Z}/9\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/360\mathbb{Z}$
$\mathbb{Z}/8\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/120\mathbb{Z}$
$\mathbb{Z}/4\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/9\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/180\mathbb{Z}$
$\mathbb{Z}/4\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/60\mathbb{Z}$
$\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/9\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/90\mathbb{Z}$
$\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/30\mathbb{Z}$

Check (one nontrivial row). Last row: 5-part has one 5, 3-part $3, 3$, 2-part $2, 2, 2$. Three columns ($k = 3$, since the 2-prime contributes 3 powers). Right-justified products: $n_3 = 2 \cdot 3 \cdot 5 = 30$, $n_2 = 2 \cdot 3 \cdot 1 = 6$, $n_1 = 2 \cdot 1 \cdot 1 = 2$. Indeed $2 \mid 6 \mid 30$ and $2 \cdot 6 \cdot 30 = 360$. All six product to 360 and are distinct, so there are exactly 6 abelian groups of order 360.

Worked Example 5.2.7 (Convert elementary divisors to invariant factors)**.** Write $\mathbb{Z}/4\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/9\mathbb{Z}\times\mathbb{Z}/3\mathbb{Z}$ in invariant factor form.

Recognition. Given elementary divisors (prime powers $4, 2$ at $p = 2$; $9, 3$ at $p = 3$), use the right-justified table; one column per invariant factor.

Solution. Sort each prime's powers in increasing order:

$$p = 2 : \ 2,\ 4; \qquad p = 3 : \ 3,\ 9.$$

Each prime contributes two powers, so $k = 2$ invariant factors. Right-justify and multiply columns:

	col n_1	col n_2
$p = 2$	2	4
$p = 3$	3	9
product	6	36

$\Rightarrow \qquad \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/36\mathbb{Z}.$

Check. $6 \mid 36$ (yes), both ≥ 2, and $6 \cdot 36 = 216$. Original order $4 \cdot 2 \cdot 9 \cdot 3 = 8 \cdot 27 = 216$. Match. So $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/36\mathbb{Z}$.

Worked Example 5.2.8 (Number of abelian groups of order p^4)**.** For a prime p, how many abelian groups have order p^4? List them.

Recognition. Single prime power p^4, so the count is $P(4)$, the number of partitions of 4; each partition is an elementary-divisor list.

Solution. The partitions of 4 are

$$4, \quad 3+1, \quad 2+2, \quad 2+1+1, \quad 1+1+1+1,$$

so $P(4) = 5$ abelian groups:

$$\mathbb{Z}/p^4\mathbb{Z}, \ \ \mathbb{Z}/p^3\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}, \ \ \mathbb{Z}/p^2\mathbb{Z} \times \mathbb{Z}/p^2\mathbb{Z}, \ \ \mathbb{Z}/p^2\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}, \ \ \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}.$$

For one prime, the elementary divisors *are* the invariant factors written in increasing order (e.g. $2 + 1 + 1$ gives invariant factors $\mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p^2\mathbb{Z}$). *Check.* Each product of orders is p^4 (e.g. $p^2 \cdot p \cdot p = p^4$). The answer is the same for *every* prime p because the count depends only on the exponent 4: there are exactly 5 abelian groups of order p^4 (so 5 of order 16, 5 of order 81, etc.).

Worked Example 5.2.9 (Which abelian groups of order 100 are cyclic)**.** List the abelian groups of order 100 and determine which are cyclic.

Recognition. $100 = 2^2 \cdot 5^2$; combine partitions of the two exponents. A finite abelian group is cyclic iff its invariant-factor list has length 1 – equivalently iff it has exactly one elementary divisor for each prime (those distinct-prime powers are then automatically coprime and CRT-merge to a single cyclic factor).

Solution. $100 = 2^2 \cdot 5^2$, $P(2) = 2$ for each exponent, so $2 \cdot 2 = 4$ groups. The 2-parts are $\mathbb{Z}/4\mathbb{Z}$ or $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$; the 5-parts are $\mathbb{Z}/25\mathbb{Z}$ or $\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$:

elementary divisors	invariant factors	cyclic?
$\mathbb{Z}/4\mathbb{Z}, \mathbb{Z}/25\mathbb{Z}$	$\mathbb{Z}/100\mathbb{Z}$	yes
$\mathbb{Z}/4\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/20\mathbb{Z}$	no
$\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/25\mathbb{Z}$	$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/50\mathbb{Z}$	no
$\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}$	$\mathbb{Z}/10\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z}$	no

A group is cyclic $\iff$ it has a single invariant factor $\iff$ for each prime there is exactly one prime-power elementary divisor (so they are automatically coprime across primes and CRT-merge to one cyclic factor). Only the first row qualifies: $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/25\mathbb{Z} \cong \mathbb{Z}/100\mathbb{Z}$ since $\gcd(4, 25) = 1$. *Check (one "no").* Last row $\mathbb{Z}/10\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z}$: exponent is $\operatorname{lcm}(10, 10) = 10 < 100$, so no element of order 100, not cyclic. Order $10 \cdot 10 = 100$. So exactly 1 of the 4 abelian groups of order 100 is cyclic, namely $\mathbb{Z}/100\mathbb{Z}$.

Worked Example 5.2.10 (Recognizing a group given in mixed form)**.** Identify the invariant factors and elementary divisors of $G = \mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/18\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$, and state $|G|$ and the exponent.

Recognition. Factors are not all prime powers, so first split each $\mathbb{Z}/n\mathbb{Z}$ via CRT into elementary divisors, then rebuild invariant factors.

Solution. Split: $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, $\mathbb{Z}/18\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$, $\mathbb{Z}/5\mathbb{Z} = \mathbb{Z}/5\mathbb{Z}$. Collect elementary divisors by prime:

$$p = 2 : \ 4,\ 2; \qquad p = 3 : \ 9,\ 3; \qquad p = 5 : \ 5.$$

Two columns ($k = 2$, the max count over primes is 2). Right-justify:

	n_1	n_2
$p = 2$	2	4
$p = 3$	3	9
$p = 5$	1	5
product	6	180

$\Rightarrow \quad G \cong \mathbb{Z}/6\mathbb{Z} \times \mathbb{Z}/180\mathbb{Z}.$

Check. $6 \mid 180$, $6 \cdot 180 = 1080$. Direct order: $12 \cdot 18 \cdot 5 = 1080$. Match. The exponent is the largest invariant factor $n_2 = 180 = \operatorname{lcm}(12, 18, 5)$. So $|G| = 1080$, exponent 180, elementary divisors $\{4, 2, 9, 3, 5\}$, invariant factors $6 \mid 180$.

Remark 5.2.2 (Why both forms are useful)*.* Elementary divisors are best for *counting* and for working "one prime at a time" (each Sylow piece is independent). Invariant factors give the *shortest* canonical name and read off the exponent (n_k) and whether G is cyclic ($k = 1$) at a glance. The CRT table converts freely between them, so a finite abelian group has a single, unambiguous fingerprint either way.

Exercises (from the text).

1. In each of parts (a) to (e) give the number of nonisomorphic abelian groups of the specified order — do not list the groups: (a) order 100, (b) order 576, (c) order 1155, (d) order 42875, (e) order 2704.
2. In each of parts (a) to (e) give the lists of invariant factors for all abelian groups of the specified order: (a) order 270, (b) order 9801, (c) order 320, (d) order 105, (e) order 44100.
3. In each of parts (a) to (e) give the lists of elementary divisors for all abelian groups of the specified order and then match each list with the corresponding list of invariant factors found in the preceding exercise: (a) order 270, (b) order 9801, (c) order 320, (d) order 105, (e) order 44100.
4. In each of parts (a) to (d) determine which pairs of abelian groups listed are isomorphic (here the expression $\{a_1, a_2, \ldots, a_k\}$ denotes the abelian group $\mathbb{Z}_{a_1} \times \mathbb{Z}_{a_2} \times \cdots \times \mathbb{Z}_{a_k}$). (a) $\{4, 9\}$, $\{6, 6\}$, $\{8, 3\}$, $\{9, 4\}$, $\{6, 4\}$, $\{64\}$. (b) $\{2^2, 2 \cdot 3^2\}$, $\{2^2 \cdot 3, 2 \cdot 3\}$, $\{2^3 \cdot 3^2\}$, $\{2^2 \cdot 3^2, 2\}$. (c) $\{5^2 \cdot 7^2, 3^2 \cdot 5 \cdot 7\}$, $\{3^2 \cdot 5^2 \cdot 7, 5 \cdot 7^2\}$, $\{3 \cdot 5^2, 7^2, 3 \cdot 5 \cdot 7\}$, $\{5^2 \cdot 7, 3^2 \cdot 5, 7^2\}$. (d) $\{2^2 \cdot 5 \cdot 7, 2^3 \cdot 5^3, 2 \cdot 5^2\}$, $\{2^3 \cdot 5^3 \cdot 7, 2^3 \cdot 5^3\}$, $\{2^2, 2 \cdot 7, 2^3, 5^3, 5^3\}$, $\{2 \cdot 5^3, 2^2 \cdot 5^3, 2^3, 7\}$.

5. Let G be a finite abelian group of type $(n_1, n_2, \ldots, n_t)$, i.e. with invariant factors listed in D&F's *decreasing* order $n_t \mid n_{t-1} \mid \cdots \mid n_1$ (the reverse of the convention $n_1 \mid \cdots \mid n_k$ used in this chapter). Prove that G contains an element of order m if and only if $m \mid n_1$. Deduce that G is of exponent n_1.

6. Prove that any finite group has a finite exponent. Give an example of an infinite group with finite exponent. Does a finite group of exponent m always contain an element of order m?

7. Let p be a prime and let $A = \langle x_1 \rangle \times \langle x_2 \rangle \times \cdots \times \langle x_n \rangle$ be an abelian p-group, where $|x_i| = p^{\alpha_i} > 1$ for all i. Define the pth-power map
$$\varphi : A \to A \quad \text{by} \quad \varphi : x \mapsto x^p.$$
(a) Prove that φ is a homomorphism. (b) Describe the image and kernel of φ in terms of the given generators. (c) Prove both $\ker \varphi$ and $A/\operatorname{im} \varphi$ have rank n (i.e., have the same rank as A) and prove these groups are both isomorphic to the elementary abelian group, E_{p^n}, of order p^n.

8. Let A be a finite abelian group (written multiplicatively) and let p be a prime. Let
$$A^p = \{a^p \mid a \in A\} \quad \text{and} \quad A_p = \{x \mid x^p = 1\}$$
(so A^p and A_p are the image and kernel of the pth-power map, respectively). (a) Prove that $A/A^p \cong A_p$. [Show that they are both elementary abelian and they have the same order.] (b) Prove that the number of subgroups of A of order p equals the number of subgroups of A of index p. [Reduce to the case where A is an elementary abelian p-group.]

9. Let $A = \mathbb{Z}_{60} \times \mathbb{Z}_{45} \times \mathbb{Z}_{12} \times \mathbb{Z}_{36}$. Find the number of elements of order 2 and the number of subgroups of index 2 in A.

10. Let n and k be positive integers and let A be the free abelian group of rank n (written additively). Prove that A/kA is isomorphic to the direct product of n copies of $\mathbb{Z}/k\mathbb{Z}$ (here $kA = \{ka \mid a \in A\}$). [See Exercise 14, Section 5.1.]

11. Let G be a nontrivial finite abelian group of rank t. (a) Prove that the rank of G equals the maximum of the ranks of its Sylow subgroups. (b) Prove that G can be generated by t elements but no subset with fewer than t elements generates G. [One way of doing this is by using part (a) together with Exercise 7.]

12. Let n and m be positive integers with $d = (n, m)$. Let $Z_n = \langle x \rangle$ and $Z_m = \langle y \rangle$. Let A be the central product of $\langle x \rangle$ and $\langle y \rangle$ with an element of order d identified, which has presentation $\langle x, y \mid x^n = y^m = 1,\ xy = yx,\ x^{n/d} = y^{m/d} \rangle$. Describe A as a direct product of two cyclic groups.

13. Let $A = \langle x_1 \rangle \times \cdots \times \langle x_r \rangle$ be a finite abelian group with $|x_i| = n_i$ for $1 \le i \le r$. Find a presentation for A. Prove that if G is any group containing commuting elements $g_1, \ldots, g_r$ such that $g_i^{n_i} = 1$ for $1 \le i \le r$, then there is a unique homomorphism from A to G which sends x_i to g_i for all i.

Practice problems.

1. List all abelian groups of order $200 = 2^3 \cdot 5^2$ in both elementary-divisor and invariant-factor form, and state how many there are.

   Answer. The count is $p(3) \cdot p(2) = 3 \cdot 2 = 6$, where $p(\cdot)$ is the partition function. Pairing elementary divisors (ED) with invariant factors (IF):

   $$\begin{array}{lll} \{8, 25\} & \to & \mathbb{Z}_{200}; \qquad \{8, 5, 5\} \to \mathbb{Z}_5 \times \mathbb{Z}_{40}; \\ \{4, 2, 25\} & \to & \mathbb{Z}_2 \times \mathbb{Z}_{100}; \qquad \{4, 2, 5, 5\} \to \mathbb{Z}_{10} \times \mathbb{Z}_{20}; \\ \{2, 2, 2, 25\} & \to & \mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_{50}; \quad \{2, 2, 2, 5, 5\} \to \mathbb{Z}_2 \times \mathbb{Z}_{10} \times \mathbb{Z}_{10}. \end{array}$$

2. List all abelian groups of order p^5 (p prime) in invariant-factor form, and state how many there are.

   Answer. There are $p(5) = 7$, one for each partition of 5. With invariant factors written in increasing order:

   $$\begin{array}{ll} 5: \ \mathbb{Z}_{p^5}; & 4{+}1: \ \mathbb{Z}_p \times \mathbb{Z}_{p^4}; \\ 3{+}2: \ \mathbb{Z}_{p^2} \times \mathbb{Z}_{p^3}; & 3{+}1{+}1: \ \mathbb{Z}_p \times \mathbb{Z}_p \times \mathbb{Z}_{p^3}; \\ 2{+}2{+}1: \ \mathbb{Z}_p \times \mathbb{Z}_{p^2} \times \mathbb{Z}_{p^2}; & 2{+}1{+}1{+}1: \ \mathbb{Z}_p \times \mathbb{Z}_p \times \mathbb{Z}_p \times \mathbb{Z}_{p^2}; \\ 1{+}1{+}1{+}1{+}1: \ (\mathbb{Z}_p)^5. & \end{array}$$

3. Convert the elementary divisors $\{2, 2, 8, 9, 3, 5\}$ to invariant factors.

   Answer. Group by prime: $p = 2$ gives $8, 2, 2$; $p = 3$ gives $9, 3$; $p = 5$ gives 5. The longest list has $k = 3$ entries, so arrange three columns aligned at the largest power:

	largest		smallest
2	8	2	2
3	9	3	1
5	5	1	1

   Column products give $n_3 = 8 \cdot 9 \cdot 5 = 360$, $n_2 = 2 \cdot 3 \cdot 1 = 6$, $n_1 = 2 \cdot 1 \cdot 1 = 2$, with $2 \mid 6 \mid 360$. Hence $G \cong \mathbb{Z}_2 \times \mathbb{Z}_6 \times \mathbb{Z}_{360}$ (order $4320 = 2^3 \cdot 3^2 \cdot 2^2 \cdot 3 \cdot 5$).

4. Convert the invariant factors of $\mathbb{Z}_2 \times \mathbb{Z}_6 \times \mathbb{Z}_{30}$ to elementary divisors.

   Answer. Factor each invariant factor into prime powers: $2 = 2$; $6 = 2 \cdot 3$; $30 = 2 \cdot 3 \cdot 5$. Collecting prime powers gives elementary divisors $\{2, 2, 2,\ 3, 3,\ 5\}$ (three 2's, two 3's, one 5). Check: the product is $2^3 \cdot 3^2 \cdot 5 = 360 = 2 \cdot 6 \cdot 30$.

5. Are $\mathbb{Z}_{12} \times \mathbb{Z}_{90}$ and $\mathbb{Z}_6 \times \mathbb{Z}_{180}$ isomorphic? Decide by comparing invariant factors.

   Answer. For $\mathbb{Z}_{12} \times \mathbb{Z}_{90}$: $12 = 2^2 \cdot 3$, $90 = 2 \cdot 3^2 \cdot 5$, so the elementary divisors are $p = 2 : \{4, 2\}$, $p = 3 : \{9, 3\}$, $p = 5 : \{5\}$. Aligning into $k = 2$ columns gives $n_2 = 4 \cdot 9 \cdot 5 = 180$ and $n_1 = 2 \cdot 3 = 6$, i.e. invariant factors $6 \mid 180$. For $\mathbb{Z}_6 \times \mathbb{Z}_{180}$: $6 = 2 \cdot 3$, $180 = 2^2 \cdot 3^2 \cdot 5$ yield exactly the same elementary divisors, hence the same invariant factors $6 \mid 180$. So $\mathbb{Z}_{12} \times \mathbb{Z}_{90} \cong \mathbb{Z}_6 \times \mathbb{Z}_{180}$, both of order 1080.

6. How many abelian groups of order $2^4 \cdot 3^4$ are there? More generally, for $n = p_1^{a_1} \cdots p_t^{a_t}$?

   Answer. For $2^4 \cdot 3^4$ the count is $p(4) \cdot p(4) = 5 \cdot 5 = 25$. In general the number of isomorphism types of abelian groups of order n is

$$\prod_{i=1}^{t} p(a_i),$$

   the product of the partition numbers of the exponents; it depends only on the multiset of exponents, not on the primes themselves.

7. Find the invariant factors of $\mathbb{Z}_{36} \times \mathbb{Z}_{40} \times \mathbb{Z}_{75}$, and state $|G|$ and the exponent of G.

   Answer. Elementary divisors: $36 = 4 \cdot 9$, $40 = 8 \cdot 5$, $75 = 3 \cdot 25$, so $p = 2 : \{8, 4\}$, $p = 3 : \{9, 3\}$, $p = 5 : \{25, 5\}$. Here $k = 2$, and aligning at the largest powers gives

$$n_2 = 8 \cdot 9 \cdot 25 = 1800, \qquad n_1 = 4 \cdot 3 \cdot 5 = 60,$$

   with $60 \mid 1800$. Thus $G \cong \mathbb{Z}_{60} \times \mathbb{Z}_{1800}$, $|G| = 60 \cdot 1800 = 108000$, and the exponent is $n_2 = 1800 = \operatorname{lcm}(36, 40, 75)$.

8. Which abelian groups of order 36 are cyclic? List all of them and identify the cyclic one.

   Answer. Since $36 = 2^2 \cdot 3^2$, there are $p(2) \cdot p(2) = 4$ groups:

$$\{4, 9\} \to \mathbb{Z}_{36}, \quad \{4, 3, 3\} \to \mathbb{Z}_3 \times \mathbb{Z}_{12}, \quad \{2, 2, 9\} \to \mathbb{Z}_2 \times \mathbb{Z}_{18}, \quad \{2, 2, 3, 3\} \to \mathbb{Z}_6 \times \mathbb{Z}_6.$$

   A finite abelian group is cyclic iff it has at most one elementary divisor per prime (equivalently, a single invariant factor). Only $\{4, 9\}$ satisfies this, so $\mathbb{Z}_{36}$ is the unique cyclic one.

9. Give the invariant-factor form of $A \times B$, where $A = \mathbb{Z}_8 \times \mathbb{Z}_4$ and $B = \mathbb{Z}_9 \times \mathbb{Z}_9$.

   Answer. The elementary divisors of $A \times B$ are $p = 2 : \{8, 4\}$ and $p = 3 : \{9, 9\}$, so $k = 2$ and

$$n_2 = 8 \cdot 9 = 72, \qquad n_1 = 4 \cdot 9 = 36,$$

   with $36 \mid 72$. Hence $A \times B \cong \mathbb{Z}_{36} \times \mathbb{Z}_{72}$, of order 2592.

Additional exercises.

1. Let G be a nontrivial finite abelian group with invariant factors $n_1 \mid n_2 \mid \cdots \mid n_k$. Prove that G is cyclic if and only if $|G|$ equals the exponent of G (the largest invariant factor n_k), and use this to decide whether $\mathbb{Z}_4 \times \mathbb{Z}_6$ is cyclic.

   Answer. Since $G \cong \mathbb{Z}_{n_1} \times \cdots \times \mathbb{Z}_{n_k}$ with each $n_i \geq 2$, we have $|G| = n_1 n_2 \cdots n_k$, while the exponent equals n_k (the lcm of all element orders, attained in the last factor). If G is cyclic then $k = 1$, so $|G| = n_1 = n_k$. Conversely, if $|G| = n_k$ then $n_1 \cdots n_{k-1} = 1$; as every $n_i \geq 2$ this forces $k = 1$, so $G \cong \mathbb{Z}_{n_k}$ is cyclic. For $\mathbb{Z}_4 \times \mathbb{Z}_6$: this is not in invariant-factor form, but $|G| = 24$ while the exponent is $\operatorname{lcm}(4, 6) = 12 \neq 24$, so G is *not* cyclic. (Indeed $\mathbb{Z}_4 \times \mathbb{Z}_6 \cong \mathbb{Z}_2 \times \mathbb{Z}_{12}$, two invariant factors.)

2. Let G be a finite abelian p-group whose elementary divisors are $p^{a_1}, \ldots, p^{a_k}$ (so k of them). Show that the number of subgroups of G of order p equals $\dfrac{p^k - 1}{p - 1}$.

   Answer. Let $G[p] = \{x \in G : px = 0\}$. In each cyclic factor $\mathbb{Z}_{p^{a_i}}$ the solutions of $px = 0$ form the unique subgroup of order p, so $G[p] \cong (\mathbb{Z}_p)^k$ is elementary abelian of rank k; it is an $\mathbb{F}_p$-vector space of dimension k. Every subgroup of order p lies in $G[p]$ and is a 1-dimensional subspace, i.e. a line through the origin. The number of lines in $\mathbb{F}_p^k$ is $\dfrac{p^k - 1}{p - 1}$ (count nonzero vectors, then identify the $p-1$ nonzero scalar multiples of each).

3. Let G be a finite abelian group and let $d \mid |G|$. Prove that G has a subgroup of order d, and that such a subgroup is unique for every divisor d of $|G|$ if and only if G is cyclic.

   Answer. Existence. Decompose $G \cong \prod_p G_p$ into primary components. Writing $d = \prod_p p^{b_p}$ with $p^{b_p} \mid |G_p|$, it suffices to find a subgroup of order p^{b_p} in each G_p and take the product. Each G_p is a direct sum of cyclic p-groups $\mathbb{Z}_{p^{a_1}} \times \cdots \times \mathbb{Z}_{p^{a_r}}$ with $a_1 \leq \cdots \leq a_r$; greedily fill the exponent b_p using the subgroups of orders $1, p, \ldots, p^{a_j}$ inside successive factors. This produces a subgroup of order d.

   Uniqueness. If G is cyclic then for each $d \mid |G|$ there is exactly one subgroup of order d, generated by $\frac{|G|}{d}$ times a generator. Conversely, if some primary part G_p is non-cyclic it contains a copy of $\mathbb{Z}_p \times \mathbb{Z}_p$, which has $p + 1 > 1$ subgroups of order p; this gives at least two subgroups of order p, so uniqueness fails for $d = p$. Hence uniqueness for all d forces every G_p cyclic, i.e. G cyclic.

4. For a finite abelian group G with invariant factors $n_1 \mid \cdots \mid n_k$ and a positive integer m, let $G[m] = \{x \in G : mx = 0\}$. Prove

$$|G[m]| = \prod_{i=1}^{k} \gcd(m, n_i),$$

   and evaluate it for $G = \mathbb{Z}_6 \times \mathbb{Z}_{12}$ with $m = 4$.

   Answer. With $G \cong \prod_i \mathbb{Z}_{n_i}$, an element $x = (x_i)$ satisfies $mx = 0$ iff $mx_i = 0$ in $\mathbb{Z}_{n_i}$ for each i. In $\mathbb{Z}_{n_i}$ the equation $mx_i = 0$ has exactly $\gcd(m, n_i)$ solutions (the unique subgroup of that order). Since the coordinates are independent, $|G[m]| = \prod_i \gcd(m, n_i)$. For $G = \mathbb{Z}_6 \times \mathbb{Z}_{12}$ and $m = 4$:

$$|G[4]| = \gcd(4, 6) \cdot \gcd(4, 12) = 2 \cdot 4 = 8.$$

Commutative-diagram exercises.

1. Realize the structure theorem for $G = \mathbb{Z}_4 \times \mathbb{Z}_6$ as a short exact sequence

$$0 \longrightarrow \mathbb{Z}^2 \xrightarrow{A} \mathbb{Z}^2 \longrightarrow G \longrightarrow 0,$$

   by writing down the relation matrix and computing its Smith normal form; read off the invariant factors.

   Answer. Generators e_1, e_2 with relations $4e_1 = 0$, $6e_2 = 0$ give the relation (presentation) matrix $A_0 = \operatorname{diag}(4, 6)$, so $G \cong \mathbb{Z}^2 / A_0 \mathbb{Z}^2$. Row/column operations over $\mathbb{Z}$ reduce A_0 to its Smith normal form

$$A = \operatorname{diag}(2, 12), \qquad \det A = 24 = \det A_0, \quad d_1 = \gcd(4, 6) = 2,$$

since the first invariant factor is the gcd of the entries and the product of the two is the determinant. Hence $G \cong \mathbb{Z}_2 \times \mathbb{Z}_{12}$, invariant factors $2 \mid 12$. The sequence

$$0 \longrightarrow \mathbb{Z}^2 \xhookrightarrow{A} \mathbb{Z}^2 \twoheadrightarrow G \longrightarrow 0$$

is exact with A in diagonal Smith normal form.

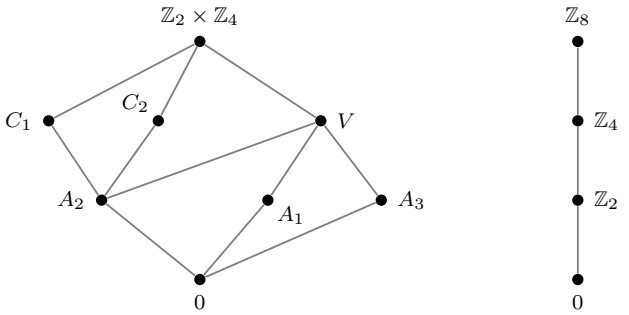
2. (Naturality of primary decomposition.) For a prime p and a finite abelian group G, let G_p be its p-primary part (elements of p-power order). Show that every homomorphism $f : G \to H$ of finite abelian groups satisfies $f(G_p) \le H_p$, so the squares below commute and primary decomposition is functorial.

   Answer. If $x \in G_p$ then $p^a x = 0$ for some a, so $p^a f(x) = f(p^a x) = 0$ and $|f(x)|$ is a power of p; thus $f(x) \in H_p$, i.e. $f(G_p) \le H_p$. Writing $f_p := f|_{G_p} : G_p \to H_p$ and letting π_p^G, π_p^H denote projections onto the p-primary parts, the diagram

$$\begin{array}{ccc} G & \xrightarrow{f} & H \\ {\scriptstyle \pi_p^G}\downarrow & & \downarrow{\scriptstyle \pi_p^H} \\ G_p & \xrightarrow[f_p]{} & H_p \end{array}$$

   commutes for every p. Hence $G \cong \prod_p G_p$ is natural in G (the CRT/primary decomposition is a functor), since f is determined by its components f_p.

3. (The p-th power sequence.) For a finite abelian p-group A, draw and verify exactness of



$$0 \longrightarrow A[p] \longhookrightarrow A \xrightarrow{p\cdot} A \twoheadrightarrow A/pA \longrightarrow 0,$$

   where $p\cdot$ is multiplication by p, and show $A[p] \cong A/pA$ as $\mathbb{F}_p$-vector spaces of equal rank.

   Answer. Multiplication-by-p has kernel $A[p] = \{x : px = 0\}$ and image pA, so the inclusion $A[p] \hookrightarrow A$, the map $p\cdot$, and the quotient $A \twoheadrightarrow A/pA$ form an exact sequence: exactness at the first A is $\ker(p\cdot) = A[p]$, and at the second A is $\mathrm{im}(p\cdot) = pA = \ker(A \to A/pA)$. If $A \cong \mathbb{Z}_{p^{a_1}} \times \cdots \times \mathbb{Z}_{p^{a_k}}$ with all $a_i \ge 1$, then both $A[p]$ and A/pA pick up exactly one factor of $\mathbb{Z}_p$ from each cyclic summand, so each is elementary abelian of rank $k =$ (number of elementary divisors of A). Being $\mathbb{F}_p$-spaces of equal dimension k, they are isomorphic: $A[p] \cong (\mathbb{Z}_p)^k \cong A/pA$.

4. (Lattice comparison.) Draw the subgroup lattice of $\mathbb{Z}_2 \times \mathbb{Z}_4$ and of $\mathbb{Z}_8$, mark the atoms (subgroups of order 2), and explain how the lattice shape reflects the invariant factors $2 \mid 4$ versus the single factor 8.

   Answer. In $\mathbb{Z}_2 \times \mathbb{Z}_4$ the 2-torsion is $(\mathbb{Z}_2 \times \mathbb{Z}_4)[2] \cong (\mathbb{Z}_2)^2$, which has $\frac{2^2-1}{2-1} = 3$ subgroups of order 2 (three atoms), and the maximal cyclic subgroup $\mathbb{Z}_4$ is *not* unique. In $\mathbb{Z}_8$ the 2-torsion is just $\mathbb{Z}_2$, so there is a single atom and a unique chain. In the lattice of $\mathbb{Z}_2 \times \mathbb{Z}_4$ below, $A_1 = \langle(1,0)\rangle$, $A_2 = \langle(0,2)\rangle$, $A_3 = \langle(1,2)\rangle$ are the atoms and $C_1 = \langle(0,1)\rangle \cong \mathbb{Z}_4$, $C_2 = \langle(1,1)\rangle \cong \mathbb{Z}_4$, $V = \langle(1,0),(0,2)\rangle \cong (\mathbb{Z}_2)^2$ are the subgroups of order 4; A_2 lies in all three, while A_1 and A_3 lie only in V:

   (here A_1, A_2, A_3 are the three order-2 subgroups). The three atoms versus one atom distinguish the two abelian groups of order 8: rank 2 (invariant factors $2 \mid 4$) gives a wide lattice with $(p^2-1)/(p-1) = 3$ atoms, while rank 1 (single invariant factor 8) gives the single chain $0 < \mathbb{Z}_2 < \mathbb{Z}_4 < \mathbb{Z}_8$.

5.3 Groups of Small Order

Classification of groups of small order

Section 5.3 is mostly a *reference*: it assembles the tools developed so far (Lagrange, Cauchy, the Sylow theorems, direct and semidirect products, recognition of $\rtimes$) into a single census. The goal is, for each small order n, to list *every* isomorphism class of group of order n and to explain how to tell them apart. We keep the theory terse and let worked classifications carry the load.

Remark 5.3.1 (The number of groups of each order up to 16). Let $g(n)$ denote the number of isomorphism classes of groups of order n.

n	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
$g(n)$	1	1	1	2	1	2	1	5	2	2	1	5	1	2	1	14

Every entry with $n \le 15$ is derived below. The jump to $g(16) = 14$ signals where hand-classification stops being pleasant; orders that are products of small primes (especially powers of 2) proliferate. Note $g(p) = 1$, $g(p^2) = 2$, and (for $p < q$ primes) $g(pq) \in \{1, 2\}$.

Remark 5.3.2 (The toolkit). Three facts do almost all the work.

1. **Lagrange / Cauchy.** If $p \mid |G|$ then G has an element (hence a subgroup) of order p.
2. **Sylow.** $n_p \equiv 1 \pmod p$ and $n_p \mid m$ where $|G| = p^a m$, $p \nmid m$. If some $n_p = 1$ the corresponding Sylow subgroup is normal.
3. **Recognition of (semi)direct products.** If $H \trianglelefteq G$, $K \le G$, $H \cap K = 1$, and $HK = G$ (e.g. $|H||K| = |G|$ with $H \cap K = 1$), then $G \cong H \rtimes_\varphi K$ where $\varphi\colon K \to \mathrm{Aut}(H)$ is conjugation. If *both* $H, K \trianglelefteq G$ the product is direct: $G \cong H \times K$.

Order p, p^2, and pq

Theorem 5.3.1 (Order p). *If $|G| = p$ is prime then $G \cong \mathbb{Z}/p\mathbb{Z}$.*

Proof. Pick $x \neq 1$. By Lagrange $|x| \mid p$ and $|x| \neq 1$, so $|x| = p$ and $G = \langle x \rangle \cong \mathbb{Z}/p\mathbb{Z}$. □

Theorem 5.3.2 (Order p^2). *If $|G| = p^2$ then G is abelian, and either $G \cong \mathbb{Z}/p^2\mathbb{Z}$ or $G \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$.*

Proof. A p-group has nontrivial center, so $|Z(G)| \in \{p, p^2\}$. If $|Z(G)| = p$ then $G/Z(G)$ is cyclic of order p, forcing G abelian and hence $Z(G) = G$, a contradiction. So G is abelian. If G has an element of order p^2 it is cyclic, $G \cong \mathbb{Z}/p^2\mathbb{Z}$. Otherwise every non-identity element has order p; pick $x \neq 1$ and $y \notin \langle x \rangle$. Then $\langle x \rangle \cap \langle y \rangle = 1$ and $\langle x \rangle \langle y \rangle$ has order p^2, so $G = \langle x \rangle \times \langle y \rangle \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$. □

Theorem 5.3.3 (Order pq, $p < q$ primes). *Let $|G| = pq$ with $p < q$.*

1. *If $p \nmid q - 1$ then $G \cong \mathbb{Z}/pq\mathbb{Z}$ (cyclic); it is the unique group of order pq.*
2. *If $p \mid q - 1$ there are exactly two groups: $\mathbb{Z}/pq\mathbb{Z}$ and a unique nonabelian group $\mathbb{Z}/q\mathbb{Z} \rtimes \mathbb{Z}/p\mathbb{Z}$.*

Proof. By Sylow, $n_q \equiv 1 \pmod q$ and $n_q \mid p$; since $p < q$ this forces $n_q = 1$, so the Sylow q-subgroup $Q \cong \mathbb{Z}/q\mathbb{Z}$ is normal. Also $n_p \equiv 1 \pmod p$ and $n_p \mid q$, so $n_p \in \{1, q\}$. Let $P \cong \mathbb{Z}/p\mathbb{Z}$ be a Sylow p-subgroup. Then $Q \cap P = 1$ and $QP = G$, so $G \cong Q \rtimes_\varphi P$ with $\varphi\colon P \to \mathrm{Aut}(Q) \cong \mathbb{Z}/(q-1)\mathbb{Z}$. The homomorphisms φ correspond to elements of $\mathrm{Aut}(Q)$ of order dividing p; there are p such iff $p \mid q - 1$, else only the trivial one. If φ is trivial, $G \cong \mathbb{Z}/q\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z} \cong \mathbb{Z}/pq\mathbb{Z}$. If $p \mid q - 1$, any two nontrivial φ, φ' have images that are the unique subgroup of order p in the cyclic group $\mathrm{Aut}(Q)$, and the resulting semidirect products are isomorphic; this gives one nonabelian class. □

Method (Classifying order pq ($p < q$)). *Trigger.* $|G|$ is a product of two distinct primes.

1. Order them $p < q$. The Sylow q-subgroup is *always* normal (since $n_q \mid p < q$).

2. Compute $q-1$ and test divisibility by p.

3. If $p \nmid q-1$: only $\mathbb{Z}/pq\mathbb{Z}$. If $p \mid q-1$: two groups, $\mathbb{Z}/pq\mathbb{Z}$ and $\mathbb{Z}/q\mathbb{Z} \rtimes \mathbb{Z}/p\mathbb{Z}$.

Worked Example 5.3.4 (Order 15)**.** Classify all groups of order 15.

Recognition. This is pq with $p=3, q=5$ (Theorem 5.3.3); check whether $3 \mid 5-1$.

Solution. $q-1=4$ and $3 \nmid 4$, so case (1) applies: the unique group is $\mathbb{Z}/15\mathbb{Z} \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$.
Check via Sylow directly: $n_5 \equiv 1 \pmod 5$, $n_5 \mid 3 \implies n_5 = 1$; $n_3 \equiv 1 \pmod 3$, $n_3 \mid 5 \implies n_3 = 1$. Both Sylow subgroups normal $\implies G \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/15\mathbb{Z}$. So $g(15)=1$. ■

Worked Example 5.3.5 (Order 21)**.** Classify all groups of order 21.

Recognition. pq with $p=3, q=7$; test $3 \mid 7-1=6$.

Solution. $3 \mid 6$, so case (2): two groups. The cyclic $\mathbb{Z}/21\mathbb{Z}$, and the nonabelian $\mathbb{Z}/7\mathbb{Z} \rtimes \mathbb{Z}/3\mathbb{Z}$. The nontrivial action: $\mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$ has a unique subgroup of order 3 (generated by $x \mapsto x^2$, since 2 has order 3 mod 7: $2, 4, 8 \equiv 1$). So $\mathbb{Z}/7\mathbb{Z} \rtimes \mathbb{Z}/3\mathbb{Z} = \langle a, b \mid a^7 = b^3 = 1,\ bab^{-1} = a^2 \rangle$.
Check. $b^3ab^{-3} = a^{2^3} = a^8 = a$, consistent with $b^3=1$. ■ Thus $g(21)=2$.

Worked Example 5.3.6 (Order 33 vs. order 35)**.** Determine $g(33)$ and $g(35)$.

Recognition. Both are pq; apply the $p \mid q-1$ test to each.

Solution. $33 = 3{\cdot}11$: $q-1=10$, $3 \nmid 10 \implies g(33)=1$, only $\mathbb{Z}/33\mathbb{Z}$. $35 = 5{\cdot}7$: $q-1=6$, $5 \nmid 6 \implies g(35)=1$, only $\mathbb{Z}/35\mathbb{Z}$.
Check. Both have all Sylow subgroups normal (e.g. for 33: $n_{11} \mid 3$ and $\equiv 1\,(11) \implies n_{11}=1$; $n_3 \mid 11$ and $\equiv 1\,(3) \implies n_3 = 1$). ■

Worked Example 5.3.7 (The smallest nonabelian pq)**.** What is the smallest order pq ($p<q$ distinct primes) admitting a nonabelian group, and exhibit it.

Recognition. Need the least q with a prime $p<q$ dividing $q-1$; the case-(2) condition.

Solution. Test $q=3$: $q-1=2$, $p=2 \mid 2$ and $p<q$. So $pq=6$ works: the nonabelian group is $\mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$ with the inversion action, i.e. $S_3 \cong D_6$.
Check. $\mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$, nontrivial action sends $r \mapsto r^{-1}$, giving $\langle r, s \mid r^3 = s^2 = 1,\ srs^{-1} = r^{-1} \rangle = D_6 \cong S_3$. ■ Smallest such order is 6.

Caution. The cyclic-uniqueness criterion is *not* just "the smaller prime p"; it is "$p \mid q-1$" with $p<q$. For $|G| = 2q$ (q odd), $p=2$ *always* divides $q-1$, so there is *always* a nonabelian group (dihedral). For odd $p<q$, you must actually check divisibility – e.g. $|G|=15$ has *no* nonabelian group even though both factors are odd primes.

Order $2p$: cyclic or dihedral

Theorem 5.3.8 (Order $2p$, p an odd prime)**.** *If $|G| = 2p$ with p odd prime, then $G \cong \mathbb{Z}/2p\mathbb{Z}$ or $G \cong D_{2p}$. These are the only two classes.*

Proof. This is the case $p=2$ of Theorem 5.3.3 after relabelling: write the primes as $2<p$. Since $2 \mid p-1$ always, there are exactly two groups. The Sylow p-subgroup $P = \langle r \rangle \cong \mathbb{Z}/p\mathbb{Z}$ is normal. Let s have order 2. Then $G = \langle r \rangle \rtimes \langle s \rangle$, and $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/(p-1)\mathbb{Z}$ has a *unique* element of order 2, namely $r \mapsto r^{-1}$. If s acts trivially, $srs^{-1} = r$ and G is abelian $\cong \mathbb{Z}/2p\mathbb{Z}$. If s acts by the order-2 automorphism, $srs^{-1} = r^{-1}$ and $G \cong D_{2p}$. □

Method (Telling $\mathbb{Z}/2p\mathbb{Z}$ from D_{2p})**.** *Trigger.* $|G| = 2p$, p odd prime. Always exactly two groups.

- Find r with $|r| = p$ (Cauchy) and s with $|s| = 2$.
- Compute srs^{-1}. If $srs^{-1} = r$ (commute): $G \cong \mathbb{Z}/2p\mathbb{Z}$. If $srs^{-1} = r^{-1}$: $G \cong D_{2p}$.
- Quick invariants: $\mathbb{Z}/2p\mathbb{Z}$ has an element of order $2p$ and is abelian with center G; D_{2p} is nonabelian with center 1 and has p elements of order 2.

Worked Example 5.3.9 (Order 6)**.** Classify all groups of order 6.

Recognition. $2p$ with $p = 3$; Theorem 5.3.8 gives exactly two.

Solution. By Cauchy take r of order 3 and s of order 2; $\langle r\rangle \trianglelefteq G$ (index 2, or $n_3 = 1$). Then $srs^{-1} \in \{r, r^{-1}\}$.

- $srs^{-1} = r$: abelian, $G \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$.
- $srs^{-1} = r^{-1}$: $G \cong \langle r, s \mid r^3 = s^2 = 1,\ srs^{-1} = r^{-1}\rangle = D_6 \cong S_3$.

Check. In S_3, take $r = (1\,2\,3)$, $s = (1\,2)$. Then $srs^{-1} = (1\,2)(1\,2\,3)(1\,2) = (1\,3\,2) = r^{-1}$. Nonabelian. ■ So $g(6) = 2$.

Worked Example 5.3.10 (Order 10)**.** Classify all groups of order 10.

Recognition. $2p$ with $p = 5$.

Solution. Sylow: $n_5 \mid 2$, $n_5 \equiv 1\,(5) \implies n_5 = 1$, so $\langle r\rangle \cong \mathbb{Z}/5\mathbb{Z}$ is normal. With s of order 2, $srs^{-1} \in \{r, r^2, r^3, r^4\}$ must have order 5, and conjugating it once more by s must give back r (since $s^2 = 1 \implies s(srs^{-1})s^{-1} = r$); only $r \mapsto r$ and $r \mapsto r^{-1} = r^4$ satisfy $\varphi^2 = \mathrm{id}$. Two groups: $\mathbb{Z}/10\mathbb{Z}$ and D_{10}.
Check. D_{10} is the symmetry group of the regular pentagon, $|D_{10}| = 10$, nonabelian; $\mathbb{Z}/10\mathbb{Z}$ has the element $r + s$-style generator of order 10. ■ $g(10) = 2$.

Worked Example 5.3.11 (Order 14 and order 22)**.** Find all groups of orders 14 and 22.

Recognition. Both are $2p$ ($p = 7$, $p = 11$).

Solution. Each gives exactly $\mathbb{Z}/2p\mathbb{Z}$ and D_{2p}: $\{\mathbb{Z}/14\mathbb{Z}, D_{14}\}$ and $\{\mathbb{Z}/22\mathbb{Z}, D_{22}\}$.
Check. $n_7 \mid 2, \equiv 1\,(7) \implies n_7 = 1$ (order 14); $n_{11} \mid 2, \equiv 1\,(11) \implies n_{11} = 1$ (order 22). Normal Sylow p-subgroup, then the inversion-or-trivial dichotomy. ■ $g(14) = g(22) = 2$.

Worked Example 5.3.12 (Why no third group of order $2p$?)**.** Explain why G of order $2p$ cannot be a "new" nonabelian group beyond D_{2p}.

Recognition. Uses that $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$ is *cyclic* of order $p - 1$, so has a unique involution.

Solution. The semidirect product $\mathbb{Z}/p\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$ is determined by $\varphi(s) \in \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$ with $\varphi(s)^2 = \mathrm{id}$. A cyclic group $\mathbb{Z}/(p-1)\mathbb{Z}$ has exactly one element of order 2 (since p is odd, $p - 1$ is even). So there are exactly two choices for $\varphi(s)$: the identity ($\implies \mathbb{Z}/2p\mathbb{Z}$) and the unique involution ($\implies D_{2p}$). No room for a third.
Check. $p = 7$: $\mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$, involution is $r \mapsto r^6 = r^{-1}$, matching D_{14}. ■

Order 4 and the small abelian cases

Worked Example 5.3.13 (Order 4)**.** Classify all groups of order 4.

Recognition. $|G| = p^2$ with $p = 2$; a p^2-group is abelian (Theorem on order p^2).

Solution. Abelian, so either an element of order 4 ($G \cong \mathbb{Z}/4\mathbb{Z}$) or every non-identity element has order 2 ($G \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} = V_4$).
Check. $\mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}$ has the generator 1 of order 4. $V_4 = \{1, a, b, ab\}$ with $a^2 = b^2 = (ab)^2 = 1$; e.g. $a = (1\,2)(3\,4), b = (1\,3)(2\,4)$ in S_4. ■ $g(4) = 2$.

Worked Example 5.3.14 (Order 9)**.** Classify all groups of order 9.

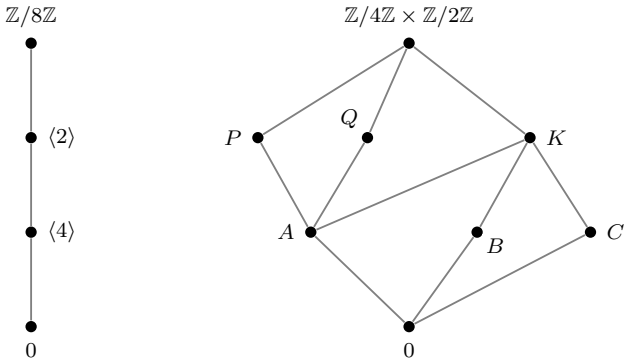
Recognition. p^2 with $p = 3$.

Solution. Abelian; either $\mathbb{Z}/9\mathbb{Z}$ (an element of order 9) or $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ (all non-identity elements have order 3).
Check. No nonabelian option since order $p^2 \implies$ abelian. $g(9) = 2$. ■

The five groups of order 8

Theorem 5.3.15 (Order 8)**.** *There are exactly five groups of order* 8*:*

$$\underbrace{\mathbb{Z}/8\mathbb{Z},\quad \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z},\quad \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}}_{\textit{abelian (3)}},\qquad \underbrace{D_8,\quad Q_8}_{\textit{nonabelian (2)}}\ .$$



Proof. Abelian case. By the Fundamental Theorem of Finite Abelian Groups, the abelian groups of order $8 = 2^3$ correspond to partitions of 3: $3 \to \mathbb{Z}/8\mathbb{Z}$, $2+1 \to \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $1+1+1 \to \mathbb{Z}/2\mathbb{Z}^3$. That is three classes.

Nonabelian case. Suppose G is nonabelian of order 8. No element has order 8 (else cyclic). Not every non-identity element has order 2 (that would force G abelian, as $x^2 = 1\,\forall x \implies$ abelian). So there is an element r of order 4; $\langle r\rangle \trianglelefteq G$ (index 2). Pick $s \notin \langle r\rangle$. Conjugation gives $srs^{-1} \in \langle r\rangle$ of order 4, so $srs^{-1} \in \{r, r^3\}$; r would make G abelian, so $srs^{-1} = r^3 = r^{-1}$. Now $s^2 \in \langle r\rangle$ and s^2 is centralized by s, so $s^2 \in \{1, r^2\}$ (as r, r^3 are not centralized by s).

- $s^2 = 1$: relations $r^4 = s^2 = 1,\ srs^{-1} = r^{-1} \implies G \cong D_8$.
- $s^2 = r^2$: relations $r^4 = 1,\ s^2 = r^2,\ srs^{-1} = r^{-1} \implies G \cong Q_8$.

These two are not isomorphic (counted below), giving exactly two nonabelian classes. Total: 5. □

The two abelian groups with an element of order ≥ 4 are separated cleanly by their subgroup lattices. The cyclic group $\mathbb{Z}/8\mathbb{Z}$ is a single chain (one subgroup of each order $1, 2, 4, 8$), whereas $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ is a wider lattice with three subgroups of order 2 and three of order 4.

Here $A = \langle(2,0)\rangle$, $B = \langle(0,1)\rangle$, $C = \langle(2,1)\rangle$ are the order-2 subgroups, while $P = \langle(1,0)\rangle \cong \mathbb{Z}/4\mathbb{Z}$, $Q = \langle(1,1)\rangle \cong \mathbb{Z}/4\mathbb{Z}$, and $K = \langle(2,0),(0,1)\rangle \cong V_4$ are the order-4 subgroups; A is the unique order-2 subgroup contained in all three of P, Q, K, whereas B and C lie only in the Klein four-group K.

Method (Distinguishing the five groups of order 8)**.** *Trigger.* $|G| = 8$. First decide abelian vs. nonabelian (is there a nontrivial commutator?).

1. **Abelian?** Use the *order spectrum* (how many elements of each order):

	# |1|	# |2|	# |4| (# |8|)
$\mathbb{Z}/8\mathbb{Z}$	1	1	2 (4)
$\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$	1	3	4
$\mathbb{Z}/2\mathbb{Z}^3$	1	7	0

2. **Nonabelian?** Both D_8, Q_8 have $|Z(G)| = 2$ and $G/Z \cong V_4$. Separate by counting elements of order 2:

   D_8 : five elements of order 2; $\quad$ Q_8 : exactly one element of order 2 (namely $-1 = r^2$).

   Equivalently: Q_8 has a *unique* involution and *every* subgroup is normal; D_8 has non-normal subgroups (the reflections).

Worked Example 5.3.16 (The five groups of order 8 and how to tell them apart)**.** Exhibit all five groups of order 8 and give a single invariant separating each from the others.

Recognition. Theorem 5.3.15; use the order-spectrum table plus the unique-involution test.

Solution. Abelian (3):

- $\mathbb{Z}/8\mathbb{Z}$: cyclic, has elements of order 8. Unique with $|x| = 8$.
- $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$: max order 4, with 3 involutions. (E.g. $(2,0), (0,1), (2,1)$ have order 2.)
- $\mathbb{Z}/2\mathbb{Z}^3$: exponent 2, all 7 non-identity elements are involutions.

Nonabelian (2):

- $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs^{-1} = r^{-1} \rangle$: involutions are r^2, s, rs, r^2s, r^3s – *five*.
- $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = ijk = -1$: only -1 has order 2 – *one*.

Separating invariant: the number of elements of order 2 is $1, 3, 7, 5, 1$ – this distinguishes all pairs except $(\mathbb{Z}/8\mathbb{Z}, Q_8)$, both having one involution; but $\mathbb{Z}/8\mathbb{Z}$ is abelian (or: $\mathbb{Z}/8\mathbb{Z}$ has elements of order 8, Q_8 does not). *Check (Q_8 involution count).* $i^2 = -1 \neq 1$, so $i, j, k, -i, -j, -k$ all have order 4; $(-1)^2 = 1$. Exactly one involution. ■ And D_8: $(r^a s)^2 = r^a s r^a s = r^a r^{-a} s^2 = 1$, so all four $r^a s$ are involutions, plus r^2, total five. ■

Worked Example 5.3.17 (Is the dihedral group of the square D_8 or Q_8?)**.** The symmetry group G of a square has order 8. Which of the five is it?

Recognition. Count involutions / use that reflections are non-central order-2 elements.

Solution. G has rotations $1, r, r^2, r^3$ (r = rotation by 90°) and four reflections s, rs, r^2s, r^3s. The four reflections and r^2 (rotation by 180°) are involutions: five of order 2. Matches D_8.
Check. A reflection s is not central ($srs^{-1} = r^{-1} \neq r$), so G is nonabelian with five involutions $\implies G \cong D_8$, not Q_8. ■

Worked Example 5.3.18 ($\mathbb{Z}/4\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}$ vs. $\mathbb{Z}/8\mathbb{Z}$ from a presentation)**.** Let $G = \langle a, b \mid a^4 = b^2 = 1,\ ab = ba \rangle$. Identify G.

Recognition. Abelian (commuting generators); read off the order spectrum.

Solution. G is abelian of order $|a| \cdot |b| / |\langle a \rangle \cap \langle b \rangle| = 4 \cdot 2 = 8$ since $\langle a \rangle \cap \langle b \rangle = 1$. Max element order is $|ab| = \operatorname{lcm}(4, 2) = 4$ (< 8), so $G \ncong \mathbb{Z}/8\mathbb{Z}$. Three involutions: a^2, b, a^2b. Thus $G \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.
Check. $(a^2)^2 = (b)^2 = (a^2b)^2 = 1$ and these are distinct nonidentity elements of order 2; spectrum $(1, 3, 4)$ matches the table. ■

Worked Example 5.3.19 (Every subgroup of Q_8 is normal)**.** Verify that Q_8 has the unusual property that all its subgroups are normal (it is *Hamiltonian*), distinguishing it sharply from D_8.

Recognition. Subgroups of order 4 have index 2 (automatically normal); the unique order-2 subgroup is central.

Solution. Subgroups: $\{1\}$, $\langle -1 \rangle = \{\pm 1\}$, $\langle i \rangle, \langle j \rangle, \langle k \rangle$ (each order 4, index 2, normal), and Q_8. The order-2 subgroup $\{\pm 1\} = Z(Q_8)$ is central hence normal. So all six subgroups are normal.
Contrast: in D_8, $\langle s \rangle = \{1, s\}$ is *not* normal: $rsr^{-1} = r^2 s \notin \langle s \rangle$. ■ This non-normal reflection subgroup cleanly separates D_8 from Q_8.

Caution. D_8 and Q_8 share many invariants: both have order 8, center of order 2, $G/Z \cong V_4$, derived subgroup $\langle r^2 \rangle$ of order 2, and the *same* character table degrees. Do *not* try to distinguish them by $|Z|$ or by G/Z. The clean separators are: number of involutions (5 vs. 1), or "has a non-normal subgroup" (D_8 yes, Q_8 no).

The five groups of order 12

Theorem 5.3.20 (Order 12)**.** *There are exactly five groups of order* 12*:*

$$\underbrace{\mathbb{Z}/12\mathbb{Z}, \quad \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}\ (\cong \mathbb{Z}/2\mathbb{Z}^2 \times \mathbb{Z}/3\mathbb{Z})}_{\textit{abelian (2)}}, \qquad \underbrace{A_4, \quad D_{12}, \quad \mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z} = \mathrm{Dic}_3}_{\textit{nonabelian (3)}}.$$

The last, Dic_3 *(the dicyclic / binary dihedral group Q_{12}), is* $\langle a, b \mid a^6 = 1,\ b^2 = a^3,\ bab^{-1} = a^{-1} \rangle$.

Proof sketch. Abelian (2): partitions of $2^2 \cdot 3$: $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/12\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$.

Nonabelian. Let $|G| = 12 = 2^2 \cdot 3$. By Sylow, $n_3 \in \{1, 4\}$ and $n_2 \in \{1, 3\}$. *Key step:* not both can fail to be normal – if $n_3 = 4$ there are $4 \cdot 2 = 8$ elements of order 3, leaving only 4 elements (which must form the unique, hence normal, Sylow 2-subgroup, so $n_2 = 1$). So either the Sylow 3-subgroup P_3 or the Sylow 2-subgroup P_2 is normal.

- $P_3 \trianglelefteq G$ (i.e. $n_3 = 1$): then $G \cong \mathbb{Z}/3\mathbb{Z} \rtimes P_2$ with $P_2 \in \{\mathbb{Z}/4\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}^2\}$ and action $\varphi\colon P_2 \to \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$. Nontrivial cases:
  - $P_2 = \mathbb{Z}/4\mathbb{Z}$, φ nontrivial (kernel $\mathbb{Z}/2\mathbb{Z}$): $\mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z} = \mathrm{Dic}_3$.
  - $P_2 = \mathbb{Z}/2\mathbb{Z}^2$, φ nontrivial: $\mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}^2 \cong D_{12}$ (since $\mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z} = S_3 = D_6$, and $\times\mathbb{Z}/2\mathbb{Z} \implies D_{12} \cong D_6 \times \mathbb{Z}/2\mathbb{Z}$).

  (Trivial φ recovers the two abelian groups.)
- P_3 **not normal** ($n_3 = 4$): forces $n_2 = 1$, $P_2 \cong \mathbb{Z}/2\mathbb{Z}^2 \trianglelefteq G$, and $G \cong \mathbb{Z}/2\mathbb{Z}^2 \rtimes \mathbb{Z}/3\mathbb{Z}$ with $\mathbb{Z}/3\mathbb{Z}$ acting by an order-3 automorphism (a 3-cycle on the three involutions). This is A_4.

Distinctness is checked by invariants (see the method box), giving exactly three nonabelian classes; total 5. □

Method (Distinguishing the five groups of order 12)**.** *Trigger.* $|G| = 12$.

1. **Abelian?** Element of order 12 $\implies \mathbb{Z}/12\mathbb{Z}$; else (max order 6) $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$.
2. **Nonabelian** – use these separators:

	normal Sylow 3-subgrp?	n_3	$\#\,\lvert 2\rvert$	has elt of order
A_4	no ($n_3 = 4$)	4	3	$1, 2, 3$ only
D_{12}	yes	1	7	$1, 2, 3, 6$
Dic_3	yes	1	1	$1, 2, 3, 4, 6$

   Fast triage: A_4 has *no* element of order 6 and *no* normal Sylow 3-subgroup (it is the only one with $n_3 = 4$). Dic_3 has a *unique* involution (like Q_8). D_{12} has *seven* involutions.

Worked Example 5.3.21 (A_4 has no subgroup of order 6)**.** Show A_4 is the nonabelian order-12 group with $n_3 = 4$, and that it has no subgroup of order 6 – the classic failure of the converse of Lagrange.

Recognition. Identify A_4's Sylow structure; a subgroup of order 6 would have index 2 hence be normal.

Solution. A_4's 3-cycles: there are 8 of them, forming four Sylow 3-subgroups (each $\langle (i\,j\,k) \rangle$ of order 3 shares only identity), so $n_3 = 4$, not normal. The three double transpositions $(1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)$ plus 1 form the unique $V_4 \trianglelefteq A_4$, so $n_2 = 1$.
No order-6 subgroup: such H has index 2, so $H \trianglelefteq A_4$, and H would contain all squares; but every 3-cycle $\sigma = \sigma^4 = (\sigma^2)^2$ is a square, and there are 8 of them > 6. Contradiction.
Check. A_4 has element orders $1, 2, 3$ only (no order 6), matching the table. ■

Worked Example 5.3.22 (Building $\mathrm{Dic}_3 = \mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z}$)**.** Construct the nonabelian group $G = \mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z}$ with the nontrivial action and find its unique involution.

Recognition. $H = \mathbb{Z}/3\mathbb{Z} \trianglelefteq G$, $K = \mathbb{Z}/4\mathbb{Z}$ acts through $\mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$ via the order-2 quotient $\mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$.

Solution. Write $\langle a \rangle = \mathbb{Z}/3\mathbb{Z}$, $\langle b \rangle = \mathbb{Z}/4\mathbb{Z}$. The generator b acts by inversion: $bab^{-1} = a^{-1} = a^2$, and b^2 acts trivially (kernel of $\mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z})$ is $\langle b^2 \rangle$). Standard presentation: $G = \langle a, b \mid a^3 = b^4 = 1,\ bab^{-1} = a^{-1} \rangle$, order 12.
The element b^2 is central (acts trivially on a and commutes with b) of order 2: it is the unique involution. Setting $x = ab$-type elements, $|x| = 4$.
Check. In the equivalent presentation $\langle a, b \mid a^6 = 1, b^2 = a^3, bab^{-1} = a^{-1} \rangle$, $b^2 = a^3$ has order 2 and is the only involution; this is the dicyclic group Q_{12}. Matches "$\#\,|2| = 1$". ■

Worked Example 5.3.23 ($D_{12} \cong S_3 \times \mathbb{Z}/2\mathbb{Z}$)**.** Show the order-12 dihedral group factors as $D_{12} \cong D_6 \times \mathbb{Z}/2\mathbb{Z} \cong S_3 \times \mathbb{Z}/2\mathbb{Z}$, and count its involutions.

Recognition. D_{12} has central element r^3 of order 2; quotient out to get D_6.

Solution. $D_{12} = \langle r, s \mid r^6 = s^2 = 1,\ srs^{-1} = r^{-1} \rangle$. The element $z = r^3$ is central ($r^3 s = sr^{-3} = sr^3$ since $r^6 = 1$) of order 2, with $\langle z \rangle \cap \langle r^2, s \rangle = 1$ and $\langle r^2, s \rangle \cong D_6 = S_3$. So $D_{12} \cong \langle r^2, s \rangle \times \langle r^3 \rangle \cong S_3 \times \mathbb{Z}/2\mathbb{Z}$.
Involutions: the six reflections $r^k s$ ($k = 0, \ldots, 5$) plus r^3: seven elements of order 2.
Check. $(r^k s)^2 = r^k s r^k s = r^k r^{-k} s^2 = 1$ for all k (six involutions); $(r^3)^2 = r^6 = 1$ (one more). Total 7, matching the table. ■

Worked Example 5.3.24 (Triage drill: a nonabelian order-12 group)**.** A nonabelian group G of order 12 has a normal Sylow 3-subgroup, exactly one element of order 2, and an element of order 4. Identify G.

Recognition. Run the order-12 method box: unique involution + order-4 element pins it down.

Solution. Normal Sylow 3-subgroup rules out A_4 ($n_3 = 4$). A unique involution rules out D_{12} (seven) and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ (three); $\mathbb{Z}/12\mathbb{Z}$, which also has a unique involution, is excluded because G is nonabelian. The only candidate with $\#\,|2| = 1$ and an order-4 element is $\mathrm{Dic}_3 = \mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z}$. So $G \cong \mathrm{Dic}_3$.
Check. Consistency – Dic_3 has element orders $\{1, 2, 3, 4, 6\}$, a unique involution b^2, and $n_3 = 1$. All three given properties hold. ■

Worked Example 5.3.25 (Classify order 12 end to end)**.** List all five groups of order 12 and assign each its Sylow data (n_2, n_3).

Recognition. Theorem 5.3.20 plus computing n_2, n_3 for each.

Solution.

G	n_2	n_3	type
$\mathbb{Z}/12\mathbb{Z}$	1	1	abelian, elt of order 12
$\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$	1	1	abelian, exponent 6
D_{12}	3	1	nonab., 7 involutions
Dic_3	3	1	nonab., unique involution
A_4	1	4	nonab., no order 6

Check. A_4 is the *only* group of order 12 with $n_3 = 4$ (the 8 three-cycles force it), confirming the count 5. For the others $n_3 = 1$, distinguished by abelian-ness and involution count. ■ Hence $g(12) = 5$.

Diagrams: the split exact sequence and the order-12 trichotomy

Every group of order $2p$, pq (nonabelian case), or 12 (nonabelian) arises as a (semi)direct product, hence sits in a *split* short exact sequence with a normal Sylow subgroup as kernel; so does $D_8 = \langle r \rangle \rtimes \langle s \rangle$, with kernel $\langle r \rangle$. The exception is Q_8: every nontrivial subgroup of Q_8 contains -1, so Q_8 is not a semidirect product of proper subgroups (it is a non-split extension). The split sequence is:

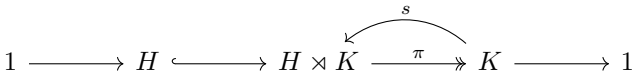


Diagram explanation. Objects: Five nodes from left to right: the trivial group 1; the normal subgroup H (the normal Sylow p-subgroup, e.g. $\mathbb{Z}/q\mathbb{Z}$ when $|G| = pq$); the semidirect product $H \rtimes K$ (the full group G); the complement K (a Sylow subgroup of complementary order); and the trivial group 1 again on the far right. Together they form a short exact sequence.

Arrows: The leftmost arrow $1 \to H$ is the zero map (inclusion of the identity). The hooked arrow $H \hookrightarrow H \rtimes K$ is the canonical inclusion $h \mapsto (h, 1_K)$, injective by definition. The two-headed arrow $H \rtimes K \xrightarrow{\pi} K$ is the projection $\pi(h, k) = k$, surjective with kernel exactly H. The rightmost arrow $K \to 1$ sends everything to the identity. The bent arrow $s\colon K \to H \rtimes K$ is the splitting: $s(k) = (1_H, k)$, a group homomorphism satisfying $\pi \circ s = \mathrm{id}_K$.

What commutes: The sequence is exact: $\mathrm{im}(1 \to H) = 1 = \ker(H \hookrightarrow H \rtimes K)$ (trivially); $\mathrm{im}(H \hookrightarrow H \rtimes K) = H = \ker(\pi)$ (this is the key exactness); $\mathrm{im}(\pi) = K = \ker(K \to 1)$. The splitting condition: $\pi \circ s = \mathrm{id}_K$, i.e. $\pi(1_H, k) = k$.

Why it commutes: Chase a coset representative: $\ker\pi = \{(h,k) \in H \rtimes K : k = 1_K\} = H \times \{1_K\}$, which is exactly the image of the inclusion $h \mapsto (h, 1_K)$. The splitting $s(k) = (1_H, k)$ is a homomorphism because the multiplication in $H \rtimes K$ restricts on $\{1_H\} \times K$ to the group law of K. The condition $\pi(s(k)) = \pi(1_H, k) = k$ holds by definition of π.

Why this matters here: Every semidirect product $H \rtimes K$ that appears in the classification of groups of small order – D_{2p}, $\mathbb{Z}/q\mathbb{Z} \rtimes \mathbb{Z}/p\mathbb{Z}$, D_8, A_4, D_{12}, Dic_3 (but not Q_8, which is not a semidirect product of proper subgroups) – sits in exactly such a sequence. The diagram encodes in one picture *why* $H \rtimes K$ is determined up to isomorphism by the conjugation action $\varphi\colon K \to \mathrm{Aut}(H)$: the splitting s records the embedding of K back into G, and the only freedom is how K acts on H by conjugation via s.

Concrete example: For $G = S_3 \cong \mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$: $H = \mathbb{Z}/3\mathbb{Z} = \langle(1\,2\,3)\rangle$, $K = \mathbb{Z}/2\mathbb{Z} = \langle(1\,2)\rangle$, π sends each permutation to its coset mod H, and s embeds $(1\,2)$ back as $(1\,2) \in S_3$. Exactness: $\ker\pi = \{1, (1\,2\,3), (1\,3\,2)\} = H$. The splitting: $\pi(s((1\,2))) = \pi((1\,2)) = (1\,2) \in K$. ■

Common pitfall: The bent arrow s is a section of π (a right inverse), not a section of the inclusion. Students sometimes think s splits the sequence "on the left" and write $s \circ \iota = \mathrm{id}_H$; that is false – s goes $K \to H \rtimes K$, not back to H. The correct condition is only $\pi \circ s = \mathrm{id}_K$.

Takeaway: The point of this diagram is that every (semi)direct product is precisely a short exact sequence equipped with a group-homomorphism section, and the isomorphism type of the whole group is determined by how the section's image acts on the normal subgroup.

Here H is the normal Sylow subgroup, K a complement (Sylow subgroup of complementary order), s the splitting, and the isomorphism type is fixed by $\varphi =$ "conjugation" $: K \to \mathrm{Aut}(H)$. A *direct* product is the special case φ trivial, where the second projection also splits and both factors are normal:

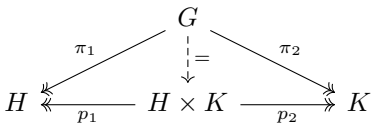

Diagram explanation. Objects: Four nodes: G at the top (a group abstractly given or arrived at via the classification argument); H at the lower-left (a normal subgroup of G, the normal Sylow subgroup in the classification); K at the lower-right (the complementary subgroup, also normal in the direct-product case); and $H \times K$ at the center bottom (the direct product, serving as the "canonical model" the diagram identifies G with).

Arrows: $\pi_1 : G \to H$ and $\pi_2 : G \to K$ are the two group homomorphisms from G to each factor. $p_1 : H \times K \to H$ and $p_2 : H \times K \to K$ are the standard coordinate projections, $p_1(h,k) = h$, $p_2(h,k) = k$. The dashed arrow $G \to H \times K$ (labelled $=$) is the canonical isomorphism $g \mapsto (\pi_1(g), \pi_2(g))$; it exists because both H and K are normal in G with $H \cap K = 1$ and $HK = G$.

What commutes: The left triangle: $p_1 \circ (=) = \pi_1$. The right triangle: $p_2 \circ (=) = \pi_2$. Concretely, for any $g \in G$ written uniquely as $g = hk$ with $h \in H, k \in K$: $p_1(h,k) = h = \pi_1(g)$ and $p_2(h,k) = k = \pi_2(g)$.

Why it commutes: Well-definedness of the isomorphism $g \mapsto (\pi_1(g), \pi_2(g))$ rests on $H \cap K = 1$ (so the decomposition $g = hk$ is unique) and $HK = G$ (so every g decomposes). Commutativity of the triangles is then definitional: $\pi_1(g)$ *is* the H-component of g, and p_1 reads that component from the pair.

Why this matters here: The diagram distinguishes the *direct* product case (φ trivial, both factors normal) from the strict semidirect product. In the split-SES diagram the arrow s is a one-sided section; here the dashed isomorphism is bilateral, reflecting that both projections split. This is the exact situation for $G \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/15\mathbb{Z}$ (both Sylow subgroups normal, φ trivial) or for the abelian groups $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/12\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$.

Concrete example: $G = \mathbb{Z}/6\mathbb{Z}$, $H = \mathbb{Z}/3\mathbb{Z} = \langle 2\rangle$, $K = \mathbb{Z}/2\mathbb{Z} = \langle 3\rangle$ (inside $\mathbb{Z}/6\mathbb{Z}$). Then $\pi_1(n) = n \bmod 3$ (projected onto the $\mathbb{Z}/3\mathbb{Z}$ factor) and $\pi_2(n) = n \bmod 2$. The isomorphism $\mathbb{Z}/6\mathbb{Z} \xrightarrow{\sim} \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ sends $1 \mapsto (1,1)$. The triangles commute: $p_1(1,1) = 1 = \pi_1(1)$. ■

Common pitfall: The dashed equality-labelled arrow is an *isomorphism*, not a literal equality; the label $=$ indicates the canonical identification, not that G and $H \times K$ are the same set. Students sometimes read this

diagram as asserting $G = H \times K$ by definition and skip checking the conditions $H \trianglelefteq G$, $K \trianglelefteq G$, $H \cap K = 1$, $HK = G$ – all four are needed for the dashed isomorphism to exist.

Takeaway: The point of this diagram is that a group G is a direct product $H \times K$ precisely when both π_1 and π_2 are well-defined group homomorphisms and the dashed canonical map is an isomorphism, which happens exactly when both factors are normal with trivial intersection and $HK = G$.

The nonabelian groups of order 12 are exactly the three nontrivial (H, K, φ) data:

$$\text{(normal } P_3) \xrightarrow[K=\mathbb{Z}/2\mathbb{Z}^2]{} \mathbb{Z}/3\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}^2 \cong D_{12}$$

$$\text{(normal } P_3) \xrightarrow[K=\mathbb{Z}/4\mathbb{Z}]{} \mathbb{Z}/3\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z} = \mathrm{Dic}_3$$

$$\text{(normal } P_2 = \mathbb{Z}/2\mathbb{Z}^2) \xrightarrow[K=\mathbb{Z}/3\mathbb{Z}]{} \mathbb{Z}/2\mathbb{Z}^2 \rtimes_\varphi \mathbb{Z}/3\mathbb{Z} \cong A_4$$

Diagram explanation. Objects: Two source nodes on the left (classification data): "(normal P_3)" stands for the datum that the Sylow 3-subgroup $P_3 \cong \mathbb{Z}/3\mathbb{Z}$ is normal in G, giving $H = \mathbb{Z}/3\mathbb{Z}$ in $H \rtimes K$; this single node sends two arrows (to the upper and middle targets), one for each choice of complement K. The bottom-left source "(normal $P_2 = \mathbb{Z}/2\mathbb{Z}^2$)" is the datum that instead the Sylow 2-subgroup $P_2 \cong \mathbb{Z}/2\mathbb{Z}^2$ is normal ($n_3 = 4$ forces this). Three target nodes on the right: $\mathrm{Dic}_3 = \mathbb{Z}/3\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z}$, $D_{12} \cong \mathbb{Z}/3\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}^2$, and $A_4 \cong \mathbb{Z}/2\mathbb{Z}^2 \rtimes_\varphi \mathbb{Z}/3\mathbb{Z}$.

Arrows: Each arrow is labelled by the complement K chosen; the arrow records the assignment $(H, K, \varphi) \mapsto H \rtimes_\varphi K$. Upper arrow from "(normal P_3)": complement $K = \mathbb{Z}/4\mathbb{Z}$, unique nontrivial action $\mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$ (via the order-2 quotient), yields Dic_3. Middle arrow: complement $K = \mathbb{Z}/2\mathbb{Z}^2$, a nontrivial action (there are three, one for each kernel of order 2 in $\mathbb{Z}/2\mathbb{Z}^2$, and all three give isomorphic groups), yields D_{12}. Bottom arrow: $H = \mathbb{Z}/2\mathbb{Z}^2$ normal, complement $K = \mathbb{Z}/3\mathbb{Z}$ acting by an order-3 automorphism permuting the three involutions cyclically, yields A_4.

What commutes: This is not a commutative diagram in the path-equality sense; it is a *classification map*. Each arrow is injective on isomorphism classes: distinct (H, K, φ) triples in the diagram produce non-isomorphic groups (verified by the invariants in the method box: involution count $1, 7, 3$ and $n_3 = 1, 1, 4$ respectively). No two arrows point to the same group.

Why it commutes: Well-definedness of each arrow – i.e. that the semidirect product $H \rtimes_\varphi K$ is a group of order 12 – follows from $|H||K| = 3 \cdot 4 = 12$ or $4 \cdot 3 = 12$, and that the action φ is a genuine group homomorphism. For Dic_3: $\varphi\colon \mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z})$ factors through $\mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}/\langle b^2 \rangle \cong \mathbb{Z}/2\mathbb{Z} \cong \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z})$, well-defined since $\langle b^2 \rangle$ is the kernel. For A_4: $\varphi\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/2\mathbb{Z}^2)$ sends the generator to the 3-cycle $(a\,b\,ab)$ on the three involutions; this is a homomorphism since that 3-cycle has order 3 in $\mathrm{Aut}(\mathbb{Z}/2\mathbb{Z}^2) \cong S_3$.

Why this matters here: The proof that $g(12) = 5$ (three nonabelian classes) reduces to showing that the three arrows in this diagram hit *distinct* and *exhaustive* targets. Exhaustiveness comes from the Sylow argument: either $P_3 \trianglelefteq G$ ($n_3 = 1$, two choices of K) or $P_2 \trianglelefteq G$ ($n_3 = 4$, one choice). Distinctness comes from the invariants. The diagram makes both halves of the argument visible simultaneously.

Concrete example: Follow the middle arrow: $H = \mathbb{Z}/3\mathbb{Z} = \langle a \rangle$, $K = \mathbb{Z}/2\mathbb{Z}^2 = \langle s, t \rangle$ with s acting by inversion ($sas^{-1} = a^{-1}$) and t acting trivially. Then $G \cong D_6 \times \mathbb{Z}/2\mathbb{Z} \cong S_3 \times \mathbb{Z}/2\mathbb{Z} \cong D_{12}$, the dihedral group of order 12 (symmetries of the regular hexagon). The seven involutions are $r^k s$ ($k = 0, \ldots, 5$) and r^3, confirming the middle target.

Common pitfall: The two left-hand sources "(normal P_3)" and "(normal P_2)" are *mutually exclusive* outcomes of Sylow theory, not two choices available simultaneously. Students sometimes think they can mix the data (e.g. take $H = \mathbb{Z}/3\mathbb{Z}$ normal *and* P_2 normal with a nontrivial action), but if P_3 is not normal ($n_3 = 4$) then the counting argument forces $P_2 \trianglelefteq G$ uniquely; there is no fourth nonabelian case.

Takeaway: The point of this diagram is that the three nonabelian groups of order 12 are in bijection with the three nontrivial choices of normal Sylow subgroup and nontrivial complement-action, making the exhaustiveness and distinctness of the classification visible in a single picture.

Caution. A semidirect product $H \rtimes K$ collapsing to a *direct* product (or to a smaller-looking group) is common: $\mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z} = S_3$, and $\mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}^2 \cong D_{12} \cong S_3 \times \mathbb{Z}/2\mathbb{Z}$ – but $D_{12} \ncong \mathbb{Z}/3\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z} = \mathrm{Dic}_3$ even though both are "$\mathbb{Z}/3\mathbb{Z}\rtimes$ (order-4 group)". The *group* K and the *action* φ both matter: $\mathbb{Z}/4\mathbb{Z}$ vs. $\mathbb{Z}/2\mathbb{Z}^2$ as the complement gives genuinely different groups. Always record the full datum (H, K, φ), never just $|H|$ and $|K|$.

Exercises (from the text).

1. Prove that D_{16}, $\mathbb{Z}_2 \times D_8$, $\mathbb{Z}_2 \times Q_8$, $\mathbb{Z}_4 * D_8$, QD_{16} and M are nonisomorphic non-abelian groups of order 16 (where $\mathbb{Z}_4 * D_8$ is described in Exercise 12, Section 1 and QD_{16} and M are described in the exercises in Section 2.5).

Practice problems.

1. Classify all groups of order 51 and all groups of order 55, and state $g(51)$ and $g(55)$. (Each is a product of two distinct primes; apply the $p \mid q-1$ test, and note one case yields a nonabelian group while the other does not.)
2. Classify all groups of order 26 directly: produce r of order 13 and s of order 2, show $\langle r\rangle \trianglelefteq G$ via Sylow ($n_{13} \mid 2$, $n_{13} \equiv 1\,(13)$), and use $srs^{-1} \in \{r, r^{-1}\}$ to recover the two classes $\mathbb{Z}/26\mathbb{Z}$ and D_{26}.
3. Show the two abelian groups of order 12 are $\mathbb{Z}/12\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$, and separate them by their element-order spectra. Which has an element of order 12? What is the exponent of the other, and how many generators does $\mathbb{Z}/12\mathbb{Z}$ have?
4. Distinguish the three abelian groups of order 8 by counting involutions: verify $\mathbb{Z}/8\mathbb{Z}$, $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z}^3$ have $1, 3, 7$ elements of order 2 respectively. (For contrast, record the involution counts of the nonabelian D_8 and Q_8 as well.)
5. Let $|G| = 12$ with G nonabelian and $n_3 = 4$. Show $G \cong A_4$: count the elements of order 3 forced by $n_3 = 4$, deduce that the remaining elements form the unique (normal) Sylow 2-subgroup V_4, and identify $G \cong V_4 \rtimes \mathbb{Z}/3\mathbb{Z}$.
6. Let $|G| = 2p$ with p an odd prime. Prove that exactly two isomorphism classes exist by counting involutions in $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$: the Sylow p-subgroup is normal, $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/(p-1)\mathbb{Z}$ has a *unique* element of order 2, so the order-2 action is either trivial ($\implies \mathbb{Z}/2p\mathbb{Z}$) or inversion ($\implies D_{2p}$), with no third possibility.
7. Determine $g(13)$, $g(14)$, and $g(15)$, justifying each with one line (prime; $2p$; pq with $p \nmid q-1$). Confirm your answers against the census table.
8. The dicyclic group Dic_3 has order 12. Give a presentation, list its element-order spectrum, and locate the unique involution inside the presentation. Explain why, like Q_8, it has exactly one element of order 2. (Compare: Q_8 is the order-8 dicyclic group.)

Additional exercises.

1. Classify all groups of order 18 up to isomorphism and compute $g(18)$. (Show the Sylow 3-subgroup of order 9 is normal, then analyze the action of $\mathbb{Z}/2\mathbb{Z}$ on each of $\mathbb{Z}/9\mathbb{Z}$ and $\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$; account for both abelian types and the three nonabelian ones, including $\mathbb{Z}/3\mathbb{Z} \times \mathrm{Sym}_3$ and the generalized dihedral $(\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}) \rtimes \mathbb{Z}/2\mathbb{Z}$.)
2. Prove that every group of order 45 is abelian and identify the two isomorphism classes. (Use Sylow to show both Sylow subgroups are normal and coprime, so $G \cong P_3 \times P_5$; then classify P_3 of order 9.)
3. Determine which orders $d \mid 12$ are realized as $|H|$ for some subgroup $H \leq A_4$, and show $d = 6$ is the unique missing divisor (a subgroup of index 2 would be normal and contain every square, but the eight 3-cycles are squares, $\sigma = (\sigma^2)^2$, giving more than 6 elements). Contrast with D_{12}, which realizes *every* divisor of 12 as a subgroup order.
4. Show there are exactly three abelian groups of order p^3, namely $\mathbb{Z}/p^3\mathbb{Z}$, $\mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p^2\mathbb{Z}$, and $\mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$, and distinguish them by the size of the p-torsion subgroup $\{x \in G \mid x^p = 1\}$ (which has order p, p^2, p^3 respectively). Specialize to list the abelian groups of orders 8 and 27.

5. Separate D_8 from Q_8 by counting Klein four-subgroups: show D_8 has exactly two subgroups isomorphic to V_4 while Q_8 has none (all three of Q_8's order-4 subgroups, $\langle i\rangle, \langle j\rangle, \langle k\rangle$, are cyclic). Note that this distinguishes them even though both have $|Z| = 2$ and $G/Z \cong V_4$; relate it to the involution counts (5 in D_8, 1 in Q_8).

Commutative-diagram exercises.

1. Let $p < q$ be primes with $p \nmid q - 1$, so that the unique group of order pq is cyclic. Draw the split short exact sequence

$$1 \longrightarrow \mathbb{Z}/q\mathbb{Z} \hookrightarrow \mathbb{Z}/pq\mathbb{Z} \underset{s}{\overset{\pi}{\twoheadrightarrow}} \mathbb{Z}/p\mathbb{Z} \longrightarrow 1$$

   with the normal Sylow q-subgroup as kernel, and explain why $p \nmid q - 1$ forces the conjugation action $\mathbb{Z}/p\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/q\mathbb{Z}) \cong \mathbb{Z}/(q-1)\mathbb{Z}$ to be trivial (no element of order p in $\mathrm{Aut}(\mathbb{Z}/q\mathbb{Z})$). Conclude that the image of the section s is also normal, so the sequence realizes a *direct* product $\mathbb{Z}/pq\mathbb{Z} \cong \mathbb{Z}/q\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$, and indicate which projection splits it on the other side.

2. For the alternating group $A_4 = V_4 \rtimes \mathbb{Z}/3\mathbb{Z}$, draw the split short exact sequence exhibiting the normal Sylow 2-subgroup V_4 as kernel and the Sylow 3-subgroup as a complement:

$$1 \longrightarrow V_4 \hookrightarrow A_4 \underset{s}{\overset{\pi}{\twoheadrightarrow}} \mathbb{Z}/3\mathbb{Z} \longrightarrow 1$$

   Identify π as the quotient by V_4, give a splitting s sending a generator of $\mathbb{Z}/3\mathbb{Z}$ to a 3-cycle, and verify $\pi \circ s = \mathrm{id}$. Explain why the action $\varphi\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{Aut}(V_4) \cong \mathrm{Sym}_3$ is nontrivial (a 3-cycle permuting the three involutions), so the product is genuinely semidirect and not direct, distinguishing A_4 from $\mathbb{Z}/12\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$.

3. Draw the lattice of normal subgroups of A_4 and use it to display the quotient $A_4/V_4 \cong \mathbb{Z}/3\mathbb{Z}$ and the absence of an index-2 subgroup:

   Verify that 1, V_4, A_4 are the only normal subgroups, read off both quotients (orders 4 and 3), and explain why the lattice's lack of an order-6 node confirms A_4 has no subgroup of order 6. Identify V_4 as the commutator subgroup A_4'.

4. For each group G of order 8, draw the quotient map $G \to G/Z(G)$ and identify the image, contrasting the abelian case with D_8 and Q_8:

$$Z(G) \hookrightarrow G \overset{q}{\twoheadrightarrow} G/Z(G)$$

   For the three abelian groups show $Z(G) = G$ so the quotient is trivial; for D_8 and Q_8 show $Z(G) = \langle r^2\rangle$ has order 2 and $G/Z(G) \cong V_4$. Conclude that this diagram separates abelian from nonabelian but fails to distinguish D_8 from Q_8, since both give image V_4.

5.4 Recognizing Direct Products

Commutators, the commutator subgroup, and internal direct products

This section develops two tightly linked ideas from Dummit & Foote, Section 5.4. First, the *commutator* $[x,y] = x^{-1}y^{-1}xy$ measures the failure of x and y to commute, and the subgroup $G' = \langle [x,y] \mid x,y \in G \rangle$ it generates is the smallest normal subgroup with abelian quotient. Second, the *recognition theorem* for internal direct products gives a clean checklist for asserting $G \cong H \times K$ from inside G.

Definition 5.4.1 (Commutator and commutator subgroup)**.** For $x, y \in G$ define the *commutator*

$$[x,y] \;=\; x^{-1}y^{-1}xy.$$

For subgroups (or subsets) $A, B \leq G$ define

$$[A,B] \;=\; \langle\, [a,b] \mid a \in A,\ b \in B \,\rangle.$$

The *commutator subgroup* of G is $G' = [G,G] = \langle\, [x,y] \mid x,y \in G \,\rangle$.

Remark 5.4.1. Two algebraic identities are used constantly and follow by direct computation:

$$xy \;=\; yx\,[x,y], \qquad\qquad [x,y]^{-1} \;=\; [y,x].$$

For the first, $yx\,[x,y] = yx\,x^{-1}y^{-1}xy = y\,y^{-1}xy = xy$. For the second, $[x,y]^{-1} = (x^{-1}y^{-1}xy)^{-1} = y^{-1}x^{-1}yx = [y,x]$. Thus $[x,y] = 1 \iff xy = yx$: a commutator is trivial exactly when its two arguments commute.

Proposition 5.4.2 (Basic properties of G'; D&F 5.4, Prop. 7)**.** *Let G be a group, $G' = [G,G]$, and let $H \trianglelefteq G$. Then:*

(1) $G' \trianglelefteq G$, and in fact G' is characteristic *in G; the quotient G/G' is abelian.*

(2) G/H is abelian $\iff$ $G' \leq H$. (G' is the smallest normal subgroup with abelian quotient.)

(3) If $\varphi\colon G \to A$ is a homomorphism with A abelian, then $G' \leq \ker\varphi$, so φ factors through G/G'.

Proof. **(1)** For any automorphism $\sigma \in \mathrm{Aut}(G)$ and any commutator, $\sigma([x,y]) = \sigma(x^{-1}y^{-1}xy) = \sigma(x)^{-1}\sigma(y)^{-1}\sigma(x)\sigma(y) = [\sigma(x),\sigma(y)] \in G'$. Since σ carries the generating set $\{[x,y]\}$ into itself, $\sigma(G') \leq G'$; applying the same to σ^{-1} gives $\sigma(G') = G'$. Hence G' is characteristic, and in particular invariant under every inner automorphism, so $G' \trianglelefteq G$. For the quotient, in G/G' we have $\overline{x}\,\overline{y} = \overline{xy} = \overline{yx\,[x,y]} = \overline{yx}\ \overline{[x,y]} = \overline{yx}$ because $[x,y] \in G'$ maps to $\overline{1}$. Thus G/G' is abelian.

(2) ($\Leftarrow$) If $G' \leq H$ then G/H is a quotient of the abelian group G/G' (by the third isomorphism theorem $G/H \cong (G/G')/(H/G')$), hence abelian. ($\Rightarrow$) If G/H is abelian then for all x,y, $\overline{x}\,\overline{y} = \overline{y}\,\overline{x}$ in G/H, i.e. $\overline{[x,y]} = \overline{x^{-1}y^{-1}xy} = \overline{1}$, so $[x,y] \in H$. As the $[x,y]$ generate G', we get $G' \leq H$.

(3) Apply (2) with $H = \ker\varphi$: since $G/\ker\varphi \cong \mathrm{im}\,\varphi \leq A$ is abelian, $G' \leq \ker\varphi$. The factoring through G/G' is the universal property of the quotient. □

Corollary 5.4.3. *G is abelian $\iff$ $G' = 1$.*

Proof. G abelian $\iff$ $xy = yx$ for all x,y $\iff$ $[x,y] = 1$ for all x,y $\iff$ the generating set of G' is $\{1\}$ $\iff$ $G' = 1$. □

Method (Computing $G' = [G,G]$)**.** *Trigger.* You are asked for the commutator subgroup, the abelianization G/G', or to test whether G is abelian / find the smallest normal subgroup with abelian quotient.

Recipe.

1. Pick generators $g_1, \ldots, g_m$ of G. It suffices to compute the commutators $[g_i, g_j]$ of generators (every commutator is a product of conjugates of these and their inverses).
2. Let $N = \langle [g_i,g_j] \rangle^G$ be the normal closure. Since $G' \trianglelefteq G$ contains every $[g_i,g_j]$, $N \leq G'$; since the images of the g_i commute in G/N, the quotient G/N is abelian and $G' \leq N$. Hence $G' = N$.

3. **Lower bound:** produce explicit nontrivial $[x, y]$ to show $G' \geq \langle \text{those} \rangle$.

4. **Upper bound:** exhibit $H \trianglelefteq G$ with G/H abelian; then $G' \leq H$ by Prop. 5.4.2(2). When the two bounds meet, you have G'.

5. Read off G/G' (the abelianization) and check $|G'| \cdot |G/G'| = |G|$.

Worked Example 5.4.4 ($G' = 1$ characterizes abelian groups)**.** Show $G' = 1 \iff G$ abelian, and verify on $G = \mathbb{Z}/12\mathbb{Z}$ and on $G = \mathrm{Sym}_3$.

Recognition. This is Corollary 5.4.3: a commutator is trivial iff its arguments commute, and G' is generated by all commutators.

Solution. By the corollary $G' = 1 \iff G$ abelian. For $\mathbb{Z}/12\mathbb{Z}$ (abelian, additive), every commutator $[x, y] = -x - y + x + y = 0$, so $G' = \{0\} = 1$; consistent with abelian. For $\mathrm{Sym}_3 = \langle (1\,2\,3), (1\,2) \rangle$, take $x = (1\,2\,3)$, $y = (1\,2)$. Then $[x, y] = x^{-1}y^{-1}xy = (1\,3\,2)(1\,2)(1\,2\,3)(1\,2)$. Compose right to left: $(1\,2\,3)(1\,2) = (1\,3)$; then $(1\,2)(1\,3) = (1\,3\,2)$; then $(1\,3\,2)(1\,3\,2) = (1\,2\,3)$. So $[x, y] = (1\,2\,3) \neq e$, hence $G' \neq 1$ and Sym_3 is nonabelian. *Check.* $A_3 = \langle (1\,2\,3) \rangle \trianglelefteq \mathrm{Sym}_3$ has abelian quotient $\mathrm{Sym}_3 / A_3 \cong \mathbb{Z}/2\mathbb{Z}$, so $G' \leq A_3$; and we found $(1\,2\,3) \in G'$, so $A_3 \leq G'$. Thus $\mathrm{Sym}_3{}' = A_3$, of order 3, and $|G'| \cdot |G/G'| = 3 \cdot 2 = 6 = |\,\mathrm{Sym}_3\,|$.

Worked Example 5.4.5 (G' for D_8)**.** Compute the commutator subgroup of the dihedral group $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$.

Recognition. Use the Method box: bound G' above by a normal subgroup with abelian quotient, below by an explicit nontrivial commutator.

Solution. **Lower bound.** Compute $[r, s] = r^{-1}s^{-1}rs$. Since $s^{-1} = s$ and $sr = r^{-1}s$ we get $s^{-1}rs = r^{-1}$, so $[r, s] = r^{-1}(s^{-1}rs) = r^{-1}r^{-1} = r^{-2} = r^2$. Thus $r^2 \in G'$, giving $\langle r^2 \rangle \leq G'$, of order 2. **Upper bound.** The subgroup $\langle r^2 \rangle = \{1, r^2\}$ is the center $Z(D_8)$ and is normal. The quotient $D_8/\langle r^2 \rangle$ has order 4; its image is generated by $\bar{r}, \bar{s}$ with $\bar{r}^2 = 1 = \bar{s}^2$ and $\bar{s}\bar{r} = \bar{r}^{-1}\bar{s} = \bar{r}\bar{s}$ (since $\bar{r} = \bar{r}^{-1}$), so the quotient is abelian ($\cong V_4$). Hence $G' \leq \langle r^2 \rangle$. *Conclusion.* ${D_8}' = \langle r^2 \rangle$, order 2, and the abelianization is $D_8/{D_8}' \cong V_4$. *Check.* $|G'| \cdot |G/G'| = 2 \cdot 4 = 8 = |D_8|$.

Worked Example 5.4.6 (G' for Q_8)**.** Compute the commutator subgroup of the quaternion group $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$ with $i^2 = j^2 = k^2 = -1$, $ij = k$, $jk = i$, $ki = j$.

Recognition. Same Method: find a nontrivial commutator (lower bound) and a normal subgroup with abelian quotient (upper bound).

Solution. **Lower bound.** $[i, j] = i^{-1}j^{-1}ij$. Now $i^{-1} = -i$, $j^{-1} = -j$, and $ij = k$, so $i^{-1}j^{-1} = (-i)(-j) = ij = k$, whence $[i, j] = k \cdot ij = k \cdot k = k^2 = -1$. So $-1 \in G'$ and $\langle -1 \rangle = \{\pm 1\} \leq G'$, order 2. **Upper bound.** $\langle -1 \rangle = Z(Q_8) \lhd Q_8$, and $Q_8/\langle -1 \rangle$ has order 4 with $\bar{i}^2 = \overline{-1} = \bar{1}$, similarly $\bar{j}^2 = \bar{k}^2 = \bar{1}$, so the quotient is $\cong V_4$, abelian; hence $G' \leq \langle -1 \rangle$. *Conclusion.* ${Q_8}' = \langle -1 \rangle = \{\pm 1\}$, order 2, abelianization $Q_8/{Q_8}' \cong V_4$. *Check.* $|G'| \cdot |G/G'| = 2 \cdot 4 = 8 = |Q_8|$. (Note D_8 and Q_8 have isomorphic commutator subgroups and abelianizations, yet are nonisomorphic groups.)

Worked Example 5.4.7 (G' for A_4)**.** Compute the commutator subgroup of the alternating group A_4 (order 12).

Recognition. Method box again: a nontrivial commutator forces G' to contain a double transposition, and the quotient by the Klein four-group is abelian, capping G' from above.

Solution. **Lower bound.** Take $x = (1\,2\,3)$ and $y = (1\,2\,4)$ in A_4. Then $[x, y] = x^{-1}y^{-1}xy = (1\,3\,2)(1\,4\,2)(1\,2\,3)(1\,2\,4)$. Composing right to left gives $[x, y] = (1\,2)(3\,4)$, a double transposition. Hence the Klein four-group $V = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\} \leq A_4$ (a single double transposition generates V together with its conjugates, and $V \leq G'$ since $G' \trianglelefteq A_4$) satisfies $V \leq G'$, so $|G'| \geq 4$. **Upper bound.** $V \trianglelefteq A_4$ and A_4/V has order $12/4 = 3$, hence is cyclic of order 3 and abelian; therefore $G' \leq V$ by Prop. 5.4.2(2). *Conclusion.* ${A_4}' = V \cong V_4$, of order 4, with abelianization $A_4/{A_4}' \cong \mathbb{Z}/3\mathbb{Z}$. *Check.* $|G'| \cdot |G/G'| = 4 \cdot 3 = 12 = |A_4|$.

Caution. G' is generated by commutators, but a single commutator need not be a typical element of G', and the *set* of commutators need not be a subgroup. Always pass through the subgroup they generate (and use the upper-bound trick) rather than asserting $\{[x, y]\}$ is closed. Also: G' is characteristic, so $G' \trianglelefteq G$ automatically; do not "check normality" of G' by hand.

Internal direct products: the recognition theorem

We now isolate exactly when a group is, internally, a direct product of two of its subgroups. First recall the universal property of the external direct product, which the internal version must reproduce.

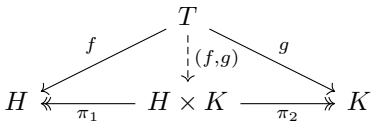

Diagram explanation. Objects: Four nodes: T is an arbitrary group (the "test object" or source); $H \times K$ is the external direct product of two groups H and K; and H, K are the factor groups (targets of the projections). $H \times K$ is the central object encoding the universal property.

Arrows: $f\colon T \to H$ and $g\colon T \to K$ are arbitrary group homomorphisms. $\pi_1\colon H \times K \to H$, $(h,k) \mapsto h$, is the canonical first projection; $\pi_2\colon H \times K \to K$, $(h,k) \mapsto k$, is the canonical second projection. The dashed arrow $(f,g)\colon T \to H \times K$, $t \mapsto (f(t), g(t))$, is the unique induced map guaranteed by the universal property.

What commutes: Two triangles: $\pi_1 \circ (f,g) = f$ (left triangle) and $\pi_2 \circ (f,g) = g$ (right triangle). That is, (f,g) is the unique map making both diagrams commute simultaneously.

Why it commutes: Take any $t \in T$. The induced map sends $t \mapsto (f(t), g(t))$; applying π_1 then gives $f(t)$, which equals $f(t)$ — so $\pi_1 \circ (f,g) = f$. Applying π_2 gives $g(t) = g(t)$ — so $\pi_2 \circ (f,g) = g$. Uniqueness: if $\phi\colon T \to H \times K$ also satisfies $\pi_1 \circ \phi = f$ and $\pi_2 \circ \phi = g$, then $\phi(t) = (\pi_1(\phi(t)), \pi_2(\phi(t))) = (f(t), g(t))$, so $\phi = (f,g)$.

Why this matters here: This diagram is placed here to anchor the meaning of the internal direct product recognition theorem that follows. The theorem asserts $G \cong H \times K$ by constructing $\psi\colon H \times K \to G$, $\psi(h,k) = hk$; the universal property here explains why having projections π_1, π_2 and the unique fill-in (f,g) is the defining feature of the product — and the internal version must reproduce exactly this structure from inside G.

Concrete example: Take $H = \mathbb{Z}/2\mathbb{Z}$, $K = \mathbb{Z}/3\mathbb{Z}$, $T = \mathbb{Z}/6\mathbb{Z}$. The map $f\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$, $n \mapsto n \bmod 2$, and $g\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$, $n \mapsto n \bmod 3$, induce $(f,g)\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, $n \mapsto (n \bmod 2, n \bmod 3)$, which is an isomorphism (CRT). Projecting back via π_1 recovers f, and via π_2 recovers g.

Common pitfall: Students sometimes think the dashed arrow (f,g) merely "exists"; the diagram records both existence *and uniqueness*. Also, do not confuse the induced map $(f,g)\colon T \to H \times K$ with the pair of maps (f,g) as abstract data — the diagram says there is exactly *one* group homomorphism into $H \times K$ whose projections are f and g.

Takeaway: The point of this diagram is that the external direct product $H \times K$ is characterized by the property that maps into it are in bijection with pairs of maps into the factors, via the unique fill-in (f,g), and the internal recognition theorem succeeds precisely by constructing the isomorphism $G \cong H \times K$ that makes this same property hold inside G.

Theorem 5.4.8 (Recognition of internal direct products; D&F 5.4, Thm. 9)**.** *Let G be a group with subgroups $H, K \leq G$ satisfying*

$$\text{(i) } H \trianglelefteq G, \qquad \text{(ii) } K \trianglelefteq G, \qquad \text{(iii) } H \cap K = 1, \qquad \text{(iv) } HK = G.$$

Then the map $\psi\colon H \times K \to G$, $\psi(h,k) = hk$, is an isomorphism; thus $G \cong H \times K$. Conditions (i)–(iv) are equivalent to: $[H,K] = 1$, $H \cap K = 1$, and $HK = G$.

Proof. **Step 1: elements of H and K commute.** Let $h \in H$, $k \in K$ and consider the commutator $[h,k] = h^{-1}k^{-1}hk$. Group it two ways. First,

$$[h,k] = h^{-1}\,(k^{-1}hk),$$

where $k^{-1}hk \in H$ because $H \trianglelefteq G$, so $[h,k] \in H$. Second,

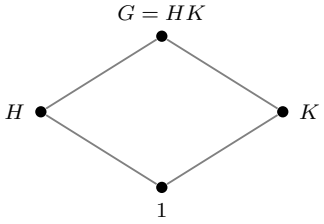
$$[h,k] = (h^{-1}k^{-1}h)\,k,$$

where $h^{-1}k^{-1}h \in K$ because $K \trianglelefteq G$, so $[h,k] \in K$. Hence $[h,k] \in H \cap K = 1$, i.e. $[h,k] = 1$ and $hk = kh$ for all h, k. This gives the equivalent reformulation with $[H,K] = 1$.

Step 2: ψ is a homomorphism. For $(h_1,k_1),(h_2,k_2) \in H \times K$,

$$\psi(h_1,k_1)\psi(h_2,k_2) = h_1k_1h_2k_2 = h_1h_2k_1k_2 = \psi\big((h_1h_2),(k_1k_2)\big) = \psi\big((h_1,k_1)(h_2,k_2)\big),$$

where we used $k_1h_2 = h_2k_1$ from Step 1. So ψ is a homomorphism.



Step 3: ψ is surjective. $\operatorname{im}\psi = HK = G$ by (iv).

Step 4: ψ is injective. Suppose $\psi(h,k) = hk = 1$. Then $h = k^{-1} \in H \cap K = 1$, so $h = k = 1$ and (h,k) is the identity of $H \times K$; thus $\ker\psi = 1$. (Equivalently each $g \in G$ has a *unique* expression $g = hk$: if $h_1k_1 = h_2k_2$ then $h_2^{-1}h_1 = k_2k_1^{-1} \in H \cap K = 1$.)

Hence ψ is a bijective homomorphism, an isomorphism, and $G \cong H \times K$. □

Remark 5.4.2. The reformulation is genuinely useful: in the presence of $H \cap K = 1$ and $HK = G$, the four-condition version (both subgroups normal) and the commuting version ($[H,K] = 1$ plus, say, just $H \trianglelefteq G$) are interchangeable. Indeed if $[H,K] = 1$ and $HK = G$ then K centralizes H and H centralizes K, and every $g = hk$ conjugates H to H (because k centralizes H and h normalizes H), so $H \trianglelefteq G$; symmetrically $K \trianglelefteq G$.

The internal picture is the lattice diamond: $G = HK$ at the top, H and K as the two normal "shoulders" meeting only in the identity at the bottom.

Method (The $H, K \trianglelefteq G$, $H \cap K = 1$, $HK = G$ checklist)**.** *Trigger.* You suspect $G \cong H \times K$ and want to prove it from inside G (no need to build the external product by hand), or you must *disprove* a direct-product decomposition.

Recipe (to establish $G \cong H \times K$).

1. **Normality:** verify $H \trianglelefteq G$ and $K \trianglelefteq G$ (e.g. both contain a generating set fixed under conjugation, or have index giving the smallest prime, or are kernels of homomorphisms). For the commuting form instead check $[H,K] = 1$.
2. **Trivial intersection:** show $H \cap K = 1$ (often by orders: a common element has order dividing $\gcd(|H|,|K|)$; if that gcd is 1 you are done).
3. **Generation:** show $HK = G$. Counting suffices when $H \cap K = 1$, since $|HK| = \dfrac{|H||K|}{|H \cap K|} = |H||K|$; if this equals $|G|$ then $HK = G$.
4. Conclude $G \cong H \times K$ via Theorem 5.4.8; the iso is $(h,k) \mapsto hk$.

To DISprove: show that *every* candidate pair H, K of proper normal subgroups fails one of (iii),(iv) — typically the intersection is nontrivial (the subgroups all share the center), or no two proper normal subgroups generate G.

Worked Example 5.4.9 ($\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ internally)**.** Realize $\mathbb{Z}/6\mathbb{Z} = \mathbb{Z}/6\mathbb{Z}$ as an internal direct product of two of its subgroups.

Recognition. Recognition theorem in an abelian group: all subgroups are normal, so only $H \cap K = 1$ and $H + K = G$ remain.

Solution. Work additively. Let $H = \langle 3\rangle = \{0,3\} \cong \mathbb{Z}/2\mathbb{Z}$ and $K = \langle 2\rangle = \{0,2,4\} \cong \mathbb{Z}/3\mathbb{Z}$. **(i)–(ii) Normal:** $\mathbb{Z}/6\mathbb{Z}$ is abelian, so $H, K \trianglelefteq \mathbb{Z}/6\mathbb{Z}$ automatically. **(iii) Intersection:** $|H \cap K|$ divides $\gcd(2,3) = 1$, so

$H \cap K = \{0\}$. (Directly, $\{0,3\} \cap \{0,2,4\} = \{0\}$.) **(iv) Generation:** $|H+K| = \dfrac{|H||K|}{|H \cap K|} = \dfrac{2 \cdot 3}{1} = 6 = |\mathbb{Z}/6\mathbb{Z}|$, so $H + K = \mathbb{Z}/6\mathbb{Z}$. By Theorem 5.4.8, $\mathbb{Z}/6\mathbb{Z} \cong H \times K \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. The iso sends $(a, b) \in \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ (with $a \in \{0,3\}$, $b \in \{0,2,4\}$) to $a + b$. **Check the table:** $(0,0) \mapsto 0$, $(3,0) \mapsto 3$, $(0,2) \mapsto 2$, $(0,4) \mapsto 4$, $(3,2) \mapsto 5$, $(3,4) \mapsto 7 = 1$. The six images $\{0,3,2,4,5,1\}$ are all of $\mathbb{Z}/6\mathbb{Z}$, confirming bijectivity. This is the Chinese Remainder Theorem for groups, internally realized.

Worked Example 5.4.10 (Recovering the factors of $\mathrm{Sym}_3 \times \mathbb{Z}/2\mathbb{Z}$)**.** In $G = \mathrm{Sym}_3 \times \mathbb{Z}/2\mathbb{Z}$ (order 12) recognize an internal direct product decomposition.

Recognition. Apply the checklist to two coordinate subgroups of an externally given product, confirming the internal recognition theorem reproduces the original factors.

Solution. Let $H = \mathrm{Sym}_3 \times \{0\}$ and $K = \{e\} \times \mathbb{Z}/2\mathbb{Z}$, viewed inside G. **Normal:** $H = \ker(\pi_2)$ where $\pi_2 \colon G \to \mathbb{Z}/2\mathbb{Z}$ is projection, and $K = \ker(\pi_1)$ where $\pi_1 \colon G \to \mathrm{Sym}_3$; kernels are normal, so $H, K \trianglelefteq G$. **Intersection:** $H \cap K = \{(e,0)\} = 1$ since a common element has trivial second coordinate (from H) and trivial first coordinate (from K). **Generation:** $|HK| = \dfrac{|H||K|}{|H \cap K|} = \dfrac{6 \cdot 2}{1} = 12 = |G|$, so $HK = G$. Hence $G \cong H \times K \cong \mathrm{Sym}_3 \times \mathbb{Z}/2\mathbb{Z}$, recovering the original factors. *Check.* A typical element $\big((1\,2), 1\big) = \big((1\,2), 0\big) \cdot \big(e, 1\big)$ with the first factor in H and second in K — a valid unique factorization, as the theorem guarantees.

Worked Example 5.4.11 ($\mathbb{Z}/15\mathbb{Z}^\times$ as an internal direct product)**.** Show the unit group $G = (\mathbb{Z}/15\mathbb{Z})^\times$ (order $\varphi(15) = 8$) is internally a direct product of two proper subgroups, and identify them.

Recognition. Recognition theorem in an abelian group via the CRT splitting over the prime factors of $15 = 3 \cdot 5$.

Solution. $G = \{1, 2, 4, 7, 8, 11, 13, 14\}$ under multiplication mod 15, abelian of order 8. Use the CRT factors

$$H = \{x \in G \mid x \equiv 1 \pmod 5\}, \qquad K = \{x \in G \mid x \equiv 1 \pmod 3\}.$$

Identify H. An element is $\equiv 1 \pmod 5$ iff $5 \mid (x-1)$; among the units only 1 and 11 qualify (since $11 - 1 = 10$), so $H = \{1, 11\}$. As $11^2 = 121 = 8 \cdot 15 + 1 \equiv 1 \pmod{15}$, $H \cong \mathbb{Z}/2\mathbb{Z}$, the internal copy of the factor $(\mathbb{Z}/3)^\times$ (the residue mod 5 is fixed at 1, while $1, 11$ have residues $1, 2 \bmod 3$). **Identify K.** An element is $\equiv 1 \pmod 3$ iff $3 \mid (x-1)$; among the units $1, 4, 7, 13$ qualify (the differences $0, 3, 6, 12$ are divisible by 3), so $K = \{1, 4, 7, 13\}$. Take 7: $7^2 = 49 \equiv 4$, $7^3 \equiv 28 \equiv 13$, $7^4 \equiv 91 \equiv 1 \pmod{15}$, so $K = \langle 7 \rangle \cong \mathbb{Z}/4\mathbb{Z}$. *Checklist.* Abelian $\Rightarrow$ both normal. For the intersection, an element of $H \cap K$ is $\equiv 1 \pmod 5$ and $\equiv 1 \pmod 3$, hence $\equiv 1 \pmod{15}$, i.e. equals 1; so $H \cap K = 1$. Then $|HK| = \dfrac{|H||K|}{|H \cap K|} = \dfrac{2 \cdot 4}{1} = 8 = |G|$, so $HK = G$. *Conclusion.* By Theorem 5.4.8, $(\mathbb{Z}/15\mathbb{Z})^\times \cong H \times K \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$. *Sanity check.* This matches the CRT statement $(\mathbb{Z}/15)^\times \cong (\mathbb{Z}/3)^\times \times (\mathbb{Z}/5)^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$, since $(\mathbb{Z}/3)^\times \cong \mathbb{Z}/2\mathbb{Z}$ and $(\mathbb{Z}/5)^\times \cong \mathbb{Z}/4\mathbb{Z}$.

Worked Example 5.4.12 ($(\mathbb{Z}/n\mathbb{Z})^\times$ splits over prime powers)**.** Show that for $n = p_1^{a_1} \cdots p_t^{a_t}$ the unit group splits as an internal direct product

$$(\mathbb{Z}/n\mathbb{Z})^\times \;\cong\; (\mathbb{Z}/p_1^{a_1}\mathbb{Z})^\times \times \cdots \times (\mathbb{Z}/p_t^{a_t}\mathbb{Z})^\times,$$

and illustrate with $n = 12$.

Recognition. Iterated recognition theorem driven by the Chinese Remainder Theorem ring isomorphism, whose unit groups multiply.

Solution. **General statement.** The CRT ring isomorphism $\mathbb{Z}/n\mathbb{Z} \cong \prod_i \mathbb{Z}/p_i^{a_i}\mathbb{Z}$ restricts to a group isomorphism on units, since a tuple is a unit iff each coordinate is. Inside $(\mathbb{Z}/n\mathbb{Z})^\times$ define $H_i = \{x \mid x \equiv 1 \pmod{p_j^{a_j}}$ for all $j \neq i\}$; then H_i is the internal copy of $(\mathbb{Z}/p_i^{a_i}\mathbb{Z})^\times$. Each $H_i \trianglelefteq G$ (abelian), each H_i meets the product $\prod_{j \neq i} H_j$ in 1 (an element of that product is $\equiv 1 \pmod{p_i^{a_i}}$, and an element of H_i is $\equiv 1$ modulo every other prime power, so an element of both is $\equiv 1 \pmod n$), and $\prod_i |H_i| = \prod_i \varphi(p_i^{a_i}) = \varphi(n) = |G|$ forces $H_1 \cdots H_t = G$. The recognition theorem (applied repeatedly) gives the internal direct product. **Illustration $n = 12 = 2^2 \cdot 3$.** $(\mathbb{Z}/12)^\times = \{1, 5, 7, 11\}$, order $\varphi(12) = 4$. Set $H = \{x \equiv 1 \pmod 3\} = \{1, 7\} \cong (\mathbb{Z}/4)^\times \cong \mathbb{Z}/2\mathbb{Z}$ (indeed $7 \equiv 1 \pmod 3$, $7 \equiv 3 \pmod 4$, $7^2 = 49 \equiv 1$), and $K = \{x \equiv 1 \pmod 4\} = \{1, 5\} \cong (\mathbb{Z}/3)^\times \cong \mathbb{Z}/2\mathbb{Z}$ ($5 \equiv 1 \pmod 4$, $5 \equiv 2 \pmod 3$, $5^2 = 25 \equiv 1$). *Checklist.* Both normal

(abelian); $H \cap K$: an element is $\equiv 1 \pmod 4$ and $\equiv 1 \pmod 3$, so $\equiv 1 \pmod{12}$, hence $H \cap K = \{1\}$; $|HK| = \frac{2\cdot 2}{1} = 4 = |G|$, so $HK = G$. *Conclusion.* $(\mathbb{Z}/12)^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} = V_4$. *Check.* Every nonidentity element $5, 7, 11$ squares to 1 ($5^2 = 25 \equiv 1,\ 7^2 = 49 \equiv 1,\ 11^2 = 121 \equiv 1$), so the group is elementary abelian of order 4, consistent with V_4.

Worked Example 5.4.13 (Why D_8 is NOT a direct product of proper subgroups)**.** Show $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s\rangle$ cannot be written as an internal direct product $H \times K$ of two proper nontrivial subgroups.

Recognition. Recognition theorem run in reverse: a direct product of two proper factors would force a specific center structure that D_8 lacks. The key obstruction is the center.

Solution. Suppose $D_8 \cong H \times K$ with H, K proper nontrivial. Then $|H||K| = 8$ with each factor > 1; the only split into *two* factors each > 1 is $\{|H|, |K|\} = \{2, 4\}$. In a direct product, the center is $Z(H \times K) = Z(H) \times Z(K)$. The order-2 factor is its own center, and the order-4 factor (either $\mathbb{Z}/4\mathbb{Z}$ or V_4) is abelian, so equals its center; hence $Z(D_8)$ would have order $|Z(H)| \cdot |Z(K)| = 2 \cdot 4 = 8$, i.e. D_8 would be abelian. But $Z(D_8) = \langle r^2\rangle$ has order 2, and D_8 is nonabelian (e.g. $rs \neq sr$). Contradiction. **Alternative direct argument via the recognition checklist.** Any normal subgroup of D_8 of order 2 must be central, hence equals $Z(D_8) = \langle r^2\rangle$ (the unique central involution). So if $|H| = 2$ then $H = \langle r^2\rangle$, and likewise the order-4 normal subgroup K contains r^2 (every subgroup of order 4 in D_8 contains $\langle r^2\rangle$). Then $r^2 \in H \cap K \neq 1$, violating condition (iii). Hence no valid decomposition exists. *Check.* D_8 does have $\langle r\rangle \cong \mathbb{Z}/4\mathbb{Z}$ normal and $\langle s\rangle \cong \mathbb{Z}/2\mathbb{Z}$ with $\langle r\rangle \cap \langle s\rangle = 1$ and $\langle r\rangle\langle s\rangle = D_8$ — but $\langle s\rangle$ is *not normal* ($rsr^{-1} = r^2 s \notin \langle s\rangle$), so condition (ii) fails; this realizes D_8 as a *semidirect* (not direct) product $\mathbb{Z}/4\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$, the subject of the next section.

Caution. Having $H \trianglelefteq G$, $H \cap K = 1$, and $HK = G$ with K *not* normal does *not* give a direct product — it gives a semidirect product $H \rtimes K$. The split exact sequence below has a section s but the extension need not be central/trivial:

$$1 \longrightarrow H \hookrightarrow H \rtimes K \underset{\overset{s}{\curvearrowleft}}{\overset{\pi}{\twoheadrightarrow}} K \longrightarrow 1$$

Diagram explanation. Objects: Five nodes in a sequence: the trivial group 1 at each end; H a normal subgroup; $H \rtimes K$ the semidirect product (the extension group); and K the quotient group. This is a short exact sequence of groups, encoding the extension of K by H.

Arrows: The leftmost $1 \to H$ is the unique map from the trivial group. $H \hookrightarrow H \rtimes K$ is the canonical inclusion $h \mapsto (h, 1)$, indicated by the hooked arrow. $H \rtimes K \twoheadrightarrow K$ is the canonical surjection $(h, k) \mapsto k$, the projection onto the quotient factor; it is surjective (two-headed). The rightward $K \to 1$ is the unique map to the trivial group. The curved arrow $s\colon K \to H \rtimes K$, $k \mapsto (1, k)$, is a *section* (splitting): it satisfies $\pi \circ s = \mathrm{id}_K$, meaning the sequence splits. Its image $s(K)$ need not centralize H; it does exactly when K acts on H trivially (i.e. $[H, K] = 1$).

What commutes: The exactness conditions: $\mathrm{im}(1 \to H) = 1 = \ker(H \hookrightarrow H \rtimes K)$; $\mathrm{im}(H \hookrightarrow H \rtimes K) = H = \ker(H \rtimes K \twoheadrightarrow K)$; $\mathrm{im}(H \rtimes K \twoheadrightarrow K) = K = \ker(K \to 1)$. Additionally the section satisfies $\pi \circ s = \mathrm{id}_K$: the composite $K \xrightarrow{s} H \rtimes K \xrightarrow{\pi} K$ is the identity.

Why it commutes: For exactness at $H \rtimes K$: every $(h, 1)$ in the image of the inclusion maps to $1 \in K$ under the projection, so image $\subseteq$ kernel; conversely $(h, k) \mapsto 1$ forces $k = 1$, giving $(h, 1) \in \mathrm{im}(H \hookrightarrow H \rtimes K)$, so kernel $\subseteq$ image. For the section: $\pi(s(k)) = \pi(1, k) = k = \mathrm{id}_K(k)$, confirmed by the formula. The section exists because the sequence splits, which means $H \rtimes K \cong H \rtimes K$ for *some* action of K on H — the choice of action (conjugation in $H \rtimes K$) is exactly what makes it semidirect rather than direct.

Why this matters here: This diagram appears in the pitfall block immediately after the recognition theorem to mark the boundary between direct and semidirect products. The sequence splits (the section s exists) in *both* cases; the difference is whether $s(K)$ centralizes H, i.e. whether $[H, K] = 1$. Displaying the split exact sequence makes that distinction concrete: the four conditions of the theorem hold for a direct product, but removing the normality of K while keeping $H \trianglelefteq G$, $H \cap K = 1$, $HK = G$ yields exactly this more general split sequence.

Concrete example: $H = \mathbb{Z}/3\mathbb{Z}$, $K = \mathbb{Z}/2\mathbb{Z}$, $H \rtimes K = \mathrm{Sym}_3$ (where K acts by inversion on H). The inclusion $\mathbb{Z}/3\mathbb{Z} \hookrightarrow \mathrm{Sym}_3$ sends $1 \mapsto (1\,2\,3)$; the projection $\mathrm{Sym}_3 \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$ is the sign map; and the section

$s\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Sym}_3$ sends $1 \mapsto (1\,2)$ (a transposition). The section does *not* centralize $H = A_3$, confirming a semidirect (not direct) product.

Common pitfall: Seeing a split exact sequence, students sometimes assume the product must be direct. Splitting means the section s exists, but the extension is direct only when $s(K)$ centralizes H — equivalently $K \trianglelefteq H \rtimes K$. In the semidirect case K is *not* normal, and conjugation by $s(k)$ acts nontrivially on H.

Takeaway: The point of this diagram is that splitting of the short exact sequence $1 \to H \to H \rtimes K \to K \to 1$ captures the existence of s but not centrality, so direct products are the special split extensions where $s(K)$ also normalizes — in fact centralizes — H.

The product is *direct* precisely when, in addition, $K \trianglelefteq G$ (equivalently $[H, K] = 1$), which makes $s(K)$ centralize H. The D_8 example above is exactly the non-direct case.

Exercises (from the text).

1. Let G be a group. Prove that if $x, y \in G$ then $[y, x] = [x, y]^{-1}$. Deduce that for any subsets A and B of G, $[A, B] = [B, A]$ (recall that $[A, B]$ is the subgroup of G generated by the commutators $[a, b]$).
2. Prove that a subgroup H of G is normal if and only if $[G, H] \leq H$.
3. Let $a, b, c \in G$. Prove that
   (a) $[a, bc] = [a, c](c^{-1}[a, b]c)$
   (b) $[ab, c] = (b^{-1}[a, c]b)[b, c]$.
4. Find the commutator subgroups of S_4 and A_4.
5. Prove that A_n is the commutator subgroup of S_n for all $n \geq 5$.
6. Exhibit a representative of each cycle type of A_5 as a commutator in S_5.
7. Prove that if p is a prime and P is a non-abelian group of order p^3 then $P' = Z(P)$.
8. Assume $x, y \in G$ and both x and y commute with $[x, y]$. Prove that for all $n \in \mathbf{Z}^+$, $(xy)^n = x^n y^n [y, x]^{\frac{n(n-1)}{2}}$.
9. Prove that if p is an odd prime and P is a group of order p^3 then the pth power map $x \mapsto x^p$ is a homomorphism of P into $Z(P)$. If P is not cyclic, show that the kernel of the pth power map has order p^2 or p^3. Is the squaring map a homomorphism in non-abelian groups of order 8? Where is the oddness of p needed in the above proof? [Use Exercise 8.]
10. Prove that a finite abelian group is the direct product of its Sylow subgroups.
11. Prove that if $G = HK$ where H and K are characteristic subgroups of G with $H \cap K = 1$ then $\mathrm{Aut}(G) \cong \mathrm{Aut}(H) \times \mathrm{Aut}(K)$. Deduce that if G is an abelian group of finite order then $\mathrm{Aut}(G)$ is isomorphic to the direct product of the automorphism groups of its Sylow subgroups.
12. Use Theorem 4.17 to describe the automorphism group of a finite cyclic group.
13. Prove that D_{8n} is not isomorphic to $D_{4n} \times \mathbf{Z}_2$.
14. Let $G = \{(a_{ij}) \in GL_n(F) \mid a_{ij} = 0 \text{ if } i > j, \text{ and } a_{11} = a_{22} = \cdots = a_{nn}\}$, where F is a field, be the group of upper triangular matrices all of whose diagonal entries are equal. Prove that $G \cong D \times U$, where D is the group of all nonzero multiples of the identity matrix and U is the group of upper triangular matrices with 1's down the diagonal.
15. If A and B are normal subgroups of G such that G/A and G/B are both abelian, prove that $G/(A \cap B)$ is abelian.
16. Prove that if K is a normal subgroup of G then $K' \trianglelefteq G$.
17. If K is a normal subgroup of G and K is cyclic, prove that $G' \leq C_G(K)$. [Recall that the automorphism group of a cyclic group is abelian.]

18. Let $K_1, K_2, \ldots, K_n$ be non-abelian simple groups and let $G = K_1 \times K_2 \times \cdots \times K_n$. Prove that every normal subgroup of G is of the form $G_I = \prod_{i \in I} K_i$ for some subset I of $\{1, 2, \ldots, n\}$ (where G_I is defined in Exercise 2 of Section 1). [If $N \trianglelefteq G$ and $x = (a_1, \ldots, a_n) \in N$ with some $a_i \neq 1$, then show that there is some $g_i \in G_i$ not commuting with a_i. Show $[(1, \ldots, g_i, \ldots, 1), x] \in K_i \cap N$ and deduce $K_i \leq N$.]

19. A group H is called perfect if $H' = H$ (i.e., H equals its own commutator subgroup).

    (a) Prove that every non-abelian simple group is perfect.

    (b) Prove that if H and K are perfect subgroups of a group G then $\langle H, K \rangle$ is also perfect. Extend this to show that the subgroup of G generated by any collection of perfect subgroups is perfect.

    (c) Prove that any conjugate of a perfect subgroup is perfect.

    (d) Prove that any group G has a unique maximal perfect subgroup and that this subgroup is normal.

20. If G_1 and G_2 are groups, prove that $\mathrm{Aut}(G_1 \times G_2)$ contains a subgroup isomorphic to $\mathrm{Aut}(G_1) \times \mathrm{Aut}(G_2)$.

21. Let $H(F)$ be the Heisenberg group over the field F, cf. Exercise 11 of Section 1.4. Find an explicit formula for the commutator $[X, Y]$, where $X, Y \in H(F)$, and show that the commutator subgroup of $H(F)$ equals the center of $H(F)$ (cf. Section 2.2, Exercise 14).

Practice problems.

1. In $D_{10} = \langle r, s \mid r^5 = s^2 = 1,\ srs^{-1} = r^{-1} \rangle$, compute the commutator $[r, s]$ explicitly and use it to determine the commutator subgroup D_{10}' and the abelianization D_{10}/D_{10}'.
   Answer. $[r, s] = r^{-1}s^{-1}rs = r^{-1}(s^{-1}rs) = r^{-1}r^{-1} = r^{-2} = r^3$. Since 5 is prime, $\langle r^3 \rangle = \langle r \rangle$, so $D_{10}' = \langle r \rangle \cong \mathbb{Z}/5\mathbb{Z}$ (a normal subgroup with abelian quotient capping it from above), and $D_{10}/D_{10}' \cong \mathbb{Z}/2\mathbb{Z}$. Check: $5 \cdot 2 = 10$.

2. In an arbitrary group G, assume the single commutator $c = [x, y]$ is central in G and expand $(xy)^2$ in the form $x^2y^2c^{\pm 1}$, identifying the sign.
   Answer. From $xy = yx\,[x, y]$ we get $yx = xy\,[x, y]^{-1} = xy\,[y, x] = xy\,c^{-1}$. Hence $(xy)^2 = x(yx)y = x(xy\,c^{-1})y = x^2y^2c^{-1}$, where the central c^{-1} slides freely past y. Thus $(xy)^2 = x^2y^2[y, x]$, the $n = 2$ instance of the centered power formula $(xy)^n = x^n y^n [y, x]^{n(n-1)/2}$.

3. Compute G' and the abelianization G/G' for (a) $G = \mathbb{Z}/8\mathbb{Z}$ (additive) and (b) $G = \mathrm{Sym}_4$.
   Answer. (a) $\mathbb{Z}/8\mathbb{Z}$ is abelian, so by Corollary 5.4.3 $G' = 0$ and $G/G' \cong \mathbb{Z}/8\mathbb{Z}$. (b) Every commutator lies in A_4 (it is even, as sgn is a homomorphism to the abelian $\{\pm 1\}$), so $\mathrm{Sym}_4{}' \leq A_4$; conversely A_4 is generated by the 3-cycles, each of which is a commutator (e.g. $[(1\,2), (1\,3)] = (1\,2)(1\,3)(1\,2)(1\,3) = (1\,2\,3)$; every 3-cycle is conjugate to this one, and conjugates of commutators are commutators), so $A_4 \leq \mathrm{Sym}_4{}'$. Since $\mathrm{Sym}_4/A_4 \cong \mathbb{Z}/2\mathbb{Z}$ is abelian, $G' \leq A_4$ too; hence $\mathrm{Sym}_4{}' = A_4$ and $\mathrm{Sym}_4/\mathrm{Sym}_4{}' \cong \mathbb{Z}/2\mathbb{Z}$. Check: $12 \cdot 2 = 24$.

4. Realize $\mathbb{Z}/10\mathbb{Z} = \mathbb{Z}/10\mathbb{Z}$ as an internal direct product of two proper subgroups via the recognition theorem.
   Answer. (Additive.) Let $H = \langle 5 \rangle = \{0, 5\} \cong \mathbb{Z}/2\mathbb{Z}$ and $K = \langle 2 \rangle = \{0, 2, 4, 6, 8\} \cong \mathbb{Z}/5\mathbb{Z}$. Abelian $\Rightarrow$ both normal. $|H \cap K| \mid \gcd(2, 5) = 1$, so $H \cap K = \{0\}$; then $|H + K| = \frac{2 \cdot 5}{1} = 10 = |\mathbb{Z}/10\mathbb{Z}|$, so $H + K = \mathbb{Z}/10\mathbb{Z}$. By Theorem 5.4.8, $\mathbb{Z}/10\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$.

5. Test the four recognition conditions for $H = \langle r \rangle$ and $K = \langle s \rangle$ in $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ sr = r^{-1}s \rangle$. Exactly one condition fails — identify it and state the correct conclusion.
   Answer. $H = \langle r \rangle \cong \mathbb{Z}/4\mathbb{Z}$ is normal (index 2); $K = \langle s \rangle \cong \mathbb{Z}/2\mathbb{Z}$; $H \cap K = 1$ (the reflection s is not a rotation, so $s \notin \langle r \rangle$, and the only common element is 1); and $HK = D_8$ (counting $|HK| = \frac{4 \cdot 2}{1} = 8$). But $K \trianglelefteq G$ *fails*: $rsr^{-1} = r^2 s \notin \langle s \rangle$. So condition (ii) breaks, and D_8 is the *semidirect* product $\mathbb{Z}/4\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$, not a direct product.

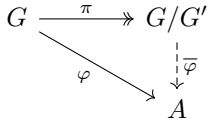
6. Show that $(\mathbb{Z}/8\mathbb{Z})^\times = (\mathbb{Z}/8\mathbb{Z})^\times$ is an internal direct product of two subgroups of order 2, and identify the resulting group up to isomorphism.
   Answer. $(\mathbb{Z}/8\mathbb{Z})^\times = \{1, 3, 5, 7\}$, order 4, abelian. Take $H = \langle 3 \rangle = \{1, 3\}$ (since $3^2 = 9 \equiv 1$) and $K = \langle 5 \rangle = \{1, 5\}$ (since $5^2 = 25 \equiv 1$), each of order 2. $H \cap K = \{1\}$, and $|HK| = \frac{2 \cdot 2}{1} = 4 = |G|$, so $HK = G$; abelian gives both normal. By Theorem 5.4.8, $(\mathbb{Z}/8\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} = V_4$ — consistent with every nonidentity element squaring to 1 ($3^2, 5^2, 7^2 \equiv 1 \pmod 8$).

7. Compute the commutator subgroup and abelianization of $D_{12} = \langle r, s \mid r^6 = s^2 = 1,\ srs^{-1} = r^{-1}\rangle$.
Answer. **Lower bound.** $[r, s] = r^{-1}(s^{-1}rs) = r^{-1}r^{-1} = r^{-2}$, so $\langle r^2\rangle = \{1, r^2, r^4\} \leq D_{12}{}'$, of order 3. **Upper bound.** $\langle r^2\rangle \trianglelefteq D_{12}$ and the quotient $D_{12}/\langle r^2\rangle$ has order 4, generated by commuting involutions $\bar{r}, \bar{s}$ (since $\bar{r}^2 = 1$ and $\bar{s}\bar{r} = \bar{r}^{-1}\bar{s} = \bar{r}\bar{s}$), hence abelian; so $D_{12}{}' \leq \langle r^2\rangle$ by Proposition 5.4.2(2). The bounds meet: $D_{12}{}' = \langle r^2\rangle \cong \mathbb{Z}/3\mathbb{Z}$, abelianization $D_{12}/D_{12}{}' \cong V_4$. Check: $3 \cdot 4 = 12$.

8. Suppose $H \trianglelefteq G$ and $K \trianglelefteq G$ with $H \cap K = 1$ and $HK = G$. Using the commutator trick, prove that every element of H commutes with every element of K.
Answer. Fix $h \in H,\ k \in K$ and form $[h, k] = h^{-1}k^{-1}hk$. Grouping as $h^{-1}(k^{-1}hk)$ shows $[h, k] \in H$ (since $k^{-1}hk \in H$ by $H \trianglelefteq G$); grouping as $(h^{-1}k^{-1}h)k$ shows $[h, k] \in K$ (since $h^{-1}k^{-1}h \in K$ by $K \trianglelefteq G$). Hence $[h, k] \in H \cap K = 1$, so $[h, k] = 1$ and $hk = kh$. This is Step 1 of Theorem 5.4.8.

Additional exercises.

1. Prove that G/G' is the *largest abelian quotient*: for every homomorphism $\varphi\colon G \to A$ with A abelian there is a unique homomorphism $\overline{\varphi}\colon G/G' \to A$ with $\varphi = \overline{\varphi} \circ \pi$, where $\pi\colon G \to G/G'$ is the quotient map.
Answer. For any x, y, $\varphi([x, y]) = [\varphi(x), \varphi(y)] = 1$ since A is abelian, so $G' \leq \ker\varphi$. With $G' \leq \ker\varphi$ in hand, the universal property of quotients yields a unique $\overline{\varphi}\colon G/G' \to A$ with $\overline{\varphi} \circ \pi = \varphi$ (well-defined because $G' \leq \ker\varphi$; unique because π is surjective). Equivalently, abelianization is left adjoint to the inclusion of abelian groups into all groups.



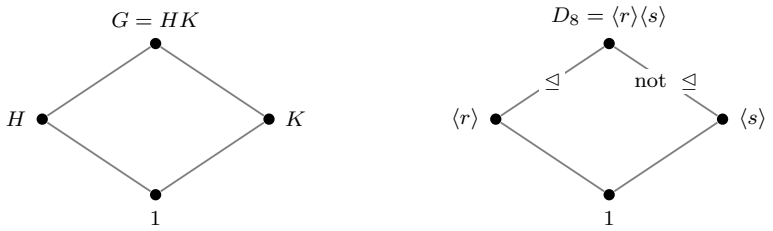
2. Let P be a nonabelian group of order p^3 (p prime). Prove $P' = Z(P)$ and that both have order p.
Answer. $Z(P) \neq 1$ (p-group), and $|Z(P)| \neq p^2$: otherwise $P/Z(P)$ would have order p, hence cyclic, forcing P abelian. Also $|Z(P)| \neq p^3$ (nonabelian). So $|Z(P)| = p$ and $P/Z(P)$ has order p^2, hence is abelian; by Proposition 5.4.2(2), $P' \leq Z(P)$, so $|P'| \leq p$. But P nonabelian gives $P' \neq 1$, so $|P'| = p = |Z(P)|$ and the inclusion $P' \leq Z(P)$ is an equality: $P' = Z(P)$.

3. Let $H, K \trianglelefteq G$ with $H \cap K = 1$, both H and K abelian, and $G = HK$. Prove G is abelian and $G \cong H \times K$. Then use the center to disprove any direct decomposition of D_8 into two proper factors.
Answer. By the recognition Step 1, $[H, K] = 1$; together with H, K abelian this makes any two elements h_1k_1, h_2k_2 commute, so G is abelian, and Theorem 5.4.8 gives $G \cong H \times K$. For D_8: a split $D_8 \cong H \times K$ with proper factors forces $\{|H|, |K|\} = \{2, 4\}$; then $Z(D_8) = Z(H) \times Z(K) = H \times K$ has order $2 \cdot 4 = 8$, making D_8 abelian — contradicting $|Z(D_8)| = 2$. So D_8 is not a direct product of proper subgroups.

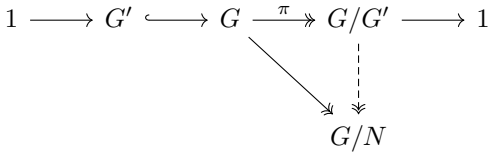
4. Determine $A_4{}'$ by the lower-/upper-bound method and confirm the order identity $|G'| \cdot |G/G'| = |G|$.
Answer. **Lower bound:** $[(1\,2\,3), (1\,2\,4)] = (1\,2)(3\,4)$, a double transposition, and its A_4-conjugates give the Klein four-group $V = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\} \leq A_4{}'$ (as $A_4{}' \trianglelefteq A_4$). **Upper bound:** $V \trianglelefteq A_4$ with $A_4/V \cong \mathbb{Z}/3\mathbb{Z}$ abelian, so $A_4{}' \leq V$ by Proposition 5.4.2(2). The bounds meet: $A_4{}' = V \cong V_4$, abelianization $A_4/A_4{}' \cong \mathbb{Z}/3\mathbb{Z}$, and $|G'| \cdot |G/G'| = 4 \cdot 3 = 12 = |A_4|$.

Commutative-diagram exercises.

1. State and prove the universal property of abelianization: the quotient $\pi\colon G \to G/G'$ is *initial* among homomorphisms from G to abelian groups. Fill in the dashed unique factorization in the triangle below and justify both existence and uniqueness.
Answer. Given $\varphi\colon G \to A$ with A abelian, set $\overline{\varphi}([x]) = \varphi(x)$. *Existence:* $G' \leq \ker\varphi$ (commutators map to 1 in the abelian A), so $\overline{\varphi}$ is well-defined and $\varphi = \overline{\varphi} \circ \pi$. *Uniqueness:* π is surjective, so any map agreeing with φ after π is determined on every $[x]$. Hence G/G' is the universal abelian quotient.



2. Recognition theorem as a commuting diagram. Show that $\psi\colon H \times K \to G$, $(h, k) \mapsto hk$, is an isomorphism (under conditions $H, K \trianglelefteq G$, $H \cap K = 1$, $HK = G$) by exhibiting its inverse via the unique factorization $g = hk$ and checking the square below with the coordinate maps $q_H\colon G \to H$, $q_K\colon G \to K$.
Answer. By Step 1, $[H, K] = 1$, so ψ is a homomorphism; $HK = G$ gives surjectivity and $H \cap K = 1$ gives



injectivity (each g has a *unique* $g = hk$). Define $\psi^{-1}(g) = (q_H(g), q_K(g))$ from that unique factorization; then for $(h,k) \in H \times K$ we have $q_H(\psi(h,k)) = q_H(hk) = h = \pi_H(h,k)$, i.e. $q_H \circ \psi = \pi_H$, so the square commutes and $G \cong H \times K$ internally.

$$\begin{array}{ccc} H \times K & \xrightarrow[\cong]{\psi} & G \\ {\scriptstyle \pi_H}\downarrow & & \downarrow{\scriptstyle q_H} \\ H & = & H \end{array}$$

3. Draw the subgroup-lattice diamond for an internal direct product $G = HK$ (top G, shoulders H, K both normal, bottom $1 = H \cap K$), and contrast it with the diamond of the semidirect product $D_8 = \langle r \rangle \rtimes \langle s \rangle$, indicating which shoulder loses normality.
Answer. **Direct:** both shoulders are normal, $H \cap K = 1$, $HK = G$, and $[H,K] = 1$ — the diamond is symmetric (both shoulders normal). **Semidirect (D_8):** same diamond but $K = \langle s \rangle$ is *not* normal ($rsr^{-1} = r^2 s \notin \langle s \rangle$), so the right shoulder is a non-normal complement and the symmetry breaks. Normality of *both* shoulders is exactly what upgrades a semidirect to a direct product.

4. Draw the abelianization short exact sequence $1 \to G' \to G \to G/G' \to 1$ and prove that every abelian quotient G/N factors through it, i.e. G/N is abelian $\iff$ $G' \leq N$. Indicate the induced commuting triangle when $G' \leq N$.
Answer. The sequence is exact: $G' \trianglelefteq G$ with cokernel G/G'. By Proposition 5.4.2(2), G/N is abelian $\iff$ $G' \leq N$; in that case the third isomorphism theorem gives $G/N \cong (G/G')/(N/G')$, so $G \to G/N$ factors as $G \xrightarrow{\pi} G/G' \to G/N$, and the triangle below commutes. Functoriality: a homomorphism $G \to H$ carries G' into H', inducing $G/G' \to H/H'$.

5.5 Semidirect Products

Semidirect products

The direct product $H \times K$ is the case in which H and K commute past one another: $(h,1)(1,k) = (h,k) = (1,k)(h,1)$. The semidirect product relaxes this. We keep H normal, but allow conjugation by elements of K to act on H as a nontrivial automorphism. The bookkeeping for that action is a homomorphism $\varphi\colon K \to \mathrm{Aut}(H)$.

Definition 5.5.1 (External semidirect product)**.** Let H and K be groups and let $\varphi\colon K \to \mathrm{Aut}(H)$ be a homomorphism. Write $\varphi(k) = \varphi_k \in \mathrm{Aut}(H)$, and write the action multiplicatively: $k \cdot h := \varphi_k(h)$. The *semidirect product* $H \rtimes_\varphi K$ is the set $H \times K$ with multiplication

$$(h_1, k_1)\,(h_2, k_2) \;=\; \big(h_1\, \varphi_{k_1}(h_2),\; k_1 k_2\big).$$

When φ is understood we write $H \rtimes K$.

Proposition 5.5.2 ($H \rtimes_\varphi K$ is a group; D&F Thm. 5.5.10)**.** *With H, K, φ as above, $H \rtimes_\varphi K$ is a group of order $|H||K|$. Identifying $h \leftrightarrow (h,1)$ and $k \leftrightarrow (1,k)$:*

1. *the maps $h \mapsto (h,1)$ and $k \mapsto (1,k)$ are injective homomorphisms, so H and K are (isomorphic to) subgroups; with these identifications every element factors uniquely as $(h,k) = hk$;*
2. *$H \trianglelefteq H \rtimes K$ and $K \leq H \rtimes K$, with $H \cap K = 1$ and $HK = H \rtimes K$;*
3. *for $h \in H,\ k \in K$ one has $khk^{-1} = \varphi_k(h)$, i.e. conjugation by k realizes φ_k;*
4. *$H \rtimes_\varphi K$ is abelian $\iff$ φ is trivial and both H, K are abelian; in particular $H \rtimes_\varphi K = H \times K$ (direct product) $\iff$ φ is the trivial homomorphism.*

Proof. Associativity. Compute both bracketings of $(h_1,k_1)(h_2,k_2)(h_3,k_3)$. Left first:

$$\big[(h_1,k_1)(h_2,k_2)\big](h_3,k_3) = \big(h_1\varphi_{k_1}(h_2),\ k_1k_2\big)(h_3,k_3) = \big(h_1\varphi_{k_1}(h_2)\,\varphi_{k_1k_2}(h_3),\ k_1k_2k_3\big).$$

Right first, using that φ is a homomorphism ($\varphi_{k_1k_2} = \varphi_{k_1}\varphi_{k_2}$) and that φ_{k_1} is an automorphism:

$$(h_1,k_1)\big[(h_2,k_2)(h_3,k_3)\big] = (h_1,k_1)\big(h_2\varphi_{k_2}(h_3),\ k_2k_3\big) = \big(h_1\varphi_{k_1}(h_2)\,\varphi_{k_1}(\varphi_{k_2}(h_3)),\ k_1k_2k_3\big).$$

Since $\varphi_{k_1}(\varphi_{k_2}(h_3)) = \varphi_{k_1k_2}(h_3)$, the two agree.

Identity and inverses. $(1,1)$ is the identity: $(1,1)(h,k) = (\varphi_1(h),k) = (h,k)$ because $\varphi_1 = \mathrm{id}_H$, and $(h,k)(1,1) = (h\varphi_k(1),k) = (h,k)$. The inverse of (h,k) is $(\varphi_{k^{-1}}(h^{-1}),\ k^{-1})$: indeed

$$(h,k)\big(\varphi_{k^{-1}}(h^{-1}),k^{-1}\big) = \big(h\,\varphi_k(\varphi_{k^{-1}}(h^{-1})),\ kk^{-1}\big) = \big(h\,\varphi_{kk^{-1}}(h^{-1}),\ 1\big) = (h\,h^{-1},1) = (1,1).$$

So $H \rtimes K$ is a group, and as a set it is $H \times K$, so $|H \rtimes K| = |H||K|$.

(1) On the slice $\{(h,1)\}$ the rule reads $(h_1,1)(h_2,1) = (h_1\varphi_1(h_2),1) = (h_1h_2,1)$, so $h \mapsto (h,1)$ is an injective homomorphism. On $\{(1,k)\}$ the rule reads $(1,k_1)(1,k_2) = (\varphi_{k_1}(1),k_1k_2) = (1,k_1k_2)$, so $k \mapsto (1,k)$ is too. Finally $(h,1)(1,k) = (h,k)$, and uniqueness of h,k is uniqueness of coordinates.

(2),(3) Compute the conjugate of $(h,1)$ by $(1,k)$:

$$(1,k)(h,1)(1,k)^{-1} = (\varphi_k(h),k)(1,k^{-1}) = (\varphi_k(h),1).$$

With the identification $khk^{-1} = \varphi_k(h) \in H$; this proves (3) and shows H is normalized by K. Since H is also normalized by itself and $H \rtimes K = HK$ (as $(h,k) = (h,1)(1,k)$), we get $H \trianglelefteq H \rtimes K$. Coordinatewise $(h,k) = (1,1)$ forces $h = 1, k = 1$, so $H \cap K = 1$, and $|HK| = |H||K| = |H \rtimes K|$ gives $HK = H \rtimes K$.

(4) If φ is trivial then $\varphi_k = \mathrm{id}_H$ for all k and the rule becomes $(h_1,k_1)(h_2,k_2) = (h_1h_2,k_1k_2)$, the direct product. Conversely, if the group is abelian then in particular $(1,k)(h,1) = (h,1)(1,k)$, i.e. $(\varphi_k(h),k) = (h,k)$, so $\varphi_k = \mathrm{id}_H$ for all k; abelianness of the product also forces H, K abelian. □

Remark 5.5.1. The rule is forced once you decide $H \trianglelefteq G$, K a complement, and $khk^{-1} = \varphi_k(h)$. Indeed $(h_1k_1)(h_2k_2) = h_1(k_1h_2k_1^{-1})k_1k_2 = h_1\varphi_{k_1}(h_2)\,k_1k_2$. So the formula is not an arbitrary convention – it is exactly "slide h_2 past k_1 by conjugating."

Method (Building an external semidirect product)**.** *Trigger.* You want a group containing a normal copy of H and a complementary copy of K in which K acts on H in a prescribed way (e.g. inversion, a cyclic permutation of generators, a field automorphism).

Recipe.

1. Pick H, K and decide the desired action of each $k \in K$ as an automorphism of H.
2. Package it as a homomorphism $\varphi\colon K \to \mathrm{Aut}(H)$, $k \mapsto \varphi_k$. *Check it is a homomorphism*: $\varphi_{k_1k_2} = \varphi_{k_1} \circ \varphi_{k_2}$ and $\varphi_1 = \mathrm{id}$. (Often you only need to send a generator of K to a chosen automorphism whose order divides the order of that generator.)
3. Form $H \rtimes_\varphi K$ with $(h_1,k_1)(h_2,k_2) = (h_1\varphi_{k_1}(h_2),k_1k_2)$.
4. Identify a presentation/known group via the relation $khk^{-1} = \varphi_k(h)$.

Caution. A function $K \to \mathrm{Aut}(H)$ must be a *homomorphism.* "Send the generator x of $K = \mathbb{Z}/n\mathbb{Z}$ to an automorphism α" is well defined as a homomorphism **iff** $\alpha^{\,n} = \mathrm{id}$, i.e. $|\alpha| \mid n$ inside $\mathrm{Aut}(H)$. Choosing α of the wrong order does not give a semidirect product at all.

Theorem 5.5.3 (Recognition / internal semidirect product; D&F Thm. 5.5.12)**.** *Let G be a group with subgroups H, K such that*

$$H \trianglelefteq G, \qquad K \leq G, \qquad H \cap K = 1, \qquad HK = G.$$

Let $\varphi\colon K \to \mathrm{Aut}(H)$ be the conjugation action $\varphi_k(h) = khk^{-1}$. Then the map

$$\Phi\colon H \rtimes_\varphi K \longrightarrow G, \qquad (h,k) \longmapsto hk,$$

is an isomorphism. In this situation we say G is the internal *semidirect product of H by K and write $G = H \rtimes K$.*

Proof. φ lands in $\mathrm{Aut}(H)$ because $H \trianglelefteq G$ makes $h \mapsto khk^{-1}$ an automorphism of H, and $k \mapsto (h \mapsto khk^{-1})$ is a homomorphism since $(k_1k_2)h(k_1k_2)^{-1} = k_1(k_2hk_2^{-1})k_1^{-1}$.

Φ *is a bijection.* Since $HK = G$, Φ is onto. If $h_1k_1 = h_2k_2$ then $h_2^{-1}h_1 = k_2k_1^{-1} \in H \cap K = 1$, so $h_1 = h_2$, $k_1 = k_2$; thus Φ is one-to-one. (As a count, Φ is an injection between finite sets of equal size, since $|H \rtimes K| = |H||K| = |HK| = |G|$, the middle equality holding because $H \cap K = 1$.)

Φ *is a homomorphism.* Using $k_1h_2k_1^{-1} = \varphi_{k_1}(h_2)$,

$$\Phi\big((h_1,k_1)(h_2,k_2)\big) = \Phi\big(h_1\varphi_{k_1}(h_2),\, k_1k_2\big) = h_1\,(k_1h_2k_1^{-1})\,k_1k_2 = h_1k_1\,h_2k_2 = \Phi(h_1,k_1)\Phi(h_2,k_2). \qquad \square$$

Remark 5.5.2 (Splitting / split exact sequences). A semidirect product is exactly a split extension. The data $1 \to H \to G \to K \to 1$ together with a homomorphic section $s\colon K \to G$ (a *splitting*, $\pi \circ s = \mathrm{id}_K$) gives $G = H \rtimes s(K)$. The diagram

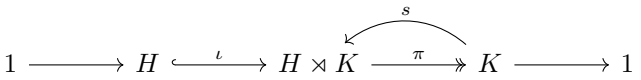


Diagram explanation. Objects: The five nodes are: the trivial group 1 (appearing at both ends), the normal subgroup H (a group), the semidirect product $H \rtimes_\varphi K$ (the middle group, containing copies of both H and K), and the complement K (a group). This is a short exact sequence of groups with an extra section arrow (a right inverse of π).

Arrows: $\iota\colon H \to H \rtimes K$, $\iota(h) = (h,1)$, is the inclusion of H as the first factor (a normal subgroup embedding). $\pi\colon H \rtimes K \to K$, $\pi(h,k) = k$, is the projection onto the second factor (a surjective homomorphism, drawn with two heads). $s\colon K \to H \rtimes K$, $s(k) = (1,k)$, is the canonical section or splitting (bent arrow, going right to left in the display), a homomorphism satisfying $\pi \circ s = \mathrm{id}_K$.

What commutes: Exactness at H: $\ker \iota = 1 = \mathrm{im}(\text{trivial map})$, so ι is injective. Exactness at $H \rtimes K$: $\mathrm{im}\,\iota = H \times \{1\} = \ker \pi$. Exactness at K: π is surjective ($\mathrm{im}\,\pi = K$). The splitting condition: $\pi \circ s = \mathrm{id}_K$, i.e. $\pi(s(k)) = \pi(1,k) = k$.

Why it commutes: For exactness, $\pi(\iota(h)) = \pi(h,1) = 1$, so $\mathrm{im}\,\iota \subseteq \ker \pi$; and if $\pi(h,k) = k = 1$ then $(h,k) = (h,1) = \iota(h)$, so $\ker \pi \subseteq \mathrm{im}\,\iota$. For the splitting: $(\pi \circ s)(k) = \pi(1,k) = k$ directly from the definitions of s and π.

Why this matters here: The diagram encodes exactly why a semidirect product is called a *split* extension: the sequence $1 \to H \to H \rtimes K \to K \to 1$ is exact (so $H \rtimes K$ is an extension of K by H), and s is a homomorphic right inverse to π (the splitting). This is the diagrammatic equivalent of Proposition 5.5.2: the section s makes K into a complement of H, and the action $\varphi_k(h) = khk^{-1}$ is read off from conjugation by $s(k)$.

Concrete example: Take $H = \mathbb{Z}/n\mathbb{Z}$, $K = \mathbb{Z}/2\mathbb{Z}$, $\varphi_s =$ inversion, giving D_{2n}. Then $\iota(r) = (r,1)$, $\pi(r,1) = 1$, $\pi(0,s) = s$, $s(s) = (0,s)$. Check: $\pi(s(s)) = \pi(0,s) = s$ and $\mathrm{im}\,\iota = \{(r^i,1)\} = \ker \pi$.

Common pitfall: Students confuse the section s with the inclusion ι. They are different maps with different domains: $\iota\colon H \to H \rtimes K$ and $s\colon K \to H \rtimes K$. Also, s need not make $s(K)$ normal in $H \rtimes K$ (it is normal only in the trivial-action / direct-product case), so do not read "splits" as "both inclusions are normal."

Takeaway: The point of this diagram is that a semidirect product $H \rtimes_\varphi K$ is precisely a short exact sequence $1 \to H \to H \rtimes K \to K \to 1$ equipped with a homomorphic splitting $s\colon K \to H \rtimes K$, and this splitting encodes the entire conjugation action φ.

commutes, where $\iota(h) = (h, 1)$, $\pi(h, k) = k$, $s(k) = (1, k)$. Exactness is $\operatorname{im}\iota = \ker\pi = H \times \{1\}$, and $\pi s = \mathrm{id}_K$ is the splitting. Conversely a direct product is the case where $s(K) \trianglelefteq G$ as well, i.e. both inclusions are normal. (D&F: the extension splits $\iff$ H has a complement in G $\iff$ G is a semidirect product.)

Corollary 5.5.4 (Trivial action = direct product)**.** *If φ is trivial, the section's image $s(K) = \{1\} \times K$ is also normal, the two projections both split, and $H \rtimes_\varphi K = H \times K$. Thus the direct product is the degenerate semidirect product.*

Method (Recognizing G as an internal semidirect product)**.** *Trigger.* You suspect a given G is $H \rtimes K$ for visible subgroups H, K (e.g. a normal Sylow subgroup and a complement).

Checklist (all four).

1. $H \trianglelefteq G$ (often: H is a unique Sylow subgroup, hence normal).
2. $K \leq G$ (any complementary subgroup).
3. $H \cap K = 1$ (e.g. coprime orders force this).
4. $HK = G$, equivalently $|H||K| = |G|$ with $H \cap K = 1$.

Then read off the action $\varphi_k(h) = khk^{-1}$ to name the group. If φ is trivial you have a direct product; otherwise a genuine (nonabelian, when H or K is nontrivially acted on) semidirect product.

Caution. You need *both* $H \trianglelefteq G$ and $HK = G$ and $H \cap K = 1$. Dropping "$HK = G$" (equivalently the order count) is fatal: in $\mathbb{Z}/4\mathbb{Z} = \{0, 1, 2, 3\}$ take $H = \{0, 2\} \trianglelefteq \mathbb{Z}/4\mathbb{Z}$ and $K = \{0, 2\}$; then $H \trianglelefteq G$, $K \leq G$, but $H \cap K = H \neq 1$ and $HK = H \neq G$ – no decomposition. Also: K need *not* be normal; if it is, you actually have a direct product.

Worked examples

Worked Example 5.5.5 ($D_{2n} \cong \mathbb{Z}/n\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$ via inversion)**.** Build the dihedral group D_{2n} as a semidirect product $\mathbb{Z}/n\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$, exhibiting the homomorphism φ explicitly, and match the standard presentation $r^n = s^2 = 1,\ srs^{-1} = r^{-1}$.

Recognition. We want a normal cyclic group of rotations $H = \langle r\rangle \cong \mathbb{Z}/n\mathbb{Z}$ and an order-2 complement $K = \langle s\rangle \cong \mathbb{Z}/2\mathbb{Z}$ with s acting on H by inversion. Inversion $\iota\colon a \mapsto -a$ is an automorphism of $\mathbb{Z}/n\mathbb{Z}$ of order ≤ 2, so it defines a homomorphism $\mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/n\mathbb{Z})$; the internal-recognition theorem then identifies $\mathbb{Z}/n\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$ with D_{2n}.

Solution. Let $H = \mathbb{Z}/n\mathbb{Z}$ (written additively, generator r of order n) and $K = \mathbb{Z}/2\mathbb{Z} = \{1, s\}$. Inversion $\iota \in \mathrm{Aut}(\mathbb{Z}/n\mathbb{Z})$ satisfies $\iota(a) = -a$ and $\iota^2(a) = -(-a) = a$, so $|\iota| \mid 2$. Define

$$\varphi\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/n\mathbb{Z}), \qquad \varphi_1 = \mathrm{id},\ \ \varphi_s = \iota.$$

This is a homomorphism because $\varphi_{s^2} = \varphi_1 = \mathrm{id} = \iota^2 = \varphi_s\varphi_s$. Form $G = \mathbb{Z}/n\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$. By Prop. 5.5.2 it has order $n \cdot 2 = 2n$, $H \trianglelefteq G$, $K \leq G$, $H \cap K = 1$, and

$$s\, r\, s^{-1} = \varphi_s(r) = \iota(r) = r^{-1}.$$

Thus $G = \langle r, s\rangle$ with $r^n = 1$, $s^2 = 1$, $srs^{-1} = r^{-1}$ – precisely the presentation of D_{2n}. The map $r \mapsto r,\ s \mapsto s$ extends to an isomorphism $G \cong D_{2n}$. *Check.* $|G| = 2n = |D_{2n}|$. Compute a product in the model: $(r, 1)(0, s)(r, 1) = (r, s)(r, 1) = (r\,\varphi_s(r), s) = (r\,r^{-1}, s) = (0, s)$, i.e. $r\,s\,r = s$, equivalently $srs^{-1} = r^{-1}$. Consistent. For $n \geq 3$ the action is nontrivial, so G is nonabelian, as expected.

Worked Example 5.5.6 (A nonabelian group of order $21 = 3 \cdot 7$)**.** Construct a nonabelian group of order 21 as $\mathbb{Z}/7\mathbb{Z} \rtimes_\varphi \mathbb{Z}/3\mathbb{Z}$, and find the order of the generators. Why does $3 \mid 7-1$ matter?

Recognition. $\mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) \cong (\mathbb{Z}/7\mathbb{Z})^\times \cong \mathbb{Z}/6\mathbb{Z}$ is cyclic of order 6, which has a (unique) subgroup of order 3 because $3 \mid 6$ (equivalently $3 \mid 7-1$). A nontrivial $\varphi\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z})$ exists exactly when $3 \mid |\mathrm{Aut}(\mathbb{Z}/7\mathbb{Z})| = 6$. That nontrivial action yields a nonabelian semidirect product.

Solution. $\mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) = (\mathbb{Z}/7\mathbb{Z})^\times = \{1,2,3,4,5,6\}$ under multiplication mod 7, cyclic of order 6 generated by 3 (powers: $3, 2, 6, 4, 5, 1$). An element of order 3 is 2, since $2^1 = 2$, $2^2 = 4$, $2^3 = 8 \equiv 1 \pmod 7$. Let $\alpha \in \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z})$ be multiplication by 2: $\alpha(a) = 2a \bmod 7$, with $|\alpha| = 3$. Define

$$\varphi\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}), \qquad \varphi(\overline{1}) = \alpha,$$

well defined because $|\alpha| = 3 \mid 3$. Set $G = \mathbb{Z}/7\mathbb{Z} \rtimes_\varphi \mathbb{Z}/3\mathbb{Z}$, of order $7 \cdot 3 = 21$. Writing x for the generator $(\overline{1}, 0)$ of $\mathbb{Z}/7\mathbb{Z}$ (order 7) and y for $(0, \overline{1})$ of $\mathbb{Z}/3\mathbb{Z}$ (order 3), the defining relation is

$$y\,x\,y^{-1} = \varphi(\overline{1})(x) = 2x = x^2 \quad (\text{additively } 2 \cdot \overline{1}),$$

so $G = \langle x, y \mid x^7 = 1,\ y^3 = 1,\ yxy^{-1} = x^2 \rangle$. *Check.* Apply the relation three times: $y^3 x y^{-3} = x^{2^3} = x^8 = x$ (since $8 \equiv 1 \bmod 7$), consistent with $y^3 = 1$. The action is nontrivial ($2 \not\equiv 1$), so G is nonabelian; its order 21 is correct. This is the unique nonabelian group of order 21.

Worked Example 5.5.7 (The nonabelian group of order pq ($q \mid p-1$))**.** For primes $q < p$ with $q \mid p-1$, build a nonabelian group of order pq as $\mathbb{Z}/p\mathbb{Z} \rtimes_\varphi \mathbb{Z}/q\mathbb{Z}$.

Recognition. $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z}) \cong (\mathbb{Z}/p\mathbb{Z})^\times \cong \mathbb{Z}/(p-1)\mathbb{Z}$ is cyclic of order $p-1$. Since $q \mid p-1$, this cyclic group has a unique subgroup of order q, giving a nontrivial homomorphism $\varphi\colon \mathbb{Z}/q\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$. (If $q \nmid p-1$ the only homomorphism is trivial and every group of order pq is cyclic.)

Solution. Let $H = \mathbb{Z}/p\mathbb{Z}$, $K = \mathbb{Z}/q\mathbb{Z}$. Choose a generator g of the cyclic group $(\mathbb{Z}/p\mathbb{Z})^\times$ and set $t = g^{(p-1)/q} \bmod p$, so that t has multiplicative order exactly q mod p (since $t^q = g^{p-1} \equiv 1$ and no smaller power is 1). Let $\alpha \in \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$ be multiplication by t; then $|\alpha| = q$. Define $\varphi\colon \mathbb{Z}/q\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$ by $\varphi(\overline{1}) = \alpha$ (legitimate since $|\alpha| = q \mid q$), and put $G = \mathbb{Z}/p\mathbb{Z} \rtimes_\varphi \mathbb{Z}/q\mathbb{Z}$, $|G| = pq$. With generators x (order p), y (order q):

$$G = \langle x, y \mid x^p = 1,\ y^q = 1,\ yxy^{-1} = x^t \rangle, \qquad t^q \equiv 1\ (\mathrm{mod} p),\ t \not\equiv 1.$$

Check. Iterating the relation q times gives $y^q x y^{-q} = x^{t^q} = x^1 = x$, consistent with $y^q = 1$. Nontriviality $t \not\equiv 1$ makes G nonabelian. Different choices of t (i.e. different generators of the order-q subgroup of $(\mathbb{Z}/p\mathbb{Z})^\times$) give isomorphic groups, because composing φ with an automorphism of $\mathbb{Z}/q\mathbb{Z}$ relabels the generator y; so there is a unique nonabelian group of order pq.

Worked Example 5.5.8 (When is $H \rtimes K$ abelian? Recognize the direct product)**.** Decide, for $H = \mathbb{Z}/5\mathbb{Z}$ and $K = \mathbb{Z}/4\mathbb{Z}$, which homomorphisms $\varphi\colon \mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/5\mathbb{Z})$ make $\mathbb{Z}/5\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z}$ abelian, and identify the abelian case.

Recognition. By Prop. 5.5.2(4) a semidirect product is abelian iff φ is trivial (and the factors abelian). So we just need to know which φ are trivial; the trivial one gives the direct product $\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \cong \mathbb{Z}/20\mathbb{Z}$.

Solution. $\mathrm{Aut}(\mathbb{Z}/5\mathbb{Z}) \cong (\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}/4\mathbb{Z}$, cyclic of order 4 generated by 2 ($2, 4, 3, 1$). A homomorphism $\varphi\colon \mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/5\mathbb{Z}) \cong \mathbb{Z}/4\mathbb{Z}$ is determined by the image of a generator, and there are $\gcd(4,4) = 4$ choices; the possible orders of $\varphi(\overline{1})$ are divisors of 4. Exactly one homomorphism is trivial: $\varphi(\overline{1}) = \mathrm{id}$. For that one,

$$\mathbb{Z}/5\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z} = \mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z} \cong \mathbb{Z}/20\mathbb{Z} \quad (\text{abelian, cyclic since } \gcd(5,4) = 1).$$

Every nontrivial φ (e.g. $\varphi(\overline{1})$ = mult. by 2, order 4; or mult. by 4, order 2) gives a nonabelian group of order 20, because then some $\varphi_k \neq \mathrm{id}$ and $(1,k)(h,1) = (\varphi_k(h), k) \neq (h,k) = (h,1)(1,k)$. *Check.* Take $\varphi(\overline{1})$ = mult. by $4 = -1$ (inversion, order 2); then $yxy^{-1} = x^{-1} \neq x$, so noncommutative, and $|G| = 20$. The unique abelian outcome is $\mathbb{Z}/20\mathbb{Z}$, matching the classification of abelian groups of order 20: of $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/20\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$, only the first contains a copy of $K = \mathbb{Z}/4\mathbb{Z}$.

Worked Example 5.5.9 (The affine group $\mathbb{Z}/n\mathbb{Z} \rtimes (\mathbb{Z}/n\mathbb{Z})^\times = \mathrm{Aff}(\mathbb{Z}/n\mathbb{Z})$)**.** Realize the group of invertible affine maps $x \mapsto ax + b$ on $\mathbb{Z}/n\mathbb{Z}$ (with $a \in (\mathbb{Z}/n\mathbb{Z})^\times$, $b \in \mathbb{Z}/n\mathbb{Z}$) as a semidirect product, and identify its order.

Recognition. Translations $T_b\colon x \mapsto x + b$ form a normal copy of $H = \mathbb{Z}/n\mathbb{Z}$ (they are the kernel of "read off the linear part a"); multiplications $M_a\colon x \mapsto ax$ form a complement $K = (\mathbb{Z}/n\mathbb{Z})^\times$ acting on translations by $M_a T_b M_a^{-1} = T_{ab}$. That conjugation *is* the action $\varphi_a(b) = ab$, so $\mathrm{Aff}(\mathbb{Z}/n\mathbb{Z}) = \mathbb{Z}/n\mathbb{Z} \rtimes_\varphi (\mathbb{Z}/n\mathbb{Z})^\times$.

Solution. Let $H = \mathbb{Z}/n\mathbb{Z}$ (additive, the b's) and $K = (\mathbb{Z}/n\mathbb{Z})^\times = \{a \in \mathbb{Z}/n\mathbb{Z} : \gcd(a, n) = 1\}$ (multiplicative, the a's). Define

$$\varphi\colon (\mathbb{Z}/n\mathbb{Z})^\times \to \mathrm{Aut}(\mathbb{Z}/n\mathbb{Z}), \qquad \varphi_a(b) = a\,b \ (\mathrm{mod} n).$$

This is a homomorphism: $\varphi_{a_1 a_2}(b) = a_1 a_2 b = \varphi_{a_1}(\varphi_{a_2}(b))$, and each φ_a is invertible (inverse $\varphi_{a^{-1}}$), hence in $\mathrm{Aut}(\mathbb{Z}/n\mathbb{Z})$ – in fact $\varphi\colon (\mathbb{Z}/n\mathbb{Z})^\times \to \mathrm{Aut}(\mathbb{Z}/n\mathbb{Z})$ is the standard isomorphism. The semidirect product law

$$(b_1, a_1)(b_2, a_2) = (b_1 + a_1 b_2,\ a_1 a_2)$$

matches composition of affine maps: $(x \mapsto a_1 x + b_1) \circ (x \mapsto a_2 x + b_2) = x \mapsto a_1 a_2 x + (a_1 b_2 + b_1)$. So $\mathrm{Aff}(\mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z} \rtimes_\varphi (\mathbb{Z}/n\mathbb{Z})^\times$. *Order.* $|\mathrm{Aff}(\mathbb{Z}/n\mathbb{Z})| = |\mathbb{Z}/n\mathbb{Z}| \cdot |(\mathbb{Z}/n\mathbb{Z})^\times| = n\,\phi(n)$. For $n = 5$: $5 \cdot 4 = 20$ (this is the nonabelian group of order 20 above with the full action). The conjugation relation $M_a T_b M_a^{-1} = T_{ab}$ is exactly $\varphi_a(b) = ab$, confirming the internal recognition with $H = \{T_b\} \trianglelefteq G$, $K = \{M_a\}$, $H \cap K = \{T_0\} = 1$, $HK = G$.

Worked Example 5.5.10 (Classify all groups of order pq)**.** Let $p > q$ be primes. Classify all groups G of order pq up to isomorphism, distinguishing the cases $q \nmid p - 1$ and $q \mid p - 1$.

Recognition. Sylow theory forces a normal Sylow p-subgroup $P \cong \mathbb{Z}/p\mathbb{Z}$ and a Sylow q-subgroup $Q \cong \mathbb{Z}/q\mathbb{Z}$ with $P \cap Q = 1$, $PQ = G$. So $G = P \rtimes_\varphi Q$ for some $\varphi\colon \mathbb{Z}/q\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/(p-1)\mathbb{Z}$, and we enumerate such φ.

Solution. Normality of P. The number n_p of Sylow p-subgroups satisfies $n_p \equiv 1 \pmod p$ and $n_p \mid q$; since $q < p$ the only possibility is $n_p = 1$, so $P \trianglelefteq G$. Take any $Q \in \mathrm{Syl}_q(G)$. Then $P \trianglelefteq G$, $Q \leq G$, $P \cap Q = 1$ (coprime orders), $|PQ| = pq = |G|$ so $PQ = G$. By Thm. 5.5.3, $G = \mathbb{Z}/p\mathbb{Z} \rtimes_\varphi \mathbb{Z}/q\mathbb{Z}$ with $\varphi\colon \mathbb{Z}/q\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$. Now $\mathrm{Aut}(\mathbb{Z}/p\mathbb{Z}) \cong \mathbb{Z}/(p-1)\mathbb{Z}$ is cyclic.

- **Case $q \nmid p - 1$.** A homomorphism $\mathbb{Z}/q\mathbb{Z} \to \mathbb{Z}/(p-1)\mathbb{Z}$ has image of order dividing $\gcd(q, p-1) = 1$, so φ is trivial. Then $G = \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/q\mathbb{Z} \cong \mathbb{Z}/pq\mathbb{Z}$. Up to isomorphism there is *one* group: the cyclic group $\mathbb{Z}/pq\mathbb{Z}$.
- **Case $q \mid p - 1$.** Now $\gcd(q, p-1) = q$, so there are exactly q homomorphisms $\mathbb{Z}/q\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/p\mathbb{Z})$ ($\varphi(\overline{1})$ any element of the order-q subgroup), one trivial and $q - 1$ nontrivial. The trivial one gives $\mathbb{Z}/pq\mathbb{Z}$. All $q - 1$ nontrivial ones give *isomorphic* nonabelian groups: if φ, φ' are nontrivial then $\varphi' = \varphi \circ \beta$ for some $\beta \in \mathrm{Aut}(\mathbb{Z}/q\mathbb{Z})$, and $(h, k) \mapsto (h, \beta^{-1}(k))$ is an isomorphism $\mathbb{Z}/p\mathbb{Z} \rtimes_\varphi \mathbb{Z}/q\mathbb{Z} \to \mathbb{Z}/p\mathbb{Z} \rtimes_{\varphi'} \mathbb{Z}/q\mathbb{Z}$. So there are exactly *two* groups: the cyclic $\mathbb{Z}/pq\mathbb{Z}$ and one nonabelian $\langle x, y \mid x^p = y^q = 1,\ yxy^{-1} = x^t \rangle$ (t of order q mod p).

Check. $pq = 21$: $p = 7, q = 3$, $3 \mid 6$, so two groups ($\mathbb{Z}/21\mathbb{Z}$ and the order-21 nonabelian group of the earlier example). $pq = 15$: $p = 5, q = 3$, $3 \nmid 4$, so one group, $\mathbb{Z}/15\mathbb{Z}$ – matching the known fact that every group of order 15 is cyclic.

Worked Example 5.5.11 (Internal recognition inside S_4: $S_4 \cong V_4 \rtimes S_3$)**.** Show S_4 is an internal semidirect product $V_4 \rtimes K$ with $K \cong S_3$, and identify the action.

Recognition. $V_4 = \{e, (12)(34), (13)(24), (14)(23)\}$ is normal in S_4 (it is the kernel of the action on the three "partitions," or: it is a union of conjugacy classes plus identity). Take $K = \mathrm{Sym}\{1, 2, 3\}$, the stabilizer of the point 4, of order 6. The orders are not coprime ($\gcd(4, 6) = 2$), but recognition does not need coprimality: we still have $|V_4||K| = 4 \cdot 6 = 24 = |S_4|$ and $V_4 \cap K = 1$, so the four-point checklist applies directly.

Solution. Normality. $V_4 \trianglelefteq S_4$: conjugating a product of two disjoint transpositions gives another such, so V_4 is closed under conjugation; with the identity it is a normal subgroup of order 4. *Complement.* Let $K = \{\sigma \in S_4 : \sigma(4) = 4\} \cong S_3$, $|K| = 6$. *Intersection.* Every non-identity element of V_4 is a product of two

disjoint transpositions, hence moves all four points; in particular it moves 4. So no non-identity element of V_4 lies in the point-stabilizer K, giving $V_4 \cap K = \{e\}$. *Product.* $|V_4K| = \frac{|V_4||K|}{|V_4 \cap K|} = \frac{4 \cdot 6}{1} = 24 = |S_4|$, so $V_4K = S_4$. By Thm. 5.5.3, $S_4 = V_4 \rtimes_\varphi K$ where $\varphi_k(v) = kvk^{-1}$. *Action.* $K \cong S_3$ permutes the three nonidentity elements of V_4 faithfully, giving $\varphi\colon S_3 \to \mathrm{Aut}(V_4) \cong S_3$ an isomorphism. So the action is the full permutation of the three involutions. *Check.* $|S_4| = 24 = 4 \cdot 6$. Since φ is nontrivial, the product is nonabelian, and indeed S_4 is nonabelian. The map $\Phi(v, k) = vk$ is the claimed isomorphism $V_4 \rtimes S_3 \to S_4$.

Remark 5.5.3 (Universal-property contrast). The direct product $A \times B$ is characterized by its projections: any pair $f\colon T \to A$, $g\colon T \to B$ factors uniquely through $A \times B$,

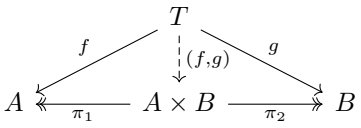

Diagram explanation. Objects: T is any group (a "test object" equipped with maps to both factors). A and B are two groups. $A \times B$ is their direct product, the universal object. Four nodes in a triangular arrangement.

Arrows: $f\colon T \to A$ and $g\colon T \to B$ are arbitrary homomorphisms (the given data). $(f, g)\colon T \to A \times B$, $t \mapsto (f(t), g(t))$, is the unique induced homomorphism (dashed, signifying existence and uniqueness). $\pi_1\colon A \times B \to A$, $(a, b) \mapsto a$, is the first projection (surjective). $\pi_2\colon A \times B \to B$, $(a, b) \mapsto b$, is the second projection (surjective).

What commutes: Two triangles commute: $\pi_1 \circ (f, g) = f$ (left triangle) and $\pi_2 \circ (f, g) = g$ (right triangle). Together: the unique dashed map satisfies both $\pi_1 \circ (f, g) = f$ and $\pi_2 \circ (f, g) = g$ simultaneously.

Why it commutes: Chase a generic $t \in T$ along the left triangle: $(f, g)(t) = (f(t), g(t))$, then $\pi_1(f(t), g(t)) = f(t)$. Along the right: $\pi_2(f(t), g(t)) = g(t)$. Both equalities hold by definition of the direct-product map. Uniqueness: if $(h_1, h_2)\colon T \to A \times B$ also satisfies $\pi_i \circ h =$ the given maps, then $h(t) = (h_1(t), h_2(t)) = (f(t), g(t))$, so $h = (f, g)$.

Why this matters here: The remark uses this diagram to contrast with the semidirect product. The direct product is a categorical product: it comes with two projections and the unique factoring property above. The semidirect product $H \rtimes K$ does *not* have this property because the second inclusion $s\colon K \to H \rtimes K$ is not a normal complement, so there is no symmetric pair of projections satisfying such a universal property.

Concrete example: $A = \mathbb{Z}/2\mathbb{Z}$, $B = \mathbb{Z}/3\mathbb{Z}$, $T = \mathbb{Z}/6\mathbb{Z}$. Map $f\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ by reduction mod 2 and $g\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$ by reduction mod 3. The unique $(f, g)\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$ sends $\overline{1} \mapsto (\overline{1}, \overline{1})$; both projections recover f and g.

Common pitfall: The dashed arrow goes *into* $A \times B$, not out of it. Students sometimes read the projections π_1, π_2 as the given data and (f, g) as a projection; it is the reverse. Also, the universality only produces a homomorphism (f, g); it does not say $T \cong A \times B$; (f, g) is an isomorphism exactly when it is bijective (for finite groups, exactly when $\ker f \cap \ker g = 1$ and $|T| = |A|\,|B|$, as for $\mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ above, although neither f nor g is an isomorphism).

Takeaway: The point of this diagram is that the direct product $A \times B$ is the unique (up to isomorphism) group equipped with projections π_1, π_2 such that any two homomorphisms out of a test group T factor through it, a property the semidirect product lacks because its two inclusions are not symmetric.

The semidirect product has *no* such symmetric universal property – it is not a product in the categorical sense, because K does not map out as a normal complement. What it does have is the split exact sequence above: the section s is the extra datum that the direct product upgrades to a normal section.

Caution. "$H \trianglelefteq G$, $K \trianglelefteq G$, $H \cap K = 1$, $HK = G$" (both normal) is the criterion for the *direct* product $G \cong H \times K$, not the semidirect one. For a genuine semidirect product you only get $H \trianglelefteq G$; the complement K need not be normal, and is not when the action is nontrivial. Conversely, do not assume $K \trianglelefteq G$ "for symmetry" – in D_{2n} ($n \geq 3$) the reflection subgroup $\langle s \rangle$ is not normal.

Exercises (from the text).

1. Prove that $C_K(H) = \ker \varphi$ (recall that $C_K(H) = C_G(H) \cap K$).

2. Prove that $C_H(K) = N_H(K)$.

3. In Example 1 following the proof of Proposition 11 prove that every element of $G - H$ has order 2. Prove that G is abelian if and only if $h^2 = 1$ for all $h \in H$.

4. Let $p = 2$ and check that the construction of the two non-abelian groups of order p^3 is valid in this case. Prove that both resulting groups are isomorphic to D_8.

5. Let $G = \text{Hol}(\mathbb{Z}_2 \times \mathbb{Z}_2)$. (a) Prove that $G = H \rtimes K$ where $H \cong \mathbb{Z}_2 \times \mathbb{Z}_2$ and $K \cong S_3$. Deduce that $|G| = 24$. (b) Prove that G is isomorphic to S_4. [Obtain a homomorphism from G into S_4 by letting G act on the left cosets of K. Use Exercise 1 to show this representation is faithful.]

6. Assume that K is a cyclic group, H is an arbitrary group and φ_1 and φ_2 are homomorphisms from K into $\text{Aut}(H)$ such that $\varphi_1(K)$ and $\varphi_2(K)$ are conjugate subgroups of $\text{Aut}(H)$. If K is infinite assume φ_1 and φ_2 are injective. Prove by constructing an explicit isomorphism that $H \rtimes_{\varphi_1} K \cong H \rtimes_{\varphi_2} K$ (in particular, if the subgroups $\varphi_1(K)$ and $\varphi_2(K)$ are equal in $\text{Aut}(H)$, then the resulting semidirect products are isomorphic). [Suppose $\sigma\varphi_1(K)\sigma^{-1} = \varphi_2(K)$ so that for some $a \in \mathbb{Z}$ we have $\sigma\varphi_1(k)\sigma^{-1} = \varphi_2(k)^a$ for all $k \in K$. Show the map $\psi : H \rtimes_{\varphi_1} K \to H \rtimes_{\varphi_2} K$ defined by $\psi(h, k) = (\sigma(h), k^a)$ is a homomorphism. Show ψ is bijective by constructing a 2-sided inverse.]

7. This exercise describes thirteen isomorphism types of groups of order 56. (It is not too difficult to show that every group of order 56 is isomorphic to one of these.) (a) Prove that there are three abelian groups of order 56. (b) Prove that every group of order 56 has either a normal Sylow 2-subgroup or a normal Sylow 7-subgroup. (c) Construct the following non-abelian groups of order 56 which have a normal Sylow 7-subgroup and whose Sylow 2-subgroup S is as specified: one group when $S \cong \mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$; two nonisomorphic groups when $S \cong \mathbb{Z}_4 \times \mathbb{Z}_2$; one group when $S \cong \mathbb{Z}_8$; two nonisomorphic groups when $S \cong Q_8$; three nonisomorphic groups when $S \cong D_8$. [For a particular S, two groups are not isomorphic if the kernels of the maps from S into $\text{Aut}(\mathbb{Z}_7)$ are not isomorphic.] (d) Let G be a group of order 56 with a nonnormal Sylow 7-subgroup. Prove that if S is the Sylow 2-subgroup of G then $S \cong \mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$. [Let an element of order 7 act by conjugation on the seven nonidentity elements of S and deduce that they all have the same order.] (e) Prove that there is a unique group of order 56 with a nonnormal Sylow 7-subgroup. [For existence use the fact that $|\text{GL}_3(\mathbb{F}_2)| = 168$; for uniqueness use Exercise 6.]

8. Construct a non-abelian group of order 75. Classify all groups of order 75 (there are three of them). [Use Exercise 6 to show that the non-abelian group is unique.] (The classification of groups of order pq^2, where p and q are primes with $p < q$ and p not dividing $q - 1$, is quite similar.)

9. Show that the matrix $\begin{pmatrix} 0 & -1 \\ 1 & 4 \end{pmatrix}$ is an element of order 5 in $\text{GL}_2(\mathbb{F}_{19})$. Use this matrix to construct a non-abelian group of order 1805 and give a presentation of this group. Classify groups of order 1805 (there are three isomorphism types). [Use Exercise 6 to prove uniqueness of the non-abelian group.] (A general method for finding elements of prime order in $\text{GL}_n(\mathbb{F}_p)$ is described in the exercises in Section 12.2; this particular matrix of order 5 in $\text{GL}_2(\mathbb{F}_{19})$ appears in Exercise 16 of that section as an illustration of the method.)

10. This exercise classifies the groups of order 147 (there are six isomorphism types). (a) Prove that there are two abelian groups of order 147. (b) Prove that every group of order 147 has a normal Sylow 7-subgroup. (c) Prove that there is a unique non-abelian group whose Sylow 7-subgroup is cyclic. (d) Let $t_1 = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}$ and $t_2 = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}$ be elements of $\text{GL}_2(\mathbb{F}_7)$. Prove $P = \langle t_1, t_2 \rangle$ is a Sylow 3-subgroup of $\text{GL}_2(\mathbb{F}_7)$ and that $P \cong \mathbb{Z}_3 \times \mathbb{Z}_3$. Deduce that every subgroup of $\text{GL}_2(\mathbb{F}_7)$ of order 3 is conjugate in $\text{GL}_2(\mathbb{F}_7)$ to a subgroup of P. (e) By Example 3 in Section 1 the group P has four subgroups of order 3 and these are: $P_1 = \langle t_1 \rangle$, $P_2 = \langle t_2 \rangle$, $P_3 = \langle t_1 t_2 \rangle$, and $P_4 = \langle t_1 t_2^2 \rangle$. For $i = 1, 2, 3, 4$ let $G_i = (\mathbb{Z}_7 \times \mathbb{Z}_7) \rtimes_{\varphi_i} \mathbb{Z}_3$, where φ_i is an isomorphism of $\mathbb{Z}_3$ with the subgroup P_i of $\text{Aut}(\mathbb{Z}_7 \times \mathbb{Z}_7)$. For each i describe G_i in terms of generators and relations. Deduce that $G_1 \cong G_2$. (f) Prove that G_1 is not isomorphic to either G_3 or G_4. [Show that the center of G_1 has order 7 whereas the centers of G_3 and G_4 are trivial.] (g) Prove that G_3 is not isomorphic to G_4. [Show that every subgroup of order 7 in G_3 is normal in G_3 but that G_4 has subgroups

of order 7 that are not normal.] (h) Classify the groups of order 147 by showing that the six nonisomorphic groups described above (two from part (a), one from part (c) and G_1, G_3, and G_4) are all the groups of order 147. [Use Exercise 6 and part (d).] (The classification of groups of order pq^2, where p and q are primes with $p < q$ and $p \mid q-1$, is quite similar.)

11. Classify groups of order 28 (there are four isomorphism types).

12. Classify the groups of order 20 (there are five isomorphism types).

13. Classify the groups of order $4p$, where p is a prime greater than 3. [There are four isomorphism types when $p \equiv 3 \pmod 4$ and five isomorphism types when $p \equiv 1 \pmod 4$.]

14. This exercise classifies the groups of order 60 (there are thirteen isomorphism types). Let G be a group of order 60, let P be a Sylow 5-subgroup of G and let Q be a Sylow 3-subgroup of G. (a) Prove that if P is not normal in G then $G \cong A_5$. [See Section 4.5.] (b) Prove that if $P \trianglelefteq G$ but Q is not normal in G then $G \cong A_4 \times \mathbb{Z}_5$. [Show in this case that $P \leq Z(G)$, $G/P \cong A_4$, a Sylow 2-subgroup T of G is normal and $TQ \cong A_4$.] (c) Prove that if both P and Q are normal in G then $G \cong \mathbb{Z}_{15} \rtimes T$ where $T \cong \mathbb{Z}_4$ or $\mathbb{Z}_2 \times \mathbb{Z}_2$. Show in this case that there are six isomorphism types when T is cyclic (one abelian) and there are five isomorphism types when T is the Klein 4-group (one abelian). [Use the same ideas as in the classifications of groups of orders 30 and 20.]

15. Let p be an odd prime. Prove that every element of order 2 in $\mathrm{GL}_2(\mathbb{F}_p)$ is conjugate to a diagonal matrix with ± 1's on the diagonal. Classify the groups of order $2p^2$. [If A is a 2×2 matrix with $A^2 = I$ and v_1, v_2 is a basis for the underlying vector space, look at A acting on the vectors $w_1 = v_1 + v_2$ and $w_2 = v_1 - v_2$.]

16. Show that there are exactly 4 distinct homomorphisms from $\mathbb{Z}_2$ into $\mathrm{Aut}(\mathbb{Z}_8)$. Prove that the resulting semidirect products are the groups: $\mathbb{Z}_8 \times \mathbb{Z}_2$, D_{16}, the quasidihedral group QD_{16} and the modular group M (cf. the exercises in Section 2.5).

17. Show that for any $n \geq 3$ there are exactly 4 distinct homomorphisms from $\mathbb{Z}_2$ into $\mathrm{Aut}(\mathbb{Z}_{2^n})$. Prove that the resulting semidirect products give 4 nonisomorphic groups of order 2^{n+1}. [Recall Exercises 21 to 23 in Section 2.3.] (These four groups together with the cyclic group and the generalized quaternion group, $Q_{2^{n+1}}$, are all the groups of order 2^{n+1} which possess a cyclic subgroup of index 2.)

18. Show that if H is any group then there is a group G that contains H as a normal subgroup with the property that for every automorphism σ of H there is an element $g \in G$ such that conjugation by g when restricted to H is the given automorphism σ, i.e., every automorphism of H is obtained as an inner automorphism of G restricted to H.

19. Let H be a group of order n, let $K = \mathrm{Aut}(H)$ and form $G = \mathrm{Hol}(H) = H \rtimes K$ (where φ is the identity homomorphism). Let G act by left multiplication on the left cosets of K in G and let π be the associated permutation representation $\pi : G \to S_n$. (a) Prove the elements of H are coset representatives for the left cosets of K in G and with this choice of coset representatives π restricted to H is the regular representation of H. (b) Prove $\pi(G)$ is the normalizer in S_n of $\pi(H)$. Deduce that under the regular representation of any finite group H of order n, the normalizer of H in S_n is isomorphic to $\mathrm{Hol}(H)$. [Show $|G| = |N_{S_n}(\pi(H))|$ using Exercises 1 and 2 above.] (c) Deduce that the normalizer of the group generated by an n-cycle in S_n is isomorphic to $\mathrm{Hol}(\mathbb{Z}_n)$ and has order $n\varphi(n)$.

20. Let p be an odd prime. Prove that if P is a non-cyclic p-group then P contains a normal subgroup U with $U \cong \mathbb{Z}_p \times \mathbb{Z}_p$. Deduce that for odd primes p a p-group that contains a unique subgroup of order p is cyclic. (For $p = 2$ it is a theorem that the generalized quaternion groups Q_{2^n} defined in Section 2.5 are the only non-cyclic 2-groups which contain a unique subgroup of order 2). [Proceed by induction on $|P|$. Let Z be a subgroup of order p in $Z(P)$ and let $\bar{P} = P/Z$. If $\bar{P}$ is cyclic then P is abelian by Exercise 36 in Section 3.1 — show the result is true for abelian groups. When $\bar{P}$ is not cyclic use induction to produce a normal subgroup $\bar{H}$ of $\bar{P}$ with $\bar{H} \cong \mathbb{Z}_p \times \mathbb{Z}_p$. Let H be the complete preimage of $\bar{H}$ in P, so $|H| = p^3$. Let $H_0 = \{x \in H \mid x^p = 1\}$ and show that H_0 is a characteristic subgroup of H of order p^2 or p^3 by Exercise 9 in Section 4. Show that a suitable subgroup of H_0 gives the desired normal subgroup U.]

21. Let p be an odd prime and let P be a p-group. Prove that if every subgroup of P is normal then P is abelian. (Note that Q_8 is a non-abelian 2-group with this property, so the result is false for $p = 2$.) [Use

the preceding exercises and Exercise 15 of Section 4.]

22. Let F be a field, let n be a positive integer and let G be the group of upper triangular matrices in $\mathrm{GL}_n(F)$ (cf. Exercise 16, Section 2.1). (a) Prove that G is the semidirect product $U \rtimes D$ where U is the set of upper triangular matrices with 1's down the diagonal (cf. Exercise 17, Section 2.1) and D is the set of diagonal matrices in $\mathrm{GL}_n(F)$. (b) Let $n = 2$. Recall that $U \cong F$ and $D \cong F^\times \times F^\times$ (cf. Exercise 11 in Section 3.1). Describe the homomorphism from D into $\mathrm{Aut}(U)$ explicitly in terms of these isomorphisms (i.e., show how each element of $F^\times \times F^\times$ acts as an automorphism on F).

23. Let K and L be groups, let n be a positive integer, let $\rho : K \to S_n$ be a homomorphism and let H be the direct product of n copies of L. In Exercise 8 of Section 1 an injective homomorphism ψ from S_n into $\mathrm{Aut}(H)$ was constructed by letting the elements of S_n permute the n factors of H. The composition $\psi \circ \rho$ is a homomorphism from K into $\mathrm{Aut}(H)$. The *wreath product* of L by K is the semidirect product $H \rtimes K$ with respect to this homomorphism and is denoted by $L \wr K$ (this wreath product depends on the choice of permutation representation ρ of K — if none is given explicitly, ρ is assumed to be the left regular representation of K). (a) Assume K and L are finite groups and ρ is the left regular representation of K. Find $|L \wr K|$ in terms of $|K|$ and $|L|$. (b) Let p be a prime, let $K = L = \mathbb{Z}_p$ and let ρ be the left regular representation of K. Prove that $\mathbb{Z}_p \wr \mathbb{Z}_p$ is a non-abelian group of order p^{p+1} and is isomorphic to a Sylow p-subgroup of S_{p^2}. [The p copies of $\mathbb{Z}_p$ whose direct product makes up H may be represented by p disjoint p-cycles; these are cyclically permuted by K.]

24. Let n be an integer > 1. Prove the following classification: every group of order n is abelian if and only if $n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}$, where $p_1, \ldots, p_r$ are distinct primes, $\alpha_i = 1$ or 2 for all $i \in \{1, \ldots, r\}$ and p_i does not divide $p_j^{\alpha_j} - 1$ for all i and j. [See Exercise 56 in Section 4.5.]

25. Let $H(\mathbb{F}_p)$ be the Heisenberg group over the finite field $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ (cf. Exercise 20 in Section 4). Prove that $H(\mathbb{F}_2) \cong D_8$ and that for odd p, $H(\mathbb{F}_p)$ has exponent p and is isomorphic to the first non-abelian group in Example 7.

Practice problems.

1. Let $H = \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ and let $\tau \in \mathrm{Aut}(H)$ be the coordinate swap $\tau(a, b) = (b, a)$. Check that $\tau^2 = \mathrm{id}$, so that $\varphi\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(H)$ with $\varphi(\overline{1}) = \tau$ is a well-defined homomorphism. Form the order-18 group $H \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$, and using the multiplication rule $(h_1, k_1)(h_2, k_2) = (h_1 \varphi_{k_1}(h_2), k_1 k_2)$ compute the product $\big((1,0), \overline{1}\big)\big((0,1), \overline{1}\big)$ and the inverse of $\big((1,0), \overline{1}\big)$. Confirm by the conjugation rule of Proposition 5.5.2(3) that the order-2 element $\big((0,0), \overline{1}\big)$ swaps the two $\mathbb{Z}/3\mathbb{Z}$ factors.

2. Build a nonabelian group of order 20 as $\mathbb{Z}/5\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z}$ by sending the generator $\overline{1} \in \mathbb{Z}/4\mathbb{Z}$ to the automorphism "multiplication by 2" of $\mathbb{Z}/5\mathbb{Z}$. Verify this automorphism has order 4 and that φ is therefore a legitimate homomorphism, give the presentation $\langle x, y \mid x^5 = y^4 = 1,\ yxy^{-1} = x^2 \rangle$, and explain precisely where the divisibility $4 \mid 5 - 1$ is used.

3. Exhibit A_4 as an internal semidirect product $V_4 \rtimes \langle (1\,2\,3) \rangle$, where $V_4 = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\}$. Verify the four conditions of Theorem 5.5.3: $V_4 \trianglelefteq A_4$, $\langle (1\,2\,3) \rangle \leq A_4$, $V_4 \cap \langle (1\,2\,3) \rangle = 1$, and $V_4 \langle (1\,2\,3) \rangle = A_4$. Then compute the conjugation action of $(1\,2\,3)$ on the three involutions of V_4 and identify $\varphi\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{Aut}(V_4)$ as a cyclic permutation of order 3.

4. For a general external product $G = H \rtimes_\varphi K$, prove that an element (h_0, k_0) is central if and only if $h_0 \in H^K$ (the set of φ-fixed points), $k_0 \in Z(K)$, and $h_0\, \varphi_{k_0}(h) = h\, h_0$ for all $h \in H$ (i.e. φ_{k_0} is conjugation by h_0^{-1}; for abelian H this says $\varphi_{k_0} = \mathrm{id}$). Deduce that $Z(G) \cap H = H^K \cap Z(H)$ (which is H^K when H is abelian), and conclude that if H is abelian and φ is faithful with no nonzero fixed points then $Z(G) = 1$. Verify the latter on the group $\mathbb{Z}/5\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z}$ of the previous problem.

5. In D_{2n} with $n \geq 3$, written $\langle r, s \mid r^n = s^2 = 1,\ srs^{-1} = r^{-1} \rangle$, show that the rotation subgroup $\langle r \rangle$ is normal but the reflection subgroup $\langle s \rangle = \{1, s\}$ is not (compute $r\, s\, r^{-1}$ and check it does not lie in $\langle s \rangle$). Explain how this exhibits D_{2n} as a genuine semidirect product rather than a direct product.

6. Determine how many semidirect products $\mathbb{Z}/11\mathbb{Z} \rtimes_\varphi \mathbb{Z}/5\mathbb{Z}$ arise up to isomorphism. Use that $\mathrm{Aut}(\mathbb{Z}/11\mathbb{Z}) \cong \mathbb{Z}/10\mathbb{Z}$ has a unique subgroup of order 5 to count the homomorphisms $\mathbb{Z}/5\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/11\mathbb{Z})$, identify the

trivial one with $\mathbb{Z}/55\mathbb{Z}$, and explain why the nontrivial ones all give isomorphic nonabelian groups of order 55.

7. Verify the internal-recognition checklist of Theorem 5.5.3 for S_3 with $H = \langle (1\,2\,3) \rangle$ and $K = \langle (1\,2) \rangle$: check $H \trianglelefteq S_3$, $K \leq S_3$, $H \cap K = 1$, and $HK = S_3$. Then compute $\varphi_{(1\,2)}\big((1\,2\,3)\big)$ by conjugation and conclude $S_3 \cong \mathbb{Z}/3\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$ with the inversion action.

8. Show that sending the generator of $\mathbb{Z}/2\mathbb{Z}$ to an automorphism of $\mathbb{Z}/7\mathbb{Z}$ of order 3 does *not* define a semidirect product. Explain, in terms of the requirement $\varphi(1)^2 = \mathrm{id}$, exactly which automorphisms of $\mathbb{Z}/7\mathbb{Z}$ *do* give a homomorphism $\mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z})$, and name the two groups $\mathbb{Z}/7\mathbb{Z} \rtimes_\varphi \mathbb{Z}/2\mathbb{Z}$ that result.

Additional exercises.

1. Let $1 \to H \xrightarrow{\iota} G \xrightarrow{\pi} K \to 1$ be a short exact sequence with K cyclic of order n. Prove that the sequence splits if and only if G contains an element t of order n with $\pi(t)$ a generator of K. (Hint: given such t, show $\langle t \rangle$ is a complement to $\iota(H)$ and define the splitting by $s\big(\pi(t)^j\big) = t^j$; conversely, $t = s(\text{generator})$ satisfies $t^n = s(1) = 1$ and $\pi(t)$ generates K.) Use this to show the sequence $1 \to \mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/9\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \to 1$ does not split, so $\mathbb{Z}/9\mathbb{Z}$ is a non-split extension of $\mathbb{Z}/3\mathbb{Z}$ by $\mathbb{Z}/3\mathbb{Z}$.

2. For $n \geq 3$ exhibit S_n as an internal semidirect product $A_n \rtimes \langle (1\,2) \rangle$. Verify $A_n \trianglelefteq S_n$, $\langle (1\,2) \rangle \cong \mathbb{Z}/2\mathbb{Z}$, $A_n \cap \langle (1\,2) \rangle = 1$, and $A_n \langle (1\,2) \rangle = S_n$ (note coprimality is *not* needed), and identify the action $\varphi\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(A_n)$ as conjugation by the transposition $(1\,2)$. Explain why φ is nontrivial, so the product is not direct.

3. Prove that Q_8 is not isomorphic to any nontrivial semidirect product $H \rtimes K$ of proper subgroups. (Hint: such a decomposition would need $H \cap K = 1$ with $\{|H|, |K|\} = \{2, 4\}$; analyze the order-2 subgroups of Q_8 and show every subgroup of order 4 contains the unique element -1 of order 2.) Conclude that Q_8 is a non-split extension.

4. Determine all isomorphism types of $\mathbb{Z}/3\mathbb{Z} \rtimes_\varphi \mathbb{Z}/4\mathbb{Z}$, i.e. all groups of order 12 with normal Sylow 3-subgroup and cyclic complement $\mathbb{Z}/4\mathbb{Z}$. Using $\mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$, count the homomorphisms $\mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z})$, show there are exactly two resulting groups, identify the trivial case as $\mathbb{Z}/12\mathbb{Z}$, and give the presentation $\langle x, y \mid x^3 = y^4 = 1,\ yxy^{-1} = x^{-1} \rangle$ of the nonabelian one (the dicyclic group of order 12).

Commutative-diagram exercises.

1. Consider the semidirect product $H \rtimes_\varphi K$ with $\iota(h) = (h, 1)$, $\pi(h, k) = k$, and $s(k) = (1, k)$. Verify that

$$1 \longrightarrow H \xhookrightarrow{\ \iota\ } H \rtimes_\varphi K \underset{\ s\ }{\overset{\ \pi\ }{\twoheadrightarrow}} K \longrightarrow 1$$

   is a short exact sequence with $\mathrm{im}\,\iota = \ker \pi = H \times \{1\}$ and $\pi \circ s = \mathrm{id}_K$ (so the extension splits). Then compute $s(k)\,\iota(h)\,s(k)^{-1}$ in $H \rtimes_\varphi K$ and confirm it equals $(\varphi_k(h), 1)$, so that the conjugation action induced by the splitting recovers φ.

2. Exhibit the sign sequence $1 \to A_n \xrightarrow{\iota} S_n \xrightarrow{\mathrm{sgn}} \mathbb{Z}/2\mathbb{Z} \to 1$ for $n \geq 3$, where ι is inclusion and sgn is the sign homomorphism (with -1 identified with the nontrivial element of $\mathbb{Z}/2\mathbb{Z}$). Define a splitting $s\colon \mathbb{Z}/2\mathbb{Z} \to S_n$ by sending the nontrivial element to the transposition $(1\,2)$, check that $s^2 = 1$ makes it a homomorphism with $\mathrm{sgn} \circ s = \mathrm{id}$, draw the resulting split exact sequence, and conclude $S_n \cong A_n \rtimes \langle (1\,2) \rangle$ with the conjugation action.

3. Compare a semidirect product with the trivial (direct-product) extension by drawing the morphism of short exact sequences

$$\begin{array}{ccccccccc}
1 & \longrightarrow & H & \hookrightarrow & H \rtimes_\varphi K & \twoheadrightarrow & K & \longrightarrow & 1 \\
 & & \| & & \downarrow{\scriptstyle u} & & \| & & \\
1 & \longrightarrow & H & \hookrightarrow & H \times K & \twoheadrightarrow & K & \longrightarrow & 1
\end{array}$$

with $u(h,k) = (h,k)$. Show that u is a homomorphism making both squares commute if and only if φ is trivial, so u is an equivalence of the two extensions exactly when $H \rtimes_\varphi K = H \times K$. Explain why this is the diagrammatic content of "the direct product is the degenerate semidirect product."

4. Draw the sequence $1 \to \mathbb{Z}/2\mathbb{Z} \xrightarrow{\iota} \mathbb{Z}/4\mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \to 1$, where ι identifies $\mathbb{Z}/2\mathbb{Z}$ with $\langle x^2\rangle \le \mathbb{Z}/4\mathbb{Z} = \langle x\rangle$ and π is reduction modulo $\langle x^2\rangle$. Prove this sequence does *not* split: any section $s\colon \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ would require an order-2 element mapping onto the generator of the quotient, but the only order-2 element x^2 lies in $\ker\pi$. Conclude that $\mathbb{Z}/4\mathbb{Z}$ is a non-split extension and in particular $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$ (which would be $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$).

5.6 Graded Problem Bank

Easy

DF 5.1.1 Show $Z(G_1 \times \cdots \times G_n) = Z(G_1) \times \cdots \times Z(G_n)$, and deduce a direct product is abelian iff each factor is.

DF 5.1.5 Exhibit a nonnormal subgroup of $Q_8 \times \mathbb{Z}_4$ (every subgroup of each factor is normal).

DF 5.1.6 Show that all subgroups of $Q_8 \times E_{2^n}$ are normal.

DF 5.1.10 For a prime p and $E = \langle x\rangle \times \langle y\rangle \cong E_{p^2}$, show the distinct order-p subgroups are $\langle x\rangle, \langle xy\rangle, \ldots, \langle xy^{p-1}\rangle, \langle y\rangle$ (there are $p+1$).

DF 5.1.11 For a prime p and $n \in \mathbb{Z}^+$, find a formula for the number of subgroups of order p in E_{p^n}.

DF 5.2.1 In parts (a)–(e) give the number of nonisomorphic abelian groups of order 100, 576, 1155, 42875, 2704 (do not list them).

DF 5.2.2 In parts (a)–(e) give the invariant factors of all abelian groups of order 270, 9801, 320, 105, 44100.

DF 5.2.3 In parts (a)–(e) give the elementary divisors of all abelian groups of order 270, 9801, 320, 105, 44100, and match each to its invariant-factor list.

DF 5.2.4 In parts (a)–(d) determine which of the listed abelian groups $\mathbb{Z}_{a_1} \times \cdots \times \mathbb{Z}_{a_k}$ are isomorphic.

DF 5.2.9 For $A = \mathbb{Z}_{60} \times \mathbb{Z}_{45} \times \mathbb{Z}_{12} \times \mathbb{Z}_{36}$, find the number of elements of order 2 and the number of subgroups of index 2.

DF 5.4.1 For $x, y \in G$ prove $[y,x] = [x,y]^{-1}$, and deduce $[A,B] = [B,A]$ for subsets A, B.

DF 5.4.4 Find the commutator subgroups of S_4 and A_4.

DF 5.4.6 Exhibit a representative of each cycle type of A_5 as a commutator in S_5.

DF 5.4.12 Use Theorem 4.17 to describe the automorphism group of a finite cyclic group.

DF 5.4.13 Prove that D_{8n} is not isomorphic to $D_{4n} \times \mathbb{Z}_2$.

DF 5.5.1 Prove $C_K(H) = \ker\varphi$ (where $C_K(H) = C_G(H) \cap K$).

DF 5.5.2 Prove $C_H(K) = N_H(K)$.

DF 5.5.4 For $p = 2$ check the construction of the two non-abelian groups of order p^3 is valid, and show both are isomorphic to D_8.

Artin 11.1 For x of order r in G and y of order s in G', find the order of (x,y) in $G \times G'$.

Artin 11.2 State what Proposition 2.11.4 says for S_3 when $H = \langle x\rangle$ and $K = \langle y\rangle$.

Artin 11.5 For groups G_1, G_2 with centers Z_i, prove $Z(G_1 \times G_2) = Z_1 \times Z_2$.

Fraleigh 9.1 List the elements of $\mathbb{Z}_2 \times \mathbb{Z}_4$, find the order of each, and decide whether the group is cyclic.

Fraleigh 9.2 List the elements of $\mathbb{Z}_3 \times \mathbb{Z}_4$, find the order of each, and decide whether the group is cyclic.

Fraleigh 9.3 Find the order of $(2, 6)$ in $\mathbb{Z}_4 \times \mathbb{Z}_{12}$.

Fraleigh 9.4 Find the order of $(3, 4)$ in $\mathbb{Z}_{21} \times \mathbb{Z}_{12}$.

Fraleigh 9.5 Find the order of $(40, 12)$ in $\mathbb{Z}_{45} \times \mathbb{Z}_{18}$.

Fraleigh 9.6 Find the order of $(3, 10, 9)$ in $\mathbb{Z}_4 \times \mathbb{Z}_{12} \times \mathbb{Z}_{15}$.

Fraleigh 9.7 Find the order of $(3, 6, 12, 16)$ in $\mathbb{Z}_4 \times \mathbb{Z}_{12} \times \mathbb{Z}_{20} \times \mathbb{Z}_{24}$.

Fraleigh 9.8 Find the largest order of a cyclic subgroup of $\mathbb{Z}_6 \times \mathbb{Z}_8$ and of $\mathbb{Z}_{12} \times \mathbb{Z}_{15}$.

Fraleigh 9.9 Find all proper nontrivial subgroups of $\mathbb{Z}_2 \times \mathbb{Z}_2$.

Fraleigh 9.10 Find all proper nontrivial subgroups of $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$.

Fraleigh 9.11 Find all subgroups of $\mathbb{Z}_2 \times \mathbb{Z}_4$ of order 4.

Fraleigh 9.12 Find all subgroups of $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_4$ isomorphic to the Klein 4-group.

Fraleigh 9.13 Write $\mathbb{Z}_{60}$ as a direct product of two or more groups $\mathbb{Z}_n$ in as many ways as possible (ignoring factor order).

Fraleigh 9.14 Fill in the blanks: order of $\langle 18 \rangle$ in $\mathbb{Z}_{24}$; order of $\mathbb{Z}_3 \times \mathbb{Z}_4$; order of $(4, 2)$ in $\mathbb{Z}_{12} \times \mathbb{Z}_8$; $V \cong \mathbb{Z}_? \times \mathbb{Z}_?$; number of finite-order elements of $\mathbb{Z}_2 \times \mathbb{Z} \times \mathbb{Z}_4$.

Fraleigh 9.15 Find the maximum order of an element of $\mathbb{Z}_4 \times \mathbb{Z}_6$.

Fraleigh 9.16 Are $\mathbb{Z}_2 \times \mathbb{Z}_{12}$ and $\mathbb{Z}_4 \times \mathbb{Z}_6$ isomorphic? Why or why not?

Fraleigh 9.17 Find the maximum order of an element of $\mathbb{Z}_8 \times \mathbb{Z}_{28} \times \mathbb{Z}_{24}$.

Fraleigh 9.18 Are $\mathbb{Z}_8 \times \mathbb{Z}_{10} \times \mathbb{Z}_{24}$ and $\mathbb{Z}_4 \times \mathbb{Z}_{12} \times \mathbb{Z}_{40}$ isomorphic? Why or why not?

Fraleigh 9.19 Find the maximum order of an element of $\mathbb{Z}_4 \times \mathbb{Z}_{18} \times \mathbb{Z}_{15}$.

Fraleigh 9.20 Are $\mathbb{Z}_4 \times \mathbb{Z}_{18} \times \mathbb{Z}_{15}$ and $\mathbb{Z}_3 \times \mathbb{Z}_{36} \times \mathbb{Z}_{10}$ isomorphic? Why or why not?

Fraleigh 9.21 Find all abelian groups up to isomorphism of order 8, with invariant factors.

Fraleigh 9.22 Find all abelian groups up to isomorphism of order 16, with invariant factors.

Fraleigh 9.23 Find all abelian groups up to isomorphism of order 32, with invariant factors.

Fraleigh 9.24 Find all abelian groups up to isomorphism of order 720, with invariant factors.

Fraleigh 9.25 Find all abelian groups up to isomorphism of order 1089, with invariant factors.

Fraleigh 9.26 How many abelian groups (up to isomorphism) are there of order 24, of order 25, and of order (24)(25)?

Fraleigh 9.32 True/false on direct products: e.g. $G_1 \times G_2 \cong G_2 \times G_1$; $\mathbb{Z}_2 \times \mathbb{Z}_4 \cong \mathbb{Z}_8$; $\mathbb{Z}_3 \times \mathbb{Z}_8 \cong S_4$; $|\mathbb{Z}_{12} \times \mathbb{Z}_{15}| = 60$.

Fraleigh 9.36 True/false: e.g. every abelian group of prime power order is cyclic; $\mathbb{Z}_8 = \langle 4, 6 \rangle$; every abelian group of order divisible by 5 has a cyclic subgroup of order 5.

Fraleigh 9.40 Find the order of the torsion subgroup of $\mathbb{Z}_4 \times \mathbb{Z} \times \mathbb{Z}_3$ and of $\mathbb{Z}_{12} \times \mathbb{Z} \times \mathbb{Z}_{12}$.

Fraleigh 9.41 Find the torsion subgroup of the multiplicative group $\mathbb{R}^\times$.

Fraleigh 9.42 Find the torsion subgroup T of the multiplicative group $\mathbb{C}^\times$.

Fraleigh 9.44 Find the torsion coefficients (invariant factors) of each of four given abelian groups.

Fraleigh 9.45 Give a two-sentence synopsis of the proof of Theorem 9.5 ($\mathbb{Z}_m \times \mathbb{Z}_n \cong \mathbb{Z}_{mn}$ iff $\gcd(m, n) = 1$).

Fraleigh 19.2 Decide whether $\{(2, 1), (3, 1)\}$ is a basis for $\mathbb{Z} \times \mathbb{Z}$ and prove it.

Fraleigh 19.3 Decide whether $\{(2, 1), (4, 1)\}$ is a basis for $\mathbb{Z} \times \mathbb{Z}$ and prove it.

Fraleigh 19.5 Correct (if needed) the definition: "the rank of a free abelian group G is the number of elements in a generating set for G."

Fraleigh 19.6 Correct (if needed) the definition of a basis for a nonzero abelian group G.

Fraleigh 19.8 True/false on free abelian groups: e.g. every free abelian group is torsion free; there is a free abelian group of every positive rank; a nonzero subgroup of a finitely generated free abelian group is free abelian.

Medium

DF 5.1.2 For $G = G_1 \times \cdots \times G_n$, proper nonempty $I \subseteq \{1, \ldots, n\}$ and J its complement, prove $G_I \cong \prod_{i \in I} G_i$, that $G_I \trianglelefteq G$ with $G/G_I \cong G_J$, and $G \cong G_I \times G_J$.

DF 5.1.3 With the preceding notation and disjoint nonempty I, K, prove $xy = yx$ for all $x \in G_I$, $y \in G_K$.

DF 5.1.7 For groups G_i and fixed $\pi \in S_n$, prove the reindexing map $\varphi_\pi : \prod G_i \to \prod G_{\pi^{-1}(i)}$, $(g_i) \mapsto (g_{\pi^{-1}(i)})$, is an isomorphism.

DF 5.1.9 For a field F, use the preceding to show the $n \times n$ permutation matrices form a subgroup of $\mathrm{GL}_n(F)$ isomorphic to S_n.

DF 5.1.14 For $G = A_1 \times \cdots \times A_n$ with $B_i \trianglelefteq A_i$, prove $\prod B_i \trianglelefteq G$ and $(\prod A_i)/(\prod B_i) \cong \prod (A_i/B_i)$.

DF 5.1.15 For an arbitrary index set I and groups $(G_i, \star_i)$, verify that componentwise multiplication on $\prod_{i \in I} G_i$ is well defined and associative, with identity $\prod 1_i$ and inverses $\prod a_i^{-1}$.

DF 5.1.16 State and prove the generalization of Proposition 2 to arbitrary direct products.

DF 5.2.5 For a finite abelian group G of type $(n_1, \ldots, n_t)$, prove G has an element of order m iff $m \mid n_1$, and deduce G has exponent n_1.

DF 5.2.6 Prove every finite group has finite exponent; give an infinite group of finite exponent; ask whether a finite group of exponent m must have an element of order m.

DF 5.2.7 For an abelian p-group $A = \langle x_1 \rangle \times \cdots \times \langle x_n \rangle$ with $|x_i| = p^{\alpha_i} > 1$, study the pth-power map $\varphi : x \mapsto x^p$: prove it is a homomorphism, describe its image and kernel by generators, and show $\ker \varphi$ and $A/\operatorname{im} \varphi$ each have rank n and are $\cong E_{p^n}$.

DF 5.2.8 For a finite abelian group A and prime p, with $A^p = \{a^p\}$ and $A_p = \{x : x^p = 1\}$, prove $A/A^p \cong A_p$, and that the number of subgroups of order p equals the number of index p.

DF 5.2.10 For the free abelian group A of rank n and $k \in \mathbb{Z}^+$, prove $A/kA \cong (\mathbb{Z}/k\mathbb{Z})^n$.

DF 5.2.13 For $A = \langle x_1 \rangle \times \cdots \times \langle x_r \rangle$ with $|x_i| = n_i$, find a presentation of A and prove the universal property: commuting g_i with $g_i^{n_i} = 1$ yield a unique homomorphism $x_i \mapsto g_i$.

DF 5.4.2 Prove a subgroup $H \leq G$ is normal iff $[G, H] \leq H$.

DF 5.4.3 Prove $[a, bc] = [a, c](c^{-1}[a, b]c)$ and $[ab, c] = (b^{-1}[a, c]b)[b, c]$.

DF 5.4.8 If $x, y \in G$ both commute with $[x, y]$, prove $(xy)^n = x^n y^n [y, x]^{n(n-1)/2}$ for all $n \in \mathbb{Z}^+$.

DF 5.4.10 Prove a finite abelian group is the direct product of its Sylow subgroups.

DF 5.4.15 If $A, B \trianglelefteq G$ with G/A and G/B abelian, prove $G/(A \cap B)$ is abelian.

DF 5.4.16 If $K \trianglelefteq G$, prove $K' \trianglelefteq G$.

DF 5.4.17 If $K \trianglelefteq G$ is cyclic, prove $G' \leq C_G(K)$.

DF 5.4.21 If G_1, G_2 are groups, prove $\mathrm{Aut}(G_1 \times G_2)$ contains a subgroup isomorphic to $\mathrm{Aut}(G_1) \times \mathrm{Aut}(G_2)$.

DF 5.5.3 In Example 1 after Proposition 11, prove every element of $G - H$ has order 2, and G is abelian iff $h^2 = 1$ for all $h \in H$.

DF 5.5.11 Classify the groups of order 28 (there are four isomorphism types).

DF 5.5.12 Classify the groups of order 20 (there are five isomorphism types).

DF 5.5.16 Show there are exactly 4 homomorphisms $\mathbb{Z}_2 \to \mathrm{Aut}(\mathbb{Z}_8)$, giving the semidirect products $\mathbb{Z}_8 \times \mathbb{Z}_2$, D_{16}, QD_{16}, and the modular group M.

Artin 11.3 Prove that the product of two infinite cyclic groups is not infinite cyclic.

Artin 11.4 In each case decide whether $G \cong H \times K$: (a) $G = \mathbb{R}^\times$, $H = \{\pm 1\}$, $K = \mathbb{R}_{>0}$; (b) G invertible upper-triangular 2×2, H diagonal, K unipotent; (c) $G = \mathbb{C}^\times$, H the unit circle, $K = \mathbb{R}_{>0}$.

Artin 11.6 If G has normal subgroups of orders 3 and 5, prove G contains an element of order 15.

Artin 11.7 For $H \leq G$ and a homomorphism $\varphi : G \to H$ restricting to the identity on H, with $N = \ker \varphi$, describe the product map $H \times N \to G$.

Artin 11.8 For groups G, G', H, establish a bijection between homomorphisms $H \to G \times G'$ and pairs (φ, φ') with $\varphi : H \to G$, $\varphi' : H \to G'$.

Artin 11.9 For subgroups $H, K \leq G$, prove HK is a subgroup iff $HK = KH$.

Artin M.2 (a) Prove every group of even order has an element of order 2; (b) prove every group of order 21 has an element of order 3.

Fraleigh 9.27 If there are r abelian groups of order m and s of order n with $\gcd(m, n) = 1$, show there are rs abelian groups of order mn.

Fraleigh 9.28 Use the multiplicativity above to count the abelian groups (up to isomorphism) of order 10^5.

Fraleigh 9.29 Fill in the count of abelian groups of order p^n for $n = 2, \ldots, 8$, then count abelian groups of order $p^3q^4r^7$, $(qr)^7$, $q^5r^4q^3$.

Fraleigh 9.34 (a) How many subgroups of $\mathbb{Z}_5 \times \mathbb{Z}_6$ are isomorphic to $\mathbb{Z}_5 \times \mathbb{Z}_6$? (b) How many subgroups of $\mathbb{Z} \times \mathbb{Z}$ are isomorphic to $\mathbb{Z} \times \mathbb{Z}$?

Fraleigh 9.37 For distinct primes p, q, compare the number of abelian groups of order p^r with the number of order q^r.

Fraleigh 9.38 For an abelian G of order 72, decide whether the number of subgroups of order 8, and of order 4, is determined.

Fraleigh 9.39 For an abelian group G, show the elements of finite order form a subgroup (the torsion subgroup).

Fraleigh 9.43 Use Theorem 9.12 to show every finitely generated abelian group is the internal direct product of its torsion subgroup and a torsion-free subgroup.

Fraleigh 19.1 Find a basis $\{(a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3)\}$ of $\mathbb{Z} \times \mathbb{Z} \times \mathbb{Z}$ with all entries nonzero.

Fraleigh 19.4 Find conditions on $a, b, c, d \in \mathbb{Z}$ for $\{(a, b), (c, d)\}$ to be a basis of $\mathbb{Z} \times \mathbb{Z}$.

Fraleigh 19.7 Show by example that a proper subgroup of a free abelian group of rank r can also have rank r.

Fraleigh 19.9 Complete the proof of Theorem 19.5 (a free abelian group with a basis of r elements is $\cong \mathbb{Z}^r$).

Fraleigh 19.10 Show a free abelian group contains no nonzero element of finite order.

Fraleigh 19.11 Show that if G, G' are free abelian, then $G \times G'$ is free abelian.

Fraleigh 19.14 For a fixed prime p, show the elements of the torsion group T whose order is a power of p, together with 0, form a subgroup T_p.

Fraleigh 19.16 For an abelian group G and $n \in \mathbb{Z}^+$, show $G[n] = \{x \in G : nx = 0\}$ is a subgroup of G.

Hard

DF 5.1.4 For finite groups A, B and prime p, prove every Sylow p-subgroup of $A \times B$ is $P \times Q$ with $P \in \mathrm{Syl}_p(A)$, $Q \in \mathrm{Syl}_p(B)$, so $n_p(A \times B) = n_p(A)n_p(B)$; generalize to finitely many factors.

DF 5.1.8 For $G_1 = \cdots = G_n$, show each $\varphi_\pi \in \mathrm{Aut}(G)$ and that $\pi \mapsto \varphi_\pi$ is an injective homomorphism $S_n \hookrightarrow \mathrm{Aut}(G)$.

DF 5.1.12 Define the central product $A * B = (A \times B)/Z$; prove the images of A, B in $A * B$ are isomorphic to A, B and meet in a central $\cong Z_1$, find $|A * B|$, and show $Z_4D_8 \cong Z_4Q_8$.

DF 5.1.13 Give presentations for the central products Z_4D_8 and Z_4Q_8 of the preceding exercise.

DF 5.1.17 For an index set I and groups G_i, prove the restricted direct product is a normal subgroup of the direct product, and for $I = \mathbb{Z}^+$ and $G_i = \mathbb{Z}/p_i\mathbb{Z}$ (p_i the ith prime) show every element has finite order while the full product has infinite-order elements (it is the torsion subgroup).

DF 5.1.18 In (a)–(e) give an example of a group with the stated property (e.g. infinite with every element of order 1 or 2; $G \cong G \times G$ nontrivial).

DF 5.2.11 For a nontrivial finite abelian G of rank t, prove the rank equals the max of the ranks of its Sylow subgroups, and G needs exactly t generators.

DF 5.2.12 For n, m with $d = (n, m)$ and the central product A of $\langle x\rangle, \langle y\rangle$ with order-d identified, describe A as a direct product of two cyclic groups.

DF 5.3.1 Prove D_{16}, $\mathbb{Z}_2 \times D_8$, $\mathbb{Z}_2 \times Q_8$, $\mathbb{Z}_4 * D_8$, QD_{16}, and M are pairwise nonisomorphic non-abelian groups of order 16.

DF 5.4.5 Prove A_n is the commutator subgroup of S_n for all $n \geq 5$.

DF 5.4.7 Prove that if p is prime and P is a non-abelian group of order p^3, then $P' = Z(P)$.

DF 5.4.9 For an odd prime p and $|P| = p^3$, prove $x \mapsto x^p$ is a homomorphism $P \to Z(P)$; if P is not cyclic the kernel has order p^2 or p^3; discuss the squaring map for order 8 and where oddness is used.

DF 5.4.11 If $G = HK$ with H, K characteristic and $H \cap K = 1$, prove $\mathrm{Aut}(G) \cong \mathrm{Aut}(H) \times \mathrm{Aut}(K)$, and deduce Aut of a finite abelian group splits over its Sylow subgroups.

DF 5.4.14 For G the upper-triangular matrices in $\mathrm{GL}_n(F)$ with equal diagonal entries, prove $G \cong D \times U$ (D scalars, U unipotent upper-triangular).

DF 5.4.18 For non-abelian simple K_i and $G = K_1 \times \cdots \times K_n$, prove every normal subgroup of G is $G_I = \prod_{i \in I} K_i$ for some I.

DF 5.4.19 (perfect groups) Prove every non-abelian simple group is perfect; $\langle H, K\rangle$ of perfect H, K is perfect; conjugates of perfect subgroups are perfect; every G has a unique maximal perfect subgroup, which is normal.

DF 5.4.20 For the Heisenberg group $H(F)$, find an explicit formula for $[X, Y]$ and show the commutator subgroup equals the center.

DF 5.5.6 For cyclic K, arbitrary H, and $\varphi_1, \varphi_2 : K \to \mathrm{Aut}(H)$ with conjugate images (both injective if K is infinite), prove $H \rtimes_{\varphi_1} K \cong H \rtimes_{\varphi_2} K$ by constructing an explicit isomorphism.

DF 5.5.5 For $G = \mathrm{Hol}(\mathbb{Z}_2 \times \mathbb{Z}_2)$, prove $G = H \rtimes K$ with $H \cong \mathbb{Z}_2 \times \mathbb{Z}_2$, $K \cong S_3$ (so $|G| = 24$), and $G \cong S_4$.

DF 5.5.7 Classify the thirteen isomorphism types of groups of order 56 (abelian count, normal Sylow analysis, and construction by Sylow 2-subgroup type).

DF 5.5.8 Construct a non-abelian group of order 75 and classify all groups of order 75 (there are three).

DF 5.5.9 Show $\begin{pmatrix} 0 & -1 \\ 1 & 4 \end{pmatrix}$ has order 5 in $\mathrm{GL}_2(\mathbb{F}_{19})$, use it to build a non-abelian group of order 1805 with a presentation, and classify order 1805 (three types).

DF 5.5.10 Classify the six isomorphism types of groups of order 147 via the normal Sylow 7-subgroup and the action of order-3 subgroups of $\mathrm{GL}_2(\mathbb{F}_7)$.

DF 5.5.13 Classify the groups of order $4p$ for a prime $p > 3$ (four types if $p \equiv 3$, five if $p \equiv 1 \pmod 4$).

DF 5.5.14 Classify the thirteen isomorphism types of groups of order 60 (cases by normality of the Sylow 5- and 3-subgroups).

DF 5.5.15 For an odd prime p, prove every order-2 element of $\mathrm{GL}_2(\mathbb{F}_p)$ is conjugate to a ± 1 diagonal matrix, and classify the groups of order $2p^2$.

DF 5.5.17 For $n \geq 3$ show there are exactly 4 homomorphisms $\mathbb{Z}_2 \to \mathrm{Aut}(\mathbb{Z}_{2^n})$ giving 4 nonisomorphic groups of order 2^{n+1}.

DF 5.5.18 Show every group H embeds as a normal subgroup of a group G in which every automorphism of H is induced by conjugation by some $g \in G$.

DF 5.5.19 For H of order n, $K = \mathrm{Aut}(H)$, $G = \mathrm{Hol}(H)$: prove the regular representation of H has $N_{S_n}(\pi(H)) \cong \mathrm{Hol}(H)$, and deduce the normalizer of $\langle n\text{-cycle} \rangle$ in S_n is $\mathrm{Hol}(\mathbb{Z}_n)$ of order $n\varphi(n)$.

DF 5.5.20 For an odd prime p and non-cyclic p-group P, prove P has a normal subgroup $\cong \mathbb{Z}_p \times \mathbb{Z}_p$, and deduce a p-group with a unique subgroup of order p is cyclic.

DF 5.5.21 For an odd prime p, prove a p-group in which every subgroup is normal is abelian (false for $p = 2$ by Q_8).

DF 5.5.22 For the upper-triangular group G in $\mathrm{GL}_n(F)$, prove $G = U \rtimes D$ (unipotent and diagonal), and for $n = 2$ describe the action of $D \cong F^\times \times F^\times$ on $U \cong F$ explicitly.

DF 5.5.23 Define the wreath product $L \wr K$; for finite K, L with the regular representation find $|L \wr K|$, and prove $\mathbb{Z}_p \wr \mathbb{Z}_p$ is non-abelian of order p^{p+1} isomorphic to a Sylow p-subgroup of S_{p^2}.

DF 5.5.24 Prove every group of order n is abelian iff $n = p_1^{\alpha_1} \cdots p_r^{\alpha_r}$ with each $\alpha_i \in \{1, 2\}$ and $p_i \nmid p_j^{\alpha_j} - 1$ for all i, j.

DF 5.5.25 For $H(\mathbb{F}_p)$ the Heisenberg group over $\mathbb{F}_p$, prove $H(\mathbb{F}_2) \cong D_8$ and that for odd p, $H(\mathbb{F}_p)$ has exponent p and is the first non-abelian group in Example 7.

Artin M.3 Classify groups of order 6 by the cases: an element of order 6; an element of order 3 but none of order 6; all elements of order 1 or 2.

Fraleigh 19.12 Show free abelian groups of finite rank are precisely the finitely generated abelian groups with no nonzero element of finite order.

Fraleigh 19.13 Show $\mathbb{Q}$ under addition is not a free abelian group.

Fraleigh 19.15 Show that in any prime-power decomposition of T, the subgroup T_p is isomorphic to the product of the cyclic factors of p-power order (reducing the uniqueness problem to T_p).

6.1 p-Groups, Nilpotent Groups, and Solvable Groups

The upper and lower central series; nilpotent groups

Throughout, G is a group and $[x,y] = x^{-1}y^{-1}xy$. For subgroups $A, B \leq G$ we write $[A,B] = \langle [a,b] : a \in A,\ b \in B \rangle$, the subgroup generated by all such commutators. Recall $[A,B] = [B,A]$ (since $[a,b]^{-1} = [b,a]$), and that $[A,B] = 1$ exactly when every element of A commutes with every element of B.

Definition 6.1.1 (Upper central series)**.** The *upper central series* of G is the chain of subgroups

$$1 = Z_0 \leq Z_1 \leq Z_2 \leq \cdots$$

defined inductively by $Z_0 = 1$ and, for $i \geq 0$,

$$Z_{i+1}/Z_i \;=\; Z(G/Z_i)\,.$$

Equivalently, $Z_{i+1} = \{\, g \in G : [g,x] \in Z_i \text{ for all } x \in G \,\}$ is the full preimage in G of the center of G/Z_i. In particular $Z_1 = Z(G)$.

Each $Z_i \trianglelefteq G$ (it is the preimage of a characteristic, hence normal, subgroup of G/Z_{i-1}), and the series is genuinely ascending until it stabilizes. We call Z_i the *ith center* of G.

Definition 6.1.2 (Lower central series)**.** The *lower central series* of G is the chain

$$G = \gamma_1 \geq \gamma_2 \geq \gamma_3 \geq \cdots, \qquad \gamma_1 = G, \quad \gamma_{i+1} = [\gamma_i, G].$$

So $\gamma_2 = [G,G] = G'$ is the commutator subgroup, $\gamma_3 = [G',G]$, and so on. Each γ_i is characteristic in G (hence normal), and γ_i/γ_{i+1} is contained in the center of G/γ_{i+1}, so the successive quotients are abelian and central.

Definition 6.1.3 (Nilpotent group; nilpotency class)**.** A group G is *nilpotent* if $Z_c = G$ for some $c \geq 0$, i.e. the upper central series reaches G in finitely many steps. The least such c is the *nilpotency class* of G. A nontrivial group has class ≥ 1; class 1 means $G = Z(G)$, i.e. G is abelian (and nontrivial).

Proposition 6.1.4 (Upper and lower series have equal length)**.** *For a group G and an integer $c \geq 0$ the following are equivalent:*

(a) $Z_c = G$ (upper central series reaches G at step c);

(b) $\gamma_{c+1} = 1$ (lower central series reaches 1 at step $c+1$).

Hence G is nilpotent iff the lower central series terminates at 1, and the two series have the same length: the class c is the least c with $Z_c = G$ and also the least c with $\gamma_{c+1} = 1$.

Proof. The two series interleave: we prove the dovetailing bound $\gamma_{i+1} \le Z_{c-i}$ for $0 \le i \le c$ whenever $Z_c = G$, and the dual bound $\gamma_{c+1-i} \le Z_i$ for $0 \le i \le c$ whenever $\gamma_{c+1} = 1$. The single ingredient is that elements of Z_j are central modulo Z_{j-1}, which gives

$$[Z_j, G] \le Z_{j-1} \qquad (j \ge 1).$$

$(a) \implies (b)$: Assume $Z_c = G$. We show $\gamma_{i+1} \le Z_{c-i}$ by induction on i. For $i = 0$: $\gamma_1 = G = Z_c = Z_{c-0}$. Assume $\gamma_i \le Z_{c-i+1}$. Then

$$\gamma_{i+1} = [\gamma_i, G] \le [Z_{c-i+1}, G] \le Z_{c-i},$$

where the last step is the displayed inclusion with $j = c - i + 1$. Taking $i = c$ gives $\gamma_{c+1} \le Z_0 = 1$, so $\gamma_{c+1} = 1$.

$(b) \implies (a)$: Assume $\gamma_{c+1} = 1$. We show $\gamma_{c+1-i} \le Z_i$ by induction on i. The base $i = 0$ is $\gamma_{c+1} = 1 \le Z_0$. For the inductive step, suppose $\gamma_{c+1-(i-1)} = \gamma_{c-i+2} \le Z_{i-1}$. Then for $g \in \gamma_{c-i+1}$ we have

$$[g, G] \le [\gamma_{c-i+1}, G] = \gamma_{c-i+2} \le Z_{i-1},$$

so g is central modulo Z_{i-1}, i.e. $g \in Z_i$; thus $\gamma_{c-i+1} \le Z_i$. Taking $i = c$ gives $G = \gamma_1 \le Z_c$, so $Z_c = G$. □

Remark 6.1.1. The two series "zip" past each other: in a class-c group, $\gamma_{i+1} \le Z_{c-i}$ for $0 \le i \le c$. Drawn as facing chains, the lower series descending on the left meets the upper series ascending on the right exactly at length c.

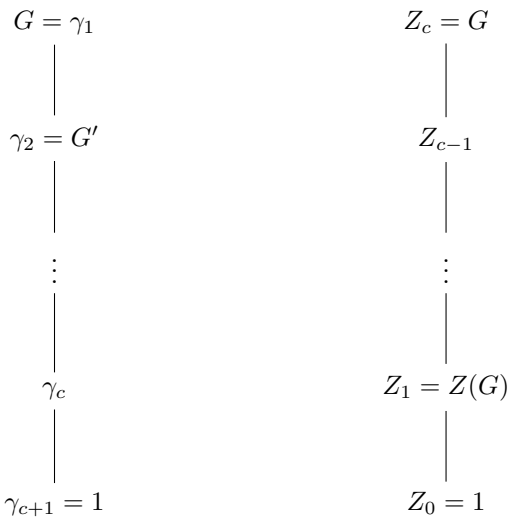

Diagram explanation. Objects: Two descending chains of normal subgroups of a nilpotent group G of class c. Left column: the lower central series $G = \gamma_1 \ge \gamma_2 \ge \cdots \ge \gamma_{c+1} = 1$, where each $\gamma_{i+1} = [\gamma_i, G]$ is generated by commutators. Right column: the upper central series $1 = Z_0 \le Z_1 \le \cdots \le Z_c = G$, where each Z_{i+1} is the full preimage of $Z(G/Z_i)$. Both chains consist of characteristic (hence normal) subgroups of G.

Arrows: Every arrow is drawn with *no head*, indicating a strict inclusion of subgroups (not a homomorphism). Downward arrows on the left record $\gamma_{i+1} \le \gamma_i$; downward arrows on the right record $Z_{i-1} \le Z_i$ (written top-to-bottom, so the upper series appears reversed). There are no horizontal arrows; the diagram juxtaposes the two chains but does not draw any explicit inter-column map.

What commutes: The diagram has no composable arrows and hence no path equality to state. Its content is the *dovetailing bound*: for all $0 \le i \le c$, $\gamma_{i+1} \le Z_{c-i}$. Reading across any horizontal level, the lower-series term γ_{i+1} sits inside the upper-series term Z_{c-i} beside it.

Why it commutes: Chase the bound by induction. Base: $\gamma_1 = G = Z_c = Z_{c-0}$. Inductive step: suppose $\gamma_i \le Z_{c-i+1}$. Then $\gamma_{i+1} = [\gamma_i, G] \le [Z_{c-i+1}, G] \le Z_{c-i}$, using the key inclusion $[Z_j, G] \le Z_{j-1}$ (elements of Z_j are central modulo Z_{j-1}). Taking $i = c$ gives $\gamma_{c+1} \le Z_0 = 1$, so the lower series terminates.

Why this matters here: This diagram appears immediately after the remark that the two series "zip past each other," and it is the geometric content of Proposition 6.1.4: the lower and upper series have the same length c. It makes the abstract induction visible — the series descend and ascend in lockstep, meeting exactly at length c on both sides.

Concrete example: For $G = D_8$ with class $c = 2$: left column is $D_8 \geq \langle r^2 \rangle \geq 1$; right column is $1 \leq \langle r^2 \rangle \leq D_8$. The bound says $\gamma_2 = \langle r^2 \rangle \leq Z_1 = \langle r^2 \rangle$, which holds with equality — the two series share the same middle term.

Common pitfall: Students read the diagram as asserting $\gamma_{i+1} = Z_{c-i}$ (equality at each level). The bound is containment $\gamma_{i+1} \leq Z_{c-i}$, which can be strict. Also, the two series run in opposite directions: the lower series descends (gets smaller) while the upper series ascends (gets larger), so level i on the left does not pair with level i on the right — it pairs with level $c - i$ on the right.

Takeaway: The point of this diagram is that the lower and upper central series of a nilpotent group interleave symmetrically, each dovetailing inside the other, so they must terminate in exactly the same number of steps.

Method (Building the upper central series of a finite group)**.** *Trigger.* You are asked for $Z_i(G)$, the class of G, or to test nilpotency of a specific finite group.
Recipe.

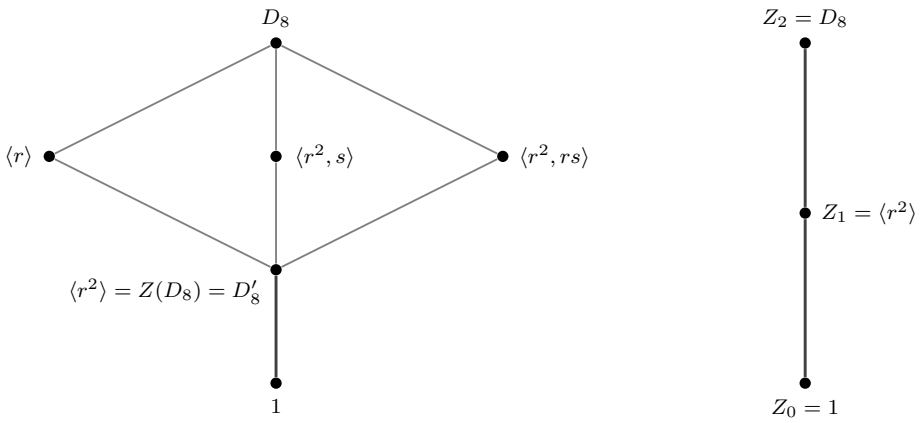
1. Compute $Z_1 = Z(G)$ directly.
2. Form $\bar{G} = G/Z_1$ and compute $Z(\bar{G})$; pull back to G to get Z_2 (the preimage of $Z(\bar{G})$).
3. Repeat: Z_{i+1} = preimage in G of $Z(G/Z_i)$. Stop when $Z_i = Z_{i-1}$ (stabilized) or $Z_i = G$ (reached the top).
4. If the series reaches G, the class is the index where it first equals G. If it stalls below G, G is *not* nilpotent.

Worked Example 6.1.5 (Center of D_8 and the start of its upper series)**.** Let $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$. Find $Z(D_8)$.

Recognition. Center first: $Z_1 = Z(G)$ is step 1 of the upper central series, and for a 2-group we expect it to be nontrivial.

Solution. We test each noncentral generator. Since $srs = r^{-1} \neq r$, $r \notin Z$; since $rs \neq sr$, $s \notin Z$. The element r^2 satisfies $sr^2s = (srs)^2 = r^{-2} = r^2$ (as $r^4 = 1$), and r^2 commutes with r, so $r^2 \in Z$. The eight elements are $1, r, r^2, r^3, s, rs, r^2s, r^3s$; checking conjugation by s sends $r^k \mapsto r^{-k}$ and conjugation by r sends $r^k s \mapsto r^{k+2}s$, so only 1 and r^2 are fixed by all conjugations. Thus $Z(D_8) = \{1, r^2\} \cong \mathbb{Z}/2\mathbb{Z}$. *Check.* $|Z| = 2$ divides $|G| = 8$, and $G/Z(G)$ has order 4; if it were cyclic G would be abelian, so $G/Z \cong V_4$. Consistent.

Worked Example 6.1.6 (Full upper central series of D_8 (class 2))**.** Compute $1 = Z_0 \leq Z_1 \leq Z_2 \leq \cdots$ for D_8 and state its nilpotency class.



Recognition. Iterate the center-of-quotient construction; D_8 is a 2-group so the series must reach G.

Solution. From the previous example $Z_1 = \{1, r^2\}$. Now $\bar{G} = D_8/Z_1$ has order 4. The images $\bar{r}, \bar{s}$ satisfy $\bar{r}^2 = \overline{r^2} = \bar{1}$ and $\bar{s}^2 = \bar{1}$ and $\bar{s}\bar{r}\bar{s} = \overline{r^{-1}} = \bar{r}$ (since r and r^{-1} differ by $r^2 \in Z_1$), so $\bar{G} \cong V_4$, which is abelian. Hence $Z(\bar{G}) = \bar{G}$, and pulling back, $Z_2 = G$. The series is

$$1 \leq \{1, r^2\} \leq D_8,$$

so D_8 is nilpotent of *class* 2. *Check.* Cross-check with the lower series: $\gamma_2 = [D_8, D_8] = \langle r^2 \rangle$ (the only nontrivial commutators are powers of r^2, e.g. $[r, s] = r^{-1}s^{-1}rs = r^{-1} \cdot r^{-1} = r^{-2} = r^2$), and $\gamma_3 = [\gamma_2, G] = [\langle r^2 \rangle, G] = 1$ since r^2 is central. So $\gamma_3 = 1$ at index $3 = c + 1$, confirming class $c = 2$.

The central chain sits inside the subgroup lattice of D_8: the central subgroup $\langle r^2 \rangle = Z(D_8) = D_8'$ lies below all three maximal (index-2) subgroups. (It is not the only minimal subgroup: $\langle s \rangle, \langle r^2 s \rangle \leq \langle r^2, s \rangle$ and $\langle rs \rangle, \langle r^3 s \rangle \leq \langle r^2, rs \rangle$ also have order 2; the picture below omits these four noncentral subgroups and shows only 1 and the subgroups containing $Z(D_8)$.) The genuine lattice covering $1 \lessdot \langle r^2 \rangle$ is bold below; but $\langle r^2 \rangle$ is *not* covered by D_8 (every maximal subgroup sits strictly between them), so the upper central series $1 \trianglelefteq \langle r^2 \rangle \trianglelefteq D_8$ is *not* a single edge-path through the lattice — after the order-2 center it jumps straight to the top, skipping the entire order-4 row. That genuine series is drawn as the standalone chain to the right.

upper central series

Worked Example 6.1.7 (Q_8 is nilpotent of class 2)**.** For the quaternion group $Q_8 = \{\pm 1, \pm i, \pm j, \pm k\}$, find the upper central series and the class.

Recognition. 2-group, so nilpotent; compute Z_1 then the quotient.

Solution. Each of i, j, k has -1 as its square and they anticommute ($ij = k = -ji$), so $i, j, k \notin Z$. But -1 commutes with everything: $(-1)x = x(-1)$ for all x. Thus $Z_1 = Z(Q_8) = \{\pm 1\} \cong \mathbb{Z}/2\mathbb{Z}$. Then $Q_8/\{\pm 1\}$ has order 4 with every nonidentity element of order 2 (the image of i squares to the image of -1, which is the identity), so it is V_4, abelian. Hence $Z_2 = Q_8$ and the class is 2:

$$1 \leq \{\pm 1\} \leq Q_8.$$

Check. $\gamma_2 = [Q_8, Q_8] = \{\pm 1\}$ (e.g. $[i, j] = i^{-1}j^{-1}ij = (-i)(-j)(i)(j) = (ij)(ij) = k^2 = -1$), and $\gamma_3 = [\{\pm 1\}, Q_8] = 1$. Class 2 again.

Worked Example 6.1.8 (S_3 is NOT nilpotent)**.** Show S_3 is not nilpotent by computing both series.

Recognition. If $Z(G) = 1$ the upper series never leaves 1; if $G' = G$ the lower series never leaves G. Either stalls $\Longrightarrow$ not nilpotent.

Solution. Center: S_3 is nonabelian with trivial center, $Z(S_3) = 1$. Hence $Z_0 = Z_1 = 1$, and since $G/Z_0 = S_3$ has trivial center, every $Z_i = 1$. The upper series stalls at $1 \neq S_3$, so S_3 is not nilpotent. Lower series: $\gamma_2 = [S_3, S_3] = A_3 = \langle (1\,2\,3) \rangle \cong \mathbb{Z}/3\mathbb{Z}$, and $\gamma_3 = [A_3, S_3]$. A transposition conjugates the 3-cycle to its inverse, so $[(1\,2\,3), (1\,2)] = (1\,3\,2)(1\,2)(1\,2\,3)(1\,2) = (1\,3\,2)(1\,3\,2) = (1\,2\,3) \in A_3$; in fact $[A_3, S_3] = A_3$, so $\gamma_2 = \gamma_3 = A_3 \neq 1$. The lower series stalls at A_3. *Check.* Both diagnostics agree: $Z_1 = 1$ and γ_2 does not descend to 1. S_3 is solvable (its derived series is $S_3 \geq A_3 \geq 1$) but not nilpotent — a clean separation of the two notions.

Finite p-groups are nilpotent

Theorem 6.1.9 (p-groups are nilpotent)**.** *Every finite p-group is nilpotent. More precisely, if $|G| = p^n$ then the upper central series of G reaches G, and the class is at most $n - 1$ when $n \geq 2$ (and class $\leq n$ in general).*

Proof. The key fact is that a nontrivial finite p-group has nontrivial center: G acts on itself by conjugation, the class equation gives $|G| = |Z(G)| + \sum [G : C_G(x_i)]$ over noncentral class representatives, every index $[G : C_G(x_i)]$ is a positive power of p, and $p \mid |G|$, so $p \mid |Z(G)|$, forcing $|Z(G)| > 1$.

Now run the upper central series. If $Z_i \neq G$, then G/Z_i is a nontrivial finite p-group, so $Z(G/Z_i) \neq 1$, i.e. $Z_{i+1}/Z_i \neq 1$ and $Z_{i+1} \gneq Z_i$. Thus the series *strictly* increases at every step below G. Since $|G| = p^n$ is finite, the chain $1 = Z_0 \lneq Z_1 \lneq \cdots$ cannot grow forever; it must reach G. Hence G is nilpotent.

For the class bound, let c be the class. Each strict step multiplies the order by at least p, so $|Z_i| \geq p^i$ for $i \leq c$, whence $c \leq n$. If $n \geq 2$ and $c = n$, then $|Z_i| = p^i$ for every $i \leq n$, so G/Z_{n-2} has order p^2 and is therefore abelian; then $Z(G/Z_{n-2}) = G/Z_{n-2}$, i.e. $Z_{n-1} = G$, contradicting $c = n$. Hence $c \leq n - 1$ when $n \geq 2$. □

Caution. "p-group" here means a finite group of prime-power order. Infinite p-groups (e.g. the semidirect product $\mathbb{Z}_{2^\infty} \rtimes \mathbb{Z}/2\mathbb{Z}$ in which $\mathbb{Z}/2\mathbb{Z}$ acts on the Prüfer 2-group $\mathbb{Z}_{2^\infty}$ by inversion, or an infinite restricted wreath product) need not be nilpotent; the Prüfer group $\mathbb{Z}_{p^\infty}$ itself is abelian, hence nilpotent of class 1. The proof above uses finiteness twice: for the class equation and to guarantee the strictly increasing chain terminates.

Worked Example 6.1.10 (Class bound is sharp: D_8 has order 2^3 and class 2)**.** Verify the bound "class $\leq n-1$" for $|G| = p^n$ on $G = D_8$.

Recognition. Apply Theorem 6.1.9 with $p = 2$, $n = 3$.

Solution. Here $n = 3$, so the bound predicts class ≤ 2. We computed $\text{class}(D_8) = 2$. Sharp. *Check.* Q_8 also has order 8 and class 2, matching. The nonabelian groups of order p^3 all have class exactly 2.

Worked Example 6.1.11 (An elementary abelian p-group is nilpotent of class 1)**.** Let $E = (\mathbb{Z}/p\mathbb{Z})^k$ with $k \geq 1$. Find its class.

Recognition. Abelian nontrivial $\implies$ class 1; it is also a p-group, so Theorem 6.1.9 applies trivially.

Solution. E is abelian, so $Z(E) = E = Z_1$, and the upper series is $1 \leq E$ of length 1. The class is 1. The lower series is $E = \gamma_1 \geq \gamma_2 = [E, E] = 1$, terminating at index $2 = c + 1$. Consistent. *Check.* Any nontrivial abelian group has class 1; "p-group of class 1" $\iff$ "nontrivial abelian p-group".

Characterizations of finite nilpotent groups

The central theorem of this section ties nilpotency to Sylow theory and to the lattice of maximal subgroups.

Theorem 6.1.12 (Characterization of finite nilpotent groups)**.** *Let G be a finite group. The following are equivalent.*

(1) G is nilpotent.

(2) Every Sylow subgroup of G is normal in G.

(3) G is the (internal) direct product of its Sylow subgroups: if $|G| = p_1^{a_1} \cdots p_r^{a_r}$ with Sylow p_i-subgroup P_i, then $G \cong P_1 \times \cdots \times P_r$.

(4) Every maximal subgroup of G is normal in G.

Proof (sketch with the key implications). (1) $\implies$ (4): Let M be maximal. A standard fact for nilpotent groups is that proper subgroups are properly contained in their normalizers ("normalizers grow"), proved by induction on the class using the central series: if $H \lneq G$ then $H \lneq N_G(H)$. Hence $M \lneq N_G(M) \leq G$ forces $N_G(M) = G$, i.e. $M \trianglelefteq G$.

(4) $\implies$ (2): Let $P \in \text{Syl}_p(G)$. If P is not normal, then $N_G(P) \lneq G$, so $N_G(P) \leq M$ for some maximal M. By (4), $M \trianglelefteq G$. By the Frattini argument (Theorem 6.1.19 below) applied with $M \trianglelefteq G$ and $P \in \text{Syl}_p(M)$ (indeed $P \leq N_G(P) \leq M$, so P is Sylow in M), $G = M\,N_G(P)$. But $N_G(P) \leq M$, so $G = M$, contradicting $M \lneq G$. Hence every Sylow subgroup is normal.

(2) $\implies$ (3): If each $P_i \trianglelefteq G$, then P_iP_j is a subgroup and, for $i \neq j$, $P_i \cap P_j = 1$ (coprime orders) and elements of P_i, P_j commute (their commutator lies in $P_i \cap P_j = 1$ since both are normal). Building up, $P_1 \cdots P_r$ is an internal direct product of order $\prod p_i^{a_i} = |G|$, so $G = P_1 \times \cdots \times P_r$.

(3) $\implies$ (1): A finite direct product of nilpotent groups is nilpotent (the upper central series of a product is the product of the upper central series, so its length is the max of the factors' classes). Each P_i is a p-group, hence nilpotent by Theorem 6.1.9; therefore G is nilpotent. This closes the cycle (1) $\implies$ (4) $\implies$ (2) $\implies$ (3) $\implies$ (1). □

Remark 6.1.2. The class of a finite nilpotent group $G = P_1 \times \cdots \times P_r$ equals $\max_i \text{class}(P_i)$. So nilpotency of a finite group is "Sylow-local": it holds iff it holds prime-by-prime, after detaching the Sylow subgroups into a direct product.

Method (Sylow-normal nilpotency test (finite groups))**.** *Trigger.* "Is this finite group nilpotent?" — when you know $|G|$ and can count Sylow subgroups.
Recipe.

1. Factor $|G| = p_1^{a_1} \cdots p_r^{a_r}$.
2. For each prime p_i, use Sylow's theorem: count n_{p_i} (the number of Sylow p_i-subgroups), with $n_{p_i} \equiv 1 \pmod{p_i}$ and $n_{p_i} \mid m_i$ where $m_i = |G|/p_i^{a_i}$.
3. G is nilpotent $\iff$ $n_{p_i} = 1$ for *every* i (all Sylow subgroups normal).
4. If so, $G \cong P_1 \times \cdots \times P_r$; the class is the max of the Sylow classes.

Shortcut. If even one prime forces $n_p > 1$, G is not nilpotent.

Worked Example 6.1.13 (Nilpotent groups of order 12: resolve carefully)**.** Decide which groups of order 12 are nilpotent.

Recognition. Sylow-normal test: $12 = 2^2 \cdot 3$; nilpotent $\iff$ both the Sylow 2- and Sylow 3-subgroups are normal $\iff$ $G \cong P_2 \times P_3$.

Solution. The five groups of order 12 are $\mathbb{Z}/12\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$, A_4, D_{12}, and $\mathrm{Dic}_3 = Q_{12}$ (the dicyclic group). A nilpotent group of order 12 would be $P_2 \times P_3$ with $|P_2| = 4$, $|P_3| = 3$: that is ($\mathbb{Z}/4\mathbb{Z}$ or V_4) $\times\, \mathbb{Z}/3\mathbb{Z}$, giving exactly $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/12\mathbb{Z}$ and $V_4 \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$. These two abelian groups *are* nilpotent (class 1). The three nonabelian groups are not: in A_4, $n_3 = 4 \neq 1$ (the four Sylow 3-subgroups), so its Sylow 3-subgroup is not normal; in D_{12} and Q_{12}, the Sylow 2-subgroup is not normal (equivalently their center is too small to climb to G). *Check.* So among order-12 groups, exactly the two abelian ones are nilpotent. In particular there is no *nonabelian* nilpotent group of order 12: that would need a nonabelian Sylow factor, impossible for $|P_2| = 4, |P_3| = 3$. Both $\mathbb{Z}/12\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$ have class 1.

Worked Example 6.1.14 (A_4 is not nilpotent)**.** Confirm A_4 (order 12) fails the Sylow-normal test.

Recognition. Count n_3 in A_4.

Solution. $|A_4| = 12 = 2^2 \cdot 3$. The Sylow 3-subgroups are generated by 3-cycles; A_4 has eight 3-cycles, grouped into four subgroups of order 3 (each containing 2 nonidentity elements). So $n_3 = 4$, which satisfies $4 \equiv 1 \pmod{3}$ and $4 \mid 4$. Since $n_3 = 4 \neq 1$, the Sylow 3-subgroup is not normal, so A_4 is not nilpotent. *Check.* Directly: $Z(A_4) = 1$ (no nonidentity element is fixed by all conjugations in A_4), so the upper series stalls at 1. A_4 is solvable but not nilpotent.

Worked Example 6.1.15 (S_4 is not nilpotent)**.** Test S_4 (order 24) for nilpotency.

Recognition. Sylow-normal test; $24 = 2^3 \cdot 3$.

Solution. n_3: Sylow 3-subgroups are generated by 3-cycles; S_4 has eight 3-cycles in four order-3 subgroups, so $n_3 = 4 \neq 1$. Already this defeats nilpotency. *Check.* Also $Z(S_4) = 1$, so the upper series stalls at 1. So S_4 is not nilpotent; it *is* solvable, illustrating again that solvable does not imply nilpotent.

Worked Example 6.1.16 (A nilpotent group of order 24: $Q_8 \times \mathbb{Z}/3\mathbb{Z}$)**.** Exhibit a nonabelian nilpotent group of order 24 and give its class.

Recognition. $G \cong P_2 \times P_3$ with both Sylow normal; pick a nonabelian Sylow 2-subgroup.

Solution. Take $G = Q_8 \times \mathbb{Z}/3\mathbb{Z}$, order $8 \cdot 3 = 24$. Both factors are the (unique, hence normal) Sylow subgroups: $Q_8 \in \mathrm{Syl}_2(G)$, $\mathbb{Z}/3\mathbb{Z} \in \mathrm{Syl}_3(G)$, and a direct factor is normal. By Theorem 6.1.12, G is nilpotent. Its class is $\max(\mathrm{class}(Q_8), \mathrm{class}(\mathbb{Z}/3\mathbb{Z})) = \max(2, 1) = 2$. *Check.* $Z(G) = Z(Q_8) \times \mathbb{Z}/3\mathbb{Z} = \{\pm 1\} \times \mathbb{Z}/3\mathbb{Z}$ has order 6, and $G/Z(G) \cong V_4 \times 1 = V_4$ is abelian, so $Z_2(G) = G$: class 2, confirming the formula.

Caution. "Every Sylow subgroup normal" is much stronger than "some Sylow subgroup normal". A group can have a normal Sylow subgroup (even be solvable) without being nilpotent: S_3 has a normal Sylow 3-subgroup but its Sylow 2-subgroups (the three order-2 subgroups) are not normal, so S_3 is not nilpotent. You need *all* primes to cooperate.

The Frattini subgroup and Frattini's argument

Definition 6.1.17 (Frattini subgroup)**.** The *Frattini subgroup* $\Phi(G)$ of a finite group G is the intersection of all maximal subgroups of G:

$$\Phi(G) = \bigcap \{\, M : M \text{ is a maximal subgroup of } G \,\}.$$

If G has no maximal subgroups (the case $G = 1$), set $\Phi(G) = G = 1$. The Frattini subgroup is characteristic in G (any automorphism permutes the maximal subgroups), hence $\Phi(G) \trianglelefteq G$.

Proposition 6.1.18 (Nongenerators)**.** *$\Phi(G)$ is exactly the set of* nongenerators *of G: an element x such that whenever $G = \langle x, Y\rangle$ for a subset Y, already $G = \langle Y\rangle$. Consequently, if $\langle Y, \Phi(G)\rangle = G$ then $\langle Y\rangle = G$ (Frattini elements are dispensable in any generating set).*

Proof. If $x \notin \Phi(G)$, then $x \notin M$ for some maximal M; then $G = \langle x, M\rangle$ but $\langle M\rangle = M \neq G$, so x is a generator-contributor, not a nongenerator. Conversely, if $x \in \Phi(G)$ and $G = \langle x, Y\rangle$ with $\langle Y\rangle \neq G$, then $\langle Y\rangle$ lies in some maximal M; since $x \in \Phi(G) \leq M$, we get $\langle x, Y\rangle \leq M \neq G$, a contradiction. So $\langle Y\rangle = G$, i.e. x is a nongenerator. □

Theorem 6.1.19 (Frattini's argument)**.** *Let G be a finite group, $N \trianglelefteq G$, and $P \in \mathrm{Syl}_p(N)$ a Sylow p-subgroup of N. Then*

$$G = N\, N_G(P),$$

where $N_G(P)$ is the normalizer of P in G.

Proof. Let $g \in G$. Since $N \trianglelefteq G$, conjugation by g maps N to itself, so $gPg^{-1} \leq N$ and $gPg^{-1} \in \mathrm{Syl}_p(N)$ (conjugation preserves order and p-subgroup-ness). By Sylow's theorem applied *inside* N, all Sylow p-subgroups of N are N-conjugate, so there is $n \in N$ with $n(gPg^{-1})n^{-1} = P$, i.e. $(ng)P(ng)^{-1} = P$. Thus $ng \in N_G(P)$. Writing $g = n^{-1}(ng)$ with $n^{-1} \in N$ and $ng \in N_G(P)$ shows $g \in N\, N_G(P)$. As g was arbitrary, $G = N\, N_G(P)$. □

$$\begin{array}{ccc} P & \hookrightarrow & N \\ \downarrow & & \downarrow \trianglelefteq \\ N_G(P) & \hookrightarrow & G \end{array} \qquad \text{with} \qquad G = N \cdot N_G(P).$$

Diagram explanation. Objects: Four subgroups of the finite group G arranged in a commutative square. Top-left: the Sylow p-subgroup P of N. Top-right: the normal subgroup $N \trianglelefteq G$. Bottom-left: the normalizer $N_G(P)$, the largest subgroup of G in which P is normal. Bottom-right: the ambient group G.

Arrows: All four arrows are inclusions (hook arrows). Top horizontal: $P \hookrightarrow N$ (given: $P \in \mathrm{Syl}_p(N)$, so $P \leq N$). Left vertical: $P \hookrightarrow N_G(P)$ (by definition P normalizes itself, so $P \leq N_G(P)$). Right vertical: $N \hookrightarrow G$ labelled $\trianglelefteq$ (the hypothesis $N \trianglelefteq G$). Bottom horizontal: $N_G(P) \hookrightarrow G$ (a normalizer is always a subgroup).

What commutes: The square commutes because both composite inclusions $P \to G$ agree: going right-then-down gives $P \leq N \leq G$, and going down-then-right gives $P \leq N_G(P) \leq G$. Both paths simply assert $P \leq G$, the same subgroup. The key output is not in the square itself but is stated alongside: $G = N \cdot N_G(P)$.

Why it commutes: An inclusion square of subgroups always commutes: both paths from P to G send every element $x \in P$ to the same element $x \in G$. No well-definedness issue arises because all maps are literal set-inclusions. The proof of $G = N \cdot N_G(P)$ is external: for any $g \in G$, use $N \trianglelefteq G$ to see $gPg^{-1} \leq N$ is Sylow in N, then Sylow-conjugacy inside N gives $n \in N$ with $ngPg^{-1}n^{-1} = P$, so $ng \in N_G(P)$ and $g = n^{-1}(ng) \in N \cdot N_G(P)$.

Why this matters here: The diagram encodes the hypothesis and conclusion of the Frattini argument in one picture, making it easy to apply in the proof that $\Phi(G)$ is nilpotent: taking $N = \Phi(G)$ and a Sylow p-subgroup P of $\Phi(G)$, the square shows $P \leq N_G(P)$ and $N_G(P) \leq G$, while Frattini's argument gives $G = \Phi(G) \cdot N_G(P)$; the nongenerator property then forces $N_G(P) = G$, so $P \trianglelefteq G$.

Concrete example: Take $G = S_3$, $N = A_3 \trianglelefteq S_3$, and $P = \langle (1\,2\,3) \rangle \in \mathrm{Syl}_3(A_3)$. Then $N_G(P) = S_3$ (since P is the unique Sylow 3-subgroup of A_3 and all of S_3 normalizes it), and indeed $S_3 = A_3 \cdot S_3 = G$. The diagram shows $P \leq A_3 \leq S_3$ and $P \leq S_3 \leq S_3$.

Common pitfall: Students confuse the square with asserting $N \cap N_G(P) = P$; the diagram says only that both containments hold, not that P is the intersection. Also, the label $\trianglelefteq$ on the right vertical arrow is a property of N in G, not of the arrow itself — the inclusion $N \hookrightarrow G$ is a map, while $\trianglelefteq$ is extra data (the normality hypothesis) used in the proof outside the square.

Takeaway: The point of this diagram is that the four subgroups $P \leq N \leq G$ and $P \leq N_G(P) \leq G$ fit into a single inclusion square whose existence, combined with normality of N, forces the product decomposition $G = N \cdot N_G(P)$.

Theorem 6.1.20 (Frattini subgroup is nilpotent)**.** *For a finite group G, $\Phi(G)$ is nilpotent.*

Proof. Let $P \in \mathrm{Syl}_p(\Phi(G))$. Since $\Phi(G) \trianglelefteq G$, the Frattini argument (Theorem 6.1.19) gives $G = \Phi(G)\, N_G(P)$. By Proposition 6.1.18, the elements of $\Phi(G)$ are nongenerators, so $G = \langle N_G(P) \rangle = N_G(P)$, i.e. $P \trianglelefteq G$ and in particular $P \trianglelefteq \Phi(G)$. Thus every Sylow subgroup of $\Phi(G)$ is normal in $\Phi(G)$, so by Theorem 6.1.12 $\Phi(G)$ is nilpotent. □

Method (Computing $\Phi(G)$)**.** *Trigger.* You need $\Phi(G)$ for a specific G (often a p-group or abelian group). *Recipe.*

1. List the maximal subgroups (in a p-group, maximal subgroups are exactly the index-p subgroups, all normal).
2. Intersect them.
3. Shortcut for p-groups: $\Phi(G) = G'\, G^p$, where $G^p = \langle g^p : g \in G \rangle$. The quotient $G/\Phi(G)$ is the largest elementary abelian p-quotient.
4. Shortcut for finite abelian G: $\Phi(G) = \bigcap_{p \,|\, |G|} pG$; equivalently $G/\Phi(G) \cong \prod_p (\mathbb{Z}/p\mathbb{Z})^{r_p}$ where r_p is the p-rank.

Worked Example 6.1.21 ($\Phi(\mathbb{Z}/p^n\mathbb{Z})$)**.** Compute the Frattini subgroup of the cyclic group $\mathbb{Z}/p^n\mathbb{Z}$.

Recognition. Cyclic p-group: a unique maximal subgroup, of index p.

Solution. $\mathbb{Z}/p^n\mathbb{Z}$ is cyclic, so its subgroups are totally ordered: $0 \leq p^{n-1}\mathbb{Z}/p^n\mathbb{Z} \leq \cdots \leq \mathbb{Z}/p^n\mathbb{Z}$. The unique maximal subgroup is the index-p subgroup $p\mathbb{Z}/p^n\mathbb{Z} \cong \mathbb{Z}/p^{n-1}\mathbb{Z}$. The intersection over the (single) maximal subgroup is itself, so $\Phi(\mathbb{Z}/p^n\mathbb{Z}) = p\mathbb{Z}/p^n\mathbb{Z} \cong \mathbb{Z}/p^{n-1}\mathbb{Z}$. *Check.* The shortcut $\Phi = G'G^p = 1 \cdot G^p = pG$ gives the same answer, and $G/\Phi \cong \mathbb{Z}/p\mathbb{Z}$ is elementary abelian of rank 1. For $n = 1$, $\Phi(\mathbb{Z}/p\mathbb{Z}) = 0$.

Worked Example 6.1.22 (Φ of an elementary abelian p-group is trivial)**.** Compute $\Phi(E)$ for $E = (\mathbb{Z}/p\mathbb{Z})^k$.

Recognition. Vector space over $\mathbb{F}_p$: maximal subgroups are the hyperplanes.

Solution. View E as a k-dimensional $\mathbb{F}_p$-vector space. Its maximal subgroups are exactly the codimension-1 subspaces (hyperplanes). For any nonzero $v \in E$ there is a hyperplane avoiding v (extend v to a basis and drop it). Hence the intersection of all hyperplanes is $\{0\}$: $\Phi(E) = 0$. *Check.* Shortcut: $E' = 0$ (abelian) and $E^p = \langle x^p \rangle = 0$ (every element has order dividing p), so $\Phi(E) = E'E^p = 0$. Then $E/\Phi(E) = E$ is itself elementary abelian of rank k, matching "$G/\Phi(G)$ is the largest elementary abelian quotient".

Worked Example 6.1.23 ($\Phi(D_8)$ and the rank of $D_8/\Phi(D_8)$)**.** Compute $\Phi(D_8)$.

Recognition. 2-group: $\Phi = G'\, G^2$; maximal subgroups have index 2.

Solution. The maximal (index-2) subgroups of D_8 are $\langle r \rangle \cong \mathbb{Z}/4\mathbb{Z}$, $\langle r^2, s \rangle \cong V_4$, and $\langle r^2, rs \rangle \cong V_4$. Their intersection: $\langle r \rangle \cap \langle r^2, s \rangle = \langle r^2 \rangle$, and $\langle r^2 \rangle \leq \langle r^2, rs \rangle$, so $\Phi(D_8) = \langle r^2 \rangle \cong \mathbb{Z}/2\mathbb{Z}$. *Check.* Shortcut: $G' = \langle r^2 \rangle$ and $G^2 = \langle g^2 \rangle = \langle r^2 \rangle$ (squares: r^2, and $(r^k s)^2 = 1$), so $\Phi = G'G^2 = \langle r^2 \rangle$. Then $D_8/\Phi(D_8)$ has order 4 and exponent 2, so it is $(\mathbb{Z}/2\mathbb{Z})^2$, elementary abelian of rank 2 — consistent with D_8 needing 2 generators.

Worked Example 6.1.24 ($\Phi(\mathbb{Z}/12\mathbb{Z})$ via the abelian shortcut)**.** Compute $\Phi(\mathbb{Z}/12\mathbb{Z})$.

Recognition. Finite abelian: $\Phi = \bigcap_p pG$ over $p \mid |G|$.

Solution. $|G| = 12 = 2^2 \cdot 3$, so the primes are $2, 3$. The maximal subgroups of $\mathbb{Z}/12\mathbb{Z}$ are the index-2 subgroup $2\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$ and the index-3 subgroup $3\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z}$. Their intersection is $6\mathbb{Z}/12\mathbb{Z} = \{0, 6\} \cong \mathbb{Z}/2\mathbb{Z}$. So $\Phi(\mathbb{Z}/12\mathbb{Z}) = \langle 6 \rangle \cong \mathbb{Z}/2\mathbb{Z}$. *Check.* Shortcut $2G \cap 3G$: $2G = \{0, 2, 4, 6, 8, 10\}$, $3G = \{0, 3, 6, 9\}$, intersection $\{0, 6\}$. Same. And $G/\Phi \cong \mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ is a product of elementary abelian groups, one for each prime (abelian of squarefree exponent 6), the largest such quotient.

Worked Example 6.1.25 ($\Phi(S_3)$)**.** Compute the Frattini subgroup of S_3.

Recognition. List maximal subgroups and intersect; S_3 is not a p-group, so no p-group shortcut.

Solution. The proper nontrivial subgroups of S_3 are $A_3 = \langle (1\,2\,3) \rangle$ (order 3, index 2) and the three order-2 subgroups $\langle (1\,2) \rangle, \langle (1\,3) \rangle, \langle (2\,3) \rangle$ (index 3). All four are maximal. Their intersection: $A_3 \cap \langle (1\,2) \rangle = 1$ already, so $\Phi(S_3) = 1$. *Check.* Consistent with S_3 being generated by a single transposition and a 3-cycle with no redundancy; there are no nontrivial nongenerators. Note $\Phi(S_3) = 1$ is nilpotent (trivially), matching Theorem 6.1.20.

Caution. The clean formula $\Phi(G) = G'G^p$ holds only for finite *p-groups*. For a general finite group you must either intersect all maximal subgroups directly or, in the abelian case, intersect pG over the primes p dividing $|G|$. Applying "$G'G^p$" to a non-p-group (e.g. choosing a single p) gives the wrong subgroup.

Remark 6.1.3 (Why this matters). For a finite p-group G, the quotient $G/\Phi(G)$ is a vector space over $\mathbb{F}_p$, and the *Burnside Basis Theorem* says a subset of G generates G iff its image spans $G/\Phi(G)$, and a minimal generating set of G maps onto a basis of $G/\Phi(G)$. Thus the minimal number of generators of a p-group equals $\dim_{\mathbb{F}_p}\big(G/\Phi(G)\big)$ — the rank we computed above (1 for $\mathbb{Z}/p^n\mathbb{Z}$, k for $(\mathbb{Z}/p\mathbb{Z})^k$, 2 for D_8 and Q_8).

The commutator subgroup, the derived series, and solvable groups

This installment turns the commutator bracket into a machine. From $[x, y] = x^{-1}y^{-1}xy$ we build a canonical subgroup $G' = [G, G]$, the smallest normal subgroup with abelian quotient. Iterating $G \mapsto G'$ produces the *derived series*, and the groups it kills off in finitely many steps are exactly the *solvable* groups – the class that sits between abelian/nilpotent on one side and the genuinely complicated (simple, perfect) groups on the other. We close with the two deep landmarks D&F states without full proof: Burnside's p^aq^b theorem and Philip Hall's theorem on Hall subgroups.

Definition 6.1.26 (Commutators and the commutator subgroup)**.** For $x, y \in G$ the *commutator* of x and y is

$$[x, y] \;=\; x^{-1}y^{-1}xy.$$

For subgroups $H, K \leq G$, the subgroup $[H, K] = \langle\, [h, k] \mid h \in H,\ k \in K \,\rangle$ is generated by all such commutators (the SET of commutators need not be a subgroup, so the generated subgroup is the right object). The *commutator subgroup* (or *derived subgroup*) of G is

$$G' \;=\; [G, G] \;=\; \langle\, [x, y] \mid x, y \in G \,\rangle.$$

Remark 6.1.4. Two identities used constantly: $[x, y]^{-1} = [y, x]$, and $g^{-1}[x, y]g = [g^{-1}xg,\, g^{-1}yg]$. The second says conjugation permutes commutators, which is exactly why G' is normal.

Proposition 6.1.27 (Universal property of G')**.** *Let G be a group.*

(a) $G' \trianglelefteq G$ (in fact G' is characteristic in G).

(b) G/G' is abelian.

(c) If $N \trianglelefteq G$ then G/N is abelian $\iff G' \leq N$.

Thus G' is the unique smallest normal subgroup with abelian quotient: G/G' is the largest abelian quotient of G (the abelianization G^{ab}*).*

Proof. (a) For $g \in G$ and any generator $[x,y]$ we have $g^{-1}[x,y]g = [g^{-1}xg, g^{-1}yg] \in G'$; as conjugation by g is an automorphism sending generators of G' into G', it maps G' into G', so $G' \trianglelefteq G$. Replacing conjugation by an arbitrary $\varphi \in \mathrm{Aut}(G)$ gives $\varphi(G') \leq G'$, hence characteristic.

(b) In G/G' we have $\overline{x}\,\overline{y}\,\overline{x}^{-1}\overline{y}^{-1} = \overline{xyx^{-1}y^{-1}} = \overline{[x^{-1},y^{-1}]} = \overline{1}$ since $[x^{-1},y^{-1}] \in G'$. So any two cosets commute.

(c) Suppose G/N abelian. For $x, y \in G$, $\overline{x}\,\overline{y} = \overline{y}\,\overline{x}$ gives $\overline{[x,y]} = \overline{1}$, i.e. $[x,y] \in N$; as N contains all generators of G', $G' \leq N$. Conversely if $G' \leq N$ then by the correspondence theorem G/N is a quotient of the abelian group G/G', hence abelian. □

Remark 6.1.5. The universal property is a factorization statement: every homomorphism $\varphi\colon G \to A$ into an abelian group A kills G' (because $\operatorname{im}\varphi$ abelian $\implies$ $G' \leq \ker\varphi$), so it factors uniquely through the abelianization.

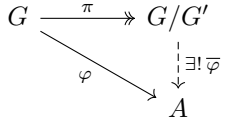


Diagram explanation. Objects: Three groups: G (the source group), G/G' (the abelianization, a quotient group), and A (an arbitrary abelian group serving as the target.

Arrows: $\pi\colon G \twoheadrightarrow G/G'$ is the canonical surjective quotient map, $x \mapsto xG'$. $\varphi\colon G \to A$ is any group homomorphism into an abelian group. $\overline{\varphi}\colon G/G' \to A$ is the unique induced (dashed) map, defined by $\overline{\varphi}(xG') = \varphi(x)$; it is the only map making the triangle commute. Well-definedness: if $xG' = yG'$ then $y^{-1}x \in G'$, so $\varphi(y^{-1}x) \in \varphi(G') \leq [A,A] = 1$ (since A is abelian, every commutator in A is trivial, and φ maps $G' = \langle [a,b] \rangle$ into $[\operatorname{im}\varphi, \operatorname{im}\varphi] = 1$), giving $\varphi(x) = \varphi(y)$. So $\overline{\varphi}$ is independent of the coset representative.

What commutes: The triangle commutes: $\overline{\varphi} \circ \pi = \varphi$. That is, for all $x \in G$: $\overline{\varphi}(\pi(x)) = \overline{\varphi}(xG') = \varphi(x)$.

Why it commutes: Start with $x \in G$. Along π then $\overline{\varphi}$: $x \xrightarrow{\pi} xG' \xrightarrow{\overline{\varphi}} \varphi(x)$. Along φ directly: $x \xrightarrow{\varphi} \varphi(x)$. Both give $\varphi(x)$, by the definition of $\overline{\varphi}$ on cosets.

Why this matters here: This is the universal property of the abelianization $G^{\mathrm{ab}} = G/G'$: it is the *initial* abelian group receiving a map from G. Every abelian-target homomorphism out of G factors uniquely through a single object. This turns the abstract characterization of G' in Proposition 6.1.27(c) into a concrete factorization principle used whenever one wants to compare maps $G \to A$ to maps $G/G' \to A$.

Concrete example: Take $G = S_3$, $G' = A_3$, $G/G' \cong \mathbb{Z}_2$, and $A = \mathbb{Z}_2$ with $\varphi = \mathrm{sgn}$ (the sign map). Then $\overline{\varphi}\colon \mathbb{Z}_2 \to \mathbb{Z}_2$ is the identity, and indeed $\mathrm{sgn} = \overline{\mathrm{sgn}} \circ \pi$.

Common pitfall: Students often assume $\overline{\varphi}$ is defined on elements of G rather than on cosets. The map lives on G/G', and its well-definedness relies entirely on $G' \leq \ker\varphi$ (i.e. A abelian), which is exactly what the arrow φ killing G' encodes. Forgetting to check $G' \leq \ker\varphi$ is the most common error.

Takeaway: The point of this diagram is that the abelianization G/G' is the universal abelian quotient of G: any homomorphism to an abelian group factors through it uniquely, so studying maps out of G into abelian groups reduces to studying maps out of G/G'.

Method (Computing G' in practice)**.** To find $G' = [G,G]$:

1. **Use a known abelianization.** If you can spot the largest abelian quotient G/N (e.g. via the sign map, a determinant, or a coordinate that becomes additive), then $G' \leq N$; check generators of N are commutators to get equality.

2. **Generate from a few commutators.** Compute $[g_i, g_j]$ for generators g_i of G. Then G' is the *normal closure* of these commutators (the subgroup generated by them and all their conjugates): if N is that normal closure, the images of the g_i commute in G/N, so G/N is abelian and $G' \leq N \leq G'$. The subgroup generated by the $[g_i, g_j]$ alone can be too small: for $A_4 = \langle (1\,2\,3), (1\,2)(3\,4) \rangle$ it is $\langle (1\,4)(2\,3) \rangle$, of order 2, whereas A_4' is the Klein four-group of double transpositions, of order 4.

3. **Read off $|G^{\mathrm{ab}}|$.** $|G/G'|$ = size of the abelianization; for a known presentation, abelianize the relations (make all generators commute) to compute G^{ab}.

4. **Perfect check.** $G' = G$ (G *perfect*) iff G has no nontrivial abelian quotient; true for nonabelian simple groups.

Worked Example 6.1.28 (Commutator subgroup of S_n)**.** Show $(S_n)' = A_n$ for all $n \geq 2$ (with $(S_2)' = 1 = A_2$).

Recognition. The sign homomorphism $\mathrm{sgn}\colon S_n \to \{\pm 1\}$ is the canonical map to an abelian group, so $(S_n)' \leq \ker(\mathrm{sgn}) = A_n$ (Method, step 1). Then show A_n is generated by commutators.

Solution. Since $\{\pm 1\}$ is abelian, Proposition 6.1.27(c) gives $(S_n)' \leq A_n$. For the reverse inclusion ($n \geq 3$): A_n is generated by 3-cycles, and every 3-cycle is a commutator. Indeed

$$[(1\,2),(1\,3)] = (1\,2)^{-1}(1\,3)^{-1}(1\,2)(1\,3) = (1\,2)(1\,3)(1\,2)(1\,3).$$

Compute right-to-left on $\{1,2,3\}$: apply $(1\,3)$ then $(1\,2)$ then $(1\,3)$ then $(1\,2)$. Track 1: $(1\,3)$ sends $1 \to 3$, $(1\,2)$ fixes 3, $(1\,3)$ sends $3 \to 1$, $(1\,2)$ sends $1 \to 2$; so $1 \to 2$. Track 2: $(1\,3) : 2 \to 2$, $(1\,2) : 2 \to 1$, $(1\,3) : 1 \to 3$, $(1\,2) : 3 \to 3$; so $2 \to 3$. Track 3: $(1\,3) : 3 \to 1$, $(1\,2) : 1 \to 2$, $(1\,3) : 2 \to 2$, $(1\,2) : 2 \to 1$; so $3 \to 1$. Hence the product is $(1\,2\,3)$, a 3-cycle. By relabeling, every 3-cycle is such a commutator, so $A_n \leq (S_n)'$. Therefore $(S_n)' = A_n$. *Check.* $|S_n/A_n| = 2$ is the largest abelian quotient; consistent with $|(S_n)^{\mathrm{ab}}| = 2$ for $n \geq 2$.

Worked Example 6.1.29 (Commutator subgroup of D_8)**.** Let $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1}\rangle$, the dihedral group of order 8. Compute D_8'.

Recognition. Use generator commutators (Method, step 2): there are few generators, so compute $[r,s]$ and friends directly.

Solution. Compute $[s,r] = s^{-1}r^{-1}sr = sr^{-1}sr$. Now $sr^{-1}s = r$ (from $srs = r^{-1}$, conjugating r^{-1} gives $sr^{-1}s = r$), so $[s,r] = r \cdot r = r^2$. Thus $r^2 \in D_8'$, giving $\langle r^2\rangle \leq D_8'$. Conversely $D_8/\langle r^2\rangle$ has order 4; its generators $\overline{r}, \overline{s}$ satisfy $\overline{r}^2 = 1,\ \overline{s}^2 = 1,\ \overline{s}\,\overline{r}\,\overline{s} = \overline{r}^{-1} = \overline{r}$, so it is abelian ($\cong \mathbb{Z}_2 \times \mathbb{Z}_2$). By Proposition 6.1.27(c), $D_8' \leq \langle r^2\rangle$. Hence

$$D_8' = \langle r^2\rangle = \{1, r^2\} = Z(D_8) \cong \mathbb{Z}_2.$$

Check. $|D_8/D_8'| = 8/2 = 4$ and $(D_8)^{\mathrm{ab}} \cong \mathbb{Z}_2 \times \mathbb{Z}_2$, the abelianization of the presentation (set $r^2 = s^2 = 1$, r, s commuting). Correct.

Worked Example 6.1.30 (Commutator subgroup of A_4)**.** Compute A_4', where A_4 has order 12.

Recognition. A_4 has a normal Klein four-subgroup $V = \{e, (1\,2)(3\,4), (1\,3)(2\,4), (1\,4)(2\,3)\}$ with $A_4/V \cong \mathbb{Z}_3$ abelian, so $A_4' \leq V$ (Method, step 1). Then produce a commutator inside V to force equality.

Solution. Since $A_4/V \cong \mathbb{Z}_3$ is abelian, $A_4' \leq V$. Now compute a single commutator landing in $V \setminus \{e\}$. Take $x = (1\,2\,3)$, $y = (1\,2\,4)$:

$$[x,y] = x^{-1}y^{-1}xy = (1\,3\,2)(1\,4\,2)(1\,2\,3)(1\,2\,4).$$

Evaluate right-to-left. 1: $(1\,2\,4) : 1 \to 2$, $(1\,2\,3) : 2 \to 3$, $(1\,4\,2) : 3 \to 3$, $(1\,3\,2) : 3 \to 2$; so $1 \to 2$. 2: $(1\,2\,4) : 2 \to 4$, $(1\,2\,3) : 4 \to 4$, $(1\,4\,2) : 4 \to 2$, $(1\,3\,2) : 2 \to 1$; so $2 \to 1$. 3: $(1\,2\,4) : 3 \to 3$, $(1\,2\,3) : 3 \to 1$, $(1\,4\,2) : 1 \to 4$, $(1\,3\,2) : 4 \to 4$; so $3 \to 4$. 4: $(1\,2\,4) : 4 \to 1$, $(1\,2\,3) : 1 \to 2$, $(1\,4\,2) : 2 \to 1$, $(1\,3\,2) : 1 \to 3$; so $4 \to 3$. Thus $[x,y] = (1\,2)(3\,4) \in V$, a nontrivial element. Since $A_4' \trianglelefteq A_4$ and V is the unique minimal normal subgroup of A_4 containing a double transposition, A_4' contains the full conjugacy class of $(1\,2)(3\,4)$, which generates V. Hence

$$A_4' = V \cong \mathbb{Z}_2 \times \mathbb{Z}_2.$$

Check. $|A_4/A_4'| = 12/4 = 3$, so $(A_4)^{\mathrm{ab}} \cong \mathbb{Z}_3$, matching $A_4/V \cong \mathbb{Z}_3$. Correct.

Worked Example 6.1.31 (GL_n is (almost) perfect: $\mathrm{SL}_2(\mathbb{F}_5)$)**.** Show $\mathrm{SL}_2(\mathbb{F}_5)$ is perfect, i.e. equals its own commutator subgroup.

Recognition. Perfect check (Method, step 4): a nonabelian group with no nontrivial abelian quotient. $\mathrm{SL}_2(\mathbb{F}_5)$ has order 120 and $\mathrm{SL}_2(\mathbb{F}_5)/\{\pm I\} \cong A_5$ is simple nonabelian; we use that A_5 is perfect plus the structure of the extension.

Solution. Let $G = \mathrm{SL}_2(\mathbb{F}_5)$, $|G| = 120$, $Z = \{\pm I\}$, $G/Z \cong A_5$. The group A_5 is simple nonabelian, hence perfect: $(A_5)' = A_5$ (its only normal subgroups are 1 and A_5, and A_5 is nonabelian so $(A_5)' \neq 1$, forcing $(A_5)' = A_5$). Now G' maps onto $(G/Z)' = (A_5)' = A_5$ under $G \to G/Z$, so $G'Z = G$ and $[G : G'] \mid |Z| = 2$.

If $[G : G'] = 2$ then G would have an index-2 (hence normal) subgroup G' with $G/G' \cong \mathbb{Z}_2$; but in fact the transvections (elementary unipotent matrices) are products of commutators and generate all of G. Concretely $\mathrm{SL}_2(\mathbb{F}_q)$ is perfect for $q \geq 4$, and $5 \geq 4$. Hence $G' = G$. *Check.* A perfect group has trivial abelianization $G^{\mathrm{ab}} = 1$, consistent with $|G/G'| = 1$. Its derived series is constant $G, G, G, \ldots$, so G is not solvable.

The derived series and solvability

Definition 6.1.32 (Derived series and solvable groups)**.** Define the *derived series* of G by

$$G^{(0)} = G, \qquad G^{(i+1)} = \big(G^{(i)}\big)' = \big[G^{(i)}, G^{(i)}\big].$$

So $G^{(1)} = G'$, $G^{(2)} = G'' = [G', G']$, and so on. Each $G^{(i+1)} \trianglelefteq G^{(i)}$ with abelian quotient, and in fact every $G^{(i)}$ is characteristic in G. The group G is *solvable* if $G^{(n)} = 1$ for some $n \geq 0$; the least such n is the *derived length*.

We picture the chain descending to the trivial group:

$$\begin{array}{c} G = G^{(0)} \\ \big| \text{ ab. quotient} \\ G^{(1)} = G' \\ \big| \\ G^{(2)} = G'' \\ \vdots \\ G^{(n)} = 1 \end{array}$$

Diagram explanation. Objects: A finite descending chain of groups: $G = G^{(0)} \supset G^{(1)} \supset G^{(2)} \supset \cdots \supset G^{(n)} = 1$. Each $G^{(i)}$ is the i-th term of the derived series, a characteristic (hence normal) subgroup of G. The terminal object is the trivial group 1.

Arrows: Each vertical dash-arrow from $G^{(i)}$ to $G^{(i+1)}$ represents the inclusion $G^{(i+1)} \hookrightarrow G^{(i)}$ together with the associated normal quotient $G^{(i)} \twoheadrightarrow G^{(i)}/G^{(i+1)}$. The label "ab. quotient" on the first arrow records that $G^{(i)}/G^{(i+1)}$ is abelian at every step (it is the abelianization of $G^{(i)}$). The dashed segment from $G^{(2)}$ downward indicates a gap of unspecified length before reaching 1.

What commutes: There is no two-path commutativity here; instead, the key condition is the abelian-quotient constraint $G^{(i+1)} = (G^{(i)})'$, which means $G^{(i+1)}$ is the smallest normal subgroup of $G^{(i)}$ making the quotient $G^{(i)}/G^{(i+1)}$ abelian. Solvability is exactly the statement that this chain terminates: $G^{(n)} = 1$.

Why it commutes: The chain is not a commutative square but a sequential filtration. Each step is canonical: $G^{(i+1)}$ is defined as $[G^{(i)}, G^{(i)}]$, the commutator subgroup of the previous term. The abelian-quotient property $G^{(i)}/G^{(i+1)}$ abelian holds by Proposition 6.1.27(b) applied to $G^{(i)}$, and there is no choice in the construction.

Why this matters here: This chain is the definition of the derived series in pictorial form, placed immediately before the characterization theorem (Theorem 6.1.33). It makes visible exactly what solvability demands: a finite number of steps from G to 1, each with an abelian quotient. The picture motivates conditions (a) and (b) of that theorem simultaneously.

Concrete example: For S_4: $S_4 \supset A_4 \supset V \supset 1$ with quotients of orders 2, 3, 4 (the last is $V/1 \cong \mathbb{Z}_2 \times \mathbb{Z}_2$). This is the derived series with $n = 3$, each quotient abelian.

Common pitfall: Students confuse this chain with the lower central series γ_i. The derived series replaces each group by its own commutator subgroup $[G^{(i)}, G^{(i)}]$, while the lower central series uses $[\gamma_i, G]$ (commutators with the whole group). They agree at the first step ($G' = \gamma_2$) but can diverge thereafter; G can be solvable without being nilpotent, meaning the derived series reaches 1 while the lower central series does not.

Takeaway: The point of this diagram is that solvability is a finiteness condition on iteration of the commutator-subgroup operator: the derived series must reach 1 in finitely many steps, with each step producing an abelian remainder.

Theorem 6.1.33 (Characterization of solvability)**.** *For a group G the following are equivalent.*

(a) G is solvable: $G^{(n)} = 1$ for some n.

(b) G has a chain $1 = G_0 \trianglelefteq G_1 \trianglelefteq \cdots \trianglelefteq G_k = G$ in which each quotient G_{i+1}/G_i is abelian (an abelian series*).*

(c) (If G is finite) G has a chain as in (b) with each G_{i+1}/G_i cyclic of prime order*.*

Proof. (a) $\Longrightarrow$ (b): Take $G_i = G^{(n-i)}$. Then $1 = G^{(n)} = G_0 \trianglelefteq \cdots \trianglelefteq G_n = G$ and $G_{i+1}/G_i = G^{(n-i-1)}/G^{(n-i)}$ is abelian by Proposition 6.1.27(b) applied to $G^{(n-i-1)}$.

(b) $\Longrightarrow$ (a): We show $G^{(i)} \leq G_{k-i}$ by induction. Base $G^{(0)} = G = G_k$. If $G^{(i)} \leq G_{k-i}$, then since G_{k-i}/G_{k-i-1} is abelian we have $(G_{k-i})' \leq G_{k-i-1}$, so $G^{(i+1)} = (G^{(i)})' \leq (G_{k-i})' \leq G_{k-i-1} = G_{k-(i+1)}$. At $i = k$: $G^{(k)} \leq G_0 = 1$, so G is solvable.

(c) $\Longrightarrow$ (b) is immediate (cyclic of prime order is abelian). (b) $\Longrightarrow$ (c) for finite G: refine each abelian quotient. A finite abelian group G_{i+1}/G_i has a composition series with quotients $\mathbb{Z}_p$ (e.g. via the structure theorem); pulling back gives intermediate normal subgroups whose successive quotients are cyclic of prime order. Inserting these refines the chain to the form (c). □

Method (Testing solvability via the derived series)**.** *Trigger.* "Is G solvable?" or "find the derived length."

1. Compute $G^{(1)} = G'$ (use the G' method above).
2. Compute $G^{(2)} = (G')'$, then $G^{(3)}$, …, halting when you reach 1 or detect a repeat.
3. **If the series reaches** 1**:** G is solvable; the derived length is the step count.
4. **If the series stabilizes at a nontrivial** H (i.e. $H' = H \neq 1$, a perfect subgroup): G is *not* solvable. In particular any nonabelian simple subquotient is a fatal obstruction.
5. *Shortcuts.* (i) $|G| = p^a$ (p-group) $\Longrightarrow$ nilpotent $\Longrightarrow$ solvable. (ii) $|G| = p^a q^b \Longrightarrow$ solvable (Burnside). (iii) $|G| < 60 \Longrightarrow$ solvable (smallest nonabelian simple group is A_5, order 60). (iv) If G has a nonabelian simple composition factor, G is not solvable.

Worked Example 6.1.34 (S_3, S_4 solvable; S_5 not)**.** Decide solvability of S_3, S_4, and S_5 via the derived series.

Recognition. Run the derived series (Method): each step replaces $G^{(i)}$ by its commutator subgroup; stop at 1 (solvable) or a perfect group (not solvable).

Solution. S_3: $S_3' = A_3 \cong \mathbb{Z}_3$ (abelian), so $S_3'' = (A_3)' = 1$. Series $S_3 \geq A_3 \geq 1$ reaches 1 in 2 steps. **Solvable**, derived length 2.

S_4: $S_4' = A_4$. From the earlier example $A_4' = V \cong \mathbb{Z}_2 \times \mathbb{Z}_2$. Then $V' = 1$ (V abelian). Series

$$S_4 \;\geq\; A_4 \;\geq\; V \;\geq\; 1, \qquad |S_4| = 24,\ |A_4| = 12,\ |V| = 4,\ |1| = 1,$$

with quotients of orders $2, 3, 4$ – all abelian. Reaches 1 in 3 steps. **Solvable**, derived length 3.

S_5: $S_5' = A_5$. But A_5 is simple and nonabelian, so $(A_5)' = A_5$. The derived series is $S_5 \geq A_5 \geq A_5 \geq \cdots$ and never reaches 1. **Not solvable**. *Check.* $|A_5| = 60$ is the smallest nonabelian simple order, the precise threshold where S_n stops being solvable; indeed S_n is solvable iff $n \leq 4$. Consistent.

Worked Example 6.1.35 (Every group of order pq is solvable)**.** Let $|G| = pq$ with primes $p < q$. Show G is solvable.

Recognition. Build an explicit abelian (in fact cyclic-prime) series (Theorem 6.1.33(c)) using Sylow theory: find a normal Sylow subgroup.

Solution. By Sylow's theorem the number n_q of Sylow q-subgroups satisfies $n_q \equiv 1 \pmod q$ and $n_q \mid p$. Since $p < q$, the only divisor of p that is $\equiv 1 \pmod q$ is 1 (the other divisor p satisfies $1 < p < q$, so $p \not\equiv 1 \pmod q$), so $n_q = 1$: the Sylow q-subgroup Q is normal, $Q \trianglelefteq G$, $|Q| = q$, $Q \cong \mathbb{Z}_q$. Then

$$1 \;\trianglelefteq\; Q \;\trianglelefteq\; G, \qquad Q/1 \cong \mathbb{Z}_q, \quad G/Q \cong \mathbb{Z}_p,$$

both cyclic of prime order. By Theorem 6.1.33(c) (or (b)), G is **solvable**, derived length ≤ 2. *Check.* If G is abelian, derived length 1; if nonabelian (only possible when $q \equiv 1 \pmod{p}$, e.g. $|G| = 6, S_3$ or $|G| = 21$), $G' = Q$ and $G'' = 1$, derived length 2. Either way solvable. Matches the general fact that $|G| = p^a q^b$ is solvable (Burnside).

Theorem 6.1.36 (Closure properties of solvable groups)**.** *Let G be a group, $H \leq G$ a subgroup, and $N \trianglelefteq G$ a normal subgroup.*

(a) If G is solvable, then H is solvable.

(b) If G is solvable, then G/N is solvable.

(c) (Extensions) If N and G/N are both solvable, then G is solvable.

Proof. (a) By induction, $H^{(i)} \leq G^{(i)}$: clearly $H^{(0)} = H \leq G = G^{(0)}$, and if $H^{(i)} \leq G^{(i)}$ then $H^{(i+1)} = [H^{(i)}, H^{(i)}] \leq [G^{(i)}, G^{(i)}] = G^{(i+1)}$. If $G^{(n)} = 1$ then $H^{(n)} \leq G^{(n)} = 1$, so H is solvable (derived length $\leq$ that of G).

(b) Let $\pi\colon G \to G/N$. A commutator maps to a commutator: $\pi([x, y]) = [\pi x, \pi y]$, so $\pi(G^{(i)}) = (G/N)^{(i)}$ by induction. If $G^{(n)} = 1$ then $(G/N)^{(n)} = \pi(G^{(n)}) = 1$, so G/N is solvable.

(c) Suppose $(G/N)^{(m)} = 1$ and $N^{(k)} = 1$. From part (b)'s identity, $\pi(G^{(m)}) = (G/N)^{(m)} = 1$ means $G^{(m)} \leq \ker \pi = N$. Then $G^{(m+k)} = (G^{(m)})^{(k)} \leq N^{(k)} = 1$. Hence G is solvable with derived length $\leq m + k$. □

Remark 6.1.6. The short exact sequence $1 \to N \to G \to G/N \to 1$ packages (a), (b) and (c): solvability of the two outer terms is equivalent to solvability of the middle term ((a) and (b) give "middle $\Longrightarrow$ outer terms", since $N \leq G$ and G/N is a quotient of G; (c) gives the converse).

$$1 \longrightarrow N \hookrightarrow G \xrightarrow{\pi} G/N \longrightarrow 1$$

Diagram explanation. Objects: Five objects in a row: the trivial groups 1 at each end (initial and terminal), the normal subgroup $N \trianglelefteq G$ (a group), the ambient group G, and the quotient group G/N. This is a short exact sequence of groups.

Arrows: $1 \to N$ is the unique map from the trivial group (sends the identity to $e \in N$). $N \hookrightarrow G$ is the inclusion (injective, the hook arrowhead records this): $n \mapsto n$. $\pi\colon G \twoheadrightarrow G/N$ is the canonical surjective quotient map (two-head arrowhead): $g \mapsto gN$. $G/N \to 1$ is the unique map to the trivial group. Well-definedness of π on cosets is automatic from the definition $gN =$ the coset of g; N normal in G makes G/N a group.

What commutes: Exactness at each node: (i) $\operatorname{im}(1 \to N) = \{e\} = \ker(N \hookrightarrow G)$, i.e. the inclusion is injective; (ii) $\operatorname{im}(N \hookrightarrow G) = N = \ker \pi$, i.e. exactly N collapses to eN under π; (iii) $\operatorname{im} \pi = G/N = \ker(G/N \to 1)$, i.e. π is surjective.

Why it commutes: For exactness at G: $\ker \pi = \{g \in G : gN = N\} = N = \operatorname{im}(N \hookrightarrow G)$. Starting with $n \in N$, the inclusion sends it to $n \in G$, and then $\pi(n) = nN = N = eN$ since $n \in N$. Conversely if $\pi(g) = eN$ then $g \in N$.

Why this matters here: This diagram packages Theorem 6.1.36(b) and (c) in a single picture. Parts (b) says solvability passes from G to G/N (the right half of the sequence), part (c) says solvability of N and G/N forces solvability of G (the two outer terms control the middle). The remark uses the exact sequence to state: "solvability of the two ends is equivalent to solvability of the middle." It is placed here to turn the algebraic proof into a structural picture of an extension.

Concrete example: For $G = S_3$, $N = A_3 \cong \mathbb{Z}_3$: the sequence is $1 \to \mathbb{Z}_3 \to S_3 \to \mathbb{Z}_2 \to 1$. Both $\mathbb{Z}_3$ (abelian) and $\mathbb{Z}_2$ (abelian) are solvable, so by part (c) S_3 is solvable; and indeed S_3 is solvable of derived length 2.

Common pitfall: Part (c) requires N normal, not merely a subgroup. Students sometimes write the sequence with a non-normal H and claim solvability of G from solvability of H and G/H. But G/H is not a group unless $H \trianglelefteq G$, so the sequence does not exist. Also, do not read the surjection $G \to G/N$ as a splitting: the sequence need not split, and G need not be a semidirect product $N \rtimes (G/N)$.

Takeaway: The point of this diagram is that the solvability of a group extension is completely determined by the solvability of its kernel and quotient, making short exact sequences the natural language for building up solvable groups from simpler abelian pieces.

Caution. Part (c) requires N *normal*. "H solvable and G/H makes sense" is meaningless for non-normal H. Also, "solvable" is NOT detected by a single quotient: G/N solvable alone does not make G solvable – you also need N solvable. Example: take $G = A_5 \times \mathbb{Z}_2$ with $N = A_5$; then $G/N \cong \mathbb{Z}_2$ is solvable but G is not, because $N = A_5$ is not.

Worked Example 6.1.37 (Closure in action: $\mathbb{Z}_2 \times A_5$ and a solvable extension)**.** (i) Show $G = \mathbb{Z}_2 \times A_5$ is not solvable. (ii) Show that any group G with a normal series $1 \trianglelefteq N \trianglelefteq G$ where $N \cong \mathbb{Z}_3$ and $G/N \cong S_3$ is solvable.

Recognition. Use Theorem 6.1.36: (a) for the obstruction, (c) for building solvability from solvable pieces.

Solution. (i) $A_5 \leq G$ as a subgroup (the second factor). If G were solvable, then by 6.1.36(a) A_5 would be solvable; but $(A_5)' = A_5 \neq 1$, contradiction. So G is **not solvable**.

(ii) $N \cong \mathbb{Z}_3$ is abelian, hence solvable (derived length 1). $G/N \cong S_3$ is solvable (derived length 2, shown above). By 6.1.36(c), G is **solvable**, with derived length $\leq 1 + 2 = 3$. *Check.* Such a G has order $|N| \cdot |G/N| = 3 \cdot 6 = 18$; indeed all groups of order $18 = 2 \cdot 3^2$ are solvable by Burnside, consistent with our conclusion.

Nilpotent implies solvable (and the converse fails)

Proposition 6.1.38. *Every nilpotent group is solvable. The converse is false.*

Proof. Let G be nilpotent with lower central series $G = \gamma_1 \geq \gamma_2 \geq \cdots \geq \gamma_{c+1} = 1$, where $\gamma_{i+1} = [\gamma_i, G]$. We claim $G^{(i)} \leq \gamma_{i+1}$ by induction. Base: $G^{(0)} = G = \gamma_1$. Inductive step: if $G^{(i)} \leq \gamma_{i+1}$ then

$$G^{(i+1)} = [G^{(i)}, G^{(i)}] \leq [\gamma_{i+1}, \gamma_{i+1}] \leq [\gamma_{i+1}, G] = \gamma_{i+2},$$

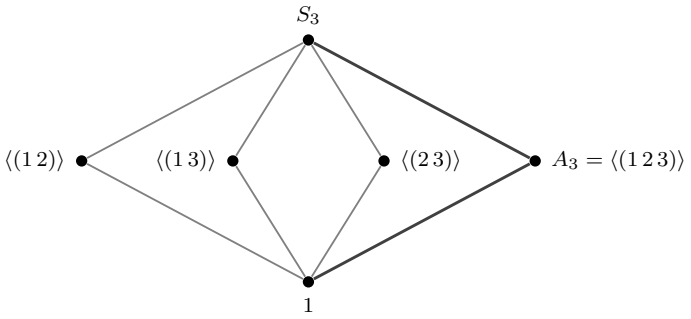
using $\gamma_{i+1} \leq G$. Hence $G^{(c)} \leq \gamma_{c+1} = 1$, so G is solvable (derived length $\leq c$).

Converse counterexample: S_3 is solvable (derived series $S_3 \geq A_3 \geq 1$) but not nilpotent. Its lower central series is $\gamma_1 = S_3$, $\gamma_2 = [S_3, S_3] = A_3$, and $\gamma_3 = [A_3, S_3]$. Since $A_3 = \langle (1\,2\,3) \rangle \trianglelefteq S_3$ and a transposition inverts the 3-cycle, $[(1\,2\,3), (1\,2)] = (1\,2\,3)^{-1}\big((1\,2)^{-1}(1\,2\,3)(1\,2)\big) = (1\,3\,2)(1\,3\,2) = (1\,2\,3) \neq 1$ lies in A_3, in fact $\gamma_3 = [A_3, S_3] = A_3$. So the lower central series stabilizes at $A_3 \neq 1$ and never reaches 1: S_3 is not nilpotent. □

Remark 6.1.7 (The hierarchy). We now have strict inclusions of group classes:

$$\text{cyclic} \subsetneq \text{abelian} \subsetneq \text{nilpotent} \subsetneq \text{solvable} \subsetneq \text{all groups}.$$

Separating examples: $\mathbb{Z}_2 \times \mathbb{Z}_2$ (abelian, noncyclic); Q_8 or D_8 (nilpotent, nonabelian); S_3 (solvable, non-nilpotent); A_5 (non-solvable).



Worked Example 6.1.39 (Nilpotent $\implies$ solvable, with S_3 as the converse counterexample)**.** (i) Verify D_8 is nilpotent and solvable. (ii) Verify S_3 is solvable but not nilpotent, exhibiting both series.

Recognition. Compute the lower central series (tests nilpotence) AND the derived series (tests solvability) for each, per Proposition 6.1.38.

Solution. (i) D_8. Lower central: $\gamma_1 = D_8$, $\gamma_2 = [D_8, D_8] = D_8' = \langle r^2 \rangle$ (computed earlier), $\gamma_3 = [\langle r^2 \rangle, D_8]$. Since $r^2 \in Z(D_8)$, every commutator $[r^2, g] = 1$, so $\gamma_3 = 1$. Thus $D_8 = \gamma_1 \geq \langle r^2 \rangle \geq 1$ is nilpotent of class 2. Derived: $D_8 \geq \langle r^2 \rangle \geq 1$ (since $\langle r^2 \rangle \cong \mathbb{Z}_2$ abelian), solvable of derived length 2. Both terminate. **Nilpotent and solvable.**

(ii) S_3. Derived series $S_3 \geq A_3 \geq 1$ (quotients $\mathbb{Z}_2, \mathbb{Z}_3$): **solvable**, length 2. Lower central series $S_3 \geq A_3 \geq A_3 \geq \cdots$ stabilizes at A_3 (since $[A_3, S_3] = A_3 \neq 1$): **not nilpotent**. *Check.* A finite group is nilpotent iff it is the direct product of its Sylow subgroups iff every Sylow subgroup is normal. In S_3 the three Sylow 2-subgroups (order 2) are not normal ($n_2 = 3$), confirming non-nilpotence; in D_8 (2-group) every p-group is nilpotent, confirming nilpotence. Consistent.

The subgroup lattice of S_3 makes the separation visible: the derived series $1 \trianglelefteq A_3 \trianglelefteq S_3$ is the highlighted spine, while the three order-2 Sylow 2-subgroups are conjugate and non-normal — exactly the obstruction to nilpotence.

Two landmark theorems (stated)

Theorem 6.1.40 (Burnside's p^aq^b theorem)**.** *Let p, q be primes and $a, b \geq 0$. Every group of order p^aq^b is solvable. Equivalently, a group whose order is divisible by at most two distinct primes is solvable.*

Sketch. The classical proof uses character theory of finite groups. One shows: if G is a finite nonabelian simple group, then no nontrivial conjugacy class has size a prime power p^k ($k \geq 1$). The key lemma (via the column-orthogonality relations and algebraic-integer arguments on character values $\chi(g)$) is that a conjugacy class of size p^k forces an irreducible character with $|\chi(g)| = |\chi(1)|$ at some $g \neq 1$, producing a proper nontrivial normal subgroup – contradicting simplicity. Now if $|G| = p^aq^b$ with G a minimal counterexample (nonabelian simple), a Sylow q-subgroup $Q \neq 1$ has nontrivial center; an element $g \in Z(Q) \setminus \{1\}$ has centralizer containing Q, so its class size divides p^a, i.e. is a power of p – contradiction. Hence no nonabelian simple group of order p^aq^b exists, and by induction on $|G|$ (using Theorem 6.1.36(c) on a minimal normal subgroup) every such group is solvable. A purely group-theoretic proof exists (Goldschmidt–Matsuyama–Bender) but is far longer. □

Remark 6.1.8. Three distinct primes can fail: $|A_5| = 60 = 2^2 \cdot 3 \cdot 5$ has three prime divisors and is not solvable. So "two primes" in Burnside is sharp. The smallest non-solvable group is A_5.

Worked Example 6.1.41 (Using Burnside: orders forcing solvability)**.** Which of the following orders force every group of that order to be solvable: 200, 108, 105, 60?

Recognition. Apply Burnside (Method shortcut (ii)): solvable is guaranteed if the order has at most two distinct prime factors; also recall $|G| < 60 \implies$ solvable.

Solution. Factor each:

- $200 = 2^3 \cdot 5^2$: two primes $\implies$ **solvable** (Burnside).
- $108 = 2^2 \cdot 3^3$: two primes $\implies$ **solvable** (Burnside).
- $105 = 3 \cdot 5 \cdot 7$: three primes, so Burnside does not apply directly. We argue by Sylow counting. For the Sylow 7-subgroups, $n_7 \equiv 1 \pmod 7$ and $n_7 \mid 15$, so $n_7 \in \{1, 15\}$ (note $15 \equiv 1 \pmod 7$, so 15 is NOT excluded by the congruence). For the Sylow 5-subgroups, $n_5 \equiv 1 \pmod 5$ and $n_5 \mid 21$, so $n_5 \in \{1, 21\}$. If both $n_7 = 15$ and $n_5 = 21$, the distinct Sylow 7-subgroups contribute $15 \cdot (7 - 1) = 90$ elements of order 7 and the distinct Sylow 5-subgroups contribute $21 \cdot (5 - 1) = 84$ elements of order 5; but $90 + 84 = 174 > 105$, impossible. So $n_5 = 1$ or $n_7 = 1$: some Sylow subgroup P of prime order (5 or 7) is normal. Then G/P has order $21 = 3 \cdot 7$ or $15 = 3 \cdot 5$, solvable by Burnside, and P is abelian; by 6.1.36(c), G is solvable. **Every group of order** 105 **is solvable** (by Sylow counting +6.1.36(c), not Burnside alone).
- $60 = 2^2 \cdot 3 \cdot 5$: three primes; NOT forced. Indeed A_5 has order 60 and is **not** solvable.

Check. Burnside gives "solvable" for $200, 108$ instantly; the congruence alone does NOT pin $n_7 = 1$ for order 105 (since $15 \equiv 1 \pmod 7$), but the element count does; 60 is the cautionary case (three primes, and a genuine non-solvable example exists). Consistent with A_5 being minimal non-solvable.

Theorem 6.1.42 (Philip Hall's theorem on Hall subgroups)**.** *Let G be a finite solvable group of order n, and let π be a set of primes. Write $n = mk$ where m is the π-part of n (product of the prime powers $p^a \,\|\, n$ with $p \in \pi$) and $\gcd(m, k) = 1$. A* Hall π-subgroup *of G is a subgroup of order m. Then:*

(a) ***(Existence)*** *G has a Hall π-subgroup.*

(b) ***(Conjugacy)*** *Any two Hall π-subgroups of G are conjugate in G.*

(c) ***(Containment)*** *Every π-subgroup of G is contained in some Hall π-subgroup.*

Conversely (Hall's converse), if G has a Hall p'-subgroup for every prime $p \mid |G|$, then G is solvable.

Sketch. Existence is by induction on $|G|$. Take a minimal normal subgroup N of the solvable group G; minimality plus solvability force N to be an elementary abelian p-group for some prime p. *Case $p \in \pi$:* by induction G/N has a Hall π-subgroup $\overline{H} = H/N$, and H has order $|N| \cdot |\overline{H}|$, which is the π-part of $|G|$; so H works. *Case $p \notin \pi$:* by induction G/N has a Hall π-subgroup H/N of order the π-part m of $|G/N| = |G|/|N|$, hence of $|G|$; now H is a group of order $m|N|$ with $N \trianglelefteq H$ a normal Hall p-subgroup ($p \notin \pi$), and the Schur–Zassenhaus theorem gives a complement of order m in H, which is the desired Hall π-subgroup of G. Conjugacy and containment are proved together by a similar induction using Schur–Zassenhaus and the conjugacy of complements. Hall generalizes Sylow ($\pi = \{p\}$) precisely to the solvable setting; for non-solvable G Hall subgroups can fail to exist (see the pitfall). □

Caution. Hall's theorem is *special to solvable groups.* In $G = A_5$ ($|G| = 60 = 2^2 \cdot 3 \cdot 5$), Hall π-subgroups can fail to exist. A Hall $\{2, 5\}$-subgroup would have order $2^2 \cdot 5 = 20$ and a Hall $\{3, 5\}$-subgroup would have order $3 \cdot 5 = 15$, but A_5 has no subgroup of order 15 or 20. For order 15: a group of order 15 is cyclic, so it would contain an element of order 15; but A_5 has no element of order 15 (element orders in A_5 are $1, 2, 3, 5$), so no such subgroup exists. (Note: $A_4 \leq A_5$ *is* a genuine Hall $\{2, 3\}$-subgroup of order 12, so SOME Hall subgroups happen to exist; the point is that existence for *every* π is exactly what fails outside the solvable case.)

Worked Example 6.1.43 (A Hall subgroup of S_4)**.** S_4 is solvable of order $24 = 2^3 \cdot 3$. For $\pi = \{2\}$ exhibit a Hall $\{2\}$-subgroup (order 8); for $\pi = \{3\}$ a Hall $\{3\}$-subgroup (order 3); verify the conjugacy clause.

Recognition. Apply Hall's theorem (Theorem 6.1.42) in a known solvable group; a Hall $\{p\}$-subgroup is just a Sylow p-subgroup, so cross-check against Sylow.

Solution. $|S_4| = 24 = 2^3 \cdot 3^1$.

Hall $\{2\}$-subgroup ($m = 2^3 = 8$): a Sylow 2-subgroup. Take $P = \langle (1\,2\,3\,4),\ (1\,3) \rangle \cong D_8$, $|P| = 8$. This is a Hall $\{2\}$-subgroup. By Sylow (or Hall conjugacy) all such are conjugate; $n_2 \mid 3$ and $n_2 \equiv 1 \pmod 2$ give $n_2 \in \{1, 3\}$, and in fact $n_2 = 3$ – three conjugate Sylow 2-subgroups, matching Hall's conjugacy clause.

Hall $\{3\}$-subgroup ($m = 3$): a Sylow 3-subgroup, e.g. $\langle (1\,2\,3) \rangle \cong \mathbb{Z}_3$, order 3. Here $n_3 \equiv 1 \pmod 3$, $n_3 \mid 8 \implies n_3 \in \{1, 4\}$, and in fact $n_3 = 4$ (the eight 3-cycles lie in four subgroups of order 3), four conjugates – again Hall conjugacy.

The complement viewpoint: inside the chain $S_4 \geq A_4 \geq V$, the Hall $\{2\}$-subgroup D_8 meets A_4 in V (order 4) and projects onto $S_4/A_4 \cong \mathbb{Z}_2$, illustrating that the order-8 Hall $\{2\}$-subgroup is a complement to the $\{3\}$-part: its order 8 and that of any Hall $\{3\}$-subgroup (3) are coprime with product 24. *Check.* Orders multiply correctly: a Hall $\{2\}$-subgroup (8) and a Hall $\{3\}$-subgroup (3) have coprime orders $8, 3$ with $8 \cdot 3 = 24 = |S_4|$. All Hall π-subgroups for each fixed π are conjugate ($n_2 = 3$, $n_3 = 4$ conjugates respectively), as Theorem 6.1.42(b) predicts. Consistent.

Caution. Do not confuse derived length with nilpotency class, and do not assume the derived series and lower central series coincide. For S_3: derived series reaches 1 (length 2) but lower central series stalls at A_3. They agree only in special cases; in general $G^{(i)} \leq \gamma_{i+1}$ (the inclusion proved in Proposition 6.1.38), and this inclusion can be strict even in a nilpotent group: in D_{16} (with r of order 8) the derived series is $D_{16} \geq \langle r^2 \rangle \geq 1$, so $D_{16}^{(2)} = 1$, while $\gamma_3(D_{16}) = \langle r^4 \rangle \neq 1$.

Exercises (from the text).

1. Prove that $Z_i(G)$ is a characteristic subgroup of G for all i.

2. Prove Parts 2 and 4 of Theorem 1 for G a finite nilpotent group, not necessarily a p-group.

3. If G is finite prove that G is nilpotent if and only if it has a normal subgroup of each order dividing $|G|$, and is cyclic if and only if it has a unique subgroup of each order dividing $|G|$.

4. Prove that a maximal subgroup of a finite nilpotent group has prime index.

5. Prove Parts 2 and 4 of Theorem 1 for G an infinite nilpotent group.

6. Show that if $G/Z(G)$ is nilpotent then G is nilpotent.

7. Prove that subgroups and quotient groups of nilpotent groups are nilpotent (your proof should work for infinite groups). Give an explicit example of a group G which possesses a normal subgroup H such that both H and G/H are nilpotent but G is not nilpotent.

8. Prove that if p is a prime and P is a non-abelian group of order p^3 then $|Z(P)| = p$ and $P/Z(P) \cong \mathbb{Z}_p \times \mathbb{Z}_p$.

9. Prove that a finite group G is nilpotent if and only if whenever $a, b \in G$ with $(|a|, |b|) = 1$ then $ab = ba$. [Use Part 4 of Theorem 3.]

10. Prove that D_{2n} is nilpotent if and only if n is a power of 2. [Use Exercise 9.]

11. Give another proof of Proposition 5 under the additional assumption that G is abelian by invoking the Fundamental Theorem of Finite Abelian Groups.

12. Find the upper and lower central series for A_4 and S_4.

13. Find the upper and lower central series for A_5 and S_5.

14. Prove that G^i is a characteristic subgroup of G for all i.

15. Prove that $Z_i(D_{2^n}) = \langle r^{2^{n-1-i}} \rangle$ for $0 \leq i \leq n-2$ and $Z_{n-1}(D_{2^n}) = D_{2^n}$, where r is the rotation of order 2^{n-1}.

16. Prove that $\mathbb{Q}$ has no maximal subgroups. [Recall Exercise 21, Section 3.2.]

17. Prove that $G^{(i)}$ is a characteristic subgroup of G for all i.

18. Show that if G'/G'' and G''/G''' are both cyclic then $G'' = G'''$. [You may assume $G''' = 1$. Then G/G'' acts by conjugation on the cyclic group G''.]

19. Show that there is no group whose commutator subgroup is isomorphic to S_4. [Use the preceding exercise.]

20. Let p be a prime, let P be a p-subgroup of the finite group G, let N be a normal subgroup of G whose order is relatively prime to p and let $\bar{G} = G/N$. Prove the following:

    (a) $N_{\bar{G}}(\bar{P}) = \overline{N_G(P)}$ [Use Frattini's Argument.]

    (b) $C_{\bar{G}}(\bar{P}) = \overline{C_G(P)}$. [Use part (a).]

21. Prove that $\Phi(G)$ is a characteristic subgroup of G.

22. When G is a finite group prove that if $N \trianglelefteq G$ then $\Phi(N) \leq \Phi(G)$. Give an explicit example where this containment does not hold if N is not normal in G.

23. Compute $\Phi(S_3)$, $\Phi(A_4)$, $\Phi(S_4)$, $\Phi(A_5)$ and $\Phi(S_5)$.

24. Say an element x of G is a *nongenerator* if for every proper subgroup H of G, $\langle x, H \rangle$ is also a proper subgroup of G. Prove that $\Phi(G)$ is the set of nongenerators of G (here $|G| > 1$).

25. Let G be a finite group. Prove that $\Phi(G)$ is nilpotent. [Use Frattini's Argument to prove that every Sylow subgroup of $\Phi(G)$ is normal in G.]

26. Let p be a prime, let P be a finite p-group and let $\bar{P} = P/\Phi(P)$.

    (a) Prove that $\bar{P}$ is an elementary abelian p-group. [Show that $P' \leq \Phi(P)$ and that $x^p \in \Phi(P)$ for all $x \in P$.]

    (b) Prove that if N is any normal subgroup of P such that P/N is elementary abelian then $\Phi(P) \leq N$. State this (universal) property in terms of homomorphisms and commutative diagrams.

(c) Let $\bar{P}$ be elementary abelian of order p^r (by (a)). Deduce from Exercise 24 that if $\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_r$ are any basis for the r-dimensional vector space $\bar{P}$ over $\mathbb{F}_p$ and if x_i is any element of the coset $\bar{x}_i$, then $P = \langle x_1, x_2, \ldots, x_r \rangle$. Show conversely that if $y_1, y_2, \ldots, y_s$ is any set of generators for P, then $s \geq r$ (you may assume that every minimal generating set for an r-dimensional vector space has r elements, i.e., every basis has r elements). Deduce *Burnside's Basis Theorem*: a set $y_1, \ldots, y_r$ is a minimal generating set for P if and only if $\bar{y}_1, \ldots, \bar{y}_r$ is a basis of $\bar{P} = P/\Phi(P)$. Deduce that any minimal generating set for P has r elements.

(d) Prove that if $P/\Phi(P)$ is cyclic then P is cyclic. Deduce that if P/P' is cyclic then so is P.

(e) Let σ be any automorphism of P of prime order q with $q \neq p$. Show that if σ fixes the coset $x\Phi(P)$ then σ fixes some element of this coset (note that since $\Phi(P)$ is characteristic in P every automorphism of P induces an automorphism of $P/\Phi(P)$). [Use the observation that σ acts as a permutation of order 1 or q on the p^a points in the coset $x\Phi(P)$.]

(f) Use parts (e) and (c) to deduce that every nontrivial automorphism of P of order prime to p induces a nontrivial automorphism on $P/\Phi(P)$. Deduce that any group of automorphisms of P which has order prime to p is isomorphic to a subgroup of $\mathrm{Aut}(\bar{P}) = \mathrm{GL}_r(\mathbb{F}_p)$.

27. Generalize part (d) of the preceding exercise as follows: let p be a prime, let P be a p-group and let $\bar{P} = P/\Phi(P)$ be elementary abelian of order p^r. Prove that P has exactly $\frac{p^r-1}{p-1}$ maximal subgroups. [Since every maximal subgroup of P contains $\Phi(P)$, the maximal subgroups of P are, by the Lattice Isomorphism Theorem, in bijective correspondence with the maximal subgroups of the elementary abelian group $\bar{P}$. It therefore suffices to show that the number of maximal subgroups of an elementary abelian p-group of order p^r is as stated above. One way of doing this is to use the result that an abelian group is isomorphic to its dual group (cf. Exercise 14 in Section 5.2) so the number of subgroups of index p equals the number of subgroups of order p.]

28. Prove that if p is a prime and $P = \mathbb{Z}_p \times \mathbb{Z}_{p^2}$ then $|\Phi(P)| = p$ and $P/\Phi(P) \cong \mathbb{Z}_p \times \mathbb{Z}_p$. Deduce that P has $p + 1$ maximal subgroups.

29. Prove that if p is a prime and P is a non-abelian group of order p^3 then $\Phi(P) = Z(P)$ and $P/\Phi(P) \cong \mathbb{Z}_p \times \mathbb{Z}_p$. Deduce that P has $p + 1$ maximal subgroups.

30. Let p be an odd prime, let $P_1 = \mathbb{Z}_p \times \mathbb{Z}_{p^2}$ and let P_2 be the non-abelian group of order p^3 which has an element of order p^2. Prove that P_1 and P_2 have the same lattice of subgroups.

31. For any group G a *minimal normal subgroup* is a normal subgroup M of G such that the only normal subgroups of G which are contained in M are 1 and M. Prove that every minimal normal subgroup of a finite solvable group is an elementary abelian p-group for some prime p. [If M is a minimal normal subgroup of G, consider its characteristic subgroups: M' and $\{x^p \mid x \in M\}$.]

32. Prove that every maximal subgroup of a finite solvable group has prime power index. [Let H be a maximal subgroup of G and let M be a minimal normal subgroup of G — cf. the preceding exercise. Apply induction to G/M and consider separately the two cases: $M \leq H$ and $M \not\leq H$.]

33. Let π be any set of primes. A subgroup H of a finite group is called a *Hall π-subgroup* of G if the only primes dividing $|H|$ are in the set π and $|H|$ is relatively prime to $[G : H]$. (Note that if $\pi = \{p\}$, Hall π-subgroups are the same as Sylow p-subgroups. Hall subgroups were introduced in Exercise 10 of Section 3.3.) Prove the following generalization of Sylow's Theorem for solvable groups: if G is a finite solvable group then for every set π of primes, G has a Hall π-subgroup and any two Hall π-subgroups (for the same set π) are conjugate in G. [Fix π and proceed by induction on $|G|$, proving both existence and conjugacy at once. Let M be a minimal normal subgroup of G, so M is a p-group for some prime p. If $p \in \pi$, apply induction to G/M. If $p \notin \pi$, reduce to the case $|G| = p^a n$, where $p^a = |M|$ and n is the order of a Hall π-subgroup of G. In this case let N/M be a minimal normal subgroup of G/M, so N/M is a q-group for some prime $q \neq p$. Let $Q \in \mathrm{Syl}_q(N)$. If $Q \trianglelefteq G$ argue as before with Q in place of M. If Q is not normal in G, use Frattini's Argument to show $N_G(Q)$ is a Hall π-subgroup of G and establish conjugacy in this case too.]

34. Let p be a prime dividing the order of the finite solvable group G. Assume G has no nontrivial normal subgroups of order prime to p. Let P be the largest normal p-subgroup of G (cf. Exercise 37, Section 4.5). Note that Exercise 31 above shows that $P \neq 1$. Prove that $C_G(P) \leq P$, i.e., $C_G(P) = Z(P)$. [Let $N = C_G(P)$ and use the preceding exercise to show $N = Z(P) \times H$ for some Hall π-subgroup H of N — here π is the set of all prime divisors of $|N|$ except for p. Show $H \trianglelefteq G$ to obtain the desired conclusion: $H = 1$.]

35. Prove that if G is a finite group in which every proper subgroup is nilpotent, then G is solvable. [Show that a minimal counterexample is simple. Let M and N be distinct maximal subgroups chosen with $|M \cap N|$ as large as possible and apply Part 2 of Theorem 3 to show that $M \cap N = 1$. Now apply the methods of Exercise 53 in Section 4.5.]

36. Let p be a prime, let V be a nonzero finite dimensional vector space over the field of p elements and let φ be an element of $\mathrm{GL}(V)$ of order a power of p (i.e., V is a nontrivial elementary abelian p-group and φ is an automorphism of V of p-power order). Prove that there is some nonzero element $v \in V$ such that $\varphi(v) = v$, i.e., φ has a nonzero fixed point on V.

37. Let V be a finite dimensional vector space over the field of 2 elements and let φ be an element of $\mathrm{GL}(V)$ of order 2 (i.e., V is a nontrivial elementary abelian 2-group and φ is an automorphism of V of order 2). Prove that the map $v \mapsto v + \varphi(v)$ is a homomorphism from V to itself. Show that every element in the image of this map is fixed by φ. Deduce that the subspace of elements of V which are fixed by φ has dimension $\geq \frac{1}{2}(\dim V)$. (Note that if G is the semidirect product of V with $\langle\varphi\rangle$, where $V \trianglelefteq G$ and φ acts by conjugation on V by sending each $v \in V$ to $\varphi(v)$, then the fixed points of φ on V are $C_V(\varphi)$ and the above map is simply the commutator map: $v \mapsto [v, \varphi]$. In this terminology the problem is to show that $|C_V(\varphi)|^2 \geq |V|$.)

38. Use the preceding exercise to prove that if P is a 2-group which has a cyclic center and M is a subgroup of index 2 in P, then the center of M has rank ≤ 2. [The group P/M of order 2 acts by conjugation on the $\mathbb{F}_2$ vector space $\{z \in Z(M) \mid z^2 = 1\}$ and the fixed points of this action are in the center of P.]

Practice problems.

1. For the dihedral group $D_{16} = \langle r, s \mid r^8 = s^2 = 1,\ srs = r^{-1}\rangle$ of order 16, compute the *lower* central series $G = \gamma_1 \geq \gamma_2 \geq \gamma_3 \geq \cdots$ and state the nilpotence class. (Do D_{16}, not the body's D_8 or Q_8.)

   Answer. $\gamma_1 = D_{16}$, $\gamma_2 = [G, G] = \langle r^2\rangle$ (order 4), $\gamma_3 = [\gamma_2, G] = \langle r^4\rangle$ (order 2), $\gamma_4 = [\gamma_3, G] = 1$. Since $\gamma_4 = 1$ but $\gamma_3 \neq 1$, the class is 3. In general for $D_{2^n} = \langle r, s \mid r^{2^{n-1}} = s^2 = 1,\ srs = r^{-1}\rangle$ one has $\gamma_{i+1} = \langle r^{2^i}\rangle$ for $i \geq 1$, giving class $n - 1$ (here $n = 4$).

2. For D_{16} compute the *upper* central series $1 = Z_0 \leq Z_1 \leq Z_2 \leq \cdots$, identify each term, and confirm the general pattern $Z_i(D_{2^n}) = \langle r^{2^{n-1-i}}\rangle$ for $0 \leq i \leq n - 2$ (a *cyclic* group), with the final term $Z_{n-1} = D_{2^n}$ jumping to the whole group; equivalently the quotients satisfy $D_{2^n}/Z_i \cong D_{2^{n-i}}$ for $0 \leq i \leq n - 2$. State the class.

   Answer. $Z_1 = Z(D_{16}) = \langle r^4\rangle$ (cyclic of order 2): only 1 and r^4 are fixed by all conjugations, since $sr^k s = r^{-k}$ forces $k \equiv -k \pmod 8$, i.e. $k \in \{0, 4\}$. Passing to $\bar{G} = D_{16}/\langle r^4\rangle \cong D_8$, its center is $\langle r^2\rangle/\langle r^4\rangle$, so $Z_2 = \langle r^2\rangle$ (cyclic of order 4). Then $D_{16}/\langle r^2\rangle \cong V_4$ is abelian, so $Z_3 = D_{16}$. Thus

   $$1 \leq \langle r^4\rangle \leq \langle r^2\rangle \leq D_{16},$$

   class 3. This matches $Z_i = \langle r^{2^{3-i}}\rangle$ for $i = 0, 1, 2$ (orders $1, 2, 4$) and the jump $Z_3 = G$, and the quotient pattern $D_{16}/Z_1 \cong D_8 = D_{2^3}$, $D_{16}/Z_2 \cong V_4 = D_{2^2}$. The upper and lower series have equal length 3 (Proposition: equal length).

3. Show that $G' = [G, G]$ is the unique smallest normal subgroup $N \trianglelefteq G$ with G/N abelian. Then compute G' for the dihedral group D_{10} (order 10) and for the dicyclic group $\mathrm{Dic}_3 = Q_{12} = \langle a, b \mid a^6 = 1,\ b^2 = a^3,\ bab^{-1} = a^{-1}\rangle$ (order 12).

   Answer. Universal property. For $N \trianglelefteq G$: G/N is abelian $\iff$ $[x, y] \in N$ for all $x, y \in G$ $\iff$ $G' \leq N$. So G' is contained in every such N, and G/G' is itself abelian, making G' the unique smallest one. *D_{10}:*

$[r,s]=r^{-2}$ generates the rotation subgroup, so $G'=\langle r\rangle\cong\mathbb{Z}/5\mathbb{Z}$ and $D_{10}/\langle r\rangle\cong\mathbb{Z}/2\mathbb{Z}$. Q_{12}*:* $[a,b]=a^{-2}$, so $G'=\langle a^2\rangle$ has order 3; the abelianization is $Q_{12}/\langle a^2\rangle\cong\mathbb{Z}/4\mathbb{Z}$ (generated by the image of b, with $b^2=a^3$ of order 2 mod $\langle a^2\rangle$).

4. Prove that a finite p-group has nontrivial center via the class equation, and deduce that every group of order p^2 is abelian (hence of class 1).

   Answer. The class equation $|G|=|Z(G)|+\sum_i[G:C_G(x_i)]$ runs over noncentral conjugacy-class representatives x_i; each index $[G:C_G(x_i)]>1$ is a positive power of p, so p divides the whole sum. Since $p\mid|G|$, it follows that $p\mid|Z(G)|$, so $Z(G)\neq1$. If $|G|=p^2$, then $|Z(G)|\in\{p,p^2\}$. If $|Z(G)|=p$, then $G/Z(G)$ has order p, hence is cyclic, which forces G abelian (a generator coset and $Z(G)$ together commute) — contradicting $|Z(G)|=p$. So $|Z(G)|=p^2$, i.e. $G=Z(G)$ is abelian, of class 1.

5. Prove the *normalizer condition* for finite nilpotent groups: every proper subgroup $H<G$ satisfies $H<N_G(H)$. Then exhibit its failure in S_3.

   Answer. Induct on the nilpotence class using $Z=Z(G)\neq1$. If $Z\not\leq H$, pick $z\in Z\setminus H$; since z is central it normalizes H, so $z\in N_G(H)\setminus H$ and $H<N_G(H)$. If $Z\leq H$, pass to $\bar G=G/Z$ (nilpotent of smaller class) and $\bar H=H/Z<\bar G$; by induction $\bar H<N_{\bar G}(\bar H)=N_G(H)/Z$, so $H<N_G(H)$. *Failure in S_3:* take the Sylow 2-subgroup $H=\langle(1\,2)\rangle$. Its normalizer is H itself (each of the four elements outside H — the two 3-cycles and the transpositions $(1\,3)$, $(2\,3)$ — conjugates $(1\,2)$ to $(1\,3)$ or $(2\,3)$, which is not in H), so $N_G(H)=H$. The condition fails, which reproves S_3 is not nilpotent.

6. Prove the closure properties of solvable groups: subgroups, quotients, and extensions (N and G/N solvable $\implies$ G solvable). State the derived-length bounds.

   Answer. Subgroups: if $H\leq G$ then $H^{(i)}\leq G^{(i)}$ by induction (commutators of H are commutators of G), so G solvable $\implies$ H solvable with $\mathrm{dl}(H)\leq\mathrm{dl}(G)$. *Quotients:* if $\pi:G\to G/N$ is the projection then $\pi(G^{(i)})=(G/N)^{(i)}$, so $\mathrm{dl}(G/N)\leq\mathrm{dl}(G)$. *Extensions:* suppose $(G/N)^{(m)}=1$ and $N^{(k)}=1$. From $\pi(G^{(m)})=(G/N)^{(m)}=1$ we get $G^{(m)}\leq N$, hence $G^{(m+k)}=(G^{(m)})^{(k)}\leq N^{(k)}=1$. Thus G is solvable with $\mathrm{dl}(G)\leq m+k=\mathrm{dl}(G/N)+\mathrm{dl}(N)$.

7. For a finite p-group G prove $\Phi(G)=G'\,G^p$ where $G^p=\langle g^p:g\in G\rangle$, and use it to compute $\Phi(G)$ and the generator rank $\dim_{\mathbb{F}_p}\big(G/\Phi(G)\big)$ for $G=\mathbb{Z}/8\mathbb{Z}$ and $G=\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/4\mathbb{Z}$.

   Answer. Every maximal subgroup M of the p-group G is normal of index p, so $G/M\cong\mathbb{Z}/p\mathbb{Z}$ is abelian of exponent p; hence $G'\leq M$ and $g^p\in M$ for all $g\in G$. Intersecting over all M gives $G'G^p\leq\Phi(G)$. Conversely $G'G^p\trianglelefteq G$ and $G/G'G^p$ is elementary abelian, i.e. an $\mathbb{F}_p$-vector space, in which the hyperplanes (the maximal subgroups) intersect in 0; their preimages are maximal subgroups of G with intersection $G'G^p$, giving $\Phi(G)\leq G'G^p$. Hence $\Phi(G)=G'G^p$, and $G/\Phi(G)$ is the largest elementary abelian p-quotient. $\mathbb{Z}/8\mathbb{Z}$*:* $G'=0$ and $G^2=2(\mathbb{Z}/8\mathbb{Z})=\langle2\rangle\cong\mathbb{Z}/4\mathbb{Z}$, so $\Phi=\langle2\rangle$ and $G/\Phi\cong\mathbb{Z}/2\mathbb{Z}$ has rank 1. $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/4\mathbb{Z}$*:* $G'=0$ and $G^2=\{(0,0),(0,2)\}=\langle(0,2)\rangle$ of order 2, so Φ has order 2 and $G/\Phi\cong(\mathbb{Z}/2\mathbb{Z})^2$ has rank 2.

8. Prove that the lower central series satisfies $[\gamma_i,\gamma_j]\leq\gamma_{i+j}$ (via the three-subgroups lemma), and deduce $\gamma_3\leq[\gamma_1,\gamma_2]$.

   Answer. Three-subgroups lemma (Hall–Witt): if $N\trianglelefteq G$ and $[[A,B],C]\leq N$ and $[[B,C],A]\leq N$, then $[[C,A],B]\leq N$. We prove $[\gamma_i,\gamma_j]\leq\gamma_{i+j}$ for all $i,j\geq1$ by induction on i, with the statement quantified over all j at once. Base $i=1$: $[\gamma_1,\gamma_j]=[G,\gamma_j]=[\gamma_j,G]=\gamma_{j+1}=\gamma_{1+j}$. Inductive step (assume the claim for i and all j): with $A=\gamma_i$, $B=\gamma_j$, $C=G$ and $N=\gamma_{i+j+1}$, the inductive hypothesis gives $[[\gamma_i,\gamma_j],G]\leq[\gamma_{i+j},G]=\gamma_{i+j+1}$ and $[[\gamma_j,G],\gamma_i]=[\gamma_{j+1},\gamma_i]=[\gamma_i,\gamma_{j+1}]\leq\gamma_{i+(j+1)}=\gamma_{i+j+1}$ (this is the hypothesis at i with second argument $j+1$), so the lemma yields $[[\gamma_i,G],\gamma_j]=[\gamma_{i+1},\gamma_j]\leq\gamma_{i+j+1}=\gamma_{(i+1)+j}$, completing the step. For $i=1$, $j=2$ the relation reads $[\gamma_1,\gamma_2]\leq\gamma_3$; but $[\gamma_1,\gamma_2]=[G,\gamma_2]=\gamma_3$ by definition, so equality holds and in particular $\gamma_3\leq[\gamma_1,\gamma_2]$.

9. Let G be a finite group with $G/Z(G)$ cyclic. Prove that G is already abelian, and deduce that the index $[G:Z(G)]$ is never a prime (more generally, never a number $n>1$ for which every group of order n is cyclic).

Answer. Write $Z = Z(G)$ and suppose G/Z is cyclic, say generated by the coset gZ. Then every element of G has the form $g^k z$ with $k \in \mathbb{Z}$ and $z \in Z$, and any two such commute:

$$(g^k z)(g^m z') = g^{k+m} zz' = g^m g^k z' z = (g^m z')(g^k z),$$

using that z, z' are central. Hence G is abelian, i.e. $G = Z$, so G/Z is the trivial group. Consequently G/Z can never be a nontrivial cyclic group; in particular $[G : Z]$ is never a prime p (a group of order p is cyclic, which would force G abelian and $[G : Z] = 1$, a contradiction). The same argument rules out $[G : Z]$ being any order forcing cyclicity (e.g. 1 excepted, any n with a unique group, all of which would make G/Z cyclic).

10. Let G be a nilpotent group and let $N \trianglelefteq G$ with $N \neq 1$. Prove that N meets the center nontrivially: $N \cap Z(G) \neq 1$.

    Answer. Use the upper central series $1 = Z_0 \leq Z_1 \leq \cdots \leq Z_c = G$ (with $Z_c = G$ since G is nilpotent of class c). Because $N \cap Z_c = N \cap G = N \neq 1$, there is a least index $i \geq 1$ with $N \cap Z_i \neq 1$; by minimality $N \cap Z_{i-1} = 1$. Pick $1 \neq x \in N \cap Z_i$. Since $x \in Z_i$ we have $[x, g] \in Z_{i-1}$ for every $g \in G$, and since $x \in N \trianglelefteq G$ we have $[x, g] = x^{-1}(g^{-1}xg) \in N$. Hence $[x, g] \in N \cap Z_{i-1} = 1$ for all g, so x is central: $x \in N \cap Z(G)$. Thus $N \cap Z(G) \neq 1$ (and in fact $i = 1$).

Additional exercises.

1. Prove that in a finite nilpotent group every maximal subgroup is normal of prime index, and that $G/\Phi(G)$ is abelian (indeed a direct product of elementary abelian pieces).

   Answer. Let M be maximal. By the normalizer condition $M < N_G(M)$, and maximality forces $N_G(M) = G$, so $M \trianglelefteq G$. Then G/M is a nontrivial group with no proper nontrivial subgroups, hence of prime order p; so $[G : M] = p$. For the Frattini quotient, use $G \cong P_1 \times \cdots \times P_r$ (Sylow factorization of a finite nilpotent group). The maximal subgroups of G are exactly those omitting one index-p_i line in a single factor, so

   $$G/\Phi(G) \cong \prod_i P_i/\Phi(P_i),$$

   and each $P_i/\Phi(P_i)$ is elementary abelian (Burnside). A product of elementary abelian groups is abelian, so $G/\Phi(G)$ is abelian.

2. Prove that the Frattini subgroup is multiplicative on finite direct products: $\Phi(G \times H) = \Phi(G) \times \Phi(H)$ for finite groups G, H. Use it to compute $\Phi(D_8 \times \mathbb{Z}/3\mathbb{Z})$.

   Answer. For M maximal in G and M' maximal in H, the subgroups $M \times H$ and $G \times M'$ are maximal in $G \times H$, so

   $$\Phi(G \times H) \leq \Big(\bigcap_M M\Big) \times H \;\cap\; G \times \Big(\bigcap_{M'} M'\Big) = \Phi(G) \times \Phi(H).$$

   These need not be all the maximal subgroups (in $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ the diagonal $\{(0,0),(1,1)\}$ is maximal too), so the reverse inclusion needs an argument. Let L be any maximal subgroup of $G \times H$ and put $F = \Phi(G) \times 1$, a normal subgroup of $G \times H$. If $F \not\leq L$, then $LF = G \times H$ by maximality; writing $(g, 1) = \ell f$ with $\ell \in L$, $f \in F \leq G \times 1$ forces $\ell \in L \cap (G \times 1)$, so $G \times 1 = \big(L \cap (G \times 1)\big)F$. Since $F = \Phi(G \times 1)$ consists of nongenerators of $G \times 1$ (Proposition 6.1.18), $G \times 1 = L \cap (G \times 1) \leq L$, contradicting $F \not\leq L$. Thus $\Phi(G) \times 1 \leq L$, and likewise $1 \times \Phi(H) \leq L$, for every maximal L; hence $\Phi(G) \times \Phi(H) \leq \Phi(G \times H)$, and equality holds. *Application.* From the body, $\Phi(D_8) = \langle r^2 \rangle$ (order 2), and $\Phi(\mathbb{Z}/3\mathbb{Z}) = 0$ (a group of prime order has no nontrivial proper subgroups). Hence

   $$\Phi(D_8 \times \mathbb{Z}/3\mathbb{Z}) = \langle r^2 \rangle \times 0 \cong \mathbb{Z}/2\mathbb{Z},$$

   of order 2.

3. Prove the equal-length theorem: for $c \geq 1$, $\gamma_{c+1} = 1 \neq \gamma_c \iff Z_c = G \neq Z_{c-1}$ (so both series give the same class c), using the dovetailing inclusions $\gamma_{i+1} \leq Z_{c-i}$.

Answer. The single ingredient is $[Z_j, G] \le Z_{j-1}$ for $j \ge 1$ (elements of Z_j are central mod Z_{j-1}). $Z_c = G \implies \gamma_{c+1} = 1$*:* show $\gamma_{i+1} \le Z_{c-i}$ by induction. Base $i = 0$: $\gamma_1 = G = Z_c$. Step: $\gamma_{i+1} = [\gamma_i, G] \le [Z_{c-i+1}, G] \le Z_{c-i}$. Taking $i = c$ gives $\gamma_{c+1} \le Z_0 = 1$. $\gamma_{c+1} = 1 \implies Z_c = G$*:* dually show $\gamma_{c+1-i} \le Z_i$ by induction. Base $i = 0$: $\gamma_{c+1} = 1 \le Z_0$. Step: if $g \in \gamma_{c-i+1}$ then $[g, G] \le \gamma_{c-i+2} \le Z_{i-1}$, so $g \in Z_i$. Taking $i = c$ gives $G = \gamma_1 \le Z_c$. Both directions give least index c, so the two series have equal length.

4. Prove that a nontrivial nilpotent group G is never perfect: $G' < G$. Deduce that a nontrivial finite p-group has a nontrivial abelian quotient and is therefore not its own commutator subgroup.

   Answer. Let $G \ne 1$ be nilpotent with lower central series $G = \gamma_1 \ge \gamma_2 \ge \cdots \ge \gamma_{c+1} = 1$, where $\gamma_2 = G'$. If we had $G' = G$, i.e. $\gamma_2 = \gamma_1$, then $\gamma_3 = [\gamma_2, G] = [\gamma_1, G] = \gamma_2 = G$, and by induction $\gamma_i = G$ for all i; the series would never reach 1, contradicting nilpotence (which requires $\gamma_{c+1} = 1$ with $G \ne 1$). Hence $G' < G$, so $G^{\mathrm{ab}} = G/G'$ is a nontrivial abelian group. In particular a nontrivial finite p-group P is nilpotent, so $P' < P$ and $P/P' \ne 1$ is a nontrivial abelian quotient; thus P is not perfect. (This is the reason every p-group of order > 1 has at least one index-p, hence maximal, subgroup.)

5. Let G be a finite group, $N \trianglelefteq G$ with N and G/N nilpotent. Show by example that G need not be nilpotent, and contrast this with solvability. Then compute the derived series and the lower central series of $\mathrm{Dic}_3 = Q_{12}$, confirming it is solvable but not nilpotent.

   Answer. Nilpotence is not extension-closed. Take $G = S_3$, $N = A_3 \cong \mathbb{Z}/3\mathbb{Z}$. Both N (abelian) and $G/N \cong \mathbb{Z}/2\mathbb{Z}$ are nilpotent, yet S_3 is not nilpotent. So, unlike solvability (which *is* closed under extensions, Practice problem on closure), nilpotence can be destroyed by an extension of nilpotent groups. $Q_{12} = \langle a, b \mid a^6 = 1,\ b^2 = a^3,\ bab^{-1} = a^{-1} \rangle$. Derived series: $G' = \langle a^2 \rangle \cong \mathbb{Z}/3\mathbb{Z}$ (since $[a, b] = a^{-2}$), and $\langle a^2 \rangle$ is cyclic hence abelian, so $G'' = 1$. Thus $G \ge \langle a^2 \rangle \ge 1$ is solvable of derived length 2. Lower central series: $\gamma_2 = [G, G] = \langle a^2 \rangle$, and $\gamma_3 = [\langle a^2 \rangle, G]$. Now $[a^2, b] = a^{-2}(b^{-1}a^2 b) = a^{-2}a^{-2} = a^{-4} = a^2$ (as $a^6 = 1$), so $\gamma_3 = \langle a^2 \rangle = \gamma_2$; the lower central series stalls at $\langle a^2 \rangle \ne 1$. Hence Q_{12} is **solvable but not nilpotent**, consistent with its Sylow 2-subgroup ($\cong \mathbb{Z}/4\mathbb{Z}$, of order 4) not being normal.

Commutative-diagram exercises.

1. (Factoring through the abelianization.) Prove that any homomorphism $\varphi : G \to A$ into an abelian group A factors uniquely through the projection $\pi : G \to G/G'$, and verify the universal triangle for $G = Q_8$, $A = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

   Answer. Since $\operatorname{im}\varphi \le A$ is abelian, $G' \le \ker\varphi$, so φ is constant on cosets of G' and descends to $\bar\varphi : G/G' \to A$ with $\bar\varphi \circ \pi = \varphi$; uniqueness holds because π is surjective. Q_8*:* $Q_8' = \langle -1 \rangle$ and $Q_8^{\mathrm{ab}} = Q_8/\langle -1 \rangle \cong V_4$. Define φ by $i \mapsto (1, 0)$, $j \mapsto (0, 1)$ (so $k = ij \mapsto (1, 1)$ and $-1 \mapsto (0, 0)$); this kills $\langle -1 \rangle$, so it factors as the isomorphism $\bar\varphi : Q_8^{\mathrm{ab}} \xrightarrow{\sim} \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

2. (Derived series of S_4 as inclusions.) Display $S_4 \hookleftarrow A_4 \hookleftarrow V_4 \hookleftarrow 1$, naming each term and annotating each hook arrow with the index $[G^{(i)} : G^{(i+1)}]$.

$$S_4 \xhookleftarrow{\qquad} A_4 \xhookleftarrow{\qquad} V_4 \xhookleftarrow{\qquad} 1$$

   Answer. $G^{(0)} = S_4$, $G^{(1)} = [S_4, S_4] = A_4$ (index 2), $G^{(2)} = [A_4, A_4] = V_4$ (index 3), $G^{(3)} = [V_4, V_4] = 1$ (index 4). The successive quotients $\mathbb{Z}/2\mathbb{Z}$, $\mathbb{Z}/3\mathbb{Z}$, $V_4 \cong (\mathbb{Z}/2\mathbb{Z})^2$ are all abelian, so S_4 is solvable of derived length 3. (This inclusion chain renders, as a diagram, the derived computation behind solvability; it is distinct from the quotient-map presentation used in 6.3.)

3. (Functoriality of the center quotient.) For nilpotent G of class ≥ 2 and $q : G \to G/Z(G)$, show $q(\gamma_2(G)) = \gamma_2(G/Z(G))$ and assemble the commuting square; verify for $G = D_{16}$.

$$\begin{array}{ccc} \gamma_2(G) & \xrightarrow{q|} & \gamma_2\big(G/Z(G)\big) \\ \downarrow & & \downarrow \\ G & \xrightarrow[q]{} & G/Z(G) \end{array}$$

Answer. A homomorphism sends commutators to commutators: $q[x,y] = [q(x), q(y)]$, so $q(\gamma_2(G)) = q([G,G]) = [q(G), q(G)] = \gamma_2(q(G)) = \gamma_2(G/Z(G))$. The square commutes since the vertical maps are inclusions and the top is the restriction of q. *D_{16}:* $Z(D_{16}) = \langle r^4 \rangle$ and $\gamma_2(D_{16}) = \langle r^2 \rangle$. The quotient $D_{16}/\langle r^4 \rangle \cong D_8$, and the image of $\langle r^2 \rangle$ is $\langle \bar{r}^2 \rangle = \gamma_2(D_8)$. Square verified.

4. (Extensions: solvability versus nilpotence.) Draw the short exact sequence $1 \to A_3 \to S_3 \to \mathbb{Z}/2\mathbb{Z} \to 1$ and use it to show that nilpotence is *not* closed under extensions, in contrast with the closure of solvability proved in the Practice problems. Label the derived-length and class data.

$$1 \longrightarrow A_3 \xhookrightarrow{\iota} S_3 \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \longrightarrow 1$$

Answer. The sequence is exact: $A_3 = \langle (1\,2\,3) \rangle \cong \mathbb{Z}/3\mathbb{Z} \trianglelefteq S_3$ with ι the inclusion, and π the sign map with $\ker \pi = A_3$ and image $\mathbb{Z}/2\mathbb{Z}$. *Both ends are nilpotent* (indeed abelian: A_3 of class 1 and $\mathbb{Z}/2\mathbb{Z}$ of class 1), *yet the middle is not*: S_3 has trivial center, so its upper central series stalls at 1, and it is not nilpotent (shown earlier). Hence nilpotence does *not* pass through extensions of nilpotent kernel and quotient. *Contrast.* Solvability *does* pass: here $A_3, \mathbb{Z}/2\mathbb{Z}$ solvable $\implies$ S_3 solvable, with $\mathrm{dl}(S_3) \leq \mathrm{dl}(\mathbb{Z}/2\mathbb{Z}) + \mathrm{dl}(A_3) = 1 + 1 = 2$, matching the derived series $S_3 \geq A_3 \geq 1$. The obstruction to nilpotence is exactly that the extension is non-central: the conjugation action of $\mathbb{Z}/2\mathbb{Z}$ on A_3 is nontrivial (a transposition inverts the 3-cycle), so no term of the upper central series climbs past 1.

5. (Upper-central tower of quotients.) For nilpotent G with $1 = Z_0 < \cdots < Z_c = G$ draw the tower $G \twoheadrightarrow G/Z_1 \twoheadrightarrow \cdots \twoheadrightarrow 1$ and prove each kernel Z_{i+1}/Z_i is central in G/Z_i; carry out $G = Q_8$ explicitly.

$$G \longrightarrow\!\!\!\!\!\rightarrow G/Z_1 \longrightarrow\!\!\!\!\!\rightarrow \cdots \longrightarrow\!\!\!\!\!\rightarrow G/Z_{c-1} \longrightarrow\!\!\!\!\!\rightarrow G/Z_c = 1$$

Answer. By definition $Z_{i+1}/Z_i = Z(G/Z_i)$, which is the center, hence central in G/Z_i; the maps $G/Z_i \twoheadrightarrow G/Z_{i+1}$ are the canonical projections, each with central kernel Z_{i+1}/Z_i. *Q_8:* from the body, $Z_1 = \langle -1 \rangle$ and $G/Z_1 \cong V_4$ is abelian, so $Z_2/Z_1 = Z(V_4) = V_4$, giving $Z_2 = Q_8$. The tower is $Q_8 \twoheadrightarrow V_4 \twoheadrightarrow 1$ with central kernels $\langle -1 \rangle$ then V_4; nilpotence class 2.

6.2 Applications in Groups of Medium Order

Pinning down groups of medium order via Sylow theory

The Sylow theorems give us *numerical* control over a finite group G: for each prime p dividing $|G| = p^a m$ (with $p \nmid m$), the number n_p of Sylow p-subgroups satisfies

$$n_p \equiv 1 \pmod{p}, \qquad n_p \mid m, \qquad n_p = [G : N_G(P)]$$

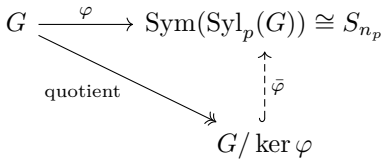
for any $P \in \mathrm{Syl}_p(G)$. The art of D&F 6.2 is to turn these arithmetic constraints into *structural* conclusions: that some Sylow subgroup is normal, that G embeds in a small symmetric group, or that G cannot be simple. We collect the standard moves, prove them, and then apply them to a battery of medium orders, culminating in the statement and proof-sketch that A_5 is the unique simple group of order 60.

Throughout, recall the three engines that convert n_p into structure.

Theorem 6.2.1 (The three structural levers)**.** *Let G be a finite group, p a prime dividing $|G|$, and $P \in \mathrm{Syl}_p(G)$.*

(L1) $n_p = 1 \iff P \trianglelefteq G$. *(A unique Sylow p-subgroup is normal.)*

(L2) ***(Sylow counting.)*** *If P has prime order p, then distinct Sylow p-subgroups intersect trivially, so the Sylow p-subgroups contribute exactly $n_p(p-1)$ elements of order p.*



(L3) ***(Action on*** $\mathrm{Syl}_p(G)$***.)*** *Conjugation gives a transitive action of G on $\mathrm{Syl}_p(G)$, hence a homomorphism $\varphi\colon G \to \mathrm{Sym}(\mathrm{Syl}_p(G)) \cong S_{n_p}$ whose kernel $\ker\varphi = \bigcap_{g\in G} gN_G(P)g^{-1}$ is the largest normal subgroup of G contained in $N_G(P)$ (the* normal core *of $N_G(P)$). If $1 < n_p$ and $|G| \nmid n_p!$, then $\ker\varphi$ is a proper nontrivial normal subgroup, so G is not simple.*

Proof. (L1) By Sylow's theorem G acts transitively on $\mathrm{Syl}_p(G)$ by conjugation, so the single Sylow p-subgroup (when $n_p = 1$) is fixed by every conjugation, i.e. $gPg^{-1} = P$ for all g, which is exactly $P \trianglelefteq G$. Conversely if $P \trianglelefteq G$ then its conjugates are all P, so $n_p = 1$.

(L2) If $|P| = p$ then P is cyclic of prime order, so any two distinct Sylow p-subgroups $P_1 \neq P_2$ have $P_1 \cap P_2$ a proper subgroup of each, forcing $P_1 \cap P_2 = 1$. Each P_i contains $p-1$ elements of order p and these sets are pairwise disjoint, giving $n_p(p-1)$ elements of order p in total.

(L3) Transitivity of the conjugation action is again Sylow's theorem, and the stabilizer of P is $N_G(P)$ by definition, so $n_p = [G : N_G(P)]$. The kernel of the induced map $\varphi\colon G \to \mathrm{Sym}(\mathrm{Syl}_p(G))$ is $\bigcap_g gN_G(P)g^{-1}$, the core of $N_G(P)$; this is normal in G and is the largest normal subgroup contained in $N_G(P)$. The image $G/\ker\varphi$ embeds in S_{n_p}, so $|G/\ker\varphi| \mid n_p!$. If $n_p > 1$ then $N_G(P) \neq G$, so $\ker\varphi \subseteq N_G(P) \subsetneq G$ shows $\ker\varphi$ is proper; and if additionally $|G| \nmid n_p!$ then $\ker\varphi \neq 1$ (else G would embed in S_{n_p}). Hence $1 \neq \ker\varphi \neq G$ and G is not simple. □

The conjugation action of (L3) is the workhorse. We picture it as:

Here $\ker\varphi = \mathrm{core}_G(N_G(P))$ and the factorization $\varphi = \bar\varphi \circ (\text{quotient})$ is the first isomorphism theorem; $\bar\varphi$ is injective.

Diagram explanation. Objects: Three groups arranged in a triangle. Upper-left: the ambient finite group G. Upper-right: the symmetric group $\mathrm{Sym}(\mathrm{Syl}_p(G)) \cong S_{n_p}$, which permutes the set of all Sylow p-subgroups (a finite set of size n_p). Lower-right: the quotient group $G/\ker\varphi$, where $\ker\varphi = \mathrm{core}_G(N_G(P))$ is the largest normal subgroup of G contained in $N_G(P)$.

Arrows: (i) $\varphi\colon G \to S_{n_p}$: the homomorphism induced by the conjugation action of G on $\mathrm{Syl}_p(G)$; g maps to the permutation $P_i \mapsto gP_ig^{-1}$. (ii) The quotient arrow $G \twoheadrightarrow G/\ker\varphi$: the canonical surjection sending g to its coset $g\ker\varphi$; it is surjective by definition. (iii) $\bar\varphi\colon G/\ker\varphi \hookrightarrow S_{n_p}$: the induced injective homomorphism given by $\bar\varphi(g\ker\varphi) = \varphi(g)$; it is the unique map making the triangle commute.

What commutes: The triangle commutes: $\varphi = \bar\varphi \circ \pi$, where $\pi\colon G \twoheadrightarrow G/\ker\varphi$ is the quotient map. In formulas: for every $g \in G$, $\bar\varphi(\pi(g)) = \bar\varphi(g\ker\varphi) = \varphi(g)$.

Why it commutes: Well-definedness of $\bar\varphi$: if $g\ker\varphi = g'\ker\varphi$, then $g'^{-1}g \in \ker\varphi$, so $\varphi(g'^{-1}g) = \mathrm{id}$, giving $\varphi(g) = \varphi(g')$. Thus the formula $\bar\varphi(g\ker\varphi) := \varphi(g)$ does not depend on which representative of the coset we choose. Injectivity follows: $\bar\varphi(g\ker\varphi) = \mathrm{id}$ iff $\varphi(g) = \mathrm{id}$ iff $g \in \ker\varphi$, i.e. the kernel of $\bar\varphi$ is trivial.

Why this matters here: This diagram is the heart of lever L3. The raw map φ may have a nontrivial kernel, but the quotient $G/\ker\varphi$ embeds *injectively* into S_{n_p}, so $|G/\ker\varphi|$ divides $n_p!$. If $|G| \nmid n_p!$ the kernel cannot be trivial, producing a proper normal subgroup and ruling out simplicity. The diagram makes the exact logical role of the first isomorphism theorem visible.

Concrete example: $G = S_4$, $p = 2$, $n_2 = 3$. Then $\varphi\colon S_4 \to S_3$ is the conjugation action on the three Sylow 2-subgroups. Its kernel is $V_4 = \{e, (12)(34), (13)(24), (14)(23)\} \trianglelefteq S_4$ with $|V_4| = 4$, and $S_4/V_4 \cong S_3$ embeds injectively as the full S_3; the triangle is $S_4 \twoheadrightarrow S_3 \hookrightarrow S_3$.

Common pitfall: Students often identify $\bar{\varphi}$ with φ and write $G/\ker\varphi \cong S_{n_p}$. But $\bar{\varphi}$ is injective, not necessarily surjective; $G/\ker\varphi$ is isomorphic to a *subgroup* of S_{n_p}, not to S_{n_p} itself (unless the action happens to be doubly transitive and hit the full symmetric group).

Takeaway: The point of this diagram is that the conjugation action on Sylow subgroups forces $G/\ker\varphi$ to embed in S_{n_p}, so whenever $|G|$ fails to divide $n_p!$ the kernel must be nontrivial, giving a proper normal subgroup that kills simplicity.

Method (The medium-order recipe)**.** To analyze a group G of order $n = p_1^{a_1}\cdots p_k^{a_k}$ (small k, modest exponents):

1. **List n_p candidates.** For each prime $p \mid n$ write $|G| = p^a m$ and list the divisors of m that are $\equiv 1 \pmod p$. These are the only allowed values of n_p.
2. **Hunt for a forced $n_p = 1$.** If for some p the only admissible value is $n_p = 1$, then $P \trianglelefteq G$ (lever L1). You have found a normal subgroup.
3. **Count elements (lever L2).** If several primes force $n_p > 1$ and the corresponding Sylow subgroups have *prime* order, add up the elements of prime order $n_p(p-1)$. If the totals overflow $|G|$, some n_p must collapse to 1. (This is the "counting elements" technique.)
4. **Embed via the action (lever L3).** If $n_p > 1$ is unavoidable but small, map $G \to S_{n_p}$. Either G embeds in S_{n_p} (often a contradiction on order, or it pins G down exactly), or the kernel is a proper normal subgroup.
5. *Conclude.* Normality of a Sylow subgroup $\implies$ not simple; often a chain of such facts builds the whole structure (semidirect product decomposition).

Caution. $n_p \equiv 1 \pmod p$ is a constraint on n_p, *not* on $|G|$ directly. A common error is to use the congruence alone and forget that n_p must also divide $m = |G|/p^a$. For $|G| = 24 = 2^3\cdot 3$ and $p = 2$: $m = 3$, so $n_2 \in \{1, 3\}$ (divisors of 3 that are odd), NOT $\{1, 3, 5, \dots\}$ (all odd numbers). (Testing divisors of $|G|$ instead of m gives the same list: a divisor of $p^a m$ that is $\equiv 1 \pmod p$ is prime to p, hence divides m.)

Caution. Lever L2 (disjointness of Sylows) needs $|P| = p$ *prime*. If $|P| = p^2$ two Sylow p-subgroups can intersect in a subgroup of order p, and the count $n_p(p^2-1)$ overcounts. Do not apply the counting bound blindly when $a \geq 2$.

Worked examples: forcing normal Sylow subgroups

Worked Example 6.2.2 (Order $30 = 2\cdot 3\cdot 5$ has normal Sylow 3- and 5-subgroups)**.** Let $|G| = 30$. Show G has a normal Sylow 5-subgroup and a normal Sylow 3-subgroup (so G is not simple).

Recognition. This is a squarefree order with three prime factors; primes $3, 5$ are large relative to the cofactors, so their n_p congruences are tight. Use lever L2 (counting elements) to rule out both $n_5 > 1$ and $n_3 > 1$ simultaneously.

Solution. **Step 1 (admissible n_p).** Here $30 = 2\cdot 3\cdot 5$.

- $n_5 \mid 6$ and $n_5 \equiv 1 \pmod 5$: divisors of 6 are $1, 2, 3, 6$; those $\equiv 1 \pmod 5$ are $1, 6$. So $n_5 \in \{1, 6\}$.
- $n_3 \mid 10$ and $n_3 \equiv 1 \pmod 3$: divisors of 10 are $1, 2, 5, 10$; those $\equiv 1 \pmod 3$ are $1, 10$. So $n_3 \in \{1, 10\}$.

Step 2 (counting, lever L2). Suppose for contradiction $n_5 = 6$ and $n_3 = 10$. Each Sylow 5-subgroup has order 5, prime, so they meet trivially and give $6\cdot(5-1) = 24$ elements of order 5. Each Sylow 3-subgroup has order 3, prime, giving $10\cdot(3-1) = 20$ elements of order 3. But $24 + 20 = 44 > 30 = |G|$, impossible. **Step 3.** Hence $n_5 = 1$ or $n_3 = 1$; either way G has a normal Sylow subgroup, say $P \trianglelefteq G$ with $|P| \in \{3, 5\}$. Let $P_3 \in \mathrm{Syl}_3(G)$, $P_5 \in \mathrm{Syl}_5(G)$. Since one of P_3, P_5 is normal, the product $H := P_5P_3$ is a subgroup, of order $|P_5||P_3|/|P_5 \cap P_3| = 5\cdot 3/1 = 15$. A group of order $15 = 3\cdot 5$ is cyclic (as $n_3 = n_5 = 1$ there: $n_5 \mid 3$, $n_5 \equiv 1 \pmod 5$ $\implies$ $n_5 = 1$; $n_3 \mid 5$, $n_3 \equiv 1 \pmod 3$ $\implies$ $n_3 = 1$), so $H \cong \mathbb{Z}_{15}$ is cyclic of index 2, hence $H \trianglelefteq G$. Inside H both its Sylow 3- and Sylow 5-subgroups are characteristic (unique), and a characteristic subgroup of a normal subgroup is normal in G. Therefore the Sylow 3- and Sylow 5-subgroups

of G are both normal in G. *Check.* With $P_3, P_5 \trianglelefteq G$ we get $P_3P_5 \cong \mathbb{Z}_{15} \trianglelefteq G$ and $G \cong \mathbb{Z}_{15} \rtimes \mathbb{Z}_2$; the four homomorphisms $\mathbb{Z}_2 \to \mathrm{Aut}(\mathbb{Z}_{15}) \cong \mathbb{Z}_2 \times \mathbb{Z}_4$ landing in the 2-torsion $\mathbb{Z}_2 \times \mathbb{Z}_2$ recover the four groups of order 30: $\mathbb{Z}_{30},\ D_{30},\ \mathbb{Z}_3 \times D_{10},\ \mathbb{Z}_5 \times S_3$. Consistent, and G is never simple.

Worked Example 6.2.3 (Order $105 = 3 \cdot 5 \cdot 7$ has normal Sylow 5- and 7-subgroups)**.** Let $|G| = 105$. Show the Sylow 5- and Sylow 7-subgroups are normal.

Recognition. Squarefree pqr with the two larger primes $5, 7$ having very tight congruences. Combine a counting bound (L2) with the fact that a normal Sylow forces a subgroup of order 35.

Solution. **Step 1 (admissible n_p).** $105 = 3 \cdot 5 \cdot 7$.

- $n_7 \mid 15$, $n_7 \equiv 1 \pmod 7$: divisors $1, 3, 5, 15$; $\equiv 1 \pmod 7$ gives $\{1, 15\}$. So $n_7 \in \{1, 15\}$.
- $n_5 \mid 21$, $n_5 \equiv 1 \pmod 5$: divisors $1, 3, 7, 21$; $\equiv 1 \pmod 5$ gives $\{1, 21\}$. So $n_5 \in \{1, 21\}$.
- $n_3 \mid 35$, $n_3 \equiv 1 \pmod 3$: divisors $1, 5, 7, 35$; $\equiv 1 \pmod 3$ gives $\{1, 7\}$. So $n_3 \in \{1, 7\}$.

Step 2 (counting, L2). Suppose $n_7 = 15$ and $n_5 = 21$. Sylow 7's have prime order 7: they give $15 \cdot 6 = 90$ elements of order 7. Sylow 5's give $21 \cdot 4 = 84$ elements of order 5. Already $90 + 84 = 174 > 105$, impossible. So $n_7 = 1$ or $n_5 = 1$. **Step 3 (get a subgroup of order 35).** Either way, let $P_5 \in \mathrm{Syl}_5(G),\ P_7 \in \mathrm{Syl}_7(G)$; since one is normal, $H := P_5P_7$ is a subgroup of order $\frac{5 \cdot 7}{1} = 35$. A group of order $35 = 5 \cdot 7$ is cyclic ($n_5 \mid 7,\ \equiv 1 \pmod 5 \implies 1$; $n_7 \mid 5,\ \equiv 1 \pmod 7 \implies 1$), so $H \cong \mathbb{Z}_{35}$ and $[G : H] = 3$. **Step 4 (both normal).** As $[G : H] = 3$ is the smallest prime dividing $|G|$, $H \trianglelefteq G$ (a subgroup of index equal to the least prime is normal). Inside $H \cong \mathbb{Z}_{35}$ the Sylow 5- and Sylow 7-subgroups are unique, hence characteristic in H, hence normal in G. Therefore $P_5 \trianglelefteq G$ and $P_7 \trianglelefteq G$. *Check.* With $P_5, P_7 \trianglelefteq G$ we have $P_5 \times P_7 \cong \mathbb{Z}_{35} = H \trianglelefteq G$ and $G \cong \mathbb{Z}_{35} \rtimes \mathbb{Z}_3$. The action $\mathbb{Z}_3 \to \mathrm{Aut}(\mathbb{Z}_{35}) \cong \mathbb{Z}_4 \times \mathbb{Z}_6$ must land in an order-3 subgroup; $\mathbb{Z}_4$ has none but $\mathbb{Z}_6$ has one, so $\mathbb{Z}_3$ can act nontrivially only on the $\mathbb{Z}_7$ factor, giving exactly two groups of order 105: $\mathbb{Z}_{105}$ and $\mathbb{Z}_5 \times (\mathbb{Z}_7 \rtimes \mathbb{Z}_3)$. Here $n_3 = 1$ in $\mathbb{Z}_{105}$ and $n_3 = 7$ in $\mathbb{Z}_5 \times (\mathbb{Z}_7 \rtimes \mathbb{Z}_3)$, but $n_5 = n_7 = 1$ in both. Consistent.

Worked Example 6.2.4 (Every group of order pqr ($p < q < r$ primes) is not simple)**.** Let $|G| = pqr$ with $p < q < r$ distinct primes. Prove G is not simple; in fact G has a normal Sylow r-subgroup.

Recognition. The general version of the previous two examples. The largest prime r has the tightest congruence; a counting argument, plus one normal-subgroup step, forces $n_r = 1$.

Solution. **Step 1.** For the largest prime r: $n_r \mid pq$ and $n_r \equiv 1 \pmod r$. The divisors of pq are $1, p, q, pq$. Since $p, q < r$ we have $p \not\equiv 1$ and $q \not\equiv 1 \pmod r$, so the only admissible values are 1 and pq. Thus $n_r \in \{1, pq\}$. **Step 2 (assume all maximal).** Suppose, for contradiction, G is simple, so every $n_p, n_q, n_r > 1$. Then $n_r = pq$, and the Sylow r-subgroups (prime order r, disjoint by L2) contribute $pq(r-1)$ elements of order r. **Step 3 (bound the others).** For q: $n_q \mid pr$ with $n_q > 1$, so n_q is a divisor of pr exceeding 1, hence $n_q \geq r$ (the divisors of pr greater than 1 are p, r, pr, and $p < q < r$, so $n_q \neq p$). Thus Sylow q-subgroups give at least $r(q-1)$ elements of order q. For p: $n_p \mid qr$ with $n_p > 1$, so $n_p \geq q$ (the smallest divisor of qr exceeding 1 is q), giving at least $q(p-1)$ elements of order p. **Step 4 (overflow).** Counting distinct nonidentity elements together with the identity:

$$pq(r-1) + r(q-1) + q(p-1) + 1 \leq |G| = pqr.$$

But $pq(r-1) = pqr - pq$, so the left side equals $pqr - pq + rq - r + qp - q + 1 = pqr + rq - r - q + 1 = pqr + (r-1)(q-1)$. Since $(r-1)(q-1) > 0$ this exceeds pqr, a contradiction. **Step 5.** Hence not all of n_p, n_q, n_r can exceed 1, so G is not simple. This count alone does not give $n_r = 1$ (it also used $n_p, n_q > 1$), so suppose $n_r = pq$. The $pqr - pq$ elements of order r leave only $pq - 1$ other nonidentity elements, while $n_q > 1$ would give at least $r(q-1) \geq (q+1)(q-1) > pq - 1$ elements of order q (Step 3); so $n_q = 1$. Then for $P_q \in \mathrm{Syl}_q(G)$ (normal) and $P_r \in \mathrm{Syl}_r(G)$, $H := P_qP_r$ is a subgroup of order qr and index p, the smallest prime dividing $|G|$, so $H \trianglelefteq G$. In H, $n_r(H) \mid q$ and $n_r(H) \equiv 1 \pmod r$ force $n_r(H) = 1$, so P_r is characteristic in H, hence normal in G, contradicting $n_r = pq$. Therefore $n_r = 1$ and the Sylow r-subgroup is normal. *Check.* For $(p, q, r) = (2, 3, 5)$ this is the order-30 result ($n_5 = 1$); for $(3, 5, 7)$ it gives $n_7 = 1$ as in the order-105 example. Specializing recovers both. Consistent.

Worked examples: small-index cores and non-simplicity

Worked Example 6.2.5 (No simple group of order 24 via $G \hookrightarrow S_4$)**.** Let $|G| = 24 = 2^3 \cdot 3$. Show G is not simple.

Recognition. $n_2 \in \{1, 3\}$ is small, and $|G| = 24$ does NOT divide $n_2!$ when $n_2 = 3$ (since $3! = 6$). This is the textbook trigger for lever L3: the action on $\mathrm{Syl}_2(G)$ gives a homomorphism into S_3 with nontrivial kernel.

Solution. **Step 1 (n_2).** $|G| = 2^3 \cdot 3$, so $m = 3$ and $n_2 \mid 3$, $n_2 \equiv 1 \pmod 2$: $n_2 \in \{1, 3\}$. If $n_2 = 1$, the Sylow 2-subgroup is normal and G is not simple. So assume $n_2 = 3$. **Step 2 (act on Sylow 2's).** Let $P \in \mathrm{Syl}_2(G)$, $|P| = 8$, with $[G : N_G(P)] = n_2 = 3$, so $|N_G(P)| = 8$, i.e. $N_G(P) = P$. The conjugation action on the 3 Sylow 2-subgroups gives

$$\varphi \colon G \longrightarrow \mathrm{Sym}(\mathrm{Syl}_2(G)) \cong S_3, \qquad |S_3| = 6.$$

Step 3 (kernel is nontrivial). $|G| = 24 \nmid 6 = |S_3|$, so φ cannot be injective: $\ker\varphi \neq 1$. Also the action is transitive (Sylow), so $\mathrm{im}\,\varphi \neq 1$, giving $\ker\varphi \neq G$. Thus $1 \neq \ker\varphi \trianglelefteq G$ is proper: G is not simple. **Step 4 (sharper).** The image $\mathrm{im}\,\varphi \subseteq S_3$ is transitive of degree 3, so $|\,\mathrm{im}\,\varphi| \in \{3, 6\}$, whence $|\ker\varphi| = 24/|\,\mathrm{im}\,\varphi| \in \{8, 4\}$. In every case $\ker\varphi$ is a proper nontrivial normal subgroup. *Check.* Concretely $G = S_4$ itself has order 24, $n_2 = 3$, and $\varphi \colon S_4 \to S_3$ is the famous surjection with kernel $V_4 = \{e, (12)(34), (13)(24), (14)(23)\}$, $|V_4| = 4$. Indeed $V_4 \trianglelefteq S_4$, confirming the predicted $|\ker\varphi| = 4$. Not simple.

Worked Example 6.2.6 (No simple group of order 36)**.** Let $|G| = 36 = 2^2 \cdot 3^2$. Show G is not simple.

Recognition. $n_3 \in \{1, 4\}$ with $|G| = 36 \nmid 4! = 24$. Pure lever L3 on $\mathrm{Syl}_3(G)$.

Solution. **Step 1.** $36 = 2^2 \cdot 3^2$, $m = 4$ for $p = 3$: $n_3 \mid 4$, $n_3 \equiv 1 \pmod 3$, so $n_3 \in \{1, 4\}$. If $n_3 = 1$ done. Assume $n_3 = 4$. **Step 2.** Act on the 4 Sylow 3-subgroups: $\varphi \colon G \to S_4$, $|S_4| = 24$. **Step 3.** $|G| = 36 \nmid 24$, so $\ker\varphi \neq 1$; transitivity gives $\ker\varphi \neq G$. Hence $1 \neq \ker\varphi \trianglelefteq G$ proper. Not simple. *Check (order of kernel).* $|\,\mathrm{im}\,\varphi|$ divides $\gcd(36, 24) = 12$ and is transitive of degree 4, so $4 \mid |\,\mathrm{im}\,\varphi|$; thus $|\,\mathrm{im}\,\varphi| \in \{4, 12\}$ and $|\ker\varphi| = 36/|\,\mathrm{im}\,\varphi| \in \{9, 3\}$. Note we did NOT use L2 here (Sylow 3-subgroups have order 9, not prime, so they can overlap; counting would be unsafe). Consistent with the pitfall above.

Worked Example 6.2.7 (No simple group of order 48)**.** Let $|G| = 48 = 2^4 \cdot 3$. Show G is not simple.

Recognition. $n_2 \in \{1, 3\}$, and $48 \nmid 3! = 6$. Same core argument as order 24, now with $|P| = 16$.

Solution. **Step 1.** $m = 3$ for $p = 2$: $n_2 \in \{1, 3\}$. If $n_2 = 1$ done; assume $n_2 = 3$. **Step 2.** $\varphi \colon G \to \mathrm{Sym}(\mathrm{Syl}_2(G)) \cong S_3$, $|S_3| = 6$. **Step 3.** $48 \nmid 6 \implies \ker\varphi \neq 1$; transitive $\implies \ker\varphi \neq G$. Proper nontrivial normal subgroup exists; not simple. *Check.* $|\,\mathrm{im}\,\varphi| \in \{3, 6\}$, so $|\ker\varphi| \in \{16, 8\}$ — a normal subgroup of order 8 or 16 (contained in the Sylow 2-subgroup). Either way G has a large normal 2-subgroup. Consistent.

Worked Example 6.2.8 (No simple group of order 56 (two ways))**.** Let $|G| = 56 = 2^3 \cdot 7$. Show G is not simple.

Recognition. Two levers available: $n_7 \in \{1, 8\}$ invites a *counting* argument (L2, since $|P_7| = 7$ is prime), while $n_2 \in \{1, 7\}$ is messier. Counting is cleanest.

Solution. **Step 1.** $n_7 \mid 8$, $n_7 \equiv 1 \pmod 7$: $n_7 \in \{1, 8\}$. If $n_7 = 1$, done. **Step 2 (counting, L2).** Suppose $n_7 = 8$. The 8 Sylow 7-subgroups have prime order 7, intersect trivially, and contribute $8 \cdot (7 - 1) = 48$ elements of order 7. **Step 3.** That leaves $56 - 48 = 8$ elements of order not equal to 7 — exactly enough for a *single* Sylow 2-subgroup of order 8 (with none to spare). So $n_2 = 1$: the Sylow 2-subgroup is normal. **Step 4.** Either $n_7 = 1$ ($P_7 \trianglelefteq G$) or $n_2 = 1$ ($P_2 \trianglelefteq G$); in both cases G has a normal Sylow subgroup. Not simple. *Check.* The bookkeeping is exact: 48 elements of order 7 plus the 8 elements of one Sylow 2-subgroup account for all 56 elements, with no room for a second Sylow 2-subgroup. This is the classic tight count. Consistent.

The unique simple group of order 60

The smallest non-abelian simple group is A_5, of order $60 = 2^2 \cdot 3 \cdot 5$. D&F prove (Section 4.5, Proposition 23) that there is essentially no other.

Theorem 6.2.9 (Uniqueness of the simple group of order 60)**.** *If G is a simple group of order 60, then $G \cong A_5$.*

We first extract the numerical skeleton forced by simplicity, then sketch the isomorphism.

Lemma 6.2.10 (A simple group of order 60 has $n_5 = 6$ and $n_2 \in \{5, 15\}$, and embeds in A_5)**.** *Let G be simple of order $60 = 2^2 \cdot 3 \cdot 5$. Then:*

(a) *$n_5 = 6$, $n_3 = 10$, $n_2 \in \{5, 15\}$.*

(b) *G has a subgroup of index 5, hence $G \hookrightarrow A_5$, hence $G \cong A_5$.*

Proof. **(a) Forcing the n_p.**

- $n_5 \mid 12$, $n_5 \equiv 1 \pmod 5$: candidates $1, 6$. Simplicity forbids $n_5 = 1$ (that would make $P_5 \trianglelefteq G$), so $n_5 = 6$.
- $n_3 \mid 20$, $n_3 \equiv 1 \pmod 3$: candidates $1, 4, 10$. If $n_3 = 4$, the action $G \to S_4$ on $\mathrm{Syl}_3(G)$ has $|S_4| = 24 < 60$, so a nontrivial proper normal kernel appears, contradicting simplicity. So $n_3 = 10$ (and $n_3 \neq 1$ by simplicity).
- $n_2 \mid 15$, $n_2 \equiv 1 \pmod 2$: candidates $1, 3, 5, 15$. Simplicity kills $n_2 = 1$. If $n_2 = 3$, then $G \to S_3$ ($|S_3| = 6 < 60$) has nontrivial proper kernel — contradiction. So $n_2 \in \{5, 15\}$.

(b) A subgroup of index 5. We claim G has a subgroup H with $[G : H] = 5$. Then the left-multiplication action of G on the 5 cosets G/H gives $\rho\colon G \to S_5$ whose kernel is the core of H. Since G is simple and ρ is nontrivial (transitive on $5 \geq 2$ points), $\ker \rho = 1$, so $G \hookrightarrow S_5$. Then $G \cap A_5 \trianglelefteq G$ is either 1 or G; if it were 1 then $G \cong G/(G \cap A_5) \hookrightarrow S_5/A_5 \cong \mathbb{Z}_2$, impossible for $|G| = 60 > 2$, so $G \subseteq A_5$. As $|G| = 60 = |A_5|$, $G = A_5$.

It remains to produce the index-5 subgroup. *Case $n_2 = 5$.* Then $[G : N_G(P_2)] = n_2 = 5$, so $H := N_G(P_2)$ has index 5. Done. *Case $n_2 = 15$.* We show two Sylow 2-subgroups meet nontrivially. If all 15 Sylow 2-subgroups (order 4) were pairwise trivially intersecting, they would contribute $15 \cdot (4 - 1) = 45$ elements of 2-power order > 1; together with $n_5(5-1) = 6 \cdot 4 = 24$ elements of order 5 that already gives $45 + 24 = 69 > 60$, impossible. So pick $P_2 \neq Q_2$ with $|P_2 \cap Q_2| = 2$; set $D := P_2 \cap Q_2$, $|D| = 2$, and let $M := N_G(D)$. Both P_2, Q_2 are 2-groups normalizing their order-2 subgroup D (a subgroup of index 2 in a group of order 4 is normal), so $P_2, Q_2 \subseteq M$, giving $|M| > 4$ and $4 \mid |M|$, so $|M| \in \{12, 20, 60\}$. Simplicity rules out $|M| = 60$ (else $D \trianglelefteq G$). If $|M| = 20$ then $[G : M] = 3$ and $G \to S_3$ has nontrivial kernel — contradiction. Hence $|M| = 12$, so $[G : M] = 5$: take $H := M$, index 5. Done.

In either case G has a subgroup of index 5, so by the first paragraph $G \cong A_5$. □

Proof sketch of the Theorem. By the Lemma, any simple G of order 60 has a subgroup of index 5 and therefore embeds in A_5; comparing orders forces $G = A_5$. Conversely A_5 is simple: a proper nontrivial normal subgroup would be a union of conjugacy classes including $\{1\}$, with order a divisor of 60, but the class sizes $1, 15, 20, 12, 12$ admit no sub-collection containing 1 whose sum is a proper nontrivial divisor of 60. Hence A_5 is, up to isomorphism, the unique simple group of order 60. □

The whole argument is the action-on-cosets / action-on-Sylows machine pushed to its limit:

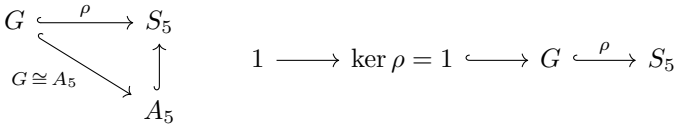


Diagram explanation. Objects: Left triangle: G (a simple group of order 60), S_5 (the symmetric group on 5 letters, order 120), and A_5 (the alternating group, order 60, index 2 in S_5). Right sequence: the trivial group 1, the kernel $\ker \rho = 1$ (which collapses to the trivial group by simplicity), G itself, and S_5.

Arrows: In the triangle: (i) $\rho\colon G \to S_5$ is the left-multiplication action of G on the cosets of an index-5 subgroup $H \leq G$, a group homomorphism. (ii) The diagonal arrow $G \hookrightarrow A_5$ is the conclusion that G lands entirely inside the subgroup A_5 (argued below) and has the same order, forcing equality. (iii) $A_5 \hookrightarrow S_5$ is the canonical subgroup inclusion, an injective homomorphism. In the exact sequence: the map $1 \to \ker \rho = 1$ is trivial, $\ker \rho \hookrightarrow G$ is inclusion of the trivial subgroup, and $G \overset{\rho}{\hookrightarrow} S_5$ is the injective homomorphism.

What commutes: In the triangle, both paths from G to S_5 agree: the direct arrow ρ equals the composite $A_5 \hookrightarrow S_5$ followed by viewing $G = A_5$, i.e. $\iota \circ (G \cong A_5) = \rho$ where ι is the inclusion $A_5 \hookrightarrow S_5$. In the exact sequence, exactness at $\ker \rho = 1$ is vacuous, and exactness at G states $\mathrm{im}(1 \to G) = \ker \rho = 1$, confirmed.

Why it commutes: Injectivity of ρ: the kernel of ρ is the core of H in G, which is a normal subgroup of G; since G is simple and ρ is nontrivial (H has index $5 \geq 2$), $\ker \rho = 1$. Hence $G \hookrightarrow S_5$. Now $G \cap A_5 \trianglelefteq G$ (it is a normal subgroup of G, being the preimage of A_5 under ρ); simplicity forces $G \cap A_5 = 1$ or G. If $G \cap A_5 = 1$ then $G \cong G/(G \cap A_5) \hookrightarrow S_5/A_5 \cong \mathbb{Z}_2$, impossible since $|G| = 60 > 2$. So $G \subseteq A_5$, and $|G| = 60 = |A_5|$ gives $G = A_5$.

Why this matters here: This double diagram is the punchline of the entire section. After enormous effort to produce an index-5 subgroup, the actual conclusion that $G \cong A_5$ is delivered in a short logical chain that the diagrams make transparent: injectivity of ρ, landing in A_5 by order, and then order-equality. Every step of the argument corresponds to one arrow.

Concrete example: Take $G = A_5$ itself. The index-5 subgroup is $H = \mathrm{Stab}_{A_5}(5) \cong A_4$ (order 12). Then $\rho\colon A_5 \to S_5$ is the natural embedding of A_5 acting on $\{1, 2, 3, 4, 5\}$, and $\ker \rho = 1$, $\mathrm{im}\, \rho = A_5$. The triangle becomes: $A_5 \xrightarrow{\mathrm{id}} A_5 \hookrightarrow S_5$, a tautology that closes the argument.

Common pitfall: Students sometimes think $G \hookrightarrow S_5$ immediately gives $G \leq A_5$ because $|G| = 60$ is even. This is wrong: $|G|$ being even does not force $G \leq A_5$; what forces it is that G is simple and cannot surject onto $S_5/A_5 \cong \mathbb{Z}_2$ (it would give a nontrivial normal subgroup, the kernel of the surjection). The order argument only applies *after* you know $G \leq A_5$.

Takeaway: The point of this diagram is that simplicity of G forces the coset-action map ρ to be injective and then forces the image to lie inside A_5, so G and A_5 are the same subgroup of S_5, completing the proof that every simple group of order 60 is isomorphic to A_5.

Worked Example 6.2.11 (A group of order 60 with $n_5 > 1$ that is simple is $\cong A_5$)**.** Suppose $|G| = 60$, $n_5(G) > 1$ (equivalently $n_5 = 6$, no normal Sylow 5-subgroup), and G is simple. Identify G.

Recognition. When $n_5 > 1$ and we further assume simplicity, the Lemma applies verbatim: G embeds into A_5 by an index-5 subgroup. This is the capstone example combining ALL three levers.

Solution. **Step 1.** Since $n_5 \in \{1, 6\}$ and $n_5 > 1$, $n_5 = 6$. Simplicity gives (Lemma (a)) $n_3 = 10$, $n_2 \in \{5, 15\}$. **Step 2 (index-5 subgroup).** By Lemma (b): if $n_2 = 5$ take $H = N_G(P_2)$ of index 5; if $n_2 = 15$, two Sylow 2-subgroups overlap in D with $|D| = 2$ and $M = N_G(D)$ has order 12, index 5. **Step 3 (embed).** The coset action $\rho\colon G \to S_5$ on G/H has trivial kernel (simplicity), so $G \hookrightarrow S_5$; since $[S_5 : A_5] = 2$ and G is simple of order > 2, $G \subseteq A_5$, and $|G| = |A_5| = 60 \implies G = A_5$. *Check (consistency of the numerics with A_5).* In A_5: $n_5 = 6$ (six Sylow 5-subgroups, e.g. generated by 5-cycles), $n_3 = 10$, $n_2 = 5$ (the five copies of V_4, normalized by the five point-stabilizers A_4 of index 5). Indeed $N_{A_5}(P_2) \cong A_4$ has order 12 and index 5 — exactly the index-5 subgroup the proof predicts. The element count $1 + 24 + 20 + 15 = 60$ (identity + order-5 + order-3 + order-2) closes perfectly. So $G \cong A_5$.

Worked Example 6.2.12 (Order 60 NOT simple: G with $n_5 = 1$)**.** Let $|G| = 60$ with $n_5 = 1$. Show G is not simple, illustrating that the simplicity hypothesis in the Theorem is essential.

Recognition. The complementary case to the Lemma: if $n_5 = 1$ outright, lever L1 hands us a normal subgroup immediately.

Solution. **Step 1.** $n_5 = 1 \implies P_5 \trianglelefteq G$ with $|P_5| = 5$ (lever L1). So G has a proper nontrivial normal subgroup and is not simple. **Step 2 (such groups exist).** Example: $G = \mathbb{Z}_5 \times A_4$ has order $5 \cdot 12 = 60$ with the $\mathbb{Z}_5$ factor a normal (central) Sylow 5-subgroup, $n_5 = 1$. Another: $G = \mathbb{Z}_{60}$, $n_5 = 1$. Neither is simple, neither is A_5. *Check.* A_5 has $n_5 = 6 \neq 1$, so these non-simple order-60 groups are correctly excluded from the Theorem's conclusion. The Theorem says: *among* order-60 groups, only the simple one is A_5; non-simple ones (there are 13 groups of order 60 total, only one simple) are governed by L1/L2/L3 producing normal Sylow subgroups. Consistent.

Remark 6.2.1 (Why 60 is the threshold)*.* For every $n < 60$ that is not a prime power, the recipe above forces a normal Sylow subgroup or a small-index core, so *no* non-abelian simple group exists below order 60. Orders like $24, 36, 48, 56$ fall to lever L3 or L2 as shown; $30, 105$, and all pqr fall to L1/L2. The order 60 is the first where the levers are exactly balanced ($n_5 = 6$, $n_2 \in \{5, 15\}$, $n_3 = 10$ all > 1, yet an index-5 subgroup survives), permitting — and pinning down uniquely — the simple group A_5.

Caution. In the $n_2 = 15$ case of the Lemma it is tempting to count Sylow 2-subgroups as if disjoint and conclude immediately. They are *not* guaranteed disjoint ($|P_2| = 4$ is not prime), and indeed the proof exploits a forced overlap $|P_2 \cap Q_2| = 2$. The clean "$n_p(p-1)$" count is only valid for the prime-order Sylow 5-subgroups here; for the order-4 Sylow 2-subgroups you must argue via the normalizer $N_G(P_2 \cap Q_2)$.

Exercises (from the text).

1. Prove that for fixed $P \in \mathrm{Syl}_p(G)$ if $P \cap R = 1$ for all $R \in \mathrm{Syl}_p(G) - \{P\}$, then $P_1 \cap P_2 = 1$ whenever P_1 and P_2 are distinct Sylow p-subgroups of G. Deduce in this case that the number of nonidentity elements of p-power order in G is $(|P| - 1)[G : N_G(P)]$.
2. In the group $S_3 \times S_3$ exhibit a pair of Sylow 2-subgroups that intersect in the identity and exhibit another pair that intersect in a group of order 2.
3. Prove that if $|G| = 380$ then G is not simple. [Just count elements of odd prime order.]
4. Prove that there are no simple groups of order 80, 351, 3875 or 5313.
5. Let G be a solvable group of order pm, where p is a prime not dividing m, and let $P \in \mathrm{Syl}_p(G)$. If $N_G(P) = P$, prove that G has a normal subgroup of order m. Where was the solvability of G needed in the proof? (This result is true for nonsolvable groups as well — it is a special case of *Burnside's N/C-Theorem.*)
6. Prove that there are no simple groups of order 2205, 4125, 5103, 6545 or 6435.
7. Prove that there are no simple groups of order 1755 or 5265. [Use Sylow 3-subgroups to show $G \leq S_{13}$ and look at the normalizer of a Sylow 13-subgroup.]
8. Prove that there are no simple groups of order 792 or 918.
9. Prove that there are no simple groups of order 336.
10. Prove that there are no simple groups of order 4095, 4389, 5313 or 6669.
11. Prove that there are no simple groups of order 4851 or 5145.
12. Prove that there are no simple groups of order 9555. [Let $Q \in \mathrm{Syl}_{13}(G)$ and let $P \in \mathrm{Syl}_7(N_G(Q))$. Argue that $Q \trianglelefteq N_G(P)$ — why is this a contradiction?]
13. Let G be a group with more than one Sylow p-subgroup. Over all pairs of distinct Sylow p-subgroups let P and Q be chosen so that $|P \cap Q|$ is maximal. Show that $N_G(P \cap Q)$ has more than one Sylow p-subgroup and that any two distinct Sylow p-subgroups of $N_G(P \cap Q)$ intersect in the subgroup $P \cap Q$. (Thus $|N_G(P \cap Q)|$ is divisible by $p \cdot |P \cap Q|$ and by some prime other than p. Note that Sylow p-subgroups of $N_G(P \cap Q)$ need not be Sylow in G.)
14. Prove that there are no simple groups of order 144, 525, 2025 or 3159.
15. Classify groups of order 105.
16. Prove that there are no non-abelian simple groups of odd order < 10000.
17. (a) Prove that there is no simple group of order 420. (b) Prove that there are no simple groups of even order < 500 except for orders 2, 60, 168 and 360.
18. Prove that if G is a group of order 36 then G has either a normal Sylow 2-subgroup or a normal Sylow 3-subgroup.
19. Show that a group of order 12 with no subgroup of order 6 is isomorphic to A_4.
20. Show that a group of order 24 with no element of order 6 is isomorphic to S_4.
21. Generalize Lemma 13 by proving that if $n_p \not\equiv 1 \pmod{p^k}$ then there are distinct Sylow p-subgroups P and R of G such that $P \cap R$ is of index $\leq p^{k-1}$ in both P and R.
22. Suppose over all pairs of distinct Sylow p-subgroups of G, P and R are chosen with $|P \cap R|$ maximal. Prove that $N_G(P \cap R)$ is not a p-group.

23. Let A and B be normal subsets of a Sylow p-subgroup P of G. Prove that if A and B are conjugate in G then they are conjugate in $N_G(P)$.

24. Let G be a group of order pqr where p, q and r are primes with $p < q < r$. Prove that a Sylow r-subgroup of G is normal.

25. Let G be a simple group of order p^2qr where p, q and r are primes. Prove that $|G| = 60$.

26. Prove or construct a counterexample to the assertion: if G is a group of order 168 with more than one Sylow 7-subgroup then G is simple.

27. Show that if $\mathcal{F}$ is any set of points and lines satisfying properties (11) to (13) in the subsection on simple groups of order 168 then the graph of incidences for $\mathcal{F}$ is uniquely determined and is the same as Figure 1 (up to relabeling points and lines). [Take a line and any point not on this line. Depict the line as the base of an equilateral triangle and the point as the vertex of this triangle not on the base. Use the axioms to show that the incidences of the remaining points and lines are then uniquely determined as in Figure 1.]

28. Let G be a simple group of order $3^3 \cdot 7 \cdot 13 \cdot 409$. Compute all permissible values of n_p for each $p \in \{3, 7, 13, 409\}$ and reduce to the case where there is a unique possible value for each n_p.

29. Given the information on the Sylow numbers for a hypothetical simple group of order $3^3 \cdot 7 \cdot 13 \cdot 409$, prove that there is no such group. [Work with the permutation representation of degree 819.]

30. Suppose G is a simple group of order 720. Find as many properties of G as you can (Sylow numbers, isomorphism type of Sylow subgroups, conjugacy classes, etc.). Is there such a group?

Practice problems.

1. **(Order $84 = 2^2 \cdot 3 \cdot 7$.)** Let $|G| = 84$. Using only the congruence and divisibility constraints on n_7, show G has a normal Sylow 7-subgroup and hence is not simple.
Answer key. Here $84 = 2^2 \cdot 3 \cdot 7$, so for $p = 7$ we have $m = 12$ and $n_7 \mid 12$, $n_7 \equiv 1 \pmod 7$. The divisors of 12 are $1, 2, 3, 4, 6, 12$; the only one congruent to $1 \pmod 7$ is 1 (since $2, 3, 4, 6, 12$ reduce to $2, 3, 4, 6, 5 \pmod 7$). Hence $n_7 = 1$, so the Sylow 7-subgroup P_7 is unique and therefore normal (lever L1). As $1 < |P_7| = 7 < 84$, P_7 is a proper nontrivial normal subgroup and G is not simple.

2. **(Order $280 = 2^3 \cdot 5 \cdot 7$ by counting.)** Let $|G| = 280$. Using lever L2 on the prime-order Sylow 5- and Sylow 7-subgroups, show some Sylow subgroup is normal, so G is not simple.
Answer key. For $p = 7$: $n_7 \mid 40$, $n_7 \equiv 1 \pmod 7$, so $n_7 \in \{1, 8\}$ (divisors of 40 that are $\equiv 1 \pmod 7$: 1 and 8). For $p = 5$: $n_5 \mid 56$, $n_5 \equiv 1 \pmod 5$, so $n_5 \in \{1, 56\}$ (the divisors $1, 2, 4, 7, 8, 14, 28, 56$ of 56, those $\equiv 1 \pmod 5$ are 1 and 56). Suppose for contradiction both exceed 1, so $n_7 = 8$ and $n_5 = 56$. Sylow 7's have prime order 7, hence meet trivially and give $8 \cdot (7 - 1) = 48$ elements of order 7; Sylow 5's have prime order 5 and give $56 \cdot (5 - 1) = 224$ elements of order 5. Thus $48 + 224 = 272$ distinct nonidentity elements have order 5 or 7. Together with the identity this leaves exactly $280 - 272 - 1 = 7$ further nonidentity elements; but a single Sylow 2-subgroup already needs $|P_2| - 1 = 7$ nonidentity elements, so those 7 elements (plus the identity) form the *unique* Sylow 2-subgroup of order 8, forcing $n_2 = 1$. Thus at least one of n_5, n_7, n_2 equals 1; a normal Sylow subgroup exists and G is not simple.

3. **(Order 24: the kernel-order computation.)** Let $|G| = 24$ with $n_2 = 3$ (no normal Sylow 2-subgroup). Let $\varphi\colon G \to \mathrm{Sym}(\mathrm{Syl}_2(G)) \cong S_3$ be the conjugation action. Determine the exact possible values of $|\operatorname{im}\varphi|$ and $|\ker\varphi|$, and identify the structural normal subgroup this produces.
Answer key. The action is transitive on the 3 Sylow 2-subgroups, so $\operatorname{im}\varphi \le S_3$ is a transitive subgroup of degree 3; the transitive subgroups of S_3 have order 3 or 6, so $|\operatorname{im}\varphi| \in \{3, 6\}$. By the first isomorphism theorem $|\ker\varphi| = 24/|\operatorname{im}\varphi| \in \{8, 4\}$. The value 8 cannot occur: $N_G(P_2)$ has index $n_2 = 3$, hence order 8, so $N_G(P_2) = P_2$; since $\ker\varphi \le N_G(P_2)$, $|\ker\varphi| = 8$ would give $\ker\varphi = P_2 \trianglelefteq G$, contradicting $n_2 = 3$. Hence exactly $|\operatorname{im}\varphi| = 6$ (so φ is onto S_3) and $|\ker\varphi| = 4$. Since φ is nontrivial, $\ker\varphi \neq G$; since $24 \nmid 6 = |S_3|$, $\ker\varphi \neq 1$. Thus $\ker\varphi$ is a proper nontrivial normal subgroup of order 4 — a normal 2-subgroup contained in $N_G(P_2)$ (it is the normal core $\bigcap_g gN_G(P_2)g^{-1}$). In particular G is not simple. (For $G = S_4$ one has $|\operatorname{im}\varphi| = 6$, $\ker\varphi = V_4$ of order 4.)

4. **(Classify order 20.)** Let $|G| = 20 = 2^2 \cdot 5$. Show the Sylow 5-subgroup is normal, and classify G up to isomorphism via the homomorphisms $\mathbb{Z}/4\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/5\mathbb{Z}) \cong \mathbb{Z}/4\mathbb{Z}$.
Answer key. For $p = 5$: $n_5 \mid 4$, $n_5 \equiv 1 \pmod 5$, so $n_5 = 1$ and $P_5 \cong \mathbb{Z}/5\mathbb{Z} \trianglelefteq G$ (L1). A Sylow 2-subgroup Q (order 4) meets P_5 trivially, and since $\gcd(4, 5) = 1$ Schur–Zassenhaus gives $G \cong P_5 \rtimes Q$, determined by a homomorphism $\theta\colon Q \to \mathrm{Aut}(\mathbb{Z}/5\mathbb{Z}) \cong \mathbb{Z}/4\mathbb{Z}$. The image must be a cyclic subgroup of $\mathbb{Z}/4\mathbb{Z}$, so $|\operatorname{im}\theta| \in \{1, 2, 4\}$, and $Q \in \{\mathbb{Z}/4\mathbb{Z},\ V_4\}$.

   - $Q \cong \mathbb{Z}/4\mathbb{Z}$, θ trivial: $G \cong \mathbb{Z}/20\mathbb{Z}$.
   - $Q \cong \mathbb{Z}/4\mathbb{Z}$, $|\operatorname{im}\theta| = 2$ (the generator inverts): with b a generator of Q, b^2 acts trivially and commutes with P_5, so b^2 is the *only* involution; hence $G \cong \mathrm{Dic}_5 = Q_{20}$, the dicyclic group of order 20 (*not* D_{20}, which has many involutions).
   - $Q \cong \mathbb{Z}/4\mathbb{Z}$, $|\operatorname{im}\theta| = 4$ (faithful): $G \cong \mathbb{Z}/5\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z}$, the Frobenius group F_{20} of order 20 (the generator of $\mathbb{Z}/4\mathbb{Z}$ acts on $\mathbb{Z}/5\mathbb{Z}$ by an automorphism of order 4, e.g. $x \mapsto 2x$, which fixes only 0).
   - $Q \cong V_4$, θ trivial: $G \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z}$.
   - $Q \cong V_4$, $|\operatorname{im}\theta| = 2$ (one $\mathbb{Z}/2\mathbb{Z}$ inverts, the other acts trivially): $G \cong D_{10} \times \mathbb{Z}/2\mathbb{Z}$, and since $D_{4k} \cong D_{2k} \times \mathbb{Z}/2\mathbb{Z}$ for k odd (here $k = 5$) this is exactly D_{20}, the dihedral group of order 20.

   Thus there are exactly five groups of order 20:

$$\mathbb{Z}/20\mathbb{Z}, \quad \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/10\mathbb{Z}, \quad D_{20}\ (\cong D_{10} \times \mathbb{Z}/2\mathbb{Z}), \quad F_{20} = \mathbb{Z}/5\mathbb{Z} \rtimes \mathbb{Z}/4\mathbb{Z}, \quad \mathrm{Dic}_5 = Q_{20}.$$

   The two cases with an order-2 action split into D_{20} (complement V_4) versus Dic_5 (complement $\mathbb{Z}/4\mathbb{Z}$): the order-2 *inversion* action of a cyclic $\mathbb{Z}/4\mathbb{Z}$ produces the dicyclic group (a single involution), while the dihedral D_{20} comes from the V_4 complement.

5. **Every group of order p^2q is non-simple.)** Let p, q be distinct primes and $|G| = p^2q$. Prove G has a normal Sylow subgroup, hence is not simple.
Answer key. If $n_q = 1$ we are done. Otherwise $n_q > 1$ with $n_q \mid p^2$ and $n_q \equiv 1 \pmod q$, so $n_q \in \{p, p^2\}$. *Case* $p > q$. Consider n_p: $n_p \mid q$ and $n_p \equiv 1 \pmod p$, so $n_p \in \{1, q\}$; since $q < p$, $q \not\equiv 1 \pmod p$, forcing $n_p = 1$ and $P \trianglelefteq G$ with $|P| = p^2$. *Case* $p < q$. Then $n_q \equiv 1 \pmod q$ with $n_q \in \{p, p^2\}$; as $p < q$ we have $p \not\equiv 1 \pmod q$, so $n_q = p^2$. The p^2 Sylow q-subgroups (prime order q) are disjoint, giving $p^2(q-1) = p^2q - p^2$ elements of order q. That leaves only p^2 elements of non-q-order, exactly enough for a single Sylow p-subgroup of order p^2; hence $n_p = 1$ and $P \trianglelefteq G$. In every case a Sylow subgroup is normal and proper ($1 < p^2 < p^2q$ or $1 < q < p^2q$), so G is not simple.

6. **($n_p = 1 \implies$ normal, but not conversely nilpotent).** Let $|G| = p^a m$ with $\gcd(p, m) = 1$ and $P \in \mathrm{Syl}_p(G)$. Prove that $n_p = 1 \implies P \trianglelefteq G$, and that this makes G non-simple whenever $P \neq G$. Then show by example that a normal Sylow subgroup at one prime does not force G to be nilpotent.
Answer key. Conjugation permutes $\mathrm{Syl}_p(G)$ transitively (Sylow's theorem); if $n_p = 1$ the single Sylow subgroup is fixed by every conjugation, i.e. $gPg^{-1} = P$ for all $g \in G$, which is exactly $P \trianglelefteq G$. (In fact P is then characteristic, being the unique subgroup of its order.) If $1 < |P| = p^a < |G|$, i.e. $P \neq G$ and $p \mid |G|$ properly, then P is a proper nontrivial normal subgroup, so G is not simple. For the converse: in S_3 ($|S_3| = 6$) the Sylow 3-subgroup $\langle(123)\rangle$ has $n_3 = 1$ and is normal, yet $n_2 = 3$ (three Sylow 2-subgroups), so S_3 is not the direct product of its Sylow subgroups and hence not nilpotent. A normal Sylow at one prime alone does not suffice for nilpotency.

7. **(Order $72 = 2^3 \cdot 3^2$ is non-simple.)** Let $|G| = 72$. By examining $n_3 \in \{1, 4\}$ and the action on $\mathrm{Syl}_3(G)$, show G is not simple.
Answer key. For $p = 3$: $m = 8$, $n_3 \mid 8$, $n_3 \equiv 1 \pmod 3$, so $n_3 \in \{1, 4\}$ (the divisors $1, 2, 4, 8$ of 8, those $\equiv 1 \pmod 3$ are 1 and 4). If $n_3 = 1$, the Sylow 3-subgroup is normal and G is not simple. If $n_3 = 4$, the conjugation action gives $\varphi\colon G \to \mathrm{Sym}(\mathrm{Syl}_3(G)) \cong S_4$ (lever L3). Since $|G| = 72 \nmid 24 = |S_4|$, φ cannot be injective, so $\ker\varphi \neq 1$; transitivity of the action gives $\operatorname{im}\varphi \neq 1$, hence $\ker\varphi \neq G$. Thus $1 \neq \ker\varphi \trianglelefteq G$ is a proper nontrivial normal subgroup (the normal core of $N_G(P_3)$), and G is not simple. In every case G has a proper nontrivial normal subgroup.

8. **(Classify order 21.)** Let $|G| = 21 = 3 \cdot 7$. Show the Sylow 7-subgroup is normal and classify G up to isomorphism.
Answer key. For $p = 7$: $n_7 \mid 3$, $n_7 \equiv 1 \pmod 7$, so $n_7 = 1$ and $P_7 \cong \mathbb{Z}/7\mathbb{Z} \trianglelefteq G$ (L1). For $p = 3$: $n_3 \mid 7$, $n_3 \equiv 1 \pmod 3$, so $n_3 \in \{1, 7\}$. A Sylow 3-subgroup $\langle t \rangle \cong \mathbb{Z}/3\mathbb{Z}$ complements P_7 (Schur–Zassenhaus, $\gcd(3, 7) = 1$), so $G \cong \mathbb{Z}/7\mathbb{Z} \rtimes \mathbb{Z}/3\mathbb{Z}$, classified by $\theta\colon \mathbb{Z}/3\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$. The image is a subgroup of $\mathbb{Z}/6\mathbb{Z}$ of order dividing 3, so $|\operatorname{im}\theta| \in \{1, 3\}$.

   - θ trivial: $G \cong \mathbb{Z}/21\mathbb{Z}$ (abelian, $n_3 = 1$).
   - $|\operatorname{im}\theta| = 3$: the two nontrivial homomorphisms $\mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ differ by an automorphism of $\mathbb{Z}/3\mathbb{Z}$, so they give isomorphic groups, namely the unique nonabelian group $\mathbb{Z}/7\mathbb{Z} \rtimes \mathbb{Z}/3\mathbb{Z}$ of order 21 (here $n_3 = 7$).

   Thus there are exactly two groups of order 21: the cyclic $\mathbb{Z}/21\mathbb{Z}$ and the nonabelian $\mathbb{Z}/7\mathbb{Z} \rtimes \mathbb{Z}/3\mathbb{Z}$ (the smallest nonabelian group of odd order).

9. **(Classify order 18.)** Let $|G| = 18 = 2 \cdot 3^2$. Show the Sylow 3-subgroup is normal and classify G up to isomorphism.
Answer key. For $p = 3$: $m = 2$, $n_3 \mid 2$, $n_3 \equiv 1 \pmod 3$, so $n_3 = 1$ and the Sylow 3-subgroup P (order 9) is normal (L1). A Sylow 2-subgroup $\langle t \rangle \cong \mathbb{Z}/2\mathbb{Z}$ complements P (Schur–Zassenhaus, $\gcd(2, 9) = 1$), so $G \cong P \rtimes \mathbb{Z}/2\mathbb{Z}$ with $P \in \{\mathbb{Z}/9\mathbb{Z},\ \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}\}$ and $\theta\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(P)$.

   - $P \cong \mathbb{Z}/9\mathbb{Z}$: $\mathrm{Aut}(\mathbb{Z}/9\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$ has a unique involution (inversion), so θ is trivial or inversion, giving $\mathbb{Z}/18\mathbb{Z}$ and D_{18} (dihedral of order 18).
   - $P \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$: $\mathrm{Aut}(P) \cong \mathrm{GL}_2(\mathbb{F}_3)$. Up to conjugacy an involution is either $-I$ (inverting both factors), giving the generalized dihedral group $(\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}) \rtimes \mathbb{Z}/2\mathbb{Z}$, or $\mathrm{diag}(1, -1)$ (inverting one factor), giving $\mathbb{Z}/3\mathbb{Z} \times S_3$; the trivial action gives the abelian $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$.

   Thus there are exactly five groups of order 18:

$$\mathbb{Z}/18\mathbb{Z}, \quad \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}, \quad D_{18}, \quad \mathbb{Z}/3\mathbb{Z} \times S_3, \quad (\mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}) \rtimes \mathbb{Z}/2\mathbb{Z},$$

   the first two abelian and the last three nonabelian. In particular every group of order 18 is non-simple, since $P \trianglelefteq G$ is proper of order 9.

10. **(Order pqr: bound the elements to force $n_r = 1$.)** Let $|G| = pqr$ with $p < q < r$ primes. Prove the Sylow r-subgroup is normal by first finding the admissible values of n_r and then ruling out $n_r = pq$ by counting (plus one normal-subgroup step).
Answer key. For the largest prime r: $n_r \mid pq$ and $n_r \equiv 1 \pmod r$. The divisors of pq are $1, p, q, pq$; since $p, q < r$ we have $p, q \not\equiv 1 \pmod r$, leaving $n_r \in \{1, pq\}$. Suppose $n_r = pq$. The Sylow r-subgroups have prime order r, intersect trivially, and contribute $pq(r - 1) = pqr - pq$ elements of order r, leaving only $pq - 1$ other nonidentity elements. If $n_q > 1$, then $n_q \geq r$ (as $n_q \mid pr$ and $p \not\equiv 1 \pmod q$), contributing at least $r(q - 1) \geq (q + 1)(q - 1) > pq - 1$ elements of order q, which is impossible; hence $n_q = 1$. So $P_q \trianglelefteq G$, and $H := P_q P_r$ is a subgroup of order qr and index p, the smallest prime dividing $|G|$; hence $H \trianglelefteq G$. In H, $n_r(H) \mid q$ and $n_r(H) \equiv 1 \pmod r$ force $n_r(H) = 1$, so P_r is characteristic in H and therefore normal in G, contradicting $n_r = pq$. Hence $n_r = 1$ and the Sylow r-subgroup is normal; G is not simple.

Additional exercises.

1. **(Classify order 30.)** Let $|G| = 30 = 2 \cdot 3 \cdot 5$. Exhibit the normal cyclic subgroup of order 15 and classify G into its four isomorphism types.
Answer key. By the body's analysis $n_3 = 1$ and $n_5 = 1$, so $P_3 \trianglelefteq G$ and $P_5 \trianglelefteq G$; then $N := P_3 P_5 \cong \mathbb{Z}/15\mathbb{Z}$ is normal of index 2 (it is the unique subgroup of order 15, automatically cyclic). A Sylow 2-subgroup $\langle t \rangle \cong \mathbb{Z}/2\mathbb{Z}$ complements N, so $G \cong \mathbb{Z}/15\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$, classified by $\theta\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/15\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$. The image lies in the 2-torsion $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ (since $t^2 = 1$), and $\mathrm{Aut}(\mathbb{Z}/15\mathbb{Z}) \cong \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \times \mathrm{Aut}(\mathbb{Z}/5\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$ has exactly four elements of order dividing 2: $(\pm 1, \pm 1)$ on $(\mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/5\mathbb{Z})$. The four resulting groups are

$$\begin{array}{ll} \mathbb{Z}/30\mathbb{Z} \text{ (trivial)}, & D_{30} \text{ (invert both)}, \\ \mathbb{Z}/3\mathbb{Z} \times D_{10} \text{ (invert } \mathbb{Z}/5\mathbb{Z} \text{ only)}, & \mathbb{Z}/5\mathbb{Z} \times S_3 \text{ (invert } \mathbb{Z}/3\mathbb{Z} \text{ only)}. \end{array}$$

These are pairwise non-isomorphic, so there are exactly four groups of order 30.

2. **(Order 12: non-simple, and five types.)** Let $|G| = 12 = 2^2 \cdot 3$. Prove G is not simple, and show G is one of $\mathbb{Z}/12\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z}$, A_4, D_{12}, Dic_3 $(= Q_{12})$ by analyzing n_3.
Answer key. For $p = 3$: $n_3 \mid 4$, $n_3 \equiv 1 \pmod 3$, so $n_3 \in \{1, 4\}$. If $n_3 = 4$, the four Sylow 3-subgroups (prime order 3, disjoint) contribute $4 \cdot 2 = 8$ elements of order 3, leaving only $12 - 8 = 4$ elements for a single Sylow 2-subgroup of order 4; hence $n_2 = 1$ and $P_2 \trianglelefteq G$. If $n_3 = 1$ then $P_3 \trianglelefteq G$. Either way a Sylow subgroup is normal, so G is not simple. Classification: when $n_3 = 4$ the Sylow 2-subgroup is normal and equals V_4, acted on by $\mathbb{Z}/3\mathbb{Z}$, giving A_4. When $n_3 = 1$, $P_3 \cong \mathbb{Z}/3\mathbb{Z} \trianglelefteq G$ and $G \cong \mathbb{Z}/3\mathbb{Z} \rtimes Q$ with $Q \in \{\mathbb{Z}/4\mathbb{Z}, V_4\}$ and $\theta\colon Q \to \mathrm{Aut}(\mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$: trivial actions give the abelian $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/6\mathbb{Z} \cong V_4 \times \mathbb{Z}/3\mathbb{Z}$; the nontrivial action with $Q = V_4$ gives $D_{12} \cong S_3 \times \mathbb{Z}/2\mathbb{Z}$; and with $Q = \mathbb{Z}/4\mathbb{Z}$ the nontrivial action gives the dicyclic group $\mathrm{Dic}_3 = Q_{12}$. These five exhaust the groups of order 12.

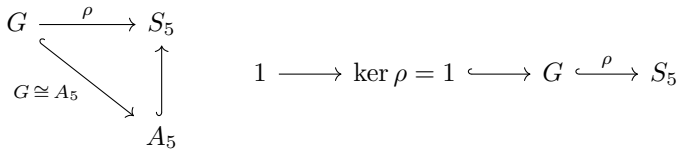
3. **(Classify order 28.)** Let $|G| = 28 = 2^2 \cdot 7$. Show the Sylow 7-subgroup is normal and classify G up to isomorphism via $\theta\colon Q \to \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$.
Answer key. For $p = 7$: $n_7 \mid 4$, $n_7 \equiv 1 \pmod 7$, so $n_7 = 1$ and $P_7 \cong \mathbb{Z}/7\mathbb{Z} \trianglelefteq G$ (L1). A Sylow 2-subgroup Q (order 4) complements P_7 (Schur–Zassenhaus), so $G \cong \mathbb{Z}/7\mathbb{Z} \rtimes Q$ with $Q \in \{\mathbb{Z}/4\mathbb{Z},\ V_4\}$ and $\theta\colon Q \to \mathrm{Aut}(\mathbb{Z}/7\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$. The image is a 2-subgroup of $\mathbb{Z}/6\mathbb{Z}$, so $|\operatorname{im}\theta| \in \{1, 2\}$.

   - $Q \cong \mathbb{Z}/4\mathbb{Z}$, θ trivial: $G \cong \mathbb{Z}/28\mathbb{Z}$.
   - $Q \cong \mathbb{Z}/4\mathbb{Z}$, $|\operatorname{im}\theta| = 2$ (the generator inverts): the square of the generator acts trivially and is the unique involution, so $G \cong \mathrm{Dic}_7 = Q_{28}$, the dicyclic group of order 28 (*not* D_{28}).
   - $Q \cong V_4$, θ trivial: $G \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/14\mathbb{Z}$.
   - $Q \cong V_4$, $|\operatorname{im}\theta| = 2$ (one $\mathbb{Z}/2\mathbb{Z}$ inverts): $G \cong D_{14} \times \mathbb{Z}/2\mathbb{Z} \cong D_{28}$, the dihedral group of order 28 (using $D_{4k} \cong D_{2k} \times \mathbb{Z}/2\mathbb{Z}$ for $k = 7$ odd).

   Thus there are exactly four groups of order 28: $\mathbb{Z}/28\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/14\mathbb{Z}$, D_{28}, and $\mathrm{Dic}_7 = Q_{28}$. (As in order 20, it is the cyclic complement acting by inversion that yields the dicyclic group, not the dihedral one.)

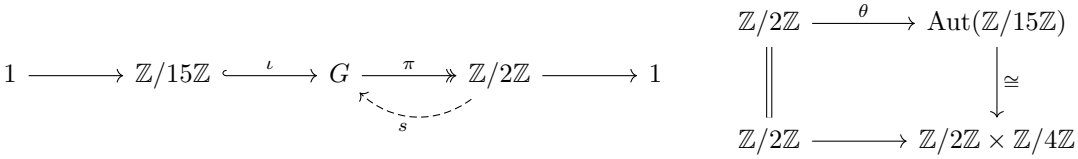
4. **(Uniqueness of the simple group of order 60.)** Let G be simple of order 60. Prove G has a subgroup of index 5, deduce $G \hookrightarrow A_5$, and conclude $G \cong A_5$.
Answer key. Simplicity forces (body Lemma) $n_5 = 6$, $n_3 = 10$, $n_2 \in \{5, 15\}$. If $n_2 = 5$ then $H := N_G(P_2)$ has $[G : H] = n_2 = 5$. If $n_2 = 15$, a count shows two Sylow 2-subgroups must overlap: 15 pairwise-disjoint copies would give $15 \cdot 3 = 45$ elements of 2-power order, and with $6 \cdot 4 = 24$ elements of order 5 that exceeds 60. So pick $P_2 \neq Q_2$ with $D := P_2 \cap Q_2$, $|D| = 2$; since D has index 2 in each (hence normal in each), $M := N_G(D) \supseteq \langle P_2, Q_2 \rangle$ has order a multiple of 4 exceeding 4, so $|M| \in \{12, 20, 60\}$. Simplicity kills $|M| = 60$ ($D \trianglelefteq G$); $|M| = 20$ gives $[G : M] = 3$ and $G \to S_3$ has a nontrivial kernel, contradiction; so $|M| = 12$, index 5. In both cases take the index-5 subgroup H and let $\rho\colon G \to S_5$ be the coset action on G/H. Its kernel is the core of H, normal in the simple group G; it is nontrivial only if it equals G, impossible since ρ is nontrivial, so $\ker\rho = 1$ and $G \hookrightarrow S_5$. Since G is simple of order > 2, the composite $G \hookrightarrow S_5 \to S_5/A_5 \cong \mathbb{Z}/2\mathbb{Z}$ must be trivial, so $G \subseteq A_5$; as $|G| = 60 = |A_5|$, $G = A_5$.

5. **(Order p^2q is solvable, with explicit series.)** Let $|G| = p^2q$, $p \neq q$ primes. Prove G is solvable and compute the derived length, working an instance of order 75 or 50.
Answer key. By the practice problem above, some Sylow subgroup P is normal with $1 < P < G$. Both P (a p- or q-group, hence solvable since prime-power groups are nilpotent) and G/P (of order q or p^2, again a prime-power group, solvable) are solvable; solvability is closed under extensions, so G is solvable. The series $1 < P < G$ has abelian or further-refinable factors, giving derived length ≤ 2. Instance $|G| = 75 = 3 \cdot 5^2$: $n_5 \mid 3$, $n_5 \equiv 1 \pmod 5$ $\implies$ $n_5 = 1$, so $P_5 \cong \mathbb{Z}/25\mathbb{Z}$ or $\mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$ is normal and abelian, and $G/P_5 \cong \mathbb{Z}/3\mathbb{Z}$ is abelian; the series $1 \trianglelefteq P_5 \trianglelefteq G$ has both quotients abelian, so $G' \leq P_5$ and $G'' = 1$, derived length ≤ 2 (in fact G abelian if the action is trivial, length ≤ 1; otherwise exactly 2). Instance $|G| = 50 = 2 \cdot 5^2$: $n_5 \mid 2$, $n_5 \equiv 1 \pmod 5$ $\implies$ $n_5 = 1$, $P_5 \trianglelefteq G$ abelian of order 25, $G/P_5 \cong \mathbb{Z}/2\mathbb{Z}$; series $1 \trianglelefteq P_5 \trianglelefteq G$, derived length ≤ 2.



Commutative-diagram exercises.

1. **(The Sylow action and its normal core.)** For $P \in \mathrm{Syl}_p(G)$ let $\varphi\colon G \to \mathrm{Sym}(\mathrm{Syl}_p(G)) \cong S_{n_p}$ be the conjugation action. Prove $\ker\varphi = \mathrm{core}_G(N_G(P)) = \bigcap_{g\in G} gN_G(P)g^{-1}$ is the largest normal subgroup of G inside $N_G(P)$, draw the factorization, and apply it to show no group of order 36 is simple.

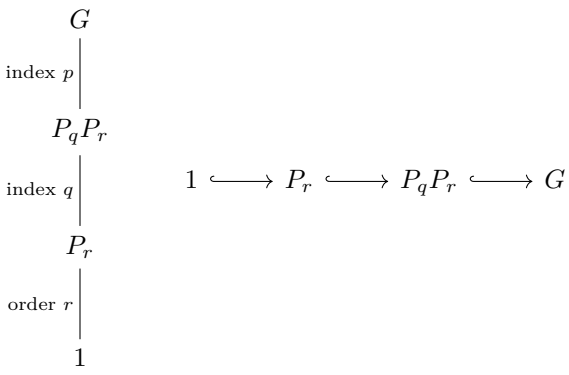


Answer key. The stabilizer of P under conjugation is $N_G(P)$, so $\ker\varphi = \bigcap_{P'\in\mathrm{Syl}_p(G)} \mathrm{Stab}(P') = \bigcap_g gN_G(P)g^{-1}$, the intersection of all conjugates of $N_G(P)$. This is normal in G (an intersection of conjugates) and contained in $N_G(P)$; any normal $K \trianglelefteq G$ with $K \le N_G(P)$ satisfies $K = gKg^{-1} \le gN_G(P)g^{-1}$ for all g, hence $K \le \ker\varphi$ — so $\ker\varphi$ is the largest such, i.e. the core. The first isomorphism theorem factors $\varphi = \bar\varphi \circ (\text{quotient})$ with $\bar\varphi$ injective, so $G/\ker\varphi \hookrightarrow S_{n_p}$ and $|G/\ker\varphi| \mid n_p!$. For $|G| = 36$, $p = 3$: $n_3 \in \{1, 4\}$; if $n_3 = 4$ then $36 \nmid 4! = 24$, so $\ker\varphi \neq 1$, and transitivity gives $\ker\varphi \neq G$. Hence $1 \neq \ker\varphi \trianglelefteq G$ is proper and G is not simple (and if $n_3 = 1$, $P_3 \trianglelefteq G$ directly).

2. **(Coset action and the index-5 embedding.)** Let G be simple of order 60 with a subgroup H of index 5. Draw the left-coset action $\rho\colon G \to S_5$ on G/H, show $\ker\rho = 1$, and complete the triangle identifying $G \cong A_5 \hookrightarrow S_5$, annotating why $\mathrm{im}\,\rho \subseteq A_5$.

Answer key. ρ is the action of G on the 5 left cosets G/H; its kernel is $\mathrm{core}_G(H)$, a normal subgroup of the simple group G. Since ρ is nontrivial (transitive on $5 \ge 2$ cosets), $\ker\rho \neq G$, so by simplicity $\ker\rho = 1$ and ρ is injective: $G \hookrightarrow S_5$. The sign map $\mathrm{sgn}\circ\rho\colon G \to S_5 \to \{\pm 1\} \cong \mathbb{Z}/2\mathbb{Z}$ has kernel $G \cap A_5 \trianglelefteq G$; by simplicity it is 1 or G, and it cannot be 1 (that would embed G into $\mathbb{Z}/2\mathbb{Z}$, impossible for $|G| = 60 > 2$), so $G \cap A_5 = G$, i.e. $\mathrm{im}\,\rho \subseteq A_5$. Comparing orders $|G| = 60 = |A_5|$ forces $\mathrm{im}\,\rho = A_5$, so ρ is the asserted isomorphism $G \cong A_5$ and the lower triangle commutes ($A_5 \hookrightarrow S_5$ is the inclusion).

3. **(Internal semidirect product of order 30.)** For $|G| = 30$ display the split short exact sequence $1 \to \mathbb{Z}/15\mathbb{Z} \to G \to \mathbb{Z}/2\mathbb{Z} \to 1$ together with the action $\mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/15\mathbb{Z})$, and build the classifying square whose four 2-torsion homomorphisms label the four groups of order 30.



Answer key. Since $\gcd(15, 2) = 1$, the normal subgroup $N = \mathbb{Z}/15\mathbb{Z}$ (the unique subgroup of order 15) has a complement by Schur–Zassenhaus, so the sequence splits: there is $s\colon \mathbb{Z}/2\mathbb{Z} \to G$ with $\pi \circ s = \mathrm{id}$. A splitting is a choice of complement $\langle t\rangle \cong \mathbb{Z}/2\mathbb{Z}$, equivalently a homomorphism $\theta\colon \mathbb{Z}/2\mathbb{Z} \to \mathrm{Aut}(\mathbb{Z}/15\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$ recording t-conjugation on N. Because θ must land in the 2-torsion of $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$, namely $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, there are exactly four homomorphisms, and the commuting square sends each to the corresponding group:

$$\theta = (1,1) \mapsto \mathbb{Z}/30\mathbb{Z}, \quad (-1,-1) \mapsto D_{30}, \quad (1,-1) \mapsto \mathbb{Z}/3\mathbb{Z} \times D_{10}, \quad (-1,1) \mapsto \mathbb{Z}/5\mathbb{Z} \times S_3,$$

where (± 1) denotes trivial/inverting action on the $\mathbb{Z}/3\mathbb{Z}$ and $\mathbb{Z}/5\mathbb{Z}$ factors respectively. Distinct θ give non-isomorphic G, classifying all four groups of order 30.

4. **(Sylow normalizer lattice for $|G| = pqr$.)** For $|G| = pqr$ with $p < q < r$ draw the Hasse fragment of subgroups $1 < P_r < P_qP_r < G$, marking the normal-containments, and prove the chain exhibits non-simplicity and solvability. Use the instance $(p, q, r) = (3, 5, 7)$, order 105.

Answer key. By the pqr analysis $n_r = 1$, so $P_r \cong \mathbb{Z}/r\mathbb{Z} \trianglelefteq G$ sits at the bottom of the lattice as a normal subgroup ($1 \trianglelefteq P_r$). Since $P_r \trianglelefteq G$, the product P_qP_r is a subgroup of order qr; being a subgroup of index p with p the smallest prime dividing $|G|$, it is normal: $P_qP_r \trianglelefteq G$ (and $P_r \trianglelefteq P_qP_r$ as the unique Sylow r-subgroup there). This yields the normal chain $1 \trianglelefteq P_r \trianglelefteq P_qP_r \trianglelefteq G$ with cyclic quotients $\mathbb{Z}/r\mathbb{Z}$, $\mathbb{Z}/q\mathbb{Z}$, $\mathbb{Z}/p\mathbb{Z}$, proving G is solvable (all factors abelian) and not simple (the proper nontrivial $P_r \trianglelefteq G$). For $(p, q, r) = (3, 5, 7)$, $|G| = 105$: $n_7 = 1$ so $P_7 \cong \mathbb{Z}/7\mathbb{Z} \trianglelefteq G$; $P_5P_7 \cong \mathbb{Z}/35\mathbb{Z}$ has index 3 (the least prime), hence is normal; the chain $1 \trianglelefteq \mathbb{Z}/7\mathbb{Z} \trianglelefteq \mathbb{Z}/35\mathbb{Z} \trianglelefteq G$ has factors $\mathbb{Z}/7\mathbb{Z}, \mathbb{Z}/5\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}$, confirming solvability and non-simplicity.

6.3 A Word on Free Groups

Free groups, generators and relations, and presentations

The constructions of this section answer two related questions. First: given a set S, is there a "most general" group generated by S, one in which the elements of S satisfy *no* relations beyond those forced by the group axioms? The answer is the *free group* $F(S)$. Second: how do we specify an arbitrary group economically? The answer is a *presentation* $\langle S \mid R \rangle$, obtained from $F(S)$ by imposing a chosen list R of relations. The technical engine driving everything is the **universal property** of $F(S)$.

Reduced words. Fix a set S (the *alphabet*). Choose a disjoint copy $S^{-1} = \{ s^{-1} : s \in S \}$ of formal inverses, so that $S \cap S^{-1} = \varnothing$ and the assignment $s \mapsto s^{-1}$ is a bijection $S \to S^{-1}$. A **word** on S is a finite string

$$w = a_1^{\epsilon_1} a_2^{\epsilon_2} \cdots a_k^{\epsilon_k}, \qquad a_i \in S,\ \epsilon_i \in \{+1, -1\},\ k \geq 0,$$

where the empty word ($k = 0$) is allowed and written 1. A word is **reduced** if it never contains a pair $s\,s^{-1}$ or $s^{-1}s$ for any $s \in S$ as consecutive letters. Two words are equal as elements of $F(S)$ exactly when they reduce to the same reduced word; reduction means repeatedly deleting adjacent cancelling pairs.

Definition 6.3.1 (Free group on a set)**.** Let S be a set. The **free group on** S, written $F(S)$, is the set of all reduced words on $S \cup S^{-1}$, with multiplication given by concatenation followed by reduction. The identity is the empty word 1; the inverse of $a_1^{\epsilon_1} \cdots a_k^{\epsilon_k}$ is $a_k^{-\epsilon_k} \cdots a_1^{-\epsilon_1}$. The map $\iota \colon S \to F(S)$, $\iota(s) = s$ (the one-letter word), is the canonical inclusion. The cardinality $|S|$ is the **rank** of $F(S)$. If $|S| = n$ we also write F_n.

Remark 6.3.1. That concatenation-then-reduction is associative and gives a group is not entirely obvious, because reductions can be performed in different orders. D&F establish this in Section 6.3 (their Theorem 16) by van der Waerden's argument: realize each generator as a bijection of the set of reduced words and show these bijections generate a group isomorphic to $F(S)$. We take well-defined group structure as given and focus on its consequences.

Theorem 6.3.2 (Reduced-word normal form)**.** *Every word on $S \cup S^{-1}$ reduces to a* unique *reduced word, independent of the order in which adjacent cancelling pairs are removed. Consequently each element of $F(S)$ has a unique reduced-word representative, and $\iota\colon S \to F(S)$ is injective.*

Proof. Uniqueness of the reduced form is the content of *Newman's diamond lemma* applied to the rewriting system whose rules delete ss^{-1} and $s^{-1}s$. One checks local confluence: if a word w admits two distinct one-step reductions, the two results have a common further reduction. The two deleted cancelling pairs either are disjoint (do the other deletion; the order does not matter) or overlap in exactly one letter, as in $ss^{-1}s$, where both reductions yield the same result s. Local confluence plus termination (each reduction shortens the word, so the process stops) gives confluence by Newman's lemma, hence a unique normal form. Injectivity of ι is immediate: distinct $s, t \in S$ are already reduced one-letter words, so $\iota(s) \neq \iota(t)$. □

Theorem 6.3.3 (Universal property of the free group, D&F 6.3 Thm. 17)**.** *Let S be a set and G any group. For every set map $\varphi\colon S \to G$ there is a* unique *group homomorphism $\Phi\colon F(S) \to G$ with $\Phi \circ \iota = \varphi$, i.e. $\Phi(s) = \varphi(s)$ for all $s \in S$. In a diagram, the dashed arrow exists and is unique making the triangle commute:*

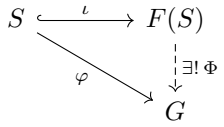


Diagram explanation. Objects: Three objects: the set S (a bare set, not yet a group); the free group $F(S)$ (the "most general" group on alphabet S, whose elements are reduced words); and an arbitrary target group G.

Arrows: $\iota\colon S \to F(S)$, $s \mapsto s$, is the canonical inclusion embedding each letter as a one-letter word. $\varphi\colon S \to G$ is any set map (no algebraic condition). The dashed $\exists!\,\Phi\colon F(S) \to G$ is the unique group homomorphism extending φ; it is the only arrow that can make the triangle commute while being a homomorphism.

What commutes: The triangle commutes: $\Phi \circ \iota = \varphi$, i.e. for every $s \in S$, $\Phi(\iota(s)) = \Phi(s) = \varphi(s)$. In words: going right along ι then down along Φ gives the same value as going diagonally along φ.

Why it commutes: Take a generator $s \in S$. Along the top-then-down path: $s \overset{\iota}{\mapsto} s \in F(S) \overset{\Phi}{\mapsto} \varphi(s)$. Along the diagonal: $s \overset{\varphi}{\mapsto} \varphi(s)$. These agree by definition of Φ on letters. On a general word $s_1^{\epsilon_1} \cdots s_k^{\epsilon_k}$, the homomorphism property of Φ forces $\Phi(s_1^{\epsilon_1} \cdots s_k^{\epsilon_k}) = \varphi(s_1)^{\epsilon_1} \cdots \varphi(s_k)^{\epsilon_k}$, so the extension is completely determined and well defined (reductions in $F(S)$ map to 1_G because $\varphi(s)\varphi(s)^{-1} = 1_G$).

Why this matters here: This diagram is the precise statement of the universal property proved in the theorem. It encodes both existence (the dashed arrow exists) and uniqueness ($\exists!$). Every subsequent result in this section — the quotient corollary, von Dyck's theorem, identifying presentations — is obtained by applying or quotienting this one diagram.

Concrete example: Take $S = \{a, b\}$, $G = S_3$, $\varphi(a) = (1\,2)$, $\varphi(b) = (1\,2\,3)$. The unique $\Phi\colon F_2 \to S_3$ sends any word, e.g. aba^{-1}, to $(1\,2)(1\,2\,3)(1\,2) = (1\,3\,2)$. No relation among $(1\,2)$ and $(1\,2\,3)$ needs to be checked; the map is automatic.

Common pitfall: Students often think defining Φ requires checking that the images satisfy some relation. For a *free* group there are *no* relations to check; φ is an unconstrained set map and Φ always exists. The well-definedness check is needed only when the source has relations (as in von Dyck's theorem for presentations).

Takeaway: The point of this diagram is that a homomorphism out of a free group is completely and freely determined by the images of the generators, with no compatibility conditions whatsoever.

Moreover this property characterizes $F(S)$ up to a unique isomorphism: if a group F' with a map $\iota'\colon S \to F'$ has the same property, then there is a unique isomorphism $F(S) \to F'$ commuting with the inclusions.

Proof. Existence. Define Φ on reduced words by

$$\Phi(a_1^{\epsilon_1} \cdots a_k^{\epsilon_k}) = \varphi(a_1)^{\epsilon_1} \cdots \varphi(a_k)^{\epsilon_k} \in G, \qquad \Phi(1) = 1_G.$$

This is forced: a homomorphism must send a product to the product of images and s^{-1} to $\varphi(s)^{-1}$. To see Φ is well defined we must check it is unchanged by a reduction. If w contains ss^{-1}, then in G the corresponding factor $\varphi(s)\varphi(s)^{-1} = 1_G$, so deleting the pair does not change the image; similarly for $s^{-1}s$. Hence Φ depends only on the reduced form, which is unique by the previous theorem. That Φ is a homomorphism: for reduced words u, v, the product uv in $F(S)$ is the reduction of the concatenation, and since reduction does not change the image, $\Phi(uv) = \Phi(\text{concat}) = \Phi(u)\Phi(v)$ in G. Finally $\Phi(\iota(s)) = \Phi(s) = \varphi(s)$.

Uniqueness. Any homomorphism agreeing with φ on S is determined on every reduced word by the homomorphism property, so it equals Φ.

Characterization. If (F', ι') also has the property, apply universality of $F(S)$ to $\iota' \colon S \to F'$ to get $\alpha \colon F(S) \to F'$, and universality of F' to $\iota \colon S \to F(S)$ to get $\beta \colon F' \to F(S)$. Then $\beta\alpha$ and $\mathrm{id}_{F(S)}$ both extend ι, so by uniqueness $\beta\alpha = \mathrm{id}$; symmetrically $\alpha\beta = \mathrm{id}$. Thus α is an isomorphism, and it is the unique one commuting with the inclusions. □

Method (Defining a homomorphism out of $F(S)$ (the universal property))**.** *Trigger.* You want a homomorphism from a free group $F(S)$ (or from a group given by generators) to some target G, OR you need to know such a map is well defined.

1. **Just name the images.** Pick any elements $g_s \in G$, one for each $s \in S$. There are *no constraints*: $S \to G$, $s \mapsto g_s$, is an arbitrary set map.
2. **Invoke Theorem 6.3.3.** It extends uniquely to a homomorphism $\Phi \colon F(S) \to G$ with $\Phi(s) = g_s$. The value on a general word is $\Phi(s_1^{\epsilon_1} \cdots) = g_{s_1}^{\epsilon_1} \cdots$.
3. **No well-definedness check is ever needed** for maps out of a *free* group. (Maps out of a presentation $\langle S \mid R \rangle$ DO need a check — see the next Method box.)
4. **To get an isomorphism / compute the image**, find $\operatorname{im}\Phi = \langle g_s : s \in S \rangle$ and $\ker\Phi$, then use the first isomorphism theorem.

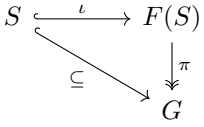
Worked Example 6.3.4 (Universal property: a map out of $F(\{a,b\})$)**.** Let $F = F(\{a,b\})$ and $G = \mathrm{GL}_2(\mathbb{R})$. Show there is a unique homomorphism $\Phi \colon F \to G$ with $\Phi(a) = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $\Phi(b) = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right)$, and compute $\Phi(aba^{-1})$.

Recognition. "Homomorphism out of a free group, images prescribed" is the exact trigger for the universal property (Theorem 6.3.3): any set map on the generators extends uniquely, no relations to verify.

Solution. Define $\varphi \colon \{a,b\} \to \mathrm{GL}_2(\mathbb{R})$ by the two matrices above. By the universal property there is a unique homomorphism $\Phi \colon F \to \mathrm{GL}_2(\mathbb{R})$ with $\Phi \circ \iota = \varphi$. Now

$$\Phi(aba^{-1}) = \Phi(a)\Phi(b)\Phi(a)^{-1} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}.$$

First $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. Then $\left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 2 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. *Check.* $\det = 2 \cdot 0 - (-1) \cdot 1 = 1$, consistent with each factor having determinant 1; and $\Phi(a)\Phi(a^{-1}) = I$ since $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix}\right) = I$. The map is unique because a homomorphism is determined by its values on generators.



Worked Example 6.3.5 (Two extensions agreeing on generators must coincide)**.** Let $\Phi, \Psi \colon F(\{x,y\}) \to S_3$ be homomorphisms with $\Phi(x) = \Psi(x) = (1\,2)$ and $\Phi(y) = \Psi(y) = (1\,2\,3)$. Prove $\Phi = \Psi$.

Recognition. This is the *uniqueness* half of the universal property: two homomorphisms out of a free group that agree on the generating set are equal, because every element is a word in those generators.

Solution. Any $w \in F(\{x,y\})$ is a reduced word $w = x^{\epsilon_1}y^{\delta_1}\cdots$ in $x^{\pm 1}, y^{\pm 1}$. Since Φ, Ψ are homomorphisms, $\Phi(w)$ is the corresponding product of $\Phi(x)^{\pm 1}, \Phi(y)^{\pm 1}$, and likewise for $\Psi(w)$. As the generator images coincide, the products coincide letter by letter, so $\Phi(w) = \Psi(w)$ for all w. *Check.* Concretely $\Phi(xy) = (1\,2)(1\,2\,3) = (2\,3)$ and $\Psi(xy) = (1\,2)(1\,2\,3) = (2\,3)$ agree, as the argument guarantees.

Every group is a quotient of a free group. The universal property has an immediate and far-reaching corollary.

Corollary 6.3.6 (Free presentation, D&F 6.3)**.** *Let G be any group and let $S \subseteq G$ generate G (e.g. $S = G$). The inclusion $S \hookrightarrow G$ extends to a surjective homomorphism $\pi\colon F(S) \twoheadrightarrow G$. Hence $G \cong F(S)/\ker\pi$: every group is a quotient of a free group. If G is finitely generated, S may be taken finite, so G is a quotient of some F_n.*

$$1 \longrightarrow \ker\pi \hookrightarrow F(S) \xrightarrow{\pi} G \longrightarrow 1$$

Diagram explanation. Objects: Left triangle: the set $S \subseteq G$ (a generating subset, not yet a group); the free group $F(S)$; and the target group G itself. Right exact sequence: the trivial group 1; the kernel $\ker\pi$, a normal subgroup of $F(S)$ encoding all relations satisfied in G; $F(S)$; and G.

Arrows: In the triangle, $\iota\colon S \to F(S)$ is the letter-inclusion, and $\subseteq\colon S \hookrightarrow G$ is the literal set-inclusion of generators. The surjection $\pi\colon F(S) \twoheadrightarrow G$ is the unique homomorphism extending $s \mapsto s$ (via the universal property); it is onto because S generates G. In the exact sequence: the first arrow sends 1 to 1; the hooked arrow $\ker\pi \hookrightarrow F(S)$ is the subgroup inclusion; π is the surjection; the last arrow sends G to 1.

What commutes: Triangle: $\pi \circ \iota = \subseteq$, i.e. for $s \in S$, $\pi(s) = s$ in G. Exact sequence: $\mathrm{im}(1 \to \ker\pi) = \{1\} = \ker(\ker\pi \hookrightarrow F(S))$; $\mathrm{im}(\ker\pi \hookrightarrow F(S)) = \ker\pi = \ker(\pi)$; $\mathrm{im}(\pi) = G = \ker(G \to 1)$.

Why it commutes: The triangle commutes because π was defined by the universal property as the unique extension of the inclusion $S \to G$. For the exact sequence: $\ker\pi$ is a subgroup (hence the inclusion is injective), π is surjective by hypothesis (S generates G), and the only element mapping to 1 under $G \to 1$ is G itself.

Why this matters here: These two pictures together package the corollary's content: the triangle says every group is a quotient of a free group (via the surjection π), and the exact sequence says the quotient structure is $G \cong F(S)/\ker\pi$. This is the starting point for all presentations: $\ker\pi$ is the "set of all relations" holding in G.

Concrete example: $G = \mathbb{Z}/3$, $S = \{1\}$ (the generator 1 mod 3). Then $F(S) = F_1 \cong \mathbb{Z}$ and $\pi\colon \mathbb{Z} \to \mathbb{Z}/3$ is reduction mod 3; $\ker\pi = 3\mathbb{Z}$. The exact sequence is $0 \to 3\mathbb{Z} \to \mathbb{Z} \to \mathbb{Z}/3 \to 0$, the standard one.

Common pitfall: The inclusion $S \hookrightarrow G$ is NOT a homomorphism (it is a set map into a group); only π is a homomorphism. Do not confuse the set map $\subseteq$ with the group homomorphism $\pi\colon F(S) \to G$. Also, π is generally far from injective; $\ker\pi$ can be enormous (e.g. infinite even if G is finite).

Takeaway: The point of this diagram is that every group — no matter how complicated — is the free group on its generators modulo the normal subgroup of all words that happen to equal the identity.

Diagram explanation. Objects: Five terms: trivial group 1; normal subgroup $\ker\pi \trianglelefteq F(S)$ (the "relation subgroup", all words reducing to 1 in G); free group $F(S)$; the quotient group $G \cong F(S)/\ker\pi$; and the trivial group 1 again.

Arrows: $1 \to \ker\pi$ is the inclusion of the identity element only (trivial map). $\ker\pi \hookrightarrow F(S)$ is the subgroup inclusion (injective, hence hooked). $\pi\colon F(S) \twoheadrightarrow G$ is the surjective quotient homomorphism (double-headed arrow). $G \to 1$ is the terminal map sending everything to the identity (trivially a homomorphism).

What commutes: Exactness at each node: (i) $\mathrm{im}(1 \to \ker\pi) = \{1\} = \ker(\ker\pi \to F(S))$; (ii) $\mathrm{im}(\ker\pi \to F(S)) = \ker\pi = \ker\pi = \ker(\pi)$; (iii) $\mathrm{im}(\pi) = G = \ker(G \to 1)$.

Why it commutes: (i) $\ker\pi \hookrightarrow F(S)$ is injective, so its kernel is $\{1\}$. (ii) The image of $\ker\pi \hookrightarrow F(S)$ is $\ker\pi$ itself, which equals the kernel of π by definition of $\ker\pi$. (iii) π is surjective (since S generates G), so its image is all of G, which equals the kernel of the terminal map.

Why this matters here: The short exact sequence is the algebraic summary of the first isomorphism theorem applied to π. It frames G as the "cokernel" of the inclusion $\ker\pi \hookrightarrow F(S)$, the standard way to record a quotient structure without writing a fraction.

Concrete example: $F_1 = \mathbb{Z}$, $\pi\colon \mathbb{Z} \to \mathbb{Z}/n \pmod n$, $\ker\pi = n\mathbb{Z}$. The sequence $0 \to n\mathbb{Z} \to \mathbb{Z} \to \mathbb{Z}/n \to 0$ is exact: $n\mathbb{Z}$ is injected into $\mathbb{Z}$, and $\mathbb{Z}/n$ is the cokernel.

Common pitfall: Exactness at $F(S)$ says $\ker\pi$ equals the *image* of the inclusion — do not confuse this with saying $\ker\pi = F(S)$. Also, this sequence being "short" (five terms, zeros on both ends) is specific to the case where $\ker\pi \hookrightarrow F(S) \twoheadrightarrow G$; longer exact sequences arise in homological algebra and carry more information.

Takeaway: The point of this diagram is that the surjection $F(S) \twoheadrightarrow G$ is exact in the sense that the kernel is precisely the normal subgroup of relations, packaging $G \cong F(S)/\ker\pi$ in a universally recognized algebraic format.

Proof. Apply Theorem 6.3.3 to the set map $\varphi\colon S \to G$, $\varphi(s) = s$. The resulting $\pi\colon F(S) \to G$ has image $\langle\, \varphi(s) : s \in S \,\rangle = \langle S\rangle = G$, so π is surjective. By the first isomorphism theorem $F(S)/\ker\pi \cong G$. Taking $S = G$ always works; if $G = \langle g_1, \dots, g_n\rangle$ take $S = \{g_1, \dots, g_n\}$ and $F(S) = F_n$. □

Worked Example 6.3.7 (Every group with generating set S is $F(S)/N$)**.** Let G be a group generated by S. Exhibit explicitly a normal subgroup $N \trianglelefteq F(S)$ with $G \cong F(S)/N$, and identify N.

Recognition. "Realize G as a quotient of a free group" is precisely Corollary 6.3.6: extend the inclusion to π, then N is its kernel.

Solution. By the universal property the inclusion $S \hookrightarrow G$ extends to $\pi\colon F(S) \to G$ with $\pi(s) = s$. Since S generates G, π is onto. Set $N = \ker\pi$, a normal subgroup of $F(S)$. The first isomorphism theorem gives $F(S)/N \cong G$. Concretely, N is the set of all reduced words $s_1^{\epsilon_1}\cdots s_k^{\epsilon_k}$ that multiply to the identity *in* G; these are exactly the "relations" satisfied by the generators. *Check.* If G is itself free on S then no nontrivial word equals 1 in G, so $N = 1$ and π is an isomorphism — consistent with $F(S)$ being its own "most general" generated group.

Presentations. To cut $F(S)$ down to a specific group we kill a chosen set of words.

Definition 6.3.8 (Normal closure, presentation, D&F 6.3)**.** Let S be a set and $R \subseteq F(S)$ a set of words (the **relators**). The **normal closure** of R is the smallest normal subgroup of $F(S)$ containing R,

$$N \;=\; \langle\, R\rangle^{F(S)} \;=\; \big\langle\, wr^{\pm 1}w^{-1} : r \in R,\ w \in F(S)\,\big\rangle,$$

equivalently the intersection of all normal subgroups of $F(S)$ containing R. The group with **presentation** $\langle S \mid R\rangle$ is

$$\langle S \mid R\rangle \;:=\; F(S)/N.$$

We call S the **generators** and R the **relations** (writing a relation either as a word r meaning "$r = 1$" or as an equation "$u = v$" meaning the relator uv^{-1}). A group is **finitely generated** if it has a presentation with $|S| < \infty$, and **finitely presented** if it has a presentation with both $|S| < \infty$ and $|R| < \infty$.

Remark 6.3.2. Why the *normal* closure and not just $\langle R\rangle$? In any quotient $F(S) \to G$ killing R, the kernel is normal, so it must contain not only each r but every conjugate wrw^{-1}. Killing R "as a normal subgroup" is exactly what makes the relations hold throughout the quotient. The same group can have many presentations; deciding whether two presentations give isomorphic groups is, in general, impossible (see the word problem below).

Theorem 6.3.9 (Universal property of a presentation / von Dyck's theorem)**.** *Let $G = \langle S \mid R\rangle = F(S)/N$ with quotient map $q\colon F(S) \to G$, $q(s) = \bar{s}$. Let H be a group and $\psi\colon S \to H$ a set map whose induced homomorphism $\Psi\colon F(S) \to H$ (from Theorem 6.3.3) kills every relator, i.e. $\Psi(r) = 1_H$ for all $r \in R$. Then Ψ factors uniquely through q: there is a unique homomorphism $\bar{\Psi}\colon G \to H$ with $\bar{\Psi}(\bar{s}) = \psi(s)$.*

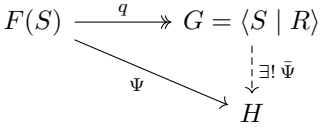


Diagram explanation. Objects: Three objects: the free group $F(S)$ (unrestricted, generated by S); the presentation group $G = \langle S \mid R\rangle = F(S)/N$ (the quotient that kills the normal closure N of the relators R); and an arbitrary target group H into which the relators map trivially.

Arrows: $q\colon F(S) \twoheadrightarrow G$ is the canonical quotient map $q(w) = \bar{w}$, surjective by definition. $\Psi\colon F(S) \to H$ is the homomorphism induced (via the free-group universal property) by a set map $\psi\colon S \to H$ satisfying $\Psi(r) = 1_H$ for all $r \in R$. The dashed $\exists!\,\bar{\Psi}\colon G \to H$ is the unique induced homomorphism on the quotient, well defined precisely because Ψ kills N.

What commutes: $\bar{\Psi} \circ q = \Psi$: for every $w \in F(S)$, $\bar{\Psi}(q(w)) = \bar{\Psi}(\bar{w}) = \Psi(w)$.

Why it commutes: Well-definedness of $\bar{\Psi}$: take two words w, w' in the same coset of N, so $w' = wn$ for some $n \in N$. Then $\Psi(w') = \Psi(w)\Psi(n) = \Psi(w) \cdot 1_H = \Psi(w)$ because $N \subseteq \ker \Psi$ (since $\ker \Psi \trianglelefteq F(S)$ is normal and contains all $r \in R$, hence all of $N = \langle R \rangle^{F(S)}$). So $\bar{\Psi}(\bar{w})$ is independent of the coset representative, making $\bar{\Psi}$ a well-defined homomorphism.

Why this matters here: Von Dyck's theorem is the *usable* version of the universal property for presentations. It converts the abstract definition $G = F(S)/N$ into a concrete tool: to build a map *out* of G, assign images to generators in H and verify each relator. This is the engine behind every proof that a presentation equals a known group (e.g. dihedral groups).

Concrete example: $G = D_8 = \langle r, s \mid r^4, s^2, srsr \rangle$, $H = \mathbb{Z}/2 \times \mathbb{Z}/2$. Set $\psi(r) = (1,0)$, $\psi(s) = (0,1)$. Check: $\Psi(r^4) = 4(1,0) = (0,0)$; $\Psi(s^2) = 2(0,1) = (0,0)$; $\Psi(srsr) = (0,1) + (1,0) + (0,1) + (1,0) = (0,0)$. Von Dyck yields $\bar{\Psi} \colon D_8 \to \mathbb{Z}/2 \times \mathbb{Z}/2$.

Common pitfall: The hypothesis "$\Psi(r) = 1_H$ for all $r \in R$" is not optional — without it, Ψ does not factor through G because $\bar{\Psi}$ would not be well defined on cosets. Forgetting to verify the relations is the most common error when defining maps out of a presentation.

Takeaway: The point of this diagram is that a homomorphism out of a presented group $\langle S \mid R \rangle$ exists (and is unique) if and only if the generator images in H happen to satisfy every relation in R.

Thus to define a homomorphism out of $\langle S \mid R \rangle$ one assigns images to the generators and verifies the relations.

Proof. By Theorem 6.3.3 the map ψ gives $\Psi \colon F(S) \to H$. The hypothesis $\Psi(R) = \{1\}$ means $R \subseteq \ker \Psi$; since $\ker \Psi \trianglelefteq F(S)$ is normal and N is the *smallest* normal subgroup containing R, we get $N \subseteq \ker \Psi$. By the universal property of the quotient (first isomorphism theorem), Ψ factors as $\bar{\Psi} \circ q$ for a unique homomorphism $\bar{\Psi} \colon F(S)/N = G \to H$, and $\bar{\Psi}(\bar{s}) = \Psi(s) = \psi(s)$. □

Method (Defining a homomorphism out of a presentation $\langle S \mid R \rangle$)**.** *Trigger.* The source group is given by generators and relations, and you want a map out of it (or to prove a presentation describes a known group).

1. **Assign generator images.** Choose $\psi(s) = h_s \in H$ for each $s \in S$ — ideally elements of H you expect to "play the role" of the generators.
2. **Check every relation.** For each relator $r \in R$, substitute and confirm $r(h_s) = 1_H$ (or, for $u = v$, confirm $u(h_s) = v(h_s)$). This is the only nontrivial step; it is mandatory here (unlike for free groups).
3. *Conclude.* By von Dyck (Theorem 6.3.9): a unique homomorphism $\bar{\Psi} \colon \langle S \mid R \rangle \to H$ exists with $\bar{\Psi}(\bar{s}) = h_s$.
4. **For an isomorphism**, build maps both ways, or show $\bar{\Psi}$ is onto and that $|\langle S \mid R \rangle| \leq |H|$ (ontoness gives $|\langle S \mid R \rangle| \geq |H|$; the reverse bound needs a separate argument, e.g. a normal form, since missing relations can make the presented group *larger* than intended — see the order-bound pitfall).

Caution. A presentation gives an *upper* bound on the order, never a lower bound by itself. If you write down generators and relations "intending" a group of order n, the relations you listed might collapse it further. To prove $|\langle S \mid R \rangle| = n$ you must (a) exhibit a group H of order n satisfying the relations, giving a surjection $\langle S \mid R \rangle \twoheadrightarrow H$ so $|\langle S \mid R \rangle| \geq n$, and (b) show every element of $\langle S \mid R \rangle$ equals one of at most n normal-form words, giving $|\langle S \mid R \rangle| \leq n$. Only then does equality hold. Forgetting (a) is the classic error: e.g. $\langle x \mid x^6, x^4 \rangle$ *looks* like it might be $\mathbb{Z}/6$ or $\mathbb{Z}/4$ but is $\mathbb{Z}/\gcd(6,4) = \mathbb{Z}/2$.

Worked Example 6.3.10 ($\mathbb{Z} = F(\{x\})$ and the cyclic group $\mathbb{Z}/n = \langle x \mid x^n \rangle$)**.** Show $F(\{x\}) \cong \mathbb{Z}$, and that for $n \geq 1$ the presentation $\langle x \mid x^n \rangle$ is $\mathbb{Z}/n\mathbb{Z}$.

Recognition. For $F(\{x\}) \cong \mathbb{Z}$: universal property + first isomorphism theorem. For $\langle x \mid x^n \rangle$: von Dyck to get a surjection, then the order-bound argument from the pitfall above.

Solution. (a) Reduced words on $\{x, x^{-1}\}$ are exactly the powers x^m, $m \in \mathbb{Z}$ (any word collapses to a single power), and $x^m x^{m'} = x^{m+m'}$. So $m \mapsto x^m$ is an isomorphism $\mathbb{Z} \to F(\{x\})$; equivalently apply the universal property to $\varphi \colon \{x\} \to \mathbb{Z}$, $\varphi(x) = 1$, getting $\Phi \colon F(\{x\}) \to \mathbb{Z}$ surjective with trivial kernel.

(b) In $\langle x \mid x^n\rangle = F(\{x\})/N$ with $N = \langle x^n\rangle^{F(\{x\})} = \langle x^n\rangle$ (automatically normal, $F(\{x\})$ being abelian), the cosets are $\{1, \bar{x}, \dots, \bar{x}^{\,n-1}\}$ since $\bar{x}^{\,n} = 1$, so the order is $\le n$. Define $\psi\colon \{x\} \to \mathbb{Z}/n$ by $x \mapsto 1$; then $\Psi(x^n) = n \equiv 0$, so the relation holds and von Dyck gives $\bar{\Psi}\colon \langle x \mid x^n\rangle \to \mathbb{Z}/n$, surjective, whence the order is $\ge n$. Therefore $\langle x \mid x^n\rangle \cong \mathbb{Z}/n$. *Check.* For $n = 1$, $\langle x \mid x\rangle$ has the single coset $\{1\}$, giving the trivial group $\mathbb{Z}/1$, as expected; for $n = 0$ (no relation) we recover $F(\{x\}) = \mathbb{Z}$.

Worked Example 6.3.11 ($F_2 = F(\{a, b\})$ is non-abelian and infinite)**.** Prove the free group on two generators is non-abelian and infinite.

Recognition. Use the universal property to map F_2 onto a *known* non-abelian group (to force non-commutativity) and onto $\mathbb{Z}$ (to force infinitude); a quotient inheriting these forces them on F_2.

Solution. Non-abelian. The words ab and ba are distinct reduced words, so $ab \neq ba$ in F_2. (Alternatively: map $F_2 \to S_3$ by $a \mapsto (1\,2)$, $b \mapsto (1\,2\,3)$; then the images $(2\,3)$ and $(1\,3)$ of ab and ba differ, so $ab \neq ba$ already in F_2.) *Infinite.* The reduced words $a, a^2, a^3, \dots$ are pairwise distinct (they are already reduced and of different length), giving infinitely many elements. Equivalently the universal property map $F_2 \to \mathbb{Z}$, $a \mapsto 1$, $b \mapsto 0$, is onto, and a finite group has no infinite quotient, so F_2 is infinite. *Check.* Contrast rank 1: $F_1 = \mathbb{Z}$ *is* abelian. The jump to non-abelian at rank 2 is exactly the absence of any relation forcing $ab = ba$.

Worked Example 6.3.12 (The dihedral group $D_{2n} = \langle r, s \mid r^n,\, s^2,\, srsr\rangle$)**.** Show the presentation $\langle r, s \mid r^n, s^2, srsr\rangle$ (with $n \ge 1$) defines the dihedral group of order $2n$.

Recognition. Standard "presentation equals a named group" task: use von Dyck for a surjection onto the geometric D_{2n}, then the normal-form/order-bound argument to pin the order at $2n$.

Solution. Let $P = \langle r, s \mid r^n, s^2, srsr\rangle$. The relation $srsr = 1$ rewrites as $srs = r^{-1}$ (using $s^2 = 1 \Rightarrow s^{-1} = s$), i.e. $srs^{-1} = r^{-1}$.

Upper bound. Using $sr = r^{-1}s$ repeatedly, every word in r, s moves all s's to the right and reduces each block, so every element of P equals $r^i s^j$ with $0 \le i < n$ (from $r^n = 1$) and $j \in \{0, 1\}$ (from $s^2 = 1$). Hence $|P| \le 2n$.

Lower bound. Let $H = D_{2n} = \langle \rho, \sigma\rangle$ be the symmetries of a regular n-gon, with ρ a rotation by $2\pi/n$ (order n) and σ a reflection (order 2) satisfying $\sigma\rho\sigma = \rho^{-1}$, so $|H| = 2n$. The assignment $r \mapsto \rho,\ s \mapsto \sigma$ satisfies all three relators: $\rho^n = 1$, $\sigma^2 = 1$, and $\sigma\rho\sigma\rho = \rho^{-1}\rho = 1$. By von Dyck there is a surjection $P \twoheadrightarrow H$, so $|P| \ge |H| = 2n$.

Combining, $|P| = 2n$ and $P \cong D_{2n}$. *Check.* The $2n$ normal forms $r^i s^j$ ($0 \le i < n$, $0 \le j \le 1$) map bijectively to the $2n$ elements $\rho^i\sigma^j$ of H; e.g. for $n = 3$ this recovers S_3. Take $\rho = (1\,2\,3)$ and $\sigma = (1\,2)$. Then $\sigma\rho\sigma = (1\,2)(1\,2\,3)(1\,2) = (1\,3\,2) = \rho^{-1}$, so the conjugation relation holds, and the last relator evaluates to $\sigma\rho\sigma\rho = \rho^{-1}\rho = 1$, as required.

Worked Example 6.3.13 (A presentation that collapses: $\langle x \mid x^6,\, x^4\rangle$)**.** Identify the group $\langle x \mid x^6, x^4\rangle$.

Recognition. The pitfall about order bounds: multiple relations on one generator combine, and the surviving order is the gcd of the exponents.

Solution. In $G = \langle x \mid x^6, x^4\rangle = F(\{x\})/N$, both x^6 and x^4 lie in N, and $N = \langle x^6, x^4\rangle$ inside the abelian $F(\{x\}) = \mathbb{Z}$ equals $\langle \gcd(6, 4)\rangle = \langle x^2\rangle$. Hence $G = \mathbb{Z}/\langle 2\rangle = \mathbb{Z}/2$, generated by $\bar{x}$ of order 2. *Check.* Indeed $x^2 = x^6 \cdot (x^4)^{-1} \in N$, so $\bar{x}^2 = 1$ in G; and $\bar{x} \neq 1$ because $x \notin \langle x^2\rangle$. So $|G| = 2$, *not* 6 or 4 — exactly the trap the pitfall warns about.

Worked Example 6.3.14 (Reading off a homomorphism from D_8's presentation)**.** Let $D_8 = \langle r, s \mid r^4, s^2, srsr\rangle$ (order 8). Construct the homomorphism $D_8 \to \mathbb{Z}/2 \times \mathbb{Z}/2$ sending $r \mapsto (1, 0)$, $s \mapsto (0, 1)$ and identify its kernel.

Recognition. Map out of a presentation: assign generator images in the abelian target, *verify each relation*, invoke von Dyck.

Solution. Put $\psi(r) = (1, 0)$, $\psi(s) = (0, 1)$ in $H = \mathbb{Z}/2 \times \mathbb{Z}/2$. Check relators (written additively, where every element has order dividing 2 and H is abelian): $\psi(r^4) = 4 \cdot (1, 0) = (0, 0)$; $\psi(s^2) = 2 \cdot (0, 1) = (0, 0)$; $\psi(srsr) = (0, 1) + (1, 0) + (0, 1) + (1, 0) = (2, 2) = (0, 0)$. All relations hold, so von Dyck yields $\bar{\psi}\colon D_8 \to H$ with the stated values. It is surjective since $(1, 0), (0, 1)$ generate H, so $|\operatorname{im}\bar{\psi}| = 4$ and $|\ker\bar{\psi}| = 8/4 = 2$. **Identify the kernel.** An element $r^i s^j$ maps to ($i \bmod 2$, $j \bmod 2$), which is 0 iff i, j are even, i.e. $r^i s^j \in \{1, r^2\}$. Thus $\ker\bar{\psi} = \{1, r^2\} = \langle r^2\rangle = Z(D_8)$. *Check.* $|Z(D_8)| = 2$ matches $|\ker\bar{\psi}| = 2$, and $D_8/\langle r^2\rangle \cong \mathbb{Z}/2 \times \mathbb{Z}/2$ is the standard abelianization of D_8 — consistent because $\bar{\psi}$ lands in an abelian group and is onto.

Generators and relations as a chain of quotients. A presentation factors the passage from the free group to G through the normal closure. Schematically, with $S \hookrightarrow F(S)$ free, $N = \langle R \rangle^{F(S)}$ the normal closure of the relators, and $G = F(S)/N$:

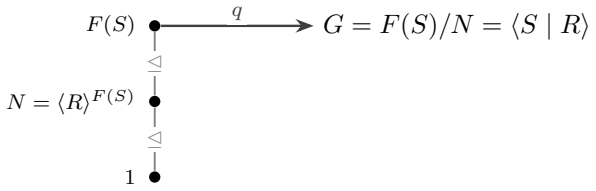

Diagram explanation. Objects: Left column: a subgroup lattice fragment with three nodes — the free group $F(S)$ at the top; the normal closure $N = \langle R \rangle^{F(S)}$, the smallest normal subgroup of $F(S)$ containing all relators; and the trivial group 1 at the bottom. Right node: the presentation group $G = F(S)/N = \langle S \mid R \rangle$.

Arrows: The two vertical edges (labeled $\trianglelefteq$) record normal containment: $N \trianglelefteq F(S)$ (reading top to bottom), and $1 \trianglelefteq N$ (trivially). These are inclusions of subgroups, not homomorphisms between separate groups. The horizontal arrow $q\colon F(S) \to G$ is the canonical surjective quotient homomorphism $q(w) = wN$.

What commutes: This picture is not a commutative square but a mixed lattice-and-map diagram. The key relation is: q is surjective with $\ker q = N$, so the kernel of the quotient map is exactly the subgroup sitting one level down from $F(S)$ in the lattice. The first isomorphism theorem then gives $F(S)/N \cong G$ as displayed.

Why it commutes: N is normal in $F(S)$ (ensured by taking the normal closure, not merely $\langle R \rangle$), so $F(S)/N$ is a group and q is a homomorphism. Every relator $r \in R$ satisfies $q(r) = rN = N = 1_G$ because $r \in N$; and conversely every $n \in N$ maps to 1_G. The lattice segment $1 \trianglelefteq N \trianglelefteq F(S)$ records the two-step normal series that the quotient collapses to G.

Why this matters here: This diagram summarizes the entire structure of a group presentation as a factorization: $S \hookrightarrow F(S)$ builds the free object, N is cut out by the relations, and q collapses N to the identity. It gives a visual reason why N must be a *normal* subgroup: the quotient must be a group, so the kernel of any homomorphism is normal.

Concrete example: $S = \{r, s\}$, $R = \{r^n, s^2, srsr\}$, $G = D_{2n}$. Here N is the normal closure of $\{r^n, s^2, srsr\}$ inside $F_2 = F(\{r, s\})$; q sends $r \mapsto \bar{r}$ and $s \mapsto \bar{s}$, with $\bar{r}^n = \bar{s}^2 = \bar{s}\bar{r}\bar{s}\bar{r} = 1$ in D_{2n}.

Common pitfall: Students sometimes think N is merely $\langle R \rangle$ (the cyclic or subgroup generated by the relators) rather than the *normal* closure. If R is not already normal-closed, $F(S)/\langle R \rangle$ is not well defined as a quotient by a normal subgroup, and the resulting object might not be a group.

Takeaway: The point of this diagram is that a presentation $\langle S \mid R \rangle$ is a two-step construction — build $F(S)$ freely, then collapse exactly the normal closure of the relators — and the quotient map q is what connects the free world to the presented group.

Here each "$\trianglelefteq$" is normal containment in the chain $1 \leq N \leq F(S)$, and q is the quotient map of Theorem 6.3.9. The relators R generate N *as a normal subgroup* (not merely as a subgroup), which is what allows finitely many relations to encode an infinite kernel.

Finitely generated vs. finitely presented; the word problem.

Proposition 6.3.15 (Finitely presented examples and a non-example)**.**

1. *Every finite group G is finitely presented: take $S = G$ (finite) and for R the multiplication-table relations $\{\, gh\,(g{\cdot}h)^{-1} : g, h \in G \,\}$, a finite set.*
2. *Free abelian groups are finitely presented: $\mathbb{Z}^k = \langle x_1, \ldots, x_k \mid [x_i, x_j]\ (1 \leq i < j \leq k) \rangle$.*
3. *There exist finitely* generated *groups that are not finitely* presented *(e.g. suitable wreath products / lamplighter-type groups); "finitely generated" is strictly weaker than "finitely presented".*

Proof. (1) With $S = G$ the canonical surjection $\pi\colon F(G) \to G$ (Corollary 6.3.6) has kernel containing every $gh(gh)^{-1}$; conversely these relations force the multiplication table, so the quotient by their normal closure is a group of order $\leq |G|$ admitting a surjection onto G, hence $\cong G$. Both S and R are finite. (2) The

commutator relations $[x_i, x_j] = 1$ make all generators commute, so the quotient is the free *abelian* group on $x_1, \dots, x_k$, namely $\mathbb{Z}^k$; here $|S| = k$ and $|R| = \binom{k}{2}$ are finite. (3) Is a theorem of combinatorial group theory (B. H. Neumann); we cite it without proof, the point being only that the two finiteness notions genuinely differ. □

Theorem 6.3.16 (The word problem; Novikov–Boone)**.** *For a general finite presentation $\langle S \mid R \rangle$ there is* no algorithm *that, given a word w in $S \cup S^{-1}$, decides whether $w = 1$ in $\langle S \mid R \rangle$. That is, the word problem for finitely presented groups is* ***undecidable****.*

Sketch / discussion. For a *free* group the word problem is trivial: $w = 1$ iff its reduced form is the empty word, decided by cancellation. The subtlety is the normal closure: to test $w = 1$ in $\langle S \mid R \rangle$ one must decide whether $w \in N = \langle R \rangle^{F(S)}$, i.e. whether w is a product of conjugates of relators. Novikov (1955) and Boone (1958) constructed an explicit finite presentation for which this membership question encodes the halting problem; since the halting problem is undecidable, so is the word problem for that presentation. Consequently the *isomorphism problem* (deciding whether two finite presentations give isomorphic groups) is undecidable as well. For specific nice classes — finite groups, free groups, finitely generated abelian groups, hyperbolic groups — the word problem *is* solvable; undecidability is a statement about the worst case over all finite presentations. □

Worked Example 6.3.17 (Word problem in an easy case vs. the general warning)**.** In $\mathbb{Z}^2 = \langle a, b \mid aba^{-1}b^{-1} \rangle$ decide whether $w = a^2ba^{-1}b^{-1}a^{-1}$ equals 1. Then explain why the same kind of decision is not algorithmic for arbitrary presentations.

Recognition. The single relator makes the group abelian, so "$w = 1$" reduces to summing exponents (an easy, decidable instance); the general warning is the Novikov–Boone theorem.

Solution. The relator $aba^{-1}b^{-1} = [a, b]$ forces $ab = ba$, so $\mathbb{Z}^2$ is free abelian. In an abelian group w depends only on its total exponent of a and of b. For $w = a^2ba^{-1}b^{-1}a^{-1}$: exponent of a is $2 + (-1) + (-1) = 0$; exponent of b is $1 + (-1) = 0$. Both are 0, so $w = a^0b^0 = 1$ in $\mathbb{Z}^2$. *Check.* Rearranging via $ab = ba$: $a^2ba^{-1}b^{-1}a^{-1} = a^2a^{-1}a^{-1}\,bb^{-1} = a^0b^0 = 1$. *Why not always so:* this worked because one relation gave a normal form (exponent sums). For a general finite R there is no uniform normal form to read off, and Novikov–Boone shows no algorithm can substitute for one.

Caution. "Finitely generated" does *not* imply "every subgroup is finitely generated," nor does it imply "finitely presented." For free groups: F_2 is finitely generated, yet it contains a free subgroup of *infinite* rank (the commutator subgroup F_2' is free on infinitely many generators). And "finitely presented" is strictly stronger than "finitely generated" by Proposition 6.3.15(3). Do not conflate these three notions.

Remark 6.3.3 (Summary of the universal-property bookkeeping). Two universal properties govern this section, each saying "a map on generators extends uniquely, once the right conditions hold":

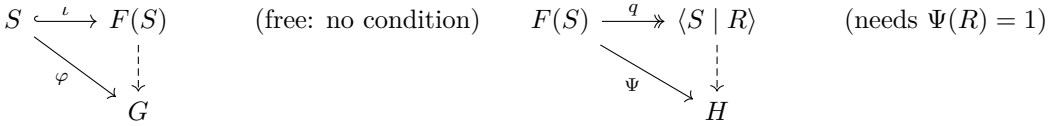

Diagram explanation. Objects: Left summary triangle: the set S; the free group $F(S)$; an arbitrary group G. Right summary triangle: the free group $F(S)$; the presentation $\langle S \mid R \rangle = F(S)/N$ (a quotient of $F(S)$); and an arbitrary target group H.

Arrows: Left: $\iota\colon S \to F(S)$ (canonical letter-inclusion) and $\varphi\colon S \to G$ (any set map); the dashed arrow is the unique homomorphism $\Phi\colon F(S) \to G$ extending φ. Right: $q\colon F(S) \twoheadrightarrow \langle S \mid R \rangle$ (canonical surjective quotient) and $\Psi\colon F(S) \to H$ (homomorphism induced by some $\psi\colon S \to H$); the dashed arrow is the unique $\bar{\Psi}\colon \langle S \mid R \rangle \to H$ when $\Psi(R) = \{1\}$.

What commutes: Left: $\Phi \circ \iota = \varphi$ (unconditionally). Right: $\bar{\Psi} \circ q = \Psi$ (only when $\Psi(r) = 1_H$ for all $r \in R$).

Why it commutes: Left: φ is a set map with no conditions, so Φ always exists (universal property of $F(S)$). Right: Ψ kills N by assumption, so it descends to a well-defined map on the coset space $F(S)/N$. The two diagrams look structurally identical, but the left has no side condition while the right requires $\Psi(R) = 1$.

Why this matters here: This pair is the remark's pedagogical punchline — it puts both universal properties side by side so the student can see the structural parallel and the single difference: the free-group property is unconditional, while the presentation property adds one relation-checking requirement. Together they explain why free groups are "maximally flexible" and presentations are "free groups with constraints."

Concrete example: Left: $S = \{x\}$, $G = \mathbb{Z}$, $\varphi(x) = 1$; then $\Phi\colon F_1 \to \mathbb{Z}$ sends $x^m \mapsto m$, no check needed. Right: same Ψ plus relation x^n; $\Psi(x^n) = n$, which is nonzero in $\mathbb{Z}$, so $\bar{\Psi}$ does NOT factor through $\langle x \mid x^n \rangle = \mathbb{Z}/n$; one must instead use $G = \mathbb{Z}/n$ as the target and verify $\Psi(x^n) = 0$.

Common pitfall: The two triangles look identical — students sometimes apply the free-group rule (no check) to a presentation, forgetting to verify the relations hold in H. The annotation "(needs $\Psi(R) = 1$)" is the crucial distinction.

Takeaway: The point of this diagram is that the only difference between building a map out of a free group and building one out of a presentation is whether the relators are sent to the identity in the target.

Diagram explanation. Objects: This is the right-hand summary triangle: $F(S)$ (the free group on generators S); $\langle S \mid R \rangle = F(S)/N$ (the presented group, a quotient); and H (any group playing the role of the "target" into which the relators vanish).

Arrows: $q\colon F(S) \twoheadrightarrow \langle S \mid R \rangle$ is the quotient map (surjective, kills N). $\Psi\colon F(S) \to H$ is the free-extension of $\psi\colon S \to H$ (no condition yet). The dashed $\bar{\Psi}\colon \langle S \mid R \rangle \to H$ is the induced homomorphism, whose existence requires and depends on $\Psi(r) = 1_H$ for all $r \in R$ (the annotation on the right of the diagram).

What commutes: $\bar{\Psi} \circ q = \Psi$: starting at $F(S)$, going right through q then down through $\bar{\Psi}$ equals going diagonally through Ψ. This holds exactly when $N \subseteq \ker \Psi$, which is equivalent to $R \subseteq \ker \Psi$, i.e. $\Psi(R) = \{1_H\}$.

Why it commutes: Well-definedness: for any $w \in F(S)$ and $n \in N$, $\Psi(wn) = \Psi(w)\Psi(n) = \Psi(w) \cdot 1_H = \Psi(w)$, so $\bar{\Psi}$ assigns the same value to every element of the coset wN. This is von Dyck's theorem in miniature.

Why this matters here: The remark places this triangle next to the free-group triangle as a contrast: the dashed arrow in the free-group case is always there, while here it is conditional. The annotation "(needs $\Psi(R) = 1$)" is the entire extra hypothesis of von Dyck.

Concrete example: $\langle S \mid R \rangle = \mathbb{Z}/n = \langle x \mid x^n \rangle$, $H = \mathbb{Z}/m$. $\psi(x) = 1 \in \mathbb{Z}/m$. $\Psi(x^n) = n \bmod m$. The dashed $\bar{\Psi}$ exists iff $m \mid n$; e.g. for $m = n$ it is the identity, for $m \nmid n$ it does not factor.

Common pitfall: The dashed arrow is drawn as already present in the diagram, which tempts students to assume it always exists. It does not: without $\Psi(R) = \{1\}$, Ψ does not descend to the quotient. The dashed style signals "existence to be proved," not "automatic."

Takeaway: The point of this diagram is that factoring a homomorphism through a quotient group requires — and is entirely equivalent to — the homomorphism killing the normal subgroup being quotiented out.

The first (Theorem 6.3.3) is unconditional; the second (Theorem 6.3.9) requires only that the relators map to the identity. Together they say: *a group is completely determined, up to isomorphism, by how you generate it and which relations you impose* — the content of "generators and relations."

Exercises (from the text).

1. Let F_1 and F_2 be free groups of finite rank. Prove that $F_1 \cong F_2$ if and only if they have the same rank. What facts do you need in order to extend your proof to infinite ranks (where the result is also true)?
2. Prove that if $|S| > 1$ then $F(S)$ is non-abelian.
3. Prove that the commutator subgroup of the free group on 2 generators is not finitely generated (in particular, subgroups of finitely generated groups need not be finitely generated).
4. Prove that every nonidentity element of a free group is of infinite order.
5. Establish a finite presentation for A_4 using 2 generators.
6. Establish a finite presentation for S_4 using 2 generators.
7. Prove that the following is a presentation for the quaternion group of order 8:

$$Q_8 = \langle a, b \mid a^2 = b^2,\ a^{-1}ba = b^{-1} \rangle.$$

8. Use presentations to find the orders of the automorphism groups of the groups $\mathbb{Z}_2 \times \mathbb{Z}_4$ and $\mathbb{Z}_4 \times \mathbb{Z}_4$.

9. Prove that $\mathrm{Aut}(Q_8) \cong S_4$.

10. This exercise exhibits an automorphism of S_6 that is not inner (hence, together with Exercise 19 in Section 4.4 it shows that $|\mathrm{Aut}(S_6) : \mathrm{Inn}(S_6)| = 2$). Let $t_1' = (1\ 2)(3\ 4)(5\ 6)$, $t_2' = (1\ 4)(2\ 5)(3\ 6)$, $t_3' = (1\ 3)(2\ 4)(5\ 6)$, $t_4' = (1\ 2)(3\ 6)(4\ 5)$, and $t_5' = (1\ 4)(2\ 3)(5\ 6)$. Show that $t_1', \ldots, t_5'$ satisfy the following relations:

$$(t_i')^2 = 1 \text{ for all } i,$$

$$(t_i' t_j')^2 = 1 \text{ for all } i \text{ and } j \text{ with } |i-j| \geq 2, \text{ and}$$

$$(t_i' t_{i+1}')^3 = 1 \text{ for all } i \in \{1,2,3,4\}.$$

Deduce that $S_6 = \langle t_1', \ldots, t_5' \rangle$ and that the map

$$(1\ 2) \mapsto t_1',\ (2\ 3) \mapsto t_2',\ (3\ 4) \mapsto t_3',\ (4\ 5) \mapsto t_4',\ (5\ 6) \mapsto t_5'$$

extends to an automorphism of S_6 (which is clearly not inner since it does not send transpositions to transpositions). [Use the presentation for S_6 described in Example 5.]

11. Let S be a set. The group with presentation (S, R), where $R = \{[s,t] \mid s,t \in S\}$ is called the *free abelian group* on S – denote it by $A(S)$. Prove that $A(S)$ has the following universal property: if G is any abelian group and $\varphi : S \to G$ is any set map, then there is a unique group homomorphism $\Phi : A(S) \to G$ such that $\Phi|_S = \varphi$. Deduce that if A is a free abelian group on a set of cardinality n then $A \cong \mathbb{Z} \times \mathbb{Z} \times \cdots \times \mathbb{Z}$ (n factors).

12. Let S be a set and let c be a positive integer. Formulate the notion of a *free nilpotent group* on S of nilpotence class c and prove it has the appropriate universal property with respect to nilpotent groups of class $\leq c$.

13. Prove that there cannot be a nilpotent group N generated by two elements with the property that *every* nilpotent group which is generated by two elements is a homomorphic image of N (i.e., the specification of the class c in the preceding problem was necessary).

Practice problems.

1. Let $F = F(\{a,b\})$ be the free group on two generators. Reduce each of the following to its normal form: (a) $(ab^{-1})(ba^2)$, (b) $(a^2b)^{-1}$, (c) $(aba^{-1})(ab^{-1}a^{-1})$.

2. Let $F = F(\{a,b\})$. Show that $\langle a^2, b\rangle$ is a proper subgroup of F, and exhibit a reduced word of F that does not lie in it. (Hint: build a homomorphism $F \to \mathbb{Z}/2\mathbb{Z}$ that kills a^2 and b but not a.)

3. Give a presentation $\langle S \mid R\rangle$ for each of the following groups, and in each case justify it by naming a group of the stated order satisfying the relations together with a matching normal-form bound: (a) $\mathbb{Z}/6\mathbb{Z}$, (b) $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, (c) the dihedral group of order 10.

4. Let $G = \langle x, y \mid x^3 = y^2 = 1,\ yxy^{-1} = x^{-1}\rangle$. Identify G up to isomorphism and list its elements as reduced words of the form $x^i y^j$ with $0 \leq i < 3$, $0 \leq j < 2$.

5. Use the universal property to produce the unique homomorphism $\varphi\colon F(\{a,b\}) \to \mathrm{Sym}_3$ with $\varphi(a) = (1\,2\,3)$ and $\varphi(b) = (1\,2)$. Compute $\varphi(abab)$ and $\varphi([a,b])$, where $[a,b] = a^{-1}b^{-1}ab$, and deduce that $[a,b] \neq 1$ in $F(\{a,b\})$.

6. Let N be the normal closure of $\{a^2, b^2, (ab)^2\}$ in $F = F(\{a,b\})$. Identify F/N up to isomorphism, explaining how the three relators force a and b to be commuting involutions.

7. Prove that the abelianization $F(S)/F(S)'$ of the free group on S is the free abelian group on S, and use this to compute the abelianization of $F(\{a,b,c\})$.

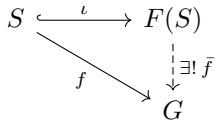
8. Let $G = \langle a, b \mid a^4 = 1,\ b^2 = a^2,\ bab^{-1} = a^{-1}\rangle$. Show that $|G| = 8$ and identify G as Q_8. (Hint: produce a normal form $a^i b^j$ with $0 \leq i < 4$, $j \in \{0,1\}$ for the upper bound, then a surjection onto Q_8 for the lower bound.)

9. Decide which of the following assignments extend to homomorphisms out of $F(\{a,b\})$, and explain in each case why no relations need to be checked: (a) $a \mapsto (1\,2)$, $b \mapsto (3\,4)$ into Sym_4; (b) $a \mapsto \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, $b \mapsto \left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right)$ into $\mathrm{GL}_2(\mathbb{Z})$. In each case describe the image.

10. Let $G = \langle x, y \mid x^2 = y^2 = 1 \rangle$ be the infinite dihedral group. Show that $\langle xy \rangle$ is an infinite cyclic normal subgroup of index 2, and conclude that $G \cong \mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$.

Additional exercises.

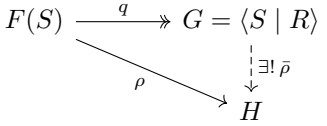
1. Prove that the free group $F(S)$ with $|S| \geq 2$ has trivial center. (Pick distinct $a, b \in S$; show that an element z commuting with both a and b must, by comparing reduced words, be the empty word. Conclude $Z(F(S)) = 1$.)



2. Show that the trivial group admits both presentations $\langle a, b \mid a,\ b \rangle$ and $\langle a, b \mid aba^{-1}b^{-2},\ bab^{-1}a^{-2} \rangle$, thereby illustrating that distinct presentations may define isomorphic groups. (The second is the classic non-obvious example: read its relators as the conjugation relations $aba^{-1} = b^2$ and $bab^{-1} = a^2$, so each generator conjugates the other to its square; abelianizing then forces $a = b = 1$, and a short argument shows the relations collapse the full group to 1 as well.)

3. Prove that the free group $F(S)$ with $|S| \geq 2$ is not solvable by exhibiting a nontrivial element of each term $F^{(i)}$ of the derived series. (Use that $[a, b] \neq 1$ lies in $F^{(1)} = F'$, and that each $F^{(i)}$ is a nonabelian free group, so its commutator subgroup $F^{(i+1)}$ is again nontrivial.) Conclude that $F(S)$ is neither solvable nor nilpotent.

4. Let $F(\{x_1, \ldots, x_n\})$ be free of rank n and fix $0 \leq k \leq n$. Prove that killing the last $n - k$ generators recovers a free group of smaller rank, $\langle x_1, \ldots, x_n \mid x_{k+1}, \ldots, x_n \rangle \cong F(\{x_1, \ldots, x_k\})$; in particular $\langle a, b \mid b \rangle \cong F(\{a\}) \cong \mathbb{Z}$. (Identify the normal closure of the killed generators and apply the universal property of the quotient.)



Commutative-diagram exercises.

1. (Universal property of $F(S)$.) For the free group $F(S)$ with inclusion $\iota\colon S \to F(S)$ and any set map $f\colon S \to G$ into a group G, complete and prove existence and uniqueness of the dashed arrow in

   State precisely what "$\bar{f}$ extends f" means as commutativity of the triangle, and use uniqueness to show that two homomorphisms out of $F(S)$ agreeing on $\iota(S)$ coincide. Instantiate with $S = \{x, y\}$, $G = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $x \mapsto (1, 0)$, $y \mapsto (0, 1)$, and identify the resulting map with the abelianization $F_2 \twoheadrightarrow \mathbb{Z} \times \mathbb{Z}$ followed by reduction mod 2.

2. (Von Dyck factorization.) Let $G = \langle S \mid R \rangle = F(S)/N$ with quotient map $q\colon F(S) \to G$, where N is the normal closure of R, and let $\rho\colon F(S) \to H$ be a homomorphism with $\rho(r) = 1$ for every $r \in R$. Show that the dashed map exists and is unique in

   and identify this factorization as the universal property of G. Instantiate with $G = \langle r, s \mid r^5,\ s^2,\ srsr \rangle \cong D_{10}$, $H = O(2)$, with r a rotation by $72°$ and s a reflection; verify the relations and explain why the induced $\bar{\rho}$ is injective, so D_{10} is the geometric symmetry group of the regular pentagon.

3. (A free presentation of $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.) Complete and prove exactness of

$$1 \longrightarrow N \hookrightarrow F(\{a, b\}) \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \longrightarrow 1,$$

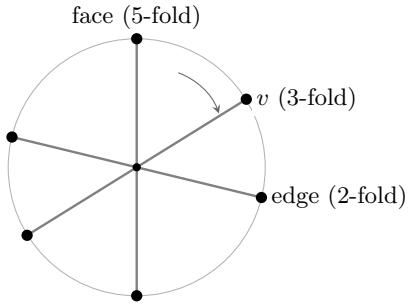
where $\pi(a) = (1, 0)$ and $\pi(b) = (0, 1)$. Show π is surjective, and describe $N = \ker \pi$ as the normal closure of the explicit relators $\{a^2,\, b^2,\, [a, b]\}$, explaining the role of each.

4. (Naturality of $S \mapsto F(S)$.) Let $\phi\colon G \to G'$ be a homomorphism, let S generate G and S' generate G' with $\phi(S) \subseteq S'$, and let $\pi\colon F(S) \to G$, $\pi'\colon F(S') \to G'$ be the canonical surjections. Writing $F(\phi|_S)\colon F(S) \to F(S')$ for the homomorphism induced by the set map $S \to S'$, prove that the square

$$\begin{array}{ccc} F(S) & \xrightarrow{\ \pi\ } & G \\ {\scriptstyle F(\phi|_S)}\downarrow & & \downarrow{\scriptstyle \phi} \\ F(S') & \xrightarrow{\ \pi'\ } & G' \end{array}$$

commutes. (Show both composites send a generator $s \in S$ to $\phi(\pi(s)) = \pi'(F(\phi|_S)(s))$, then invoke the previous uniqueness statement.) Interpret this as the naturality of the surjection π, i.e. the statement that $F \dashv U$ exhibits the free-group functor as left adjoint to the forgetful functor.

6.4 The Icosahedral Group and the Simplicity of A_5



The icosahedral group: class equation, simplicity, and $I \cong A_5$

The **icosahedral group** I is the group of rotational symmetries of a regular dodecahedron (equivalently, of its dual the icosahedron). It has order 60, and Artin uses it as the showcase application of the class equation: by splitting I into geometric conjugacy classes one reads off the class equation, and from the class equation alone the simplicity of I falls out by pure arithmetic. A second geometric observation — I permutes the five cubes inscribed in the dodecahedron — then identifies I with the alternating group A_5, so that A_5 is simple as well.

The rotations of the dodecahedron. A nontrivial rotation in SO(3) is determined by an axis and an angle. For the dodecahedron the axes come in three geometric types, and each type carries a definite rotation angle dictated by the local symmetry:

- **Vertex axes.** Through each of the 20 vertices (and the antipodal vertex) runs a 3-fold axis; the nontrivial rotations about it have angle $\pm 2\pi/3$, since three pentagonal faces meet at a vertex.
- **Face axes.** Through each of the 12 face centers (and the opposite face) runs a 5-fold axis; its rotations have angle $2\pi k/5$, $k = 1, 2, 3, 4$, because each face is a regular pentagon.
- **Edge axes.** Through each of the 30 edge midpoints (and the opposite edge midpoint) runs a 2-fold axis; the only nontrivial rotation about it has angle π.

Counting: the identity, $20{\cdot}2/2 = 20$ vertex rotations, $12{\cdot}4/2 = 24$ face rotations, and $30{\cdot}1/2 = 15$ edge rotations (each axis is shared by an antipodal pair of features, hence the division by 2) give $1 + 20 + 24 + 15 = 60 = |I|$. We now group these 60 rotations into conjugacy classes.

Theorem 6.4.1 (Class equation of the icosahedral group, Artin 7.4)**.** *The conjugacy classes of I are: the identity (size 1); the 20 vertex rotations of angle $\pm 2\pi/3$ (one class of size 20); the 12 face rotations of angle*

$2\pi/5$ *(size* 12*); the* 12 *face rotations of angle* $4\pi/5$ *(size* 12*); and the* 15 *edge rotations of angle* π *(size* 15*). Hence*

$$60 \;=\; 1 + 20 + 12 + 12 + 15.$$

Proof. Two rotations are conjugate in I exactly when one is carried to the other by a symmetry of the dodecahedron. Concretely, if $g \in I$ and ρ is the rotation of angle θ about an axis through a feature f (vertex, face center, or edge midpoint), then $g\rho g^{-1}$ is the rotation of the *same* angle θ about the axis through $g(f)$. Therefore the conjugacy class of a rotation is governed by the I-orbit of its axis together with its angle.

Vertex rotations. The 20 vertices form a single I-orbit (any vertex can be moved to any other by a rotation of the dodecahedron), so all the rotations ρ_v of angle $2\pi/3$ about a vertex axis are conjugate. They are also distinct: the same rotation is named by the spin $(v, 2\pi/3)$ and by $(-v, -2\pi/3)$ at the antipodal vertex, and $-2\pi/3 \neq 2\pi/3$, so the 20 vertices give 20 *distinct* rotations, forming one class of size 20.

Face rotations. The 12 faces form a single orbit. About a face axis the rotation of angle $2\pi/5$ is conjugate to no rotation of a different angle (angle is conjugation-invariant), so the 12 rotations of angle $2\pi/5$ form a class of size 12. Independently, the 12 rotations of angle $4\pi/5$ form a second class of size 12. (The angles $2\pi/5$ and $4\pi/5$ are *not* fused, since conjugation preserves the angle up to sign and $\pm 2\pi/5 \neq \pm 4\pi/5$. By contrast ρ and ρ^{-1} about a face *are* conjugate: ρ^{-1} is the rotation of angle $2\pi/5$ about the opposite face, and the faces form one orbit.)

Edge rotations. The 30 edges fall into 15 antipodal pairs sharing a 2-fold axis. The rotation of angle π about such an axis is named by (e, π) and equally by $(-e, -\pi)$; since $\pi = -\pi$, these are the *same* rotation, so the 30 edges give only 15 distinct half-turns. They form a single class of size 15.

Adding the class sizes, $1 + 20 + 12 + 12 + 15 = 60 = |I|$, which both verifies the count and shows we have found *all* conjugacy classes. □

Remark 6.4.1. The fact used throughout is that conjugation in a rotation group permutes axes while preserving angles: $g\,\rho(\ell, \theta)\,g^{-1} = \rho(g\ell, \theta)$ for the rotation about the line ℓ through angle θ. This is why each class is "an orbit of axes at a fixed angle." It also explains the subtle splitting of the face rotations into two classes of 12 rather than one of 24.

Normal subgroups are unions of classes. The bridge from the class equation to simplicity is Artin's Lemma 7.4.2, an immediate consequence of normality.

Lemma 6.4.2 (Normal subgroups are unions of conjugacy classes, Artin 7.4.2)**.** *Let* $N \trianglelefteq G$*. Then:*

1. *if* $x \in N$ *then the entire conjugacy class* $C(x) \subseteq N$*;*
2. N *is a union of conjugacy classes of* G*; and*
3. $|N|$ *is the sum of the sizes of the classes contained in* N*. In particular that sum, which always includes the class* $\{1\}$*, divides* $|G|$*.*

Proof. (1) If $x \in N$ and $g \in G$, normality gives $gxg^{-1} \in N$; ranging over all g yields $C(x) \subseteq N$. (2) Each element of N drags in its whole class by (1), so N is the union of the classes of its elements. (3) These classes are disjoint, so $|N|$ is the sum of their sizes; $1 \in N$ contributes $\{1\}$, and $|N| \mid |G|$ by Lagrange. □

Theorem 6.4.3 (The icosahedral group is simple, Artin 7.4.3)**.** I *is a simple group: its only normal subgroups are* 1 *and* I*.*

Proof. Let $N \trianglelefteq I$. By Lemma 6.4.2, $|N|$ is a sum of a sub-collection of the class sizes $\{1, 20, 12, 12, 15\}$ that necessarily includes the term 1, and $|N|$ divides 60. We check that no such sub-sum — other than 1 itself and the full 60 — divides 60. The divisors of 60 are $1, 2, 3, 4, 5, 6, 10, 12, 15, 20, 30, 60$. A candidate $|N|$ has the form $1 +$ (a subset of $\{20, 12, 12, 15\}$), i.e. one of

$$1, \;\; 13, \;\; 16, \;\; 21, \;\; 25, \;\; 28, \;\; 33, \;\; 36, \;\; 40, \;\; 45, \;\; 48, \;\; 60,$$

namely 1 plus a sum of some of $20, 12, 12, 15$. None of $13, 16, 21, 25, 28, 33, 36, 40, 45, 48$ divides 60. Hence the only possibilities are $|N| = 1$ (so $N = 1$) or $|N| = 60$ (so $N = I$). Therefore I is simple. □

Worked Example 6.4.4 (Why the term 1 is mandatory, and how it kills $|N|$)**.** Show that no normal subgroup of I can have order 15, even though 15 is a class size and $15 \mid 60$.

Recognition. By Lemma 6.4.2, a normal subgroup's order is a sum of class sizes that *must include* the identity class $\{1\}$. So "a single class of size 15" is not an admissible $|N|$.

Solution. If $N \trianglelefteq I$ had order 15, then N would be a union of classes including $\{1\}$, so $|N| = 1 +$ (sum of other class sizes) ≥ 1. To total 15 we would need the remaining classes to sum to 14, but the available class sizes are $20, 12, 12, 15$, and no sub-collection sums to 14. Hence $|N| = 15$ is impossible. *Check.* The genuine 15-element *subset* (the fifteen half-turns) is a union of one class but omits 1, so it is not even a subgroup — it does not contain the identity. The lemma's "includes $\{1\}$" clause is exactly what rules it out.

Worked Example 6.4.5 (Intersecting the class-sums with the divisors of 60)**.** Using only the class equation $60 = 1 + 20 + 12 + 12 + 15$, list every candidate order a proper nontrivial normal subgroup of I *could* have on divisibility grounds, and confirm each is excluded.

Recognition. Two constraints must hold simultaneously (Lemma 6.4.2 + Lagrange): $|N|$ is a class-sum containing 1, and $|N| \mid 60$. We intersect the two lists.

Solution. The class-sums containing 1 are $\{1, 13, 16, 21, 25, 28, 33, 36, 40, 45, 48, 60\}$ (each is 1 plus a subset of $\{20, 12, 12, 15\}$). The proper nontrivial divisors of 60 are $\{2, 3, 4, 5, 6, 10, 12, 15, 20, 30\}$. The intersection of the two lists is *empty*: no class-sum strictly between 1 and 60 is a divisor of 60. *Check.* Spot-check the "closest calls": $16 \nmid 60$ (60/16 is not an integer), $36 \nmid 60$, $40 \nmid 60$, $45 \nmid 60$. So the only surviving orders are 1 and 60, reproving Theorem 6.4.3.

The five inscribed cubes and the isomorphism $I \cong A_5$. Inside a regular dodecahedron one can inscribe exactly five cubes: the 8 vertices of each cube are 8 of the 20 vertices of the dodecahedron, and each cube uses its own diagonal directions. Every rotational symmetry of the dodecahedron permutes these five cubes, which gives an action of I on a 5-element set.

Theorem 6.4.6 ($I \cong A_5$, hence A_5 is simple, Artin 7.4.4)**.** *The action of I on the five inscribed cubes defines an isomorphism $I \cong A_5$. Consequently A_5 is a simple group.*

Proof. The action on the five cubes is a homomorphism $\varphi\colon I \to S_5$ (the associated permutation representation). Its kernel $\ker\varphi$ is a normal subgroup of I. Since I is simple (Theorem 6.4.3), $\ker\varphi$ is either 1 or all of I. It is not all of I, because the action is *nontrivial*: some rotation moves at least one cube. (For instance, a $2\pi/5$ rotation about a face axis cyclically permutes the five cubes.) Therefore $\ker\varphi = 1$ and φ is **injective**, identifying I with its image $\varphi(I) \leq S_5$.

Now compose φ with the sign homomorphism $\operatorname{sgn}\colon S_5 \to \{\pm 1\}$ to get $\operatorname{sgn}\circ\varphi\colon I \to \{\pm 1\}$. If this were surjective, its kernel would be a normal subgroup of I of index 2 — a *proper nontrivial* normal subgroup, impossible since I is simple. Hence $\operatorname{sgn}\circ\varphi$ is trivial, which means $\varphi(I) \subseteq \ker(\operatorname{sgn}) = A_5$. So φ maps I injectively into A_5.

Finally count: $|I| = 60 = |A_5|$, and an injection between finite sets of the same size is a bijection. Therefore $\varphi\colon I \to A_5$ is an isomorphism. As I is simple, the isomorphic group A_5 is simple too. □

Remark 6.4.2. The proof is a model of how simplicity is *used*: the only inputs about the action are (i) it gives a homomorphism into S_5 and (ii) it is nontrivial. Simplicity converts "nontrivial kernel-or-everything" into "injective," and converts "possible index-2 kernel" into "image lands in A_5." No explicit description of which permutation each rotation induces is needed. This same $I \cong A_5$ gives a geometric proof that A_5 is simple. (The simplicity of A_n for all $n \geq 5$ is proved separately: Artin, Theorem 7.5.4, by commutator computations with 3-cycles; D&F, Section 4.6, by induction on n starting from A_5.)

Worked Example 6.4.7 (Locating a generator's image: a face rotation is a 5-cycle)**.** Show that the image under φ of a rotation by $2\pi/5$ about a face axis is a 5-cycle in A_5, and confirm it is an even permutation (consistent with $\varphi(I) \subseteq A_5$).

Recognition. A 5-fold rotation has order 5 in I; under the injective φ its image has order 5 in S_5, and the only order-5 elements of S_5 are 5-cycles. The parity check then confirms it lands in A_5.

Solution. Let ρ be a rotation of angle $2\pi/5$ about a face axis. Then $|\rho| = 5$. Since φ is injective (proof of Theorem 6.4.6), $|\varphi(\rho)| = |\rho| = 5$ in S_5. An element of S_5 has order 5 iff its cycle type is a single

5-cycle (cycle types of S_5 are 1^5, $2\,1^3$, $2^2 1$, $3\,1^2$, $3\,2$, $4\,1$, 5, and only the 5-cycle has order 5). So $\varphi(\rho)$ is a 5-cycle, e.g. $(1\,2\,3\,4\,5)$ after labelling the cubes. *Check.* A 5-cycle is a product of 4 transpositions, so $\operatorname{sgn}(\varphi(\rho)) = (-1)^4 = +1$: it is even, hence in A_5, exactly as the theorem requires. Geometrically, ρ cyclically permutes the five inscribed cubes, which is visibly a 5-cycle.

Worked Example 6.4.8 (Reading the class equation of A_5 off the geometry)**.** Use the isomorphism $I \cong A_5$ to predict the class equation of A_5, and compare with the cycle types of A_5.

Recognition. An isomorphism carries conjugacy classes to conjugacy classes of the same size, so the geometric class equation of I *is* the class equation of A_5. We then match each geometric class to a cycle type.

Solution. Transporting Theorem 6.4.1 across $I \cong A_5$ gives the class equation

$$|A_5| = 60 = 1 + 15 + 20 + 12 + 12.$$

Matching sizes to cycle types in A_5: the identity (1); the 15 products of two disjoint transpositions such as $(1\,2)(3\,4)$ (the edge half-turns, order 2, size 15); the 20 three-cycles such as $(1\,2\,3)$ (the vertex rotations, order 3, size 20); and the 24 five-cycles, which in A_5 split into *two* classes of 12 (the two face-rotation classes of angles $2\pi/5$ and $4\pi/5$). *Check.* In S_5 all 24 five-cycles are conjugate, but in A_5 a 5-cycle and its non-conjugate partner are separated because the conjugating permutation is necessarily odd; this is precisely the geometric splitting of the two 5-fold rotation classes of size 12. The totals agree: $1 + 15 + 20 + 12 + 12 = 60$.

Caution. Do not expect the two face-rotation classes (angles $2\pi/5$ and $4\pi/5$) to merge into one class of size 24. Conjugation preserves the rotation angle up to sign, so a rotation by $\pm 2\pi/5$ is never conjugate to one by $\pm 4\pi/5$; the two classes stay separate, giving the $12 + 12$ split. (A 5-fold rotation *is* conjugate to its inverse: a half-turn about a 2-fold axis perpendicular to the 5-fold axis reverses that axis.) The same phenomenon on the A_5 side is the fact that the 24 five-cycles, a *single* class in S_5, break into *two* classes of 12 inside A_5: a 5-cycle σ is conjugate in A_5 to σ^{-1} but not to σ^2. Collapsing them would wrongly make the class equation read $60 = 1 + 20 + 24 + 15$ and would no longer match the arithmetic that forces simplicity.

6.5 The Todd–Coxeter Coset Enumeration Algorithm

The Todd–Coxeter coset enumeration algorithm

A presentation $G = \langle x_1, \ldots, x_m \mid r_1, \ldots, r_k \rangle$ tells us *which* group we mean but offers no direct way to compute in it: the word problem is undecidable in general. The Todd–Coxeter algorithm sidesteps this by computing something more concrete — the action of G by right multiplication on the set of right cosets of an explicitly given subgroup H. From the resulting *coset table* we read off the index $[G : H]$, a permutation representation $G \to \operatorname{Sym}([G : H])$, and — when H is understood — often the order and even the isomorphism type of G. It is, in Artin's words, an amazing method for determining the operation of a finite group on the cosets of a subgroup.

Setup and conventions. We are given $G = \langle x_1, \ldots, x_m \mid r_1, \ldots, r_k \rangle$ together with a subgroup $H = \langle h_1, \ldots, h_s \rangle$, where each h_j is a word in the free group F whose image generates H. The tables read most naturally for *right* cosets Hg, on which G acts by right multiplication. This forces the "do-it-first" reading of composition: a product gh acts as "first multiply by g, then by h," so for permutations acting on the right one reads left to right,

$$(2\,3\,4) \circ (1\,2\,3) \;=\; (1\,2)(3\,4),$$

the opposite order from the usual functional convention. Cosets are recorded as indices $1, 2, 3, \ldots$, with index 1 standing for the coset H itself. One does not know in advance how many indices are needed; new ones are introduced as required.

Definition 6.5.1 (Coset table)**.** Let $G = \langle x_1, \ldots, x_m \mid r_1, \ldots, r_k \rangle$ act on the right cosets of H, labelled by indices. A **coset table** records, for each index i and each generator x_t, the index $i \cdot x_t$ to which right multiplication by x_t sends i. A **partial operation** is a coset table some of whose entries are not yet filled in: the action of some generators on some indices has been assigned, the rest left blank. A **relation table** for a relator $r = a_1 a_2 \cdots a_\ell$ has the letters $a_1, \ldots, a_\ell$ across the top and one row per index i; the row begins and ends with the same index i, the intermediate entries being $i \cdot a_1$, $i \cdot a_1 a_2$, and so on.

The four rules. The action of G on right cosets is completely pinned down by four facts. They are what we enforce when filling tables.

Theorem 6.5.2 (The Todd–Coxeter rules, Artin 7.11.3)**.** *The operation of $G = \langle x_1, \dots, x_m \mid r_1, \dots, r_k \rangle$ on the set of right cosets of $H = \langle h_1, \dots, h_s \rangle$ satisfies, and is determined by:*

(R1) Each generator acts as a permutation. *For every x_t, the assignment $i \mapsto i \cdot x_t$ is a bijection of the index set; in particular the x_t-column of the coset table lists every index exactly once, and x_t^{-1} acts as its inverse.*

(R2) Each relation fixes every coset. *For every relator r_j and every index i, $i \cdot r_j = i$; the relation table of r_j has equal entries at both ends of each row.*

(R3) Each generator of H fixes coset 1. *For every h_j, $1 \cdot h_j = 1$.*

(R4) The operation is transitive. *Every index lies in the orbit of 1; equivalently no index is introduced that is not needed.*

Proof. (R1) holds because group elements are invertible: right multiplication by x_t on cosets has right multiplication by x_t^{-1} as a two-sided inverse, so it is a bijection. (R2) holds because a relator r_j represents the identity of G, and the identity fixes every coset; thus tracing i through the letters of r_j returns to i. (R3) holds because $h_j \in H$, so $Hh_j = H$, i.e. index 1 (the coset H) is fixed. (R4) holds because right multiplication makes the coset space a single orbit of G through H: any coset Hg is $1 \cdot g$. That these four together *determine* the action is the content of Theorem 6.5.6 below. □

Method (Running Todd–Coxeter by hand)**.** *Trigger.* You have a finite presentation $\langle x_1, \dots, x_m \mid r_1, \dots, r_k \rangle$ and an explicit subgroup H, and you want the index, a permutation representation, or the order of G.

1. **Seed with (R3).** Set index $1 = [H]$. For each generator h_j of H, enter $1 \cdot h_j = 1$.
2. **Define forward when stuck.** If some entry $i \cdot x_t$ is unknown and no rule forces its value, *introduce a new index j* and set $i \cdot x_t = j$ (step (ii) below). Record the inverse entry $j \cdot x_t^{-1} = i$ as well, by (R1).
3. **Close relation tables with (R2).** In each relator's table, fill rows from both ends; whenever the two ends of a row meet, you learn a new entry.
4. **Coincidences via (R1)/(R2).** If two routes force $i \cdot x_t = j$ and $i \cdot x_t = j'$, then $j = j'$: *equate* the indices (step (i)) and merge their rows, propagating any further forced equalities.
5. **Stop** when the table is complete and consistent with all four rules. Always prefer equating (step (i)) over introducing (step (ii)), and make the definitions (ii) systematically (e.g. always fill the first blank entry of the table); then for finite G this terminates.

Remark 6.5.1. The two atomic steps are exactly Artin's (7.11.9): *(i)* equate indices i and j when the rules force $i = j$, and *(ii)* pick a generator x_t and an index i with $i \cdot x_t$ undetermined and set $i \cdot x_t = j$ for a new index j. One never equates indices unless equality is forced. For finite groups the process terminates provided step (i) is given preference and the definitions (ii) are made systematically, so that every surviving index eventually has all its entries determined; with a careless order of definitions it can run forever.

Worked example: a presentation of S_3. We carry out the algorithm in full on Artin's first example, where the answer is small enough to check by hand.

Worked Example 6.5.3 (Index 3 for $\langle x, y, z \mid x^3, y^2, z^2, xyz \rangle$ over $H = \langle z \rangle$)**.** Let $G = \langle x, y, z \mid x^3,\ y^2,\ z^2,\ xyz \rangle$ and $H = \langle z \rangle$. Enumerate the right cosets of H, find the index, and read off the permutation representation.

Recognition. Pure Todd–Coxeter: seed with (R3) on the generator z of H, define forward by step (ii) when stuck, then close the relation tables for x^3, y^2, z^2, xyz by (R2), merging via (R1).

Solution. Seed. By (R3), z fixes index 1: $1 \cdot z = 1$, and $1 \cdot z^2 = 1$ is then automatic (consistent with the relator z^2).

Open up x. Nothing yet tells us $1 \cdot x$, so introduce index 2: $1 \cdot x = 2$ (step (ii)). Likewise $2 \cdot x$ is unknown, so introduce index 3: $2 \cdot x = 3$. Now (R2) on the relator x^3 says $1 \cdot x^3 = 1$, and since $1 \cdot x^2 = 3$ we are forced to $3 \cdot x = 1$. The relation table for xxx closes:

	x	x	x	
1	2	3	1	1
2	3	1	2	2
3	1	2	3	3

$\Longrightarrow$ $x = (1\,2\,3)$ (so far).

The same index appears at both ends of every row, as (R2) demands.

Open up y. We do not know $1 \cdot y$, so introduce index 4: $1 \cdot y = 4$. By (R2) the relator y^2 forces $4 \cdot y = 1$, giving $y = (1\,4)\cdots$.

Use xyz to find a coincidence. The relator xyz fixes every index (R2). Trace index 2: from the relation table for xyz, we have $1 \cdot x = 2$, so the row for 1 reads $1 \xrightarrow{x} 2 \xrightarrow{y} ? \xrightarrow{z} 1$; since z fixes 1 we need the y-step to land on the index that z sends to 1, namely 1 itself, forcing $2 \cdot y = 1$. But we already have $4 \cdot y = 1$, and y is a permutation (R1), so $2 = 4$. We replace 4 by 2.

Complete. With 4 merged into 2 we have $y = (1\,2)$. Re-reading xyz on index 3: $3 \xrightarrow{x} 1 \xrightarrow{y} 2 \xrightarrow{z} 3$ forces $2 \cdot z = 3$, hence $3 \cdot z = 2$ and $z = (2\,3)$. All four relation tables now close. The final tables are

	x	y	z
1	2	2	1
2	3	1	3
3	1	3	2

$\Longrightarrow$ $x = (1\,2\,3)$, $y = (1\,2)$, $z = (2\,3)$.

Check. Three distinct indices give index $[G : H] = 3$. The relations hold under the right-action convention: $x^3 = \mathrm{id}$, $y^2 = \mathrm{id}$, $z^2 = \mathrm{id}$, and $x \circ y \circ z = (1\,2\,3)(1\,2)(2\,3) = \mathrm{id}$. Since $z = (2\,3) \neq \mathrm{id}$ but $z^2 = 1$, $|z| = 2$, so $|H| = 2$; the counting formula gives $|G| = |H|\,[G : H] = 2 \cdot 3 = 6$. The three permutations generate S_3, so $G \cong S_3$.

Remark 6.5.2. A coset table always yields the index (the number of distinct indices) and a permutation representation $G \to \mathrm{Sym}([G : H])$. It need not, on its own, give $|G|$: if $H = 1$ the cosets correspond bijectively to group elements and the representation determines G completely, but at the cost of many indices. Choosing a larger H keeps the table small while still revealing $|G|$ once $|H|$ is known — the trade-off illustrated by the two examples here.

Worked example: the tetrahedral group is A_4. The payoff example uses the algorithm to *verify a presentation*: that $\langle x, y \mid x^3, y^3, (xy)^2 \rangle$ has order 12 and is the tetrahedral group $T \cong A_4$.

Worked Example 6.5.4 ($T = \langle x, y \mid x^3, y^3, (xy)^2 \rangle$ has order 12 and equals A_4)**.** Let $G = \langle x, y \mid x^3,\ y^3,\ (xy)^2 \rangle$ and $H = \langle x \rangle$. Show $[G : H] = 4$ and $|H| = 3$, conclude $|G| = 12$, and identify the permutation representation.

Recognition. Again Todd–Coxeter with $H = \langle x \rangle$: (R3) makes x fix index 1. We expect $|H| \leq 3$ (since x^3 is a relation), so showing index 4 and $|x| = 3$ pins $|G| = 12$. Note $(xy)^2 = xyxy$, the form in which we run the relation table.

Solution. Seed. By (R3), x fixes 1: $1 \cdot x = 1$ (and $1 \cdot x^2 = 1 \cdot x^3 = 1$).

Open up y. Set $1 \cdot y = 2$ (step (ii)), then $2 \cdot y = 3$, and (R2) on y^3 forces $3 \cdot y = 1$, so $y \supseteq (1\,2\,3)$. We do not yet know $2 \cdot x$; set $2 \cdot x = 4$ (new index), and by x^3 (R2) on the row of 2, $2 \xrightarrow{x} 4 \xrightarrow{x} ? \xrightarrow{x} 2$, while $4 \cdot x$ is new — take $4 \cdot x = 3'$; closing forces these into a 3-cycle $(2\,4\,\cdot)$. Running the relation table for $xyxy$ from both ends and equating the forced coincidences (preferring step (i)) collapses the new indices until exactly four remain: the row of 1 reads $1 \xrightarrow{x} 1 \xrightarrow{y} 2 \xrightarrow{x} 4 \xrightarrow{y} 1$, and since already $3 \cdot y = 1$ this forces $4 = 3$; the x-cycle becomes $(2\,3\,3')$, and renaming $3'$ as 4 gives the completed coset table

	x	y
1	1	2
2	3	3
3	4	1
4	2	4

$\Longrightarrow$ $x = (2\,3\,4)$, $y = (1\,2\,3)$.

Verify the rules on the table. Relation x^3: $x = (2\,3\,4)$ has order 3, fixing 1. Relation y^3: $y = (1\,2\,3)$ has order 3. Relation $(xy)^2$: $x \circ y = (2\,3\,4) \circ (1\,2\,3) = (1\,2)(3\,4)$, whose square is the identity. All three relations fix every index, and x fixes index 1 as required by (R3).

Counting. There are four indices, so $[G : H] = 4$. The permutation $x = (2\,3\,4)$ has order 3, not 1, so $|x| = 3$ and $|H| = 3$. Hence $|G| = |H|\,[G : H] = 3 \cdot 4 = 12$, the order of T. *Check.* The von Dyck map $G \to T$ onto the rotation group of the tetrahedron is onto and both groups have order 12, so it is an isomorphism: the relations $x^3, y^3, (xy)^2$ are defining relations for T. Moreover $x = (2\,3\,4)$ and $y = (1\,2\,3)$ are even permutations generating Alt(4) (indeed they generate a group of order 12 of even permutations, which is all of A_4), so $T \cong A_4$.

A cautionary example: bad relations collapse the group.
