Worked Example 6.5.5 ($\langle x, y \mid x^3, y^3, yxyxy\rangle$ over $H = \langle y\rangle$ collapses)**.** Run Todd–Coxeter on $G = \langle x, y \mid x^3,\ y^3,\ yxyxy\rangle$ with $H = \langle y\rangle$ and identify G.

Recognition. The mechanics are identical, but here the relation $yxyxy$ over-constrains the table and forces a chain of coincidences (step (i)) collapsing every index into 1. This is the warning that any slip — or any genuinely strong relation — forces total collapse.

Solution. Seed. (R3): $1 \cdot y = 1$. *Open up x:* $1 \cdot x = 2$, $2 \cdot x = 3$, and x^3 forces $3 \cdot x = 1$, tentatively $x = (1\,2\,3)$. Now examine the relation table for $yxyxy$ on index 2. Working the row from the left gives one value for $2 \cdot (\cdots)$ and from the right another; the two ends meet and force $2 = 3$. Feeding $2 = 3$ back into the table for $x^3 = xxx$ then forces $2 = 1$. Only one index survives. *Check.* With a single index $1 = [H]$ there is one coset, so $H = G$. The group is generated by y with $y^3 = 1$, hence G is cyclic of order (dividing) 3. The lesson: $[G : H] = 1$ signals $H = G$; here the extra relation $yxyxy$ forced collapse, exactly as "bad" relations are meant to.

Subgroups generated by words. In each example H was generated by a single generator of G, which is what makes (R3) trivial to apply. If instead $H = \langle h\rangle$ for a *word* h, Artin's device is to introduce a new generator u and a new relation $u^{-1}h = 1$ (so $u = h$); then G is unchanged up to isomorphism and $H = \langle u\rangle$ is generated by a generator. Repeat once per generator of H.

Caution. A coset table bounds $|G|$ only *through* $|H|$. The table by itself gives the index $[G : H]$ and a permutation representation, never $|G|$ in isolation; you must independently determine $|H|$ (often from the relations, as $|x| = 3$ above). And the algorithm is unforgiving: a single wrong entry forces spurious coincidences and collapses the operation. Always prefer equating forced indices (step (i)) to introducing new ones (step (ii)), and make the definitions systematically — together these guarantee termination for finite G, and the preference for step (i) keeps the table small.

Why the algorithm is correct. The procedure manipulates a finite index set I with a partial operation, applying steps (i) (equate forced indices) and (ii) (introduce a new index). We never equate unless forced. When it halts on a consistent table, that table *is* the coset action.

Theorem 6.5.6 (Correctness of Todd–Coxeter, Artin 7.11.10)**.** *Suppose finitely many repetitions of steps (i) and (ii) yield a consistent table compatible with the rules* (R1)–(R4)*. Then the table defines a permutation representation of G that, after a suitable renumbering, is the representation of G on the right cosets of H. (For finite G, with preference given to step (i) and the definitions (ii) made systematically, so that every surviving index eventually has all its entries determined, the process always terminates.)*

Proof sketch. Write $G = \langle x_1, \ldots, x_n \mid r_1, \ldots, r_k\rangle$ and let I^* be the final index set. Because the table makes each x_t act as a permutation (R1) and every relator act trivially (R2), the von Dyck / universal property of the presentation gives a homomorphism $G \to \mathrm{Sym}(I^*)$, hence a right action of G on I^*; this action is transitive (R4) and H fixes index 1 (R3). Let C be the set of right cosets of H. Build a bijection $\varphi^*\colon I^* \to C$ compatible with the G-action, inductively along the construction: start with $\varphi_0(1) = [H]$. For a step (ii) that sets $i \cdot x_t = j$ (new), define $\varphi'(j) = [Hg\,x_t]$ where $\varphi(i) = [Hg]$, unchanged elsewhere. For a step (i) that equates i and j, the key lemma is that whenever the rules force $i = j$, already $\varphi(i) = \varphi(j)$ — true because the genuine coset action satisfies the rules — so φ descends to the collapsed index set. Surjectivity of φ^* is transitivity of G on C. Injectivity uses that the stabilizer of $[H]$ is exactly H: if $i = 1 \cdot a$ and $j = 1 \cdot b$ have $\varphi^*(i) = \varphi^*(j)$, i.e. $Ha = Hb$, then $ba^{-1} \in H$ stabilizes index 1, so $i = 1 \cdot a = 1 \cdot b = j$. Thus φ^* is a G-equivariant bijection, identifying the table's action with the coset action. □

Remark 6.5.3. The structure of one step is captured by the diagram below: index i, carrying the coset $\varphi(i) = Hg$, is sent by generator x_t to a (possibly new) index j carrying Hgx_t. The square *commutes* precisely because φ is compatible with the action — which is what steps (i) and (ii) preserve.

$$\begin{array}{ccc} i & \xrightarrow{\;x_t\;} & j \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\varphi} \\ Hg & \xrightarrow[\cdot\, x_t]{} & Hg\,x_t \end{array}$$

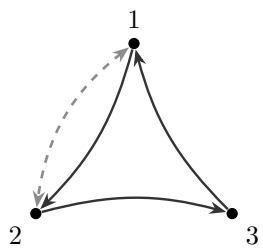
Diagram explanation. Objects: The upper row holds two elements of the index set I^*: the source index i (representing the coset Hg) and the target index j (representing $Hg\,x_t$). The lower row holds the actual right cosets of H in G: Hg on the left and $Hg\,x_t$ on the right. Both rows live inside the respective sets where G acts, but at different levels of abstraction — indices versus actual cosets.

Arrows: The top horizontal arrow sends index i to index j by the partial table entry $i \cdot x_t = j$; this records rule (R1), the permutation action of generator x_t on indices. The bottom horizontal arrow sends coset Hg to coset $Hg\,x_t$ by right multiplication by x_t, the genuine coset action of G. Both vertical arrows are instances of the inductive bijection $\varphi\colon I^* \to C$ from the proof: $\varphi(i) = Hg$ and $\varphi(j) = Hg\,x_t$.

What commutes: The square commutes: going right-then-down equals going down-then-right, i.e. $\varphi(i \cdot x_t) = \varphi(i) \cdot x_t$, or explicitly $\varphi(j) = Hg\,x_t$.

Why it commutes: Take the index i with $\varphi(i) = Hg$. Along the top then down: i maps to $j = i \cdot x_t$ by the table entry, then $\varphi(j)$ is defined (at step (ii)) to be $\varphi(i) \cdot x_t = Hg\,x_t$. Along the down then right: $\varphi(i) = Hg$ maps by right multiplication to $Hg\,x_t$. Both paths land on $Hg\,x_t$. Well-definedness at step (i): when two indices are equated because two table paths force the same value, φ sends both to the same coset (since the genuine coset action already satisfies the rules), so φ descends consistently to the collapsed index.

Why this matters here: This square is the key lemma in the correctness proof of Todd–Coxeter: every step (ii) that introduces a new index j for $i \cdot x_t$ is justified by defining $\varphi(j) = Hg\,x_t$, and every step (i) that merges indices is safe because φ already identifies them. The diagram organizes why the algorithm produces a G-equivariant bijection, not merely a table.



Concrete example: In the S_3 computation with $H = \langle z \rangle$, take $i = 1$ and $x_t = x$. The table entry $1 \cdot x = 2$ gives $j = 2$. The bijection sends $\varphi(1) = H$ and $\varphi(2) = Hx$. Right multiplication sends $H \cdot x = Hx$. Both paths agree.

Common pitfall: Students often think φ is given in advance and the square is just a check. In fact φ is built inductively: each step (ii) defines φ on a new index by the commutativity requirement, and each step (i) checks that this commutativity is not contradicted. The diagram records a definition, not a coincidence.

Takeaway: The point of this diagram is that each table entry $i \cdot x_t = j$ is secretly the statement that φ intertwines the two actions of x_t, and the entire algorithm is the inductive construction of this intertwining bijection.

Reading every such square for every generator and index recovers the entire coset operation — which is exactly the claim of Theorem 6.5.6.

We close with a schematic of the coset action just computed for S_3: the three indices $1, 2, 3$ with the edges of the two generators $x = (1\,2\,3)$ (the 3-cycle, drawn around the triangle) and $y = (1\,2)$ (the transposition).

solid: $x = (1\,2\,3)$ dashed: $y = (1\,2)$

Diagram explanation. Objects: Three nodes labelled 1, 2, 3 represent the three right cosets of $H = \langle z \rangle$ in S_3: coset $1 = H$, coset $2 = Hx$, coset $3 = Hx^2$. The diagram is not an abstract group; it is the coset space S_3/H (as a set with G-action), and the nodes are the output of the Todd–Coxeter algorithm.

Arrows: Solid directed arrows (drawn around the triangle, style `cgr`) show $x = (1\,2\,3)$ acting by right multiplication: $1 \to 2 \to 3 \to 1$. The dashed double-headed arrow between 1 and 2 shows $y = (1\,2)$ acting as a transposition: it swaps cosets 1 and 2 and fixes 3. (The third generator $z = (2\,3)$ is not drawn; it swaps 2 and 3 and fixes 1.) Each arrow is the permutation action of a generator of G on the index set.

What commutes: There is no single commutativity equation here, but the diagram encodes the permutation representation $\rho\colon G \to \mathrm{Sym}(\{1,2,3\})$ defined by the coset table: $\rho(x) = (1\,2\,3)$, $\rho(y) = (1\,2)$, $\rho(z) = (2\,3)$, and the relations $x^3 = y^2 = z^2 = xyz = \mathrm{id}$ all hold as permutations.

Why it commutes: Trace relation x^3: follow the solid cycle $1 \to 2 \to 3 \to 1$ — three steps return to the start, confirming $\rho(x)^3 = \mathrm{id}$. Trace y^2: the dashed arrow $1 \leftrightarrow 2$ applied twice is the identity. Trace xyz on index 1: x sends $1 \to 2$, then y sends $2 \to 1$, then z fixes 1 (z swaps $2, 3$, so $1 \cdot z = 1$) — result 1, confirming rule (R2).

Why this matters here: The diagram is the visual payoff of the S_3 worked example. It displays the concrete permutation representation extracted from the completed coset table, confirming that the three rules (R1)–(R3) produce a genuine action of G and that $G \cong S_3$ (generated by a 3-cycle and a transposition on three points).

Concrete example: This picture IS the concrete example: $G = S_3$, $H = \langle z \rangle \cong \mathbb{Z}/2\mathbb{Z}$, index 3. The three nodes are the three vertices of a regular triangle. The solid arrows are the rotation x and the dashed arrow is the reflection y.

Common pitfall: The arrows show the action of G on the coset set, not the Cayley graph of G itself. In the Cayley graph of S_3 there would be six nodes (one per group element); here there are only three because we divided by H. Reading this as the Cayley graph would suggest $|G| = 3$, which is wrong.

Takeaway: The point of this diagram is that the completed coset table yields a concrete permutation representation of G on the index set, and drawing the action makes the structure of S_3 geometrically immediate.

The third generator $z = (2\,3)$ swaps indices 2 and 3, completing the action of S_3 on the three cosets of $H = \langle z \rangle$.

6.6 Groups of Order 12 and 21

Groups of order 12 and 21: explicit realizations

The Sylow theorems do more than count subgroups: they let us pin down, up to isomorphism, every group of a given small order. We follow Artin's treatment of two instructive cases, $|G| = 21$ and $|G| = 12$. The first is the smallest *odd* order at which a *nonabelian* group appears (with a prime-to-prime semidirect structure); the second is the first order with *several* factors, where the classification genuinely branches. Throughout, $n = p^e m$ with $p \nmid m$, a Sylow p-subgroup has order p^e, and the number s_p of Sylow p-subgroups satisfies $s_p \mid m$ and $s_p \equiv 1 \pmod{p}$ (Third Sylow Theorem). The payoff in each case is an *explicit* matrix model that proves the would-be group does not collapse.

Method (Sylow census for a fixed small order n)**.** *Trigger.* You must list all groups of order $n = p^e m$ (here $n = 21$ or 12).

1. **Count each s_p.** Solve $s_p \mid m$, $s_p \equiv 1 \pmod{p}$ for every prime $p \mid n$. Whenever the only solution is $s_p = 1$, that Sylow subgroup is *normal* (Corollary: one Sylow p-subgroup $\iff$ it is normal).

2. **Split into a product.** If a normal K and a complement H meet trivially and $|H||K| = n$, the set map $H \times K \to G$ is a bijection, so every element is uniquely hk.

3. **Read the conjugation action.** $K \trianglelefteq G$ makes H act on K by conjugation; the action (trivial or not) names the group. Trivial action $\Rightarrow$ direct product (abelian when H, K are); nontrivial action $\Rightarrow$ a presentation $\langle x, y \mid \dots \rangle$.

4. **Defeat collapse with a model.** A presentation only *bounds* the order from above. Exhibit explicit matrices satisfying the relations and generating a group of the right order to prove the group exists.

Groups of order 21

Theorem 6.6.1 (Artin 7.7.7(c))**.** *There are exactly two isomorphism classes of groups of order* 21*: the cyclic group* C_{21}*, and the nonabelian group*

$$G \;=\; \langle\, x, y \mid x^7 = 1,\; y^3 = 1,\; yxy^{-1} = x^2 \,\rangle.$$

Proof. Let $|G| = 21 = 3 \cdot 7$. By the Third Sylow Theorem $s_7 \mid 3$ and $s_7 \equiv 1 \pmod 7$, forcing $s_7 = 1$: the Sylow 7-subgroup $K = \langle x \rangle$ is *normal*. Also $s_3 \mid 7$ and $s_3 \equiv 1 \pmod 3$, so $s_3 \in \{1, 7\}$. Let $H = \langle y \rangle$ be a Sylow 3-subgroup. Since $K \trianglelefteq G$ and $H \cap K = \{1\}$ (orders 7 and 3 are coprime), the product map $H \times K \to G$ is injective, hence bijective by counting; every element is $x^i y^j$ with $0 \le i < 7$, $0 \le j < 3$.

Because $K \trianglelefteq G$, conjugation gives $yxy^{-1} = x^i$ for some i with $1 \le i < 7$. Now $y^3 = 1$ forces a constraint on i:

$$x \;=\; y^3 x\, y^{-3} \;=\; y^2 x^i y^{-2} \;=\; y\, x^{i^2} y^{-1} \;=\; x^{i^3},$$

so $i^3 \equiv 1 \pmod 7$. The cubes that equal 1 modulo 7 are $i \in \{1, 2, 4\}$ (indeed $1^3 = 1$, $2^3 = 8 \equiv 1$, $4^3 = 64 \equiv 1$).

- $i = 1$: then $yx = xy$, so G is abelian; with H, K both normal and cyclic of coprime orders, $G \cong C_3 \times C_7 \cong C_{21}$.
- $i = 2$: the relations are $x^7 = 1$, $y^3 = 1$, $yxy^{-1} = x^2$. This is the nonabelian group; it exists by the matrix model of Example 6.6.2 below.
- $i = 4$: replace the generator y by y^2 (another generator of H, also of order 3). Since $y^2 x y^{-2} = x^{i^2} = x^{16} = x^2$, the exponent 4 is converted to 2; this is the *same* group as the $i = 2$ case.

Thus the only classes are C_{21} and the $i = 2$ group. □

Remark 6.6.1. The collapse one must rule out is genuine. Had the constraint admitted $i = 3$, then $yxy^{-1} = x^3$ would give, after the same y^3 computation, $x = x^{27} = x^6$, hence $x^5 = 1$; with $x^7 = 1$ this yields $x^{\gcd(5,7)} = x = 1$, and the "group of order 21" would degenerate to C_3. The exponent i being a cube root of unity mod 7 is exactly what prevents this.

Worked Example 6.6.2 (Matrices over $\mathbb{F}_7$ realizing the nonabelian group of order 21)**.** *Problem.* Exhibit explicit matrices that satisfy $x^7 = 1$, $y^3 = 1$, $yxy^{-1} = x^2$ and generate a group of order 21, proving the presentation does not collapse.

Recognition. Method step 4: kill collapse by a model. Since G must contain an element of order 7, work in $\mathrm{GL}_2(\mathbb{F}_7)$ where a unipotent shear has order 7, and choose y diagonal so that conjugation rescales the shear.

Solution. Over the field $\mathbb{F}_7$ put

$$x = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}, \qquad y = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}.$$

Then $x^k = \left(\begin{smallmatrix} 1 & k \\ 0 & 1 \end{smallmatrix}\right)$, so $x^7 = \left(\begin{smallmatrix} 1 & 7 \\ 0 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) = I$ in $\mathbb{F}_7$, and x has order 7. Next y is diagonal with entries of multiplicative order dividing 3: $2^3 = 8 \equiv 1 \pmod 7$, so $y^3 = I$ and y has order 3. Finally

$$y\, x\, y^{-1} = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 4 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} = x^2,$$

using $y^{-1} = \mathrm{diag}(4, 1)$ since $2 \cdot 4 = 8 \equiv 1$. All three relations hold, so $\langle x, y \rangle$ is a homomorphic image of the presented group and $|\langle x, y \rangle| \le 21$. Conversely $\langle x \rangle \cong C_7$ and $\langle y \rangle \cong C_3$ meet trivially, so $|\langle x, y \rangle| \ge 21$. Hence $\langle x, y \rangle$ has order exactly 21 and the group exists. *Check.* The relation forces $yx = x^2 y$, so $\langle x, y \rangle = \{x^i y^j : 0 \le i < 7,\, 0 \le j < 3\}$ has at most 21 elements; equality of the two bounds confirms order 21 and nonabelianness ($yx = x^2 y \ne xy$).

Groups of order 12

Theorem 6.6.3 (Artin 7.8.1)**.** *There are exactly five isomorphism classes of groups of order* 12*:*

$$C_4 \times C_3 \,(\cong C_{12}), \quad C_2 \times C_2 \times C_3 \,(\cong C_2 \times C_6), \quad A_4, \quad D_6, \quad Q$$

where D_6 *is the dihedral group of the regular hexagon (order* 12*) and*

$$Q = \langle\, x, y \mid x^4 = 1,\ y^3 = 1,\ xyx^{-1} = y^{-1} \,\rangle$$

is the dicyclic group of order 12 *(also written* Dic_3*).*

Proof. Let $|G| = 12 = 2^2 \cdot 3$, with Sylow 2-subgroup H (order 4, so $H \cong C_4$ or $H \cong C_2 \times C_2$) and Sylow 3-subgroup $K = \langle y \rangle \cong C_3$. The Third Sylow Theorem gives $s_2 \in \{1, 3\}$ and $s_3 \in \{1, 4\}$.

At least one of H, K *is normal.* If K is not normal then $s_3 = 4$. Four subgroups of prime order 3 pairwise intersect in $\{1\}$, so they account for $4 \cdot (3 - 1) = 8$ elements of order 3, leaving only $12 - 8 = 4$ elements not of order 3: the identity and the three elements lying outside all of them. A Sylow 2-subgroup H has order 4, meets each K_i trivially, and therefore must be exactly these four remaining elements. This forces H to be unique, so $s_2 = 1$ and $H \trianglelefteq G$. Thus not both $s_2 = 3$ and $s_3 = 4$ can occur.

Since some Sylow subgroup is normal and $H \cap K = \{1\}$, the set map $H \times K \to G$ is a bijection; every element is uniquely hk.

Case 1: H **and** K **both normal.** Then $G \cong H \times K$. With two choices of H this gives $C_4 \times C_3 \cong C_{12}$ and $C_2 \times C_2 \times C_3 \cong C_2 \times C_6$ — the abelian groups.

Case 2: K **not normal** ($s_3 = 4$). By the paragraph above $H \trianglelefteq G$ and G permutes the four conjugates $K_1, \ldots, K_4$ by conjugation, giving $\varphi\colon G \to S_4$. Each normalizer $N(K_i) = K_i$ has order 3, so only the identity fixes all four; φ is injective. The eight elements of order 3 map to the eight 3-cycles of S_4, which generate A_4. As $|G| = |A_4| = 12$, φ is an isomorphism $G \cong A_4$.

Case 3: K **normal,** H **not normal** ($s_2 = 3$). Then H acts on $K = \{1, y, y^2\}$ by conjugation; nontriviality (else $H \trianglelefteq G$) forces an $x \in H$ with $xyx^{-1} = y^2 = y^{-1}$.

- $H \cong C_4$, generated by x. Then $G = \langle x, y \rangle$ with $x^4 = 1$, $y^3 = 1$, $xyx^{-1} = y^{-1}$ — the group Q. It exists by the complex-matrix model of Example 6.6.4 and is the *dicyclic* group Dic_3.
- $H \cong C_2 \times C_2$. The stabilizer of y under the action of H on $\{y, y^2\}$ has order 2, so H contains $z \neq 1$ with $zy = yz$ and x with $xyx^{-1} = y^{-1}$, and $xz = zx$. The resulting group has $x^2 = z^2 = 1$ and x, z both inverting/centralizing y; it is the dihedral group D_6 of the hexagon (the only order-12 group not among the other four).

The five classes C_{12}, $C_2 \times C_6$, A_4, D_6, Q exhaust the possibilities. □

Worked Example 6.6.4 (Complex matrices realizing the dicyclic group Q of order 12)**.** *Problem.* With $\omega = e^{2\pi i/3}$ a primitive cube root of unity, exhibit complex matrices satisfying $x^4 = 1$, $y^3 = 1$, $xyx^{-1} = y^{-1}$ that generate a group of order 12.

Recognition. Method step 4 again: prove Q does not collapse by a model. Take y diagonal of order 3 (eigenvalues ω, ω^{-1}) and x a rotation-type matrix of order 4 that swaps the eigenvalues, so conjugation inverts y.

Solution. Put

$$x = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad y = \begin{pmatrix} \omega & 0 \\ 0 & \omega^{-1} \end{pmatrix}.$$

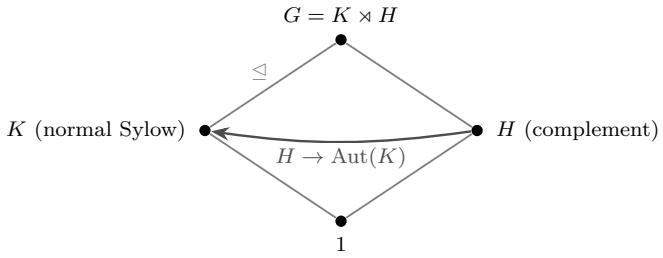
Then $x^2 = \left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = -I$ and $x^4 = I$, so x has order 4 (note $x^2 \neq I$). Since $\omega^3 = 1$ we get $y^3 = I$, and $y \neq I$, so y has order 3. For the conjugation, $x^{-1} = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ and

$$x\,y\,x^{-1} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} \omega & 0 \\ 0 & \omega^{-1} \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} \omega^{-1} & 0 \\ 0 & \omega \end{pmatrix} = y^{-1}.$$

All three relations hold, so $\langle x, y \rangle$ is a quotient of Q and has order ≤ 12. Conversely $\langle y \rangle \cong C_3$ is normalized by x, and $x^2 = -I$ lies in $\langle x \rangle \cong C_4$ but not in $\langle y \rangle$, so $\langle x, y \rangle$ contains the $4 \cdot 3 = 12$ distinct elements $x^i y^j$

$(0 \le i < 4,\ 0 \le j < 3)$. Hence $|\langle x, y\rangle| = 12$ and Q exists. *Check.* Q is *not* D_6: in D_6 every reflection has order 2, but here the only element of order 2 is $x^2 = -I$ (the unique central involution of a dicyclic group), so $Q \ncong D_6$. It is also nonabelian ($xy \neq yx$), so Q is the genuinely new fifth class.

Worked Example 6.6.5 (Distinguishing the three nonabelian order-12 groups by element orders)**.** Show A_4, D_6, and Q are pairwise non-isomorphic by counting elements of each order.



Recognition. Isomorphisms preserve the multiset of element orders. Tabulate orders from each model: A_4 as even permutations, D_6 as hexagon symmetries, Q via $x^i y^j$.

Solution. In A_4: the identity (1), three double transpositions of order 2, and eight 3-cycles of order 3 — *no* element of order 4 or 6. In $D_6 = \langle r, s \mid r^6, s^2, srsr\rangle$: the rotations r, r^5 of order 6, r^2, r^4 of order 3, r^3 of order 2, and six reflections of order 2 — so seven elements of order 2 and two elements of order 6. In Q: the central x^2 is the *only* element of order 2, the six elements $x^i y^j$ with i odd have order 4, y, y^2 have order 3, and $x^2 y, x^2 y^2$ have order 6. *Check.* The order-2 counts already separate all three: A_4 has 3, D_6 has 7, Q has 1. A single such invariant suffices, so A_4, D_6, Q are pairwise non-isomorphic, confirming five distinct classes together with the two abelian ones.

Caution. A presentation such as $\langle x, y \mid x^4, y^3, xyx^{-1}y\rangle$ for Q only proves $|Q| \le 12$ on its own. Writing down the relations is *not* a proof that a group of order 12 exists — exactly as with $i = 3$ for order 21, ill-chosen relations can silently collapse the group. The matrix realizations in Examples 6.6.2 and 6.6.4 supply the missing lower bound; never skip that step.

The structural picture

Both classifications run on the same engine: a normal Sylow subgroup K, a complement H acting by conjugation, and a matrix model to certify the nonabelian case. The diagram below records the action $H \to \mathrm{Aut}(K)$ that selects each group.

For $|G| = 21$: $K = C_7$, $H = C_3$, and the map $C_3 \to \mathrm{Aut}(C_7) \cong C_6$ is either trivial (C_{21}) or has image of order 3 (the nonabelian group, $i = 2$). For $|G| = 12$ in Case 3: $K = C_3$, H a Sylow 2-subgroup, and the map $H \to \mathrm{Aut}(C_3) \cong C_2$ is nontrivial, giving Q when $H \cong C_4$ and D_6 when $H \cong C_2 \times C_2$. The trivial action recovers the abelian products, and the "rogue" Case 2 ($s_3 = 4$, no normal Sylow 3-subgroup) produces the one group, A_4, that is not such a semidirect product over C_3.

Remark 6.6.2. The recurring slogan is that the Third Sylow Theorem first *normalizes* one Sylow subgroup, after which the entire classification is bookkeeping about a single conjugation action $H \to \mathrm{Aut}(K)$ — and the only real work is exhibiting matrices that prove the nonabelian candidate does not collapse. Artin's choices ($\mathbb{F}_7$ for order 21, complex roots of unity for order 12) are the smallest arenas in which an element of the required prime order is visibly available.

DF 6.1.16 Prove that $\mathbb{Q}$ has no maximal subgroups.

DF 6.1.17 Prove that $G^{(i)}$ is a characteristic subgroup of G for all i.

DF 6.1.20 Prove that $\Phi(G)$ is a characteristic subgroup of G.

DF 6.1.22 Compute $\Phi(S_3)$, $\Phi(A_4)$, $\Phi(S_4)$, $\Phi(A_5)$ and $\Phi(S_5)$.

DF 6.1.28 Prove that if p is a prime and $P = \mathbb{Z}_p \times \mathbb{Z}_{p^2}$ then $|\Phi(P)| = p$ and $P/\Phi(P) \cong \mathbb{Z}_p \times \mathbb{Z}_p$; deduce P has $p+1$ maximal subgroups.

DF 6.2.2 In $S_3 \times S_3$ exhibit a pair of Sylow 2-subgroups intersecting in the identity and another pair intersecting in a group of order 2.

DF 6.2.3 Prove that if $|G| = 380$ then G is not simple. [Count elements of odd prime order.]

DF 6.2.15 Classify groups of order 105.

DF 6.2.19 Prove that a group of order 36 has a normal Sylow 2-subgroup or a normal Sylow 3-subgroup.

DF 6.3.2 Prove that if $|S| > 1$ then the free group $F(S)$ is non-abelian.

DF 6.3.4 Prove that every nonidentity element of a free group has infinite order.

Artin 3.1 Prove the Fixed Point Theorem: a p-group acting on a finite set S with $p \nmid |S|$ has a fixed point.

Artin 3.2 Let Z be the center of G. Prove that if G/Z is cyclic then G is abelian (so $G = Z$).

Artin 3.4 Classify groups of order 8.

Artin 8.1 Which of the five groups of order 12 in the classification is isomorphic to $S_3 \times C_2$?

Artin 8.3 Determine the class equations of the groups of order 12.

Artin 8.4 Prove that a group of order $n = 2p$, with p prime, is either cyclic or dihedral.

Artin 9.1 In the free group on $\{x, y\}$, show $u = x^2$, $v = y^2$, $z = xy$ generate a subgroup free on u, v, z.

Artin 11.1 Complete the proof that the group of Example 7.11.8 is cyclic of order 3.

Artin 11.5 Let $G = \langle x, y \mid x^4 = 1,\ y^3 = 1,\ x^2 = yxy \rangle$. Prove G is trivial, by Todd–Coxeter and by working with the relations directly.

Fraleigh 18.1 Give isomorphic refinements of $\{0\} < 10\mathbb{Z} < \mathbb{Z}$ and $\{0\} < 25\mathbb{Z} < \mathbb{Z}$.

Fraleigh 18.2 Give isomorphic refinements of $\{0\} < 60\mathbb{Z} < 20\mathbb{Z} < \mathbb{Z}$ and $\{0\} < 245\mathbb{Z} < 49\mathbb{Z} < \mathbb{Z}$.

Fraleigh 18.3 Give isomorphic refinements of $\{0\} < \langle 9 \rangle < \mathbb{Z}_{54}$ and $\{0\} < \langle 2 \rangle < \mathbb{Z}_{54}$.

Fraleigh 18.4 Give isomorphic refinements of $\{0\} < \langle 9 \rangle < \langle 3 \rangle < \mathbb{Z}_{72}$ and $\{0\} < \langle 36 \rangle < \langle 12 \rangle < \mathbb{Z}_{72}$.

Fraleigh 18.5 Give isomorphic refinements of $\{(0,0)\} < (60\mathbb{Z}) \times \mathbb{Z} < (10\mathbb{Z}) \times \mathbb{Z} < \mathbb{Z} \times \mathbb{Z}$ and $\{(0,0)\} < \mathbb{Z} \times (80\mathbb{Z}) < \mathbb{Z} \times (20\mathbb{Z}) < \mathbb{Z} \times \mathbb{Z}$.

Fraleigh 18.6 Find all composition series of $\mathbb{Z}_{90}$ and show they are isomorphic.

Fraleigh 18.7 Find all composition series of $\mathbb{Z}_{48}$ and show they are isomorphic.

Fraleigh 18.8 Find all composition series of $\mathbb{Z}_5 \times \mathbb{Z}_5$.

Fraleigh 18.9 Find all composition series of $S_3 \times \mathbb{Z}_2$.

Fraleigh 18.10 Find all composition series of $\mathbb{Z}_2 \times \mathbb{Z}_5 \times \mathbb{Z}_7$.

Fraleigh 18.11 Find the center of $S_3 \times \mathbb{Z}_4$.

Fraleigh 18.12 Find the center of $S_3 \times D_4$.

Fraleigh 18.13 Find the ascending central series of $S_3 \times \mathbb{Z}_4$.

Fraleigh 18.14 Find the ascending central series of $S_3 \times D_4$.

Fraleigh 18.15 Correct, if needed, the stated definition of a composition series.

Fraleigh 18.16 Correct, if needed, the stated definition of a solvable group.

Fraleigh 18.17 Decide the truth of ten short statements on subnormal/normal/composition/principal series and solvability.

Fraleigh 18.19 Is the dihedral group D_4 solvable?

Fraleigh 20.1 Find the reduced form and the inverse of the reduced form of each of two given words.

Fraleigh 20.2 Compute the two products of Exercise 20.1 when $\{a, b, c\}$ is a basis for a free abelian group, and find their inverses.

Fraleigh 20.3 How many homomorphisms are there from a free group of rank 2 into (a) $\mathbb{Z}_4$, (b) $\mathbb{Z}_6$, (c) S_3?

Fraleigh 20.4 How many homomorphisms are there from a free group of rank 2 onto (a) $\mathbb{Z}_4$, (b) $\mathbb{Z}_6$, (c) S_3?

Fraleigh 20.5 How many homomorphisms are there from a free abelian group of rank 2 into (a) $\mathbb{Z}_4$, (b) $\mathbb{Z}_6$, (c) S_3?

Fraleigh 20.6 How many homomorphisms are there from a free abelian group of rank 2 onto (a) $\mathbb{Z}_4$, (b) $\mathbb{Z}_6$, (c) S_3?

Fraleigh 20.7 Correct, if needed, the stated definition of a reduced word.

Fraleigh 20.8 Correct, if needed, the stated definition of the rank of a free group.

Fraleigh 20.10 Decide the truth of ten short statements on free and free abelian groups.

Fraleigh 21.1 Give presentations of $\mathbb{Z}_4$ using one, two, and three generators.

Fraleigh 21.2 Give a presentation of S_3 involving three generators.

Fraleigh 21.3 Give the group tables for the octic group $\langle a, b \mid a^4 = 1, b^2 = 1, ba = a^3b\rangle$ and the quaternion group $\langle a, b \mid a^4 = 1, b^2 = a^2, ba = a^3b\rangle$.

Fraleigh 21.6 Correct, if needed, the stated definition of a consequence of a set of relators.

Fraleigh 21.7 Correct, if needed, the stated definition of isomorphic group presentations.

Fraleigh 21.8 Decide the truth of ten short statements on group presentations.

Medium

DF 6.1.2 Prove Parts 2 and 4 of Theorem 1 for G a finite nilpotent group, not necessarily a p-group.

DF 6.1.4 Prove that a maximal subgroup of a finite nilpotent group has prime index.

DF 6.1.5 Prove Parts 2 and 4 of Theorem 1 for G an infinite nilpotent group.

DF 6.1.6 Show that if $G/Z(G)$ is nilpotent then G is nilpotent.

DF 6.1.8 Prove that if p is prime and P is non-abelian of order p^3 then $|Z(P)| = p$ and $P/Z(P) \cong \mathbb{Z}_p \times \mathbb{Z}_p$.

DF 6.1.9 Prove that a finite group G is nilpotent iff $ab = ba$ whenever $a, b \in G$ with $(|a|, |b|) = 1$. [Use Part 4 of Theorem 3.]

DF 6.1.10 Prove that D_{2n} is nilpotent iff n is a power of 2. [Use Exercise 9.]

DF 6.1.11 Give another proof of Proposition 5 assuming G abelian, via the Fundamental Theorem of Finite Abelian Groups.

DF 6.1.15 Prove that $Z_i(D_{2^n}) = \langle r^{2^{n-1-i}}\rangle$ for $0 \le i \le n-2$ and $Z_{n-1}(D_{2^n}) = D_{2^n}$, where r is the rotation of order 2^{n-1}.

DF 6.1.19 Show that there is no group whose commutator subgroup is isomorphic to S_4. [Use DF 6.1.18.]

DF 6.1.21 Prove that if $N \trianglelefteq G$ then $\Phi(N) \leq \Phi(G)$; give an example where this fails when N is not normal.

DF 6.1.23 Prove that $\Phi(G)$ is the set of nongenerators of G (for $|G| > 1$).

DF 6.1.24 Let G be a finite group. Prove that $\Phi(G)$ is nilpotent. [Use Frattini's Argument on the Sylow subgroups of $\Phi(G)$.]

DF 6.1.27 Prove that P has exactly $\frac{p^r-1}{p-1}$ maximal subgroups when $P/\Phi(P)$ is elementary abelian of order p^r.

DF 6.1.29 Prove that if p is prime and P is non-abelian of order p^3 then $\Phi(P) = Z(P)$ and $P/\Phi(P) \cong \mathbb{Z}_p \times \mathbb{Z}_p$; deduce $p+1$ maximal subgroups.

DF 6.1.30 Let p be an odd prime, $P_1 = \mathbb{Z}_p \times \mathbb{Z}_{p^2}$ and P_2 the non-abelian group of order p^3 with an element of order p^2. Prove P_1 and P_2 have the same subgroup lattice.

DF 6.2.1 If $P \cap R = 1$ for all distinct $R \in \mathrm{Syl}_p(G)$, prove all distinct Sylow p-subgroups meet trivially, and the number of nonidentity p-power elements is $(|P|-1)[G : N_G(P)]$.

DF 6.2.4 Prove that there are no simple groups of order 80, 351, 3875 or 5313.

DF 6.2.8 Prove that there are no simple groups of order 792 or 918.

DF 6.2.9 Prove that there are no simple groups of order 336.

DF 6.2.10 Prove that there are no simple groups of order 4095, 4389, 5313 or 6669.

DF 6.2.11 Prove that there are no simple groups of order 4851 or 5145.

DF 6.2.14 Prove that there are no simple groups of order 144, 525, 2025 or 3159.

DF 6.2.18 Show that a group of order 12 with no subgroup of order 6 is isomorphic to A_4.

DF 6.2.20 Show that a group of order 24 with no element of order 6 is isomorphic to S_4.

DF 6.2.23 Prove that if A, B are normal subsets of a Sylow p-subgroup P and are conjugate in G, then they are conjugate in $N_G(P)$.

DF 6.2.24 Let $|G| = pqr$ with primes $p < q < r$. Prove a Sylow r-subgroup of G is normal.

DF 6.2.26 Prove or give a counterexample: a group of order 168 with more than one Sylow 7-subgroup is simple.

DF 6.3.1 Prove that finite-rank free groups F_1, F_2 are isomorphic iff they have equal rank; what is needed to extend to infinite rank?

DF 6.3.5 Establish a finite presentation for A_4 using 2 generators.

DF 6.3.6 Establish a finite presentation for S_4 using 2 generators.

DF 6.3.7 Prove that $Q_8 = \langle a, b \mid a^2 = b^2,\ a^{-1}ba = b^{-1} \rangle$ is a presentation of the quaternion group of order 8.

DF 6.3.8 Use presentations to find the orders of the automorphism groups of $\mathbb{Z}_2 \times \mathbb{Z}_4$ and $\mathbb{Z}_4 \times \mathbb{Z}_4$.

DF 6.3.12 Define the free abelian group $A(S)$ via the relators $[s,t]$; prove its universal property and deduce $A(S) \cong \mathbb{Z}^n$ for $|S| = n$.

Artin 3.3 For a non-abelian group G of order p^3: (a) possible orders of Z; (b) order of $Z(x)$ for $x \notin Z$; (c) possible class equations.

Artin 8.2 (a) Smallest n with S_n containing a subgroup isomorphic to the group (7.8.2); (b) find such a subgroup of $\mathrm{SL}_2(\mathbb{F}_5)$.

Artin 9.2 Establish a bijection between reduced closed words and conjugacy classes in the free group.

Artin 10.1 Prove the mapping properties of free groups and of quotient groups.

Artin 10.2 If $\varphi : G \to G'$ is surjective, $\varphi(S)$ generates G', and T generates $\ker \varphi$, prove $S \cup T$ generates G.

Artin 10.3 Can every finite group be presented by a finite set of generators and a finite set of relations?

Artin 10.4 For the free abelian group $G = \langle x, y \mid xyx^{-1}y^{-1} \rangle$, prove the mapping property: any u, v in an abelian A extend uniquely to $\varphi : G \to A$.

Artin 10.5 Prove that the group generated by x, y, z with the single relation $yxyz^{-2} = 1$ is free.

Artin 10.6 For characteristic subgroups: (a) prove characteristic implies normal and that Z is characteristic; (b) find the normal and characteristic subgroups of Q_8.

Artin 10.7 Prove the commutator subgroup C of G is characteristic and that G/C is abelian.

Artin 10.8 Determine the commutator subgroups of SO(2), O(2), the isometry group M of the plane, S_n, and SO(3).

Artin 10.9 For G the group of 3×3 upper unitriangular matrices over $\mathbb{F}_p$, find its center, commutator subgroup, and element orders.

Artin 11.3 Use Todd–Coxeter to find the order, and identify if possible, each of the ten groups $\langle x, y \mid \dots \rangle$ given by the listed relations.

Artin 11.4 How is normality of a subgroup $H \leq G$ reflected in the coset-operation table?

Artin 11.6 For the triangle group $G_{pqr} = \langle x, y, z \mid x^p, y^q, z^r, xyz \rangle$, prove it is D_n for $(2, 2, n)$, octahedral for $(2, 3, 4)$, icosahedral for $(2, 3, 5)$.

Artin 11.7 For reflections a, b, c of the plane in the sides of an equilateral triangle, set $x = ab$, $y = bc$, $z = ca$; prove x, y, z generate a triangle group.

Artin M.5 For subgroups $H, N \leq G$ with N normal: (a) find the kernels of the canonical map restricted to H and HN; (b) deduce the Second Isomorphism Theorem.

Artin M.6 For $N \leq H$ both normal in G, set $\bar{H} = H/N$, $\bar{G} = G/N$: (a) prove $\bar{H} \trianglelefteq \bar{G}$; (b) deduce the Third Isomorphism Theorem.

Fraleigh 18.18 Find a composition series of $S_3 \times S_3$; is $S_3 \times S_3$ solvable?

Fraleigh 18.20 For $G = \mathbb{Z}_{36}$ with the two given subnormal series, build chains (3) and (4) and exhibit the isomorphic factor groups in the rectangular array.

Fraleigh 18.21 Repeat the preceding for $\mathbb{Z}_{24}$ with the two given subnormal series.

Fraleigh 18.22 Let $H^* \trianglelefteq H$ and $K \leq G$. Show that $H^* \cap K$ is normal in $H \cap K$.

Fraleigh 18.23 If $\{e\} = H_0 < \cdots < H_n = G$ is subnormal with each $|H_{i+1}/H_i| = s_{i+1}$ finite, show $|G| = s_1 s_2 \cdots s_n$.

Fraleigh 18.24 Show that an infinite abelian group has no composition series.

Fraleigh 18.25 Show that a finite direct product of solvable groups is solvable.

Fraleigh 18.27 Show that for $n \geq 3$, D_n is solvable.

Fraleigh 18.32 Prove that a finite p-group is solvable.

Fraleigh 20.9 Discuss one instance where the phrase “It would seem obvious that” was used in the section.

Fraleigh 20.11 For a finitely generated abelian G and the stated notion of basis: (a) show $\{2, 3\}$ is not a basis for $\mathbb{Z}_4$ and find one; (b) show $\{1\}$ and $\{2, 3\}$ are bases for $\mathbb{Z}_6$; (c)–(d) relate to the free abelian basis and exhibit a divisor-chain basis for finite abelian groups.

Fraleigh 21.4 Determine all groups of order 14 up to isomorphism.

Fraleigh 21.5 Determine all groups of order 21 up to isomorphism.

Fraleigh 21.9 Show, using the order-mn criterion, that there are no non-abelian groups of order 15.

Fraleigh 21.10 Show that $\langle a, b \mid a^3 = 1, b^2 = 1, ba = a^2 b \rangle$ gives a group of order 6, and that it is non-abelian.

Fraleigh 21.12 Show by considering element orders that A_4 has no subgroup of order 6.

Fraleigh 21.14 Without using Exercise 13, prove that $\langle a, b \mid a^5 = 1, b^2 = 1, ba = a^3 b \rangle$ is a presentation of $\mathbb{Z}_2$.

Fraleigh 21.15 Is the group presented by the letters a through z as generators and all dictionary words as relators trivial? Justify.

Hard

DF 6.1.3 Prove G finite is nilpotent iff it has a normal subgroup of each order dividing $|G|$, and is cyclic iff it has a unique subgroup of each such order.

DF 6.1.7 Prove subgroups and quotients of nilpotent groups are nilpotent (also for infinite groups); give G with $H \trianglelefteq G$ where H, G/H nilpotent but G is not.

DF 6.1.18 Show that if G'/G'' and G''/G''' are both cyclic then $G'' = G'''$.

DF 6.1.25 For a p-subgroup P of G, $N \trianglelefteq G$ with $p \nmid |N|$, $\bar{G} = G/N$: prove $N_{\bar{G}}(\bar{P}) = \overline{N_G(P)}$ and $C_{\bar{G}}(\bar{P}) = \overline{C_G(P)}$ via Frattini's Argument.

DF 6.1.26 Prove the full set of properties of $\bar{P} = P/\Phi(P)$ for a finite p-group P, including Burnside's Basis Theorem and the embedding of prime-to-p automorphisms into $\mathrm{GL}_r(\mathbb{F}_p)$.

DF 6.1.31 Prove every minimal normal subgroup of a finite solvable group is an elementary abelian p-group.

DF 6.1.32 Prove every maximal subgroup of a finite solvable group has prime power index.

DF 6.1.33 Prove the Hall π-subgroup theorem for finite solvable groups: existence and conjugacy of Hall π-subgroups for every set π of primes.

DF 6.1.34 For a finite solvable G with no nontrivial normal subgroup of order prime to p, and P its largest normal p-subgroup, prove $C_G(P) \le P$, i.e. $C_G(P) = Z(P)$.

DF 6.1.35 Prove that a finite group in which every proper subgroup is nilpotent is solvable.

DF 6.1.36 Let $\varphi \in \mathrm{GL}(V)$ have p-power order, $V \neq 0$ over $\mathbb{F}_p$. Prove φ has a nonzero fixed point.

DF 6.1.37 For $\varphi \in \mathrm{GL}(V)$ of order 2 over $\mathbb{F}_2$, prove $v \mapsto v + \varphi(v)$ is a homomorphism with image fixed by φ, and deduce $\dim \mathrm{Fix}(\varphi) \ge \frac{1}{2} \dim V$.

DF 6.1.38 Prove that if a 2-group P has cyclic center and M has index 2 in P, then $Z(M)$ has rank ≤ 2.

DF 6.2.5 For a solvable G of order pm ($p \nmid m$) and $P \in \mathrm{Syl}_p(G)$ with $N_G(P) = P$, prove G has a normal subgroup of order m; where was solvability used?

DF 6.2.6 Prove that there are no simple groups of order 2205, 4125, 5103, 6545 or 6435.

DF 6.2.7 Prove that there are no simple groups of order 1755 or 5265.

DF 6.2.12 Prove that there are no simple groups of order 9555.

DF 6.2.13 Over all pairs of distinct Sylow p-subgroups choose P, Q with $|P \cap Q|$ maximal; show $N_G(P \cap Q)$ has more than one Sylow p-subgroup, any two meeting in $P \cap Q$.

DF 6.2.16 Prove that there are no non-abelian simple groups of odd order < 10000.

DF 6.2.17 (a) No simple group of order 420; (b) no simple groups of even order < 500 except orders 2, 60, 168, 360.

DF 6.2.21 Generalize Lemma 13: if $n_p \not\equiv 1 \pmod{p^k}$ there are distinct $P, R \in \mathrm{Syl}_p(G)$ with $P \cap R$ of index $\le p^{k-1}$ in both.

DF 6.2.22 For P, R distinct Sylow p-subgroups with $|P \cap R|$ maximal, prove $N_G(P \cap R)$ is not a p-group.

DF 6.2.25 Let G be simple of order p^2qr with p, q, r primes. Prove $|G| = 60$.

DF 6.2.27 Show that a set of points and lines satisfying (11)–(13) has incidence graph uniquely determined and equal to Figure 1.

DF 6.2.28 For a simple group of order $3^3 \cdot 7 \cdot 13 \cdot 409$, compute all permissible n_p for $p \in \{3, 7, 13, 409\}$ and reduce to a unique value each.

DF 6.2.29 Given the Sylow data for a hypothetical simple group of order $3^3 \cdot 7 \cdot 13 \cdot 409$, prove no such group exists. [Use the degree-819 representation.]

DF 6.2.30 For a simple group G of order 720, find as many properties as possible (Sylow numbers, Sylow types, conjugacy classes); does such a group exist?

DF 6.3.3 Prove that the commutator subgroup of the free group on 2 generators is not finitely generated.

DF 6.3.9 Prove that $\mathrm{Aut}(Q_8) \cong S_4$.

DF 6.3.10 Exhibit an outer automorphism of S_6 via the elements $t'_1, \ldots, t'_5$ and the stated relations, and deduce it extends to $\mathrm{Aut}(S_6)$.

DF 6.3.11 Formulate the free nilpotent group on S of class c and prove its universal property among nilpotent groups of class $\leq c$.

DF 6.3.13 Prove no nilpotent group N on two generators has every two-generated nilpotent group as a homomorphic image (so specifying the class c was necessary).

Artin 11.2 Use Todd–Coxeter to show the group of relations (7.8.2) has order 12 and the group of (7.7.8) has order 21.

Artin 11.8 For $G = \langle x, y, z \mid x^2, y^3, z^5, xyz \rangle$: prove $|G| = 60$, analyze the coset representations on G/H and G/K for the stated subgroups, and prove $G \cong A_5$.

Artin M.1 Classify groups generated by two elements x, y of order 2. [Use $z = xy$.]

Fraleigh 18.26 Show that if $H \trianglelefteq G$ with H and G/H solvable, then G is solvable.

Fraleigh 18.28 Show that a subgroup K of a solvable group G is solvable.

Fraleigh 18.29 For a composition series $\{H_i\}$ of G and a simple normal subgroup N, show the distinct groups among $H_0, H_i N$ form a composition series for G.

Fraleigh 18.30 For a composition series $\{H_i\}$, $N \trianglelefteq G$, and $\gamma : G \to G/N$, show the distinct $\gamma[H_i]$ form a composition series for G/N.

Fraleigh 18.31 Prove that a homomorphic image of a solvable group is solvable.

Fraleigh 18.33 Prove that a group with $2^n p^k$ elements is solvable if $p > 2^n$ is prime.

Fraleigh 20.12 Define a "blip group" G^* of G by its universal property; show any two are isomorphic, one exists for every G, and identify the concept (abelianization).

Fraleigh 20.13 Define a "blop group" on S by its universal property; show uniqueness up to isomorphism and existence, and identify the concept (free group).

Fraleigh 20.14 Characterize a free abelian group by a universal property, in the style of the preceding exercise.

Fraleigh 21.11 Show that $\langle a, b \mid a^3 = 1, b^2 = 1, ba = a^2 b \rangle$ is, up to isomorphism, the only non-abelian group of order 6, hence isomorphic to S_3.

Fraleigh 21.13 For $S = \{a^i b^j\}$ with the multiplication $(a^s b^t)(a^u b^v) = a^x b^y$ given by $x \equiv s + ur^t$, $y \equiv t + v$: prove S is a group iff $r^n \equiv 1 \pmod{m}$, and deduce $\langle a, b \mid a^m = 1, b^n = 1, ba = a^r b \rangle$ has order mn iff $r^n \equiv 1 \pmod{m}$.

Chapter 7

Introduction to Rings

7.1 Basic Definitions and Examples

Rings, domains, division rings, and fields

Definition 7.1.1 (Ring)**.** A *ring* is a set R together with two binary operations $+$ and $\cdot$ such that:

1. $(R, +)$ is an abelian group (with identity 0 and inverses $-a$);
2. $\cdot$ is associative: $(ab)c = a(bc)$ for all $a, b, c \in R$;
3. the distributive laws hold: $(a + b)c = ac + bc$ and $a(b + c) = ab + ac$.

R is *commutative* if $ab = ba$ for all a, b. R *has an identity* (or 1) if there is $1 \in R$ with $1 \cdot a = a \cdot 1 = a$ for all a. Unless stated otherwise our rings have an identity with $1 \neq 0$.

Definition 7.1.2 (Units, zero divisors)**.** Let R be a ring with 1.

- $u \in R$ is a *unit* if there is $v \in R$ with $uv = vu = 1$; the units form a group $R^\times$ under multiplication.
- A nonzero $a \in R$ is a *(left) zero divisor* if there exists $b \neq 0$ with $ab = 0$ (or $ba = 0$ for a right zero divisor).

Definition 7.1.3 (Domain, division ring, field)**.** Let R be a ring with $1 \neq 0$.

- R is an *integral domain* if R is commutative and has no zero divisors.
- R is a *division ring* if every nonzero element is a unit, i.e. $R^\times = R \setminus \{0\}$.
- R is a *field* if it is a commutative division ring.

Thus: field = commutative division ring $\implies$ integral domain.

Definition 7.1.4 (Subring)**.** A nonempty subset $S \subseteq R$ is a *subring* if S is closed under subtraction and multiplication (so $(S, +) \leq (R, +)$ and S is closed under $\cdot$). Then S is itself a ring. (D&F do not require $1_R \in S$.)

Proposition 7.1.5 (D&F 7.1, Prop. 1)**.** *Let R be a ring. For all $a, b \in R$:*

1. $0 \cdot a = a \cdot 0 = 0$;
2. $(-a)b = a(-b) = -(ab)$;
3. $(-a)(-b) = ab$;
4. *if R has an identity 1, then 1 is unique and $(-1)a = -a$.*

Proof. (1) $0 \cdot a = (0+0)a = 0 \cdot a + 0 \cdot a$ by distributivity. Adding $-(0 \cdot a)$ to both sides gives $0 = 0 \cdot a$. Symmetrically $a \cdot 0 = 0$.

(2) $ab + (-a)b = (a + (-a))b = 0 \cdot b = 0$ by (1), so $(-a)b$ is the additive inverse of ab, i.e. $(-a)b = -(ab)$. Likewise $ab + a(-b) = a(b + (-b)) = a \cdot 0 = 0$, so $a(-b) = -(ab)$.

(3) Using (2) twice: $(-a)(-b) = -(a(-b)) = -(-(ab)) = ab$.

(4) If $1, 1'$ are identities then $1 = 1 \cdot 1' = 1'$. By (2) with $a = 1$, $(-1)b = -(1 \cdot b) = -b$. □

Proposition 7.1.6 (Cancellation in a domain)**.** *Let R be an integral domain. If $a \neq 0$ and $ab = ac$, then $b = c$. (Nonzero elements cancel.)*

Proof. $ab = ac \implies a(b-c) = 0$. Since $a \neq 0$ and R has no zero divisors, $b - c = 0$, i.e. $b = c$. □

Theorem 7.1.7 (Finite domains are fields, D&F 7.1 Cor. to Prop. 2)**.** *Every finite integral domain is a field.*

Proof. Let R be a finite integral domain and fix $a \neq 0$. The map $\mu_a \colon R \to R$, $\mu_a(x) = ax$, is injective: $ax = ay \implies x = y$ by cancellation (Prop. 7.1.6). An injective map from a finite set to itself is surjective, so some $b \in R$ has $ab = 1$. As R is commutative, $ba = 1$ too, so $a \in R^\times$. Every nonzero a is a unit, hence R is a field. □

Definition 7.1.8 (Characteristic)**.** The *characteristic* $\operatorname{char}(R)$ of a ring with 1 is the least $n > 0$ with $n \cdot 1 = \underbrace{1 + \cdots + 1}_{n} = 0$, if such n exists; otherwise $\operatorname{char}(R) = 0$.

Proposition 7.1.9 (Characteristic of a domain)**.** *If R is an integral domain then* $\operatorname{char}(R)$ *is either* 0 *or a prime p.*

Proof. Suppose $\operatorname{char}(R) = n = st$ with $1 < s, t < n$. Then $0 = n \cdot 1 = (s \cdot 1)(t \cdot 1)$. Since R has no zero divisors, $s \cdot 1 = 0$ or $t \cdot 1 = 0$, contradicting minimality of n. So n is prime (or 0). □

Method (Deciding: domain vs. field vs. neither)**.** Given a ring R with $1 \neq 0$:

1. **Commutative?** If not, the best you can hope for is a division ring (e.g. $\mathbb{H}$); a field requires commutativity.
2. **Hunt for zero divisors.** Find $a, b \neq 0$ with $ab = 0$. One pair kills "domain" (hence "field"). In $\mathbb{Z}/n\mathbb{Z}$ look at $\gcd(a, n) > 1$; in M_n look at $\det = 0$; in products $R \times S$ try $(1,0)(0,1) = (0,0)$.
3. **If no zero divisors, it's a domain.** Now ask: is every nonzero element a unit? Solve $ax = 1$. If always solvable $\implies$ field; if some nonzero a has no inverse $\implies$ domain but not field.
4. *Shortcut.* A *finite* domain is automatically a field (Thm. 7.1.7). So for finite R you only need step 2.

Caution. $1 \neq 0$ *is part of the definition of a field/domain.* The zero ring $\{0\}$ (where $1 = 0$) has no zero divisors and trivially every element is invertible, yet it is *not* a field or domain. Always exclude it.

Caution. A zero divisor is never a unit. If a is a unit with inverse a^{-1} and $ab = 0$, then $b = a^{-1}(ab) = a^{-1} \cdot 0 = 0$; symmetrically, $ba = 0$ gives $b = (ba)a^{-1} = 0 \cdot a^{-1} = 0$. So a cannot kill a nonzero b from either side. Consequently in any ring, $R^\times$ and the set of zero divisors are disjoint.

Worked Example 7.1.10 ($\mathbb{Z}/n\mathbb{Z}$: field iff n prime; zero divisors of $\mathbb{Z}/12\mathbb{Z}$)**.** For which n is $\mathbb{Z}/n\mathbb{Z}$ a field? List the zero divisors and units of $\mathbb{Z}/12\mathbb{Z}$.

Recognition. Step 2–3 of the Method: look for $\gcd(a, n) > 1$ to find zero divisors; a finite domain is a field. The criterion "$\bar{a}$ unit $\iff \gcd(a, n) = 1$" is the key fact about $\mathbb{Z}/n\mathbb{Z}$.

Solution. In $\mathbb{Z}/n\mathbb{Z}$, $\bar{a}$ is a unit $\iff \gcd(a, n) = 1$ (Bézout: $au + nv = 1 \implies au \equiv 1$). And $\bar{a} \neq 0$ is a zero divisor $\iff \gcd(a, n) = d > 1$: then $\bar{a} \cdot \overline{(n/d)} = \overline{a(n/d)} = \bar{0}$ with $\overline{n/d} \neq 0$.

Field criterion. For $n \geq 2$, $\mathbb{Z}/n\mathbb{Z}$ is a field $\iff$ every nonzero residue is a unit $\iff \gcd(a, n) = 1$ for all $1 \leq a \leq n-1 \iff n$ is prime. (If $n = st$ with $1 < s, t < n$, then $\bar{s}\,\bar{t} = \bar{0}$ shows $\bar{s}$ is a zero divisor, so not even a domain.) For $n = 1$, $\mathbb{Z}/1\mathbb{Z}$ is the zero ring, which is not a field (and 1 is not prime), so "$\mathbb{Z}/n\mathbb{Z}$ is a field $\iff n$ is prime" holds for every $n \geq 1$.

$\mathbb{Z}/12\mathbb{Z}$. Compute $\gcd(a,12)$ for $a = 1,\dots,11$:

a	0	1	2	3	4	5	6	7	8	9	10	11
$\gcd(a,12)$	–	1	2	3	4	1	6	1	4	3	2	1

Units (gcd = 1): $(\mathbb{Z}/12\mathbb{Z})^\times = \{\bar1,\bar5,\bar7,\bar{11}\}$, so $|(\mathbb{Z}/12\mathbb{Z})^\times| = 4 = \varphi(12)$. Zero divisors (gcd > 1, nonzero): $\{\bar2,\bar3,\bar4,\bar6,\bar8,\bar9,\overline{10}\}$, that is 7 of them.

Check. $4 + 7 + 1 = 12 = |\mathbb{Z}/12\mathbb{Z}|$ (units + zero divisors + the element $\bar0$), partitioning $\mathbb{Z}/12\mathbb{Z}$ as it must. And e.g. $\bar4 \cdot \bar3 = \overline{12} = \bar0$ confirms $\bar4, \bar3$ are zero divisors. ■

Worked Example 7.1.11 (Units and zero divisors of $\mathrm{M}_2(\mathbb{R})$)**.** Describe $\mathrm{M}_2(\mathbb{R})^\times = \mathrm{GL}_2(\mathbb{R})$ and the zero divisors of $\mathrm{M}_2(\mathbb{R})$.

Recognition. Step 1–2: $\mathrm{M}_2(\mathbb{R})$ is noncommutative, so not a field. Use the determinant: invertible $\iff$ $\det \neq 0$; singular nonzero $\iff$ zero divisor.

Solution. $A \in \mathrm{M}_2(\mathbb{R})$ is a unit $\iff$ there is B with $AB = BA = I$ $\iff$ $\det A \neq 0$. So $\mathrm{M}_2(\mathbb{R})^\times = \mathrm{GL}_2(\mathbb{R}) = \{A : \det A \neq 0\}$, with $A^{-1} = \frac{1}{\det A}\left(\begin{smallmatrix} d & -b \\ -c & a \end{smallmatrix}\right)$ for $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$.

Zero divisors. Every nonzero singular matrix ($\det A = 0$, $A \neq 0$) is a zero divisor. Concretely take

$$A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \qquad B = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}: \quad AB = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} = BA,$$

and both $A, B \neq 0$. More generally if $\det A = 0$ then A has nontrivial kernel, so $Av = 0$ for some $v \neq 0$; let $B = \left(\begin{smallmatrix} v & v \end{smallmatrix}\right)$ (columns v), then $AB = 0$ with $B \neq 0$.

Check. $\det A = 1 \cdot 0 - 0 \cdot 0 = 0$, and the product is indeed 0; meanwhile $\det\left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right) = 0$ confirms $A \notin \mathrm{GL}_2(\mathbb{R})$. Also note $AB = 0$ but $A, B \neq 0$ shows cancellation fails, so $\mathrm{M}_2(\mathbb{R})$ is *not* a domain. ■

Worked Example 7.1.12 (The Gaussian integers $\mathbb{Z}[i]$: a domain; find its units)**.** Show $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$ is an integral domain and determine $\mathbb{Z}[i]^\times$.

Recognition. Step 2–3: $\mathbb{Z}[i] \subseteq \mathbb{C}$ inherits no zero divisors (subring of a field), so it's a domain; for units use the multiplicative norm $N(a + bi) = a^2 + b^2$.

Solution. Domain. $\mathbb{Z}[i]$ is a subring of the field $\mathbb{C}$: it is closed under subtraction and multiplication, since $(a + bi)(c + di) = (ac - bd) + (ad + bc)i$. A subring of a field is commutative with $1 = 1 + 0i \neq 0$ and has no zero divisors (a product of nonzero complex numbers is nonzero). Hence $\mathbb{Z}[i]$ is an integral domain.

Units. Define $N(a+bi) = (a+bi)\overline{(a+bi)} = a^2+b^2 \in \mathbb{Z}_{\geq 0}$. The norm is multiplicative: $N(\alpha\beta) = N(\alpha)N(\beta)$. If α is a unit, $\alpha\beta = 1 \implies N(\alpha)N(\beta) = N(1) = 1$, so $N(\alpha) = 1$. Thus $a^2 + b^2 = 1$ with $a, b \in \mathbb{Z}$, forcing $(a, b) \in \{(\pm1, 0), (0, \pm1)\}$. Conversely each of these is a unit:

$$1 \cdot 1 = 1, \quad (-1)(-1) = 1, \quad i \cdot (-i) = -i^2 = 1.$$

Therefore $\mathbb{Z}[i]^\times = \{1, -1, i, -i\} = \langle i \rangle$, a cyclic group of order 4.

Check. $N(i) = 0^2 + 1^2 = 1$■ and $i^{-1} = -i$ since $i(-i) = 1$. No other small element has norm 1: e.g. $N(1 + i) = 2$, so $1 + i$ is *not* a unit. ■

Worked Example 7.1.13 (The real quaternions $\mathbb{H}$ form a division ring)**.** Let $\mathbb{H} = \{a + bi + cj + dk : a, b, c, d \in \mathbb{R}\}$ with $i^2 = j^2 = k^2 = ijk = -1$. Show $\mathbb{H}$ is a division ring that is not a field.

Recognition. Step 1 plus the definition of division ring: $\mathbb{H}$ is noncommutative (so not a field), but every nonzero element is invertible via the conjugate/norm.

Solution. From $i^2 = j^2 = k^2 = ijk = -1$ one derives $ij = k,\ jk = i,\ ki = j$ and $ji = -k,\ kj = -i,\ ik = -j$; in particular $ij = k \neq -k = ji$, so $\mathbb{H}$ is *noncommutative*, hence not a field.

For $q = a+bi+cj+dk$ define the conjugate $\bar q = a-bi-cj-dk$ and norm $N(q) = q\bar q = a^2+b^2+c^2+d^2 \in \mathbb{R}_{\geq 0}$. A direct computation gives $q\bar q = \bar q q = N(q)$ (a real scalar). If $q \neq 0$ then $N(q) > 0$, and

$$q^{-1} = \frac{\bar q}{N(q)} = \frac{a - bi - cj - dk}{a^2 + b^2 + c^2 + d^2}, \qquad q\,q^{-1} = q^{-1}q = 1.$$

So every nonzero q is a unit, i.e. $\mathbb{H}^\times = \mathbb{H} \setminus \{0\}$ and $\mathbb{H}$ is a division ring.

Check. For $q = i$: $\bar q = -i$, $N(i) = 1$, $q^{-1} = -i$, and $i(-i) = -i^2 = 1$■. For $q = 1 + i + j + k$: $N(q) = 1 + 1 + 1 + 1 = 4$, so $q^{-1} = \frac14(1 - i - j - k)$; then $q\bar q = 4$ and $q\,q^{-1} = \frac14 \cdot 4 = 1$■. ■

Worked Example 7.1.14 ($\mathbb{Z}$ vs. $\mathbb{Q}$, and a non-domain product)**.** Classify each of $\mathbb{Z}$, $\mathbb{Q}$, and $\mathbb{Z} \times \mathbb{Z}$ as field / domain-not-field / not-a-domain.

Recognition. Run the Method on three contrasting rings: an infinite domain that is not a field, a field, and a product with built-in zero divisors.

Solution. $\mathbb{Z}$. Commutative, $1 \neq 0$, and $mn = 0 \implies m = 0$ or $n = 0$, so no zero divisors: $\mathbb{Z}$ is an integral domain. But $\mathbb{Z}^\times = \{\pm 1\}$, e.g. 2 has no inverse in $\mathbb{Z}$ ($2x = 1$ has no integer solution). So $\mathbb{Z}$ is a *domain that is not a field*. (Thm. 7.1.7 does not apply: $\mathbb{Z}$ is infinite.)

$\mathbb{Q}$. Commutative, and every nonzero $\frac{a}{b}$ has inverse $\frac{b}{a}$. So $\mathbb{Q}$ is a *field*.

$\mathbb{Z} \times \mathbb{Z}$ (componentwise operations, $1 = (1, 1)$). Here $(1, 0) \neq 0$ and $(0, 1) \neq 0$ but

$$(1, 0) \cdot (0, 1) = (1 \cdot 0,\ 0 \cdot 1) = (0, 0).$$

So $(1, 0), (0, 1)$ are zero divisors: $\mathbb{Z} \times \mathbb{Z}$ is *not a domain* (hence not a field), even though it is commutative with identity.

Check. $\mathrm{char}(\mathbb{Z}) = \mathrm{char}(\mathbb{Q}) = 0$ (no $n > 0$ has $n \cdot 1 = 0$). In $\mathbb{Z} \times \mathbb{Z}$, $(1, 0)$ is idempotent: $(1, 0)^2 = (1, 0)$, a nonzero non-identity idempotent, which can only exist when there are zero divisors since $e(e - 1) = 0$. ■

Worked Example 7.1.15 (Characteristic computations)**.** Compute $\mathrm{char}(R)$ for $R = \mathbb{Z}$, $\mathbb{Z}/6\mathbb{Z}$, $\mathbb{Z}/5\mathbb{Z}$, $\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, and decide in each case whether char is forced to be 0 or prime by Prop. 7.1.9.

Recognition. Apply Def. 7.1.8 directly, then use Prop. 7.1.9 as a consistency check (only domains are constrained to 0 or prime).

Solution. $\mathbb{Z}$. $n \cdot 1 = n \neq 0$ for every $n > 0$, so $\mathrm{char}(\mathbb{Z}) = 0$. ($\mathbb{Z}$ is a domain; 0 is allowed.)

$\mathbb{Z}/6\mathbb{Z}$. $n \cdot \bar{1} = \bar{n}$; the least $n > 0$ with $\bar{n} = \bar{0}$ is $n = 6$. So $\mathrm{char}(\mathbb{Z}/6\mathbb{Z}) = 6$. This is *not* prime — consistent because $\mathbb{Z}/6\mathbb{Z}$ is *not* a domain ($\bar{2}\,\bar{3} = \bar{0}$), so Prop. 7.1.9 does not apply.

$\mathbb{Z}/5\mathbb{Z}$. Least n with $\bar{n} = \bar{0}$ is 5, so $\mathrm{char}(\mathbb{Z}/5\mathbb{Z}) = 5$, prime. Indeed $\mathbb{Z}/5\mathbb{Z}$ is a field (Example with n prime), hence a domain, so prime is required. ■

$\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. Identity $(1, \bar{1})$; $n \cdot (1, \bar{1}) = (n, \overline{n})$. For this to be $(0, \bar{0})$ we need $n = 0$ in $\mathbb{Z}$, impossible for $n > 0$. So char = 0. (It is not a domain, so 0 is fine without contradiction.)

Check. In $\mathbb{Z}/6\mathbb{Z}$: $6 \cdot \bar{1} = \bar{6} = \bar{0}$ and $5 \cdot \bar{1} = \bar{5} \neq \bar{0}$, confirming 6 is minimal. The one composite characteristic here (6) occurs in a ring with zero divisors, as Prop. 7.1.9 requires; the converse fails, since $\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ has zero divisors ($(1, \bar{0})(0, \bar{1}) = (0, \bar{0})$) but characteristic 0. ■

The chain of implications among these classes is worth fixing visually:

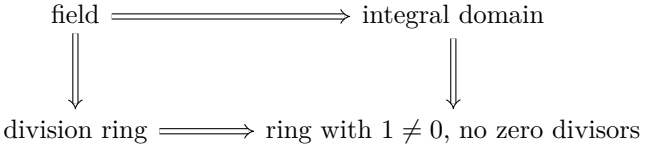

Diagram explanation. Objects: Four classes of rings, each a node. Top-left: *field* — a commutative division ring ($\mathbb{Q}$, $\mathbb{F}_p$, $\mathbb{R}$, $\mathbb{C}$). Top-right: *integral domain* — a commutative ring with $1 \neq 0$ and no zero divisors ($\mathbb{Z}$, $\mathbb{Z}[i]$, $k[x]$). Bottom-left: *division ring* — every nonzero element is a unit, but commutativity may fail ($\mathbb{H}$). Bottom-right: *ring with* $1 \neq 0$*, no zero divisors* — the weakest of the four; it is the intersection property shared by all of them.

Arrows: Each $\Rightarrow$ is a logical implication between definitions, not a ring homomorphism. (Right, top): field $\Rightarrow$ integral domain — a field is commutative and every nonzero element is a unit, hence certainly has no zero divisors. (Down, left): field $\Rightarrow$ division ring — a field satisfies every nonzero element invertible; commutativity is extra, so it is automatically a division ring. (Down, right): integral domain $\Rightarrow$ ring with $1 \neq 0$, no zero divisors — an integral domain is commutative and has no zero divisors, so it satisfies the weaker condition. (Right, bottom): division ring $\Rightarrow$ ring with $1 \neq 0$, no zero divisors — in a division ring every nonzero element is a unit; a unit is never a zero divisor (if $uv = 0$ and u is a unit then $v = u^{-1}(uv) = 0$), so there are no zero divisors.

What commutes: The two paths from field to the bottom-right node agree: both conclude that a field has $1 \neq 0$ and no zero divisors. Path 1 (right then down): field $\Rightarrow$ integral domain $\Rightarrow$ ring with $1 \neq 0$, no zero

divisors. Path 2 (down then right): field ⇒ division ring ⇒ ring with $1 \neq 0$, no zero divisors. Both paths land on the same conclusion, so the square commutes as a diagram of implications.

Why it commutes: Chase a field F through each path. Path 1: F is commutative with no zero divisors (definition of field), so F is an integral domain; an integral domain has no zero divisors and $1 \neq 0$, landing in the bottom-right box. Path 2: every nonzero element of F is a unit (definition of field), so F is a division ring; as shown above units cannot be zero divisors, so F lands in the bottom-right box. Both paths conclude "F has $1 \neq 0$ and no zero divisors," and those are the same statement, so the paths agree.

Why this matters here: This diagram consolidates the three definitions just given (field, integral domain, division ring) into a single picture before the chapter uses them. It makes immediately visible that "field" is the most special class (top-left, source of all arrows) and clarifies the two independent ways one can weaken it: drop commutativity (go down to division ring) or drop the invertibility of all nonzero elements (go right to integral domain). The diagram also telegraphs the two main non-example families: $\mathbb{H}$ (division ring, not a field) lives in the bottom-left; $\mathbb{Z}$ (integral domain, not a field) lives in the top-right.

Concrete example: Take $F = \mathbb{F}_5 = \mathbb{Z}/5\mathbb{Z}$ (a field), $R = \mathbb{Z}$ (integral domain, not a field), $S = \mathbb{H}$ (division ring, not a field). Path 1 for $\mathbb{F}_5$: $\mathbb{F}_5$ is commutative with no zero divisors ⇒ integral domain ⇒ no zero divisors and $1 \neq 0$. Path 2 for $\mathbb{F}_5$: every nonzero element of $\mathbb{F}_5$ is invertible ⇒ division ring ⇒ no zero divisors. Both paths give the same property of $\mathbb{F}_5$, confirming the square. The ring $\mathbb{Z} \times \mathbb{Z}$ is commutative with $1 \neq 0$ yet fails the bottom-right condition ($(1,0)(0,1) = (0,0)$), so it lies outside all four boxes.

Common pitfall: Students sometimes read the square as also saying "integral domain ⇒ division ring" or the reverse, since both classes sit between field and the bottom-right class. The diagram has *no* arrow in either direction between integral domain (top right) and division ring (bottom left); those classes are incomparable ($\mathbb{Z}$ is an integral domain but not a division ring; $\mathbb{H}$ is a division ring but not an integral domain, since it is not commutative). The finite-domain collapse (finite domain ⇒ field, Thm. 7.1.7) is a *bonus theorem*, not a general arrow in this square.

Takeaway: The point of this diagram is that "field" sits at the intersection of two independent strengthenings of the weakest class, one requiring commutativity (the vertical direction) and one requiring every nonzero element to be invertible (the horizontal direction), so losing either property separately gives a distinct and genuine class of rings.

(A field is both a division ring and a domain; the only thing separating a field from a division ring is commutativity, e.g. $\mathbb{H}$.) For *finite* rings the top row collapses: a finite domain is a field (Thm. 7.1.7), so over finite ground all four boxes for a commutative such ring coincide.

Remark 7.1.1. The condition "no zero divisors" is exactly cancellation (Prop. 7.1.6): nonzero elements cancel $\iff$ there are no zero divisors. This is why $\mathbb{Z}/n\mathbb{Z}$ ($n \geq 2$) supports cancellation precisely when n is prime, and why solving linear equations $ax = b$ behaves well only in domains.

Exercises (from the text).

1. Show that $(-1)^2 = 1$ in R.
2. Prove that if u is a unit in R then so is $-u$.
3. Let R be a ring with identity and let S be a subring of R containing the identity. Prove that if u is a unit in S then u is a unit in R. Show by example that the converse is false.
4. Prove that the intersection of any nonempty collection of subrings of a ring is also a subring.
5. Decide which of the following (a)–(f) are subrings of $\mathbb{Q}$:
   (a) the set of all rational numbers with odd denominators (when written in lowest terms)
   (b) the set of all rational numbers with even denominators (when written in lowest terms)
   (c) the set of nonnegative rational numbers
   (d) the set of squares of rational numbers
   (e) the set of all rational numbers with odd numerators (when written in lowest terms)
   (f) the set of all rational numbers with even numerators (when written in lowest terms).

6. Decide which of the following are subrings of the ring of all functions from the closed interval $[0,1]$ to $\mathbb{R}$:
   (a) the set of all functions $f(x)$ such that $f(q) = 0$ for all $q \in \mathbb{Q} \cap [0,1]$
   (b) the set of all polynomial functions
   (c) the set of all functions which have only a finite number of zeros, together with the zero function
   (d) the set of all functions which have an infinite number of zeros
   (e) the set of all functions f such that $\lim_{x \to 1^-} f(x) = 0$
   (f) the set of all rational linear combinations of the functions $\sin nx$ and $\cos mx$, where $m, n \in \{0, 1, 2, \dots\}$.
7. The center of a ring R is $\{z \in R \mid zr = rz \text{ for all } r \in R\}$ (i.e., is the set of all elements which commute with every element of R). Prove that the center of a ring is a subring that contains the identity. Prove that the center of a division ring is a field.
8. Describe the center of the real Hamilton Quaternions $\mathbb{H}$. Prove that $\{a + bi \mid a, b \in \mathbb{R}\}$ is a subring of $\mathbb{H}$ which is a field that is not contained in the center of $\mathbb{H}$.
9. For a fixed element $a \in R$ define $C(a) = \{r \in R \mid ra = ar\}$. Prove that $C(a)$ is a subring of R containing a. Prove that the center of R is the intersection of the subrings $C(a)$ over all $a \in R$.
10. Prove that if D is a division ring then $C(a)$ is a division ring for all $a \in D$ (cf. the preceding exercise).
11. Prove that if R is an integral domain and $x^2 = 1$ for some $x \in R$ then $x = \pm 1$.
12. Prove that any subring of a field which contains the identity is an integral domain.
13. An element x in R is called nilpotent if $x^m = 0$ for some $m \in \mathbb{Z}^+$.
   (a) Show that if $n = a^k b$ for some integers a and b then $\overline{ab}$ is a nilpotent element of $\mathbb{Z}/n\mathbb{Z}$.
   (b) If $a \in \mathbb{Z}$ is an integer, show that the element $\bar{a} \in \mathbb{Z}/n\mathbb{Z}$ is nilpotent if and only if every prime divisor of n is also a divisor of a. In particular, determine the nilpotent elements of $\mathbb{Z}/72\mathbb{Z}$ explicitly.
   (c) Let R be the ring of functions from a nonempty set X to a field F. Prove that R contains no nonzero nilpotent elements.
14. Let x be a nilpotent element of the commutative ring R (cf. the preceding exercise).
   (a) Prove that x is either zero or a zero divisor.
   (b) Prove that rx is nilpotent for all $r \in R$.
   (c) Prove that $1 + x$ is a unit in R.
   (d) Deduce that the sum of a nilpotent element and a unit is a unit.
15. A ring R is called a Boolean ring if $a^2 = a$ for all $a \in R$. Prove that every Boolean ring is commutative.
16. Prove that the only Boolean ring that is an integral domain is $\mathbb{Z}/2\mathbb{Z}$.
17. Let R and S be rings. Prove that the direct product $R \times S$ is a ring under componentwise addition and multiplication. Prove that $R \times S$ is commutative if and only if both R and S are commutative. Prove that $R \times S$ has an identity if and only if both R and S have identities.
18. Prove that $\{(r, r) \mid r \in R\}$ is a subring of $R \times R$.
19. Let I be any nonempty index set and let R_i be a ring for each $i \in I$. Prove that the direct product $\prod_{i \in I} R_i$ is a ring under componentwise addition and multiplication.
20. Let R be the collection of sequences $(a_1, a_2, a_3, \dots)$ of integers $a_1, a_2, a_3, \dots$ where all but finitely many of the a_i are 0 (called the direct sum of infinitely many copies of $\mathbb{Z}$). Prove that R is a ring under componentwise addition and multiplication which does not have an identity.

21. Let X be any nonempty set and let $\mathcal{P}(X)$ be the set of all subsets of X (the power set of X). Define addition and multiplication on $\mathcal{P}(X)$ by

$$A + B = (A - B) \cup (B - A) \quad \text{and} \quad A \times B = A \cap B$$

i.e., addition is symmetric difference and multiplication is intersection.

(a) Prove that $\mathcal{P}(X)$ is a ring under these operations ($\mathcal{P}(X)$ and its subrings are often referred to as rings of sets).

(b) Prove that this ring is commutative, has an identity and is a Boolean ring.

22. Give an example of an infinite Boolean ring.

23. Let D be a squarefree integer, and let $\mathcal{O}$ be the ring of integers in the quadratic field $\mathbb{Q}(\sqrt{D})$. Write $\mathcal{O} = \mathbb{Z}[\omega]$, where $\omega = \sqrt{D}$ if $D \equiv 2, 3 \pmod 4$ and $\omega = \frac{1+\sqrt{D}}{2}$ if $D \equiv 1 \pmod 4$. For any positive integer f prove that the set $\mathcal{O}_f = \mathbb{Z}[f\omega] = \{a + bf\omega \mid a, b \in \mathbb{Z}\}$ is a subring of $\mathcal{O}$ containing the identity. Prove that $[\mathcal{O} : \mathcal{O}_f] = f$ (index as additive abelian groups). Prove conversely that a subring of $\mathcal{O}$ containing the identity and having finite index f in $\mathcal{O}$ (as additive abelian group) is equal to $\mathcal{O}_f$. The ring $\mathcal{O}_f$ is called the order of conductor f in the field $\mathbb{Q}(\sqrt{D})$. The ring of integers $\mathcal{O}$ is called the maximal order in $\mathbb{Q}(\sqrt{D})$.

24. Show for $D = 3, 5, 6$, and 7 that the group of units $\mathcal{O}^\times$ of the quadratic integer ring $\mathcal{O}$ is infinite by exhibiting an explicit unit of infinite (multiplicative) order in each case.

25. Let I be the ring of integral Hamilton Quaternions and define

$$N : I \to \mathbb{Z} \quad \text{by} \quad N(a + bi + cj + dk) = a^2 + b^2 + c^2 + d^2.$$

(The map N is called a norm.)

(a) Prove that $N(\alpha) = \alpha\bar{\alpha}$ for all $\alpha \in I$, where if $\alpha = a + bi + cj + dk$ then $\bar{\alpha} = a - bi - cj - dk$.

(b) Prove that $N(\alpha\beta) = N(\alpha)N(\beta)$ for all $\alpha, \beta \in I$.

(c) Prove that an element of I is a unit if and only if it has norm $+1$. Show that $I^\times$ is isomorphic to the quaternion group of order 8. [The inverse in the ring of rational quaternions of a nonzero element α is $\frac{\bar{\alpha}}{N(\alpha)}$.]

26. Let K be a field. A discrete valuation on K is a function $\nu : K^\times \to \mathbb{Z}$ satisfying

(i) $\nu(ab) = \nu(a) + \nu(b)$ (i.e., ν is a homomorphism from the multiplicative group of nonzero elements of K to $\mathbb{Z}$),

(ii) ν is surjective, and

(iii) $\nu(x + y) \geq \min\{\nu(x), \nu(y)\}$ for all $x, y \in K^\times$ with $x + y \neq 0$.

The set $R = \{x \in K^\times \mid \nu(x) \geq 0\} \cup \{0\}$ is called the valuation ring of ν.

(a) Prove that R is a subring of K which contains the identity. (In general, a ring R is called a discrete valuation ring if there is some field K and some discrete valuation ν on K such that R is the valuation ring of ν.)

(b) Prove that for each nonzero element $x \in K$ either x or x^{-1} is in R.

(c) Prove that an element x is a unit of R if and only if $\nu(x) = 0$.

27. A specific example of a discrete valuation ring (cf. the preceding exercise) is obtained when p is a prime, $K = \mathbb{Q}$ and

$$\nu_p : \mathbb{Q}^\times \to \mathbb{Z} \quad \text{by} \quad \nu_p\left(\frac{a}{b}\right) = \alpha \quad \text{where} \quad \frac{a}{b} = p^\alpha \frac{c}{d}, \quad p \nmid c \text{ and } p \nmid d.$$

Prove that the corresponding valuation ring R is the ring of all rational numbers whose denominators are relatively prime to p. Describe the units of this valuation ring.

28. Let R be a ring with $1 \neq 0$. A nonzero element a is called a left zero divisor in R if there is a nonzero element $x \in R$ such that $ax = 0$. Symmetrically, $b \neq 0$ is a right zero divisor if there is a nonzero element $y \in R$ such that $yb = 0$ (so a zero divisor is an element which is either a left or a right zero divisor). An element $u \in R$ has a left inverse in R if there is some $s \in R$ such that $su = 1$. Symmetrically, v has a right inverse if $vt = 1$ for some $t \in R$.

    (a) Prove that u is a unit if and only if it has both a right and a left inverse (i.e., u must have a two-sided inverse).

    (b) Prove that if u has a right inverse then u is not a right zero divisor.

    (c) Prove that if u has more than one right inverse then u is a left zero divisor.

    (d) Prove that if R is a finite ring then every element that has a right inverse is a unit (i.e., has a two-sided inverse).

29. Let A be any commutative ring with identity $1 \neq 0$. Let R be the set of all group homomorphisms of the additive group A to itself with addition defined as pointwise addition of functions and multiplication defined as function composition. Prove that these operations make R into a ring with identity. Prove that the units of R are the group automorphisms of A (cf. Exercise 20, Section 1.6).

30. Let $A = \mathbb{Z} \times \mathbb{Z} \times \mathbb{Z} \times \cdots$ be the direct product of copies of $\mathbb{Z}$ indexed by the positive integers (so A is a ring under componentwise addition and multiplication) and let R be the ring of all group homomorphisms from A to itself as described in the preceding exercise. Let φ be the element of R defined by $\varphi(a_1, a_2, a_3, \dots) = (a_2, a_3, \dots)$. Let ψ be the element of R defined by $\psi(a_1, a_2, a_3, \dots) = (0, a_1, a_2, a_3, \dots)$.

    (a) Prove that $\varphi\psi$ is the identity of R but $\psi\varphi$ is not the identity of R (i.e., ψ is a right inverse for φ but not a left inverse).

    (b) Exhibit infinitely many right inverses for φ.

    (c) Find a nonzero element $\pi \in R$ such that $\varphi\pi = 0$ but $\pi\varphi \neq 0$.

    (d) Prove that there is no nonzero element $\lambda \in R$ such that $\lambda\varphi = 0$ (i.e., φ is a left zero divisor but not a right zero divisor).

Practice problems.

1. Determine whether each of the following is a ring under the usual addition and multiplication; if so, decide whether it is commutative and whether it has a 1: (a) the set of even integers $2\mathbb{Z}$; (b) the set $\{a + b\sqrt{2} \mid a, b \in \mathbb{Z}\}$; (c) the set of 2×2 matrices over $\mathbb{R}$ with zero second row; (d) the set of functions $f : \mathbb{R} \to \mathbb{R}$ under pointwise operations.

2. In the ring $\mathbb{Z}/12\mathbb{Z}$, list all the zero divisors, all the units $(\mathbb{Z}/12\mathbb{Z})^\times$, and all the nilpotent elements. Verify directly that $\mathbb{Z}/12\mathbb{Z}$ is not an integral domain.

3. Let $R = \mathbb{Z}/10\mathbb{Z}$. Compute $R^\times$ and show that the idempotents of R (elements with $x^2 = x$) are exactly $\{0, 1, 5, 6\}$.

4. Let R be a commutative ring and let $x, y \in R$ be nilpotent, say $x^m = 0$ and $y^n = 0$. Using the binomial theorem, show that $(x + y)^{m+n-1} = 0$, and conclude that the set $\mathrm{nil}(R)$ of nilpotent elements is closed under addition. (Together with closure under multiplication by ring elements, this shows $\mathrm{nil}(R)$ is an ideal.)

5. Let R be a ring with 1. Show that if x is nilpotent then $1 - x$ is a unit, and exhibit its inverse explicitly when $x^3 = 0$.

6. Work in $\mathbb{Z}[x]$. (a) Compute $(2x^2 - x + 3)(x^2 + 4x - 1)$. (b) Find $\deg(fg)$ and $\deg(f + g)$ for $f = 3x^4 - x$, $g = -3x^4 + x^2 + 5$. (c) Show $\mathbb{Z}[x]^\times = \{\pm 1\}$.

7. In $\mathbb{Z}/4\mathbb{Z}[x]$ show that $2x + 1$ is a unit by exhibiting its inverse, and that $2x$ is nilpotent. Conclude that $\deg(fg) < \deg f + \deg g$ is possible here, with an explicit example.

8. Let $R = \mathrm{M}_2(\mathbb{R})$. Find two nonzero matrices A, B with $AB = 0$, and find a nonzero A with $A^2 = 0$. Show $R^\times = \mathrm{GL}_2(\mathbb{R})$.

9. Decide which of the following maps are ring homomorphisms; for those that are, compute the kernel and image: (a) $\varphi : \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$, reduction mod 6; (b) $\psi : \mathbb{Z}[x] \to \mathbb{Z}$, $f \mapsto f(2)$; (c) $\chi : \mathbb{C} \to \mathbb{C}$, $z \mapsto \bar{z}$ (complex conjugation); (d) $\theta : \mathbb{R} \to \mathrm{M}_2(\mathbb{R})$, $r \mapsto \begin{pmatrix} r & 0 \\ 0 & 0 \end{pmatrix}$.

10. Let R be commutative and let $S \subseteq R$ be any subset. Prove that the annihilator $\mathrm{Ann}(S) = \{r \in R \mid r \cdot s = 0 \text{ for all } s \in S\}$ is an ideal of R.

11. In $\mathbb{Z}$, identify all ideals and determine which are prime and which are maximal. Justify why (0) is prime but not maximal and (p) is maximal for p prime.

12. Determine whether each ideal of $\mathbb{Z}[x]$ is prime, maximal, both, or neither: (a) $\langle x \rangle$; (b) $\langle 2 \rangle$; (c) $\langle 2, x \rangle$; (d) $\langle x^2 + 1 \rangle$.

13. Compute the field of fractions $\mathrm{Frac}(R)$ for each integral domain: (a) $R = \mathbb{Z}$; (b) $R = 2\mathbb{Z}$ (treated as a rng without identity — explain the subtlety); (c) $R = \mathbb{Z}[i]$; (d) $R = \mathbb{F}_2[x]$.

14. Use the CRT to find the unique $x \in \mathbb{Z}/35\mathbb{Z}$ with $x \equiv 3 \pmod 5$ and $x \equiv 4 \pmod 7$, and write down the explicit ring isomorphism $\mathbb{Z}/35\mathbb{Z} \cong \mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/7\mathbb{Z}$.

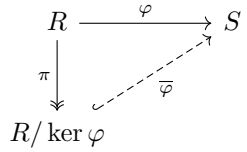
15. Let $R = \mathbb{Z}[i]$ be the Gaussian integers. Show that R is an integral domain, compute $R^\times$, and verify that $N(a + bi) = a^2 + b^2$ is multiplicative: $N(\alpha\beta) = N(\alpha)N(\beta)$.

Additional exercises.

1. Let R be a ring in which $x^2 = x$ for every $x \in R$ (a *Boolean ring*). Prove that $2x = 0$ for all x and that R is commutative.

2. Let R be a finite integral domain. Prove that R is a field. (Hint: for $a \neq 0$ the map $x \mapsto ax$ is injective, hence surjective.)

3. In the Hamilton quaternions $\mathbb{H}$, write $\alpha = 1 + i + j + k$. Compute $\alpha\overline{\alpha}$ where $\overline{\alpha} = 1 - i - j - k$, and use it to find α^{-1}. Conclude that $\mathbb{H}$ is a division ring.



4. Let R be a commutative ring with $1 \neq 0$. Prove that R is a field if and only if its only ideals are (0) and R.

5. Let $\varphi : R \to S$ be a nonzero ring homomorphism with R commutative and S an integral domain. Show that $\ker \varphi$ is a prime ideal of R. Show by example (with S a field) that $\ker \varphi$ need not be maximal.

6. Let $R = C[0,1]$ be the ring of continuous real-valued functions on $[0,1]$ under pointwise operations. For $c \in [0,1]$ let $M_c = \{f \mid f(c) = 0\}$. Prove M_c is a maximal ideal and that $R/M_c \cong \mathbb{R}$.

Commutative-diagram exercises.

1. Let $\varphi : R \to S$ be a ring homomorphism and $\pi : R \to R/\ker\varphi$ the natural projection. State and prove the First Isomorphism Theorem for rings by constructing the dashed map $\overline{\varphi}$ that makes the diagram commute and showing it is an injective homomorphism onto $\mathrm{im}\,\varphi$:

   Apply this to $\varphi : \mathbb{Z}[x] \to \mathbb{C}$, $f \mapsto f(i)$, to identify $\mathbb{Z}[x]/\langle x^2 + 1 \rangle$.

2. Let I_1, I_2 be ideals of a commutative ring R with $I_1 + I_2 = R$ (comaximal). Prove the Chinese Remainder Theorem: the map $r \mapsto (r + I_1,\, r + I_2)$ induces a ring isomorphism, by showing it has kernel $I_1 \cap I_2 = I_1 I_2$

and is surjective:

$$\begin{array}{ccc} R & \xrightarrow{r\mapsto(r+I_1,\,r+I_2)} & R/I_1 \times R/I_2 \\ & \searrow^{\pi} & \uparrow \cong \\ & & R/(I_1 \cap I_2) \end{array}$$

Instantiate with $R = \mathbb{Z}$, $I_1 = \langle 5 \rangle$, $I_2 = \langle 7 \rangle$.

3. State and verify the universal property of the polynomial ring: for any ring homomorphism $\varphi : R \to S$ with $\varphi(1_R) = 1_S$ into a commutative ring S and any choice of $s \in S$, there is a unique ring homomorphism $\Phi : R[x] \to S$ extending φ with $\Phi(x) = s$, making the diagram commute:

$$\begin{array}{ccc} R & \xhookrightarrow{\iota} & R[x] \\ & \searrow^{\varphi} & \downarrow \exists!\, \Phi \\ & & S \end{array}$$

Use it to define the homomorphism $\mathbb{Z}[x] \to \mathbb{Z}/n\mathbb{Z}[x]$ induced by reduction mod n on coefficients, with $x \mapsto x$.

4. State the universal property of the field of fractions of an integral domain R: every injective ring homomorphism $f : R \to F$ into a field F factors uniquely through $\mathrm{Frac}(R)$:

$$\begin{array}{ccc} R & \xhookrightarrow{\iota} & \mathrm{Frac}(R) \\ & \searrow^{f} & \downarrow \exists!\, \bar{f} \\ & & F \end{array}$$

Verify the property explicitly for $R = \mathbb{Z}$, $F = \mathbb{R}$, f the inclusion, by giving the formula for $\bar{f}$ on a/b.

5. Let $n = p_1^{a_1} \cdots p_k^{a_k}$. Iterate the CRT to produce the ring isomorphism displayed below, and describe the induced isomorphism on unit groups $(\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_i (\mathbb{Z}/p_i^{a_i}\mathbb{Z})^\times$:

$$\mathbb{Z}/n\mathbb{Z} \xrightarrow{\ \sim\ } \mathbb{Z}/p_1^{a_1}\mathbb{Z} \times \cdots \times \mathbb{Z}/p_k^{a_k}\mathbb{Z}$$

7.2 Polynomial Rings, Matrix Rings, and Group Rings

The polynomial ring $R[x]$, matrix rings, and group rings

Fix a commutative ring R with $1 \neq 0$ (we relax commutativity where noted). This section builds three of the most important constructions in the book: adjoining an indeterminate to get $R[x]$, the matrix ring $\mathrm{M}_n(R)$, and the group ring RG. Each is a ring; together they exhibit nearly every phenomenon (zero divisors, noncommutativity, units shrinking) that the rest of Chapter 7 dissects.

Definition 7.2.1 (The polynomial ring)**.** Let R be a commutative ring with 1. The *polynomial ring* $R[x]$ in the indeterminate x with coefficients in R is the set of formal sums

$$p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0, \qquad a_i \in R,\ n \geq 0,$$

with the usual addition (coefficientwise) and multiplication (Cauchy convolution):

$$\Big(\sum_i a_i x^i\Big)\Big(\sum_j b_j x^j\Big) = \sum_k \Big(\sum_{i+j=k} a_i b_j\Big) x^k.$$

If $a_n \neq 0$ we call $n = \deg p$ the *degree*, a_n the *leading coefficient*, and a_0 the *constant term*; p is *monic* if $a_n = 1$. The zero polynomial has, by convention, degree $-\infty$. A constant polynomial is one of degree 0 (or the zero polynomial). The natural inclusion $R \hookrightarrow R[x]$ as constants makes R a subring.

Remark 7.2.1. $R[x]$ is commutative because R is and x commutes with the constants by fiat; its identity is the constant 1. One iterates the construction: $R[x,y] := (R[x])[y]$, and so on.

Theorem 7.2.2 (Degree and integrality in $R[x]$)**.** *Let R be an integral domain and $p, q \in R[x]$ be nonzero. Then:*

(1) $\deg(pq) = \deg p + \deg q$*;*

(2) the units of $R[x]$ are exactly the units of R: $R[x]^\times = R^\times$*;*

(3) $R[x]$ is an integral domain.

Proof. Write $p = a_m x^m + \cdots$, $q = b_n x^n + \cdots$ with leading coefficients $a_m, b_n \neq 0$. The top coefficient of pq is $a_m b_n$ (the x^{m+n} coefficient), and every term of higher degree is absent. Since R is a domain, $a_m b_n \neq 0$, so this top term survives: thus $pq \neq 0$ (proving (3)) and $\deg(pq) = m + n = \deg p + \deg q$ (proving (1)). For (2): a unit $u \in R$ has inverse $u^{-1} \in R \subseteq R[x]$, so $R^\times \subseteq R[x]^\times$. Conversely if $pq = 1$ then by (1) $\deg p + \deg q = \deg(1) = 0$, forcing $\deg p = \deg q = 0$; so $p, q \in R$ are constants with $pq = 1$, i.e. $p \in R^\times$. Hence $R[x]^\times \subseteq R^\times$. □

Caution. All three statements can fail when R has zero divisors. In $\mathbb{Z}/4\mathbb{Z}[x]$, $(2x)(2x) = 4x^2 = 0$, so deg drops (and $R[x]$ acquires zero divisors). And $\mathbb{Z}/4\mathbb{Z}[x]^\times \supsetneq (\mathbb{Z}/4\mathbb{Z})^\times$: indeed $(1+2x)(1+2x) = 1 + 4x + 4x^2 = 1$, so $1 + 2x$ is a unit of degree 1. The hypothesis "R a domain" in Theorem 7.2.2 is essential.

Method (Degree arguments in $R[x]$)**.** *Trigger.* You must decide whether a product is nonzero, find its degree, or rule out a unit/factorization in a polynomial ring.
Recipe. (1) Identify the ring R of coefficients and ask: *is R an integral domain?* (2) If yes, multiply leading coefficients: the leading coefficient of pq is the product of the leading coefficients, so $\deg(pq) = \deg p + \deg q$ and $pq \neq 0$. (3) To test units: if $pq = 1$ over a domain, take degrees to get $\deg p = \deg q = 0$, so only constant units of R survive. (4) If R has zero divisors, do *not* use these shortcuts – compute the top coefficient $a_m b_n$ explicitly and check whether it vanishes; the degree may drop and stray units may appear.

Worked Example 7.2.3 (Multiplying in $\mathbb{Z}/3\mathbb{Z}[x]$)**.** Compute $(x^2 + 2x + 2)(2x + 1)$ in $\mathbb{Z}/3\mathbb{Z}[x]$.

Recognition. This is Cauchy multiplication of polynomials with coefficients reduced mod 3; since $\mathbb{Z}/3\mathbb{Z}$ is a field (hence a domain), I also expect the degree to add to $2 + 1 = 3$.

Solution. Multiply termwise, then reduce each coefficient mod 3:

$$(x^2 + 2x + 2)(2x + 1) = 2x^3 + (1 + 4)x^2 + (2 + 4)x + 2 = 2x^3 + 5x^2 + 6x + 2.$$

Reduce: $5 \equiv 2$, $6 \equiv 0$, $2 \equiv 2 \pmod 3$, giving

$$(x^2 + 2x + 2)(2x + 1) = 2x^3 + 2x^2 + 2 \quad \text{in } \mathbb{Z}/3\mathbb{Z}[x].$$

Check. Degree is $3 = 2+1$ as predicted (leading coeff $1 \cdot 2 = 2 \neq 0$). Evaluate at $x = 1$: left $= (1+2+2)(2+1) = 5 \cdot 3 = 15 \equiv 0$; right $= 2 + 2 + 2 = 6 \equiv 0 \pmod 3$. Consistent.

Worked Example 7.2.4 (Units of $\mathbb{Z}[x]$ versus $\mathbb{Q}[x]$)**.** Determine $\mathbb{Z}[x]^\times$ and $\mathbb{Q}[x]^\times$.

Recognition. Both $\mathbb{Z}$ and $\mathbb{Q}$ are integral domains, so Theorem 7.2.2(2) applies: the units of $R[x]$ are exactly $R^\times$. The work is just to compute $R^\times$ for $R = \mathbb{Z}, \mathbb{Q}$.

Solution. By Theorem 7.2.2(2), $\mathbb{Z}[x]^\times = \mathbb{Z}^\times = \{1, -1\}$ and $\mathbb{Q}[x]^\times = \mathbb{Q}^\times = \mathbb{Q}^\times = \mathbb{Q} \setminus \{0\}$. So in $\mathbb{Z}[x]$ the only units are ± 1; in $\mathbb{Q}[x]$ every nonzero *constant* is a unit, but no polynomial of positive degree is. *Check.* If x were a unit in $\mathbb{Q}[x]$ with inverse q, then $\deg(x) + \deg(q) = 0$ forces $\deg q = -1$, impossible. And $\frac{1}{2} \in \mathbb{Q}[x]$ has inverse 2, confirming nonzero constants are units there but not in $\mathbb{Z}[x]$ (where 2 has no inverse).

Worked Example 7.2.5 (Degree drop in $\mathbb{Z}/4\mathbb{Z}[x]$)**.** In $\mathbb{Z}/4\mathbb{Z}[x]$ compute $(2x+1)^2$ and $(2x)(2x)$, and exhibit a unit of positive degree.

Recognition. $\mathbb{Z}/4\mathbb{Z}$ is *not* a domain ($2 \cdot 2 = 0$), so degree need not add and units may exceed $(\mathbb{Z}/4\mathbb{Z})^\times$; I must compute top coefficients directly.

Solution. $(2x)(2x) = 4x^2 = 0$ in $\mathbb{Z}/4\mathbb{Z}[x]$: a product of two degree-1 polynomials is 0, so $2x$ is a (nonzero) zero divisor and the degree "drops" from an expected 2 to $-\infty$. Next,

$$(2x+1)^2 = 4x^2 + 4x + 1 = 0 + 0 + 1 = 1.$$

Thus $1 + 2x \in \mathbb{Z}/4\mathbb{Z}[x]^\times$ with $(1+2x)^{-1} = 1 + 2x$, a unit of degree 1. *Check.* $(\mathbb{Z}/4\mathbb{Z})^\times = \{1, 3\}$ has order 2, yet $1 + 2x \notin \mathbb{Z}/4\mathbb{Z}$, so $\mathbb{Z}/4\mathbb{Z}[x]^\times \supsetneq (\mathbb{Z}/4\mathbb{Z})^\times$ – exactly the failure of Theorem 7.2.2(2) when R is not a domain.

Worked Example 7.2.6 ($R[x]$ a domain forces R a domain)**.** Show that if R has a nonzero zero divisor, so does $R[x]$ (hence $R[x]$ a domain $\implies$ R a domain).

Recognition. Zero divisors of R live inside $R[x]$ as constants, and a constant times a constant is the same product computed in R.

Solution. Suppose $ab = 0$ with $a, b \in R$ nonzero. Viewing a, b as constant polynomials, their product in $R[x]$ is the constant $ab = 0$, while $a, b \neq 0$ in $R[x]$. So a, b are nonzero zero divisors in $R[x]$. Contrapositively, $R[x]$ a domain $\implies$ R a domain. (Combined with Theorem 7.2.2(3), $R[x]$ is a domain *iff* R is.) *Check.* In $\mathbb{Z}/6\mathbb{Z}[x]$: $2 \cdot 3 = 6 \equiv 0$, and indeed $(2)(3) = 0$ with $2, 3 \neq 0$, so $\mathbb{Z}/6\mathbb{Z}[x]$ is not a domain, matching that $\mathbb{Z}/6\mathbb{Z}$ is not.

Worked Example 7.2.7 (Multiplication with carries in $\mathbb{Z}[x]$)**.** Compute $(x^2 - x + 1)(x + 1)$ in $\mathbb{Z}[x]$ and confirm the degree law.

Recognition. $\mathbb{Z}$ is a domain, so I expect degree $2 + 1 = 3$ and a nonzero leading coefficient $1 \cdot 1 = 1$.

Solution. Convolution:

$$(x^2 - x + 1)(x + 1) = x^3 + (1 - 1)x^2 + (-1 + 1)x + 1 = x^3 + 1.$$

Check. $\deg = 3 = 2 + 1$, leading coefficient 1. Sanity: this is the factorization $x^3 + 1 = (x + 1)(x^2 - x + 1)$, a standard sum-of-cubes identity. Evaluating at $x = 2$: left $= (4 - 2 + 1)(3) = 3 \cdot 3 = 9$; right $= 8 + 1 = 9$. Consistent.

Definition 7.2.8 (The matrix ring)**.** Let R be a ring with 1 and $n \geq 1$. The *matrix ring* $\mathrm{M}_n(R)$ is the set of $n \times n$ matrices with entries in R, under entrywise addition and the usual matrix multiplication $(AB)_{ij} = \sum_{k=1}^{n} A_{ik}B_{kj}$. Its identity is the identity matrix I_n, and its zero is the zero matrix. Let $E_{ij} \in \mathrm{M}_n(R)$ denote the *matrix unit* with 1 in position (i, j) and 0 elsewhere; these multiply by the rule $E_{ij}E_{k\ell} = \delta_{jk}E_{i\ell}$.

Proposition 7.2.9 (Structure of $\mathrm{M}_n(R)$)**.** *Let R be a ring with $1 \neq 0$ and $n \geq 2$. Then $\mathrm{M}_n(R)$ is a noncommutative ring with zero divisors, and its group of units is*

$$\mathrm{M}_n(R)^\times = \mathrm{GL}_n(R) = \{A \in \mathrm{M}_n(R) : A \text{ is invertible}\}.$$

Proof. Noncommutative: using $E_{ij}E_{k\ell} = \delta_{jk}E_{i\ell}$, $E_{11}E_{12} = E_{12}$ but $E_{12}E_{11} = \delta_{21}E_{11} = 0$, so $E_{11}E_{12} \neq E_{12}E_{11}$. *Zero divisors:* $E_{11}E_{22} = \delta_{12}E_{12} = 0$ while $E_{11}, E_{22} \neq 0$. (These sit in the top-left 2×2 block, so they exist for all $n \geq 2$.) *Units:* by definition $\mathrm{M}_n(R)^\times$ is the set of A with a two-sided multiplicative inverse, which is precisely the set of invertible matrices, denoted $\mathrm{GL}_n(R)$. □

Remark 7.2.2. When R is commutative, $A \in \mathrm{GL}_n(R)$ iff $\det A \in R^\times$, and then $A^{-1} = (\det A)^{-1} \operatorname{adj}(A)$. So $\mathrm{GL}_n(\mathbb{Z}) = \{A : \det A = \pm 1\}$ and $\mathrm{GL}_n(\mathbb{Q}) = \{A : \det A \neq 0\}$. The bare definition $\mathrm{M}_n(R)^\times = \mathrm{GL}_n(R)$ holds for any R; the determinant criterion needs commutativity.

Method (Detecting zero divisors / units in $\mathrm{M}_n(R)$)**.** *Trigger.* A question about whether matrices commute, multiply to zero, or are invertible.
Recipe. (1) For zero divisors over $n \geq 2$, reach for matrix units: $E_{ij}E_{k\ell} = 0$ whenever $j \neq k$. The pair E_{11}, E_{22} always gives $E_{11}E_{22} = 0$. (2) For noncommutativity, compute both AB and BA on a small example such as E_{11}, E_{12}. (3) For units when R is commutative, compute $\det A$ and check $\det A \in R^\times$. (4) Never assume a nonzero matrix is a unit: in $\mathrm{M}_n(R)$ a matrix can be nonzero, even nonzero-on-the-diagonal, yet singular.

Worked Example 7.2.10 ($E_{11}E_{22}=0$ and noncommutativity in $\mathrm{M}_2(\mathbb{R})$)**.** In $\mathrm{M}_2(\mathbb{R})$ show $E_{11}E_{22}=0$ and $E_{11}E_{12}\neq E_{12}E_{11}$.

Recognition. These are exactly the matrix-unit identities $E_{ij}E_{k\ell}=\delta_{jk}E_{i\ell}$ witnessing zero divisors and noncommutativity in M_n for $n\geq 2$.

Solution. Write $E_{11}=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)$, $E_{22}=\left(\begin{smallmatrix}0&0\\0&1\end{smallmatrix}\right)$, $E_{12}=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)$. Then

$$E_{11}E_{22}=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)\left(\begin{smallmatrix}0&0\\0&1\end{smallmatrix}\right)=\left(\begin{smallmatrix}0&0\\0&0\end{smallmatrix}\right)=0,$$

with $E_{11},E_{22}\neq 0$: nonzero zero divisors. Next

$$E_{11}E_{12}=\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)=E_{12},\qquad E_{12}E_{11}=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)\left(\begin{smallmatrix}1&0\\0&0\end{smallmatrix}\right)=\left(\begin{smallmatrix}0&0\\0&0\end{smallmatrix}\right)=0.$$

So $E_{11}E_{12}=E_{12}\neq 0=E_{12}E_{11}$: $\mathrm{M}_2(\mathbb{R})$ is noncommutative. *Check.* Both agree with $E_{ij}E_{k\ell}=\delta_{jk}E_{i\ell}$: $E_{11}E_{22}$ has $j=1\neq 2=k$ so 0; $E_{11}E_{12}$ has $j=1=k$ so E_{12}; $E_{12}E_{11}$ has $j=2\neq 1=k$ so 0.

Worked Example 7.2.11 (A nonzero singular matrix is not a unit)**.** Is $A=\left(\begin{smallmatrix}1&1\\1&1\end{smallmatrix}\right)\in\mathrm{M}_2(\mathbb{R})$ a unit? Find a zero divisor partner.

Recognition. Units of $\mathrm{M}_2(\mathbb{R})$ are $\mathrm{GL}_2(\mathbb{R})$; over the field $\mathbb{R}$ that means $\det A\neq 0$.

Solution. $\det A=1\cdot 1-1\cdot 1=0$, so $A\notin\mathrm{GL}_2(\mathbb{R})=\mathrm{M}_2(\mathbb{R})^\times$: A is not a unit. It is in fact a zero divisor:

$$A\left(\begin{smallmatrix}1\\-1\end{smallmatrix}\right)=\left(\begin{smallmatrix}0\\0\end{smallmatrix}\right),\quad\text{so}\quad\left(\begin{smallmatrix}1&1\\1&1\end{smallmatrix}\right)\left(\begin{smallmatrix}1&1\\-1&-1\end{smallmatrix}\right)=\left(\begin{smallmatrix}0&0\\0&0\end{smallmatrix}\right).$$

Thus $AB=0$ with $B=\left(\begin{smallmatrix}1&1\\-1&-1\end{smallmatrix}\right)\neq 0$. *Check.* A unit can never be a zero divisor (if A were invertible, $AB=0\Rightarrow B=A^{-1}0=0$); since $B\neq 0$, A is confirmed non-invertible, consistent with $\det A=0$.

Worked Example 7.2.12 (Units of $\mathrm{M}_2(\mathbb{Z})$ via determinant)**.** Decide whether $A=\left(\begin{smallmatrix}2&1\\3&2\end{smallmatrix}\right)$ and $B=\left(\begin{smallmatrix}2&1\\4&2\end{smallmatrix}\right)$ lie in $\mathrm{M}_2(\mathbb{Z})^\times=\mathrm{GL}_2(\mathbb{Z})$.

Recognition. Over the commutative ring $\mathbb{Z}$, $A\in\mathrm{GL}_2(\mathbb{Z})$ iff $\det A\in\mathbb{Z}^\times=\{\pm 1\}$.

Solution. $\det A=2\cdot 2-1\cdot 3=1\in\{\pm 1\}$, so A is a unit with $A^{-1}=\frac{1}{\det A}\left(\begin{smallmatrix}2&-1\\-3&2\end{smallmatrix}\right)=\left(\begin{smallmatrix}2&-1\\-3&2\end{smallmatrix}\right)\in\mathrm{M}_2(\mathbb{Z})$. For B: $\det B=2\cdot 2-1\cdot 4=0\notin\{\pm 1\}$, so $B\notin\mathrm{GL}_2(\mathbb{Z})$. *Check.* $A\left(\begin{smallmatrix}2&-1\\-3&2\end{smallmatrix}\right)=\left(\begin{smallmatrix}4-3&-2+2\\6-6&-3+4\end{smallmatrix}\right)=\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)=I_2$. Confirmed. Note $\det B=0$ also makes B a zero divisor in $\mathrm{M}_2(\mathbb{Z})$.

Worked Example 7.2.13 (A nilpotent matrix)**.** In $\mathrm{M}_2(\mathbb{R})$ let $N=E_{12}=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)$. Show $N^2=0$ and that I_2+N is a unit.

Recognition. N is a single matrix unit, so $N^2=E_{12}E_{12}=\delta_{21}E_{12}=0$; nilpotents give units via the geometric series $(I+N)^{-1}=I-N$ when $N^2=0$.

Solution. $N^2=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)=\left(\begin{smallmatrix}0&0\\0&0\end{smallmatrix}\right)=0$, so N is nilpotent (hence a zero divisor: $N\cdot N=0$). Then $(I_2+N)(I_2-N)=I_2-N^2=I_2$, so $I_2+N\in\mathrm{GL}_2(\mathbb{R})$ with inverse I_2-N. *Check.* $\det(I_2+N)=\det\left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)=1\neq 0$, confirming I_2+N is invertible over $\mathbb{R}$.

Definition 7.2.14 (The group ring)**.** Let R be a commutative ring with $1\neq 0$ and let $G=\{g_1,\dots,g_n\}$ be a *finite* group. The *group ring* RG is the set of all formal R-linear combinations

$$a_1g_1+a_2g_2+\cdots+a_ng_n,\qquad a_i\in R,$$

with componentwise addition and with multiplication determined by the group law on basis elements, extended R-bilinearly:

$$\Big(\sum_i a_ig_i\Big)\Big(\sum_j b_jg_j\Big)=\sum_{i,j}a_ib_j\,(g_ig_j)=\sum_{g\in G}\Big(\sum_{hk=g}a_hb_k\Big)g.$$

The identity is $1\cdot 1_G$ (the coefficient $1\in R$ on the group identity), and R embeds as $a\mapsto a\,1_G$, G embeds as $g\mapsto 1\cdot g$.

Proposition 7.2.15. *RG is a ring with 1; it is commutative iff G is abelian. If $|G|>1$ then RG is never a domain: for $g\neq 1_G$ of order m, the element $1-g$ is a zero divisor.*

Proof. Associativity and distributivity follow from those of R and the associativity of G; $1 \cdot 1_G$ is the identity. Commutativity of RG requires $g_i g_j = g_j g_i$ for all basis elements, i.e. G abelian (and R commutative, assumed). For the last claim, let g have order $m \geq 2$. Then

$$(1-g)(1+g+g^2+\cdots+g^{m-1}) = 1-g^m = 1-1_G = 0,$$

and both factors are nonzero in RG (distinct group elements are R-linearly independent), so $1-g$ is a zero divisor. □

Remark 7.2.3. $|G| > 1$ also forces zero divisors whenever R has positive characteristic dividing $|G|$, etc.; the argument above needs only $g \neq 1_G$. Group rings are the gateway to representation theory: an RG-module is exactly a representation of G over R.

Method (Computing in a group ring RG)**.** *Trigger.* Multiply, or find zero divisors/units, in RG for an explicit finite G.
Recipe. (1) Fix the group multiplication table of G once. (2) To multiply $\big(\sum a_h h\big)\big(\sum b_k k\big)$, expand bilinearly: each cross term $a_h b_k$ lands on the basis element hk (computed in G); then collect like group elements and add coefficients in R. (3) For a quick zero divisor when $|G| > 1$: pick $g \neq 1_G$ of order m and use $(1-g)(1+g+\cdots+g^{m-1}) = 0$. (4) Keep R-coefficients and G-elements separate: R is central, so scalars float freely, but group elements multiply by the group law (and need not commute).

Worked Example 7.2.16 (Arithmetic in $\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$)**.** Let $\mathbb{Z}/2\mathbb{Z} = \{1, t\}$ with $t^2 = 1$. In $\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$ compute $(1+t)^2$ and exhibit a zero divisor.

Recognition. This is bilinear expansion using $t^2 = 1$; since $|\mathbb{Z}/2\mathbb{Z}| > 1$, Proposition 7.2.15 predicts $1-t$ (and $1+t$) are zero divisors.

Solution. Expand:

$$(1+t)(1+t) = 1\cdot 1 + 1\cdot t + t\cdot 1 + t\cdot t = 1 + t + t + t^2 = 1 + 2t + 1 = 2 + 2t.$$

And, as in the proposition,

$$(1-t)(1+t) = 1 + t - t - t^2 = 1 - 1 = 0,$$

so $1-t$ and $1+t$ are nonzero zero divisors: $\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$ is not a domain. *Check.* The map $\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}] \to \mathbb{Z} \times \mathbb{Z}$, $a + bt \mapsto (a+b,\, a-b)$ is an injective ring homomorphism (not an isomorphism: its image is $\{(u,v) : u \equiv v \pmod 2\}$, which misses $(1,0)$); under it $1+t \mapsto (2,0)$ and $1-t \mapsto (0,2)$, whose product is $(0,0)$ – confirming the zero divisor relation in a transparent way.

Worked Example 7.2.17 (A product in $\mathbb{Q}[D_8]$)**.** In $\mathbb{Q}[D_8]$, with $D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1}\rangle$, compute $(r+s)(r-s)$.

Recognition. Bilinear expansion with the dihedral relations; D_8 is nonabelian so order of factors matters.

Solution. Expand and use $s^2 = 1$, $sr = r^{-1}s = r^3 s$:

$$(r+s)(r-s) = r\cdot r - r\cdot s + s\cdot r - s\cdot s = r^2 - rs + sr - s^2 = r^2 - rs + r^3 s - 1.$$

So $(r+s)(r-s) = -1 + r^2 - rs + r^3 s$ in $\mathbb{Q}[D_8]$. *Check.* Compare with $(r-s)(r+s) = r^2 + rs - sr - s^2 = r^2 + rs - r^3 s - 1$. The two differ ($-rs + r^3 s$ versus $+rs - r^3 s$), as expected since D_8 is nonabelian, so $\mathbb{Q}[D_8]$ is noncommutative. The "$-s^2 = -1$" term is common to both, a good partial sanity check.

Worked Example 7.2.18 (Zero divisor in $\mathbb{Q}[\mathbb{Z}/3\mathbb{Z}]$)**.** Let $\mathbb{Z}/3\mathbb{Z} = \langle g \mid g^3 = 1\rangle$. Find a zero divisor in $\mathbb{Q}[\mathbb{Z}/3\mathbb{Z}]$ and verify it.

Recognition. $|\mathbb{Z}/3\mathbb{Z}| = 3 > 1$ and g has order 3, so $(1-g)(1+g+g^2) = 1 - g^3 = 0$ by the proposition.

Solution. Take $\alpha = 1-g$ and $\beta = 1+g+g^2$. Both are nonzero. Compute:

$$\alpha\beta = (1-g)(1+g+g^2) = 1 + g + g^2 - g - g^2 - g^3 = 1 - g^3 = 1 - 1 = 0.$$

So $\alpha = 1-g$ is a (nonzero) zero divisor in $\mathbb{Q}[\mathbb{Z}/3\mathbb{Z}]$. *Check.* Telescoping: $1 + g + g^2 - g - g^2 - g^3$ leaves only $1 - g^3$, and $g^3 = 1$, giving 0. Independently, $\beta = 1+g+g^2$ satisfies $g\beta = g + g^2 + g^3 = g + g^2 + 1 = \beta$, so $(1-g)\beta = \beta - g\beta = \beta - \beta = 0$.

Worked Example 7.2.19 (Multiplying general elements of $\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$)**.** In $\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$ ($t^2 = 1$) compute $(2+3t)(1-t)$.

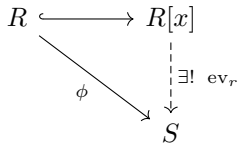
Recognition. Bilinear expansion collecting the 1- and t-components; coefficients add in $\mathbb{Z}$.

Solution.

$$(2+3t)(1-t) = 2\cdot 1 - 2t + 3t - 3t^2 = 2 - 2t + 3t - 3 = (2-3) + (-2+3)t = -1 + t.$$

Check. Via the injective homomorphism $a + bt \mapsto (a+b, a-b)$ into $\mathbb{Z}\times\mathbb{Z}$: $2+3t \mapsto (5,-1)$, $1-t \mapsto (0,2)$; product $(0,-2)$. Inverting, $a+b=0$, $a-b=-2$ gives $a=-1, b=1$, i.e. $-1+t$. Matches.

Worked Example 7.2.20 (A nonzero nilpotent in the group ring $\mathbb{F}_2[\mathbb{Z}/2\mathbb{Z}]$)**.** Show $\mathbb{F}_2[\mathbb{Z}/2\mathbb{Z}]$ has a nontrivial nilpotent, and find its units.



Recognition. In characteristic 2, $(1+t)^2 = 1 + 2t + t^2 = 1 + 0 + 1 = 0$, a nilpotent zero divisor; nilpotents are never units.

Solution. With $\mathbb{Z}/2\mathbb{Z} = \{1, t\}$, $t^2 = 1$, over $\mathbb{F}_2$ (so $2 = 0$):

$$(1+t)^2 = 1 + 2t + t^2 = 1 + 0 + 1 = 2 = 0.$$

Hence $1+t$ is nilpotent and a zero divisor. The ring $\mathbb{F}_2[\mathbb{Z}/2\mathbb{Z}]$ has 4 elements $\{0, 1, t, 1+t\}$; 0 and the nilpotent $1+t$ are not units, while $1\cdot 1 = t\cdot t = 1$, so $\mathbb{F}_2[\mathbb{Z}/2\mathbb{Z}]^\times = \{1, t\}$: the units are exactly the elements of the group $\mathbb{Z}/2\mathbb{Z}$. It is a 4-element local ring whose unique maximal ideal is $\{0, 1+t\}$. *Check.* $1+t \neq 0$ yet $(1+t)^2 = 0$: a nonzero nilpotent. It cannot be a unit (a unit times itself is a unit, but $(1+t)^2 = 0$ is not), confirming RG is not a domain even over a field.

Remark 7.2.4 (Putting the three together). These constructions interlock with the universal properties to come. For any commutative ring R and any element r of an R-algebra S, "evaluation at r" is the unique homomorphism $R[x] \to S$ fixing R and sending $x \mapsto r$:

the dashed map sends $\sum a_i x^i \mapsto \sum a_i r^i$.

Diagram explanation. Objects: Three rings/algebras. R is the base commutative ring (upper-left node, the corner of the triangle from which the two maps out of R start). $R[x]$ is the polynomial ring in one indeterminate over R (upper-right node): a commutative ring with 1 that contains R as the subring of constants. S is a fixed R-algebra (lower-right node): a ring with 1 equipped with a ring homomorphism $R \to S$ sending 1_R to 1_S whose image lies in the center of S, and containing a chosen element $r \in S$.

Arrows: The horizontal arrow $R \hookrightarrow R[x]$ is the canonical inclusion of R as constant polynomials, a unital ring homomorphism. The diagonal arrow $\phi\colon R \to S$ is the structure map of the R-algebra S, which sends $a \in R$ to $a \cdot 1_S \in S$ (or more generally the given ring map $R \to S$ making S an R-algebra). The dashed vertical arrow $\mathrm{ev}_r\colon R[x] \to S$ is the *evaluation map* sending $p(x) = \sum_i a_i x^i$ to $p(r) = \sum_i a_i r^i \in S$; it is the unique ring homomorphism extending the structure map and sending x to r.

What commutes: The triangle commutes: the composition $R \xrightarrow{\text{incl}} R[x] \xrightarrow{\mathrm{ev}_r} S$ equals the structure map $R \to S$ directly. In symbols, $\mathrm{ev}_r \circ (\iota) = \phi$ where $\iota\colon R \hookrightarrow R[x]$ is the inclusion and $\phi\colon R \to S$ is the R-algebra structure map.

Why it commutes: Chase a constant $a \in R$. Along the top-then-down path: $\iota(a) = a \in R[x]$ (the constant polynomial), then $\mathrm{ev}_r(a) = a \cdot r^0 = a \cdot 1_S = \phi(a)$. Along the direct diagonal: $\phi(a)$. Both give $\phi(a)$. Well-definedness of ev_r: it is defined by the formula $\sum a_i x^i \mapsto \sum a_i r^i$, which uses only the ring operations of S and the given R-module structure (scalars a_i act via ϕ); no coset representative choice is involved, so the map is well-defined. Uniqueness holds because a ring map out of $R[x]$ fixing R is entirely determined by where x goes, and we prescribe $x \mapsto r$.

Why this matters here: This universal property is the conceptual glue uniting the section's three constructions. The remark is signaling that $R[x]$, $\mathrm{M}_n(R)$, and RG are not ad hoc – they are universal objects. Specifically, choosing $S = \mathrm{M}_n(R)$ and $r = A$ (any $n \times n$ matrix) gives the matrix-polynomial evaluation map, which is the engine behind the Cayley–Hamilton theorem to come. The uniqueness clause ("$\exists!$") is what gives universal properties their power: they characterize objects up to isomorphism.

Concrete example: Take $R = \mathbb{Z}$, $S = \mathbb{Z}[i]$ (Gaussian integers), $r = i$. The structure map is $\mathbb{Z} \hookrightarrow \mathbb{Z}[i]$. Then $\mathrm{ev}_i \colon \mathbb{Z}[x] \to \mathbb{Z}[i]$ sends $p(x) \mapsto p(i)$; e.g. $x^2 + 1 \mapsto i^2 + 1 = 0$, so $\ker \mathrm{ev}_i = (x^2 + 1)$ and the first isomorphism theorem gives $\mathbb{Z}[x]/(x^2 + 1) \cong \mathbb{Z}[i]$. The commutativity of the triangle is just the fact that $p(i)$ for a constant $p = n$ gives n itself (the copy of $\mathbb{Z}$ inside $\mathbb{Z}[i]$).

Common pitfall: Students sometimes think the dashed arrow exists for *any* ring map $R[x] \to S$ – but it is the *unique* one that both fixes R and sends x to r. There can be many ring maps $R[x] \to S$; the diagram singles out exactly one for each pair (S, r). Also: the arrow $\phi \colon R \to S$ in the diagram is the R-algebra structure map, not a subset inclusion – it need not be injective, so R need not literally be a subset of S.

Takeaway: The point of this diagram is that $R[x]$ is the *free* R-algebra on one generator, meaning specifying where x goes in any R-algebra S completely and uniquely determines the ring map $R[x] \to S$, so the triangle always commutes.

Matrix rings give the most familiar target $S = \mathrm{M}_n(R)$ (so a single matrix A yields $\mathrm{ev}_A \colon R[x] \to \mathrm{M}_n(R)$, the engine behind the Cayley–Hamilton theorem), and group rings RG are the universal way to turn a G-action into module structure. We develop these universal properties systematically in the next sections.

Exercises (from the text).

1. Let $p(x) = 2x^3 - 3x^2 + 4x - 5$ and let $q(x) = 7x^3 + 33x - 4$. In each of parts (a), (b) and (c) compute $p(x) + q(x)$ and $p(x)q(x)$ under the assumption that the coefficients of the two given polynomials are taken from the specified ring (where the integer coefficients are taken mod n in parts (b) and (c)): (a) $R = \mathbb{Z}$, (b) $R = \mathbb{Z}/2\mathbb{Z}$, (c) $R = \mathbb{Z}/3\mathbb{Z}$.

2. Let $p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be an element of the polynomial ring $R[x]$. Prove that $p(x)$ is a zero divisor in $R[x]$ if and only if there is a nonzero $b \in R$ such that $bp(x) = 0$. [Let $g(x) = b_m x^m + b_{m-1}x^{m-1} + \cdots + b_0$ be a nonzero polynomial of minimal degree such that $g(x)p(x) = 0$. Show that $b_m a_n = 0$ and so $a_n g(x)$ is a polynomial of degree less than m that also gives 0 when multiplied by $p(x)$. Conclude that $a_n g(x) = 0$. Apply a similar argument to show by induction on i that $a_{n-i}g(x) = 0$ for $i = 0, 1, \ldots, n$, and show that this implies $b_m p(x) = 0$.]

3. Define the set $R[[x]]$ of *formal power series* in the indeterminate x with coefficients from R to be all formal infinite sums
$$\sum_{n=0}^{\infty} a_n x^n = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \cdots .$$
Define addition and multiplication of power series in the same way as for power series with real or complex coefficients i.e., extend polynomial addition and multiplication to power series as though they were "polynomials of infinite degree":
$$\sum_{n=0}^{\infty} a_n x^n \; + \; \sum_{n=0}^{\infty} b_n x^n = \sum_{n=0}^{\infty} (a_n + b_n) x^n$$
$$\sum_{n=0}^{\infty} a_n x^n \; \times \; \sum_{n=0}^{\infty} b_n x^n = \sum_{n=0}^{\infty} \Big(\sum_{k=0}^{n} a_k b_{n-k} \Big) x^n .$$
(The term "formal" is used here to indicate that convergence is not considered, so that formal power series need not represent functions on R.) (a) Prove that $R[[x]]$ is a commutative ring with 1. (b) Show that $1 - x$ is a unit in $R[[x]]$ with inverse $1 + x + x^2 + \cdots$. (c) Prove that $\sum_{n=0}^{\infty} a_n x^n$ is a unit in $R[[x]]$ if and only if a_0 is a unit in R.

4. Prove that if R is an integral domain then the ring of formal power series $R[[x]]$ is also an integral domain.

5. Let F be a field and define the ring $F((x))$ of *formal Laurent series* with coefficients from F by

$$F((x)) = \Big\{ \sum_{n \geq N} a_n x^n \;\Big|\; a_n \in F \text{ and } N \in \mathbb{Z} \Big\}.$$

(Every element of $F((x))$ is a power series in x plus a polynomial in $1/x$, i.e., each element of $F((x))$ has only a finite number of terms with negative powers of x.) (a) Prove that $F((x))$ is a field. (b) Define the map

$$\nu : F((x))^\times \to \mathbb{Z} \qquad \text{by} \qquad \nu\Big(\sum_{n \geq N} a_n x^n \Big) = N$$

where a_N is the first nonzero coefficient of the series (i.e., N is the "order of zero or pole of the series at 0"). Prove that ν is a discrete valuation on $F((x))$ whose discrete valuation ring is $F[[x]]$, the ring of formal power series (cf. Exercise 26, Section 1).

6. Let S be a ring with identity $1 \neq 0$. Let $n \in \mathbb{Z}^+$ and let A be an $n \times n$ matrix with entries from S whose i, j entry is a_{ij}. Let E_{ij} be the element of $\mathrm{M}_n(S)$ whose i, j entry is 1 and whose other entries are all 0. (a) Prove that $E_{ij}A$ is the matrix whose ith row equals the jth row of A and all other rows are zero. (b) Prove that AE_{ij} is the matrix whose jth column equals the ith column of A and all other columns are zero. (c) Deduce that $E_{pq}AE_{rs}$ is the matrix whose p, s entry is a_{qr} and all other entries are zero.

7. Prove that the center of the ring $\mathrm{M}_n(R)$ is the set of scalar matrices (cf. Exercise 7, Section 1). [Use the preceding exercise.]

8. Let S be any ring and let $n \geq 2$ be an integer. Prove that if A is any strictly upper triangular matrix in $\mathrm{M}_n(S)$ then $A^n = 0$ (a strictly upper triangular matrix is one whose entries on and below the main diagonal are all zero).

9. Let $\alpha = r + r^2 - 2s$ and $\beta = -3r^2 + rs$ be the two elements of the integral group ring $\mathbb{Z}D_8$ described in this section. Compute the following elements of $\mathbb{Z}D_8$: (a) $\beta\alpha$, (b) α^2, (c) $\alpha\beta - \beta\alpha$, (d) $\beta\alpha\beta$.

10. Consider the following elements of the integral group ring $\mathbb{Z}S_3$:

$$\alpha = 3(1\ 2) - 5(2\ 3) + 14(1\ 2\ 3) \qquad \text{and} \qquad \beta = 6(1) + 2(2\ 3) - 7(1\ 3\ 2)$$

(where (1) is the identity of S_3). Compute the following elements: (a) $\alpha + \beta$, (b) $2\alpha - 3\beta$, (c) $\alpha\beta$, (d) $\beta\alpha$, (e) α^2.

11. Repeat the preceding exercise under the assumption that the coefficients of α and β are in $\mathbb{Z}/3\mathbb{Z}$ (i.e., $\alpha, \beta \in \mathbb{Z}/3\mathbb{Z}S_3$).

12. Let $G = \{g_1, \ldots, g_n\}$ be a finite group. Prove that the element $N = g_1 + g_2 + \cdots + g_n$ is in the center of the group ring RG (cf. Exercise 7, Section 1).

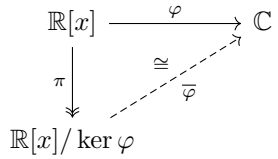
13. Let $\mathcal{K} = \{k_1, \ldots, k_m\}$ be a conjugacy class in the finite group G. (a) Prove that the element $K = k_1 + \cdots + k_m$ is in the center of the group ring RG (cf. Exercise 7, Section 1). [Check that $g^{-1}Kg = K$ for all $g \in G$.] (b) Let $\mathcal{K}_1, \ldots, \mathcal{K}_r$ be the conjugacy classes of G and for each $\mathcal{K}_i$ let K_i be the element of RG that is the sum of the members of $\mathcal{K}_i$. Prove that an element $\alpha \in RG$ is in the center of RG if and only if $\alpha = a_1K_1 + a_2K_2 + \cdots + a_rK_r$ for some $a_1, a_2, \ldots, a_r \in R$.

Practice problems.

1. In $\mathbb{Z}[x]$ compute $(2x^2 - 3x + 1)(x^3 + x - 4)$ and verify that the degree of the product equals the sum of the degrees.

2. Let $R = \mathbb{Z}/6\mathbb{Z}$. Find two nonzero polynomials $f, g \in R[x]$, each of degree 1, whose product has degree strictly less than 2 (the leading terms cancel). Conclude that $\deg(fg) < \deg f + \deg g$ can occur when R is not an integral domain.

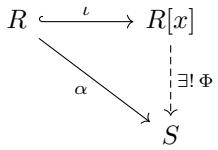
3. Prove that if R is an integral domain then $R[x]^\times = R^\times$. (Show every unit of $R[x]$ has degree 0.)



4. Exhibit a unit of $\mathbb{Z}/4\mathbb{Z}[x]$ of degree 1, thereby showing the hypothesis "integral domain" in the previous problem cannot be dropped.
5. In $\mathrm{M}_2(\mathbb{R})$ let $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$. Compute AB and BA, observe $AB \neq BA$, and exhibit a zero divisor in $\mathrm{M}_2(\mathbb{R})$.
6. Determine $\mathrm{M}_2(\mathbb{Z}/2\mathbb{Z})^\times$: list all invertible 2×2 matrices over $\mathbb{Z}/2\mathbb{Z}$ and state $|\mathrm{GL}_2(\mathbb{Z}/2\mathbb{Z})|$.
7. Let R be a commutative ring. Show that the map $\varphi\colon R[x] \to R$ given by $\varphi(f) = f(0)$ (evaluation at 0) is a surjective ring homomorphism and identify $\ker\varphi$.
8. With φ as above for $R = \mathbb{Z}$, prove $\ker\varphi = \langle x \rangle$ and deduce $\mathbb{Z}[x]/\langle x \rangle \cong \mathbb{Z}$ from the First Isomorphism Theorem.
9. Let $\varphi\colon \mathbb{Z}[x] \to \mathbb{Z}/5\mathbb{Z}$ be the unique homomorphism with $\varphi(x) = 2$ and $\varphi|_{\mathbb{Z}}$ reduction mod 5. Compute $\varphi(x^3 + x + 1)$ and describe $\ker\varphi$ as a generated ideal.
10. In $\mathbb{Q}[x]$ show that $\langle x^2 + 1 \rangle$ is a maximal ideal but $\langle x^2 - 1 \rangle$ is not. (For the second, exhibit a proper containment.)
11. Prove that $\langle x \rangle$ is a prime ideal of $\mathbb{Z}[x]$ but not maximal, while $\langle 2, x \rangle$ is maximal. Identify $\mathbb{Z}[x]/\langle 2, x \rangle$.
12. Let R be an integral domain with field of fractions $\mathrm{Frac}(R)$. Show $\mathrm{Frac}(\mathbb{Z}) = \mathbb{Q}$ and, more generally, describe $\mathrm{Frac}(\mathbb{Q}[x])$.
13. Use the Chinese Remainder Theorem to prove $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$ explicitly: give the isomorphism on the element 5 and find the element of $\mathbb{Z}/12\mathbb{Z}$ corresponding to $(2, 1)$.
14. Let $S = \mathbb{Z}[x]/\langle x^2 - 2 \rangle$. Show S is an integral domain by exhibiting an injective ring homomorphism $S \to \mathbb{R}$, and find the image of the class of x.
15. For the group ring $\mathbb{Z}/2\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$ with $\mathbb{Z}/2\mathbb{Z} = \{1, g\}$, write out the multiplication of $(1 + g)$ with itself and conclude that $1 + g$ is a nonzero element with $(1 + g)^2 = 0$; hence $\mathbb{Z}/2\mathbb{Z}[\mathbb{Z}/2\mathbb{Z}]$ has nonzero nilpotents.

Additional exercises.

1. Let R be a commutative ring. Prove that the nilradical $\mathrm{nil}(R[x])$ consists of all polynomials $a_0 + a_1 x + \cdots + a_n x^n$ with every $a_i \in \mathrm{nil}(R)$. (Hint: first show $a_0 + a_1 x$ is nilpotent iff a_0, a_1 are; then induct.)
2. Show that $f = a_0 + a_1 x + \cdots + a_n x^n \in R[x]$ (R commutative) is a unit iff $a_0 \in R^\times$ and $a_1, \ldots, a_n$ are all nilpotent.
3. Let R be a ring (not necessarily commutative). Prove that the center of $\mathrm{M}_n(R)$ is $\{cI : c \in Z(R)\}$, where $Z(R)$ is the center of R and I is the identity matrix.
4. Let G be a finite group and R a commutative ring. Show that the augmentation map $\varepsilon\colon R[G] \to R$, $\varepsilon\Big(\sum_g a_g\, g\Big) = \sum_g a_g$, is a surjective ring homomorphism. Its kernel (the augmentation ideal) is generated as an ideal by $\{g - 1 : g \in G\}$; prove this.
5. Let R be an integral domain and let $f \in R[x]$ have degree $n \geq 1$. Prove f has at most n roots in R. Show this can fail in $\mathrm{M}_2(\mathbb{R})$ by exhibiting a degree-2 polynomial with infinitely many roots in $\mathrm{M}_2(\mathbb{R})$.
6. Let p be prime. Prove that $\mathbb{Z}/p\mathbb{Z}[x]/\langle x^2 + 1 \rangle$ is a field iff -1 is not a square mod p, and determine for which of $p = 2, 3, 5, 7$ it is a field.

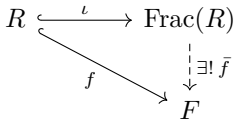


Commutative-diagram exercises.

1. (First Isomorphism Theorem for rings.) Let $\varphi\colon \mathbb{R}[x] \to \mathbb{C}$ be the unique ring homomorphism fixing $\mathbb{R}$ with $\varphi(x) = i$. Compute $\ker\varphi$, and complete the diagram

by identifying $\ker\varphi$ explicitly and proving $\overline{\varphi}$ is an isomorphism.

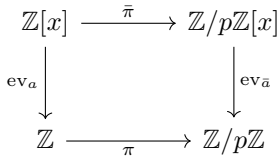
2. (Universal property of $R[x]$.) Let R be a commutative ring, S a commutative R-algebra with structure map $\alpha\colon R \to S$, and fix $s \in S$. Prove there is a unique ring homomorphism Φ making



commute with $\Phi(x) = s$, where ι is the inclusion of constants. Describe Φ on a general polynomial.

3. (CRT as an isomorphism.) Let I_1, I_2 be ideals of a commutative ring R with $I_1 + I_2 = R$. Show the diagonal-style map fits in

$$R \xrightarrow{\ \rho\ } R/I_1 \times R/I_2$$



after passing to the quotient by $I_1 \cap I_2$. Precisely: prove $r \mapsto (r + I_1,\, r + I_2)$ has kernel $I_1 \cap I_2 = I_1 I_2$ and induces an isomorphism $R/(I_1 \cap I_2) \cong R/I_1 \times R/I_2$.

4. (Universal property of fractions.) Let R be an integral domain and $f\colon R \to F$ an injective ring homomorphism into a field F. Prove there is a unique homomorphism $\bar{f}$ making

commute, where $\iota(r) = r/1$. Give the formula for $\bar{f}(a/b)$ and show it is well defined.

5. (Reduction mod p on polynomials.) For a prime p let $\pi\colon \mathbb{Z} \to \mathbb{Z}/p\mathbb{Z}$ be reduction and let $\bar{\pi}\colon \mathbb{Z}[x] \to \mathbb{Z}/p\mathbb{Z}[x]$ apply π to coefficients. Show $\bar{\pi}$ is a surjective ring homomorphism and that the square

commutes for every $a \in \mathbb{Z}$ with $\bar{a} = \pi(a)$, where ev_a denotes evaluation at a.

7.3 Ring Homomorphisms and Quotient Rings

Ring homomorphisms, ideals, and quotient rings

We now develop the ring-theoretic analogues of the group homomorphism / normal subgroup / quotient group machinery. The structural parallel is exact, but rings carry *two* operations, so a homomorphism must respect both, and the role of "normal subgroup" is played by an object that absorbs multiplication on both sides: an ideal.

Definition 7.3.1 (Ring homomorphism)**.** Let R and S be rings. A *ring homomorphism* is a map $\varphi : R \to S$ satisfying, for all $a, b \in R$,

$$\varphi(a+b) = \varphi(a) + \varphi(b), \qquad \varphi(ab) = \varphi(a)\varphi(b).$$

The *kernel* is $\ker\varphi = \{r \in R : \varphi(r) = 0\}$. A bijective ring homomorphism is an *isomorphism*, written $R \cong S$.

Remark 7.3.1. Since φ is in particular a homomorphism of the additive groups $(R,+) \to (S,+)$, we automatically get $\varphi(0) = 0$ and $\varphi(-a) = -\varphi(a)$. D&F do *not* build $\varphi(1_R) = 1_S$ into the definition; it can fail (e.g. $r \mapsto 0$, or $\mathbb{Z} \to \mathbb{Z} \times \mathbb{Z}$, $n \mapsto (n, 0)$). When 1_R is preserved one says φ is *unital*. Every surjective homomorphism onto a ring with 1 *is* unital, and every evaluation/quotient map below is unital.

Proposition 7.3.2 (Kernel is an ideal, image is a subring)**.** *Let $\varphi : R \to S$ be a ring homomorphism. Then:*

1. *$\varphi(R)$ is a subring of S.*
2. *$\ker\varphi$ is a subring of R that is closed under multiplication by arbitrary elements of R on both sides: if $k \in \ker\varphi$ and $r \in R$ then $rk \in \ker\varphi$ and $kr \in \ker\varphi$.*
3. *φ is injective $\iff \ker\varphi = \{0\}$.*

Proof. (1) $\varphi(R)$ contains $0 = \varphi(0)$ and is closed under the additive-subgroup operations because $(R,+) \to (S,+)$ is a group homomorphism. For products, $\varphi(a)\varphi(b) = \varphi(ab) \in \varphi(R)$. So $\varphi(R)$ is a subring.

(2) As above $\ker\varphi$ is an additive subgroup, and $0 \in \ker\varphi$. If $k \in \ker\varphi$ and $r \in R$ then $\varphi(rk) = \varphi(r)\varphi(k) = \varphi(r)\cdot 0 = 0$, so $rk \in \ker\varphi$; symmetrically $kr \in \ker\varphi$. In particular $\ker\varphi$ is closed under products, hence a subring (without 1, in general).

(3) Identical to the group statement applied to $(R,+)$: $\varphi(a) = \varphi(b) \iff \varphi(a-b) = 0 \iff a - b \in \ker\varphi$. Thus φ is injective iff $\ker\varphi = \{0\}$. □

Definition 7.3.3 (Ideal)**.** Let R be a ring and $I \subseteq R$ a subset. Say I is a *left ideal* if I is an additive subgroup and $rI \subseteq I$ for all $r \in R$; a *right ideal* if instead $Ir \subseteq I$ for all $r \in R$; and a *(two-sided) ideal* if it is both. In a commutative ring all three notions coincide; "ideal" then means "two-sided ideal" and we write $I \trianglelefteq R$.

Remark 7.3.2 (An ideal is rarely a subring with 1). An ideal I is closed under the ring operations, but $1 \in I$ forces $r = r\cdot 1 \in I$ for every r, i.e. $I = R$. So a *proper* ideal never contains 1, i.e. it is never a subring containing the identity of R (it can still have an identity of its own: the ideal $\mathbb{Z}\times 0$ of $\mathbb{Z}\times\mathbb{Z}$ has identity $(1,0)$). The point of Proposition 7.3.2 is precisely that kernels are the right absorbing objects to quotient by.

Definition 7.3.4 (Ideal generated by a set)**.** For $A \subseteq R$, the ideal $\langle A\rangle$ *generated by* A is the smallest two-sided ideal containing A; concretely in a commutative ring with 1,

$$\langle A\rangle = \Big\{ \textstyle\sum_{i=1}^{n} r_i a_i : n \geq 0,\ r_i \in R,\ a_i \in A \Big\}.$$

A *principal ideal* is $\langle a\rangle = Ra = \{ra : r \in R\}$ (commutative case).

Theorem 7.3.5 (Quotient ring)**.** *Let I be a two-sided ideal of R. The additive quotient group $R/I = \{r + I : r \in R\}$ becomes a ring under*

$$(r+I)+(s+I) = (r+s)+I, \qquad (r+I)(s+I) = rs + I,$$

and the canonical projection $\pi : R \to R/I$, $\pi(r) = r + I$, is a surjective ring homomorphism with $\ker\pi = I$.

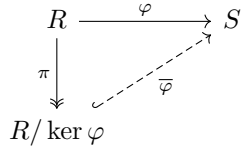
Proof. The additive structure is the usual quotient of abelian groups. We must check multiplication is *well defined*: suppose $r + I = r' + I$ and $s + I = s' + I$, so $r' = r + a$, $s' = s + b$ with $a, b \in I$. Then

$$r's' = (r+a)(s+b) = rs + \underbrace{rb}_{\in I} + \underbrace{as}_{\in I} + \underbrace{ab}_{\in I},$$

where $rb \in I$ because I is a *left* ideal, $as \in I$ because I is a *right* ideal, and $ab \in I$ since I is closed under products. Hence $r's' - rs \in I$, i.e. $r's' + I = rs + I$. Associativity, distributivity, and the identity $1 + I$ are inherited from R. Finally $\pi(rs) = rs + I = (r+I)(s+I) = \pi(r)\pi(s)$ and $\pi(r) = 0 + I \iff r \in I$, so $\ker\pi = I$. □

Caution. The well-definedness proof uses both sidedness conditions *separately* (rb needs left-absorption, as needs right-absorption). If I is only a left ideal, $r's' + I = rs + I$ can fail and R/I is merely a left R-module, not a ring. This is exactly why one quotients by *two-sided* ideals only.

Theorem 7.3.6 (First Isomorphism Theorem for rings)**.** *Let $\varphi : R \to S$ be a ring homomorphism. Then $\ker\varphi$ is a two-sided ideal of R, $\varphi(R)$ is a subring of S, and there is a unique ring isomorphism $\overline{\varphi} : R/\ker\varphi \to \varphi(R)$ with $\overline{\varphi}(r + \ker\varphi) = \varphi(r)$, i.e. $\varphi = \overline{\varphi}\circ\pi$. Thus*



$$R/\ker\varphi \ \cong\ \varphi(R).$$

Proof. By Proposition 7.3.2, $K := \ker\varphi$ is a two-sided ideal, so R/K is a ring. Define $\overline{\varphi}(r+K) = \varphi(r)$. Well-defined: if $r+K = r'+K$ then $r-r' \in K$, so $\varphi(r)-\varphi(r') = \varphi(r-r') = 0$. It is a homomorphism:

$$\overline{\varphi}\big((r+K)(s+K)\big) = \overline{\varphi}(rs+K) = \varphi(rs) = \varphi(r)\varphi(s) = \overline{\varphi}(r+K)\,\overline{\varphi}(s+K),$$

and additivity is identical. It is surjective onto $\varphi(R)$ by construction, and injective since $\overline{\varphi}(r+K) = 0 \iff \varphi(r) = 0 \iff r \in K \iff r+K = 0+K$. Uniqueness: any ψ with $\psi\circ\pi = \varphi$ satisfies $\psi(r+K) = \psi(\pi(r)) = \varphi(r) = \overline{\varphi}(r+K)$. □

The content of Theorem 7.3.6 is the factorization triangle: every homomorphism splits as "project, then embed."

The dashed arrow is an isomorphism *onto its image* $\varphi(R) \subseteq S$.

Diagram explanation. Objects: Three objects: R, a ring (the domain); S, a ring (the codomain); and $R/\ker\varphi$, the quotient ring of R by the two-sided ideal $\ker\varphi$. Note $\varphi(R) \subseteq S$ is the image subring, not all of S.

Arrows: $\varphi : R \to S$ is the given ring homomorphism. $\pi : R \twoheadrightarrow R/\ker\varphi$ is the canonical surjective projection, $r \mapsto r + \ker\varphi$. The dashed arrow $\overline{\varphi} : R/\ker\varphi \xrightarrow{\cong} \varphi(R)$ is the induced ring isomorphism defined by $\overline{\varphi}(r+\ker\varphi) = \varphi(r)$; it is both injective (the kernel of φ has been killed) and surjective onto $\varphi(R)$.

What commutes: The triangle commutes: $\overline{\varphi}\circ\pi = \varphi$. Concretely, for every $r \in R$, applying π then $\overline{\varphi}$ gives $\varphi(r)$, the same as applying φ directly.

Why it commutes: Chase a generic $r \in R$. Via π: $r \mapsto r+\ker\varphi$. Via $\overline{\varphi}$: $r+\ker\varphi \mapsto \varphi(r)$. So the composite is $\varphi(r)$, matching the direct arrow. Well-definedness of $\overline{\varphi}$: if $r+\ker\varphi = r'+\ker\varphi$ then $r-r' \in \ker\varphi$, so $\varphi(r)-\varphi(r') = \varphi(r-r') = 0$, hence $\varphi(r) = \varphi(r')$. This check uses only that the ideal we quotient by is contained in $\ker\varphi$ (compare Theorem 7.3.7); that it is all of $\ker\varphi$ is what makes $\overline{\varphi}$ injective.

Why this matters here: This diagram is the First Isomorphism Theorem made visual. Every ring homomorphism decomposes canonically into a surjection followed by an injection (an isomorphism onto $\varphi(R)$). This is why the theorem is the workhorse of ring theory: to identify $R/I \cong S$, one builds $\varphi : R \twoheadrightarrow S$ with $\ker\varphi = I$ and reads off the isomorphism from this triangle.

Concrete example: $R = \mathbb{Z}$, $S = \mathbb{Z}/n\mathbb{Z}$, $\varphi(k) = k \bmod n$. Then $\ker\varphi = n\mathbb{Z}$, $\pi : \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$, and $\overline{\varphi} : \mathbb{Z}/n\mathbb{Z} \xrightarrow{\cong} \mathbb{Z}/n\mathbb{Z}$ sends $k+n\mathbb{Z} \mapsto k \bmod n$. The triangle commutes: $(k+n\mathbb{Z}) \mapsto k \bmod n = \varphi(k)$.

Common pitfall: The dashed arrow $\overline{\varphi}$ is an isomorphism *onto its image* $\varphi(R)$, not onto all of S (unless φ is surjective). This is why it is drawn as a hooked (injective) arrow into S. Students sometimes read the triangle as saying $R/\ker\varphi \cong S$; the correct conclusion is $R/\ker\varphi \cong \varphi(R)$. The diagram is drawn with the dashed arrow targeting S only because $\varphi(R)$ lives inside S.

Takeaway: The point of this diagram is that every ring homomorphism factors uniquely as a surjection onto a quotient followed by an injection, so any ring map is, up to isomorphism, completely described by its kernel.

Theorem 7.3.7 (Universal property of the quotient)**.** *Let $I \trianglelefteq R$ and $\pi : R \to R/I$ the projection. If $\varphi : R \to S$ is any ring homomorphism with $I \subseteq \ker\varphi$, then there is a* unique *ring homomorphism $\overline{\varphi} : R/I \to S$ with $\varphi = \overline{\varphi}\circ\pi$, namely $\overline{\varphi}(r+I) = \varphi(r)$.*

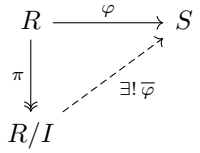


Diagram explanation. Objects: Three objects: R, a ring (the domain); S, a ring (the codomain/target); and R/I, the quotient ring formed by the two-sided ideal $I \trianglelefteq R$. The ideal I is given to be contained in $\ker\varphi$.

Arrows: $\varphi : R \to S$ is any ring homomorphism with $I \subseteq \ker\varphi$ (the "given" map). $\pi : R \twoheadrightarrow R/I$ is the canonical surjective quotient map, $r \mapsto r + I$. The dashed arrow $\overline{\varphi} : R/I \to S$ is the *unique* induced ring homomorphism asserted by the universal property, defined by $\overline{\varphi}(r + I) = \varphi(r)$.

What commutes: $\overline{\varphi} \circ \pi = \varphi$, i.e. the two paths from R to S agree: project to R/I then apply $\overline{\varphi}$, or apply φ directly.

Why it commutes: For any $r \in R$: along π then $\overline{\varphi}$, we get $r \mapsto r + I \mapsto \varphi(r)$; along φ directly, $r \mapsto \varphi(r)$. They agree by the very definition of $\overline{\varphi}$. Well-definedness: if $r + I = r' + I$ then $r - r' \in I \subseteq \ker\varphi$, so $\varphi(r - r') = 0$, i.e. $\varphi(r) = \varphi(r')$. This is why the condition $I \subseteq \ker\varphi$ is the necessary and sufficient hypothesis.

Why this matters here: This universal property is the mechanism behind all three remaining isomorphism theorems. Whenever we want to factor a map through a quotient, we need only check that the ideal being quotiented by is contained in the kernel; the induced map then exists and is unique. The theorem after the diagram also records $\ker\overline{\varphi} = \ker\varphi/I$, from which the First Isomorphism Theorem is recovered as the special case $I = \ker\varphi$.

Concrete example: Let $R = \mathbb{Z}$, $I = 6\mathbb{Z}$, $S = \mathbb{Z}/2\mathbb{Z}$, and $\varphi(n) = n \bmod 2$. Since $6\mathbb{Z} \subseteq 2\mathbb{Z} = \ker\varphi$, there is a unique $\overline{\varphi} : \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ with $\overline{\varphi}(n + 6\mathbb{Z}) = n \bmod 2$. Indeed $\ker\overline{\varphi} = 2\mathbb{Z}/6\mathbb{Z} = \{\overline{0}, \overline{2}, \overline{4}\}$, consistent with $\ker\overline{\varphi} = \ker\varphi/I = (2\mathbb{Z})/(6\mathbb{Z})$.

Common pitfall: Students sometimes apply this theorem without verifying $I \subseteq \ker\varphi$; the induced map $\overline{\varphi}$ simply does not exist if $I \not\subseteq \ker\varphi$ (if some $i \in I$ has $\varphi(i) \neq 0$, then 0 and i represent the same coset $0 + I = i + I$ but have different images $0 \neq \varphi(i)$). Always check the kernel containment before claiming an induced map exists.

Takeaway: The point of this diagram is that any ring map φ whose kernel contains I factors uniquely through the quotient R/I, making π the universal map out of R that kills I.

Moreover $\ker\overline{\varphi} = \ker\varphi/I$*, so* $\overline{\varphi}$ *is injective iff* $I = \ker\varphi$ *(recovering Theorem 7.3.6).*

Proof. $\overline{\varphi}$ is well defined: if $r + I = r' + I$ then $r - r' \in I \subseteq \ker\varphi$, so $\varphi(r) = \varphi(r')$. The homomorphism axioms transfer verbatim as in Theorem 7.3.6, and uniqueness follows since π is surjective: $\varphi = \overline{\varphi} \circ \pi$ pins down $\overline{\varphi}$ on all of R/I. Finally $r + I \in \ker\overline{\varphi} \iff \varphi(r) = 0 \iff r \in \ker\varphi$, i.e. $\ker\overline{\varphi} = \{r + I : r \in \ker\varphi\} = \ker\varphi/I$. □

Theorem 7.3.8 (Second, Third, Fourth Isomorphism Theorems for rings)**.** *Let R be a ring.*

(2nd) *If A is a subring and I a two-sided ideal of R, then $A + I$ is a subring, $A \cap I$ is a two-sided ideal of A, and*

$$(A + I)/I \;\cong\; A/(A \cap I).$$

(3rd) *If $I \subseteq J$ are two-sided ideals of R, then J/I is a two-sided ideal of R/I and*

$$(R/I)/(J/I) \;\cong\; R/J.$$

(4th, Lattice) *If $I \trianglelefteq R$, the map $J \mapsto J/I$ is an inclusion-preserving bijection between the two-sided ideals of R containing I and the two-sided ideals of R/I; the same holds for subrings.*

Proof. (2nd) Define $\varphi : A \to (A + I)/I$ by $a \mapsto a + I$ (restrict π to A). It is a homomorphism, surjective because every $a + i + I = a + I$ lies in its image, and $\ker\varphi = \{a \in A : a \in I\} = A \cap I$. Theorem 7.3.6 gives $A/(A \cap I) \cong (A + I)/I$.

(3rd) Apply Theorem 7.3.7 to $\varphi = \pi_J : R \to R/J$, whose kernel is $J \supseteq I$, to get a surjection $\overline{\pi_J} : R/I \to R/J$ with kernel J/I. Then Theorem 7.3.6 yields $(R/I)/(J/I) \cong R/J$.

(4th) Since π is a surjective ring homomorphism (Theorem 7.3.5), ideals/subrings of R/I pull back along π to ideals/subrings of R containing $\ker\pi = I$, and push forward as $J \mapsto J/I$; these are mutually inverse and preserve inclusion. (Same argument as the group lattice theorem applied to the absorbing structure.) □

Method (Recognizing a quotient: identify R/I via a surjection with the right kernel)**.** To prove $R/I \cong S$ (or to identify an unfamiliar quotient):

1. Build a *surjective* ring homomorphism $\varphi : R \to S$ onto the target you suspect. Evaluation maps $p \mapsto p(c)$, reduction maps, and "set this generator to 0" maps are the standard sources.

2. Compute $\ker\varphi$ exactly. Show $\ker\varphi = I$ by two inclusions: $I \subseteq \ker\varphi$ (check each generator of I maps to 0) and $\ker\varphi \subseteq I$ (often via a division/normal-form argument).

3. Conclude $R/I = R/\ker\varphi \cong \varphi(R) = S$ by Theorem 7.3.6.

Recognition triggers: "identify $R[x]/(f)$," "show $\mathbb{Z}/n\mathbb{Z} \cong \ldots$," "compute a quotient" — almost always solved by a one-line evaluation/reduction surjection plus a kernel computation.

Worked Example 7.3.9 (Reduction mod n: $\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$)**.** Show the reduction map $\varphi : \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$, $\varphi(a) = a \bmod n$, is a surjective ring homomorphism with $\ker\varphi = n\mathbb{Z} = \langle n\rangle$, and recover $\mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/n\mathbb{Z}$.

Recognition. First Isomorphism Theorem: produce the canonical surjection and read off its kernel.

Solution. φ respects both operations by definition of arithmetic in $\mathbb{Z}/n\mathbb{Z}$: $(a+b) \bmod n = (a \bmod n) + (b \bmod n)$ and $(ab) \bmod n = (a \bmod n)(b \bmod n)$, and $\varphi(1) = 1$. It is surjective since every residue class $\overline{k}$ $(0 \le k < n)$ equals $\varphi(k)$. The kernel is

$$\ker\varphi = \{a \in \mathbb{Z} : a \equiv 0 \pmod{n}\} = n\mathbb{Z} = \langle n\rangle.$$

By Theorem 7.3.6, $\mathbb{Z}/n\mathbb{Z} = \mathbb{Z}/\ker\varphi \cong \operatorname{im}\varphi = \mathbb{Z}/n\mathbb{Z}$. *Check.* For $n = 6$, $\varphi(4) = 4$, $\varphi(5) = 5$, and $\varphi(4\cdot 5) = \varphi(20) = 20 \bmod 6 = 2$, while $\varphi(4)\varphi(5) = 4 \cdot 5 = 20 = 2$ in $\mathbb{Z}/6\mathbb{Z}$. Consistent. The notation $\mathbb{Z}/n\mathbb{Z}$ for the ring $\mathbb{Z}/n\mathbb{Z}$ is now literally a quotient ring, not just suggestive.

Worked Example 7.3.10 (Evaluation at 0: $\mathbb{R}[x] \to \mathbb{R}$, kernel $\langle x\rangle$)**.** Let $\mathrm{ev}_0 : \mathbb{R}[x] \to \mathbb{R}$ send $p(x) \mapsto p(0)$ (the constant term). Show it is a surjective ring homomorphism and $\ker(\mathrm{ev}_0) = \langle x\rangle$, hence $\mathbb{R}[x]/\langle x\rangle \cong \mathbb{R}$.

Recognition. First Iso: an evaluation map is a homomorphism; its kernel is "polynomials vanishing at the point."

Solution. Evaluation is a homomorphism: if $p(x) = \sum a_i x^i$, $q(x) = \sum b_j x^j$, then $(p+q)(0) = a_0 + b_0 = p(0) + q(0)$ and $(pq)(0)$ is the constant term of pq, which is $a_0 b_0 = p(0)q(0)$; also $\mathrm{ev}_0(1) = 1$. Surjective: for $c \in \mathbb{R}$ the constant polynomial c has $\mathrm{ev}_0(c) = c$. Kernel:

$$p(0) = 0 \iff a_0 = 0 \iff p(x) = a_1 x + a_2 x^2 + \cdots = x\,(a_1 + a_2 x + \cdots) \in \langle x\rangle,$$

and conversely every $x \cdot g(x)$ has constant term 0. So $\ker(\mathrm{ev}_0) = \langle x\rangle$, and Theorem 7.3.6 gives $\mathbb{R}[x]/\langle x\rangle \cong \mathbb{R}$.

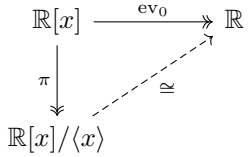

Diagram explanation. Objects: Three objects: $\mathbb{R}[x]$, the polynomial ring over $\mathbb{R}$; $\mathbb{R}$, the target field (here viewed as the codomain ring); and $\mathbb{R}[x]/\langle x\rangle$, the quotient ring obtained by killing the ideal $\langle x\rangle$ of polynomials with zero constant term.

Arrows: $\mathrm{ev}_0 : \mathbb{R}[x] \to \mathbb{R}$ is evaluation at 0, the ring homomorphism $p(x) \mapsto p(0)$ (picks the constant term); it is surjective since every $c \in \mathbb{R}$ equals $\mathrm{ev}_0(c)$. $\pi : \mathbb{R}[x] \twoheadrightarrow \mathbb{R}[x]/\langle x\rangle$ is the canonical surjective quotient projection $p \mapsto p + \langle x\rangle$. The dashed arrow $\overline{\mathrm{ev}_0} : \mathbb{R}[x]/\langle x\rangle \to \mathbb{R}$ is the induced isomorphism given by $\overline{\mathrm{ev}_0}(p + \langle x\rangle) = p(0)$.

What commutes: The triangle commutes: $\overline{\mathrm{ev}_0} \circ \pi = \mathrm{ev}_0$, i.e. project then evaluate equals evaluate directly.

Why it commutes: For $p \in \mathbb{R}[x]$: along π then $\overline{\mathrm{ev}_0}$, $p \mapsto p + \langle x\rangle \mapsto p(0)$; along ev_0 directly, $p \mapsto p(0)$. They agree. Well-definedness of $\overline{\mathrm{ev}_0}$: if $p + \langle x\rangle = q + \langle x\rangle$ then $p - q \in \langle x\rangle$, so $p - q = xh(x)$ for some h, and $(p-q)(0) = 0$, giving $p(0) = q(0)$. Hence the output does not depend on the choice of coset representative.

Why this matters here: This diagram is the canonical instance of the First Isomorphism Theorem for the evaluation map ev_0. It shows that "quotienting $\mathbb{R}[x]$ by $\langle x\rangle$" and "evaluating at 0" are two descriptions of the same identification: every polynomial is reduced to its constant term.

Concrete example: Take $p(x) = 3 + 5x + x^2$. Then $\mathrm{ev}_0(p) = 3$. Under π, $p + \langle x\rangle = \overline{3 + 5x + x^2} = \overline{3}$ since $5x + x^2 \in \langle x\rangle$. Then $\overline{\mathrm{ev}_0}(\overline{3}) = 3$. Both paths give 3.

Common pitfall: Students sometimes think $\mathbb{R}[x]/\langle x\rangle \cong \mathbb{R}$ is "obvious" because $x = 0$ collapses everything, and skip checking that $\overline{\mathrm{ev}_0}$ is well defined. The check — that two polynomials in the same coset have the same constant term — is the essential step, because the ideal $\langle x\rangle$ is precisely the set of polynomials that disappear under ev_0.

Takeaway: The point of this diagram is that evaluation at 0 is the concrete realization of the abstract quotient $\mathbb{R}[x]/\langle x\rangle$, confirming that killing the generator x in a polynomial ring recovers the coefficient field.

Check. In $\mathbb{R}[x]/\langle x\rangle$ we have $\overline{x} = 0$, so $\overline{p} = \overline{a_0}$; the iso sends $\overline{p} \mapsto a_0 = p(0)$. E.g. $\overline{3 + 5x + x^2} = \overline{3} \mapsto 3 = p(0)$.

Worked Example 7.3.11 ($\mathbb{R}[x]/\langle x^2+1\rangle \cong \mathbb{C}$)**.** Show $\mathbb{R}[x]/\langle x^2+1\rangle$ is isomorphic to the complex numbers $\mathbb{C}$.

Recognition. First Iso: evaluation at a root of the generator; the generator must become 0, so substitute $x \mapsto i$.

Solution. Define $\varphi : \mathbb{R}[x] \to \mathbb{C}$ by $\varphi(p) = p(i)$, i.e. $x \mapsto i$, fixing $\mathbb{R}$. This is the evaluation homomorphism at $i \in \mathbb{C}$, hence a ring homomorphism, and it is surjective: any $a + bi \in \mathbb{C}$ equals $\varphi(a + bx)$.

Kernel. Since $\varphi(x^2 + 1) = i^2 + 1 = 0$, we have $\langle x^2 + 1\rangle \subseteq \ker\varphi$. Conversely, $x^2 + 1$ is monic, so divide any $p \in \ker\varphi$:

$$p(x) = (x^2 + 1)q(x) + r(x), \qquad \deg r \le 1, \quad r(x) = \alpha + \beta x.$$

Evaluating at i: $0 = p(i) = 0 \cdot q(i) + (\alpha + \beta i) = \alpha + \beta i$, forcing $\alpha = \beta = 0$ (real and imaginary parts). Hence $r = 0$ and $p \in \langle x^2 + 1\rangle$. Therefore $\ker\varphi = \langle x^2 + 1\rangle$, and Theorem 7.3.6 gives

$$\mathbb{R}[x]/\langle x^2 + 1\rangle \;\cong\; \mathbb{C}.$$

Check. In the quotient $\overline{x}^2 = \overline{x^2} = \overline{-1} = -\overline{1}$, so $\overline{x}$ plays the role of i; the iso sends $\overline{a + bx} \mapsto a + bi$, and $(\overline{a + bx})(\overline{c + dx}) = \overline{ac + (ad + bc)x + bdx^2} = (ac - bd) + (ad + bc)x \mapsto (ac - bd) + (ad + bc)i$, matching complex multiplication exactly.

Worked Example 7.3.12 (All ring homomorphisms $\mathbb{Z} \to \mathbb{Z}/30\mathbb{Z}$)**.** Determine all ring homomorphisms $\varphi : \mathbb{Z} \to \mathbb{Z}/30\mathbb{Z}$ (i) requiring $\varphi(1) = 1$ (unital), and (ii) dropping that requirement.

Recognition. A homomorphism out of $\mathbb{Z}$ is determined by $\varphi(1)$, which must be an idempotent ($e^2 = e$); unital forces $e = 1$.

Solution. Since $\mathbb{Z}$ is generated as a ring by 1 under addition, φ is completely determined by $e := \varphi(1)$: for $n \ge 0$, $\varphi(n) = \varphi(\underbrace{1 + \cdots + 1}_{n}) = n \cdot e$, and $\varphi(-n) = -ne$. The multiplicative constraint at 1 gives

$$e = \varphi(1) = \varphi(1 \cdot 1) = \varphi(1)\varphi(1) = e^2,$$

so e must be an *idempotent* of $\mathbb{Z}/30\mathbb{Z}$. Conversely any idempotent e gives a valid homomorphism $n \mapsto ne$ (additivity is clear; multiplicativity: $\varphi(mn) = mne = mne^2 = (me)(ne) = \varphi(m)\varphi(n)$ using $e^2 = e$).

Idempotents of $\mathbb{Z}/30\mathbb{Z}$. By CRT, $\mathbb{Z}/30\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$, and idempotents of a product are tuples of idempotents in each factor. Each $\mathbb{Z}/p\mathbb{Z}$ (a field) has idempotents $\{0, 1\}$, so there are $2^3 = 8$ idempotents, namely the CRT-preimages of $(\epsilon_2, \epsilon_3, \epsilon_5) \in \{0, 1\}^3$:

$$0,\ 1,\ 6,\ 10,\ 15,\ 16,\ 21,\ 25 \pmod{30}.$$

(E.g. $6^2 = 36 = 6$, $10^2 = 100 = 10$, $15^2 = 225 = 15$, $16^2 = 256 = 16$, $21^2 = 441 = 21$, $25^2 = 625 = 25$ in $\mathbb{Z}/30\mathbb{Z}$.)

(ii) There are exactly 8 ring homomorphisms $\mathbb{Z} \to \mathbb{Z}/30\mathbb{Z}$, namely $n \mapsto ne$, one for each idempotent

$$e \in \{0, 1, 6, 10, 15, 16, 21, 25\}.$$

(i) Requiring $\varphi(1) = 1$ singles out $e = 1$: a *unique* unital homomorphism, the reduction map $n \mapsto n \bmod 30$.

Check. $e = 6$ gives $\varphi(n) = 6n$; then $\varphi(1) = 6$, $\varphi(1)^2 = 36 = 6 = \varphi(1)$, and $\varphi(2 \cdot 3) = \varphi(6) = 36 = 6$ while $\varphi(2)\varphi(3) = 12 \cdot 18 = 216 = 216 - 7 \cdot 30 = 6$. Consistent, and indeed $6 \neq 1$ so this φ is non-unital.

Worked Example 7.3.13 (Killing a generator: $\mathbb{Q}[x]/\langle x-3\rangle \cong \mathbb{Q}$)**.** Identify the quotient $\mathbb{Q}[x]/\langle x-3\rangle$.

Recognition. First Iso: "set $x-3=0$" means $x=3$; use evaluation at 3.

Solution. Let $\varphi : \mathbb{Q}[x] \to \mathbb{Q}$ be $\mathrm{ev}_3 : p \mapsto p(3)$, a surjective ring homomorphism fixing $\mathbb{Q}$. Since $\varphi(x-3) = 3-3=0$, $\langle x-3\rangle \subseteq \ker\varphi$. Conversely, $x-3$ is monic so divide: $p(x) = (x-3)q(x)+r$ with $r \in \mathbb{Q}$ constant; then $p(3)=r$, so $p \in \ker\varphi \iff r=0 \iff p \in \langle x-3\rangle$. Thus $\ker\varphi = \langle x-3\rangle$ and

$$\mathbb{Q}[x]/\langle x-3\rangle \cong \mathbb{Q}.$$

Check. In the quotient $\overline{x}=\overline{3}$, so $\overline{p(x)} = \overline{p(3)}$, a constant — consistent with the image being all of $\mathbb{Q}$. E.g. $\overline{x^2} = \overline{9} \mapsto 9 = 3^2$.

Worked Example 7.3.14 (Matrices over a quotient: $\mathrm{M}_n(R)/\mathrm{M}_n(I) \cong \mathrm{M}_n(R/I)$)**.** Let $I \trianglelefteq R$ be a two-sided ideal. Show the set $\mathrm{M}_n(I)$ of matrices with all entries in I is a two-sided ideal of $\mathrm{M}_n(R)$, and $\mathrm{M}_n(R)/\mathrm{M}_n(I) \cong \mathrm{M}_n(R/I)$.

Recognition. First Iso: apply the projection $R \to R/I$ entrywise; the kernel is matrices with entries in I.

Solution. Define $\Phi : \mathrm{M}_n(R) \to \mathrm{M}_n(R/I)$ by reducing each entry, $\Phi\big((a_{ij})\big) = (a_{ij}+I)$. This is the projection $\pi : R \to R/I$ applied entrywise. It respects addition entrywise, and respects multiplication because matrix product entries are sums of products and π is a homomorphism:

$$\Phi(AB)_{ij} = \Big(\sum_k a_{ik}b_{kj}\Big) + I = \sum_k (a_{ik}+I)(b_{kj}+I) = \big(\Phi(A)\Phi(B)\big)_{ij}.$$

$\Phi(\mathbf{1}) = \mathbf{1}$, and Φ is surjective since π is. Its kernel is exactly the matrices reducing to 0 entrywise:

$$\ker\Phi = \{(a_{ij}) : a_{ij} \in I \ \forall i,j\} = \mathrm{M}_n(I).$$

Being a kernel, $\mathrm{M}_n(I)$ is a two-sided ideal of $\mathrm{M}_n(R)$. Theorem 7.3.6 gives

$$\mathrm{M}_n(R)/\mathrm{M}_n(I) \ \cong\ \mathrm{M}_n(R/I).$$

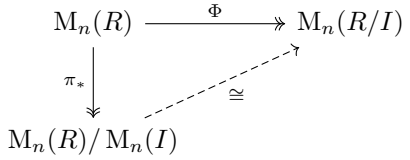

Diagram explanation. Objects: Three objects: $\mathrm{M}_n(R)$, the ring of $n\times n$ matrices over R; $\mathrm{M}_n(R/I)$, the ring of $n\times n$ matrices over the quotient ring R/I; and $\mathrm{M}_n(R)/\mathrm{M}_n(I)$, the quotient ring obtained by modding out the two-sided ideal $\mathrm{M}_n(I)$ of matrices with all entries in I.

Arrows: $\Phi : \mathrm{M}_n(R) \to \mathrm{M}_n(R/I)$ is the entrywise projection, $(a_{ij}) \mapsto (a_{ij}+I)$; it is a surjective ring homomorphism. $\pi_* : \mathrm{M}_n(R) \twoheadrightarrow \mathrm{M}_n(R)/\mathrm{M}_n(I)$ is the canonical quotient projection, $A \mapsto A + \mathrm{M}_n(I)$. The dashed arrow $\mathrm{M}_n(R)/\mathrm{M}_n(I) \to \mathrm{M}_n(R/I)$ is the induced isomorphism $\overline{\Phi}$, asserted by the First Isomorphism Theorem.

What commutes: The triangle commutes: $\overline{\Phi}\circ\pi_* = \Phi$, i.e. reducing entrywise equals projecting to the quotient and then applying the isomorphism.

Why it commutes: Take any $A = (a_{ij}) \in \mathrm{M}_n(R)$. Along π_* then $\overline{\Phi}$: $A \mapsto A + \mathrm{M}_n(I) \mapsto (a_{ij}+I)$. Along Φ directly: $A \mapsto (a_{ij}+I)$. Both paths produce the same matrix of cosets because $\overline{\Phi}$ is defined by $\overline{\Phi}(A+\mathrm{M}_n(I)) = \Phi(A)$, which is well-defined: if $A+\mathrm{M}_n(I) = A'+\mathrm{M}_n(I)$ then $A-A' \in \mathrm{M}_n(I)$, so every entry $a_{ij}-a'_{ij} \in I$, hence $(a_{ij}+I) = (a'_{ij}+I)$ entrywise.

Why this matters here: This diagram certifies that the "reduce entrywise" map Φ factors through the universal quotient π_*, and the resulting induced map is an isomorphism. The whole point of the exercise is to name $\ker\Phi = \mathrm{M}_n(I)$ and apply the First Isomorphism Theorem; the diagram makes the factorization visible.

Concrete example: Take $n=2$, $R=\mathbb{Z}$, $I=2\mathbb{Z}$. Then $\Phi : \mathrm{M}_2(\mathbb{Z}) \to \mathrm{M}_2(\mathbb{Z}/2\mathbb{Z})$ reduces each entry mod 2. For $A = \left(\begin{smallmatrix}3&4\\5&6\end{smallmatrix}\right)$, $\Phi(A) = \left(\begin{smallmatrix}1&0\\1&0\end{smallmatrix}\right)$ and $A + \mathrm{M}_2(2\mathbb{Z})$ maps to the same matrix under $\overline{\Phi}$.

Common pitfall: Students sometimes confuse Φ (the entrywise projection, which goes between two distinct matrix rings) with π_* (which stays "inside" $\mathrm{M}_n(R)$ and only changes the equivalence class label). Φ is the concrete map; π_* is the abstract quotient; the dashed isomorphism bridges them.

Takeaway: The point of this diagram is that reducing a matrix of ring elements mod an ideal is the same operation as taking the matrix modulo the corresponding matrix ideal, and the two descriptions are canonically isomorphic.

Check ($n = 2,\ R = \mathbb{Z},\ I = 2\mathbb{Z}$, so $R/I = \mathbb{Z}/2\mathbb{Z}$). Take $A = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$. Then $\Phi(A) = \left(\begin{smallmatrix} 1 & 0 \\ 1 & 0 \end{smallmatrix}\right)$ over $\mathbb{Z}/2\mathbb{Z}$. And $A - \left(\begin{smallmatrix} 1 & 0 \\ 1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 2 \\ 2 & 4 \end{smallmatrix}\right) \in \mathrm{M}_2(2\mathbb{Z}) = \ker \Phi$, as expected.

Worked Example 7.3.15 (Third Iso in action: $(\mathbb{Z}/12\mathbb{Z})/(3\mathbb{Z}/12\mathbb{Z}) \cong \mathbb{Z}/3\mathbb{Z}$)**.** Use the Third Isomorphism Theorem to identify $(\mathbb{Z}/12\mathbb{Z})/(3\mathbb{Z}/12\mathbb{Z})$.

Recognition. Third Iso: $I = 12\mathbb{Z} \subseteq J = 3\mathbb{Z}$ gives $(R/I)/(J/I) \cong R/J$.

Solution. Take $R = \mathbb{Z}$, $I = 12\mathbb{Z}$, $J = 3\mathbb{Z}$; indeed $12\mathbb{Z} \subseteq 3\mathbb{Z}$ since $12 = 4 \cdot 3$. The ideal $J/I = 3\mathbb{Z}/12\mathbb{Z}$ of $R/I = \mathbb{Z}/12\mathbb{Z}$ is $\{\overline{0}, \overline{3}, \overline{6}, \overline{9}\}$. Theorem 7.3.8(3rd) gives

$$(\mathbb{Z}/12\mathbb{Z})/(3\mathbb{Z}/12\mathbb{Z}) \ \cong\ \mathbb{Z}/3\mathbb{Z}.$$

Check. $|\mathbb{Z}/12\mathbb{Z}| = 12$, $|3\mathbb{Z}/12\mathbb{Z}| = 4$, so the quotient has $12/4 = 3$ elements, matching $|\mathbb{Z}/3\mathbb{Z}| = 3$. Concretely the cosets of $\{\overline{0}, \overline{3}, \overline{6}, \overline{9}\}$ are represented by $\overline{0}, \overline{1}, \overline{2}$, and addition/multiplication there is exactly mod-3 arithmetic.

Worked Example 7.3.16 (Second Iso: $A = \mathbb{Z}$, $I = 6\mathbb{Z}$ inside $R = \mathbb{Z}$ is too easy — do it in $\mathbb{Z}[x]$)**.** Inside $R = \mathbb{Z}[x]$, let $A = \mathbb{Z}$ (constant polynomials, a subring) and $I = \langle x \rangle$ (the ideal of polynomials with zero constant term). Verify the Second Isomorphism Theorem.

Recognition. Second Iso: $(A + I)/I \cong A/(A \cap I)$; compute $A + I$, $A \cap I$.

Solution. Here $A = \mathbb{Z} \subseteq \mathbb{Z}[x]$ is a subring and $I = \langle x \rangle$ is a two-sided ideal. Then $A + I = \{c + xg(x) : c \in \mathbb{Z},\ g \in \mathbb{Z}[x]\} = \mathbb{Z}[x]$ (every polynomial is its constant term plus an element of $\langle x \rangle$). And

$$A \cap I = \{\text{constants with zero constant term}\} = \{0\}.$$

Theorem 7.3.8(2nd) gives

$$(A + I)/I = \mathbb{Z}[x]/\langle x \rangle \ \cong\ A/(A \cap I) = \mathbb{Z}/\{0\} = \mathbb{Z}.$$

Check. This agrees with $\mathrm{ev}_0 : \mathbb{Z}[x] \to \mathbb{Z}$ (constant term), whose kernel is $\langle x \rangle$, so $\mathbb{Z}[x]/\langle x \rangle \cong \mathbb{Z}$ directly — the two routes give the same answer.

Remark 7.3.3 (The dictionary). The group-theoretic dictionary transfers verbatim, with "two-sided ideal" replacing "normal subgroup":

groups	rings
homomorphism	ring homomorphism
normal subgroup $N \trianglelefteq G$	two-sided ideal $I \trianglelefteq R$
kernel is normal	kernel is a two-sided ideal
G/N	R/I
$G/\ker\varphi \cong \operatorname{im}\varphi$	$R/\ker\varphi \cong \varphi(R)$

The one genuinely new wrinkle is sidedness: a one-sided ideal does *not* produce a quotient ring (only a module), which is why noncommutative ring theory distinguishes left/right/two-sided so carefully.

Exercises (from the text).

1. Prove that the rings $2\mathbb{Z}$ and $3\mathbb{Z}$ are not isomorphic.
2. Prove that the rings $\mathbb{Z}[x]$ and $\mathbb{Q}[x]$ are not isomorphic.
3. Find all homomorphic images of $\mathbb{Z}$.
4. Find all ring homomorphisms from $\mathbb{Z}$ to $\mathbb{Z}/30\mathbb{Z}$. In each case describe the kernel and the image.

5. Describe all ring homomorphisms from the ring $\mathbb{Z} \times \mathbb{Z}$ to $\mathbb{Z}$. In each case describe the kernel and the image.

6. Decide which of the following are ring homomorphisms from $M_2(\mathbb{Z})$ to $\mathbb{Z}$: (a) $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto a$ (projection onto the 1,1 entry) (b) $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto a + d$ (the trace of the matrix) (c) $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto ad - bc$ (the determinant of the matrix).

7. Let $R = \left\{ \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \mid a, b, d \in \mathbb{Z} \right\}$ be the subring of $M_2(\mathbb{Z})$ of upper triangular matrices. Prove that the map
$$\varphi : R \to \mathbb{Z} \times \mathbb{Z} \quad \text{defined by} \quad \varphi : \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \mapsto (a, d)$$
is a surjective homomorphism and describe its kernel.

8. Decide which of the following are ideals of the ring $\mathbb{Z} \times \mathbb{Z}$: (a) $\{(a, a) \mid a \in \mathbb{Z}\}$ (b) $\{(2a, 2b) \mid a, b \in \mathbb{Z}\}$ (c) $\{(2a, 0) \mid a \in \mathbb{Z}\}$ (d) $\{(a, -a) \mid a \in \mathbb{Z}\}$.

9. Decide which of the sets in Exercise 6 of Section 1 are ideals of the ring of all functions from $[0, 1]$ to $\mathbb{R}$.

10. Decide which of the following are ideals of the ring $\mathbb{Z}[x]$: (a) the set of all polynomials whose constant term is a multiple of 3 (b) the set of all polynomials whose coefficient of x^2 is a multiple of 3 (c) the set of all polynomials whose constant term, coefficient of x and coefficient of x^2 are zero (d) $\mathbb{Z}[x^2]$ (i.e., the polynomials in which only even powers of x appear) (e) the set of polynomials whose coefficients sum to zero (f) the set of polynomials $p(x)$ such that $p'(0) = 0$, where $p'(x)$ is the usual first derivative of $p(x)$ with respect to x.

11. Let R be the ring of all continuous real valued functions on the closed interval $[0, 1]$. Prove that the map $\varphi : R \to \mathbb{R}$ defined by $\varphi(f) = \int_0^1 f(t)\, dt$ is a homomorphism of additive groups but not a ring homomorphism.

12. Let D be an integer that is not a perfect square in $\mathbb{Z}$ and let $S = \left\{ \begin{pmatrix} a & b \\ Db & a \end{pmatrix} \mid a, b \in \mathbb{Z} \right\}$. (a) Prove that S is a subring of $M_2(\mathbb{Z})$. (b) If D is not a perfect square in $\mathbb{Z}$ prove that the map $\varphi : \mathbb{Z}[\sqrt{D}] \to S$ defined by $\varphi(a + b\sqrt{D}) = \begin{pmatrix} a & b \\ Db & a \end{pmatrix}$ is a ring isomorphism. (c) If $D \equiv 1 \bmod 4$ is squarefree, prove that the set $\left\{ \begin{pmatrix} a & b \\ (D-1)b/4 & a+b \end{pmatrix} \mid a, b \in \mathbb{Z} \right\}$ is a subring of $M_2(\mathbb{Z})$ and is isomorphic to the quadratic integer ring $\mathcal{O}$.

13. Prove that the ring $M_2(\mathbb{R})$ contains a subring that is isomorphic to $\mathbb{C}$.

14. Prove that the ring $M_4(\mathbb{R})$ contains a subring that is isomorphic to the real Hamilton Quaternions, $\mathbb{H}$.

15. Let X be a nonempty set and let $\mathcal{P}(X)$ be the Boolean ring of all subsets of X defined in Exercise 21 of Section 1. Let R be the ring of all functions from X into $\mathbb{Z}/2\mathbb{Z}$. For each $A \in \mathcal{P}(X)$ define the function
$$\chi_A : X \to \mathbb{Z}/2\mathbb{Z} \quad \text{by} \quad \chi_A(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A \end{cases}$$
(χ_A is called the *characteristic function* of A with values in $\mathbb{Z}/2\mathbb{Z}$). Prove that the map $\mathcal{P}(X) \to R$ defined by $A \mapsto \chi_A$ is a ring isomorphism.

16. Let $\varphi : R \to S$ be a surjective homomorphism of rings. Prove that the image of the center of R is contained in the center of S (cf. Exercise 7 of Section 1).

17. Let R and S be nonzero rings with identity and denote their respective identities by 1_R and 1_S. Let $\varphi : R \to S$ be a nonzero homomorphism of rings. (a) Prove that if $\varphi(1_R) \neq 1_S$ then $\varphi(1_R)$ is a zero divisor in S. Deduce that if S is an integral domain then every nonzero ring homomorphism from R to S sends

the identity of R to the identity of S. (b) Prove that if $\varphi(1_R) = 1_S$ then $\varphi(u)$ is a unit in S and that $\varphi(u^{-1}) = \varphi(u)^{-1}$ for each unit u of R.

18. Let I and J be ideals of R. (a) If I and J are ideals of R prove that their intersection $I \cap J$ is also an ideal of R. (b) Prove that the intersection of an arbitrary nonempty collection of ideals is again an ideal (do not assume the collection is countable).

19. Prove that if $I_1 \subseteq I_2 \subseteq \cdots$ are ideals of R then $\bigcup_{n=1}^{\infty} I_n$ is an ideal of R.

20. Let I be an ideal of R and let S be a subring of R. Prove that $I \cap S$ is an ideal of S. Show by example that not every ideal of a subring S of a ring R need be of the form $I \cap S$ for some ideal I of R.

21. Prove that every (two-sided) ideal of $M_n(R)$ is equal to $M_n(J)$ for some (two-sided) ideal J of R. [Use Exercise 6(c) of Section 2 to show first that the set of entries of matrices in an ideal of $M_n(R)$ form an ideal in R.]

22. Let a be an element of the ring R. (a) Prove that $\{x \in R \mid ax = 0\}$ is a right ideal and $\{y \in R \mid ya = 0\}$ is a left ideal (called respectively the right and left *annihilators* of a in R). (b) Prove that if L is a left ideal of R then $\{x \in R \mid xa = 0 \text{ for all } a \in L\}$ is a two-sided ideal (called the left *annihilator* of L in R).

23. Let S be a subring of R and let I be an ideal of R. Prove that if $S \cap I = 0$ then $\overline{S} \cong S$, where the bar denotes passage to R/I.

24. Let $\varphi : R \to S$ be a ring homomorphism. (a) Prove that if J is an ideal of S then $\varphi^{-1}(J)$ is an ideal of R. Apply this to the special case when R is a subring of S and φ is the inclusion homomorphism to deduce that if J is an ideal of S then $J \cap R$ is an ideal of R. (b) Prove that if φ is surjective and I is an ideal of R then $\varphi(I)$ is an ideal of S. Give an example where this fails if φ is not surjective.

25. Assume R is a commutative ring with 1. Prove that the Binomial Theorem

$$(a+b)^n = \sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k}$$

holds in R, where the binomial coefficient $\binom{n}{k}$ is interpreted in R as the sum $1 + 1 + \cdots + 1$ of the identity 1 in R taken $\binom{n}{k}$ times.

26. The *characteristic* of a ring R is the smallest positive integer n such that $1 + 1 + \cdots + 1 = 0$ (n times) in R; if no such integer exists the characteristic of R is said to be 0. For example, $\mathbb{Z}/n\mathbb{Z}$ is a ring of characteristic n for each positive integer n and $\mathbb{Z}$ is a ring of characteristic 0. (a) Prove that the map $\mathbb{Z} \to R$ defined by

$$k \mapsto \begin{cases} 1 + 1 + \cdots + 1 \ (k \text{ times}) & \text{if } k > 0 \\ 0 & \text{if } k = 0 \\ -1 - 1 - \cdots - 1 \ (-k \text{ times}) & \text{if } k < 0 \end{cases}$$

is a ring homomorphism whose kernel is $n\mathbb{Z}$, where n is the characteristic of R (this explains the use of the terminology "characteristic 0" instead of the archaic phrase "characteristic ∞" for rings in which no sum of 1's is zero). (b) Determine the characteristics of the rings $\mathbb{Q}$, $\mathbb{Z}[x]$, $\mathbb{Z}/n\mathbb{Z}[x]$. (c) Prove that if p is a prime and if R is a commutative ring of characteristic p, then $(a+b)^p = a^p + b^p$ for all $a, b \in R$.

27. Prove that a nonzero Boolean ring has characteristic 2 (cf. Exercise 15, Section 1).

28. Prove that an integral domain has characteristic p, where p is either a prime or 0 (cf. Exercise 26).

29. Let R be a commutative ring. Recall (cf. Exercise 13, Section 1) that an element $x \in R$ is nilpotent if $x^n = 0$ for some $n \in \mathbb{Z}^+$. Prove that the set of nilpotent elements form an ideal — called the *nilradical* of R and denoted by $\mathfrak{N}(R)$. [Use the Binomial Theorem to show $\mathfrak{N}(R)$ is closed under addition.]

30. Prove that if R is a commutative ring and $\mathfrak{N}(R)$ is its nilradical (cf. the preceding exercise) then zero is the only nilpotent element of $R/\mathfrak{N}(R)$ i.e., prove that $\mathfrak{N}(R/\mathfrak{N}(R)) = 0$.

31. Prove that the elements $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$ are nilpotent elements of $M_2(\mathbb{Z})$ whose sum is not nilpotent (note that these two matrices do not commute). Deduce that the set of nilpotent elements in the noncommutative ring $M_2(\mathbb{Z})$ is not an ideal.

32. Let $\varphi : R \to S$ be a homomorphism of rings. Prove that if x is a nilpotent element of R then $\varphi(x)$ is nilpotent in S.

33. Assume R is commutative. Let $p(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be an element of the polynomial ring $R[x]$. (a) Prove that $p(x)$ is a unit in $R[x]$ if and only if a_0 is a unit and $a_1, a_2, \ldots, a_n$ are nilpotent in R. [See Exercise 14 of Section 1.] (b) Prove that $p(x)$ is nilpotent in $R[x]$ if and only if $a_0, a_1, \ldots, a_n$ are nilpotent elements of R.

34. Let I and J be ideals of R. (a) Prove that $I + J$ is the smallest ideal of R containing both I and J. (b) Prove that IJ is an ideal contained in $I \cap J$. (c) Give an example where $IJ \neq I \cap J$. (d) Prove that if R is commutative and if $I + J = R$ then $IJ = I \cap J$.

35. Let I, J, K be ideals of R. (a) Prove that $I(J + K) = IJ + IK$ and $(I + J)K = IK + JK$. (b) Prove that if $J \subseteq I$ then $I \cap (J + K) = J + (I \cap K)$.

36. Show that if I is the ideal of all polynomials in $\mathbb{Z}[x]$ with zero constant term then $I^n = \{a_n x^n + a_{n+1}x^{n+1} + \cdots + a_{n+m}x^{n+m} \mid a_i \in \mathbb{Z},\ m \geq 0\}$ is the set of polynomials whose first nonzero term has degree at least n.

37. An ideal N is called a *nilpotent* ideal if N^n is the zero ideal for some $n \geq 1$. Prove that the ideal $p\mathbb{Z}/p^m\mathbb{Z}$ is a nilpotent ideal in the ring $\mathbb{Z}/p^m\mathbb{Z}$.

Practice problems.

1. Decide whether each map is a ring homomorphism. If yes, find its kernel and image; if no, give the failing axiom.

   (a) $f\colon \mathbb{Z} \to \mathbb{Z}$, $f(n) = 2n$.

   (b) $g\colon \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$, $g(n) = 4n \bmod 6$.

   (c) $h\colon \mathbb{R}[x] \to \mathbb{R}$, $h(p) = p(2)$.

   (d) $k\colon \mathrm{M}_2(\mathbb{R}) \to \mathbb{R}$, $k(A) = \det A$.

2. Let $\varphi\colon \mathbb{Z} \to \mathbb{Z}/12\mathbb{Z} \times \mathbb{Z}/8\mathbb{Z}$ be $\varphi(n) = (n \bmod 12,\ n \bmod 8)$. Show φ is a ring homomorphism and compute $\ker\varphi$.

3. In $\mathbb{Z}/20\mathbb{Z}$ list all idempotents (elements e with $e^2 = e$) and all zero divisors. Which elements lie in $(\mathbb{Z}/20\mathbb{Z})^\times$?

4. Let $R = \mathbb{Z}[x]$ and $I = \langle x, 2\rangle$ (the ideal generated by x and 2). Describe the elements of I explicitly and prove $R/I \cong \mathbb{Z}/2\mathbb{Z}$ as rings.

5. Prove that in $\mathbb{Z}[x]$ the ideal $\langle x^2 + 1\rangle$ is prime but not maximal, while $\langle x^2 + 1,\ p\rangle$ for a prime p may be maximal. Specifically, decide whether $\langle x^2 + 1\rangle$ is prime in $\mathbb{R}[x]$ and in $\mathbb{C}[x]$.

6. Let $\varphi\colon \mathbb{R}[x] \to \mathbb{C}$ be the unique homomorphism fixing $\mathbb{R}$ with $\varphi(x) = i$. Find $\ker\varphi$ and use the First Isomorphism Theorem to identify $\mathbb{R}[x]/\ker\varphi$.

7. Let R be a commutative ring and $I \subseteq R$ an ideal. Prove that R/I is an integral domain $\iff$ I is prime, and R/I is a field $\iff$ I is maximal.

8. Determine all ring homomorphisms $\mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}/18\mathbb{Z}$. (Hint: each is determined by the image of 1, which must be an idempotent of $\mathbb{Z}/18\mathbb{Z}$ satisfying the order condition.)

9. In $\mathbb{Z}/2\mathbb{Z}[x]$ decide which of the following are irreducible: $x^2 + x + 1$, $x^2 + 1$, $x^3 + x + 1$, $x^3 + x^2 + x + 1$. For each irreducible one, state the size of the field $\mathbb{Z}/2\mathbb{Z}[x]/\langle f\rangle$.

10. Let D be the ring of 2×2 diagonal matrices over $\mathbb{R}$. Exhibit an isomorphism $D \cong \mathbb{R} \times \mathbb{R}$ and identify the kernel of the projection $D \to \mathbb{R}$ onto the upper-left entry as an ideal.

11. Compute $\mathrm{Frac}(R)$ for each integral domain: (a) $R=\mathbb{Z}$; (b) $R=\mathbb{Z}[x]$; (c) $R=\mathbb{Z}/5\mathbb{Z}$; (d) $R=\mathbb{R}[x]$. State each answer concretely.

12. Use the Chinese Remainder Theorem to solve $x\equiv 2 \pmod 5$, $x\equiv 3 \pmod 7$, $x\equiv 1 \pmod 9$ for x modulo 315, and write down the corresponding isomorphism $\mathbb{Z}/315\mathbb{Z}\cong\mathbb{Z}/5\mathbb{Z}\times\mathbb{Z}/7\mathbb{Z}\times\mathbb{Z}/9\mathbb{Z}$.

13. Let $\varphi\colon R\to S$ be a surjective ring homomorphism. Prove that if I is an ideal of R containing $\ker\varphi$, then $\varphi(I)$ is an ideal of S, and the assignment $I\mapsto\varphi(I)$ is a bijection between ideals of R containing $\ker\varphi$ and ideals of S.

14. Find the nilradical $\mathrm{nil}(R)$ for $R=\mathbb{Z}/72\mathbb{Z}$. (Hint: $72=2^3\cdot 3^2$; an element is nilpotent iff every prime dividing 72 divides it.)

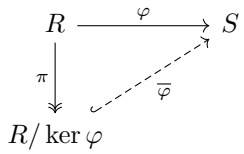
15. Let R be a commutative ring with 1. For $a\in R$ define $\mathrm{Ann}(a)=\{r\in R : ra=0\}$. Prove $\mathrm{Ann}(a)$ is an ideal of R, and compute $\mathrm{Ann}(\overline{4})$ in $\mathbb{Z}/12\mathbb{Z}$.

Additional exercises.

1. Let R be a commutative ring with 1 and let $N=\mathrm{nil}(R)$ be its set of nilpotent elements. Prove N is an ideal and that R/N has no nonzero nilpotent elements (i.e. $\mathrm{nil}(R/N)=\{0\}$).

2. Let $\varphi\colon R\to S$ be a ring homomorphism of commutative rings with 1 such that $\varphi(1_R)=1_S$, and let $Q\subseteq S$ be a prime ideal. Prove $\varphi^{-1}(Q)$ is a prime ideal of R. Give an example showing φ^{-1} of a maximal ideal need not be maximal.

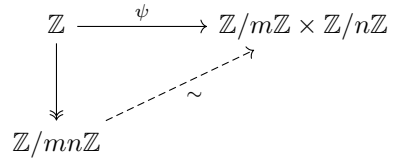
3. Let $R=\mathbb{Z}[i]=\{a+bi : a,b\in\mathbb{Z}\}$, the Gaussian integers. Show the map $\mathbb{Z}[x]\to\mathbb{Z}[i]$, $x\mapsto i$, is a surjective homomorphism with kernel $\langle x^2+1\rangle$, hence $\mathbb{Z}[i]\cong\mathbb{Z}[x]/\langle x^2+1\rangle$. Then prove $\mathbb{Z}[i]/\langle 1+i\rangle\cong\mathbb{Z}/2\mathbb{Z}$.



4. Let R be a finite integral domain. Prove R is a field. (Hint: for $a\neq 0$ consider the injective map $x\mapsto ax$.)

5. Let I and J be ideals of a commutative ring R with $I+J=R$ (comaximal). Prove $IJ=I\cap J$ and deduce the CRT isomorphism $R/IJ\cong R/I\times R/J$. Where is comaximality used?

6. Let $R=C[0,1]$ be the ring of continuous real-valued functions on $[0,1]$ under pointwise operations. For $c\in[0,1]$ let $M_c=\{f\in R : f(c)=0\}$. Prove each M_c is a maximal ideal and that $R/M_c\cong\mathbb{R}$ via evaluation at c.



Commutative-diagram exercises.

1. (First Isomorphism Theorem, factoring through the quotient.) Let $\varphi\colon R\to S$ be a ring homomorphism and $\pi\colon R\to R/\ker\varphi$ the natural projection. Prove there is a unique injective homomorphism $\overline{\varphi}$ making the diagram commute, and that $\overline{\varphi}$ is an isomorphism onto $\mathrm{im}\,\varphi$:

   Apply this to $\varphi\colon\mathbb{R}[x]\to\mathbb{C}$, $x\mapsto i$, to obtain $\mathbb{R}[x]/\langle x^2+1\rangle\cong\mathbb{C}$.

2. (CRT as an isomorphism.) Let m,n be coprime positive integers and define $\psi\colon\mathbb{Z}\to\mathbb{Z}/m\mathbb{Z}\times\mathbb{Z}/n\mathbb{Z}$ by $\psi(a)=(a \bmod m,\ a \bmod n)$. Show ψ is a surjective homomorphism with kernel $\langle mn\rangle$, and fill in the induced isomorphism (the dashed diagonal):

   Verify surjectivity explicitly for $m=4$, $n=9$ by exhibiting a preimage of $(1,0)$.

3. (Universal property of the polynomial ring.) Let R be a commutative ring, S a commutative R-algebra via $\iota\colon R \to S$, and $s \in S$. Prove there is a unique ring homomorphism $\mathrm{ev}_s\colon R[x] \to S$ with $\mathrm{ev}_s|_R = \iota$ and $\mathrm{ev}_s(x) = s$, making the diagram commute:

   Use it to define the evaluation map $\mathbb{Z}[x] \to \mathbb{Z}/5\mathbb{Z}$ sending $x \mapsto 3$ and compute the image of $x^2 + x + 1$.

4. (Universal property of fractions.) Let R be an integral domain with field of fractions $\mathrm{Frac}(R)$ and embedding $\iota\colon R \to \mathrm{Frac}(R)$. Prove that any injective homomorphism $f\colon R \to F$ into a field F extends uniquely to $\bar{f}$:

   Why must f be injective for $\bar{f}$ to be well defined?

5. (Pulling back ideals through a quotient.) Let $I \subseteq J$ be ideals of R and consider the projections $\pi\colon R \to R/I$ and $q\colon R/I \to R/J$. Show that $q \circ \pi = \pi_J$, the projection $R \to R/J$, and deduce the third isomorphism theorem $(R/I)/(J/I) \cong R/J$:

   Illustrate with $R = \mathbb{Z}$, $I = \langle 12\rangle$, $J = \langle 4\rangle$.

7.4 Properties of Ideals

Ideals generated by subsets; maximal and prime ideals

We work in a ring R with identity $1 \neq 0$. Recall that a (two-sided) *ideal* I is an additive subgroup with $rI \subseteq I$ and $Ir \subseteq I$ for all $r \in R$. We now ask: given an arbitrary subset $A \subseteq R$, what is the smallest ideal containing A? And which ideals are "maximal" or "prime"? The slogan of this section is: *study an ideal I through the quotient ring R/I.*

Definition 7.4.1 (Ideal generated by a subset)**.** Let A be a subset of a ring R. The *ideal generated by A*, written $\langle A\rangle$, is the intersection of all ideals of R that contain A:

$$\langle A\rangle \;=\; \bigcap_{\substack{I \text{ ideal}\\ A\subseteq I}} I.$$

This is the smallest ideal of R containing A. We define the *left ideal* RA generated by A and the *right ideal* AR similarly. An ideal I is *finitely generated* if $I = \langle a_1, \dots, a_n\rangle$ for some finite set, and *principal* if $I = \langle a\rangle$ for a single element.

Proposition 7.4.2 (Concrete description of $\langle A\rangle$)**.** *Let $A \subseteq R$ where R has identity* 1*.*

(1) $RA = \{\sum_{i=1}^{n} r_i a_i \;:\; r_i \in R,\ a_i \in A,\ n \geq 0\}$ is the left ideal generated by A.

(2) The (two-sided) ideal generated by A is

$$\langle A\rangle \;=\; RAR \;=\; \left\{\sum_{i=1}^{n} r_i a_i s_i \;:\; r_i, s_i \in R,\; a_i \in A,\; n \geq 0\right\}.$$

(3) If R is commutative, then $\langle A\rangle = RA = \{\sum_{i=1}^{n} r_i a_i : r_i \in R,\; a_i \in A\}$. In particular for a single element, $\langle a\rangle = Ra = aR = \{ra : r \in R\}$.

Proof. The right side of (1), call it J, is closed under addition and under left multiplication by R (since $r\sum r_i a_i = \sum (rr_i)a_i$), so it is a left ideal; it contains A because $1 \in R$ gives $a = 1 \cdot a \in J$. Any left ideal containing A must contain every $r_i a_i$ and their sums, so it contains J; hence $J = RA$ is the smallest left ideal containing A. The argument for (2) is identical using two-sided products ras, which form the smallest set closed under addition and under multiplication by R on both sides; again $1 \cdot a \cdot 1 = a$ shows $A \subseteq RAR$. For (3), commutativity collapses $ras = (rs)a$, so $RAR = RA$, and $Ra = aR$. □

Method (Computing $\langle A\rangle$ and recognizing principal/f.g. ideals)**.** *Trigger.* You are handed a subset A and asked for the ideal it generates, or asked whether an ideal is principal.

1. If R is *commutative with* 1: $\langle a_1, \ldots, a_n\rangle = Ra_1 + \cdots + Ra_n = \{\sum r_i a_i\}$. This is the set of all R-linear combinations of the generators.
2. For a *single* generator: $\langle a\rangle = \{ra : r \in R\}$ — the multiples of a.
3. To test "*is I principal?*" look for a single $d \in I$ with $I = \langle d\rangle$. In $\mathbb{Z}$ or any PID, take $d = \gcd$ of the generators.
4. Noncommutative warning: you must allow products on *both* sides, $\sum r_i a_i s_i$.

Worked Example 7.4.3 (The ideal $\langle 2, x\rangle$ in $\mathbb{Z}[x]$)**.** Describe $\langle 2, x\rangle$ inside $R = \mathbb{Z}[x]$.

Recognition. Two generators in a commutative ring with 1: use $\langle 2, x\rangle = R\cdot 2 + R\cdot x$, the set of $\mathbb{Z}[x]$-combinations.

Solution. An element of $\langle 2, x\rangle$ is $2f(x) + x\,g(x)$ for $f, g \in \mathbb{Z}[x]$. The term $2f(x)$ contributes an even constant term; $x\,g(x)$ has zero constant term. So every element has *even constant term.* Conversely, if $p(x) = a_0 + a_1 x + \cdots$ has a_0 even, write $p = a_0 + x(a_1 + a_2 x + \cdots) = 2 \cdot (a_0/2) + x \cdot g(x) \in \langle 2, x\rangle$. Hence

$$\langle 2, x\rangle = \{\, p(x) \in \mathbb{Z}[x] : p(0) \text{ is even} \,\}.$$

Check. $3 + x \notin \langle 2, x\rangle$ since its constant term 3 is odd; $4 + 5x = 2 \cdot 2 + x \cdot 5 \in \langle 2, x\rangle$. We will see below this ideal is maximal.

Worked Example 7.4.4 ($\langle 6, 10\rangle$ collapses to a principal ideal in $\mathbb{Z}$)**.** Find a single generator for $\langle 6, 10\rangle \subseteq \mathbb{Z}$.

Recognition. In $\mathbb{Z}$ a sum of multiples $6a + 10b$ ranges over all multiples of $\gcd(6, 10)$; so the two-generator ideal is principal.

Solution. $\langle 6, 10\rangle = 6\mathbb{Z} + 10\mathbb{Z} = \{6a + 10b : a, b \in \mathbb{Z}\}$. By Bézout this equals $\gcd(6, 10)\mathbb{Z} = 2\mathbb{Z} = \langle 2\rangle$ (indeed $2 = 6 \cdot 2 + 10 \cdot (-1)$). *Check.* $2 \mid 6$ and $2 \mid 10$ so $\langle 6, 10\rangle \subseteq \langle 2\rangle$; and $2 \in \langle 6, 10\rangle$ gives the reverse. So $\langle 6, 10\rangle = \langle 2\rangle$.

Worked Example 7.4.5 (A non-principal ideal: $\langle 2, x\rangle$ is not principal in $\mathbb{Z}[x]$)**.** Show $\langle 2, x\rangle$ is *not* principal in $\mathbb{Z}[x]$.

Recognition. If $\langle 2, x\rangle = \langle d\rangle$ then $d \mid 2$ and $d \mid x$ in $\mathbb{Z}[x]$; analyze degrees and units.

Solution. Suppose $\langle 2, x\rangle = \langle d\rangle$. From $2 \in \langle d\rangle$ we get $d \mid 2$, so d is a degree-0 polynomial dividing 2 in $\mathbb{Z}[x]$: $d \in \{\pm 1, \pm 2\}$. From $x \in \langle d\rangle$ we get $d \mid x$, i.e. $x = d\,h(x)$; comparing leading coefficients forces $d \mid 1$, so $d = \pm 1$. But then $\langle d\rangle = \mathbb{Z}[x] \ni 1$, while $1 \notin \langle 2, x\rangle$ (constant term odd). Contradiction. *Check.* $\langle 2, x\rangle$ needs two generators; $\mathbb{Z}[x]$ is not a PID.

Proposition 7.4.6 (Unit criterion: when is $I = R$?)**.** *Let I be an ideal of a ring R with identity* 1*.*

(1) $I = R$ if and only if I contains a unit.

(2) If R is commutative, then R is a field if and only if its only ideals are 0 and R.

Proof. (1) If $I = R$ then $1 \in I$ and 1 is a unit. Conversely, if $u \in I$ is a unit with inverse u^{-1}, then $1 = u^{-1}u \in I$ (ideals absorb multiplication), so for any $r \in R$, $r = r \cdot 1 \in I$; thus $I = R$.

(2) ($\Longrightarrow$) Let R be a field and $I \neq 0$ an ideal. Pick $0 \neq a \in I$; since a is a unit, $I = R$ by (1). ($\Leftarrow$) Suppose the only ideals are 0 and R, and let $0 \neq a \in R$. The principal ideal $\langle a \rangle \neq 0$, so $\langle a \rangle = R$, whence $1 \in \langle a \rangle = Ra$, i.e. $1 = ra$ for some r. Thus a is a unit and R is a field. □

Caution. The unit criterion needs an identity $1 \neq 0$. In a rng (ring without 1), an ideal containing a left-invertible element need not be the whole ring. Also note "I contains a unit $\Longrightarrow$ $I = R$" is the workhorse for proving fields have no nontrivial ideals — and for showing R/M is a field below.

Worked Example 7.4.7 ($\langle 1/2 \rangle$ in $\mathbb{Q}$, and ideals of a field)**.** What is the ideal $\langle 1/2 \rangle$ in $\mathbb{Q}$? List all ideals of $\mathbb{Q}$.

Recognition. $1/2$ is a unit in $\mathbb{Q}$; apply the unit criterion.

Solution. Since $1/2$ is a unit ($(1/2)^{-1} = 2$), Proposition 7.4.6(1) gives $\langle 1/2 \rangle = \mathbb{Q}$. More generally every nonzero element of $\mathbb{Q}$ is a unit, so the only ideals of $\mathbb{Q}$ are 0 and $\mathbb{Q}$. *Check.* Consistent with Proposition 7.4.6(2): a field has exactly two ideals.

Worked Example 7.4.8 (A non-unit generates a proper ideal: $\langle 3 \rangle$ in $\mathbb{Z}$)**.** Is $\langle 3 \rangle \subsetneq \mathbb{Z}$?

Recognition. 3 is not a unit in $\mathbb{Z}$ (units are ± 1); so by contrapositive of the unit criterion $\langle 3 \rangle$ can be proper.

Solution. $\langle 3 \rangle = 3\mathbb{Z} = \{\ldots, -3, 0, 3, 6, \ldots\}$. Since $1 \notin 3\mathbb{Z}$ (no integer n has $3n = 1$), $\langle 3 \rangle \neq \mathbb{Z}$. *Check.* $\mathbb{Z}^\times = \{\pm 1\}$, and indeed $3 \notin \mathbb{Z}^\times$, consistent with $\langle 3 \rangle \neq \mathbb{Z}$.

Maximal ideals

Definition 7.4.9 (Maximal ideal)**.** An ideal M of R is a *maximal ideal* if $M \neq R$ and the only ideals containing M are M and R. Equivalently, M is a maximal element (under inclusion) of the set of proper ideals of R.

Theorem 7.4.10 (Existence of maximal ideals via Zorn's Lemma)**.** *In a ring R with identity $1 \neq 0$, every proper ideal $I \subsetneq R$ is contained in a maximal ideal. In particular, R has at least one maximal ideal.*

Proof sketch. Let Σ be the set of proper ideals of R containing I, partially ordered by inclusion; $\Sigma \neq \varnothing$ since $I \in \Sigma$. Let $\mathcal{C} = \{J_\alpha\}$ be a chain in Σ and put $J = \bigcup_\alpha J_\alpha$. A union of a chain of ideals is an ideal (any two elements lie in a common J_α, so closure holds). Moreover J is *proper*: if $1 \in J$ then $1 \in J_\alpha$ for some α, forcing $J_\alpha = R$, contradicting $J_\alpha \in \Sigma$. So $J \in \Sigma$ is an upper bound for $\mathcal{C}$. By Zorn's Lemma Σ has a maximal element M, which is a maximal ideal containing I. □

Theorem 7.4.11 (M maximal $\Longleftrightarrow$ R/M a field)**.** *Let R be a* commutative *ring with $1 \neq 0$ and M an ideal. Then*

$$M \text{ is maximal} \quad \Longleftrightarrow \quad R/M \text{ is a field.}$$

Proof. By the lattice (correspondence) theorem, ideals of R/M correspond bijectively, preserving inclusion, to ideals of R containing M:

$$\{\text{ideals } J \text{ with } M \subseteq J \subseteq R\} \xleftrightarrow{\text{1-1}} \{\text{ideals of } R/M\}$$

Diagram explanation. Objects: The left node is the poset of ideals J of R satisfying $M \subseteq J \subseteq R$; the right node is the poset of all ideals of the quotient ring R/M. Both are sets of ideals, ordered by inclusion.

Arrows: A single double-headed left-right arrow labelled 1-1 represents the lattice isomorphism (bijection preserving inclusion in both directions) $J \mapsto J/M = \{\, j + M : j \in J \,\}$ and its inverse $\bar{I} \mapsto \pi^{-1}(\bar{I})$, where $\pi : R \to R/M$ is the quotient map.

What commutes: Because there is only one arrow, the content is the bijection itself: every ideal J with $M \subseteq J$ maps to the ideal J/M of R/M, and every ideal $\bar{I}$ of R/M pulls back to the ideal $\pi^{-1}(\bar{I})$ of R; these two operations are mutually inverse and inclusion-preserving.

Why it commutes: Well-definedness of $J \mapsto J/M$: for $j \in J$ and $r \in R$, $(r+M)(j+M) = rj + M \in J/M$ since $rj \in J$; closure under addition and the subgroup property are inherited similarly. The inverse is well-defined because preimages of ideals under ring homomorphisms are ideals. Inclusion-preservation: $J_1 \subseteq J_2 \Leftrightarrow J_1/M \subseteq J_2/M$ because adding the same coset class cannot create new containments.

Why this matters here: This correspondence is the core of the proof: M maximal means the only J with $M \subseteq J \subseteq R$ are M and R themselves, which by the bijection means the only ideals of R/M are $M/M = 0$ and R/M — exactly the field condition.

Concrete example: Take $R = \mathbb{Z}$, $M = \langle 6 \rangle$. Ideals containing $\langle 6 \rangle$ are $\langle 6 \rangle, \langle 3 \rangle, \langle 2 \rangle, \langle 1 \rangle = \mathbb{Z}$. On the right, ideals of $\mathbb{Z}/6\mathbb{Z}$ are $\langle \bar{0} \rangle, \langle \bar{3} \rangle, \langle \bar{2} \rangle, \langle \bar{1} \rangle$ — four ideals in bijection. Since there are ideals strictly between $\langle 6 \rangle$ and $\mathbb{Z}$, the ideal $\langle 6 \rangle$ is not maximal.

Common pitfall: Students often confuse the correspondence with the isomorphism $R/M \cong$ something concrete: the diagram says nothing about what R/M looks like internally, only that its ideal lattice mirrors the ideals of R above M. Also, the correspondence requires M to be an *ideal* (not just a subgroup) for J/M to be a ring ideal.

Takeaway: The point of this diagram is that the ideal lattice of the quotient R/M is an exact copy of the portion of R's ideal lattice sitting above M, so maximality of M translates into R/M having the simplest possible ideal structure.

under $J \mapsto J/M$. Thus M is maximal $\iff$ the only ideals containing M are M, R $\iff$ the only ideals of R/M are $0 = M/M$ and R/M. Since R/M is a commutative ring with 1, Proposition 7.4.6(2) says this happens $\iff$ R/M is a field. □

The map at the heart of this is the quotient projection, and a maximal ideal makes the quotient as "small and rigid" as possible:

$$R \xrightarrow{\ \pi\ } R/M \qquad \text{with } R/M \text{ a field iff } M \text{ maximal.}$$

Diagram explanation. Objects: R is a commutative ring with $1 \neq 0$ (the domain); R/M is the quotient ring by the ideal M, whose elements are cosets $r + M$.

Arrows: The double-headed arrow $\pi : R \to R/M$ is the canonical quotient ring homomorphism, defined by $\pi(r) = r + M$. It is surjective by construction and its kernel is exactly M. The double head ($\twoheadrightarrow$) signals surjectivity.

What commutes: There is one arrow, so no path-equality to verify. The content is the well-definedness and surjectivity of π: every element of R/M is $\pi(r)$ for some r.

Why it commutes: $\pi(r) = r + M$ is defined on elements of R, so no choice of coset representative is involved; this part needs nothing about M. What uses that M is an ideal (an additive subgroup with $rM \subseteq M$ and $Mr \subseteq M$ for all $r \in R$) is that the coset multiplication $(r+M)(s+M) = rs + M$ is well defined, so that R/M is a ring and π a ring homomorphism (Theorem 7.3.5).

Why this matters here: This diagram distills the entire theorem into one sentence: passing from R to R/M via π collapses M to zero, and the resulting ring is a field precisely when M is maximal. It reminds us that the strategy for every maximality test is to compute R/M and check invertibility of nonzero elements.

Concrete example: $R = \mathbb{Z}$, $M = \langle p \rangle$ for a prime p. Then $\pi : \mathbb{Z} \to \mathbb{Z}/p\mathbb{Z} = \mathbb{F}_p$, which is a field. The surjectivity is clear ($0, 1, \ldots, p-1$ are hit), kernel is $p\mathbb{Z} = \langle p \rangle$, and $\mathbb{F}_p$ is a field, confirming $\langle p \rangle$ is maximal.

Common pitfall: Students sometimes treat π as if it were injective (an isomorphism), forgetting it collapses all of M to zero. The whole point is that M is *not* injected into R/M; it vanishes. Also, R/M being a field does not mean R is a field — $\mathbb{Z}$ is not a field but $\mathbb{Z}/p\mathbb{Z}$ is.

Takeaway: The point of this diagram is that the quotient map π is the canonical tool for converting a question about the ideal M inside R into a question about the arithmetic of the simpler ring R/M.

Method (Testing maximality via the quotient)**.** *Trigger.* Asked whether M is maximal in a commutative ring R.

1. Form the quotient R/M and identify it as a familiar ring (use the First Isomorphism Theorem: realize R/M as the image of a homomorphism with kernel M).

2. M maximal $\iff$ R/M is a field. So: simplify R/M, then ask "is every nonzero element invertible?"

3. Shortcut in $\mathbb{Z}$: $\langle n\rangle$ maximal $\iff$ $\mathbb{Z}/n\mathbb{Z}$ a field $\iff$ n prime.

4. Shortcut in $\mathbb{F}[x]$ ($\mathbb{F}$ a field): $\langle p(x)\rangle$ maximal $\iff$ p irreducible.

Worked Example 7.4.12 ($\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$ is a field, so (x^2+1) is maximal)**.** Show $M = \langle x^2+1\rangle$ is a maximal ideal of $\mathbb{R}[x]$.

Recognition. Test maximality by the quotient: compute $\mathbb{R}[x]/\langle x^2+1\rangle$ and check it is a field.

Solution. Define $\varphi : \mathbb{R}[x] \to \mathbb{C}$ by $\varphi(f) = f(i)$ (evaluation at i). It is a surjective ring homomorphism (it hits $a+bi$ via $a+bx$). Its kernel is $\{f : f(i) = 0\}$; since $x^2+1 = (x-i)(x+i)$ is the minimal polynomial of i over $\mathbb{R}$, $\ker\varphi = \langle x^2+1\rangle$. By the First Isomorphism Theorem,

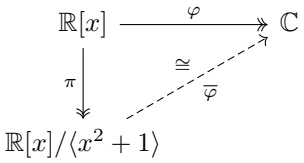


Diagram explanation. Objects: $\mathbb{R}[x]$ is the polynomial ring over the reals; $\mathbb{C}$ is the field of complex numbers; $\mathbb{R}[x]/\langle x^2+1\rangle$ is the quotient ring obtained by forcing $x^2 = -1$, whose elements are cosets $f + \langle x^2+1\rangle$, i.e. cosets of the form $(a+bx) + \langle x^2+1\rangle$.

Arrows: $\varphi : \mathbb{R}[x] \to \mathbb{C}$ is evaluation at i, the surjective ring homomorphism $f \mapsto f(i)$, with $\ker\varphi = \langle x^2+1\rangle$. $\pi : \mathbb{R}[x] \to \mathbb{R}[x]/\langle x^2+1\rangle$ is the canonical surjective quotient map, $f \mapsto f + \langle x^2+1\rangle$. $\overline{\varphi} : \mathbb{R}[x]/\langle x^2+1\rangle \to \mathbb{C}$ is the induced (dashed) isomorphism, defined by $\overline{\varphi}(f + \langle x^2+1\rangle) = f(i)$.

What commutes: The triangle commutes: $\overline{\varphi} \circ \pi = \varphi$, i.e. for every $f \in \mathbb{R}[x]$, evaluating f at i equals first quotienting and then applying $\overline{\varphi}$.

Why it commutes: Well-definedness of $\overline{\varphi}$: if $f + \langle x^2+1\rangle = g + \langle x^2+1\rangle$, then $f - g = (x^2+1)h$ for some $h \in \mathbb{R}[x]$, so $f(i) - g(i) = (i^2+1)h(i) = 0 \cdot h(i) = 0$, hence $f(i) = g(i)$. Element-chase: take $f \in \mathbb{R}[x]$; the upper path gives $\varphi(f) = f(i)$; the lower path gives $\overline{\varphi}(\pi(f)) = \overline{\varphi}(f + \langle x^2+1\rangle) = f(i)$. They agree.

Why this matters here: The First Isomorphism Theorem converts the abstract quotient $\mathbb{R}[x]/\langle x^2+1\rangle$ into the concrete field $\mathbb{C}$, proving $\langle x^2+1\rangle$ is maximal without any direct lattice argument. This is the template for all quotient-identifies-as-field arguments.

Concrete example: Take $f = x^3$. Upper path: $\varphi(x^3) = i^3 = -i$. Lower path: $x^3 + \langle x^2+1\rangle$; since $x^3 = x(x^2+1) - x$, the coset equals $-x + \langle x^2+1\rangle$, and $\overline{\varphi}(-x + \langle x^2+1\rangle) = -i$. Both paths give $-i$.

Common pitfall: The dashed arrow $\overline{\varphi}$ is *induced* by φ; it does not exist by magic — it exists precisely because $\langle x^2+1\rangle = \ker\varphi$. If the kernel were larger or smaller, the induced map would not be well-defined or would fail to be injective. Do not assume an induced map exists before checking the kernel-containment condition.

Takeaway: The point of this diagram is that the First Isomorphism Theorem converts the abstract quotient ring $\mathbb{R}[x]/\langle x^2+1\rangle$ into the familiar field $\mathbb{C}$, making maximality of $\langle x^2+1\rangle$ an immediate consequence.

so $\mathbb{R}[x]/\langle x^2+1\rangle \cong \mathbb{C}$, which is a field. By Theorem 7.4.11, $\langle x^2+1\rangle$ is maximal. *Check.* x^2+1 is irreducible over $\mathbb{R}$ (no real roots), matching the $\mathbb{F}[x]$ shortcut.

Worked Example 7.4.13 ($\langle 2, x\rangle$ is maximal in $\mathbb{Z}[x]$ because $\mathbb{Z}[x]/\langle 2, x\rangle \cong \mathbb{F}_2$)**.** Show $\langle 2, x\rangle$ is maximal in $\mathbb{Z}[x]$.

Recognition. Quotient test: identify $\mathbb{Z}[x]/\langle 2, x\rangle$ and check it is a field.

Solution. Define $\varphi : \mathbb{Z}[x] \to \mathbb{Z}/2\mathbb{Z} = \mathbb{F}_2$ by reducing coefficients mod 2 and setting $x \mapsto 0$, i.e. $\varphi(f) = f(0) \bmod 2 =$ (constant term of f) mod 2. This is a surjective homomorphism. Its kernel is exactly the polynomials with even constant term, which we computed in the first worked example to be $\langle 2, x\rangle$. Hence

$$\mathbb{Z}[x]/\langle 2, x\rangle \;\cong\; \mathbb{F}_2,$$

a field with two elements. By Theorem 7.4.11, $\langle 2, x\rangle$ is maximal. *Check.* $|\mathbb{F}_2| = 2$ and every nonzero element (1) is a unit, so it is a field.

Worked Example 7.4.14 ($\langle x\rangle$ is maximal in $\mathbb{F}[x]$ for a field $\mathbb{F}$)**.** Let $\mathbb{F}$ be a field. Show $\langle x\rangle$ is a maximal ideal of $\mathbb{F}[x]$.

Recognition. Evaluation-at-0 has kernel $\langle x\rangle$; check the quotient is a field.

Solution. Let $\mathrm{ev}_0 : \mathbb{F}[x] \to \mathbb{F}$, $\mathrm{ev}_0(f) = f(0)$. It is a surjective ring homomorphism (constants map onto $\mathbb{F}$). Its kernel is $\{f : f(0) = 0\} = \{f : x \mid f\} = \langle x\rangle$. So

$$\mathbb{F}[x]/\langle x\rangle \;\cong\; \mathbb{F},$$

which is a field. By Theorem 7.4.11, $\langle x\rangle$ is maximal. *Check.* x is irreducible (degree 1) in $\mathbb{F}[x]$, matching the irreducibility shortcut.

Worked Example 7.4.15 (A maximal ideal of $\mathbb{Z}$ that is determined by primality)**.** Which principal ideals $\langle n\rangle$ of $\mathbb{Z}$ are maximal?

Recognition. In $\mathbb{Z}$, $\langle n\rangle$ maximal $\iff$ $\mathbb{Z}/n\mathbb{Z}$ a field $\iff$ n prime.

Solution. $\mathbb{Z}/n\mathbb{Z}$ is a field iff n is prime (for n prime every nonzero residue is a unit by Bézout; for $n = ab$ composite, $\bar{a}$ is a zero divisor, not a unit). So $\langle n\rangle$ is maximal exactly when $n = p$ is prime. *Check.* $\langle 0\rangle = 0$ is not maximal since $0 \subsetneq \langle 2\rangle \subsetneq \mathbb{Z}$; $\langle 1\rangle = \mathbb{Z}$ is not proper; $\langle 6\rangle$ is not maximal since $\langle 6\rangle \subsetneq \langle 2\rangle \subsetneq \mathbb{Z}$.

Prime ideals

Definition 7.4.16 (Prime ideal)**.** Let R be a commutative ring. A proper ideal $P \subsetneq R$ is a *prime ideal* if for all $a, b \in R$,

$$ab \in P \quad\Longrightarrow\quad a \in P \;\text{ or }\; b \in P.$$

(This generalizes Euclid's lemma: $p \mid ab \implies p \mid a$ or $p \mid b$.)

Theorem 7.4.17 (P prime $\iff$ R/P an integral domain)**.** *Let R be a commutative ring with $1 \neq 0$ and P a proper ideal. Then*

$$P \text{ is prime} \quad\Longleftrightarrow\quad R/P \text{ is an integral domain.}$$

Proof. Write $\bar{r} = r + P$ for the image in R/P, so $\bar{r} = \bar{0} \iff r \in P$. Then:

$$P \text{ prime} \iff \big(ab \in P \implies a \in P \text{ or } b \in P\big) \iff \big(\bar{a}\bar{b} = \bar{0} \implies \bar{a} = \bar{0} \text{ or } \bar{b} = \bar{0}\big),$$

which is precisely the statement that R/P has *no zero divisors*. Since $P \neq R$, the quotient R/P has $1 \neq 0$ and is commutative, so this says R/P is an integral domain. □

Corollary 7.4.18 (Every maximal ideal is prime)**.** *In a commutative ring R with $1 \neq 0$, every maximal ideal is prime.*

Proof. Let M be maximal. By Theorem 7.4.11, R/M is a field. Every field is an integral domain (a unit is never a zero divisor: if $ab = 0$ with $a \neq 0$, multiply by a^{-1} to get $b = 0$). By Theorem 7.4.17, M is prime. □

The implications, and the quotient ladder, are summarized by:

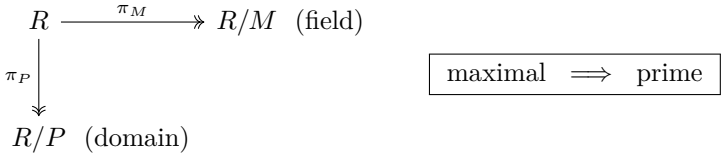

Diagram explanation. Objects: R is a commutative ring with $1 \neq 0$ (upper-left); R/M is the quotient by a maximal ideal M (upper-right, labelled "field"); R/P is the quotient by a prime ideal P (lower-left, labelled "domain"). There is no lower-right object — the diagram is an L-shape, not a square.

Arrows: $\pi_M : R \twoheadrightarrow R/M$ is the canonical surjective quotient map modulo M. $\pi_P : R \twoheadrightarrow R/P$ is the canonical surjective quotient map modulo P. Both are ring homomorphisms with $\ker \pi_M = M$ and $\ker \pi_P = P$. There is no arrow between R/M and R/P.

What commutes: The two paths do not share a target, so commutativity is not the point. The diagram instead records that from the single ring R, two different quotients are available: one by M (yielding a field) and one by P (yielding a domain). The implication maximal $\implies$ prime corresponds to the fact that every field is an integral domain.

Why it commutes: When M is maximal, R/M is a field; every field is an integral domain (if $ab = 0$ with $a \neq 0$, multiply by a^{-1} to get $b = 0$); so R/M is also a domain. The two quotients live independently, but the algebraic hierarchy field $\implies$ domain mirrors the ideal hierarchy maximal $\implies$ prime.

Why this matters here: This is the organizing summary of Corollary 7.4.18: the L-shape reminds you that maximality is strictly stronger than primality, both notions are tested via the corresponding quotient, and the one-way implication has a concrete reason (fields are domains) rather than being a coincidence.

Concrete example: In $\mathbb{Z}$: $M = \langle 5 \rangle$ gives $\pi_M : \mathbb{Z} \to \mathbb{F}_5$ (a field, so $\langle 5 \rangle$ is maximal); $P = \langle 3 \rangle$ gives $\pi_P : \mathbb{Z} \to \mathbb{F}_3$ (also a field, so also prime). For a domain-only example: take $R = \mathbb{Z}[x]$, $P = \langle x \rangle$, giving $\pi_P : \mathbb{Z}[x] \to \mathbb{Z}$ (a domain, so $\langle x \rangle$ prime but not maximal since $\mathbb{Z}$ is not a field).

Common pitfall: Students sometimes read the L-shape as if R/M and R/P are related by a map (a projection or inclusion). They are not: no arrow connects R/M to R/P in general. If $M \supseteq P$ one can factor the quotient maps, but the diagram here does not assert that.

Takeaway: The point of this diagram is that the two canonical quotient maps of R organize the ideal hierarchy — maximal gives a field, prime gives a domain — making the implication maximal $\implies$ prime a structural consequence of field $\implies$ domain.

$$M \text{ maximal} \Longrightarrow P \text{ prime} \Longrightarrow I \text{ proper ideal}$$

Diagram explanation. Objects: The three nodes are not rings or groups but *properties* that an ideal $I \subsetneq R$ can satisfy: being maximal (strongest), being prime (intermediate), and being a proper ideal (weakest).

Arrows: Two double-line implication arrows ($\Rightarrow$). The left arrow, "M maximal $\Rightarrow$ P prime," is Corollary 7.4.18: R/M a field implies R/M a domain. The right arrow, "P prime $\Rightarrow$ I proper," is definitional: the prime ideal condition explicitly requires $P \subsetneq R$.

What commutes: Transitivity of implication: maximal $\Rightarrow$ prime $\Rightarrow$ proper. So maximal $\Rightarrow$ proper directly, which is also clear from the definition of maximal.

Why it commutes: Left arrow: R/M is a field (Theorem 7.4.11), every field is an integral domain (nonzero elements are units, hence not zero-divisors), so R/M is a domain and M is prime (Theorem 7.4.17). Right arrow: prime ideals are defined to be proper by assumption.

Why this matters here: The diagram is a roadmap for the section: it tells you the logical hierarchy and reminds you that *neither arrow reverses* — the counterexamples (prime-not-maximal: $\langle x \rangle \subsetneq \mathbb{Z}[x]$; proper-not-prime: $\langle 4 \rangle \subsetneq \mathbb{Z}$) are essential knowledge, not edge cases.

Concrete example: In $\mathbb{Z}$: $\langle 7 \rangle$ is maximal (hence prime, hence proper). $\langle 0 \rangle$ is prime (since $\mathbb{Z}$ is a domain) but not maximal. $\langle 4 \rangle$ is proper but not prime ($2 \cdot 2 = 4 \in \langle 4 \rangle$ yet $2 \notin \langle 4 \rangle$). All three levels are populated.

Common pitfall: The arrows are one-way implications about *ideal properties*, not maps between objects. A student may try to "go backwards" and conclude a prime is maximal — this fails exactly when R/P is a domain but not a field, e.g. $R/\langle x \rangle \cong \mathbb{Z}$.

Takeaway: The point of this diagram is that the three tiers of ideals (maximal, prime, proper) are strictly ordered by implication, and tracking which quotient ring each tier corresponds to (field, domain, nonzero ring) gives the proof of every arrow.

(neither arrow reverses: $\langle x \rangle \subsetneq \mathbb{Z}[x]$ is prime but not maximal; $\langle 4 \rangle \subsetneq \mathbb{Z}$ is proper but not prime).

Method (Testing primality via the quotient)**.** *Trigger.* Asked whether P is prime in a commutative ring R.

1. Form R/P and identify it. P prime $\iff$ R/P a domain (no zero divisors); P maximal $\iff$ R/P a field. Since field $\implies$ domain, maximal $\implies$ prime.

2. Direct test: assume $ab \in P$ and deduce $a \in P$ or $b \in P$.

3. In $\mathbb{Z}$: $\langle n\rangle$ prime $\iff$ $n = 0$ or $n = p$ prime (because $\mathbb{Z}/n\mathbb{Z}$ a domain $\iff$ $n = 0$ or n prime).

4. To show *not* maximal but prime: exhibit a domain quotient that is *not* a field (e.g. $\mathbb{Z}[x]/\langle x\rangle \cong \mathbb{Z}$).

Worked Example 7.4.19 (The ideals of $\mathbb{Z}$: which are prime, which maximal)**.** Classify all ideals of $\mathbb{Z}$ and determine which are prime and which maximal.

Recognition. $\mathbb{Z}$ is a PID, so every ideal is $\langle n\rangle$; test each via $\mathbb{Z}/n\mathbb{Z}$.

Solution. Every ideal of $\mathbb{Z}$ is principal: $I = \langle n\rangle = n\mathbb{Z}$ for a unique $n \geq 0$ (take n the least positive element, or $n = 0$). Now use the quotients:

- $\langle 0\rangle = 0$: $\mathbb{Z}/0\mathbb{Z} \cong \mathbb{Z}$ is a domain but not a field, so $\langle 0\rangle$ is *prime, not maximal.*
- $\langle 1\rangle = \mathbb{Z}$: not a proper ideal, so neither prime nor maximal.
- $\langle p\rangle$, p prime: $\mathbb{Z}/p\mathbb{Z} = \mathbb{F}_p$ is a field, so *prime and maximal.*
- $\langle n\rangle$, $n = ab$ composite ($1 < a, b < n$): $\bar{a}\bar{b} = \bar{n} = \bar{0}$ with $\bar{a}, \bar{b} \neq \bar{0}$, so $\mathbb{Z}/n\mathbb{Z}$ has zero divisors — *neither prime nor maximal.*

Check. Prime ideals of $\mathbb{Z}$ are exactly $\langle 0\rangle$ and $\langle p\rangle$; the maximal ones are exactly the $\langle p\rangle$. Consistent with maximal $\implies$ prime, and $\langle 0\rangle$ shows the converse fails.

Worked Example 7.4.20 ($\langle x\rangle$ is prime but not maximal in $\mathbb{Z}[x]$)**.** Show $P = \langle x\rangle$ is prime but not maximal in $\mathbb{Z}[x]$.

Recognition. Use $\mathbb{Z}[x]/\langle x\rangle$: prime $\iff$ domain, maximal $\iff$ field.

Solution. Evaluation at 0, $\mathrm{ev}_0 : \mathbb{Z}[x] \to \mathbb{Z}$, $f \mapsto f(0)$, is a surjective homomorphism with kernel $\{f : f(0) = 0\} = \langle x\rangle$. So

$$\mathbb{Z}[x] \xrightarrow{\ \pi\ } \mathbb{Z}[x]/\langle x\rangle \xrightarrow{\ \cong\ } \mathbb{Z}.$$

Diagram explanation. Objects: $\mathbb{Z}[x]$ is the polynomial ring with integer coefficients; $\mathbb{Z}[x]/\langle x\rangle$ is the quotient ring forcing $x = 0$, whose elements are cosets $f + \langle x\rangle$ (canonically represented by the constant terms); $\mathbb{Z}$ is the ring of integers.

Arrows: $\pi : \mathbb{Z}[x] \twoheadrightarrow \mathbb{Z}[x]/\langle x\rangle$ is the canonical surjective quotient map $f \mapsto f + \langle x\rangle$, whose kernel is $\langle x\rangle = \{f : f(0) = 0\}$. The second arrow $\mathbb{Z}[x]/\langle x\rangle \xrightarrow{\cong} \mathbb{Z}$ is the natural isomorphism sending $f + \langle x\rangle$ to $f(0)$, the constant term of (any representative of) the coset.

What commutes: The composite $\mathbb{Z}[x] \to \mathbb{Z}[x]/\langle x\rangle \xrightarrow{\cong} \mathbb{Z}$ equals the evaluation-at-zero map $\mathrm{ev}_0 : f \mapsto f(0)$ directly. That is, reducing mod $\langle x\rangle$ and then reading the constant term is the same as plugging in $x = 0$.

Why it commutes: Well-definedness of the isomorphism: if $f + \langle x\rangle = g + \langle x\rangle$, then $f - g \in \langle x\rangle$, so $x \mid (f - g)$, so $f(0) - g(0) = 0$. Hence $f(0) = g(0)$, and the map is well-defined. It is a ring homomorphism because evaluation at any point is a homomorphism; it is surjective because every integer n is the constant term of the constant polynomial n, and injective because $f(0) = 0$ means $x \mid f$, i.e. $f + \langle x\rangle = \langle x\rangle$.

Why this matters here: The composite identifies $\mathbb{Z}[x]/\langle x\rangle$ concretely as $\mathbb{Z}$. Since $\mathbb{Z}$ is an integral domain (no zero divisors) but not a field (2 has no inverse), the diagram simultaneously proves $\langle x\rangle$ is prime (Theorem 7.4.17) and not maximal (Theorem 7.4.11), giving the key counterexample to "prime $\implies$ maximal."

Concrete example: Take $f = 3x^2 + 5x + 7$. Directly: $\mathrm{ev}_0(f) = 7$. Along the diagram: $f \mapsto f + \langle x\rangle \mapsto$ constant term $= 7$. For the zero-divisor test in $\mathbb{Z}[x]/\langle x\rangle$: $(2 + \langle x\rangle)(3 + \langle x\rangle) = 6 + \langle x\rangle \neq \langle x\rangle$ in $\mathbb{Z}[x]/\langle x\rangle \cong \mathbb{Z}$, confirming no zero divisors.

Common pitfall: Students sometimes confuse $\mathbb{Z}[x]/\langle x\rangle \cong \mathbb{Z}$ with the statement that $\langle x\rangle$ is prime in $\mathbb{Z}$ (which makes no sense, as $\langle x\rangle \not\subseteq \mathbb{Z}$). The prime in question is $\langle x\rangle \subsetneq \mathbb{Z}[x]$, and the domain produced is $\mathbb{Z}$, not $\mathbb{Z}/x\mathbb{Z}$ (a meaningless expression).

Takeaway: The point of this diagram is that quotienting $\mathbb{Z}[x]$ by $\langle x\rangle$ is the same as setting $x = 0$, yielding $\mathbb{Z}$, which is an integral domain but not a field, so $\langle x\rangle$ is prime but not maximal in $\mathbb{Z}[x]$.

Now $\mathbb{Z}$ is an integral domain, so $\langle x\rangle$ is *prime* (Theorem 7.4.17). But $\mathbb{Z}$ is *not* a field (2 has no inverse in $\mathbb{Z}$), so $\langle x\rangle$ is *not maximal* (Theorem 7.4.11). *Check.* Indeed $\langle x\rangle \subsetneq \langle 2, x\rangle \subsetneq \mathbb{Z}[x]$, a strict chain of ideals above $\langle x\rangle$, confirming non-maximality; the strictly larger $\langle 2, x\rangle$ is a maximal ideal sitting over it (so is $\langle p, x\rangle$ for every prime p).

Worked Example 7.4.21 (Prime vs. maximal in $\mathbb{Z}/n\mathbb{Z}$)**.** Find the prime and maximal ideals of $R = \mathbb{Z}/n\mathbb{Z}$ for $n = 12$.

Recognition. Ideals of $\mathbb{Z}/n\mathbb{Z}$ correspond to divisors of n; test each quotient.

Solution. By the lattice theorem, ideals of $\mathbb{Z}/12\mathbb{Z}$ correspond to ideals of $\mathbb{Z}$ containing $\langle 12\rangle$, i.e. to $\langle d\rangle$ with $d \mid 12$. The ideal $\langle \bar{d}\rangle = d\mathbb{Z}/12\mathbb{Z}$ has quotient

$$(\mathbb{Z}/12\mathbb{Z})\big/(d\mathbb{Z}/12\mathbb{Z}) \cong \mathbb{Z}/d\mathbb{Z}.$$

So $\langle \bar{d}\rangle$ is prime/maximal $\iff$ $\mathbb{Z}/d\mathbb{Z}$ is a domain/field $\iff$ d is prime (for a proper ideal we need $d > 1$). Divisors $d \mid 12$ with d prime: $d = 2, 3$. Hence the prime ideals are $\langle \bar{2}\rangle$ and $\langle \bar{3}\rangle$, and they are *also maximal*. *Check.* In a finite commutative ring *every* prime ideal is maximal (a finite integral domain is a field), so "prime" and "maximal" coincide here — consistent with $\{\langle \bar{2}\rangle, \langle \bar{3}\rangle\}$ being both lists. Note $\langle \bar{0}\rangle$ is not prime since $\mathbb{Z}/12\mathbb{Z}$ itself has zero divisors ($\bar{3} \cdot \bar{4} = \bar{0}$).

Worked Example 7.4.22 ($\langle x^2 + 1\rangle$ is prime in $\mathbb{Z}[x]$ but not maximal)**.** Determine whether $\langle x^2 + 1\rangle$ is prime/maximal in $\mathbb{Z}[x]$.

Recognition. Identify $\mathbb{Z}[x]/\langle x^2 + 1\rangle$ and check domain vs. field.

Solution. Map $\mathbb{Z}[x] \to \mathbb{Z}[i]$ (the Gaussian integers) by $x \mapsto i$, i.e. $f \mapsto f(i)$. This is surjective ($a + bx \mapsto a + bi$) with kernel $\langle x^2 + 1\rangle$ (as $x^2 + 1$ is the minimal polynomial of i over $\mathbb{Z}$, and $\mathbb{Z}[x]$ reductions confirm it). So

$$\mathbb{Z}[x]/\langle x^2 + 1\rangle \;\cong\; \mathbb{Z}[i].$$

$\mathbb{Z}[i]$ is an integral domain (a subring of $\mathbb{C}$), so $\langle x^2 + 1\rangle$ is *prime*. But $\mathbb{Z}[i]$ is not a field ($2 = (1 + i)(1 - i)$ is not invertible; $\frac{1}{2} \notin \mathbb{Z}[i]$), so $\langle x^2 + 1\rangle$ is *not maximal*. *Check.* Contrast with $\mathbb{R}[x]/\langle x^2 + 1\rangle \cong \mathbb{C}$ (a field, so maximal) — the base ring matters: over the field $\mathbb{R}$ we get a field, over $\mathbb{Z}$ only a domain.

Worked Example 7.4.23 (A prime that is not maximal in two variables: $\langle y\rangle$ in $\mathbb{F}[x, y]$)**.** Let $\mathbb{F}$ be a field. Show $\langle y\rangle$ is prime but not maximal in $\mathbb{F}[x, y]$.

Recognition. Quotient out y and identify the ring.

Solution. Send $\mathbb{F}[x, y] \to \mathbb{F}[x]$ by $y \mapsto 0$ (reduce mod y). This is surjective with kernel $\langle y\rangle$, so

$$\mathbb{F}[x, y]/\langle y\rangle \;\cong\; \mathbb{F}[x].$$

$\mathbb{F}[x]$ is an integral domain (no zero divisors among polynomials), so $\langle y\rangle$ is *prime*. It is not a field (x has no inverse), so $\langle y\rangle$ is *not maximal*. *Check.* $\langle y\rangle \subsetneq \langle x, y\rangle \subsetneq \mathbb{F}[x, y]$, and $\mathbb{F}[x, y]/\langle x, y\rangle \cong \mathbb{F}$ is a field, so $\langle x, y\rangle$ is a maximal ideal above $\langle y\rangle$ (so is $\langle x - a, y\rangle$ for every $a \in \mathbb{F}$).

Caution. "Prime" does not imply "maximal." The gap is exactly: R/P a domain vs. R/P a field. The standard counterexamples: $\langle 0\rangle$ in any domain that is not a field (e.g. $\mathbb{Z}$, $\mathbb{F}[x]$), and $\langle x\rangle \subsetneq \mathbb{Z}[x]$. The reverse implication *maximal* $\implies$ *prime* always holds (Corollary 7.4.18) because every field is a domain. Also: the prime-ideal definition is only stated for *commutative* rings in this section; do not apply $ab \in P \implies a \in P$ or $b \in P$ as the definition in a noncommutative ring.

Caution. $\langle 0\rangle$ (the zero ideal) is prime $\iff$ R is an integral domain, and maximal $\iff$ R is a field. So in $\mathbb{Z}$ the zero ideal is prime but not maximal; in $\mathbb{Q}$ it is both. Always check whether your ideal is proper before calling it prime or maximal — R itself is excluded by definition.

Exercises (from the text).

1. Let L_j be the left ideal of $\mathrm{M}_n(R)$ consisting of arbitrary entries in the jth column and zero in all other entries and let E_{ij} be the element of $\mathrm{M}_n(R)$ whose i, j entry is 1 and whose other entries are all 0. Prove that $L_j = \mathrm{M}_n(R)E_{ij}$ for any i. [See Exercise 6, Section 2.]

2. Assume R is commutative. Prove that the augmentation ideal in the group ring RG is generated by $\{g-1 \mid g \in G\}$. Prove that if $G = \langle \sigma \rangle$ is cyclic then the augmentation ideal is generated by $\sigma - 1$.

3. (a) Let p be a prime and let G be an abelian group of order p^n. Prove that the nilradical of the group ring $\mathbb{F}_p G$ is the augmentation ideal (cf. Exercise 29, Section 3). [Use the preceding exercise.]
(b) Let $G = \{g_1, \ldots, g_n\}$ be a finite group and assume R is commutative. Prove that if r is any element of the augmentation ideal of RG then $r(g_1 + g_2 + \cdots + g_n) = 0$. [Use the preceding exercise.]

4. Assume R is commutative. Prove that R is a field if and only if 0 is a maximal ideal.

5. Prove that if M is an ideal such that R/M is a field then M is a maximal ideal (do not assume R is commutative).

6. Prove that R is a division ring if and only if its only left ideals are (0) and R. (The analogous result holds when "left" is replaced by "right.")

7. Let R be a commutative ring with 1. Prove that the principal ideal generated by x in the polynomial ring $R[x]$ is a prime ideal if and only if R is an integral domain. Prove that (x) is a maximal ideal if and only if R is a field.

8. Let R be an integral domain. Prove that $(a) = (b)$ for some elements $a, b \in R$ if and only if $a = ub$ for some unit u of R.

9. Let R be the ring of all continuous functions on $[0, 1]$ and let I be the collection of functions $f(x)$ in R with $f(1/3) = f(1/2) = 0$. Prove that I is an ideal of R but is not a prime ideal.

10. Assume R is commutative. Prove that if P is a prime ideal of R and P contains no zero divisors then R is an integral domain.

11. Assume R is commutative. Let I and J be ideals of R and assume P is a prime ideal of R that contains IJ (for example, if P contains $I \cap J$). Prove either I or J is contained in P.

12. Assume R is commutative and suppose $I = (a_1, a_2, \ldots, a_n)$ and $J = (b_1, b_2, \ldots, b_m)$ are two finitely generated ideals in R. Prove that the product ideal IJ is finitely generated by the elements $a_i b_j$ for $i = 1, 2, \ldots, n$, and $j = 1, 2, \ldots, m$.

13. Let $\varphi : R \to S$ be a homomorphism of commutative rings.
(a) Prove that if P is a prime ideal of S then either $\varphi^{-1}(P) = R$ or $\varphi^{-1}(P)$ is a prime ideal of R. Apply this to the special case when R is a subring of S and φ is the inclusion homomorphism to deduce that if P is a prime ideal of S then $P \cap R$ is either R or a prime ideal of R.
(b) Prove that if M is a maximal ideal of S and φ is surjective then $\varphi^{-1}(M)$ is a maximal ideal of R. Give an example to show that this need not be the case if φ is not surjective.

14. Assume R is commutative. Let x be an indeterminate, let $f(x)$ be a monic polynomial in $R[x]$ of degree $n \geq 1$ and use the bar notation to denote passage to the quotient ring $R[x]/(f(x))$.
(a) Show that every element of $R[x]/(f(x))$ is of the form $\overline{p(x)}$ for some polynomial $p(x) \in R[x]$ of degree less than n, i.e.,

$$R[x]/(f(x)) = \{\overline{a_0} + \overline{a_1 x} + \cdots + \overline{a_{n-1} x^{n-1}} \mid a_0, a_1, \ldots, a_{n-1} \in R\}.$$

[If $f(x) = x^n + b_{n-1}x^{n-1} + \cdots + b_0$ then $\overline{x}^n = -(\overline{b_{n-1}}\,\overline{x}^{n-1} + \cdots + \overline{b_0})$. Use this to reduce powers of $\overline{x}$ in the quotient ring.]
(b) Prove that if $p(x)$ and $q(x)$ are distinct polynomials in $R[x]$ which are both of degree less than n, then $\overline{p(x)} \neq \overline{q(x)}$. [Otherwise $p(x) - q(x)$ is an $R[x]$-multiple of the monic polynomial $f(x)$.]
(c) If $f(x) = a(x)b(x)$ where both $a(x)$ and $b(x)$ have degree less than n, prove that $\overline{a(x)}$ is a zero divisor in $R[x]/(f(x))$.
(d) If $f(x) = x^n - a$ for some nilpotent element $a \in R$, prove that $\overline{x}$ is nilpotent in $R[x]/(f(x))$.
(e) Let p be a prime, assume $R = \mathbb{F}_p$ and $f(x) = x^p - a$ for some $a \in \mathbb{F}_p$. Prove that $\overline{x - a}$ is nilpotent in $R[x]/(f(x))$. [Use Exercise 26(c) of Section 3.]

15. Let x^2+x+1 be an element of the polynomial ring $E=\mathbb{F}_2[x]$ and use the bar notation to denote passage to the quotient ring $\mathbb{F}_2[x]/(x^2+x+1)$.
(a) Prove that $\overline{E}$ has 4 elements: $\overline{0},\overline{1},\overline{x}$ and $\overline{x+1}$.
(b) Write out the 4×4 addition table for $\overline{E}$ and deduce that the additive group $\overline{E}$ is isomorphic to the Klein 4-group.
(c) Write out the 4×4 multiplication table for $\overline{E}$ and prove that $\overline{E}^\times$ is isomorphic to the cyclic group of order 3. Deduce that $\overline{E}$ is a field.

16. Let x^4-16 be an element of the polynomial ring $E=\mathbb{Z}[x]$ and use the bar notation to denote passage to the quotient ring $\mathbb{Z}[x]/(x^4-16)$.
(a) Find a polynomial of degree ≤ 3 that is congruent to $7x^{13}-11x^9+5x^5-2x^3+3$ modulo (x^4-16).
(b) Prove that $\overline{x-2}$ and $\overline{x+2}$ are zero divisors in $\overline{E}$.

17. Let x^3-2x+1 be an element of the polynomial ring $E=\mathbb{Z}[x]$ and use the bar notation to denote passage to the quotient ring $\mathbb{Z}[x]/(x^3-2x+1)$. Let $p(x)=2x^7-7x^5+4x^3-9x+1$ and let $q(x)=(x-1)^4$.
(a) Express each of the following elements of $\overline{E}$ in the form $\overline{f(x)}$ for some polynomial $f(x)$ of degree ≤ 2: $\overline{p(x)},\overline{q(x)},\overline{p(x)+q(x)}$ and $\overline{p(x)q(x)}$.
(b) Prove that $\overline{E}$ is not an integral domain.
(c) Prove that $\overline{x}$ is a unit in $\overline{E}$.

18. Prove that if R is an integral domain and $R[[x]]$ is the ring of formal power series in the indeterminate x then the principal ideal generated by x is a prime ideal (cf. Exercise 3, Section 2). Prove that the principal ideal generated by x is a maximal ideal if and only if R is a field.

19. Let R be a finite commutative ring with identity. Prove that every prime ideal of R is a maximal ideal.

20. Prove that a nonzero finite commutative ring that has no zero divisors is a field (if the ring has an identity, this is Theorem 7.1.7, so do not assume the ring has a 1).

21. Prove that a finite ring with identity $1\neq 0$ that has no zero divisors is a field (you may quote Wedderburn's Theorem).

22. Let $p\in\mathbb{Z}^+$ be a prime and let the $\mathbb{F}_p$-Quaternions be defined by

$$a+bi+cj+dk,\quad a,b,c,d\in\mathbb{Z}/p\mathbb{Z},$$

where addition is componentwise and multiplication is defined using the same relations on i,j,k as for the real Quaternions.
(a) Prove that the $\mathbb{F}_p$-Quaternions are a homomorphic image of the integral Quaternions (cf. Section 1).
(b) Prove that the $\mathbb{F}_p$-Quaternions contain zero divisors (and so they cannot be a division ring). [Use the preceding exercise.]

23. Prove that in a Boolean ring (cf. Exercise 15, Section 1) every prime ideal is a maximal ideal.

24. Prove that in a Boolean ring every finitely generated ideal is principal.

25. Assume R is commutative and for each $a\in R$ there is an integer $n>1$ (depending on a) such that $a^n=a$. Prove that every prime ideal of R is a maximal ideal.

26. Prove that a prime ideal in a commutative ring R contains every nilpotent element (cf. Exercise 13, Section 1). Deduce that the nilradical of R (cf. Exercise 29, Section 3) is contained in the intersection of all the prime ideals of R. (It is shown in Section 15.1 that the nilradical of R is equal to the intersection of all prime ideals of R.)

27. Let R be a commutative ring with $1\neq 0$. Prove that if a is a nilpotent element of R then $1-ab$ is a unit for all $b\in R$.

28. Prove that if R is a commutative ring and $N=(a_1,a_2,\ldots,a_m)$ where each a_i is a nilpotent element, then N is a nilpotent ideal (cf. Exercise 37, Section 3). Deduce that if the nilradical of R is finitely generated then it is a nilpotent ideal.

29. Let p be a prime and let G be a finite group of order a power of p (i.e., a p-group). Prove that the augmentation ideal in the group ring $\mathbb{Z}/p\mathbb{Z}G$ is a nilpotent ideal. (Note that this ring may be noncommutative.) [Use Exercise 2.]

30. Let I be an ideal of the commutative ring R and define

$$\operatorname{rad} I = \{r \in R \mid r^n \in I \text{ for some } n \in \mathbb{Z}^+\}$$

called the *radical of* I. Prove that $\operatorname{rad} I$ is an ideal containing I and that the ideal $(\operatorname{rad} I)/I$ is the nilradical of the quotient ring R/I, i.e., $(\operatorname{rad} I)/I = \mathfrak{N}(R/I)$ (cf. Exercise 29, Section 3).

31. An ideal I of the commutative ring R is called a *radical ideal* if $\operatorname{rad} I = I$.
(a) Prove that every prime ideal of R is a radical ideal.
(b) Let $n > 1$ be an integer. Prove that 0 is a radical ideal in $\mathbb{Z}/n\mathbb{Z}$ if and only if n is a product of distinct primes to the first power (i.e., n is square free). Deduce that (n) is a radical ideal of $\mathbb{Z}$ if and only if n is a product of distinct primes in $\mathbb{Z}$.

32. Let I be an ideal of the commutative ring R and define

$$\operatorname{Jac} I \text{ to be the intersection of all maximal ideals of } R \text{ that contain } I$$

where the convention is that $\operatorname{Jac} R = R$. (If I is the zero ideal, $\operatorname{Jac} 0$ is called the *Jacobson radical* of the ring R, so $\operatorname{Jac} I$ is the preimage in R of the Jacobson radical of R/I.)
(a) Prove that $\operatorname{Jac} I$ is an ideal of R containing I.
(b) Prove that $\operatorname{rad} I \subseteq \operatorname{Jac} I$, where $\operatorname{rad} I$ is the radical of I defined in Exercise 30.
(c) Let $n > 1$ be an integer. Describe $\operatorname{Jac} n\mathbb{Z}$ in terms of the prime factorization of n.

33. Let R be the ring of all continuous functions from the closed interval $[0, 1]$ to $\mathbb{R}$ and for each $c \in [0, 1]$ let $M_c = \{f \in R \mid f(c) = 0\}$ (recall that M_c was shown to be a maximal ideal of R).
(a) Prove that if M is any maximal ideal of R then there is a real number $c \in [0, 1]$ such that $M = M_c$.
(b) Prove that if b and c are distinct points in $[0, 1]$ then $M_b \neq M_c$.
(c) Prove that M_c is not equal to the principal ideal generated by $x - c$.
(d) Prove that M_c is not a finitely generated ideal.

34. Let R be the ring of all continuous functions from $\mathbb{R}$ to $\mathbb{R}$ and for each $c \in \mathbb{R}$ let M_c be the maximal ideal $\{f \in R \mid f(c) = 0\}$.
(a) Let I be the collection of functions $f(x)$ in R with *compact support* (i.e., $f(x) = 0$ for $|x|$ sufficiently large). Prove that I is an ideal of R that is not a prime ideal.
(b) Let M be a maximal ideal of R containing I (properly, by (a)). Prove that $M \neq M_c$ for any $c \in \mathbb{R}$ (cf. the preceding exercise).

35. Let $A = (a_1, a_2, \ldots, a_n)$ be a nonzero finitely generated ideal of R. Prove that there is an ideal B which is maximal with respect to the property that it does not contain A. [Use Zorn's Lemma.]

36. Assume R is commutative. Prove that the set of prime ideals in R has a minimal element with respect to inclusion (possibly the zero ideal). [Use Zorn's Lemma.]

37. A commutative ring R is called a *local ring* if it has a unique maximal ideal. Prove that if R is a local ring with maximal ideal M then every element of $R - M$ is a unit. Prove conversely that if R is a commutative ring with 1 in which the set of nonunits forms an ideal M, then R is a local ring with unique maximal ideal M.

38. Prove that the ring of all rational numbers whose denominators is odd is a local ring whose unique maximal ideal is the principal ideal generated by 2.

39. Following the notation of Exercise 26 in Section 1, let K be a field, let v be a discrete valuation on K and let R be the valuation ring of v. For each integer $k \geq 0$ define $A_k = \{r \in R \mid v(r) \geq k\} \cup \{0\}$.
(a) Prove that A_k is a principal ideal and that $A_0 \supseteq A_1 \supseteq A_2 \supseteq \cdots$.
(b) Prove that if I is any nonzero ideal of R, then $I = A_k$ for some $k \geq 0$. Deduce that R is a local ring with unique maximal ideal A_1.

40. Assume R is commutative. Prove that the following are equivalent: (see also Exercises 13 and 14 in Section 1)
(i) R has exactly one prime ideal
(ii) every element of R is either nilpotent or a unit
(iii) $R/\mathfrak{N}(R)$ is a field (cf. Exercise 29, Section 3).

41. A proper ideal Q of the commutative ring R is called *primary* if whenever $ab \in Q$ and $a \notin Q$ then $b^n \in Q$ for some positive integer n. (Note that the symmetry between a and b in this definition implies that if Q is a primary ideal and $ab \in Q$ with *neither* a nor b in Q, then a positive power of a and a positive power of b both lie in Q.) Establish the following facts about primary ideals.
(a) The primary ideals of $\mathbb{Z}$ are 0 and (p^n), where p is a prime and n is a positive integer.
(b) Every prime ideal of R is a primary ideal.
(c) An ideal Q of R is primary if and only if every zero divisor in R/Q is a nilpotent element of R/Q.
(d) If Q is a primary ideal then $\text{rad}(Q)$ is a prime ideal (cf. Exercise 30).

Practice problems.

1. Let R be a commutative ring with 1. Prove that an ideal I is the unit ideal (i.e. $I = R$) if and only if I contains a unit. Deduce that the only ideals of a field F are $\langle 0\rangle$ and F.

2. In $\mathbb{Z}$, describe the ideal $\langle 6, 15\rangle$ explicitly as a principal ideal $\langle d\rangle$, and find d. More generally show $\langle a, b\rangle = \langle \gcd(a, b)\rangle$ for $a, b \in \mathbb{Z}$.

3. Determine whether each ideal of $\mathbb{Z}$ is prime, maximal, both, or neither: $\langle 0\rangle$, $\langle 7\rangle$, $\langle 12\rangle$, $\langle 1\rangle$.

4. Let R be a commutative ring with 1 and P an ideal. Prove P is prime $\iff$ R/P is an integral domain, and M is maximal $\iff$ R/M is a field. Use this to re-derive the previous problem's answers.

5. Show that every nonzero prime ideal of $\mathbb{Z}$ is maximal. Give an example of a commutative ring in which some nonzero prime ideal is *not* maximal.

6. In $R = \mathbb{Z}$, compute the ideal $\langle 4\rangle \cap \langle 6\rangle$, the product $\langle 4\rangle\langle 6\rangle$, and the sum $\langle 4\rangle + \langle 6\rangle$. Express each as a principal ideal $\langle n\rangle$.

7. Let $R = \mathbb{Q}[x]$. Show that $\langle x^2 - 1\rangle$ is neither prime nor maximal, that $\langle x - 1\rangle$ is maximal, and identify the field $R/\langle x - 1\rangle$.

8. Let $R = \mathbb{Z}[x]$. Show that $\langle x\rangle$ is prime but not maximal, and that $\langle 2, x\rangle$ is maximal. Identify $R/\langle 2, x\rangle$.

9. Let $\varphi\colon \mathbb{Z} \to \mathbb{Z}/12\mathbb{Z}$ be the natural projection. List all ideals of $\mathbb{Z}/12\mathbb{Z}$, and for each determine whether it is prime or maximal. (Recall ideals of $\mathbb{Z}/n\mathbb{Z}$ correspond to divisors of n.)

10. Let R be a finite commutative ring with 1. Prove that every prime ideal of R is maximal. (Hint: a finite integral domain is a field.)

11. Let I, J be ideals of a commutative ring R with $I + J = R$ (comaximal). Prove $IJ = I \cap J$.

12. Use the Chinese Remainder Theorem to write down an explicit ring isomorphism $\mathbb{Z}/15\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$, and find the element of $\mathbb{Z}/15\mathbb{Z}$ corresponding to $(2, 3)$.

13. Let R be a commutative ring with 1. An element x is nilpotent if $x^n = 0$ for some $n \geq 1$. Prove the set $\text{nil}(R)$ of nilpotent elements (the nilradical) is an ideal, and compute $\text{nil}(\mathbb{Z}/12\mathbb{Z})$.

14. Prove that in a commutative ring with 1, the nilradical is contained in every prime ideal. Conclude $\text{nil}(\mathbb{Z}/12\mathbb{Z})$ lies in $\langle 2\rangle$ and $\langle 3\rangle$.

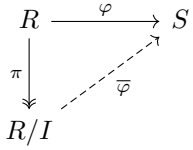
15. Let I be an ideal of a commutative ring R with 1. Define $\text{rad}(I) = \{x \in R : x^n \in I \text{ for some } n \geq 1\}$. Show $\text{rad}(I)$ is an ideal containing I, and compute $\text{rad}(\langle 12\rangle)$ in $\mathbb{Z}$.

Additional exercises.

1. Let R be a commutative ring with 1. Prove that R is a field if and only if its only ideals are $\langle 0\rangle$ and R. Show this fails for noncommutative rings by exhibiting the only two-sided ideals of $\text{M}_2(\mathbb{F})$ for a field $\mathbb{F}$ (and noting it is not a field).

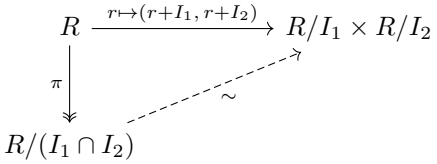
2. (Prime avoidance, two-prime case.) Let P_1, P_2 be prime ideals of a commutative ring R and let I be an ideal with $I \subseteq P_1 \cup P_2$. Prove $I \subseteq P_1$ or $I \subseteq P_2$.

3. Let R be a commutative ring with $1 \neq 0$. Prove that R contains a maximal ideal, and that every proper ideal is contained in some maximal ideal. (You may invoke Zorn's Lemma.)



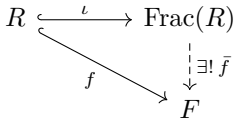
4. Let $R = \mathbb{R}[x]$. Classify all maximal ideals of R, showing each has the form $\langle x - a \rangle$ (with $R/\langle x-a\rangle \cong \mathbb{R}$) or $\langle x^2 + bx + c \rangle$ with $b^2 - 4c < 0$ (with quotient $\cong \mathbb{C}$). Conclude $\langle x^2 + 1 \rangle$ is maximal.

5. Let R be a commutative ring with 1 in which every element x satisfies $x^2 = x$ (a Boolean ring). Prove every prime ideal of R is maximal, and that $R/P \cong \mathbb{Z}/2\mathbb{Z}$ for each prime P.



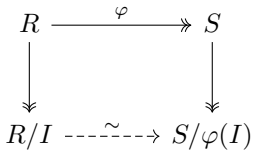
6. Let I and J be comaximal ideals of a commutative ring R with 1. Prove I^m and J^n are comaximal for all $m, n \geq 1$.

Commutative-diagram exercises.



1. Let $\varphi\colon R \to S$ be a ring homomorphism with $I \subseteq \ker\varphi$ an ideal of R, and let $\pi\colon R \to R/I$ be the projection. State and prove the universal property: there is a unique ring homomorphism $\overline{\varphi}\colon R/I \to S$ making the diagram commute, and $\overline{\varphi}$ is injective iff $I = \ker\varphi$.

2. Let R be a commutative ring with 1 and let I_1, I_2 be comaximal ideals. Prove the map $r \mapsto (r + I_1,\, r + I_2)$ induces a ring isomorphism, so that the dashed arrow below is well defined and an isomorphism. Identify its kernel before passing to the quotient.



3. Let R be an integral domain with field of fractions $\mathrm{Frac}(R)$, $\iota\colon R \to \mathrm{Frac}(R)$ the inclusion. Suppose $f\colon R \to F$ is an injective ring homomorphism into a field F. State and prove the universal property of the field of fractions exhibited by the diagram, identifying the formula for $\bar{f}$.

4. Let $R = \mathbb{Z}$, $I_1 = \langle 4 \rangle$, $I_2 = \langle 9 \rangle$. Verify $I_1 + I_2 = \mathbb{Z}$ and use the previous CRT diagram to produce an explicit isomorphism $\mathbb{Z}/36\mathbb{Z} \xrightarrow{\sim} \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z}$. Draw the diagram with all arrows labeled, and compute the image of $\overline{17}$.

5. Let $\varphi\colon R \to S$ be a surjective ring homomorphism with kernel K. Show that the assignment $I \mapsto \varphi(I)$ gives an inclusion-preserving bijection between ideals of R containing K and ideals of S, and that this bijection sends prime (resp. maximal) ideals to prime (resp. maximal) ideals. Illustrate with $\varphi\colon \mathbb{Z} \to \mathbb{Z}/12\mathbb{Z}$ in a diagram of the relevant quotients.

7.5 Rings of Fractions

Rings of fractions and the field of fractions

Throughout this section R is a *commutative* ring with 1. The motivating question of D&F 7.5 is: *given a ring, how do we adjoin inverses to certain elements so that they become units?* For $R = \mathbb{Z}$ we want to invert all nonzero integers and arrive at $\mathbb{Q}$; more generally we invert the elements of a chosen "denominator set." The whole construction is a vast generalization of building $\mathbb{Q}$ out of $\mathbb{Z}$, with the equality $a/b = c/d \iff ad = bc$ replaced by a careful equivalence relation.

Definition 7.5.1 (Multiplicatively closed set)**.** A subset $D \subseteq R$ is *multiplicatively closed* if $1 \in D$ and D is closed under multiplication: $a, b \in D \implies ab \in D$. In this section we additionally require that D consist of nonzero elements that are *not zero divisors*, i.e. $0 \notin D$ and no $d \in D$ satisfies $dr = 0$ for some $r \neq 0$. (Such a D is the admissible denominator set of D&F's Theorem 15.)

Remark 7.5.1. The condition "no zero divisors in D" is exactly what makes the cancellation $ad = bd \implies a = b$ legal for $d \in D$, which is what is needed for the fraction relation below to be an equivalence relation and for R to embed (rather than collapse). If one drops it one gets a more general localization $D^{-1}R$ in which R need not embed – that is the subject of the more general theory; here we stay in the zero-divisor-free case of D&F.

Theorem 7.5.2 (D&F 7.5, Theorem 15: existence of the ring of fractions)**.** *Let R be a commutative ring and let D be a nonempty multiplicatively closed subset of R containing no zero divisors (and $0 \notin D$). On the set $R \times D$ define*

$$(a, d) \sim (b, e) \quad \iff \quad ae = bd.$$

Then $\sim$ is an equivalence relation. Write $\dfrac{a}{d}$ for the class of (a, d) and let $D^{-1}R$ be the set of classes. The operations

$$\frac{a}{d} + \frac{b}{e} = \frac{ae + bd}{de}, \qquad \frac{a}{d} \cdot \frac{b}{e} = \frac{ab}{de}$$

are well defined and make $D^{-1}R$ into a commutative ring with $1 = \frac{d}{d}$ (any $d \in D$) and $0 = \frac{0}{1}$. Moreover:

(1) The map $\iota\colon R \to D^{-1}R$, $\iota(r) = \dfrac{rd}{d}$ (any $d \in D$; equivalently $\dfrac{r}{1}$) is an injective *ring homomorphism, so R is identified with the subring $\iota(R)$.*

(2) Every $d \in D$ becomes a unit in $D^{-1}R$: $\iota(d)^{-1} = \dfrac{1}{d}$.

Proof. Equivalence relation. Reflexivity and symmetry are clear from $ad = ad$ and symmetry of $ae = bd$. For transitivity suppose $(a, d) \sim (b, e)$ and $(b, e) \sim (c, f)$, so $ae = bd$ and $bf = ce$. Then

$$(af)e = (ae)f = (bd)f = (bf)d = (ce)d = (cd)e.$$

Thus $afe = cde$, and since $e \in D$ is not a zero divisor we cancel e to get $af = cd$, i.e. $(a, d) \sim (c, f)$.

Well-defined operations. Suppose $\frac{a}{d} = \frac{a'}{d'}$, i.e. $ad' = a'd$. For multiplication, $\frac{a}{d}\frac{b}{e} = \frac{ab}{de}$ and $\frac{a'}{d'}\frac{b}{e} = \frac{a'b}{d'e}$; we must check $(ab)(d'e) = (a'b)(de)$. Indeed $(ab)(d'e) = (ad')(be) = (a'd)(be) = (a'b)(de)$. Addition is similar (and one also varies the second fraction); the not-a-zero-divisor hypothesis is not even needed for well-definedness once $\sim$ is an equivalence relation, but it *is* needed for transitivity above.

Ring axioms. These are routine verifications mirroring the familiar arithmetic of $\mathbb{Q}$; associativity, distributivity and commutativity follow from those of R after clearing denominators. The additive identity is $\frac{0}{1}$ (note $\frac{0}{d} = \frac{0}{1}$ since $0 \cdot 1 = 0 \cdot d$) and $1_{D^{-1}R} = \frac{d}{d}$, which equals $\frac{1}{1}$.

(1) ι is a homomorphism. $\iota(r) = \frac{r}{1}$. Then $\iota(r) + \iota(s) = \frac{r}{1} + \frac{s}{1} = \frac{r+s}{1} = \iota(r + s)$ and $\iota(r)\iota(s) = \frac{rs}{1} = \iota(rs)$, and $\iota(1) = \frac{1}{1} = 1$. *Injectivity:* $\iota(r) = 0$ means $\frac{r}{1} = \frac{0}{1}$, i.e. $r \cdot 1 = 0 \cdot 1$ so $r = 0$. (Here is where "no zero divisors in D" matters: $\frac{r}{1} = \frac{0}{1} \iff rd = 0$ for the chosen d; cancel d to get $r = 0$.)

(2) D becomes units. For $d \in D$, $\frac{d}{1} \cdot \frac{1}{d} = \frac{d}{d} = 1$, so $\iota(d)$ is a unit with inverse $\frac{1}{d}$. □

Method (Building / recognizing a ring of fractions $D^{-1}R$)**.** *Trigger.* You want to make a chosen multiplicatively closed set D of non-zero- divisors invertible, or you meet a ring described as "R with the elements of D inverted," "fractions a/d with $d \in D$," or "smallest ring containing R in which the $d \in D$ are units." *Recipe.*

1. Identify R (commutative) and the denominator set D. Check $1 \in D$, D closed under products, $0 \notin D$, and D has no zero divisors.
2. Form symbols a/d with $a \in R,\ d \in D$, modulo $a/d = b/e \iff ae = bd$.
3. Add/multiply by the schoolbook rules $\frac{a}{d} + \frac{b}{e} = \frac{ae+bd}{de}$, $\frac{a}{d} \cdot \frac{b}{e} = \frac{ab}{de}$.
4. Identify $r \in R$ with $r/1$; each $d \in D$ is a unit with inverse $1/d$.
5. **Special case (the most common):** if R is an integral domain and $D = R\setminus\{0\}$, then $D^{-1}R = \mathrm{Frac}(R)$ is a *field*.

Check. Verify $1/d$ really inverts d, and confirm ι is injective by checking $r/1 = 0/1 \implies r = 0$.

Worked Example 7.5.3 (The relation really needs "no zero divisors")**.** Show that if D contains a zero divisor the relation $\sim$ can fail to be transitive (or ι fails to be injective), using $R = \mathbb{Z}/6\mathbb{Z}$ and the multiplicatively closed set $D = \{1, 2, 4\}$.

Recognition. Transitivity of $\sim$ used cancellation by $e \in D$; the example tests what happens when an element of D kills something nonzero.

Solution. In $\mathbb{Z}/6\mathbb{Z}$, $2 \cdot 3 = 0$ and $3 \neq 0$, so 2 is a zero divisor; $D = \{1, 2, 4\}$ is multiplicatively closed ($2 \cdot 2 = 4,\ 2 \cdot 4 = 8 = 2,\ 4 \cdot 4 = 16 = 4$) but contains the zero divisor 2. For the relation of Theorem 7.5.2, $(3, 1) \sim (0, 2)$ since $3 \cdot 2 = 0 = 0 \cdot 1$, and $(0, 2) \sim (0, 1)$ since $0 \cdot 1 = 0 \cdot 2$, but $(3, 1) \not\sim (0, 1)$ since $3 \cdot 1 \neq 0 \cdot 1$; so $\sim$ is *not* transitive. Repairing this with the localization relation $\frac{a}{d} = \frac{b}{e} \iff (\exists u \in D)\ u(ae - bd) = 0$, whose zero test is $\frac{r}{1} = \frac{0}{1} \iff (\exists d \in D)\ rd = 0$, we get $\frac{3}{1} = \frac{0}{1}$ because $3 \cdot 2 = 0$. So $\iota(3) = 0$: the element $3 \neq 0$ would die. This is exactly the pathology the hypothesis "D has no zero divisors" rules out, guaranteeing ι injective (Theorem 7.5.2(1)). *Check.* Indeed $3 \neq 0$ in $\mathbb{Z}/6\mathbb{Z}$ yet maps to 0, confirming injectivity fails when the hypothesis is dropped.

Solution.

The field of fractions of an integral domain

Definition 7.5.4 (Field of fractions)**.** Let R be an integral domain. Take $D = R\setminus\{0\}$, which is multiplicatively closed (product of nonzeros is nonzero in a domain) and contains no zero divisors (a domain has none). The ring $D^{-1}R$ is then a field, called the *field of fractions* (or quotient field) of R, written $\mathrm{Frac}(R)$ or $Q(R)$.

Corollary 7.5.5 (D&F 7.5, Corollary 16: $\mathrm{Frac}(R)$ is a field)**.** *If R is an integral domain then* $\mathrm{Frac}(R)$ *is a field, and it is the* smallest *field containing (an isomorphic copy of) R in the following sense: if K is any field containing R as a subring, then the subfield of K generated by R is isomorphic to* $\mathrm{Frac}(R)$*. Concretely* $\mathrm{Frac}(R) = \{\, a/b : a \in R,\ b \in R,\ b \neq 0 \,\}$.

Proof. $\mathrm{Frac}(R)$ is commutative with $1 = \frac{1}{1} \neq \frac{0}{1} = 0$ (since $1 \neq 0$ in R). Take any nonzero $\frac{a}{b} \in \mathrm{Frac}(R)$. Nonzero means $\frac{a}{b} \neq \frac{0}{1}$, i.e. $a \cdot 1 \neq 0 \cdot b$, i.e. $a \neq 0$; hence $a \in D = R\setminus\{0\}$ and $\frac{b}{a} \in \mathrm{Frac}(R)$. Then $\frac{a}{b} \cdot \frac{b}{a} = \frac{ab}{ab} = 1$, so $\frac{a}{b}$ is a unit. Thus every nonzero element is invertible and $\mathrm{Frac}(R)$ is a field. Minimality is the universal property, Theorem 7.5.6 below: any field $K \supseteq R$ induces an injection $\mathrm{Frac}(R) \hookrightarrow K$ whose image is the subfield R generates. □

Theorem 7.5.6 (Universal property of $\mathrm{Frac}(R)$, D&F 7.5 Theorem 15(2)/Cor. 16)**.** *Let R be an integral domain with field of fractions* $\mathrm{Frac}(R)$ *and embedding $\iota\colon R \hookrightarrow \mathrm{Frac}(R)$, $\iota(r) = r/1$. If F is a field and $f\colon R \to F$ is an* injective *ring homomorphism (more generally any ring hom sending every nonzero element of R to a unit of F), then there is a* unique *ring homomorphism $\bar{f}\colon \mathrm{Frac}(R) \to F$ with $\bar{f} \circ \iota = f$, namely*

$$\bar{f}\Big(\frac{a}{b}\Big) = f(a)\, f(b)^{-1}.$$

Moreover $\bar{f}$ is itself injective. In a diagram:

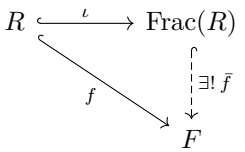


Diagram explanation. Objects: R is an integral domain (upper left). $\mathrm{Frac}(R)$ is the field of fractions of R (upper right), a field in which every nonzero element of R is a unit. F is any field (lower right) together with an injective ring homomorphism from R.

Arrows: $\iota\colon R \hookrightarrow \mathrm{Frac}(R)$ is the canonical embedding $r \mapsto r/1$, a ring homomorphism that is injective because R has no zero divisors. $f\colon R \to F$ is an injective ring homomorphism (the given data). $\bar{f}\colon \mathrm{Frac}(R) \to F$ is the induced (dashed) map defined by $\bar{f}(a/b) = f(a)f(b)^{-1}$; it is asserted to exist and be unique.

What commutes: The triangle commutes: $\bar{f} \circ \iota = f$. That is, for every $r \in R$, $\bar{f}(\iota(r)) = f(r)$.

Why it commutes: Take $r \in R$. Along the top-then-down path: $\iota(r) = r/1$, then $\bar{f}(r/1) = f(r)f(1)^{-1} = f(r) \cdot 1 = f(r)$. Along the direct path (the diagonal f): $f(r)$. Both give $f(r)$. Well-definedness of $\bar{f}$ on cosets: if $a/b = a'/b'$ then $ab' = a'b$, so $f(a)f(b') = f(a')f(b)$; multiplying both sides by $f(b)^{-1}f(b')^{-1}$ (units in F since $b, b' \neq 0$ and f is injective into a field) gives $f(a)f(b)^{-1} = f(a')f(b')^{-1}$, confirming $\bar{f}$ is independent of the representative chosen.

Why this matters here: This is the universal property of $\mathrm{Frac}(R)$: it encodes in one picture that $\mathrm{Frac}(R)$ is the *smallest* field containing R, in the categorical sense that any field F receiving an injection from R already receives one from $\mathrm{Frac}(R)$ via the unique $\bar{f}$. The dashed arrow and the uniqueness are the entire content of Theorem 15(2)/Corollary 16.

Concrete example: $R = \mathbb{Z}$, $\mathrm{Frac}(R) = \mathbb{Q}$, $F = \mathbb{R}$, $f(n) = n$. Then $\bar{f}(a/b) = a/b \in \mathbb{R}$ is the standard embedding $\mathbb{Q} \hookrightarrow \mathbb{R}$, the unique ring hom extending f. There is no other way to embed $\mathbb{Q}$ in $\mathbb{R}$ that fixes $\mathbb{Z}$.

Common pitfall: Students sometimes think $\bar{f}$ exists for any ring hom $f\colon R \to F$, not just injective ones. If f kills a nonzero r, then $f(r) = 0$ would need to be a unit (since $r/1 \in \mathrm{Frac}(R)$ has an inverse $1/r$), but 0 is not a unit in F. The injectivity hypothesis is essential; without it the formula $\bar{f}(a/b) = f(a)f(b)^{-1}$ breaks down: if $f(r) = 0$ for some $r \neq 0$, it would require $\bar{f}(1/r) = f(1)f(r)^{-1}$, and $f(r)^{-1} = 0^{-1}$ is undefined.

Takeaway: The point of this diagram is that $\mathrm{Frac}(R)$ is the universal initial step in embedding R into a field: every injection of R into a field factors uniquely and injectively through $\iota\colon R \hookrightarrow \mathrm{Frac}(R)$.

Proof. Necessity of the formula (uniqueness). If $\bar{f}$ exists with $\bar{f} \circ \iota = f$, then for $b \neq 0$, $\bar{f}(\frac{b}{1}) = f(b)$, and from $\frac{b}{1} \cdot \frac{1}{b} = 1$ we get $f(b)\,\bar{f}(\frac{1}{b}) = 1$, so $\bar{f}(\frac{1}{b}) = f(b)^{-1}$ (which exists since $f(b)$ is a unit as $b \neq 0$ and f injective into a field). Hence $\bar{f}(\frac{a}{b}) = \bar{f}(\frac{a}{1})\bar{f}(\frac{1}{b}) = f(a)f(b)^{-1}$. The value is forced, giving uniqueness.

Existence / well-defined. Define $\bar{f}(\frac{a}{b}) = f(a)f(b)^{-1}$. If $\frac{a}{b} = \frac{c}{d}$ then $ad = bc$, so $f(a)f(d) = f(b)f(c)$ in F; since $f(b), f(d)$ are units (as $b, d \neq 0$) multiply by $f(b)^{-1}f(d)^{-1}$ to get $f(a)f(b)^{-1} = f(c)f(d)^{-1}$. Well-defined. It is a homomorphism:

$$\bar{f}\big(\tfrac{a}{b} + \tfrac{c}{d}\big) = \bar{f}\big(\tfrac{ad+bc}{bd}\big) = f(ad+bc)f(bd)^{-1} = \big(f(a)f(d)+f(b)f(c)\big)f(b)^{-1}f(d)^{-1} = f(a)f(b)^{-1}+f(c)f(d)^{-1},$$

and multiplicativity is immediate; $\bar{f}(\frac{1}{1}) = 1$.

$\bar{f}$ injective. If $\bar{f}(\frac{a}{b}) = 0$ then $f(a)f(b)^{-1} = 0$, so $f(a) = 0$, so $a = 0$ (as f injective), so $\frac{a}{b} = 0$. A nonzero ring hom of a field is automatically injective, recovering this. □

Method (Using the universal property to embed a domain in a field)**.** *Trigger.* You must show a domain R sits inside a field, or you have a map $f\colon R \to F$ into a field and want to extend it to fractions, or you need to prove two fields-of-fractions are isomorphic. *Recipe.*

1. Confirm R is an integral domain (so $\mathrm{Frac}(R)$ exists and is a field).
2. Produce an injective ring hom $f\colon R \to F$ into your target field F.
3. Invoke Theorem 7.5.6: get the unique $\bar{f}(\frac{a}{b}) = f(a)f(b)^{-1}$, automatically injective, so $\mathrm{Frac}(R) \hookrightarrow F$.
4. For an isomorphism $\mathrm{Frac}(R) \cong K$: show K is a field containing R in which every element is ab^{-1} with $a, b \in R,\ b \neq 0$; then $\bar{f}$ is onto, hence iso.

Check. Verify $\bar{f} \circ \iota = f$ on generators of R and that $\bar{f}$ hits every element of K for surjectivity.

Caution. $\mathrm{Frac}(R)$ is only defined (as a field) when R is an *integral domain*. For a general commutative ring you may still form $D^{-1}R$ for a multiplicatively closed zero-divisor-free D, but "$D = R \setminus \{0\}$" is usually *not* multiplicatively closed and the result need not be a field. E.g. $\mathbb{Z}/6\mathbb{Z}$ is not a domain; there is no "field of fractions of $\mathbb{Z}/6\mathbb{Z}$."

Caution. $\bar{f}$ in the universal property is unique *only because* $\frac{a}{b} = \frac{a}{1}\frac{1}{b}$ forces its value. Do not try to "choose" a different extension: any ring hom out of $\mathrm{Frac}(R)$ agreeing with f on R must be $\bar{f}$. Also note f must send nonzero elements to units; an arbitrary ring hom into F that kills some nonzero r does *not* extend.

Worked Example 7.5.7 ($\mathrm{Frac}(\mathbb{Z}) = \mathbb{Q}$)**.** Identify the field of fractions of $\mathbb{Z}$ and verify the universal property by recovering the standard embedding $\mathbb{Z} \hookrightarrow \mathbb{Q}$.

Recognition. $\mathbb{Z}$ is an integral domain and $D = \mathbb{Z} \setminus \{0\}$, so $\mathrm{Frac}(\mathbb{Z})$ is the field of all a/b – this is the definition of $\mathbb{Q}$.

Solution. $\mathbb{Z}$ is a domain, so $\mathrm{Frac}(\mathbb{Z}) = \{a/b : a \in \mathbb{Z}, b \in \mathbb{Z} \setminus \{0\}\}$ with $\frac{a}{b} = \frac{c}{d} \iff ad = bc$. That is precisely the usual construction of $\mathbb{Q}$, so $\mathrm{Frac}(\mathbb{Z}) \cong \mathbb{Q}$ via $\frac{a}{b} \mapsto a/b$. Universal property: let F be any field of characteristic 0 and $f\colon \mathbb{Z} \to F$ the unique ring hom $f(n) = n \cdot 1_F$, which is injective (char 0). Then $\bar{f}(\frac{a}{b}) = f(a)f(b)^{-1} = (a \cdot 1_F)(b \cdot 1_F)^{-1}$ embeds $\mathbb{Q} \hookrightarrow F$; this is the familiar fact that every characteristic-0 field contains a copy of $\mathbb{Q}$ (its prime subfield). *Check.* $\bar{f}(\frac{1}{1}) = 1_F$ and $\bar{f}(\frac{2}{1}) = 2 \cdot 1_F$, agreeing with f on $\mathbb{Z}$.

Solution.

Worked Example 7.5.8 ($\mathrm{Frac}(\mathbb{F}[x]) = \mathbb{F}(x)$, the field of rational functions)**.** For a field $\mathbb{F}$, identify $\mathrm{Frac}(\mathbb{F}[x])$.

Recognition. $\mathbb{F}[x]$ is an integral domain (a polynomial ring over a field has no zero divisors, by additivity of degrees), so its field of fractions is the quotients of polynomials.

Solution. Since $\mathbb{F}$ is a field, $\mathbb{F}[x]$ is an integral domain: if $p, q \neq 0$ then $\deg(pq) = \deg p + \deg q$, so $pq \neq 0$. Hence

$$\mathrm{Frac}(\mathbb{F}[x]) = \left\{ \tfrac{p(x)}{q(x)} : p, q \in \mathbb{F}[x],\ q \neq 0 \right\} =: \mathbb{F}(x),$$

the field of *rational functions* in x over $\mathbb{F}$, with $\frac{p}{q} = \frac{r}{s} \iff ps = qr$. It is a field by Corollary 7.5.5: the inverse of nonzero $\frac{p}{q}$ is $\frac{q}{p}$. *Check.* $\frac{x}{x^2+1} \cdot \frac{x^2+1}{x} = \frac{x(x^2+1)}{x(x^2+1)} = 1$, so $\frac{x}{x^2+1}$ is indeed a unit in $\mathbb{F}(x)$, as every nonzero element must be.

Solution.

Worked Example 7.5.9 ($\mathrm{Frac}(\mathbb{Z}[i]) = \mathbb{Q}(i)$, the Gaussian rationals)**.** Let $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$ be the Gaussian integers. Show $\mathrm{Frac}(\mathbb{Z}[i]) = \mathbb{Q}(i)$.

Recognition. $\mathbb{Z}[i]$ is an integral domain (subring of $\mathbb{C}$), so $\mathrm{Frac}(\mathbb{Z}[i])$ is the smallest subfield of $\mathbb{C}$ containing $\mathbb{Z}[i]$; compute it.

Solution. $\mathbb{Z}[i] \subseteq \mathbb{C}$ is a subring of a field, hence an integral domain, so $\mathrm{Frac}(\mathbb{Z}[i])$ exists and by Corollary 7.5.5 embeds as the subfield of $\mathbb{C}$ generated by $\mathbb{Z}[i]$. That subfield is $\mathbb{Q}(i) = \{p + qi : p, q \in \mathbb{Q}\}$. To see this, every quotient $\frac{a+bi}{c+di}$ (with $c + di \neq 0$) is computed by rationalizing:

$$\frac{a+bi}{c+di} = \frac{(a+bi)(c-di)}{(c+di)(c-di)} = \frac{(ac+bd)+(bc-ad)i}{c^2+d^2} = \frac{ac+bd}{c^2+d^2} + \frac{bc-ad}{c^2+d^2}\,i \ \in\ \mathbb{Q}(i),$$

where $c^2 + d^2 \neq 0$ since $c + di \neq 0$. Conversely each $p + qi \in \mathbb{Q}(i)$ with $p = \frac{a}{m}, q = \frac{b}{m}$ $(m \neq 0)$ equals $\frac{a+bi}{m} \in \mathrm{Frac}(\mathbb{Z}[i])$. Hence $\mathrm{Frac}(\mathbb{Z}[i]) = \mathbb{Q}(i)$. *Check.* The inverse of $1 + i$ is $\frac{1}{1+i} = \frac{1-i}{(1+i)(1-i)} = \frac{1-i}{2} = \frac{1}{2} - \frac{1}{2}i \in \mathbb{Q}(i)$, and $(1+i)(\frac{1}{2} - \frac{1}{2}i) = \frac{1}{2} - \frac{1}{2}i + \frac{1}{2}i - \frac{1}{2}i^2 = \frac{1}{2} + \frac{1}{2} = 1$.

Solution.

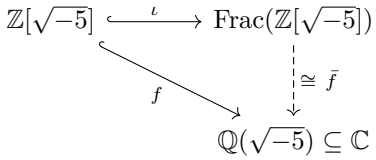
Worked Example 7.5.10 (Localizing $\mathbb{Z}$ at powers of 2: $D^{-1}\mathbb{Z} = \mathbb{Z}[1/2]$)**.** Let $R = \mathbb{Z}$ and $D = \{1, 2, 4, 8, \dots\} = \{2^k : k \geq 0\}$. Describe $D^{-1}\mathbb{Z}$ and show it is *not* a field.

Recognition. D is multiplicatively closed and contains no zero divisors (subset of the domain $\mathbb{Z}$), so Theorem 7.5.2 applies; we are inverting only the powers of 2, not all nonzero integers.

Solution. $D = \{2^k\}$ is multiplicatively closed ($2^j 2^k = 2^{j+k}$, $1 = 2^0 \in D$) and zero-divisor-free. So

$$D^{-1}\mathbb{Z} = \left\{ \tfrac{a}{2^k} : a \in \mathbb{Z},\ k \geq 0 \right\} = \mathbb{Z}[1/2] \subseteq \mathbb{Q},$$

the ring of dyadic rationals, with $\frac{a}{2^j} = \frac{b}{2^k} \iff a2^k = b2^j$. The only new units we created are the $\pm 2^k$; for instance 3 is *not* a unit in $\mathbb{Z}[1/2]$ because $\frac{1}{3} \notin \mathbb{Z}[1/2]$ (it would require $3 \mid 2^k$). Therefore $D^{-1}\mathbb{Z}$ is a proper



subring of $\mathbb{Q}$ and is *not* a field. *Check.* The units of $\mathbb{Z}[1/2]$ are exactly $\pm 2^k$; e.g. $\frac{1}{2}$ inverts 2 since $\frac{1}{2} \cdot 2 = 1$, but $\frac{1}{5}$ is not in the ring, so 5^{-1} does not exist. Note $\mathrm{Frac}(\mathbb{Z}[1/2]) = \mathbb{Q}$ still, since $\mathbb{Z}[1/2]$ is a domain whose fractions recover all of $\mathbb{Q}$.

Solution.

Worked Example 7.5.11 (Universal property to embed a domain in a field)**.** Let R be the domain $\mathbb{Z}[\sqrt{-5}] = \{a + b\sqrt{-5} : a, b \in \mathbb{Z}\}$. Show R embeds in a field and identify $\mathrm{Frac}(R)$, using the universal property.

Recognition. $R \subseteq \mathbb{C}$ is a domain; the inclusion $f\colon R \hookrightarrow \mathbb{C}$ is an injective ring hom into a field, so Theorem 7.5.6 extends it uniquely to $\mathrm{Frac}(R)$.

Solution. $R = \mathbb{Z}[\sqrt{-5}]$ is a subring of $\mathbb{C}$, hence an integral domain, so $\mathrm{Frac}(R)$ is a field. Let $f\colon R \hookrightarrow \mathbb{C}$ be inclusion, an injective ring hom into the field $\mathbb{C}$. By the universal property there is a unique injective ring hom $\bar{f}\colon \mathrm{Frac}(R) \to \mathbb{C}$, $\bar{f}(\frac{a+b\sqrt{-5}}{c+d\sqrt{-5}}) = (a+b\sqrt{-5})(c+d\sqrt{-5})^{-1}$. Its image is the subfield of $\mathbb{C}$ generated by R, which is $\mathbb{Q}(\sqrt{-5}) = \{p + q\sqrt{-5} : p, q \in \mathbb{Q}\}$ (rationalize denominators using $(c + d\sqrt{-5})(c - d\sqrt{-5}) = c^2 + 5d^2 \in \mathbb{Q}$). Hence $\mathrm{Frac}(\mathbb{Z}[\sqrt{-5}]) \cong \mathbb{Q}(\sqrt{-5})$. *Check.* $(2 + \sqrt{-5})^{-1} = \frac{2-\sqrt{-5}}{(2)^2+5} = \frac{2-\sqrt{-5}}{9} = \frac{2}{9} - \frac{1}{9}\sqrt{-5} \in \mathbb{Q}(\sqrt{-5})$, and $(2 + \sqrt{-5})(\frac{2}{9} - \frac{1}{9}\sqrt{-5}) = \frac{4}{9} - \frac{2}{9}\sqrt{-5} + \frac{2}{9}\sqrt{-5} - \frac{1}{9}(-5) = \frac{4}{9} + \frac{5}{9} = 1$. The diagram

commutes, with $\bar{f}$ the asserted isomorphism.

Solution.

Diagram explanation. Objects: $\mathbb{Z}[\sqrt{-5}] = \{a + b\sqrt{-5} : a, b \in \mathbb{Z}\}$ is an integral domain (upper left), a subring of $\mathbb{C}$. $\mathrm{Frac}(\mathbb{Z}[\sqrt{-5}])$ is its abstract field of fractions (upper right). $\mathbb{Q}(\sqrt{-5}) = \{p + q\sqrt{-5} : p, q \in \mathbb{Q}\} \subseteq \mathbb{C}$ is the concrete subfield of $\mathbb{C}$ generated by $\mathbb{Z}[\sqrt{-5}]$ (lower right).

Arrows: $\iota\colon \mathbb{Z}[\sqrt{-5}] \hookrightarrow \mathrm{Frac}(\mathbb{Z}[\sqrt{-5}])$ is the canonical embedding $z \mapsto z/1$, injective since $\mathbb{Z}[\sqrt{-5}]$ is a domain. $f\colon \mathbb{Z}[\sqrt{-5}] \hookrightarrow \mathbb{Q}(\sqrt{-5}) \subseteq \mathbb{C}$ is the natural ring inclusion, injective as a subring map. $\bar{f}\colon \mathrm{Frac}(\mathbb{Z}[\sqrt{-5}]) \xrightarrow{\sim} \mathbb{Q}(\sqrt{-5})$ is the induced map $\bar{f}(\frac{z}{w}) = zw^{-1}$ (computed in $\mathbb{C}$), asserted to be an isomorphism.

What commutes: $\bar{f} \circ \iota = f$: for every $z \in \mathbb{Z}[\sqrt{-5}]$, $\bar{f}(z/1) = z \cdot 1^{-1} = z = f(z)$.

Why it commutes: Take $z \in \mathbb{Z}[\sqrt{-5}]$. Via ι then $\bar{f}$: $z \mapsto z/1 \mapsto f(z)f(1)^{-1} = f(z)$. Via f directly: $z \mapsto f(z)$. Equal. Well-definedness of $\bar{f}$: if $z/w = z'/w'$ in $\mathrm{Frac}(\mathbb{Z}[\sqrt{-5}])$ then $zw' = z'w$; applying f (a ring hom) gives $f(z)f(w') = f(z')f(w)$ in $\mathbb{C}$; since $w, w' \neq 0$ and f injective (into a field), $f(w), f(w')$ are nonzero hence units in $\mathbb{C}$, so $f(z)f(w)^{-1} = f(z')f(w')^{-1}$ and $\bar{f}$ is well defined on equivalence classes.

Why this matters here: The diagram makes concrete the abstract universal property from the theorem: instead of an unknown field F, here $F = \mathbb{C}$ and the image of $\bar{f}$ is computed explicitly as $\mathbb{Q}(\sqrt{-5})$. Surjectivity of $\bar{f}$ (rationalization of denominators shows every $p + q\sqrt{-5} \in \mathbb{Q}(\sqrt{-5})$ is a quotient of elements of $\mathbb{Z}[\sqrt{-5}]$) upgrades the injection to an isomorphism, identifying the abstract $\mathrm{Frac}(\mathbb{Z}[\sqrt{-5}])$ with the concrete $\mathbb{Q}(\sqrt{-5})$.

Concrete example: $(2 + \sqrt{-5})^{-1} = \frac{2-\sqrt{-5}}{9} = \frac{2}{9} - \frac{1}{9}\sqrt{-5} \in \mathbb{Q}(\sqrt{-5})$. In $\mathrm{Frac}(\mathbb{Z}[\sqrt{-5}])$ this is the element $1/(2 + \sqrt{-5})$, and $\bar{f}$ sends it to $1 \cdot (2 + \sqrt{-5})^{-1}$ in $\mathbb{C}$, landing in $\mathbb{Q}(\sqrt{-5})$.

Common pitfall: The isomorphism label $\cong$ on the dashed arrow is the conclusion of a proof, not the starting assumption. Students sometimes read the diagram as defining $\bar{f}$ to be an isomorphism; in fact one must first show it is well defined (coset check above), then a homomorphism, then injective (automatic for a nonzero map of fields), then surjective (by the rationalization calculation). The dashed arrow starts as a candidate map.

Takeaway: The point of this diagram is that the universal property of $\mathrm{Frac}(\mathbb{Z}[\sqrt{-5}])$ identifies it concretely with $\mathbb{Q}(\sqrt{-5})$ by providing a computable isomorphism via rationalization of denominators.

Worked Example 7.5.12 (Two presentations of the same field of fractions)**.** Show that $\mathrm{Frac}\big(\mathbb{Z}[x]\big)$ and $\mathrm{Frac}\big(\mathbb{Q}[x]\big)$ are isomorphic (both equal $\mathbb{Q}(x)$), illustrating that enlarging the domain inside its own fraction field changes nothing.

Recognition. Both $\mathbb{Z}[x]$ and $\mathbb{Q}[x]$ are integral domains lying in the field $\mathbb{Q}(x)$; the universal property forces both fraction fields to be the subfield they generate.

Solution. $\mathbb{Z}[x] \subseteq \mathbb{Q}[x] \subseteq \mathbb{Q}(x)$ are domains; $\mathbb{Q}(x) = \mathrm{Frac}(\mathbb{Q}[x])$ by the rational functions example. The inclusion $f\colon \mathbb{Z}[x] \hookrightarrow \mathbb{Q}(x)$ is injective into a field, so $\bar{f}\colon \mathrm{Frac}(\mathbb{Z}[x]) \hookrightarrow \mathbb{Q}(x)$ is an injective ring hom onto the subfield generated by $\mathbb{Z}[x]$. That subfield already contains $\frac{1}{n}$ for every nonzero integer n (as $\frac{1}{n\cdot 1}$) and contains x, hence contains $\mathbb{Q}[x]$ and all its quotients, i.e. all of $\mathbb{Q}(x)$. So $\bar{f}$ is onto: $\mathrm{Frac}(\mathbb{Z}[x]) \cong \mathbb{Q}(x) \cong \mathrm{Frac}(\mathbb{Q}[x])$.
Check. $\frac{x}{2} = \frac{x}{2} \in \mathrm{Frac}(\mathbb{Z}[x])$ maps to the same element of $\mathbb{Q}(x)$ as the obvious element of $\mathrm{Frac}(\mathbb{Q}[x])$, and $\frac{1}{2} \in \mathbb{Q} \subseteq \mathbb{Q}(x)$ is hit by $\frac{1}{2} \in \mathrm{Frac}(\mathbb{Z}[x])$, confirming surjectivity.
Solution.

Worked Example 7.5.13 (Recognizing a fraction ring: a subring of $\mathbb{Q}$ from integers coprime to 6)**.** Let $D = \{n \in \mathbb{Z} : \gcd(n, 6) = 1\} = \{\pm 1, \pm 5, \pm 7, \pm 11, \dots\}$ (integers coprime to 6). Show D is multiplicatively closed and describe $D^{-1}\mathbb{Z}$.

Recognition. D is closed under multiplication (coprimality to 6 is multiplicative) and is zero-divisor-free in the domain $\mathbb{Z}$, so $D^{-1}\mathbb{Z}$ is the subring of $\mathbb{Q}$ where we invert exactly the integers coprime to 6.

Solution. If $\gcd(m, 6) = \gcd(n, 6) = 1$ then $\gcd(mn, 6) = 1$, and $1 \in D$, $0 \notin D$; so D is multiplicatively closed with no zero divisors. Then

$$D^{-1}\mathbb{Z} = \left\{ \tfrac{a}{b} \in \mathbb{Q} : a \in \mathbb{Z},\ \gcd(b, 6) = 1 \right\},$$

the subring of $\mathbb{Q}$ of fractions whose reduced denominator is coprime to 6, equivalently divisible only by primes $\neq 2, 3$. The units we created are all $\pm$ integers coprime to 6; 2 and 3 are *not* inverted, so this is not a field.
Check. $\frac{1}{5} \in D^{-1}\mathbb{Z}$ and $5 \cdot \frac{1}{5} = 1$, but $\frac{1}{2} \notin D^{-1}\mathbb{Z}$ since 2 is not coprime to 6; thus 2 stays a non-unit, consistent with D excluding multiples of 2.
Solution.

Remark 7.5.2 (The construction as a universal arrow). Theorem 7.5.6 says $\iota\colon R \to \mathrm{Frac}(R)$ is the *initial* object among ring homomorphisms from R to fields that are injective: every such f factors uniquely through ι. This is the same shape of statement as the First Isomorphism Theorem triangle and the universal property of $R[x]$; recognizing the pattern

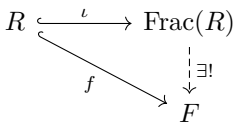


Diagram explanation. Objects: R is an integral domain (upper left). $\mathrm{Frac}(R)$ is the field of fractions of R (upper right). F is any field that receives an injective ring hom from R (lower right). This remark strips the theorem down to its categorical skeleton.

Arrows: $\iota\colon R \to \mathrm{Frac}(R)$ is the embedding $r \mapsto r/1$. $f\colon R \to F$ is the given injective ring hom (or more generally any ring hom sending nonzero elements to units). The dashed arrow $\exists!\colon \mathrm{Frac}(R) \to F$ is the unique extension, given by $a/b \mapsto f(a)f(b)^{-1}$; its uniqueness is signaled by the exclamation mark.

What commutes: The triangle commutes: $(\exists!) \circ \iota = f$. Spelling it out: for every $r \in R$, the unique extension evaluated at $r/1$ returns $f(r)$.

Why it commutes: The formula $a/b \mapsto f(a)f(b)^{-1}$ is forced: $\iota(r) = r/1$ must map to $f(r)$ to agree with f; writing $a/b = (a/1)(1/b)$ and $1/b = \iota(b)^{-1}$ in $\mathrm{Frac}(R)$, any ring hom must send $1/b$ to $f(b)^{-1}$. So the formula is the *only* candidate, and one checks (as in the proof) that it is indeed well defined and a homomorphism.

Why this matters here: The remark reframes the theorem as a universal property of the same categorical shape as the First Isomorphism Theorem triangle and the universal property of polynomial rings. Recognizing this shape immediately tells you: (a) the extension exists, (b) it is unique, and (c) it is given by the explicit formula. No computation is needed once you see the triangle.

Concrete example: $R = \mathbb{Q}[x]$, $\mathrm{Frac}(R) = \mathbb{Q}(x)$, $F = \mathbb{R}(t)$ (rational functions in t with real coefficients), f the injective map $p(x) \mapsto p(t)$. The unique extension sends $p(x)/q(x)$ to the rational function $p(t)/q(t) \in \mathbb{R}(t)$.

Common pitfall: The "$\exists!$" on the dashed arrow refers to uniqueness *among ring homs extending* f, not uniqueness of ring homs from $\mathrm{Frac}(R)$ to F in general. There can be many ring homs $\mathrm{Frac}(R) \to F$; the universal property pins down the one that makes the triangle commute.

Takeaway: The point of this diagram is that knowing only the triangle shape and the uniqueness label is enough to reconstruct the extension formula $a/b \mapsto f(a)f(b)^{-1}$ and to recognize $\mathrm{Frac}(R)$ as an initial object in the category of fields receiving R.

is the fastest way to remember that the extension exists, is unique, and is given by $a/b \mapsto f(a)f(b)^{-1}$.

Exercises (from the text).

1. Fill in all the details in the proof of Theorem 15.
2. Let R be an integral domain and let D be a nonempty subset of R that does not contain 0 and is closed under multiplication. Prove that the ring of fractions $D^{-1}R$ is isomorphic to a subring of the quotient field of R (hence is also an integral domain).
3. Let F be a field. Prove that F contains a unique smallest subfield F_0 and that F_0 is isomorphic to either $\mathbb{Q}$ or $\mathbb{Z}/p\mathbb{Z}$ for some prime p (F_0 is called the *prime subfield* of F). [See Exercise 26, Section 3.]
4. Prove that any subfield of $\mathbb{R}$ must contain $\mathbb{Q}$.
5. If F is a field, prove that the field of fractions of $F[[x]]$ (the ring of formal power series in the indeterminate x with coefficients in F) is the ring $F((x))$ of formal Laurent series (cf. Exercises 3 and 5 of Section 2). Show the field of fractions of the power series ring $\mathbb{Z}[[x]]$ is *properly* contained in the field of Laurent series $\mathbb{Q}((x))$. [Consider the series for e^x.]
6. Prove that the real numbers, $\mathbb{R}$, contain a subring A with $1 \in A$ and A maximal (under inclusion) with respect to the property that $\frac{1}{2} \notin A$. [Use Zorn's Lemma.] (Exercise 13 in Section 15.3 shows $\mathbb{R}$ is the quotient field of A, so $\mathbb{R}$ is the quotient field of a proper subring.)

Practice problems.

1. Let R be a commutative ring with $1 \neq 0$ and let D be a nonempty multiplicatively closed subset of R with $0 \notin D$ and $1 \in D$. Recall $D^{-1}R$ consists of equivalence classes $\frac{r}{d}$ under $\frac{r}{d} \sim \frac{r'}{d'} \iff s(rd' - r'd) = 0$ for some $s \in D$. Verify directly that addition $\frac{a}{b} + \frac{c}{d} = \frac{ad+bc}{bd}$ is well defined (independent of representatives).
2. In $D^{-1}R$ above, verify that multiplication $\frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd}$ is well defined and that $\frac{0}{1}$ and $\frac{1}{1}$ are the additive and multiplicative identities.
3. Let $R = \mathbb{Z}$ and $D = \{1, 2, 4, 8, \dots\} = \{2^k : k \geq 0\}$. Show D is multiplicatively closed, describe the elements of $D^{-1}\mathbb{Z}$ explicitly as a subring of $\mathbb{Q}$, and find $(D^{-1}\mathbb{Z})^\times$.
4. Let $R = \mathbb{Z}$ and let $P = (5)$, so $D = \mathbb{Z} \setminus P = \{n \in \mathbb{Z} : 5 \nmid n\}$. Show D is multiplicatively closed and that $D^{-1}\mathbb{Z} = \mathbb{Z}_{(5)} = \{\frac{a}{b} \in \mathbb{Q} : 5 \nmid b\}$. Identify the units and the unique maximal ideal of $\mathbb{Z}_{(5)}$.
5. Let R be an integral domain. Prove that the map $\iota : R \to \mathrm{Frac}(R)$, $r \mapsto \frac{r}{1}$, is an injective ring homomorphism, and that every nonzero element of $\mathrm{Frac}(R)$ has the form $\frac{a}{b}$ with $a, b \in R$, $b \neq 0$.
6. Compute $\mathrm{Frac}(R)$ for each: (a) $R = \mathbb{Z}$; (b) $R = \mathbb{F}[x]$ with $\mathbb{F}$ a field; (c) $R = \mathbb{Z}[i]$ (the Gaussian integers); (d) $R = \mathbb{Z}[x]$.
7. Let $D = \{1, 3, 9, 27, \dots\} \subseteq \mathbb{Z}$. In $D^{-1}\mathbb{Z}$, write $\frac{2}{9} + \frac{5}{3}$ and $\frac{2}{9} \cdot \frac{5}{3}$ as single fractions in lowest terms.
8. Let R be a commutative ring, D multiplicatively closed with $0 \notin D$. Prove that the kernel of the canonical map $\iota : R \to D^{-1}R$, $r \mapsto \frac{r}{1}$, equals $\{r \in R : dr = 0 \text{ for some } d \in D\}$. Deduce ι is injective iff D contains no zero divisor of R.
9. Let D be a multiplicatively closed subset of the commutative ring R with $0 \in D$. Prove that $D^{-1}R$ is the zero ring (i.e. $\frac{1}{1} = \frac{0}{1}$).

10. Let $R = \mathbb{Z}/6\mathbb{Z}$ and $D = \{1, 2, 4\}$ (the powers of 2 mod 6, where 2^k cycles through $\{2, 4, 2, 4, \dots\}$ and $2^0 = 1$). Show D is multiplicatively closed, determine $\ker \iota$, and identify the ring $D^{-1}R$ (it is isomorphic to a familiar ring).

11. Let R be an integral domain with field of fractions $F = \mathrm{Frac}(R)$. Show that any field K containing (an isomorphic copy of) R contains an isomorphic copy of F. In particular $\mathrm{Frac}(R)$ is the smallest field containing R.

12. Let D be multiplicatively closed in the commutative ring R, with $0 \notin D$. Show that for $\frac{a}{b} \in D^{-1}R$, we have $\frac{a}{b} = 0$ iff $sa = 0$ for some $s \in D$.

13. Suppose R is a commutative ring and $f \in R$ is not nilpotent. Let $D = \{1, f, f^2, f^3, \dots\}$. Show $0 \notin D$, so $D^{-1}R$ (often written R_f) is a nonzero ring, and prove $\frac{f}{1}$ is a unit in R_f.

14. Let F be a field. Show that for any multiplicatively closed $D \subseteq F$ with $0 \notin D$, the natural map $F \to D^{-1}F$ is an isomorphism. (A field is already its own ring of fractions for every legal D.)

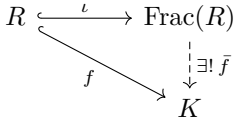
15. Let $R = \mathbb{Z}[i]$ and $D = \{1, (1+i), (1+i)^2, \dots\}$. Show $1 + i$ is not a zero divisor, so ι is injective, and exhibit the inverse of $\frac{1+i}{1}$ in $D^{-1}R$ as a fraction.

Additional exercises.

1. (Universal property.) Let R be commutative with D multiplicatively closed, $0 \notin D$. Let S be any commutative ring and $\varphi : R \to S$ a ring homomorphism with $\varphi(d) \in S^\times$ for all $d \in D$. Prove there is a unique ring homomorphism $\Phi : D^{-1}R \to S$ with $\Phi \circ \iota = \varphi$, given by $\Phi(\frac{r}{d}) = \varphi(r)\varphi(d)^{-1}$. Verify Φ is well defined.

2. Let R be an integral domain and D a multiplicatively closed subset with $0 \notin D$. Prove that $D^{-1}R$ is also an integral domain, and that $\mathrm{Frac}(D^{-1}R) \cong \mathrm{Frac}(R)$.

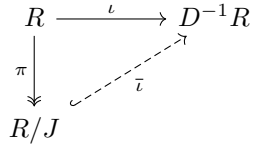
3. (Localization commutes with quotients.) Let R be commutative, D multiplicatively closed with $0 \notin D$, and I an ideal of R with $I \cap D = \varnothing$. Let $\bar{D}$ be the image of D in R/I. Prove $D^{-1}R/(D^{-1}I) \cong \bar{D}^{-1}(R/I)$, where $D^{-1}I = \{\frac{a}{d} : a \in I,\, d \in D\}$ is an ideal of $D^{-1}R$.



4. Let R be a commutative ring and P a prime ideal. Set $D = R \setminus P$. Show D is multiplicatively closed and $0 \notin D$, so the localization $R_P := D^{-1}R$ exists. Prove R_P is a local ring whose unique maximal ideal is $P_P = \{\frac{a}{d} : a \in P,\, d \notin P\}$, and that $R_P/P_P \cong \mathrm{Frac}(R/P)$.

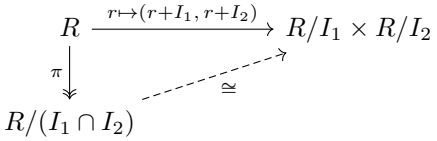
5. Let R be a commutative ring. Prove that the set of zero divisors together with 0 is a union of prime ideals, and using the multiplicative set D of non–zero-divisors, describe the "total ring of fractions" $D^{-1}R$. Show that when R is an integral domain this recovers $\mathrm{Frac}(R)$.

6. Let R be a PID and $0 \neq p \in R$ a prime element. Describe $R_{(p)}^\times$ and show $R_{(p)}$ is a discrete valuation ring: every nonzero element has the form up^n with $u \in R_{(p)}^\times$ and $n \geq 0$, and the ideals of $R_{(p)}$ are exactly (p^n) for $n \geq 0$ together with (0).

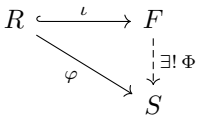


Commutative-diagram exercises.

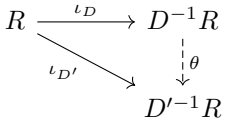
1. (Universal property of fractions.) Let R be an integral domain with fraction field $F = \mathrm{Frac}(R)$ and embedding $\iota : R \to F$. Let $f : R \to K$ be an injective ring homomorphism into a field K. Prove there is a unique ring homomorphism $\bar{f}$ making the diagram commute, and show $\bar{f}$ is injective.



2. Let R be commutative, D multiplicatively closed with $0 \notin D$, and $\iota : R \to D^{-1}R$ the canonical map with $J = \ker \iota = \{r : dr = 0 \text{ for some } d \in D\}$. Show ι factors through R/J and that the induced map is



injective, giving the diagram below (a fractions version of the First Isomorphism Theorem). Identify the dashed arrow explicitly.



3. (CRT as an isomorphism.) Let R be a commutative ring with ideals I_1, I_2 satisfying $I_1 + I_2 = R$. Prove that the dashed map below, induced by $\varphi\colon r \mapsto (r + I_1,\, r + I_2)$, is a ring isomorphism, and identify $\ker\varphi$ as $I_1 \cap I_2 = I_1 I_2$.

4. (Universal property of fractions for R-algebras.) Let R be an integral domain with $F = \mathrm{Frac}(R)$ and let S be a commutative R-algebra via $\varphi : R \to S$ in which every nonzero element of R maps to a unit. Using the universal property of fractions, complete the diagram with a unique R-algebra map Φ, and state precisely the condition on φ that makes Φ exist.

5. Let R be a commutative ring and $D \subseteq D'$ two multiplicatively closed subsets with $0 \notin D'$. Show the canonical maps fit into a commutative triangle and that there is a unique ring homomorphism $\theta : D^{-1}R \to D'^{-1}R$ filling it in. Give θ on a fraction $\frac{r}{d}$.

7.6 The Chinese Remainder Theorem

Comaximal ideals and the Chinese remainder theorem

Throughout, R is a commutative ring with $1 \neq 0$ (D&F's standing assumption for this section). We study how a single ring can be decomposed as a direct product of smaller quotient rings, generalizing the classical fact that arithmetic modulo mn splits into arithmetic modulo m and modulo n when $\gcd(m, n) = 1$.

Definition 7.6.1 (Product of ideals; comaximal ideals)**.** Let $I, J \subseteq R$ be ideals. Their *product* IJ is the ideal generated by all products ab with $a \in I$, $b \in J$:

$$IJ \;=\; \langle\, ab \mid a \in I,\ b \in J \,\rangle \;=\; \Big\{ \textstyle\sum_{k=1}^{n} a_k b_k \mid n \geq 0,\ a_k \in I,\ b_k \in J \Big\}.$$

The ideals I and J are *comaximal* (D&F's term) if

$$I + J \;=\; R.$$

A finite family $I_1, \ldots, I_k$ is *pairwise comaximal* if $I_i + I_j = R$ whenever $i \neq j$.

Remark 7.6.1. Comaximal means: no proper ideal (in particular no maximal ideal) contains both I and J. Equivalently, $I + J = R$ iff $1 \in I + J$ iff there exist $a \in I$, $b \in J$ with $a + b = 1$. In $\mathbb{Z}$, where every ideal is $\langle n \rangle = n\mathbb{Z}$, we have $m\mathbb{Z} + n\mathbb{Z} = \gcd(m, n)\mathbb{Z}$, so $m\mathbb{Z}$ and $n\mathbb{Z}$ are comaximal exactly when $\gcd(m, n) = 1$. Always $IJ \subseteq I \cap J$ (each generator $ab \in I$ and $ab \in J$); comaximality forces equality (Theorem 7.6.2), but it is not necessary for it: $(x) \cap (y) = (xy) = (x)(y)$ in $\mathbb{Q}[x, y]$, although $(x) + (y) = (x, y) \neq \mathbb{Q}[x, y]$.

Theorem 7.6.2 (Chinese Remainder Theorem, D&F 7.6 Thm. 17)**.** *Let $I_1, \ldots, I_k$ be ideals of R. The map*

$$\varphi \colon R \longrightarrow R/I_1 \times R/I_2 \times \cdots \times R/I_k, \qquad \varphi(r) = \big(r + I_1,\ r + I_2,\ \ldots,\ r + I_k\big),$$

is a ring homomorphism with kernel $I_1 \cap I_2 \cap \cdots \cap I_k$. If for each $i \neq j$ the ideals I_i and I_j are comaximal, then φ is surjective*, and*

$$I_1 \cap I_2 \cap \cdots \cap I_k \ = \ I_1 I_2 \cdots I_k,$$

so that φ induces a ring isomorphism

$$R/(I_1 I_2 \cdots I_k) \ = \ R/(I_1 \cap \cdots \cap I_k) \ \cong \ R/I_1 \times R/I_2 \times \cdots \times R/I_k.$$

Proof. Homomorphism and kernel. Each coordinate $r \mapsto r + I_j$ is the canonical projection $R \to R/I_j$, a ring homomorphism; a map into a product is a homomorphism iff each coordinate is, so φ is a ring homomorphism. Now $\varphi(r) = 0$ means $r + I_j = I_j$, i.e. $r \in I_j$, for every j; hence $\ker \varphi = I_1 \cap \cdots \cap I_k$.

Surjectivity (case $k = 2$). Suppose $I_1 + I_2 = R$. Choose $x \in I_1$, $y \in I_2$ with $x + y = 1$. Then

$$\varphi(y) = (y + I_1,\ y + I_2) = (1 + I_1,\ 0 + I_2) = (\overline{1}, \overline{0}),$$

since $y = 1 - x \equiv 1 \pmod{I_1}$ and $y \in I_2$. Symmetrically $\varphi(x) = (\overline{0}, \overline{1})$. For an arbitrary target $(a + I_1,\ b + I_2)$ set $r = bx + ay$; then $r \equiv b \cdot 0 + a \cdot 1 = a \pmod{I_1}$ and $r \equiv b \cdot 1 + a \cdot 0 = b \pmod{I_2}$, so $\varphi(r) = (a + I_1, b + I_2)$. Thus φ is onto.

Intersection equals product (case $k = 2$). Always $I_1 I_2 \subseteq I_1 \cap I_2$. Conversely take $c \in I_1 \cap I_2$. With $x + y = 1$ as above,

$$c = c \cdot 1 = c(x + y) = \underbrace{cx}_{\in I_1 I_2} + \underbrace{cy}_{\in I_1 I_2},$$

because $c \in I_2,\ x \in I_1 \Rightarrow cx \in I_2 I_1 = I_1 I_2$ and $c \in I_1,\ y \in I_2 \Rightarrow cy \in I_1 I_2$. Hence $I_1 \cap I_2 \subseteq I_1 I_2$, giving equality. Combined with the First Isomorphism Theorem applied to the surjection φ, we get $R/(I_1 \cap I_2) = R/(I_1 I_2) \cong R/I_1 \times R/I_2$.

Induction to general k. Suppose $I_1, \ldots, I_k$ are pairwise comaximal. We first show I_1 is comaximal with $J := I_2 \cdots I_k$. For each $j \geq 2$ pick $a_j \in I_1$, $b_j \in I_j$ with $a_j + b_j = 1$. Then

$$1 = \prod_{j=2}^{k} (a_j + b_j) = \underbrace{(\text{terms with some } a_j)}_{\in I_1} + b_2 b_3 \cdots b_k,$$

and $b_2 \cdots b_k \in I_2 \cdots I_k = J$. Thus $1 \in I_1 + J$, so $I_1 + J = R$. By the $k = 2$ case, $I_1 \cap J = I_1 J$ and $R/(I_1 \cap J) \cong R/I_1 \times R/J$. By induction $J = I_2 \cdots I_k = I_2 \cap \cdots \cap I_k$ and $R/J \cong R/I_2 \times \cdots \times R/I_k$. Composing,

$$I_1 \cap \cdots \cap I_k = I_1 \cap J = I_1 J = I_1 I_2 \cdots I_k,$$

and $R/(I_1 \cdots I_k) \cong R/I_1 \times (R/I_2 \times \cdots \times R/I_k)$, as claimed. □

The structural picture is the factorization of φ through the quotient by the kernel (First Isomorphism Theorem): writing π for the quotient map $R \to R/(I_1 \cap I_2)$, there is a unique $\overline{\varphi}$ with $\varphi = \overline{\varphi} \circ \pi$, and under comaximality $\overline{\varphi}$ is an isomorphism.

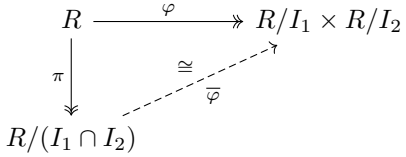


Diagram explanation. Objects: Three rings arranged in a triangle. The top-left vertex is R itself (the ambient commutative ring with 1). The top-right vertex is the product ring $R/I_1 \times R/I_2$ (pairs of cosets, with coordinate-wise addition and multiplication). The bottom vertex is the quotient ring $R/(I_1 \cap I_2)$, which equals $R/(I_1 I_2)$ under comaximality.

Arrows: $\varphi\colon R \to R/I_1 \times R/I_2$, $r \mapsto (r+I_1, r+I_2)$, is the simultaneous-reduction map (a ring homomorphism whose kernel is $I_1 \cap I_2$; it is onto when $I_1 + I_2 = R$, the case drawn here). $\pi\colon R \twoheadrightarrow R/(I_1 \cap I_2)$ (double-headed arrow) is the canonical surjective quotient map, $r \mapsto r+(I_1 \cap I_2)$. $\overline{\varphi}\colon R/(I_1 \cap I_2) \to R/I_1 \times R/I_2$ (dashed arrow) is the induced map guaranteed by the First Isomorphism Theorem; it satisfies $\overline{\varphi}(r+(I_1 \cap I_2)) = (r+I_1, r+I_2)$.

What commutes: The triangle commutes: $\varphi = \overline{\varphi} \circ \pi$. That is, going directly across the top (apply φ) gives the same result as going down then diagonally up (apply π then $\overline{\varphi}$).

Why it commutes: Take any $r \in R$. Along the top: $r \mapsto (r+I_1, r+I_2)$. Along the bottom path: $r \overset{\pi}{\mapsto} r+(I_1 \cap I_2) \overset{\overline{\varphi}}{\mapsto} (r+I_1, r+I_2)$. These agree by definition of $\overline{\varphi}$. Well-definedness of $\overline{\varphi}$: if $r+(I_1 \cap I_2) = r'+(I_1 \cap I_2)$ then $r - r' \in I_1 \cap I_2$, so $r - r' \in I_1$ and $r - r' \in I_2$, giving $(r+I_1, r+I_2) = (r'+I_1, r'+I_2)$; hence $\overline{\varphi}$ does not depend on the choice of coset representative.

Why this matters here: This diagram records the First Isomorphism Theorem step in the proof of CRT. The text has just established that $\ker\varphi = I_1 \cap I_2$; the diagram makes visible that φ factors through the quotient by its own kernel, and that under comaximality the dashed arrow $\overline{\varphi}$ upgrades to an isomorphism (marked $\cong$). Without seeing this factorization, the isomorphism $R/(I_1 \cap I_2) \cong R/I_1 \times R/I_2$ can look unmotivated.

Concrete example: Take $R = \mathbb{Z}$, $I_1 = 3\mathbb{Z}$, $I_2 = 4\mathbb{Z}$. Then $\varphi(r) = (r \bmod 3, r \bmod 4)$, $\pi(r) = r \bmod 12$, and $\overline{\varphi}(\bar{r}) = (r \bmod 3, r \bmod 4)$. For $r = 5$: top path gives $(2,1)$; bottom path gives $5 \bmod 12 = 5$, then $\overline{\varphi}(5) = (2,1)$. Both agree.

Common pitfall: Students often read the dashed $\overline{\varphi}$ as automatically existing and being an isomorphism for any ideals. In fact the FIT gives the *injection* $\overline{\varphi}$ for free (since $\ker\pi = I_1 \cap I_2 = \ker\varphi$); surjectivity – and hence the $\cong$ label – requires the separate comaximality argument. The dashed arrow signals "existence guaranteed by a universal property," not that it is automatically onto.

Takeaway: The point of this diagram is that the CRT isomorphism is simply the First Isomorphism Theorem applied to φ, with comaximality supplying the surjectivity that turns the canonical injection $\overline{\varphi}$ into a full ring isomorphism.

And the clean comaximal statement, with the two natural coordinate projections of the product displayed:

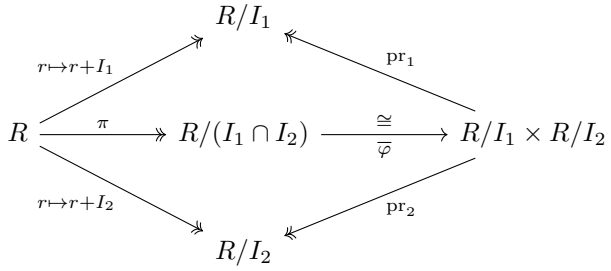

Diagram explanation. Objects: Five rings in a "bowtie" arrangement. On the far left, R is the ambient ring. In the center, $R/(I_1 \cap I_2)$ is the quotient by the intersection (equal to the product ideal $I_1 I_2$ under comaximality). On the far right, $R/I_1 \times R/I_2$ is the direct product. Directly above and below the center, R/I_1 (top) and R/I_2 (bottom) are the individual quotient rings (fields if I_1, I_2 are maximal).

Arrows: $\pi\colon R \twoheadrightarrow R/(I_1 \cap I_2)$ is the canonical surjective quotient map. $r \mapsto r + I_1$ (upper diagonal from R) and $r \mapsto r + I_2$ (lower diagonal from R) are the two individual canonical projections, each a surjective ring homomorphism. $\overline{\varphi}\colon R/(I_1 \cap I_2) \xrightarrow{\cong} R/I_1 \times R/I_2$ is the CRT isomorphism induced from φ. $\mathrm{pr}_1\colon R/I_1 \times R/I_2 \to R/I_1$ and $\mathrm{pr}_2\colon R/I_1 \times R/I_2 \to R/I_2$ are the coordinate projection maps of the product ring.

What commutes: The two paths from R to R/I_1 agree: the direct arrow $(r \mapsto r + I_1)$ and $\mathrm{pr}_1 \circ \overline{\varphi} \circ \pi$, which is $\mathrm{pr}_1 \circ \varphi$ since $\varphi = \overline{\varphi} \circ \pi$. Likewise the two paths to R/I_2 agree. Concisely: $\mathrm{pr}_1 \circ \overline{\varphi} \circ \pi = (r \mapsto r + I_1)$ and $\mathrm{pr}_2 \circ \overline{\varphi} \circ \pi = (r \mapsto r + I_2)$.

Why it commutes: Take $r \in R$. Path to R/I_1 via center: $r \overset{\pi}{\mapsto} r + (I_1 \cap I_2) \overset{\overline{\varphi}}{\mapsto} (r + I_1, r + I_2) \overset{\mathrm{pr}_1}{\longmapsto} r + I_1$. Direct path: $r \mapsto r + I_1$. These are the same. The map $\overline{\varphi}$ out of the center ring $R/(I_1 \cap I_2)$ is well defined because its output depends only on the coset of r modulo $I_1 \cap I_2$: if $r \equiv r' \pmod{I_1 \cap I_2}$ then $r - r' \in I_j$ for each j, so both coordinates of $\overline{\varphi}$ are unchanged.

Why this matters here: This diagram upgrades the first (triangular) diagram by making the coordinate projections pr_j explicit and showing that the two direct maps $R \to R/I_j$ factor *both* through the center quotient and through the product. It gives a complete, symmetric picture of CRT: the product ring is universally characterized by having consistent maps to each R/I_j, and comaximality ensures the two incoming paths from R synchronize perfectly.

Concrete example: $R = \mathbb{Z}$, $I_1 = 5\mathbb{Z}$, $I_2 = 7\mathbb{Z}$. Center node: $\mathbb{Z}/35\mathbb{Z}$. The map $\overline{\varphi}(r \bmod 35) = (r \bmod 5, r \bmod 7)$ is an isomorphism. Take $r = 23$: $\overline{\varphi}(23 \bmod 35) = (3, 2)$; $\mathrm{pr}_1(3, 2) = 3 = 23 \bmod 5$ and $\mathrm{pr}_2(3, 2) = 2 = 23 \bmod 7$. Every arrow gives consistent output.

Common pitfall: The two diagonal arrows from R straight to R/I_1 and R/I_2 look like "shortcuts" that bypass the center. Students sometimes think those arrows make π and $\overline{\varphi}$ redundant. They are not: π and $\overline{\varphi}$ encode the *simultaneous* action (giving both coordinates at once via a single ring map), while the direct diagonals give only one coordinate each. The diagram shows compatibility, not redundancy.

Takeaway: The point of this diagram is that the CRT isomorphism $R/(I_1 \cap I_2) \cong R/I_1 \times R/I_2$ is the unique ring map making every path to each individual quotient R/I_j commute, so the product ring is not merely isomorphic to $R/(I_1 \cap I_2)$ but is in fact its universal factorization through comaximal quotients.

Method (Applying the Chinese Remainder Theorem)**.** *Recognition trigger.* You see a quotient R/N where the modulus N factors as a product (or intersection) of ideals — e.g. $\mathbb{Z}/n\mathbb{Z}$ with $n = p_1^{a_1} \cdots p_r^{a_r}$, $\mathbb{F}[x]/(f)$ with $f = f_1 \cdots f_r$ coprime — or you must solve simultaneous congruences $r \equiv a_j \pmod{I_j}$.

1. **Check comaximality pairwise.** Show $I_i + I_j = R$ for all $i \neq j$, i.e. exhibit $a_{ij} \in I_i,\ b_{ij} \in I_j$ with $a_{ij} + b_{ij} = 1$. In $\mathbb{Z}$: gcd of the moduli is 1. In $\mathbb{F}[x]$: the polynomials are pairwise coprime (run the Euclidean algorithm / Bézout).
2. **Conclude the splitting.** Comaximality $\Rightarrow I_1 \cap \cdots \cap I_k = I_1 \cdots I_k$ and $R/(I_1 \cdots I_k) \cong \prod_j R/I_j$.
3. **Build the inverse (to solve systems).** For each j form an "idempotent" e_j with $e_j \equiv 1 \pmod{I_j}$ and $e_j \equiv 0 \pmod{I_i}$ for $i \neq j$, using the Bézout coefficients. Then $r = \sum_j a_j e_j$ realizes the target $(a_1, \ldots, a_k)$.

Sanity check. Reduce your candidate r modulo each I_j and confirm you recover a_j; check the cardinalities multiply ($|R/N| = \prod |R/I_j|$) in the finite case.

Worked Example 7.6.3 ($\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ explicitly)**.** Exhibit the isomorphism $\mathbb{Z}/12\mathbb{Z} \xrightarrow{\sim} \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ and its inverse.

Recognition. Take $R = \mathbb{Z}$, $I_1 = 4\mathbb{Z}$, $I_2 = 3\mathbb{Z}$; since $\gcd(4, 3) = 1$ these are comaximal, and $4\mathbb{Z} \cap 3\mathbb{Z} = 4\mathbb{Z} \cdot 3\mathbb{Z} = 12\mathbb{Z}$, so Theorem 7.6.2 gives the iso $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$.

Solution. Comaximality / Bézout: $1 = \underbrace{(-2) \cdot 4}_{=-8} + \underbrace{3 \cdot 3}_{=9}$, with $-8 \in 4\mathbb{Z}$ and $9 \in 3\mathbb{Z}$. So $x = -8 \equiv 4 \pmod{12}$ lies in $4\mathbb{Z}$ and $y = 9$ lies in $3\mathbb{Z}$, with $x + y = 1$.

Forward map $\varphi(a) = (a \bmod 4,\ a \bmod 3)$. The full table:

a	$(a \bmod 4,\ a \bmod 3)$	a	$(a \bmod 4,\ a \bmod 3)$
0	$(0, 0)$	6	$(2, 0)$
1	$(1, 1)$	7	$(3, 1)$
2	$(2, 2)$	8	$(0, 2)$
3	$(3, 0)$	9	$(1, 0)$
4	$(0, 1)$	10	$(2, 1)$
5	$(1, 2)$	11	$(3, 2)$

All 12 pairs in $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ appear exactly once, confirming the bijection.

Inverse via idempotents. We need $e_1 \equiv (1,0)$ and $e_2 \equiv (0,1)$. From $x + y = 1$ with $y = 9 \in 3\mathbb{Z}$, $y \equiv 1 \pmod 4$, so $e_1 = 9$ gives $\varphi(9) = (9 \bmod 4, 9 \bmod 3) = (1,0)$. And $x = 4$ (the residue of $-8 \bmod 12$) gives $\varphi(4) = (0,1)$, so $e_2 = 4$. Hence the inverse of $(u,v) \in \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ is

$$\psi(u,v) = 9u + 4v \pmod{12}.$$

Check. $\psi(3,2) = 27 + 8 = 35 \equiv 11 \pmod{12}$, and indeed $\varphi(11) = (3,2)$. Cardinalities: $|\mathbb{Z}/12\mathbb{Z}| = 12 = 4 \cdot 3$. ■

Worked Example 7.6.4 (Solving a system of congruences)**.** Find all integers x with $x \equiv 2 \pmod 3$, $x \equiv 3 \pmod 5$, $x \equiv 2 \pmod 7$.

Recognition. This is the surjectivity half of Theorem 7.6.2 in $R = \mathbb{Z}$ with $I_1 = 3\mathbb{Z}, I_2 = 5\mathbb{Z}, I_3 = 7\mathbb{Z}$. Pairwise gcd's are 1, so $\varphi\colon \mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/7\mathbb{Z}$ is onto with kernel $3 \cdot 5 \cdot 7\,\mathbb{Z} = 105\mathbb{Z}$; the solution set is a single residue class mod 105.

Solution. Let $N = 105$, $N_1 = N/3 = 35$, $N_2 = N/5 = 21$, $N_3 = N/7 = 15$.

Invert each N_j modulo its prime. $35 \equiv 2 \pmod 3$, and $2 \cdot 2 = 4 \equiv 1$, so $N_1^{-1} \equiv 2 \pmod 3$. $21 \equiv 1 \pmod 5$, so $N_2^{-1} \equiv 1 \pmod 5$. $15 \equiv 1 \pmod 7$, so $N_3^{-1} \equiv 1 \pmod 7$.

Assemble.

$$x \equiv a_1 N_1 (N_1^{-1}) + a_2 N_2 (N_2^{-1}) + a_3 N_3 (N_3^{-1}) = 2 \cdot 35 \cdot 2 + 3 \cdot 21 \cdot 1 + 2 \cdot 15 \cdot 1.$$

Compute: $2 \cdot 35 \cdot 2 = 140$, $3 \cdot 21 = 63$, $2 \cdot 15 = 30$; sum $= 140 + 63 + 30 = 233$. Reduce: $233 - 105 = 128$, $128 - 105 = 23$, so $x \equiv 23 \pmod{105}$.

Check. $23 = 3 \cdot 7 + 2 \Rightarrow 23 \equiv 2 \pmod 3$; $23 = 5 \cdot 4 + 3 \Rightarrow 23 \equiv 3 \pmod 5$; $23 = 7 \cdot 3 + 2 \Rightarrow 23 \equiv 2 \pmod 7$. All three hold. ■The full solution set is $\{23 + 105k \mid k \in \mathbb{Z}\}$.

Worked Example 7.6.5 (Decomposing $(\mathbb{Z}/n\mathbb{Z})^\times$ and recomputing $\varphi(n)$)**.** For $n = 360$, use CRT to decompose $(\mathbb{Z}/360\mathbb{Z})^\times$ and recover Euler's totient $\varphi(360)$.

Recognition. The ring iso $\mathbb{Z}/n\mathbb{Z} \cong \prod_i \mathbb{Z}/p_i^{a_i}\mathbb{Z}$ restricts to its units, giving $(\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_i (\mathbb{Z}/p_i^{a_i}\mathbb{Z})^\times$, because a unit in a product is a tuple of units. Then $\varphi(n) = \prod_i \varphi(p_i^{a_i})$.

Solution. Factor $360 = 2^3 \cdot 3^2 \cdot 5 = 8 \cdot 9 \cdot 5$. The three prime-power factors $8, 9, 5$ are pairwise coprime, so $8\mathbb{Z}, 9\mathbb{Z}, 5\mathbb{Z}$ are pairwise comaximal in $\mathbb{Z}$ and

$$\mathbb{Z}/360\mathbb{Z} \;\cong\; \mathbb{Z}/8\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}.$$

Passing to units (a ring iso carries units to units, multiplicatively),

$$(\mathbb{Z}/360\mathbb{Z})^\times \;\cong\; (\mathbb{Z}/8\mathbb{Z})^\times \times (\mathbb{Z}/9\mathbb{Z})^\times \times (\mathbb{Z}/5\mathbb{Z})^\times.$$

Counting orders: $\varphi(8) = 8(1 - \frac{1}{2}) = 4$, $\varphi(9) = 9(1 - \frac{1}{3}) = 6$, $\varphi(5) = 5 - 1 = 4$. Hence

$$\varphi(360) = \varphi(8)\,\varphi(9)\,\varphi(5) = 4 \cdot 6 \cdot 4 = 96.$$

Check (direct totient formula). $\varphi(360) = 360\big(1 - \frac{1}{2}\big)\big(1 - \frac{1}{3}\big)\big(1 - \frac{1}{5}\big) = 360 \cdot \frac{1}{2} \cdot \frac{2}{3} \cdot \frac{4}{5} = 360 \cdot \frac{8}{30} = 96$. ■The decomposition also shows $(\mathbb{Z}/360\mathbb{Z})^\times \cong (\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}) \times (\mathbb{Z}/6\mathbb{Z}) \times (\mathbb{Z}/4\mathbb{Z})$ as abelian groups (since $(\mathbb{Z}/8\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$), confirming order $4 \cdot 6 \cdot 4 = 96$.

Worked Example 7.6.6 (A non-comaximal example: surjectivity fails)**.** Let $R = \mathbb{Z}$, $I_1 = 2\mathbb{Z}$, $I_2 = 4\mathbb{Z}$. Show the CRT map $\varphi\colon \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$ is *not* surjective, and that $I_1 \cap I_2 \neq I_1 I_2$.

Recognition. Here $I_1 + I_2 = 2\mathbb{Z} + 4\mathbb{Z} = \gcd(2,4)\mathbb{Z} = 2\mathbb{Z} \neq \mathbb{Z}$, so I_1, I_2 are *not* comaximal. The hypothesis of Theorem 7.6.2 fails, and we expect both conclusions (surjectivity and $\cap =$ product) to break.

Solution. Kernel and image. $\ker\varphi = 2\mathbb{Z} \cap 4\mathbb{Z} = 4\mathbb{Z}$, so φ factors as an *injection* $\mathbb{Z}/4\mathbb{Z} \hookrightarrow \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$. But $|\mathbb{Z}/4\mathbb{Z}| = 4$ while $|\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}| = 8$, so φ cannot be onto.

A missed target. Consider $(1 + 2\mathbb{Z},\ 0 + 4\mathbb{Z})$. If $\varphi(r)$ equaled this, then $r \equiv 0 \pmod 4$, forcing $r \equiv 0 \pmod 2$ (as $4 \mid r \Rightarrow 2 \mid r$); but the first coordinate demands $r \equiv 1 \pmod 2$ — contradiction. So $(\overline{1}, \overline{0})$ is not in the image.

Intersection vs. product. $I_1 \cap I_2 = 2\mathbb{Z} \cap 4\mathbb{Z} = 4\mathbb{Z}$, whereas $I_1 I_2 = (2\mathbb{Z})(4\mathbb{Z}) = 8\mathbb{Z}$. Since $4\mathbb{Z} \neq 8\mathbb{Z}$, indeed $I_1 \cap I_2 \supsetneq I_1 I_2$. *Check.* $4 \in 4\mathbb{Z} = I_1 \cap I_2$ but $4 \notin 8\mathbb{Z} = I_1 I_2$. ■The two coordinates carry overlapping (2-adic) information, which is exactly the obstruction comaximality removes.

Worked Example 7.6.7 (CRT in $\mathbb{F}[x]$ for coprime polynomials)**.** In $R = \mathbb{Q}[x]$ let $f = x - 1$, $g = x - 2$. Realize the isomorphism $\mathbb{Q}[x]/\big((x-1)(x-2)\big) \cong \mathbb{Q}[x]/(x-1) \times \mathbb{Q}[x]/(x-2) \cong \mathbb{Q} \times \mathbb{Q}$, and find the polynomial p of degree < 2 with $p \equiv 5 \pmod{(x-1)}$ and $p \equiv 9 \pmod{(x-2)}$.

Recognition. $\mathbb{Q}[x]$ is a PID; $(f) + (g) = (\gcd(f, g))$ and $\gcd(x - 1, x - 2) = 1$, so the ideals are comaximal. By Theorem 7.6.2, $\mathbb{Q}[x]/(fg) \cong \mathbb{Q}[x]/(f) \times \mathbb{Q}[x]/(g)$. Evaluation $p \mapsto p(1)$ identifies $\mathbb{Q}[x]/(x - 1) \cong \mathbb{Q}$ (and similarly at 2), turning "$p \bmod (x - c)$" into "$p(c)$".

Solution. Bézout. $(x - 1) - (x - 2) = 1$, so with $u = x - 1 \in (f)$ and $v = -(x - 2) = 2 - x \in (g)$ we have $u + v = 1$. Then $v = 2 - x \equiv 1 \pmod{(x-1)}$ (value 1 at $x = 1$) and $v \equiv 0 \pmod{(x-2)}$; symmetrically $u = x - 1 \equiv 0 \pmod{(x-1)}$ and $\equiv 1 \pmod{(x-2)}$ (value 1 at $x = 2$). So the idempotents are

$$e_1 = 2 - x \ \text{ (the } (x-1)\text{-component)}, \qquad e_2 = x - 1 \ \text{ (the } (x-2)\text{-component)}.$$

Assemble. $p = 5\,e_1 + 9\,e_2 = 5(2 - x) + 9(x - 1) = 10 - 5x + 9x - 9 = 4x + 1$.

Check by evaluation: $p(1) = 4+1 = 5$ and $p(2) = 8+1 = 9$. ■Also $\deg p = 1 < 2 = \deg(fg)$, the canonical representative in $\mathbb{Q}[x]/(fg)$. The whole isomorphism reads $\overline{p} \mapsto (p(1), p(2))$, i.e. $\mathbb{Q}[x]/\big((x-1)(x-2)\big) \xrightarrow{\sim} \mathbb{Q} \times \mathbb{Q}$ by simultaneous evaluation.

Worked Example 7.6.8 (CRT over a finite field: $\mathbb{F}_2[x]/(x^2 + x)$)**.** Show $\mathbb{F}_2[x]/(x^2 + x) \cong \mathbb{F}_2 \times \mathbb{F}_2$ and identify the four elements concretely.

Recognition. Over $\mathbb{F}_2$, $x^2 + x = x(x + 1)$ with $\gcd(x, x + 1) = 1$ (Bézout: $(x + 1) - x = 1$). So (x) and $(x + 1)$ are comaximal in $\mathbb{F}_2[x]$, and CRT gives $\mathbb{F}_2[x]/(x(x + 1)) \cong \mathbb{F}_2[x]/(x) \times \mathbb{F}_2[x]/(x + 1) \cong \mathbb{F}_2 \times \mathbb{F}_2$.

Solution. Identify each factor. Evaluation at 0 gives $\mathbb{F}_2[x]/(x) \cong \mathbb{F}_2$, $p \mapsto p(0)$; evaluation at 1 gives $\mathbb{F}_2[x]/(x + 1) \cong \mathbb{F}_2$, $p \mapsto p(1)$. So the iso is $\overline{p} \mapsto (p(0), p(1))$.

Tabulate the 4 *classes* (representatives of degree < 2: $0, 1, x, x + 1$):

$\overline{p}$	$(p(0),\, p(1))$
0	$(0, 0)$
1	$(1, 1)$
x	$(0, 1)$
$x + 1$	$(1, 0)$

All four pairs of $\mathbb{F}_2 \times \mathbb{F}_2$ occur once — the map is a bijection, hence a ring iso. *Check (idempotents).* $e_1 = x + 1$ has $(p(0), p(1)) = (1, 0)$ and $e_2 = x$ has $(0, 1)$; indeed $e_1 + e_2 = 2x + 1 = 1$ in $\mathbb{F}_2[x]$ and $e_1 e_2 = x(x + 1) = x^2 + x \equiv 0$, the defining relation. ■So $\overline{x + 1}$ and $\overline{x}$ are complementary idempotents, the algebraic shadow of the product decomposition.

Worked Example 7.6.9 (Comaximality of distinct maximal ideals)**.** Let R be commutative with 1 and let $M_1 \neq M_2$ be maximal ideals. Show $M_1 + M_2 = R$, and deduce $R/(M_1 M_2) \cong R/M_1 \times R/M_2$ (a product of two fields).

Recognition. "Distinct maximal ideals" is the recognition cue for automatic comaximality: $M_1 + M_2$ is an ideal containing M_1 properly, and maximality of M_1 leaves only R.

Solution. Since $M_1 \neq M_2$ and both are maximal, neither contains the other; pick $m \in M_2 \setminus M_1$. Then $M_1 + \langle m \rangle \supsetneq M_1$, and as M_1 is maximal, $M_1 + \langle m \rangle = R$. But $M_1 + \langle m \rangle \subseteq M_1 + M_2$, so $M_1 + M_2 = R$: the ideals are comaximal. By Theorem 7.6.2,

$$M_1 \cap M_2 = M_1 M_2, \qquad R/(M_1 M_2) \cong R/M_1 \times R/M_2.$$

Each R/M_i is a field (quotient by a maximal ideal), so $R/(M_1 M_2)$ is a product of two fields.

Check (instance). $R = \mathbb{Z}$, $M_1 = 5\mathbb{Z}$, $M_2 = 7\mathbb{Z}$: $5\mathbb{Z} \cap 7\mathbb{Z} = 35\mathbb{Z} = 5\mathbb{Z} \cdot 7\mathbb{Z}$, and $\mathbb{Z}/35\mathbb{Z} \cong \mathbb{Z}/5\mathbb{Z} \times \mathbb{Z}/7\mathbb{Z} \cong \mathbb{F}_5 \times \mathbb{F}_7$, a product of two fields of sizes $5, 7$, total 35. ■

Caution. **Comaximality is required for surjectivity, and it is what guarantees $\cap =$ product — not merely a convenience.** Without it the kernel of φ is $\bigcap I_j$, which can strictly contain $\prod I_j$ (see the $2\mathbb{Z}, 4\mathbb{Z}$ example), and φ need not be onto. The First Isomorphism Theorem *always* gives the *injection* $R/\bigcap I_j \hookrightarrow \prod R/I_j$; surjectivity is the extra content of the CRT.

Caution. **Pairwise comaximal is genuinely needed for $k \geq 3$; "jointly $I_1 + \cdots + I_k = R$" is not enough.** For example in $\mathbb{Z}$ take $I_1 = 2\mathbb{Z}$, $I_2 = 2\mathbb{Z}$, $I_3 = 3\mathbb{Z}$: then $I_1 + I_2 + I_3 = \mathbb{Z}$, yet I_1, I_2 are not comaximal ($2\mathbb{Z} + 2\mathbb{Z} = 2\mathbb{Z}$), and $\mathbb{Z}/(I_1 \cap I_2 \cap I_3) = \mathbb{Z}/(2\mathbb{Z} \cap 3\mathbb{Z}) = \mathbb{Z}/6\mathbb{Z}$ has 6 elements while $\prod R/I_j$ has $2 \cdot 2 \cdot 3 = 12$ — no isomorphism. Always verify $I_i + I_j = R$ for *every* pair.

Caution. IJ **is the ideal generated by products, not the set of single products.** Elements of IJ are finite *sums* $\sum a_k b_k$. Writing "$IJ = \{ab \mid a \in I, b \in J\}$" is wrong in general (that set need not be closed under addition). For principal ideals in a commutative ring it does collapse: $\langle a \rangle \langle b \rangle = \langle ab \rangle$.

Remark 7.6.2 (Idempotents and the product structure). When $R \cong R_1 \times R_2$ the elements $e_1 = (1, 0)$ and $e_2 = (0, 1)$ are *orthogonal idempotents*: $e_i^2 = e_i$, $e_1 e_2 = 0$, $e_1 + e_2 = 1$. Conversely such a pair in any commutative ring R splits it as $R \cong Re_1 \times Re_2$. In the CRT setting the idempotents are exactly the Bézout-built elements e_j of the Method box (e.g. 9 and 4 in $\mathbb{Z}/12\mathbb{Z}$; $x + 1$ and x in $\mathbb{F}_2[x]/(x^2 + x)$). Thus "solve a congruence system" and "find the complementary idempotents" are the same computation.

Exercises (from the text).

1. Let R be a ring with identity $1 \neq 0$. An element $e \in R$ is called an *idempotent* if $e^2 = e$. Assume e is an idempotent in R and $er = re$ for all $r \in R$. Prove that Re and $R(1 - e)$ are two-sided ideals of R and that $R \cong Re \times R(1 - e)$. Show that e and $1 - e$ are identities for the subrings Re and $R(1 - e)$ respectively.

2. Let R be a finite Boolean ring with identity $1 \neq 0$ (cf. Exercise 15 of Section 1). Prove that $R \cong \mathbb{Z}/2\mathbb{Z} \times \cdots \times \mathbb{Z}/2\mathbb{Z}$. [Use the preceding exercise.]

3. Let R and S be rings with identities. Prove that every ideal of $R \times S$ is of the form $I \times J$ where I is an ideal of R and J is an ideal of S.

4. Prove that if R and S are nonzero rings then $R \times S$ is never a field.

5. Let $n_1, n_2, \ldots, n_k$ be integers which are relatively prime in pairs: $(n_i, n_j) = 1$ for all $i \neq j$.

   (a) Show that the Chinese Remainder Theorem implies that for any $a_1, \ldots, a_k \in \mathbb{Z}$ there is a solution $x \in \mathbb{Z}$ to the simultaneous congruences

   $$x \equiv a_1 \bmod n_1, \quad x \equiv a_2 \bmod n_2, \quad \ldots, \quad x \equiv a_k \bmod n_k$$

   and that the solution x is unique mod $n = n_1 n_2 \cdots n_k$.

   (b) Let $n_i' = n/n_i$ be the quotient of n by n_i, which is relatively prime to n_i by assumption. Let t_i be the inverse of n_i' mod n_i. Prove that the solution x in (a) is given by

   $$x = a_1 t_1 n_1' + a_2 t_2 n_2' + \cdots + a_k t_k n_k' \bmod n.$$

   Note that the elements t_i can be quickly found by the Euclidean Algorithm as described in Section 8.1 (writing $an_i + bn_i' = (n_i, n_i') = 1$ gives $t_i = b$) and that these then quickly give the solutions to the system of congruences above for any choice of $a_1, a_2, \ldots, a_k$.

   (c) Solve the simultaneous system of congruences

   $$x \equiv 1 \bmod 8, \quad x \equiv 2 \bmod 25, \quad \text{and} \quad x \equiv 3 \bmod 81$$

   and the simultaneous system

   $$y \equiv 5 \bmod 8, \quad y \equiv 12 \bmod 25, \quad \text{and} \quad y \equiv 47 \bmod 81.$$

6. Let $f_1(x), f_2(x), \ldots, f_k(x)$ be polynomials with integer coefficients of the same degree d. Let $n_1, n_2, \ldots, n_k$ be integers which are relatively prime in pairs (i.e., $(n_i, n_j) = 1$ for all $i \neq j$). Use the Chinese Remainder Theorem to prove there exists a polynomial $f(x)$ with integer coefficients and of degree d with

   $$f(x) \equiv f_1(x) \bmod n_1, \quad f(x) \equiv f_2(x) \bmod n_2, \quad \ldots, \quad f(x) \equiv f_k(x) \bmod n_k,$$

   i.e., the coefficients of $f(x)$ agree with the coefficients of $f_i(x)$ mod n_i. Show that if all the $f_i(x)$ are monic, then $f(x)$ may also be chosen monic. [Apply the Chinese Remainder Theorem in $\mathbb{Z}$ to each of the coefficients separately.]

7. Let m and n be positive integers with n dividing m. Prove that the natural surjective ring projection $\mathbb{Z}/m\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ is also surjective on the units: $(\mathbb{Z}/m\mathbb{Z})^\times \to (\mathbb{Z}/n\mathbb{Z})^\times$.

8. In the next four exercises I is a nonempty index set with a partial order $\leq$, and for each $i \in I$ let A_i be an additive abelian group; assume also that I is a *directed set*: for every $i, j \in I$ there is some $k \in I$ with $i \leq k$ and $j \leq k$. Suppose for every pair of indices i, j with $i \leq j$ there is a map $\rho_{ij} : A_i \to A_j$ such that the following hold:

   i. $\rho_{jk} \circ \rho_{ij} = \rho_{ik}$ whenever $i \leq j \leq k$, and

   ii. $\rho_{ii} = 1$ for all $i \in I$.

   Let B be the disjoint union of all the A_i. Define a relation $\sim$ on B by

   $$a \sim b \text{ if and only if there exists } k \text{ with } i \leq k,\ j \leq k \text{ and } \rho_{ik}(a) = \rho_{jk}(b),$$

   for $a \in A_i$ and $b \in A_j$.

   (a) Show that $\sim$ is an equivalence relation on B. (The set of equivalence classes is called the *direct* or *inductive limit* of the directed system $\{A_i\}$, and is denoted $\varinjlim A_i$. In the remaining parts of this exercise let $A = \varinjlim A_i$.)

   (b) Let $\overline{x}$ denote the class of x in A and define $\rho_i : A_i \to A$ by $\rho_i(a) = \overline{a}$. Show that if each ρ_{ij} is injective, then so is ρ_i for all i (so we may then identify each A_i as a subset of A).

   (c) Assume all ρ_{ij} are group homomorphisms. For $a \in A_i$, $b \in A_j$ show that the operation

   $$\overline{a} + \overline{b} = \overline{\rho_{ik}(a) + \rho_{jk}(b)}$$

   where k is any index with $i, j \leq k$, is well defined and makes A into an abelian group. Deduce that the maps ρ_i in (b) are group homomorphisms from A_i to A.

   (d) Show that if all A_i are commutative rings with 1 and all ρ_{ij} are ring homomorphisms that send 1 to 1, then A may likewise be given the structure of a commutative ring with 1 such that all ρ_i are ring homomorphisms.

   (e) Under the hypotheses in (c) prove that the direct limit has the following *universal property*: if C is any abelian group and $\varphi_i : A_i \to C$ are group homomorphisms such that $\varphi_i = \varphi_j \circ \rho_{ij}$ whenever $i \leq j$, then there is a unique group homomorphism $\varphi : A \to C$ such that $\varphi \circ \rho_i = \varphi_i$ for all i.

9. Let I be the collection of open intervals $U = (a, b)$ on the real line containing a fixed real number p. Order these by reverse inclusion: $U \leq V$ if $V \subseteq U$ (note that I is a directed set). For each U let A_U be the ring of continuous real valued functions on U. For $V \subseteq U$ define the *restriction maps* $\rho_{UV} : A_U \to A_V$ by $f \mapsto f|_V$, the usual restriction of a function on U to the smaller set V (which is easily seen to be a ring homomorphism). Let $A = \varinjlim A_U$ be the direct limit. In the notation of the preceding exercise, show that the maps $\rho_U : A_U \to A$ are not injective but are all surjective (A is called the ring of *germs of continuous functions at* p).

10. We now develop the notion of *inverse limits*; continue to assume I is a partially ordered set (but not necessarily directed), and A_i is a group for all $i \in I$. Suppose for every pair of indices i, j with $i \leq j$ there is a map $\mu_{ji} : A_j \to A_i$ such that the following hold:

    i. $\mu_{ji} \circ \mu_{kj} = \mu_{ki}$ whenever $i \leq j \leq k$, and

    ii. $\mu_{ii} = 1$ for all $i \in I$.

    Let P be the subset of elements $(a_i)_{i \in I}$ in the direct product $\prod_{i \in I} A_i$ such that $\mu_{ji}(a_j) = a_i$ whenever $i \leq j$ (here again $i, j \in I$). The set P is called the *inverse* or *projective limit* of the system $\{A_i\}$, and is denoted $\varprojlim A_i$.

    (a) Assume all μ_{ji} are group homomorphisms. Show that P is a subgroup of the direct product group (cf. Exercise 15, Section 5.1).

(b) Assume the hypotheses in (a), and let $I = \mathbb{Z}^+$ (usual ordering). For each $i \in I$ let $\mu_i : P \to A_i$ be the projection of P onto its ith component. Show that if each μ_{ji} is surjective, then so is μ_i for all i (so each A_i is a quotient group of P).

(c) Show that if all A_i are commutative rings with 1 and all μ_{ji} are ring homomorphisms that send 1 to 1, then P may likewise be given the structure of a commutative ring with 1 such that all μ_i are ring homomorphisms.

(d) Under the hypotheses in (a) prove that the inverse limit has the following *universal property*: if D is any group and $\pi_i : D \to A_i$ are group homomorphisms such that $\pi_i = \mu_{ji} \circ \pi_j$ whenever $i \leq j$, then there is a unique homomorphism $\pi : D \to P$ such that $\mu_i \circ \pi = \pi_i$ for all i.

11. Let p be a prime, let $I = \mathbb{Z}^+$, let $A_i = \mathbb{Z}/p^i\mathbb{Z}$ and let μ_{ji} be the natural projection maps $\mu_{ji} : a \pmod{p^j} \mapsto a \pmod{p^i}$. The inverse limit $\varprojlim \mathbb{Z}/p^i\mathbb{Z}$ is called the ring of *p-adic integers*, and is denoted by $\mathbb{Z}_p$.

(a) Show that every element of $\mathbb{Z}_p$ may be written uniquely as an infinite formal sum $b_0 + b_1 p + b_2 p^2 + b_3 p^3 + \cdots$ with each $b_i \in \{0, 1, \ldots, p-1\}$. Describe the rules for adding and multiplying such formal sums corresponding to addition and multiplication in the ring $\mathbb{Z}_p$. [Write a least residue in each $\mathbb{Z}/p^i\mathbb{Z}$ in its base p expansion and then describe the maps μ_{ji}.] (Note in particular that $\mathbb{Z}_p$ is uncountable.)

(b) Prove that $\mathbb{Z}_p$ is an integral domain that contains a copy of the integers.

(c) Prove that $b_0 + b_1 p + b_2 p^2 + b_3 p^3 + \cdots$ as in (a) is a unit in $\mathbb{Z}_p$ if and only if $b_0 \neq 0$.

(d) Prove that $p\mathbb{Z}_p$ is the unique maximal ideal of $\mathbb{Z}_p$ and $\mathbb{Z}_p/p\mathbb{Z}_p \cong \mathbb{Z}/p\mathbb{Z}$ (where $p = 0 + 1p + 0p^2 + 0p^3 + \cdots$). Prove that every nonzero ideal of $\mathbb{Z}_p$ is of the form $p^n\mathbb{Z}_p$ for some integer $n \geq 0$.

(e) Show that if $a_1 \neq 0 \pmod{p}$ then there is an element $a = (a_i)$ in the inverse limit $\mathbb{Z}_p$ satisfying $a_i^{p-1} \equiv 1 \pmod{p^i}$ and $\mu_{j1}(a_j) = a_1$ for all j. Deduce that $\mathbb{Z}_p$ contains $p-1$ distinct $(p-1)^{\text{st}}$ roots of 1.

Practice problems.

1. Let R be a commutative ring with 1. State precisely what it means for two ideals $I, J \subseteq R$ to be *comaximal* (coprime), and show that $I + J = R$ holds iff there exist $x \in I$, $y \in J$ with $x + y = 1$.

2. In $\mathbb{Z}$, decide which of the following pairs of ideals are comaximal: $(\langle 6\rangle, \langle 35\rangle)$, $(\langle 12\rangle, \langle 18\rangle)$, $(\langle 8\rangle, \langle 15\rangle)$, $(\langle 10\rangle, \langle 25\rangle)$. Justify each answer.

3. Use the CRT to exhibit the ring isomorphism $\mathbb{Z}/60\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$ explicitly: give the image of the generator $\overline{1}$ and find the element of $\mathbb{Z}/60\mathbb{Z}$ corresponding to the triple $(\overline{3}, \overline{2}, \overline{4})$.

4. Solve the simultaneous congruences

$$x \equiv 2 \pmod{5}, \qquad x \equiv 3 \pmod{7}, \qquad x \equiv 1 \pmod{8}$$

and write the complete solution set as a residue class mod 280.

5. Let R be a commutative ring with 1 and let $I_1, \ldots, I_k$ be pairwise comaximal ideals. Prove that $I_1 \cap \cdots \cap I_k = I_1 I_2 \cdots I_k$.

6. Determine the number of units in $\mathbb{Z}/72\mathbb{Z}$ by first writing $\mathbb{Z}/72\mathbb{Z}$ as a product of rings via the CRT, then computing the unit group of each factor.

7. In the polynomial ring $\mathbb{F}_2[x]$, the polynomials $x^2 + x + 1$ and $x^3 + x + 1$ are irreducible and distinct. State the ring isomorphism the CRT gives for $\mathbb{F}_2[x]/\langle (x^2 + x + 1)(x^3 + x + 1)\rangle$ and identify each factor as a field of how many elements.

8. Let m, n be positive integers with $\gcd(m, n) = 1$. Prove directly from the CRT isomorphism $\mathbb{Z}/mn\mathbb{Z} \cong \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z}$ that the Euler φ-function is multiplicative: $\varphi(mn) = \varphi(m)\varphi(n)$.

9. Give an example of a commutative ring R with 1 and two ideals I, J such that the natural map $R/(I \cap J) \to R/I \times R/J$ is injective but *not* surjective. (Take $R = \mathbb{Z}$ and a non-comaximal pair.)

10. Let $R = \mathbb{Z}[x]$. Show that the ideals $\langle x\rangle$ and $\langle 2\rangle$ are *not* comaximal (indeed $\langle x\rangle + \langle 2\rangle = \langle 2, x\rangle$ is the proper maximal ideal with $R/\langle 2, x\rangle \cong \mathbb{F}_2$). Verify that $\langle x\rangle \cap \langle 2\rangle = \langle 2x\rangle$, and conclude that the CRT does *not* apply: the natural map $R/\langle 2x\rangle \to R/\langle x\rangle \times R/\langle 2\rangle$ is injective but not surjective.

11. Find all solutions in $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ of the system $2u = 0$, $u + v = (\overline{1}, \overline{2})$ where u, v are unknown elements of the ring $\mathbb{Z}/6\mathbb{Z}$ pulled back through the CRT isomorphism. (Translate componentwise.)

12. Let $I_1, \dots, I_k$ be ideals of a commutative ring R with 1. Prove that the kernel of the diagonal-style map $\varphi\colon R \to R/I_1 \times \cdots \times R/I_k$, $r \mapsto (r + I_1, \dots, r + I_k)$, is exactly $I_1 \cap \cdots \cap I_k$.

13. Decide whether $\mathbb{Z}/8\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$ as rings. Explain why or why not, referencing the hypotheses of the CRT.

14. Let $n = p_1^{a_1} \cdots p_r^{a_r}$ be the prime factorization of $n > 1$. Using the CRT, prove the ring isomorphism $\mathbb{Z}/n\mathbb{Z} \cong \prod_{i=1}^{r} \mathbb{Z}/p_i^{a_i}\mathbb{Z}$ and deduce the corresponding isomorphism of unit groups $(\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_{i=1}^{r} (\mathbb{Z}/p_i^{a_i}\mathbb{Z})^\times$.

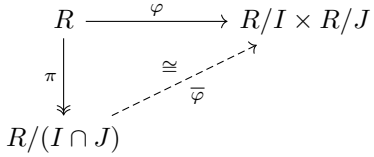
15. Compute, using the CRT, the last two digits of 7^{2026} by working separately modulo 4 and modulo 25 and recombining.

Additional exercises.

1. Let R be a commutative ring with 1 and let I, J be comaximal ideals. Prove that I^a and J^b are comaximal for all positive integers a, b.

2. (Idempotents from the CRT.) Let R be a commutative ring with 1 and suppose $R \cong R_1 \times R_2$ with R_1 and R_2 nonzero. Show that R contains a nontrivial idempotent e (i.e. $e^2 = e$, $e \neq 0, 1$), and conversely that a nontrivial idempotent $e \in R$ yields a decomposition $R \cong Re \times R(1 - e)$ as rings, where Re and $R(1 - e)$ are rings with identities e and $1 - e$ respectively.

3. Let R be a commutative ring with 1 in which $I_1, \dots, I_k$ are pairwise comaximal. Prove the surjectivity half of the CRT directly: construct, for each i, an element $e_i \in R$ with $e_i \equiv 1 \pmod{I_i}$ and $e_i \equiv 0 \pmod{I_j}$ for $j \neq i$, and use the e_i to solve any prescribed system of congruences.

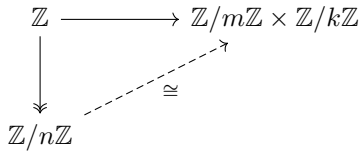


4. Show that $\mathbb{Z}[i]/\langle 1 + 3i\rangle$ is isomorphic to $\mathbb{Z}/10\mathbb{Z}$. (Hint: $\langle 1 + 3i\rangle$ has norm 10; relate $\mathbb{Z}[i]/\langle 1 + 3i\rangle$ to $\mathbb{Z}[i]/\langle 2\rangle$ and $\mathbb{Z}[i]/\langle 5\rangle$ via comaximality of the relevant ideals, or reduce the relation $1 + 3i = 0$.)

5. Let $f(x) \in \mathbb{F}_p[x]$ factor as $f = g_1^{a_1} \cdots g_r^{a_r}$ into distinct monic irreducibles. Prove $\mathbb{F}_p[x]/\langle f\rangle \cong \prod_{i=1}^{r} \mathbb{F}_p[x]/\langle g_i^{a_i}\rangle$, and conclude that $\mathbb{F}_p[x]/\langle f\rangle$ is a product of fields iff f is squarefree (all $a_i = 1$).

6. (Failure without comaximality.) Give ideals I, J in a commutative ring R with 1 for which $IJ \subsetneq I \cap J$ strictly, and verify that the natural surjection $R/IJ \to R/(I \cap J)$ has nonzero kernel. Use $R = \mathbb{Z}$, $I = J = \langle 2\rangle$.

Commutative-diagram exercises.

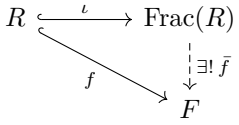


1. Let R be a commutative ring with 1 and I, J comaximal ideals. Consider the map $\varphi\colon R \to R/I \times R/J$, $r \mapsto (r + I, r + J)$. Fill in the dashed arrow making the diagram commute, and state which theorem identifies it as an isomorphism:

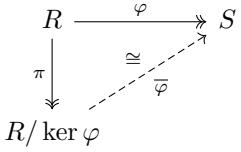
   Prove the dashed map is well defined, injective (using $\ker\varphi = I \cap J$), and surjective (using $I + J = R$).

2. For $n = mk$ with $\gcd(m, k) = 1$, draw and justify the commutative triangle exhibiting the CRT isomorphism for $\mathbb{Z}/n\mathbb{Z}$. Label the top arrow $1 \mapsto (\overline{1}, \overline{1})$ and explain why the top map and the vertical reduction map

are ring homomorphisms:



3. (Universal property of $R[x]$.) Let R be a commutative ring with 1, let S be a commutative R-algebra via $\psi\colon R \to S$, and fix $s \in S$. Show there is a unique ring homomorphism $\Phi\colon R[x] \to S$ extending ψ with $\Phi(x) = s$, by completing the diagram and proving uniqueness:



Then describe $\ker \Phi$ when $R = S = \mathbb{Z}$ and $s = 2$.

4. (Universal property of fractions.) Let R be an integral domain with field of fractions $\mathrm{Frac}(R)$, and let $f\colon R \to F$ be an injective ring homomorphism into a field F. Prove there is a unique $\bar{f}$ making the triangle commute, and explain why injectivity of f is needed:

5. Let $\varphi\colon R \to S$ be a surjective ring homomorphism of commutative rings with 1. Using the First Isomorphism Theorem for rings, complete the factorization and identify $\overline{\varphi}$:

Apply this with $R = \mathbb{Z}[x]$, φ evaluation at $i \in \mathbb{C}$ landing in $\mathbb{Z}[i]$, to identify $\ker \varphi$ and the resulting isomorphism.

7.7 Graded Problem Bank

Unless an item says otherwise, the standing hypotheses of its source apply: in the items from D&F Section 7.k, R is a ring with 1 (and $1 \neq 0$ when $k \geq 3$), commutative when $k = 2$ or $k = 5$; in the Artin items every ring is commutative with 1.

Easy

DF 7.1.1 Show that $(-1)^2 = 1$ in R.

DF 7.1.2 Prove that if u is a unit in R then so is $-u$.

DF 7.1.5 Decide which of six listed subsets of $\mathbb{Q}$ (odd/even denominators, nonnegative rationals, squares, odd/even numerators) are subrings.

DF 7.1.6 Decide which of six listed sets of functions $[0,1] \to \mathbb{R}$ (vanishing on rationals, polynomials, finitely many zeros, etc.) are subrings.

DF 7.1.8 Describe the center of the Hamilton quaternions $\mathbb{H}$, and show $\{a+bi \mid a,b \in \mathbb{R}\}$ is a subfield not contained in the center.

DF 7.1.11 Prove that if R is an integral domain and $x^2 = 1$ for some $x \in R$ then $x = \pm 1$.

DF 7.1.12 Prove that any subring of a field which contains the identity is an integral domain.

DF 7.1.15 Prove that every Boolean ring (with $a^2 = a$ for all a) is commutative.

DF 7.1.18 Prove that $\{(r,r) \mid r \in R\}$ is a subring of $R \times R$.

DF 7.1.22 Give an example of an infinite Boolean ring.

DF 7.2.1 For $p(x) = 2x^3 - 3x^2 + 4x - 5$, $q(x) = 7x^3 + 33x - 4$, compute $p+q$ and pq with coefficients in $\mathbb{Z}$, in $\mathbb{Z}/2\mathbb{Z}$, and in $\mathbb{Z}/3\mathbb{Z}$.

DF 7.2.9 For $\alpha = r + r^2 - 2s$, $\beta = -3r^2 + rs$ in $\mathbb{Z}D_8$, compute $\beta\alpha$, α^2, $\alpha\beta - \beta\alpha$, $\beta\alpha\beta$.

DF 7.2.10 For $\alpha, \beta \in \mathbb{Z}S_3$ given explicitly, compute $\alpha + \beta$, $2\alpha - 3\beta$, $\alpha\beta$, $\beta\alpha$, α^2.

DF 7.2.11 Repeat the preceding $\mathbb{Z}S_3$ computation with coefficients in $\mathbb{Z}/3\mathbb{Z}$.

DF 7.3.1 Prove that the rings $2\mathbb{Z}$ and $3\mathbb{Z}$ are not isomorphic.

DF 7.3.2 Prove that the rings $\mathbb{Z}[x]$ and $\mathbb{Q}[x]$ are not isomorphic.

DF 7.3.3 Find all homomorphic images of $\mathbb{Z}$.

DF 7.3.4 Find all ring homomorphisms from $\mathbb{Z}$ to $\mathbb{Z}/30\mathbb{Z}$, describing each kernel and image.

DF 7.3.6 Decide which of the maps $\mathrm{M}_2(\mathbb{Z}) \to \mathbb{Z}$ (the $1,1$ entry, the trace, the determinant) are ring homomorphisms.

DF 7.3.8 Decide which of $\{(a,a)\}$, $\{(2a,2b)\}$, $\{(2a,0)\}$, $\{(a,-a)\}$ are ideals of $\mathbb{Z} \times \mathbb{Z}$.

DF 7.3.13 Prove that $\mathrm{M}_2(\mathbb{R})$ contains a subring isomorphic to $\mathbb{C}$.

DF 7.4.4 Prove that a commutative ring R is a field if and only if 0 is a maximal ideal.

DF 7.4.8 In an integral domain R, prove $(a) = (b)$ if and only if $a = ub$ for some unit u.

DF 7.4.15 For $E = \mathbb{F}_2[x]/(x^2 + x + 1)$, show $\overline{E}$ has four elements and write its addition and multiplication tables, deducing it is a field.

DF 7.4.16 In $\mathbb{Z}[x]/(x^4 - 16)$, reduce $7x^{13} - 11x^9 + 5x^5 - 2x^3 + 3$ to degree ≤ 3, and show $\overline{x-2}, \overline{x+2}$ are zero divisors.

DF 7.5.4 Prove that any subfield of $\mathbb{R}$ must contain $\mathbb{Q}$.

Artin 1.1 Prove that $7 + \sqrt{2}$ and $\sqrt{2}$ are algebraic numbers.

Artin 1.2 Prove that for $n \neq 0$, $\cos(2\pi/n)$ is an algebraic number.

Artin 1.6 Decide whether S is a subring of R: (a) S the rationals a/b with $3 \nmid b$, $R = \mathbb{Q}$; (b) S integer combinations of $\{1, \cos nt, \sin nt\}$, R the real functions of t.

Artin 1.8 Determine the units in $\mathbb{Z}/12\mathbb{Z}$, $\mathbb{Z}/8\mathbb{Z}$, and $\mathbb{Z}/n\mathbb{Z}$.

Artin 4.3 Identify the rings $\mathbb{Z}[x]/(x^2-3,\ 2x+4)$, $\mathbb{Z}[i]/(2+i)$, $\mathbb{Z}[x]/(6,\ 2x-1)$, $\mathbb{Z}[x]/(2x^2-4,\ 4x-5)$, $\mathbb{Z}[x]/(x^2+3,\ 5)$.

Artin 5.1 Let α be the residue of x in $R = \mathbb{Z}[x]/(x^4 + x^3 + x^2 + x + 1)$; express $(\alpha^3 + \alpha^2 + \alpha)(\alpha^5 + 1)$ in the basis $(1, \alpha, \alpha^2, \alpha^3)$.

Artin 5.3 Describe the ring obtained from $\mathbb{Z}/12\mathbb{Z}$ by adjoining an inverse of 2.

Artin 6.2 Is $\mathbb{Z}/(6) \cong \mathbb{Z}/(2) \times \mathbb{Z}/(3)$? Is $\mathbb{Z}/(8) \cong \mathbb{Z}/(2) \times \mathbb{Z}/(4)$?

Artin 6.4 Describe the ring obtained from $\mathbb{F}_2$ by adjoining a with (a) $a^2 + a + 1 = 0$, (b) $a^2 + 1 = 0$, (c) $a^2 + a = 0$.

Artin 6.5 Adjoin a with $a^2 = 1$ to $\mathbb{R}$; prove the result is isomorphic to $\mathbb{R} \times \mathbb{R}$.

Artin 6.6 Describe the ring obtained from $\mathbb{R} \times \mathbb{R}$ by inverting the element $(2,0)$.

Artin 7.1 Prove that a domain of finite order is a field.

Artin 8.1 Which principal ideals in $\mathbb{Z}[x]$ are maximal ideals?

Artin 8.2 Determine the maximal ideals of $\mathbb{R} \times \mathbb{R}$, $\mathbb{R}[x]/(x^2)$, $\mathbb{R}[x]/(x^2 - 3x + 2)$, $\mathbb{R}[x]/(x^2 + x + 1)$.

Fraleigh 22.1 Compute $(12)(16)$ in $\mathbb{Z}_{24}$.

Fraleigh 22.2 Compute $(16)(3)$ in $\mathbb{Z}_{32}$.

Fraleigh 22.3 Compute $(11)(-4)$ in $\mathbb{Z}_{15}$.

Fraleigh 22.4 Compute $(20)(-8)$ in $\mathbb{Z}_{26}$.

Fraleigh 22.5 Compute $(2, 3)(3, 5)$ in $\mathbb{Z}_5 \times \mathbb{Z}_9$.

Fraleigh 22.6 Compute $(-3, 5)(2, -4)$ in $\mathbb{Z}_4 \times \mathbb{Z}_{11}$.

Fraleigh 22.7 Decide whether $n\mathbb{Z}$ with usual operations is a ring; state if commutative, has unity, is a field.

Fraleigh 22.8 Decide whether $\mathbb{Z}^+$ with usual operations is a ring.

Fraleigh 22.9 Decide whether $\mathbb{Z} \times \mathbb{Z}$ with componentwise operations is a ring (commutative? unity? field?).

Fraleigh 22.10 Decide whether $2\mathbb{Z} \times \mathbb{Z}$ with componentwise operations is a ring.

Fraleigh 22.11 Decide whether $\{a + b\sqrt{2} \mid a, b \in \mathbb{Z}\}$ is a ring.

Fraleigh 22.12 Decide whether $\{a + b\sqrt{2} \mid a, b \in \mathbb{Q}\}$ is a ring.

Fraleigh 22.13 Decide whether the pure imaginaries ri $(r \in \mathbb{R})$ form a ring.

Fraleigh 22.14 Describe all units in $\mathbb{Z}$.

Fraleigh 22.15 Describe all units in $\mathbb{Z} \times \mathbb{Z}$.

Fraleigh 22.16 Describe all units in $\mathbb{Z}_5$.

Fraleigh 22.17 Describe all units in $\mathbb{Q}$.

Fraleigh 22.18 Describe all units in $\mathbb{Z} \times \mathbb{Q} \times \mathbb{Z}$.

Fraleigh 22.19 Describe all units in $\mathbb{Z}_4$.

Fraleigh 22.20 For $\mathrm{M}_2(\mathbb{Z}_2)$: find its order, and list all its units.

Fraleigh 22.23 Describe all ring homomorphisms of $\mathbb{Z}$ into $\mathbb{Z}$.

Fraleigh 22.24 Describe all ring homomorphisms of $\mathbb{Z}$ into $\mathbb{Z} \times \mathbb{Z}$.

Fraleigh 22.25 Describe all ring homomorphisms of $\mathbb{Z} \times \mathbb{Z}$ into $\mathbb{Z}$.

Fraleigh 22.26 How many homomorphisms are there of $\mathbb{Z} \times \mathbb{Z} \times \mathbb{Z}$ into $\mathbb{Z}$?

Fraleigh 22.28 Find all solutions of $x^2 + x - 6 = 0$ in $\mathbb{Z}_{14}$ by factoring.

Fraleigh 22.29 Find all solutions of $x^2 + x - 6 = 0$ in $\mathbb{Z}_{13}$ by factoring.

Fraleigh 22.33 Give a ring having a, b with $ab = 0$ but neither a nor b zero.

Fraleigh 22.34 Give a ring with unity $1 \neq 0$ having a subring with nonzero unity $1' \neq 1$.

Fraleigh 22.46 Find all idempotents in the ring $\mathbb{Z}_6 \times \mathbb{Z}_{12}$.

Fraleigh 23.1 Find all solutions of $x^3 - 2x^2 - 3x = 0$ in $\mathbb{Z}_{12}$.

Fraleigh 23.2 Solve $3x = 2$ in the field $\mathbb{Z}_7$ and in the field $\mathbb{Z}_{23}$.

Fraleigh 23.3 Find all solutions of $x^2 + 2x + 2 = 0$ in $\mathbb{Z}_6$.

Fraleigh 23.4 Find all solutions of $x^2 + 2x + 4 = 0$ in $\mathbb{Z}_6$.

Fraleigh 23.5 Find the characteristic of $2\mathbb{Z}$.

Fraleigh 23.6 Find the characteristic of $\mathbb{Z} \times \mathbb{Z}$.

Fraleigh 23.7 Find the characteristic of $\mathbb{Z}_3 \times 3\mathbb{Z}$.

Fraleigh 23.8 Find the characteristic of $\mathbb{Z}_3 \times \mathbb{Z}_3$.

Fraleigh 23.9 Find the characteristic of $\mathbb{Z}_3 \times \mathbb{Z}_4$.

Fraleigh 23.10 Find the characteristic of $\mathbb{Z}_6 \times \mathbb{Z}_{15}$.

Fraleigh 23.11 Classify each nonzero element of $\mathbb{Z}_6$ as a unit, a zero divisor, or neither.

Fraleigh 23.12 Classify each nonzero element of $\mathbb{Z}_8$ as a unit, a zero divisor, or neither.

Fraleigh 23.13 Classify each nonzero element of $\mathbb{Z}_{15}$ as a unit, a zero divisor, or neither.

Fraleigh 23.14 Classify each nonzero element of $\mathbb{Z}$ as a unit, a zero divisor, or neither.

Fraleigh 23.15 Classify each nonzero element of $\mathbb{Z}_3 \times \mathbb{Z}_3$ as a unit, a zero divisor, or neither.

Fraleigh 23.16 Classify each nonzero element of $\mathbb{Z}_4 \times \mathbb{Z}_5$ as a unit, a zero divisor, or neither.

Fraleigh 23.17 In a commutative ring with unity of characteristic 4, simplify $(a+b)^4$.

Fraleigh 23.18 In a commutative ring with unity of characteristic 3, simplify $(a+b)^9$.

Fraleigh 23.19 In a commutative ring with unity of characteristic 3, simplify $(a+b)^6$.

Fraleigh 23.20 Show that $\left(\begin{smallmatrix} \frac{1}{2} & 2 \\ 4 & \end{smallmatrix}\right)$ is a zero divisor in $\mathrm{M}_2(\mathbb{Z})$.

Fraleigh 24.1 Find a generator of the multiplicative group of nonzero elements of $\mathbb{Z}_7$.

Fraleigh 24.2 Find a generator of the multiplicative group of nonzero elements of $\mathbb{Z}_{11}$.

Fraleigh 24.3 Find a generator of the multiplicative group of nonzero elements of $\mathbb{Z}_{17}$.

Fraleigh 24.4 Using Fermat's theorem, find the remainder of 3^{47} divided by 23.

Fraleigh 24.5 Use Fermat's theorem to find the remainder of 37^{49} divided by 7.

Fraleigh 24.7 Make a table of $\varphi(n)$ for $n \leq 30$.

Fraleigh 24.8 Compute $\varphi(p^2)$ for p prime.

Fraleigh 24.9 Compute $\varphi(pq)$ for p, q prime.

Fraleigh 24.10 Use Euler's theorem to find the remainder of 7^{1000} divided by 24.

Fraleigh 24.11 Describe all solutions of $2x \equiv 6 \pmod 4$.

Fraleigh 24.12 Describe all solutions of $22x \equiv 5 \pmod{15}$.

Fraleigh 24.13 Describe all solutions of $36x \equiv 15 \pmod{24}$.

Fraleigh 24.14 Describe all solutions of $45x \equiv 15 \pmod{24}$.

Fraleigh 24.15 Describe all solutions of $39x \equiv 125 \pmod 9$.

Fraleigh 24.16 Describe all solutions of $41x \equiv 125 \pmod 9$.

Fraleigh 24.17 Describe all solutions of $155x \equiv 75 \pmod{65}$.

Fraleigh 24.18 Describe all solutions of $39x \equiv 52 \pmod{130}$.

Fraleigh 25.1 For $p = 3$, $q = 5$ find n and all RSA pairs (r, s).

Fraleigh 25.2 For $p = 3$, $q = 7$ find n and all RSA pairs (r, s).

Fraleigh 25.3 For $p = 3$, $q = 11$ find n and all RSA pairs (r, s).

Fraleigh 25.4 For $p = 5$, $q = 7$ find n and all RSA pairs (r, s).

Fraleigh 25.5 For $p = 13$, $q = 17$, $r = 5$ find the value of s.

Fraleigh 26.1 Describe the field of quotients of the Gaussian integers $D = \{n + mi \mid n, m \in \mathbb{Z}\}$ inside $\mathbb{C}$.

Fraleigh 26.2 Describe the field of quotients of $D = \{n + m\sqrt{3} \mid n, m \in \mathbb{Z}\}$ inside $\mathbb{R}$.

Fraleigh 30.3 Find all ideals N of $\mathbb{Z}_{12}$ and identify each quotient $\mathbb{Z}_{12}/N$.

Fraleigh 30.4 Give addition and multiplication tables for $2\mathbb{Z}/8\mathbb{Z}$; decide whether $2\mathbb{Z}/8\mathbb{Z} \cong \mathbb{Z}_4$.

Fraleigh 30.12 Give an example showing a factor ring of an integral domain may be a field.

Fraleigh 30.13 Give an example showing a factor ring of an integral domain may have zero divisors.

Fraleigh 30.14 Give an example showing a factor ring of a ring with zero divisors may be an integral domain.

Fraleigh 30.15 Find a subring of $\mathbb{Z} \times \mathbb{Z}$ that is not an ideal of $\mathbb{Z} \times \mathbb{Z}$.

Fraleigh 31.1 Find all prime ideals and all maximal ideals of $\mathbb{Z}_6$.

Fraleigh 31.2 Find all prime ideals and all maximal ideals of $\mathbb{Z}_{12}$.

Fraleigh 31.3 Find all prime ideals and all maximal ideals of $\mathbb{Z}_2 \times \mathbb{Z}_2$.

Fraleigh 31.4 Find all prime ideals and all maximal ideals of $\mathbb{Z}_2 \times \mathbb{Z}_4$.

Fraleigh 31.5 Find all $c \in \mathbb{Z}_3$ with $\mathbb{Z}_3[x]/\langle x^2 + c\rangle$ a field.

Fraleigh 31.8 Find all $c \in \mathbb{Z}_5$ with $\mathbb{Z}_5[x]/\langle x^2 + x + c\rangle$ a field.

Fraleigh 31.9 Find all $c \in \mathbb{Z}_5$ with $\mathbb{Z}_5[x]/\langle x^2 + cx + 1\rangle$ a field.

Fraleigh 31.15 Find a maximal ideal of $\mathbb{Z} \times \mathbb{Z}$.

Fraleigh 31.16 Find a prime ideal of $\mathbb{Z} \times \mathbb{Z}$ that is not maximal.

Fraleigh 31.17 Find a nontrivial proper ideal of $\mathbb{Z} \times \mathbb{Z}$ that is not prime.

Fraleigh 31.18 Is $\mathbb{Q}[x]/\langle x^2 - 5x + 6\rangle$ a field? Why?

Fraleigh 31.19 Is $\mathbb{Q}[x]/\langle x^2 - 6x + 6\rangle$ a field? Why?

Fraleigh 32.1 In $\mathbb{Z}_5 G$ (G cyclic of order 3), compute $(2e + 3a + 0b) + (4e + 2a + 3b)$.

Fraleigh 32.2 In $\mathbb{Z}_5 G$ (G cyclic of order 3), compute $(2e + 3a + 0b)(4e + 2a + 3b)$.

Fraleigh 32.4 Write $(i + 3j)(4 + 2j - k)$ in the form $a_1 + a_2 i + a_3 j + a_4 k$.

Fraleigh 32.5 Write $i^2 j^3 k j i^5$ in the form $a_1 + a_2 i + a_3 j + a_4 k$.

Fraleigh 32.6 Write $(i + j)^{-1}$ in the form $a_1 + a_2 i + a_3 j + a_4 k$.

Fraleigh 32.8 In $\mathbb{Z}_2 D_3$, compute the product of two given group-ring elements.

Fraleigh 32.10 Find two subfields of $\mathbb{H}$, distinct from $\mathbb{C}$ and from each other, each isomorphic to $\mathbb{C}$.

Medium

DF 7.1.3 Let $S \leq R$ contain the identity; prove a unit of S is a unit of R, and show the converse fails.

DF 7.1.4 Prove the intersection of any nonempty collection of subrings is a subring.

DF 7.1.7 Prove the center of a ring is a subring containing the identity, and that the center of a division ring is a field.

DF 7.1.9 For fixed $a \in R$, prove $C(a) = \{r \mid ra = ar\}$ is a subring containing a, and the center is $\bigcap_a C(a)$.

DF 7.1.13 For nilpotents in $\mathbb{Z}/n\mathbb{Z}$: show $\overline{ab}$ is nilpotent when $n = a^k b$; characterize nilpotent $\bar{a}$ via prime divisors and list them in $\mathbb{Z}/72\mathbb{Z}$; show function rings into a field have no nonzero nilpotents.

DF 7.1.14 For a nilpotent x in a commutative ring: show x is 0 or a zero divisor, rx is nilpotent, $1 + x$ is a unit, and unit + nilpotent is a unit.

DF 7.1.16 Prove the only Boolean ring that is an integral domain is $\mathbb{Z}/2\mathbb{Z}$.

DF 7.1.17 Prove $R \times S$ is a ring under componentwise operations, commutative iff both are, with identity iff both have one.

DF 7.1.19 Prove $\prod_{i \in I} R_i$ is a ring under componentwise operations for any index set I.

DF 7.1.20 Prove the eventually-zero integer sequences form a ring under componentwise operations with no identity.

DF 7.1.21 On the power set $\mathcal{P}(X)$ with symmetric difference and intersection, prove it is a commutative Boolean ring with identity.

DF 7.2.3 Define formal power series $R[[x]]$; prove it is a commutative ring with 1, that $1 - x$ is a unit, and that $\sum a_n x^n$ is a unit iff a_0 is a unit.

DF 7.2.6 For $E_{ij} \in \mathrm{M}_n(S)$: describe $E_{ij}A$, AE_{ij}, and deduce the entry pattern of $E_{pq}AE_{rs}$.

DF 7.2.8 Prove that any strictly upper triangular $A \in \mathrm{M}_n(S)$ satisfies $A^n = 0$.

DF 7.2.12 Prove $N = g_1 + \cdots + g_n$ lies in the center of the group ring RG for a finite group G.

DF 7.3.5 Describe all ring homomorphisms $\mathbb{Z} \times \mathbb{Z} \to \mathbb{Z}$, with kernel and image.

DF 7.3.7 Show $\varphi : \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right) \mapsto (a, d)$ from upper-triangular integer matrices to $\mathbb{Z} \times \mathbb{Z}$ is a surjective homomorphism; describe its kernel.

DF 7.3.10 Decide which of six listed subsets of $\mathbb{Z}[x]$ (constant term 3 |, etc.) are ideals.

DF 7.3.11 Show $\varphi(f) = \int_0^1 f$ on continuous functions $[0, 1] \to \mathbb{R}$ is an additive but not a ring homomorphism.

DF 7.3.14 Prove $\mathrm{M}_4(\mathbb{R})$ contains a subring isomorphic to the Hamilton quaternions $\mathbb{H}$.

DF 7.3.15 For the Boolean ring $\mathcal{P}(X)$ and $R = \mathrm{Fun}(X, \mathbb{Z}/2\mathbb{Z})$, prove $A \mapsto \chi_A$ is a ring isomorphism.

DF 7.3.16 For a surjective $\varphi : R \to S$, prove the image of the center of R lies in the center of S.

DF 7.3.18 Prove $I \cap J$ is an ideal, and so is the intersection of any nonempty collection of ideals.

DF 7.3.19 Prove that an increasing union $\bigcup_n I_n$ of ideals is an ideal.

DF 7.3.20 Prove $I \cap S$ is an ideal of the subring S, and show by example not every ideal of S has this form.

DF 7.3.22 For $a \in R$: prove the right and left annihilators are one-sided ideals, and the left annihilator of a left ideal L is two-sided.

DF 7.3.24 For $\varphi : R \to S$: prove $\varphi^{-1}(J)$ is an ideal; if φ is surjective prove $\varphi(I)$ is an ideal, with a counterexample when not surjective.

DF 7.3.25 Prove the Binomial Theorem holds in any commutative ring with 1.

DF 7.3.27 Prove a nonzero Boolean ring has characteristic 2.

DF 7.3.29 Prove the nilpotent elements of a commutative ring R form an ideal (the nilradical).

DF 7.3.31 Show the matrices $\left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $\left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$ are nilpotent with non-nilpotent sum, so nilpotents in $\mathrm{M}_2(\mathbb{Z})$ are not an ideal.

DF 7.3.32 For $\varphi : R \to S$, prove φ sends nilpotents to nilpotents.

DF 7.3.34 For ideals I, J: prove $I + J$ is the smallest ideal containing both, $IJ \subseteq I \cap J$, give $IJ \neq I \cap J$, and show $I + J = R$ forces $IJ = I \cap J$ (commutative).

DF 7.3.35 For ideals I, J, K: prove $I(J + K) = IJ + IK$ and the modular law $I \cap (J + K) = J + (I \cap K)$ when $J \subseteq I$.

DF 7.3.36 For the ideal I of zero-constant-term polynomials in $\mathbb{Z}[x]$, identify I^n.

DF 7.3.37 Prove $p\mathbb{Z}/p^m\mathbb{Z}$ is a nilpotent ideal in $\mathbb{Z}/p^m\mathbb{Z}$.

DF 7.5.1 Fill in all details in the proof of Theorem 15 (rings of fractions).

DF 7.4.5 Prove that if R/M is a field then M is a maximal ideal (without assuming commutativity).

DF 7.4.6 Prove R is a division ring iff its only left ideals are (0) and R.

DF 7.4.7 In $R[x]$ (R commutative with 1), prove (x) is prime iff R is a domain, and maximal iff R is a field.

DF 7.4.9 For R continuous on $[0,1]$ and $I = \{f \mid f(1/3) = f(1/2) = 0\}$, prove I is an ideal but not prime.

DF 7.4.10 If P is a prime ideal of a commutative ring containing no zero divisors, prove R is an integral domain.

DF 7.4.11 If a prime ideal P contains IJ, prove $I \subseteq P$ or $J \subseteq P$.

DF 7.4.12 For commutative R: if $I = (a_1, \ldots, a_n)$, $J = (b_1, \ldots, b_m)$, prove IJ is generated by the products $a_i b_j$.

DF 7.4.17 In $\mathbb{Z}[x]/(x^3 - 2x + 1)$, reduce given polynomials to degree ≤ 2, show the quotient is not a domain, and that $\overline{x}$ is a unit.

DF 7.4.19 Prove every prime ideal of a finite commutative ring with identity is maximal.

DF 7.4.23 Prove every prime ideal in a Boolean ring is maximal.

DF 7.4.24 Prove every finitely generated ideal in a Boolean ring is principal.

DF 7.4.26 Prove a prime ideal of a commutative ring contains every nilpotent, so the nilradical lies in the intersection of all primes.

DF 7.4.27 Prove that if a is nilpotent then $1 - ab$ is a unit for all b (commutative R).

DF 7.4.30 For an ideal I of commutative R, prove $\operatorname{rad} I$ is an ideal containing I and $(\operatorname{rad} I)/I = \mathfrak{N}(R/I)$.

DF 7.4.31 Prove every prime ideal is a radical ideal, and, for $n > 1$, (n) is radical in $\mathbb{Z}$ iff n is squarefree.

DF 7.4.1 In $\mathrm{M}_n(R)$, prove $L_j = \mathrm{M}_n(R)E_{ij}$ for the column left ideal L_j (any i).

DF 7.4.2 Prove the augmentation ideal of RG (R commutative) is generated by $\{g - 1\}$, and by $\sigma - 1$ when $G = \langle \sigma \rangle$ is cyclic.

DF 7.4.3 For a p-group G over $\mathbb{F}_p$, prove the nilradical of $\mathbb{F}_p G$ is the augmentation ideal; and for finite G with R commutative, prove $r(g_1 + \cdots + g_n) = 0$ for every r in the augmentation ideal.

DF 7.6.1 For a central idempotent e, prove Re and $R(1-e)$ are ideals with $R \cong Re \times R(1-e)$, and identify their unities.

DF 7.6.3 Prove every ideal of $R \times S$ (R, S with identity) has the form $I \times J$.

DF 7.6.4 Prove that if R, S are nonzero rings then $R \times S$ is never a field.

DF 7.6.5 Solve the simultaneous congruences $x \equiv 1$ (8), $x \equiv 2$ (25), $x \equiv 3$ (81) (and a second system) via CRT, including the explicit $t_i n_i'$ formula.

DF 7.6.7 For $n \mid m$, prove the projection $\mathbb{Z}/m\mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ is surjective on units.

Artin 1.3 For $\alpha = \sqrt{2}$, $\beta = \sqrt[3]{2}$, $\gamma = \alpha + \beta$, decide whether $\mathbb{Q}[\alpha, \beta] = \mathbb{Q}[\gamma]$ and whether $\mathbb{Z}[\alpha, \beta] = \mathbb{Z}[\gamma]$.

Artin 1.7 Decide whether each structure is a ring; if not, say which axioms hold and fail: (a) subsets of U under symmetric difference and intersection, (b) continuous $f : \mathbb{R} \to \mathbb{R}$ under $+$ and composition.

Artin 2.1 For which positive integers n does $x^2 + x + 1$ divide $x^4 + 3x^3 + x^2 + 7x + 5$ in $(\mathbb{Z}/n\mathbb{Z})[x]$?

Artin 3.1 Prove that an ideal of a ring R is a subgroup of the additive group R^+.

Artin 3.2 Prove that every nonzero ideal of the Gaussian integers contains a nonzero integer.

Artin 3.3 Find generators for the kernels of the evaluation maps $\mathbb{R}[x,y] \to \mathbb{R}$ at $(0,0)$, $\mathbb{R}[x] \to \mathbb{C}$ at $2+i$, and $\mathbb{Z}[x] \to \mathbb{R}$ at $1+\sqrt{2}$.

Artin 3.7 Determine the automorphisms of the polynomial ring $\mathbb{Z}[x]$.

Artin 3.8 Let R have prime characteristic p; prove $x \mapsto x^p$ is a ring homomorphism (the Frobenius map).

Artin 3.9 Prove that if x is nilpotent then $1+x$ is a unit; and if $\operatorname{char} R = p > 0$ and a is nilpotent, then $1+a$ is unipotent.

Artin 3.10 Determine all ideals of the formal power series ring $F[[t]]$ over a field F.

Artin 3.12 For ideals I, J, prove $I + J = \{x + y \mid x \in I,\ y \in J\}$ is an ideal.

Artin 3.13 Prove $I \cap J$ is an ideal; show $\{xy\}$ need not be, but finite sums $\sum x_\nu y_\nu$ form the product ideal IJ; relate IJ and $I \cap J$.

Artin 4.1 Apply the Correspondence Theorem to $\mathbb{Z}[x] \to \mathbb{Z}$, $x \mapsto 1$, describing the ideals of $\mathbb{Z}[x]$ it identifies.

Artin 4.2 What does the Correspondence Theorem say about ideals of $\mathbb{Z}[x]$ containing x^2+1?

Artin 4.4 Are the rings $\mathbb{Z}[x]/(x^2+7)$ and $\mathbb{Z}[x]/(2x^2+7)$ isomorphic?

Artin 5.2 Adjoining α to R with the relation $\alpha = a$ for $a \in R$; prove the result is isomorphic to R.

Artin 5.5 Are there fields F with $F[x]/(x^2) \cong F[x]/(x^2-1)$?

Artin 6.1 For $\varphi : \mathbb{R}[x] \to \mathbb{C} \times \mathbb{C}$, $\varphi(x) = (1,i)$, $\varphi(r) = (r,r)$, determine the kernel and image.

Artin 6.3 Classify rings of order 10.

Artin 7.2 Prove the polynomial ring $R[x]$ over a domain R is a domain, and identify its units.

Artin 7.3 Is there a domain containing exactly 15 elements?

Artin 7.5 Given a multiplicative set S in a domain R, show the equivalence classes of S-fractions form a ring.

Artin 8.3 Prove $\mathbb{F}_2[x]/(x^3+x+1)$ is a field but $\mathbb{F}_3[x]/(x^3+x+1)$ is not.

Artin M.1 Prove or disprove: if $a^2 = a$ for every a in a nonzero ring R, then R has characteristic 2.

Fraleigh 22.21 Give a homomorphism $\varphi : R \to R'$ of rings with unity with $\varphi(1) \neq 0'$ and $\varphi(1) \neq 1'$, or explain.

Fraleigh 22.22 Is $\det : \mathrm{M}_n(\mathbb{R}) \to \mathbb{R}$ a ring homomorphism? Justify.

Fraleigh 22.27 Critique the factoring argument that $X^2 = I_3$ in $\mathrm{M}_3(\mathbb{R})$ forces $X = \pm I_3$.

Fraleigh 22.30 Find the error in the "proof" $(-a)b = ((-1)a)b = (-1)(ab) = -(ab)$.

Fraleigh 22.36 Show the function multiplication on $F = \operatorname{Fun}(\mathbb{R},\mathbb{R})$ satisfies axioms R2 and R3.

Fraleigh 22.39 Show the set U of units of a ring with unity is a group under multiplication.

Fraleigh 22.40 Show $a^2 - b^2 = (a+b)(a-b)$ holds for all $a, b \in R$ iff R is commutative.

Fraleigh 22.41 For an abelian group $(R,+)$, show defining $ab = 0$ makes R a ring.

Fraleigh 22.42 Show $2\mathbb{Z}$ and $3\mathbb{Z}$ are not isomorphic rings; show $\mathbb{R}$ and $\mathbb{C}$ are not isomorphic fields.

Fraleigh 22.43 Show $(a+b)^p = a^p + b^p$ in $\mathbb{Z}_p$ for p prime.

Fraleigh 22.44 Show the unity of a subfield of a field is the unity of the whole field.

Fraleigh 22.45 Show a multiplicative inverse of a unit in a ring with unity is unique.

Fraleigh 22.50 Show $S \subseteq R$ is a subring iff $0 \in S$, $a - b \in S$, and $ab \in S$ for all $a, b \in S$.

Fraleigh 22.51 Show an intersection of subrings is a subring, and an intersection of subfields is a subfield.

Fraleigh 22.52 For fixed $a \in R$, show $I_a = \{x \mid ax = 0\}$ is a subring.

Fraleigh 22.54 Use the $\mathbb{Z}_{rs} \cong \mathbb{Z}_r \times \mathbb{Z}_s$ isomorphism to prove the two-congruence Chinese Remainder Theorem.

Fraleigh 23.29 Show a division ring contains exactly two idempotents.

Fraleigh 23.30 Show an intersection of subdomains of an integral domain is a subdomain.

Fraleigh 26.5 Give an example where a field of quotients of a proper subdomain $D' \subset D$ is also a field of quotients of D.

Fraleigh 30.1 Describe all ring homomorphisms $\mathbb{Z} \times \mathbb{Z} \to \mathbb{Z} \times \mathbb{Z}$.

Fraleigh 30.2 Find all positive integers n such that $\mathbb{Z}_n$ contains a subring isomorphic to $\mathbb{Z}_2$.

Fraleigh 30.8 Decide whether differentiation $\delta : f \mapsto f'$ on smooth functions is a ring homomorphism.

Fraleigh 30.16 Prove R/N is commutative iff $(rs - sr) \in N$ for all $r, s \in R$.

Fraleigh 30.17 Show $R = \{a + b\sqrt{2} \mid a, b \in \mathbb{Z}\}$ is isomorphic to the ring of matrices $\left(\begin{smallmatrix} a & 2b \\ b & a \end{smallmatrix}\right)$.

Fraleigh 30.18 Show each homomorphism from a field to a ring is injective or maps everything to 0.

Fraleigh 30.19 Show the composite of two ring homomorphisms is a ring homomorphism.

Fraleigh 30.20 For commutative R of prime characteristic p, show $\varphi_p(a) = a^p$ is a homomorphism (Frobenius).

Fraleigh 30.21 If $\varphi : R \to R'$ is nonzero, R has unity, and R' has no zero divisors, show $\varphi(1)$ is unity for R'.

Fraleigh 30.24 Show a factor ring of a field is the zero ring or is isomorphic to the field.

Fraleigh 30.25 Show if R has unity and $N \neq R$ is an ideal, then R/N has unity.

Fraleigh 30.26 For commutative R and $a \in R$, show $I_a = \{x \mid ax = 0\}$ is an ideal.

Fraleigh 30.27 Show an intersection of ideals of R is an ideal.

Fraleigh 31.6 Find all $c \in \mathbb{Z}_3$ with $\mathbb{Z}_3[x]/\langle x^3 + x^2 + c\rangle$ a field.

Fraleigh 31.7 Find all $c \in \mathbb{Z}_3$ with $\mathbb{Z}_3[x]/\langle x^3 + cx^2 + 1\rangle$ a field.

Fraleigh 31.24 Give an ideal of $\mathbb{Q}[x, y]$ that is not principal, concluding R a PID need not make $R[x]$ a PID.

Fraleigh 31.25 For commutative R with unity and $a \in R$, show $\langle a\rangle = \{ra \mid r \in R\}$ is an ideal.

Fraleigh 31.26 Show every prime ideal of a finite commutative ring with unity is maximal.

Fraleigh 31.33 For a field F and $f, g \in F[x]$, show $f \mid g$ iff $g \in \langle f\rangle$.

Fraleigh 31.36 For ideals A, B, show the sum $A + B = \{a + b\}$ is an ideal containing both.

Fraleigh 32.13 Show the endomorphism φ of $\mathbb{Z} \times \mathbb{Z}$ that is a right zero divisor is also a left zero divisor.

Fraleigh 32.14 Show $\mathrm{M}_2(F)$ has at least six units for every field F, exhibiting them.

Fraleigh 32.15 Show $\mathrm{End}(\mathbb{Z}) \cong \mathbb{Z}$ and $\mathrm{End}(\mathbb{Z}_n) \cong \mathbb{Z}_n$ as rings.

Fraleigh 32.16 Show $\mathrm{End}(\mathbb{Z}_2 \times \mathbb{Z}_2)$ is not isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_2$.

Fraleigh 32.18 For the trivial group $G = \{e\}$, show the group ring $RG \cong R$ for any ring R.

Hard

DF 7.1.10 Prove that if D is a division ring then $C(a)$ is a division ring for every $a \in D$.

DF 7.1.23 For a squarefree D and the ring of integers $\mathcal{O}$ of $\mathbb{Q}(\sqrt{D})$, prove $\mathcal{O}_f = \mathbb{Z}[f\omega]$ is a subring of index f, and conversely every index-f subring containing 1 equals $\mathcal{O}_f$.

DF 7.1.24 For $D = 3, 5, 6, 7$, exhibit an explicit unit of infinite order in the quadratic integer ring $\mathcal{O}$, showing $\mathcal{O}^\times$ is infinite.

DF 7.1.25 For the norm N on integral quaternions I, prove $N(\alpha) = \alpha\bar{\alpha}$, $N(\alpha\beta) = N(\alpha)N(\beta)$, and that α is a unit iff $N(\alpha) = 1$, with $I^\times$ the quaternion group of order 8.

DF 7.1.26 For a discrete valuation ν on K, prove the valuation ring R is a subring with 1, that x or x^{-1} lies in R for $x \neq 0$, and that x is a unit iff $\nu(x) = 0$.

DF 7.1.27 For ν_p on $\mathbb{Q}$, prove the valuation ring is the rationals with denominator prime to p, and describe its units.

DF 7.1.28 For left/right zero divisors and one-sided inverses: prove u is a unit iff it has two-sided inverse; a right inverse blocks right-zero-divisibility; more than one right inverse forces a left zero divisor; in a finite ring a right inverse is a unit.

DF 7.1.29 For $R = \mathrm{End}(A^+)$ of a commutative ring with 1, prove these operations make R a ring with identity whose units are the group automorphisms of A.

DF 7.1.30 For the shift maps φ, ψ on $A = \mathbb{Z} \times \mathbb{Z} \times \cdots$: prove $\varphi\psi = 1 \neq \psi\varphi$, exhibit infinitely many right inverses for φ, find $\pi \neq 0$ with $\varphi\pi = 0$ but $\pi\varphi \neq 0$, and show no nonzero λ has $\lambda\varphi = 0$.

DF 7.2.2 Prove $p(x) \in R[x]$ is a zero divisor iff some nonzero $b \in R$ has $bp(x) = 0$.

DF 7.2.4 Prove that if R is an integral domain then $R[[x]]$ is an integral domain.

DF 7.2.5 Define formal Laurent series $F((x))$; prove it is a field, and that the order map ν is a discrete valuation with valuation ring $F[[x]]$.

DF 7.2.7 Prove the center of $\mathrm{M}_n(R)$ is the set of scalar matrices.

DF 7.2.13 For a conjugacy class $\mathcal{K}$ in finite G, prove $K = \sum_i k_i$ is central in RG, and that the class sums form a basis of the center of RG.

DF 7.3.9 Decide which of the function subsets from 7.1.6 are ideals of $\mathrm{Fun}([0,1], \mathbb{R})$.

DF 7.3.12 For non-square D and $S = \{\left(\begin{smallmatrix} a & b \\ Db & a \end{smallmatrix}\right)\}$: prove S is a subring, $\mathbb{Z}[\sqrt{D}] \cong S$, and, for squarefree $D \equiv 1\ (4)$, the variant is isomorphic to the quadratic integer ring $\mathcal{O}$.

DF 7.3.17 For a nonzero homomorphism $\varphi : R \to S$: prove if $\varphi(1_R) \neq 1_S$ then it is a zero divisor (so domains force $1 \mapsto 1$), and if $\varphi(1_R) = 1_S$ then $\varphi(u^{-1}) = \varphi(u)^{-1}$.

DF 7.3.21 Prove every two-sided ideal of $\mathrm{M}_n(R)$ equals $\mathrm{M}_n(J)$ for some two-sided ideal J of R.

DF 7.3.23 For $S \leq R$ and ideal I with $S \cap I = 0$, prove $\overline{S} \cong S$ in R/I.

DF 7.3.26 Prove the $\mathbb{Z} \to R$ characteristic map is a homomorphism with kernel $n\mathbb{Z}$; find char of $\mathbb{Q}, \mathbb{Z}[x], (\mathbb{Z}/n\mathbb{Z})[x]$; prove $(a+b)^p = a^p + b^p$ when R is commutative of prime characteristic p.

DF 7.3.28 Prove an integral domain has characteristic 0 or a prime.

DF 7.3.30 Prove that in a commutative ring $\mathfrak{N}(R/\mathfrak{N}(R)) = 0$.

DF 7.3.33 For $p(x) \in R[x]$ (R commutative): prove p is a unit iff a_0 is a unit and $a_1, \ldots, a_n$ are nilpotent, and p is nilpotent iff all a_i are nilpotent.

DF 7.4.13 For $\varphi : R \to S$ of commutative rings: prove $\varphi^{-1}(P)$ is prime or all of R, and $\varphi^{-1}(M)$ is maximal when φ is surjective, with a counterexample otherwise.

DF 7.4.14 For commutative R and monic $f \in R[x]$ of degree n: prove every class in $R[x]/(f)$ has a unique degree-$< n$ representative; if $f = ab$ with $\deg a, \deg b < n$ then $\overline{a}$ is a zero divisor; handle the nilpotent cases $f = x^n - a$ and $f = x^p - a$ over $\mathbb{F}_p$.

DF 7.4.15 For $E = \mathbb{F}_2[x]/(x^2 + x + 1)$: prove $\overline{E}$ has 4 elements, its additive group is the Klein four-group, and $\overline{E}^\times$ is cyclic of order 3, so $\overline{E}$ is a field.

DF 7.4.18 For a domain R, prove (x) is prime in $R[[x]]$, and maximal iff R is a field.

DF 7.4.20 Prove a nonzero finite commutative ring with no zero divisors is a field (without assuming a 1).

DF 7.4.21 Prove a finite ring with $1 \neq 0$ and no zero divisors is a field (quoting Wedderburn).

DF 7.4.22 For the $\mathbb{F}_p$-quaternions, prove they are a homomorphic image of the integral quaternions and contain zero divisors.

DF 7.4.25 If for each a there is $n > 1$ with $a^n = a$ (commutative R), prove every prime ideal is maximal.

DF 7.4.28 Prove that if R is commutative and $N = (a_1, \ldots, a_m)$ with each a_i nilpotent then N is a nilpotent ideal; deduce a finitely generated nilradical is nilpotent.

DF 7.4.29 For a p-group G, prove the augmentation ideal of $(\mathbb{Z}/p\mathbb{Z})G$ is a nilpotent ideal.

DF 7.4.32 For $\operatorname{Jac} I$ (intersection of maximal ideals containing I): prove it is an ideal containing I, that $\operatorname{rad} I \subseteq \operatorname{Jac} I$, and describe $\operatorname{Jac} n\mathbb{Z}$.

DF 7.4.33 For continuous $f : [0,1] \to \mathbb{R}$ and $M_c = \{f \mid f(c) = 0\}$: prove every maximal ideal is some M_c, distinct points give distinct M_c, and M_c is not principal nor finitely generated.

DF 7.4.34 For continuous $f : \mathbb{R} \to \mathbb{R}$: prove the compact-support functions form a non-prime ideal I, and a maximal ideal containing I is not any M_c.

DF 7.4.35 Using Zorn's Lemma, prove there is an ideal maximal with respect to not containing a fixed nonzero finitely generated ideal A.

DF 7.4.36 Using Zorn's Lemma, prove the set of prime ideals of a commutative ring has a minimal element.

DF 7.4.37 Prove a local ring's non-maximal-ideal elements are units, and conversely a ring whose nonunits form an ideal is local.

DF 7.4.38 Prove the ring of rationals with odd denominator is local with maximal ideal (2).

DF 7.4.39 For a valuation ring R and $A_k = \{r \mid \nu(r) \geq k\}$: prove each A_k is principal, every nonzero ideal is some A_k, and R is local with maximal ideal A_1.

DF 7.4.40 For commutative R, prove the equivalence: R has exactly one prime ideal $\iff$ every element is nilpotent or a unit $\iff$ $R/\mathfrak{N}(R)$ is a field.

DF 7.4.41 For a primary ideal Q: prove the primary ideals of $\mathbb{Z}$ are 0 and (p^n); every prime is primary; Q primary iff every zero divisor in R/Q is nilpotent; and $\operatorname{rad} Q$ is prime.

DF 7.5.2 For a domain R and multiplicative $D \subseteq R$, prove $D^{-1}R$ embeds as a subring of the quotient field of R.

DF 7.5.3 Prove a field F has a unique prime subfield $F_0 \cong \mathbb{Q}$ or $\mathbb{Z}/p\mathbb{Z}$.

DF 7.5.5 Prove the field of fractions of $F[[x]]$ is $F((x))$, and that the fraction field of $\mathbb{Z}[[x]]$ is properly contained in $\mathbb{Q}((x))$ (consider e^x).

DF 7.5.6 Using Zorn's Lemma, prove $\mathbb{R}$ contains a subring $A \ni 1$ maximal with respect to $\frac{1}{2} \notin A$.

DF 7.6.2 Prove every finite Boolean ring with identity is isomorphic to a product $\mathbb{Z}/2\mathbb{Z} \times \cdots \times \mathbb{Z}/2\mathbb{Z}$.

DF 7.6.6 Use CRT to construct an integer polynomial f of degree d with $f \equiv f_i \pmod{n_i}$ for pairwise-coprime n_i (all $f_i \in \mathbb{Z}[x]$ of degree d), monic when all f_i are.

DF 7.6.8 Develop the direct (inductive) limit $\varinjlim A_i$ of a directed system: prove $\sim$ is an equivalence relation, ρ_i is injective when each ρ_{ij} is, the operations are well defined, and establish the universal property.

DF 7.6.9 For open intervals about p and rings of continuous functions, prove the maps ρ_U into the ring of germs $\varinjlim A_U$ are surjective but not injective.

DF 7.6.10 Develop the inverse (projective) limit $\varprojlim A_i$: prove P is a subgroup of the product, the projections μ_i are surjective when $I = \mathbb{Z}^+$ and each μ_{ji} is, the ring structure, and the universal property.

DF 7.6.11 For the p-adic integers $\mathbb{Z}_p = \varprojlim \mathbb{Z}/p^i\mathbb{Z}$: prove the unique base-$p$ expansion, that $\mathbb{Z}_p$ is a domain containing $\mathbb{Z}$, the unit criterion $b_0 \neq 0$, that $p\mathbb{Z}_p$ is the unique maximal ideal with every nonzero ideal $p^n\mathbb{Z}_p$, and the existence of $p-1$ roots of unity.

Artin 3.4 For $\varphi : \mathbb{C}[x,y] \to \mathbb{C}[t]$, $x \mapsto t+1$, $y \mapsto t^3 - 1$, determine the kernel K and prove every ideal containing K is generated by two elements.

Artin 3.5 For the formal derivative over a field F: prove the product and chain rules, and that α is a multiple root of f iff it is a common root of f and f'.

Artin 3.6 For $f(y) \in R[y]$, prove the map $R[x,y] \to R[x,y]$, $x \mapsto x + f(y)$, $y \mapsto y$, is an automorphism.

Artin 3.11 For an ideal I of $R[x]$ with least nonzero degree n, prove or disprove: I contains a monic of degree n iff I is principal.

Artin 5.4 Determine the ring R' obtained from $\mathbb{Z}$ by adjoining a with each relation set: (a) $2a = 6,\ 6a = 15$; (b) $2a - 6 = 0,\ a - 10 = 0$; (c) $a^3 + a^2 + 1 = 0,\ a^2 + a = 0$.

Artin 5.6 For $R' = R[x]/(ax - 1)$ with α the residue of x: show every element is $\alpha^n b$ ($b \in R$), the kernel of $R \to R'$ is $\{b \mid a^n b = 0\}$, and $R' = 0$ iff a is nilpotent.

Artin 5.7 For $R = F[t]$, prove $R[x]/(tx - 1)$ is the ring of Laurent polynomials in t.

Artin 6.7 Prove $(2) \cap (x) = (2x)$ in $\mathbb{Z}[x]$, and that $\mathbb{Z}[x]/(2x)$ is isomorphic to the subring of $\mathbb{F}_2[x] \times \mathbb{Z}$ of pairs (f, n) with $f(0) \equiv n\ (2)$.

Artin 6.8 For ideals with $I + J = R$: prove $IJ = I \cap J$, the Chinese Remainder Theorem for R, that $IJ = 0$ gives $R \cong (R/I) \times (R/J)$, and describe the idempotents.

Artin 7.4 Prove the field of fractions of $F[[x]]$ is obtained by inverting x, and describe its elements neatly.

Artin 8.4 Establish a bijection between maximal ideals of $\mathbb{R}[x]$ and points of the closed upper half plane $\{z \in \mathbb{C} : \operatorname{Im} z \geq 0\}$.

Artin M.2 For a commutative cancellative semigroup S, prove S embeds into a group.

Artin M.3 For the ring R of eventually-constant real sequences, prove R is a ring and determine its maximal ideals.

Artin M.4 Classify the rings containing $\mathbb{C}$ of dimension 2 over $\mathbb{C}$, and likewise dimension 3.

Artin M.5 For $\varphi : \mathbb{C}[x,y] \to \mathbb{C}[x] \times \mathbb{C}[y] \times \mathbb{C}[t]$, $f \mapsto (f(x,0), f(0,y), f(t,t))$, determine the image and find generators of the kernel.

Artin M.7 For R the continuous functions on $[0,1]$: prove functions with no common zero generate the unit ideal, and establish a bijection between maximal ideals and points of the interval.

Fraleigh 22.47 Show that if $A^T A$ is invertible then $P = A(A^T A)^{-1} A^T$ is idempotent in the matrix ring.

Fraleigh 22.48 Show the sum of two nilpotent elements of a commutative ring is nilpotent.

Fraleigh 22.49 Show a ring R has no nonzero nilpotent iff $x^2 = 0$ has only $x = 0$.

Fraleigh 22.53 Show the additive group of the subring R_a generated by a is generated by $\{a^n \mid n \in \mathbb{Z}^+\}$.

Fraleigh 22.55 State and prove the n-factor generalization of $\mathbb{Z}_{rs} \cong \prod \mathbb{Z}_{r_i}$ and deduce the full Chinese Remainder Theorem.

Fraleigh 22.56 Investigate $\langle S, +, \cdot \rangle$ with $(S, +)$ a group, $(S^*, \cdot)$ a group, and both distributive laws: show this forces a (skew) field structure.

Fraleigh 23.25 Give five characterizations of the matrices $A \in \mathrm{M}_n(F)$ that are zero divisors.

Fraleigh 23.31 Show a finite ring R with $1 \neq 0$ and no zero divisors is a division ring (left inverse equals right inverse).

Fraleigh 23.35 Show the characteristic of an integral domain is 0 or a prime p.

Fraleigh 26.12 Build the partial ring of quotients $Q(R, T)$ for a commutative R and multiplicative T without zero divisors: show $Q(R, T)$ has unity and every nonzero element of T becomes a unit.

Fraleigh 26.13 Using the previous construction, prove every nonzero commutative ring with a non-zero-divisor can be enlarged to a ring with unity.

Fraleigh 26.15 Describe the ring $Q(\mathbb{Z}, \{2^n\})$ as a subring of $\mathbb{R}$.

Fraleigh 26.16 Describe the ring $Q(3\mathbb{Z}, \{6^n\})$ as a subring of $\mathbb{R}$.

Fraleigh 26.17 For $R = \mathbb{Z}_6$ and $T = \{1, 2, 4\}$, locate where the field-of-quotients construction first fails when T has zero divisors.

Fraleigh 30.16c Prove R/N is commutative iff $rs - sr \in N$ for all $r, s \in R$ (the if-and-only-if).

Fraleigh 30.22 For $\varphi : R \to R'$ and ideal N: show $\varphi[N]$ is an ideal of $\varphi[R]$ but need not be of R', and $\varphi^{-1}[N']$ is an ideal of R.

Fraleigh 30.23 For a field F and $S \subseteq F^n$, show the polynomials in $F[x_1, \ldots, x_n]$ vanishing on S form an ideal.

Fraleigh 30.28 Show a homomorphism $\varphi : R \to R'$ with $\varphi[N] \subseteq N'$ induces a natural map $R/N \to R'/N'$.

Fraleigh 31.27 Prove that if R has unity it cannot contain subrings isomorphic to both $\mathbb{Z}_n$ and $\mathbb{Z}_m$ for $n \neq m$, or give an example.

Fraleigh 31.28 Decide whether a ring with unity can contain subrings isomorphic to fields $\mathbb{Z}_p$ and $\mathbb{Z}_q$ for distinct primes.

Fraleigh 31.29 Decide whether an integral domain can contain subrings isomorphic to $\mathbb{Z}_p$ and $\mathbb{Z}_q$ for $p \neq q$ prime.

Fraleigh 31.30 Prove directly that every maximal ideal of a commutative ring with unity is prime.

Fraleigh 31.31 Show N is maximal in R iff R/N is a simple ring.

Fraleigh 31.32 Prove that for a field F, every proper nontrivial prime ideal of $F[x]$ is maximal.

Fraleigh 31.34 For $f, g \in F[x]$, show $N = \{rf + sg\}$ is an ideal, and if $\deg f \neq \deg g$ with $N \neq F[x]$ then f, g cannot both be irreducible.

Fraleigh 31.35 Use the correspondence of maximal ideals to prove the equivalence of the Fundamental Theorem of Algebra and the Nullstellensatz for $\mathbb{C}[x]$.

Fraleigh 32.9 Find the center of the multiplicative group $\langle \mathbb{H}^*, \cdot \rangle$ of nonzero quaternions.

Fraleigh 32.17 For the maps X, Y of Example 32.3, show $YX - XY = 1$.

Fraleigh 32.19 Find the matrix K making $\varphi : \mathbb{H} \to \mathrm{M}_2(\mathbb{C})$ an isomorphism onto its image, and state what must be checked.

Fraleigh 32.20 For a ring R with unity, prove the ring analogue of Cayley's theorem: R is isomorphic to the subring $\{\lambda_a \mid a \in R\}$ of $\mathrm{End}(R^+)$.

Chapter 8

Euclidean Domains, PIDs, and UFDs

8.1 Euclidean Domains

Euclidean domains

We are at the bottom of the refinement ladder of integral domains. The next three sections strengthen "integral domain" in stages. Section 8.1 isolates the strongest useful hypothesis: a domain equipped with a *division algorithm*. Everything good about $\mathbb{Z}$ and $\mathbb{F}[x]$ – a working Euclidean algorithm, gcds as linear combinations, every ideal principal – flows from this one axiom.

$$\text{ED} \Longrightarrow \text{PID} \Longrightarrow \text{UFD} \Longrightarrow \text{domain}$$

Diagram explanation. Objects: Each node is a *class of integral domains*. From left to right: ED = Euclidean domains (equipped with a norm admitting a Division Algorithm); PID = principal ideal domains (every ideal is principal); UFD = unique factorization domains (every nonzero nonunit factors uniquely into irreducibles up to order and units); domain = arbitrary integral domains (nonzero, no zero divisors). These are nested classes of increasing generality.

Arrows: Each double arrow $\Rightarrow$ means "every ring in the class on the left belongs to the class on the right." They are logical implications, not ring homomorphisms. There is no formula; the arrow records a strict containment of classes.

What commutes: This is a linear chain, not a square, so there is no commutativity condition. The content is: ED $\Rightarrow$ PID $\Rightarrow$ UFD $\Rightarrow$ domain, and all implications are strict (none reverses).

Why it commutes: ED $\Rightarrow$ PID: the Division Algorithm forces every ideal to be generated by the element of minimal norm (proved in this section). PID $\Rightarrow$ UFD: in a PID every irreducible is prime (an irreducible generates a maximal ideal, and maximal ideals are prime), giving unique factorization. UFD $\Rightarrow$ domain: the definition of UFD already assumes the ring is an integral domain.

Why this matters here: Placed at the very opening of Section 8.1, the chain orients the entire chapter. Section 8.1 proves the leftmost implication; Sections 8.2–8.3 fill in the rest and supply counterexamples showing each arrow is strict.

Concrete example: $\mathbb{Z}$ is an ED ($\mathrm{N}(n) = |n|$), hence a PID (every ideal $n\mathbb{Z}$), hence a UFD (prime factorization), hence an integral domain. $\mathbb{Z}[x]$ is a UFD but not a PID (since $\langle 2, x\rangle$ is not principal), showing UFD $\not\Rightarrow$ PID.

Common pitfall: Students sometimes read $\Rightarrow$ as an isomorphism or a ring map. These arrows say nothing about maps between individual rings; they record class containments. Also, the diagram does not assert domain $\Rightarrow$ UFD; that arrow is absent on purpose.

Takeaway: The point of this diagram is that the four principal classes of integral domains form a strict left-to-right hierarchy, and Section 8.1 focuses on Euclidean domains because they sit at the strongest (leftmost) rung.

Definition 8.1.1 (Norm)**.** Let R be an integral domain. A *norm* on R is any function $\mathrm{N}\colon R \to \mathbb{Z}_{\geq 0}$ with $\mathrm{N}(0) = 0$. The norm is *positive* if in addition $\mathrm{N}(a) > 0$ for all $a \neq 0$. (No multiplicativity or other property is assumed; a norm is just a way to measure "size" by a nonnegative integer.)

Definition 8.1.2 (Euclidean domain)**.** An integral domain R is a *Euclidean domain* (ED) if there is a norm N on R admitting a *Division Algorithm*: for every $a, b \in R$ with $b \neq 0$ there exist $q, r \in R$ with

$$a = qb + r, \qquad \text{where } r = 0 \ \text{ or } \ \mathrm{N}(r) < \mathrm{N}(b).$$

We call q the *quotient* and r the *remainder*. Uniqueness of q, r is *not* required.

Remark 8.1.1. The remainder need not be unique. In $\mathbb{Z}$ with $\mathrm{N}(n) = |n|$ we may write $5 = 1 \cdot 3 + 2$ *or* $5 = 2 \cdot 3 + (-1)$; both have $|r| < |3|$. The definition demands only that *some* valid (q, r) exists, not a canonical one.

Definition 8.1.3 (Flagship examples)**.** Each of the following is a Euclidean domain.

(a) $\mathbb{Z}$, with $\mathrm{N}(n) = |n|$. Division with remainder is grade-school division.

(b) Any field $\mathbb{F}$, with $\mathrm{N}(a) = 0$ for all a (or $\mathrm{N}(a) = 1$ for $a \neq 0$): for $b \neq 0$ take $q = ab^{-1}$, $r = 0$. Fields are (degenerately) Euclidean.

(c) $\mathbb{F}[x]$ for a field $\mathbb{F}$, with $\mathrm{N}(f) = \deg f$ (and $\mathrm{N}(0) = 0$). This is polynomial long division; it works precisely because the leading coefficient of b is a unit. (Theorem 8.1.8 below.)

(d) $\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$, the Gaussian integers, with $\mathrm{N}(a + bi) = a^2 + b^2$. Division is "divide in $\mathbb{C}$, then round to the nearest lattice point" (Theorem 8.1.12 below).

Caution. "Has a norm" is not the same as "is Euclidean." *Every* integral domain carries the trivial norm $\mathrm{N}(a) = 0$. Being Euclidean is about the existence of a norm for which the Division Algorithm *holds*. Conversely a ring can fail to be Euclidean for *every* possible norm (Section 8.2: $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$); the tool for proving such a thing is the universal side divisor, below.

The Euclidean algorithm and Bezout

In a Euclidean domain the Division Algorithm can be iterated to extract greatest common divisors. Recall d is a *greatest common divisor* of a, b if $d \mid a$, $d \mid b$, and any common divisor d' has $d' \mid d$. In a general domain a gcd need not exist; in an ED it always does, and it is the last nonzero remainder.

Theorem 8.1.4 (Euclidean Algorithm)**.** *Let R be a Euclidean domain and $a, b \in R$ with $b \neq 0$. Apply the Division Algorithm repeatedly:*

$$\begin{aligned}
a &= q_0 b + r_0, && \mathrm{N}(r_0) < \mathrm{N}(b),\\
b &= q_1 r_0 + r_1, && \mathrm{N}(r_1) < \mathrm{N}(r_0),\\
r_0 &= q_2 r_1 + r_2, && \mathrm{N}(r_2) < \mathrm{N}(r_1),\\
&\vdots\\
r_{k-2} &= q_k r_{k-1} + r_k, && \mathrm{N}(r_k) < \mathrm{N}(r_{k-1}),\\
r_{k-1} &= q_{k+1} r_k + 0.
\end{aligned}$$

The remainders have strictly decreasing nonnegative-integer norms, so the process terminates with a zero remainder. The last nonzero remainder r_k is a gcd of a and b. (If already $r_0 = 0$, then $b \mid a$ and b itself is a gcd.)

Proof. Termination: $\mathrm{N}(r_0) > \mathrm{N}(r_1) > \cdots \geq 0$ is a strictly decreasing sequence of nonnegative integers, hence finite. Let r_k be the last nonzero remainder. Reading the *last* equation $r_{k-1} = q_{k+1} r_k$ gives $r_k \mid r_{k-1}$. Substituting upward, $r_k \mid r_{k-2} = q_k r_{k-1} + r_k$, then $r_k \mid r_{k-3}$, …, and finally $r_k \mid b$ and $r_k \mid a$. So r_k is a common divisor. Conversely, if $d' \mid a$ and $d' \mid b$, then reading the equations *downward*, $d' \mid r_0 = a - q_0 b$, then $d' \mid r_1$, …, $d' \mid r_k$. Hence r_k is a greatest common divisor. □

Theorem 8.1.5 (Bezout / $(a,b)=(d)$ in an ED)**.** *Let R be a Euclidean domain and $a,b\in R$ not both zero, with gcd d. Then $\langle d\rangle=\langle a,b\rangle$ as ideals; equivalently there exist $x,y\in R$ with*

$$d=ax+by.$$

Proof. Back-substitute the Euclidean Algorithm. From $r_k=r_{k-2}-q_kr_{k-1}$, and recursively expressing each r_j as an R-combination of a,b, we obtain $d=r_k=ax+by$ for some $x,y\in R$. Thus $d\in\langle a,b\rangle$, so $\langle d\rangle\subseteq\langle a,b\rangle$. The reverse inclusion is $d\mid a$ and $d\mid b$, i.e. $a,b\in\langle d\rangle$. Hence $\langle a,b\rangle=\langle d\rangle$. □

Method (Division / Euclidean / Bezout recipe)**.** *Trigger.* You are in $\mathbb{Z}$, $\mathbb{F}[x]$, or $\mathbb{Z}[i]$ (anything with a stated norm and Division Algorithm) and you need to (a) divide with remainder, (b) compute a gcd, or (c) write the gcd as a linear combination.

1. **One division.** To compute q,r in $a=qb+r$:
   - $\mathbb{Z}$: $q=\lfloor a/b\rfloor$ (or nearest integer), $r=a-qb$.
   - $\mathbb{F}[x]$: long division; cancel the leading term repeatedly until $\deg r<\deg b$.
   - $\mathbb{Z}[i]$: form $a/b=\frac{a\bar{b}}{\mathrm{N}(b)}\in\mathbb{Q}(i)$, round each coordinate to the nearest integer to get q, set $r=a-qb$.
2. **gcd.** Iterate: replace $(a,b)\mapsto(b,r)$ until $r=0$. The last nonzero remainder is the gcd (unique up to a unit multiple).
3. **Bezout.** Solve each division equation for its remainder and back-substitute from the bottom up, eliminating intermediate remainders, until only a,b remain.
4. *Check.* Recompute $ax+by$ and confirm it equals d; confirm $d\mid a$ and $d\mid b$.

Worked Example 8.1.6 (Euclidean algorithm in $\mathbb{Z}$ with Bezout)**.** Compute $\gcd(3220,2299)$ in $\mathbb{Z}$ and write it as $3220x+2299y$.

Recognition. This is $\mathbb{Z}$ with $\mathrm{N}(n)=|n|$, an ED; the Euclidean Algorithm gives the gcd and back-substitution gives Bezout.

Solution. Divisions:

$$\begin{aligned}3220&=1\cdot2299+921,\\2299&=2\cdot921+457,\\921&=2\cdot457+7,\\457&=65\cdot7+2,\\7&=3\cdot2+1,\\2&=2\cdot1+0.\end{aligned}$$

Last nonzero remainder: gcd $=1$, so $3220,2299$ are coprime. Back-substitute:

$$\begin{aligned}1&=7-3\cdot2\\&=7-3(457-65\cdot7)=196\cdot7-3\cdot457\\&=196(921-2\cdot457)-3\cdot457=196\cdot921-395\cdot457\\&=196\cdot921-395(2299-2\cdot921)=986\cdot921-395\cdot2299\\&=986(3220-2299)-395\cdot2299=986\cdot3220-1381\cdot2299.\end{aligned}$$

Check. $986\cdot3220=3{,}174{,}920$ and $1381\cdot2299=3{,}174{,}919$, so $986\cdot3220-1381\cdot2299=1$. Thus $x=986$, $y=-1381$.

Worked Example 8.1.7 (A non-coprime gcd in $\mathbb{Z}$)**.** Compute $\gcd(252,198)$ and a Bezout expression.

Recognition. Same machine; here the gcd exceeds 1, so it shows up as the last nonzero remainder >1.

Solution.

$$252=1\cdot198+54,\qquad198=3\cdot54+36,\qquad54=1\cdot36+18,\qquad36=2\cdot18+0.$$

So $\gcd(252, 198) = 18$. Back-substitute:

$$18 = 54 - 36 = 54 - (198 - 3 \cdot 54) = 4 \cdot 54 - 198 = 4(252 - 198) - 198 = 4 \cdot 252 - 5 \cdot 198.$$

Check. $4 \cdot 252 = 1008$, $5 \cdot 198 = 990$, difference 18. And $252 = 18 \cdot 14$, $198 = 18 \cdot 11$, confirming $18 \mid 252, 198$.

Division in $\mathbb{F}[x]$

Theorem 8.1.8 ($\mathbb{F}[x]$ is Euclidean)**.** *If $\mathbb{F}$ is a field then $\mathbb{F}[x]$ with $\mathrm{N}(f) = \deg f$ is a Euclidean domain: for $a, b \in \mathbb{F}[x]$ with $b \neq 0$ there are unique q, r with $a = qb + r$ and $r = 0$ or $\deg r < \deg b$.*

Proof. Existence by induction on $\deg a$. If $a = 0$ or $\deg a < \deg b$, take $q = 0$, $r = a$. Otherwise let $a = \alpha x^n + \cdots$ and $b = \beta x^m + \cdots$ with $n \geq m$. Because $\mathbb{F}$ is a field, β^{-1} exists, so $a' := a - \alpha\beta^{-1}x^{n-m}b$ kills the leading term and has $\deg a' < \deg a$. By induction $a' = q'b + r$ with $r = 0$ or $\deg r < \deg b$; then $a = (\alpha\beta^{-1}x^{n-m} + q')b + r$. Uniqueness: if $q_1 b + r_1 = q_2 b + r_2$ then $(q_1 - q_2)b = r_2 - r_1$; if $q_1 \neq q_2$ the left side has degree $\geq \deg b$ while the right has degree $< \deg b$, a contradiction. So $q_1 = q_2$ and $r_1 = r_2$. □

Caution. The leading coefficient of b must be a *unit*. Over $\mathbb{Z}$ (not a field) you cannot divide x by $2x$ inside $\mathbb{Z}[x]$ with a smaller-degree remainder, and indeed $\mathbb{Z}[x]$ is *not* a Euclidean domain (it is not even a PID, since $\langle 2, x\rangle$ is not principal). The field hypothesis is what makes $\mathbb{F}[x]$ Euclidean.

Worked Example 8.1.9 (Long division in $\mathbb{Q}[x]$)**.** Divide $a = x^4 - 3x^3 + 2x^2 + 4x - 1$ by $b = x^2 - x + 1$ in $\mathbb{Q}[x]$.

Recognition. $\mathbb{Q}$ is a field, so $\mathbb{Q}[x]$ is Euclidean with $\mathrm{N} = \deg$; perform long division until the remainder has degree < 2.

Solution.

$$\begin{aligned} x^4 - 3x^3 + 2x^2 + 4x - 1 &= (x^2)(x^2 - x + 1) + (-2x^3 + x^2 + 4x - 1) \\ &= (x^2 - 2x)(x^2 - x + 1) + (-x^2 + 6x - 1) \\ &= (x^2 - 2x - 1)(x^2 - x + 1) + 5x. \end{aligned}$$

So $q = x^2 - 2x - 1$ and $r = 5x$, with $\deg r = 1 < 2 = \deg b$. *Check.* $(x^2 - 2x - 1)(x^2 - x + 1) = x^4 - 3x^3 + 2x^2 - x - 1$; adding $5x$ gives $x^4 - 3x^3 + 2x^2 + 4x - 1 = a$. ■

Worked Example 8.1.10 (Division over a finite field $\mathbb{F}_2$)**.** Divide $a = x^4 + x^3 + 1$ by $b = x^2 + x + 1$ in $\mathbb{F}_2[x]$ (coefficients mod 2).

Recognition. $\mathbb{F}_2 = \mathbb{Z}/2\mathbb{Z}$ is a field, so $\mathbb{F}_2[x]$ is Euclidean; reduce every coefficient mod 2 as you go.

Solution. Subtract (= add, in characteristic 2) leading terms. First $(x^2)(x^2 + x + 1) = x^4 + x^3 + x^2$, and a minus this is $(x^4 + x^3 + 1) - (x^4 + x^3 + x^2) = x^2 + 1$ (in $\mathbb{F}_2$, $-x^2 = x^2$):

$$\begin{aligned} x^4 + x^3 + 1 &= (x^2)(x^2 + x + 1) + (x^2 + 1) \\ &= (x^2 + 1)(x^2 + x + 1) + x. \end{aligned}$$

Indeed $(x^2 + 1)(x^2 + x + 1) = x^4 + x^3 + x^2 + x^2 + x + 1 = x^4 + x^3 + x + 1$ over $\mathbb{F}_2$ (the x^2 terms cancel), and adding the remainder x recovers $x^4 + x^3 + 1$. So $q = x^2 + 1$, $r = x$, $\deg r = 1 < 2$. *Check.* $a - qb = x$, degree $1 < 2$. ■

Worked Example 8.1.11 (gcd in $\mathbb{F}[x]$ via the Euclidean algorithm)**.** Compute $\gcd(x^3 - 1,\ x^2 - 1)$ in $\mathbb{Q}[x]$ and express it as a combination.

Recognition. Two polynomials over a field: iterate division. The (monic) last nonzero remainder is the gcd.

Solution.

$$x^3 - 1 = x\,(x^2 - 1) + (x - 1), \qquad x^2 - 1 = (x + 1)(x - 1) + 0.$$

Last nonzero remainder $x - 1$, so $\gcd = x - 1$. Bezout from the first line:

$$x - 1 = (x^3 - 1) - x\,(x^2 - 1),$$

i.e. the coefficients are 1 and $-x$. *Check.* $x - 1 \mid x^2 - 1 = (x - 1)(x + 1)$ and $x - 1 \mid x^3 - 1 = (x - 1)(x^2 + x + 1)$. ■

Division in the Gaussian integers $\mathbb{Z}[i]$

Theorem 8.1.12 ($\mathbb{Z}[i]$ is Euclidean)**.** *The Gaussian integers $\mathbb{Z}[i]$ with $\mathrm{N}(a+bi)=a^2+b^2$ form a Euclidean domain. Concretely, for $\alpha,\beta\in\mathbb{Z}[i]$ with $\beta\neq 0$ there exist $q,r\in\mathbb{Z}[i]$ with $\alpha=q\beta+r$ and $\mathrm{N}(r)\le\frac{1}{2}\,\mathrm{N}(\beta)<\mathrm{N}(\beta)$.*

Proof. Compute the exact quotient in $\mathbb{Q}(i)$: $\frac{\alpha}{\beta}=\frac{\alpha\overline{\beta}}{\mathrm{N}(\beta)}=s+ti$ with $s,t\in\mathbb{Q}$. Pick integers m,n nearest to s,t, so $|s-m|\le\frac{1}{2}$ and $|t-n|\le\frac{1}{2}$, and set $q=m+ni$, $r=\alpha-q\beta$. Then $\frac{r}{\beta}=(s-m)+(t-n)i$, so

$$\mathrm{N}(r)=\mathrm{N}(\beta)\big((s-m)^2+(t-n)^2\big)\le\mathrm{N}(\beta)\big(\tfrac{1}{4}+\tfrac{1}{4}\big)=\tfrac{1}{2}\,\mathrm{N}(\beta)<\mathrm{N}(\beta).$$

Since $r=\alpha-q\beta\in\mathbb{Z}[i]$, this is a valid division step. □

Remark 8.1.2. N on $\mathbb{Z}[i]$ is multiplicative: $\mathrm{N}(\alpha\beta)=\mathrm{N}(\alpha)\,\mathrm{N}(\beta)$ (it is $|\alpha|^2$). Consequently the units of $\mathbb{Z}[i]$ are exactly the elements of norm 1, namely $\mathbb{Z}[i]^\times=\{\pm1,\pm i\}$, and $\beta\mid\alpha$ forces $\mathrm{N}(\beta)\mid\mathrm{N}(\alpha)$ in $\mathbb{Z}$ – a powerful divisibility test.

Method (Dividing in $\mathbb{Z}[i]$ (round to nearest lattice point))**.** *Trigger.* You must divide, gcd, or factor in $\mathbb{Z}[i]$.

1. Multiply numerator and denominator by $\overline{\beta}$: $\dfrac{\alpha}{\beta}=\dfrac{\alpha\overline{\beta}}{\mathrm{N}(\beta)}=s+ti$.
2. Round: $m=\mathrm{round}(s)$, $n=\mathrm{round}(t)$; set $q=m+ni$.
3. Remainder $r=\alpha-q\beta$. It automatically satisfies $\mathrm{N}(r)<\mathrm{N}(\beta)$.
4. For a gcd, iterate $(\alpha,\beta)\mapsto(\beta,r)$. For factoring, use multiplicativity: if $\mathrm{N}(\alpha)=p$ is a prime in $\mathbb{Z}$, then α is irreducible in $\mathbb{Z}[i]$; factor $\mathrm{N}(\alpha)$ in $\mathbb{Z}$ first to know what norms to look for.

Worked Example 8.1.13 (One division step in $\mathbb{Z}[i]$)**.** Divide $\alpha=4+5i$ by $\beta=1+2i$.

Recognition. $\mathbb{Z}[i]$, $\mathrm{N}=a^2+b^2$: rationalize and round to the nearest Gaussian integer.

Solution. $\mathrm{N}(\beta)=1^2+2^2=5$ and $\overline{\beta}=1-2i$, so

$$\frac{4+5i}{1+2i}=\frac{(4+5i)(1-2i)}{5}=\frac{4-8i+5i+10}{5}=\frac{14-3i}{5}=2.8-0.6i.$$

Round $2.8\to3$ and $-0.6\to-1$, so $q=3-i$. Then

$$r=\alpha-q\beta=(4+5i)-(3-i)(1+2i)=(4+5i)-(3+6i-i+2)=(4+5i)-(5+5i)=-1.$$

So $4+5i=(3-i)(1+2i)+(-1)$ with $\mathrm{N}(r)=1<5=\mathrm{N}(\beta)$. *Check.* $(3-i)(1+2i)=5+5i$, and $5+5i-1=4+5i=\alpha$. ■

Worked Example 8.1.14 (Euclidean algorithm in $\mathbb{Z}[i]$)**.** Compute a gcd of $\alpha=11+3i$ and $\beta=1+8i$.

Recognition. Iterate Gaussian division; the last nonzero remainder (up to a unit) is the gcd.

Solution. Step 1. $\mathrm{N}(1+8i)=65$, $\dfrac{11+3i}{1+8i}=\dfrac{(11+3i)(1-8i)}{65}=\dfrac{35-85i}{65}=0.54-1.31i$, round to $q=1-i$:

$$r_0=(11+3i)-(1-i)(1+8i)=(11+3i)-(9+7i)=2-4i,\quad \mathrm{N}=20<65.$$

Step 2. Divide $1+8i$ by $2-4i$: $\mathrm{N}(2-4i)=20$, $\dfrac{(1+8i)(2+4i)}{20}=\dfrac{-30+20i}{20}=-1.5+i$, round to $q=-2+i$:

$$r_1=(1+8i)-(-2+i)(2-4i)=(1+8i)-(0+10i)=1-2i,\quad \mathrm{N}=5<20.$$

Step 3. Divide $2-4i$ by $1-2i$: $\dfrac{(2-4i)(1+2i)}{5}=\dfrac{10}{5}=2$, so $q=2$, $r_2=(2-4i)-2(1-2i)=0$. The last nonzero remainder is $\gcd=1-2i$. *Check.* $(1-2i)(1+5i)=11+3i$ and $(1-2i)(-3+2i)=1+8i$, so $1-2i$ divides both; $\mathrm{N}(1-2i)=5$ divides $\mathrm{N}(11+3i)=130$ and $\mathrm{N}(1+8i)=65$. ■

Worked Example 8.1.15 (Factoring a Gaussian integer)**.** Factor $\alpha = 4 + 7i$ into irreducibles in $\mathbb{Z}[i]$.

Recognition. Multiplicativity of N: factor $\mathrm{N}(\alpha)$ in $\mathbb{Z}$, then split each rational prime into Gaussian primes and match.

Solution. $\mathrm{N}(4 + 7i) = 4^2 + 7^2 = 65 = 5 \cdot 13$. In $\mathbb{Z}[i]$, $5 = (2 + i)(2 - i)$ and $13 = (3 + 2i)(3 - 2i)$, and each factor has prime norm (5 resp. 13), hence is irreducible. Since $\mathrm{N}(\alpha) = 5 \cdot 13$, α is a product of one norm-5 and one norm-13 irreducible. Try $(2 + i)(3 + 2i) = 6 + 4i + 3i - 2 = 4 + 7i$. **Hit.**

$$4 + 7i = (2 + i)(3 + 2i), \qquad \mathrm{N} : 65 = 5 \cdot 13.$$

Check. $(2 + i)(3 + 2i) = 6 + 4i + 3i + 2i^2 = 6 + 7i - 2 = 4 + 7i$. ■Each factor has prime norm so is irreducible; the factorization is complete (up to units $\pm 1, \pm i$).

Worked Example 8.1.16 (A norm divisibility test)**.** Show $1 + 2i$ does *not* divide $1 + 3i$ in $\mathbb{Z}[i]$, but $1 + 2i$ *does* divide 5.

Recognition. $\beta \mid \alpha \Rightarrow \mathrm{N}(\beta) \mid \mathrm{N}(\alpha)$ in $\mathbb{Z}$; if the norm fails, divisibility fails. When the norm passes, finish by exact division.

Solution. $\mathrm{N}(1 + 2i) = 5$. For $1 + 3i$: $\mathrm{N}(1 + 3i) = 10$, and $5 \mid 10$, so the norm test is inconclusive – do the division: $\dfrac{1 + 3i}{1 + 2i} = \dfrac{(1 + 3i)(1 - 2i)}{5} = \dfrac{7 + i}{5} = 1.4 + 0.2i \notin \mathbb{Z}[i]$. So $1 + 2i$ does *not* divide $1 + 3i$: the norm test passed but the quotient is not a Gaussian integer. (Moral: a divisible norm is necessary, not sufficient.) For 5: $\dfrac{5}{1 + 2i} = \dfrac{5(1 - 2i)}{5} = 1 - 2i \in \mathbb{Z}[i]$, so $1 + 2i \mid 5$ with $5 = (1 + 2i)(1 - 2i)$. *Check.* $(1 + 2i)(1 - 2i) = 1 + 4 = 5$. ■

Every ideal of a Euclidean domain is principal

Proposition 8.1.17 (ED ⇒ PID)**.** *Every ideal in a Euclidean domain R is principal. More precisely, if $I \neq (0)$ then $I = \langle d \rangle$ where d is any nonzero element of I of* minimal norm*.*

Proof. The zero ideal is $(0) = \langle 0 \rangle$. Let $I \neq (0)$. The set $\{\mathrm{N}(a) : a \in I,\ a \neq 0\}$ is a nonempty subset of $\mathbb{Z}_{\geq 0}$, so by well-ordering it has a least element; choose $d \in I$, $d \neq 0$, achieving it, i.e. $\mathrm{N}(d)$ is minimal. Clearly $\langle d \rangle \subseteq I$. Conversely, take any $a \in I$ and divide: $a = qd + r$ with $r = 0$ or $\mathrm{N}(r) < \mathrm{N}(d)$. Now $r = a - qd \in I$ (as $a, qd \in I$). If $r \neq 0$ then $\mathrm{N}(r) < \mathrm{N}(d)$ contradicts the minimality of $\mathrm{N}(d)$ among nonzero elements of I. Hence $r = 0$, so $a = qd \in \langle d \rangle$. Therefore $I \subseteq \langle d \rangle$, giving $I = \langle d \rangle$. □

Remark 8.1.3 (The inclusion is strict elsewhere). This is exactly the ED ⇒ PID arrow of the hierarchy. The remaining arrows (PID ⇒ UFD, and the strictness of every inclusion) are Sections 8.2–8.3. For context: $\mathbb{Z}[x]$ is a UFD that is not a PID (so UFD ⇏ PID), and $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a PID that is *not* Euclidean (so PID ⇏ ED). The latter is proved using universal side divisors.

$$\text{ED} \xRightarrow{\text{Sec. 8.1}} \text{PID} \xRightarrow{\text{Sec. 8.3}} \text{UFD}$$

Diagram explanation. Objects: Three classes of integral domains: ED (Euclidean domains), PID (principal ideal domains), UFD (unique factorization domains). Unlike the opening diagram, this version omits the bare "domain" node and carries explicit reference labels, serving as a precise theorem-map.

Arrows: Two labeled double implications. The label "Sec. 8.1" on the first arrow points to this section, where it is proved that every ED is a PID, witnessed by the minimal-norm generator argument. The label "Sec. 8.3" on the second arrow refers to Section 8.3, where the PID ⇒ UFD implication is established. Neither arrow represents a ring homomorphism; both are logical entailments between domain classes.

What commutes: Again a linear chain; the relevant statement is the transitivity ED ⇒ UFD, which follows by composing the two labeled arrows. Neither implication reverses: $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a PID but not an ED; $\mathbb{Z}[x]$ is a UFD but not a PID.

Why it commutes: Prop. 8.1 (proved just above): take $d \in I$ of minimal norm; the Division Algorithm forces every other element of I to be a multiple of d, so $I = \langle d \rangle$. Section 8.2 then uses PID to get irreducible ⇔ prime, which yields unique factorization.

Why this matters here: This annotated version of the opening diagram closes the remark that justifies why each arrow is strict. By attaching theorem numbers, it lets the reader immediately locate the proof of each step, making the chapter's logical structure self-documenting.

Concrete example: $\mathbb{Z}[i]$ (Gaussian integers) is an ED (proved in this section via the rounding argument), hence a PID (Prop. 8.1), hence a UFD (Section 8.3). The chain is witnessed concretely: $\langle 11+3i, 1+8i\rangle = \langle 1-2i\rangle$ in $\mathbb{Z}[i]$.

Common pitfall: Seeing "Prop. 8.1" on the first arrow, students sometimes think the proposition *is* the implication diagram. The diagram is a schematic summary; the proposition is the actual proof that every ideal of an ED has a minimal-norm generator. The diagram does not prove the result—it just records where it lives.

Takeaway: The point of this diagram is that the two-step implication ED $\xRightarrow{\text{Prop. 8.1}}$ PID $\xRightarrow{8.3}$ UFD maps each class to its proof reference, so the reader knows exactly which theorems establish the refinement hierarchy.

Worked Example 8.1.18 (Reading off the generator from minimal norm in $\mathbb{Z}$)**.** Use the proposition to find a generator of $I = \langle 12, 30\rangle \subseteq \mathbb{Z}$.

Recognition. $\mathbb{Z}$ is Euclidean; the generator is the nonzero element of I of least absolute value, which the Euclidean algorithm produces as gcd.

Solution. $I = \langle 12, 30\rangle = \{12s + 30t : s, t \in \mathbb{Z}\}$. The smallest positive element is $\gcd(12, 30)$: $30 = 2 \cdot 12 + 6$, $12 = 2 \cdot 6 + 0$, so gcd $= 6$ and $6 = 30 - 2 \cdot 12 \in I$. By the proposition $I = \langle 6\rangle$. *Check.* $12 = 6 \cdot 2$, $30 = 6 \cdot 5 \in \langle 6\rangle$, and $6 \in I$, so $\langle 12, 30\rangle = \langle 6\rangle$. ■

Worked Example 8.1.19 (Principal ideal in $\mathbb{Q}[x]$)**.** Show $I = \langle x^3 - 1,\ x^2 - 1\rangle \subseteq \mathbb{Q}[x]$ is principal and find a generator.

Recognition. $\mathbb{Q}[x]$ is Euclidean (N = deg); the generator is the nonzero element of least degree in I, i.e. the gcd.

Solution. From the earlier worked example $\gcd(x^3 - 1, x^2 - 1) = x - 1$ and $x - 1 = (x^3 - 1) - x(x^2 - 1) \in I$. Both generators lie in $\langle x - 1\rangle$ since $x^3 - 1 = (x - 1)(x^2 + x + 1)$ and $x^2 - 1 = (x - 1)(x + 1)$. Hence $I = \langle x - 1\rangle$. *Check.* $x - 1 \in I$ and $I \subseteq \langle x - 1\rangle$, so equality. ■

Worked Example 8.1.20 (A principal ideal in $\mathbb{Z}[i]$)**.** Show $I = \langle 11 + 3i,\ 1 + 8i\rangle \subseteq \mathbb{Z}[i]$ is principal and find a generator.

Recognition. $\mathbb{Z}[i]$ is Euclidean; the generator is a Gaussian gcd of the two elements.

Solution. From the Gaussian Euclidean algorithm above, $\gcd(11 + 3i, 1 + 8i) = 1 - 2i$, with $11 + 3i = (1 - 2i)(1 + 5i)$ and $1 + 8i = (1 - 2i)(-3 + 2i)$. Hence both generators lie in $\langle 1 - 2i\rangle$, and (by Bezout in the ED) $1 - 2i \in I$. Therefore $I = \langle 1 - 2i\rangle$. *Check.* $\mathrm{N}(1 - 2i) = 5$ divides $\mathrm{N}(11 + 3i) = 130$ and $\mathrm{N}(1 + 8i) = 65$; explicit quotients $1 + 5i$ and $-3 + 2i$ confirm divisibility. ■

Universal side divisors: a non-Euclidean test

To prove a domain is *not* Euclidean (for any norm whatsoever) we need an obstruction that does not mention a particular norm. D&F's device is the universal side divisor.

Definition 8.1.21 (Universal side divisor)**.** Let R be an integral domain and $\tilde{R} = R^\times \cup \{0\}$. A nonzero nonunit $u \in R$ is a *universal side divisor* if for every $x \in R$ there is some $z \in \tilde{R}$ with $u \mid (x - z)$ in R – i.e. u divides x "up to a unit or zero." Equivalently, u divides $x - z$ for some z that is 0 or a unit.

Proposition 8.1.22 (Existence of a universal side divisor in any ED)**.** *Let R be a Euclidean domain that is not a field. Then R possesses a universal side divisor.*

Proof. Choose u a nonzero nonunit of *minimal norm* among all nonzero nonunits (such u exists by well-ordering of norms; the set is nonempty as R is not a field). For any $x \in R$ divide: $x = qu + r$ with $r = 0$ or $\mathrm{N}(r) < \mathrm{N}(u)$. If $r = 0$ then $u \mid x$, take $z = 0$. If $r \neq 0$ then $\mathrm{N}(r) < \mathrm{N}(u)$ forces r to be a unit (by minimality of $\mathrm{N}(u)$ among nonzero nonunits, anything of strictly smaller positive norm is a unit). Then $u \mid (x - r)$ with $r \in R^\times$, so $z = r$ works. Hence u is a universal side divisor. □

Method (Proving "not Euclidean" via side divisors)**.** *Trigger.* You suspect a domain R (not a field) is not Euclidean and want a proof that rules out *all* norms.

1. Identify $R^\times$ (often just $\{\pm 1\}$), so $\tilde{R} = R^\times \cup \{0\}$ is small.
2. Find *all* candidate universal side divisors by applying the definition to one well-chosen x: a universal side divisor u divides $x - z$ for some $z \in \tilde{R}$, so it is a nonunit divisor of one of these finitely many elements (e.g. for $x = 2$ and $\tilde{R} = \{0, \pm 1\}$: a divisor of 2 or 3). Do not simply take the elements of smallest field norm: the norm in the Proposition is an unknown Euclidean norm, not the field norm.
3. For each candidate u, exhibit an x such that $u \nmid (x - z)$ for *every* $z \in \tilde{R}$. This kills u.
4. If no universal side divisor exists, the contrapositive of the Proposition shows R is not Euclidean (for any norm).

Theorem 8.1.23 (A PID that is not Euclidean (Section 8.2, stated))**.** *The ring* $R = \mathbb{Z}\left[\frac{1+\sqrt{-19}}{2}\right]$ *is a principal ideal domain but is* not *a Euclidean domain (for any norm).*

Sketch. One shows $R^\times = \{\pm 1\}$, so $\tilde{R} = \{0, \pm 1\}$. If R were Euclidean it would have a universal side divisor u. Taking $x = 2$ in the definition, u divides 2, 1 or 3, and $u \nmid 1$ since u is not a unit. The field norm $\mathrm{N}(a + b\frac{1+\sqrt{-19}}{2}) = a^2 + ab + 5b^2$ never equals 2 or 3, so 2 and 3 are irreducible in R and $u \in \{\pm 2, \pm 3\}$. But neither ± 2 nor ± 3 is a universal side divisor: taking $x = \frac{1+\sqrt{-19}}{2}$, one checks $u \nmid (x - z)$ for $z \in \{0, 1, -1\}$ in each case (the relevant norm equations have no solution in R). With no universal side divisor, the Proposition forces R non-Euclidean. That R is nonetheless a PID is shown by a Dedekind–Hasse style norm argument; the details are in Section 8.2. □

Caution. "Not Euclidean" is a strong claim: it must hold for *every* possible norm, not just the obvious field norm. That is exactly why the universal side divisor (a norm-free condition) is the right tool – ruling out one norm proves nothing, but the absence of a universal side divisor rules out all norms at once.

Worked Example 8.1.24 ($\mathbb{Z}$ has a universal side divisor)**.** Exhibit a universal side divisor in $\mathbb{Z}$.

Recognition. $\mathbb{Z}$ is a non-field ED, so one must exist; the Proposition says to take a nonzero nonunit of minimal norm.

Solution. Units are ± 1, so $\tilde{\mathbb{Z}} = \{0, 1, -1\}$. The nonzero nonunits of least $|\cdot|$ are ± 2; take $u = 2$. For any $x \in \mathbb{Z}$, divide by 2: the remainder is 0 or 1, i.e. $x \equiv 0$ or $1 \pmod 2$. If x even, $2 \mid (x - 0)$; if x odd, $2 \mid (x - 1)$. Since $0, 1 \in \tilde{\mathbb{Z}}$, $u = 2$ is a universal side divisor. *Check.* Every residue mod 2 is 0 or a unit (1), exactly as the Proposition predicts. ■

Worked Example 8.1.25 (A universal side divisor in $\mathbb{Q}[x]$)**.** Find a universal side divisor in $\mathbb{Q}[x]$.

Recognition. Non-field ED; minimal-norm nonzero nonunit means least positive degree, i.e. degree 1.

Solution. $\mathbb{Q}[x]^\times = \mathbb{Q}^\times$ (nonzero constants), so $\tilde{R} = \mathbb{Q}^\times \cup \{0\} = \mathbb{Q}$. Take $u = x$. For any $f \in \mathbb{Q}[x]$, divide by x: $f = x\,g + f(0)$ with remainder the constant $f(0) \in \mathbb{Q} = \tilde{R}$. Thus $x \mid (f - f(0))$, so $u = x$ is a universal side divisor. *Check.* The remainder $f(0)$ is always 0 or a unit (a nonzero constant), matching the definition. ■

Exercises (from the text).

1. For each of the following five pairs of integers a and b, determine their greatest common divisor d and write d as a linear combination $ax + by$ of a and b.
   (a) $a = 20$, $b = 13$.
   (b) $a = 69$, $b = 372$.
   (c) $a = 11391$, $b = 5673$.
   (d) $a = 507885$, $b = 60808$.
   (e) $a = 91442056588823$, $b = 779086434385541$ (the Euclidean Algorithm requires only 7 steps for these integers).

2. For each of the following pairs of integers a and n, show that a is relatively prime to n and determine the inverse of a mod n (cf. D&F, Section 0.3).

   (a) $a = 13$, $n = 20$.

   (b) $a = 69$, $n = 89$.

   (c) $a = 1891$, $n = 3797$.

   (d) $a = 6003722857$, $n = 77695236973$ (the Euclidean Algorithm requires only 3 steps for these integers).

3. Let R be a Euclidean Domain. Let m be the minimum integer in the set of norms of nonzero elements of R. Prove that every nonzero element of R of norm m is a unit. Deduce that a nonzero element of norm zero (if such an element exists) is a unit.

4. Let R be a Euclidean Domain.

   (a) Prove that if $(a, b) = 1$ and a divides bc, then a divides c. More generally, show that if a divides bc with nonzero a, b then $\frac{a}{(a,b)}$ divides c.

   (b) Consider the Diophantine Equation $ax + by = N$ where a, b and N are integers and a, b are nonzero. Suppose x_0, y_0 is a solution: $ax_0 + by_0 = N$. Prove that the full set of solutions to this equation is given by

   $$x = x_0 + \frac{b}{(a,b)}t \qquad y = y_0 - \frac{a}{(a,b)}t$$

   as t ranges over the integers. [If x, y is a solution to $ax + by = N$, show that $a(x - x_0) = b(y_0 - y)$ and use (a).]

5. Determine all integer solutions of the following equations:

   (a) $2x + 4y = 5$

   (b) $17x + 29y = 31$

   (c) $85x + 145y = 505$.

6. (*The Postage Stamp Problem*) Let a and b be two relatively prime positive integers. Prove that every sufficiently large positive integer N can be written as a linear combination $ax + by$ of a and b where x and y are both nonnegative, i.e., there is an integer N_0 such that for all $N \geq N_0$ the equation $ax + by = N$ can be solved with both x and y nonnegative integers. Prove in fact that the integer $ab - a - b$ cannot be written as a nonnegative integer combination of a and b but that every integer greater than $ab - a - b$ is a nonnegative integer combination of a and b (so every "postage" greater than $ab - a - b$ can be obtained using only stamps in denominations a and b).

7. Find a generator for the ideal $(85, 1 + 13i)$ in $\mathbb{Z}[i]$, i.e., a greatest common divisor for 85 and $1 + 13i$, by the Euclidean Algorithm. Do the same for the ideal $(47 - 13i, 53 + 56i)$.

8. Let $F = \mathbb{Q}(\sqrt{D})$ be a quadratic field ($D \neq 0, 1$ a squarefree integer) with associated quadratic integer ring $\mathcal{O} = \mathbb{Z}[\omega]$, where $\omega = \sqrt{D}$ if $D \equiv 2, 3 \pmod 4$ and $\omega = \frac{1+\sqrt{D}}{2}$ if $D \equiv 1 \pmod 4$, and field norm $N(a + b\sqrt{D}) = (a + b\sqrt{D})(a - b\sqrt{D}) = a^2 - Db^2$ $(a, b \in \mathbb{Q})$, as in D&F, Section 7.1.

   (a) Suppose D is -1, -2, -3, -7 or -11. Prove that $\mathcal{O}$ is a Euclidean Domain with respect to N. [Modify the proof for $\mathbb{Z}[i]$ ($D = -1$) in the text. For $D = -3, -7, -11$ prove that every element of F differs from an element in $\mathcal{O}$ by an element whose norm is at most $(1 + |D|)^2/(16|D|)$, which is less than 1 for these values of D. Plotting the points of $\mathcal{O}$ in $\mathbb{C}$ may be helpful.]

   (b) Suppose that $D = -43$, -67, or -163. Prove that $\mathcal{O}$ is not a Euclidean Domain with respect to any norm. [Apply the same proof as for $D = -19$ in the text.]

9. Prove that the ring of integers $\mathcal{O} = \mathbb{Z}[\sqrt{2}]$ in the quadratic field $\mathbb{Q}(\sqrt{2})$ is a Euclidean Domain with respect to the norm given by the absolute value of the field norm $N(a + b\sqrt{2}) = a^2 - 2b^2$ (cf. the previous exercise).

10. Prove that the quotient ring $\mathbb{Z}[i]/I$ is finite for any nonzero ideal I of $\mathbb{Z}[i]$. [Use the fact that $I = (\alpha)$ for some nonzero α and then use the Division Algorithm in this Euclidean Domain to see that every coset of I is represented by an element of norm less than $N(\alpha)$.]

Practice problems.

1. Use the Euclidean algorithm in $\mathbb{Z}$ to compute $\gcd(2024, 748)$, and express it in the form $2024s + 748t$ with $s, t \in \mathbb{Z}$.
2. Use the Euclidean algorithm in $\mathbb{Z}$ to compute $\gcd(1573, 308)$, and write it as an integer combination of 1573 and 308.
3. In $\mathbb{Q}[x]$, compute $\gcd\big(x^3 + 2x^2 - x - 2,\ x^3 - x^2 - 4x + 4\big)$ (normalized to be monic) and express it as $a(x)\big(x^3 + 2x^2 - x - 2\big) + b(x)\big(x^3 - x^2 - 4x + 4\big)$.
4. In $\mathbb{F}_5[x]$, divide $x^4 + 3x^2 + 1$ by $x^2 + x + 1$, finding the quotient q and remainder r, and verify that $\deg r < \deg(x^2+x+1)$. (Reduce every coefficient mod 5 as you go, and confirm $q\,(x^2+x+1)+r = x^4+3x^2+1$ in $\mathbb{F}_5[x]$.)
5. In $\mathbb{Z}[i]$, divide $\alpha = 11 + 7i$ by $\beta = 3 + i$: find $q, r \in \mathbb{Z}[i]$ with $\alpha = q\beta + r$ and $\mathrm{N}(r) < \mathrm{N}(\beta)$. What does the value of r tell you about a gcd of α and β?
6. Use the Euclidean algorithm in $\mathbb{Z}[i]$ to compute a gcd of $\alpha = 8 + 6i$ and $\beta = 5 - 15i$, giving your answer up to a unit of $\mathbb{Z}[i]$.
7. In $\mathbb{Z}$, exhibit explicit integers x, y with $\gcd(240, 46) = 240x + 46y$, obtained by back-substitution in the Euclidean algorithm.
8. In the Euclidean domain $\mathbb{Z}[i]$, find a gcd of $\alpha = 7 + i$ and $\beta = 4 - 3i$, and express it as a $\mathbb{Z}[i]$-linear combination $\mu\alpha + \nu\beta$.
9. Prove that every field F is a Euclidean domain with the norm $\mathrm{N}(a) = 0$ for all $a \in F$ (equivalently, any constant norm on $F \setminus \{0\}$). Conclude that the only nonzero ideal of F is F itself, and that it is principal.
10. Find a universal side divisor in $\mathbb{F}_2[x]$ and a universal side divisor in $\mathbb{F}_3[x]$. (In each case identify $\tilde{R} = R^\times \cup \{0\}$ first, then verify the defining divisibility condition.)

Additional exercises.

1. Let R be a Euclidean domain with norm N. Prove that if $a \in R$ is a nonzero nonunit and $\mathrm{N}(a)$ is minimal among the norms of all nonzero nonunits of R, then a is irreducible. (If $a = bc$, divide b by a: $b = qa + r$ with $r = 0$ or $\mathrm{N}(r) < \mathrm{N}(a)$. By minimality r is 0 or a unit, and $r = b(1 - qc)$; conclude that c or b is a unit.)
2. Let R be a Euclidean domain and $a, b \in R$ not both zero. Prove that any two greatest common divisors of a and b are associates, and conversely that any associate of a gcd of a, b is again a gcd. (Use $\langle a, b\rangle = \langle d\rangle$ for a gcd d, together with the mutual-divisibility characterization of associates.)
3. Let R be a Euclidean domain whose norm N satisfies $\mathrm{N}(a) \le \mathrm{N}(ab)$ for all nonzero $a, b \in R$ (as $|\cdot|$ on $\mathbb{Z}$, deg on $\mathbb{F}[x]$ and $\mathrm{N}(c + di) = c^2 + d^2$ on $\mathbb{Z}[i]$ do). Prove the divisibility lemma: if a divides b and $b \neq 0$, then $\mathrm{N}(a) \le \mathrm{N}(b)$. Deduce that two nonzero elements $a, b \in R$ are associates if and only if $a \mid b$ and $b \mid a$. Show that the hypothesis on N is needed: on $\mathbb{Z}$, the norm with $\mathrm{N}(2) = 100$ and $\mathrm{N}(n) = |n|$ for $n \neq 2$ admits a Division Algorithm, yet $2 \mid 4$ and $\mathrm{N}(2) > \mathrm{N}(4)$.
4. Let F be a field. Prove that every nonzero ideal I of $F[x]$ is generated by a *unique monic* polynomial $g \in F[x]$, namely the monic polynomial of least degree in I. (Use that $F[x]$ is a Euclidean domain with $\mathrm{N} = \deg$: pick a least-degree nonzero element of I, divide an arbitrary element of I by it, and rescale to make it monic; then argue uniqueness of the monic generator.)

Commutative-diagram exercises.

1. Let R be a Euclidean domain and $a, b \in R$ with gcd d. Justify both inclusions of the ideal diagram

$$\langle a, b\rangle \quad = \quad \langle d\rangle$$

by proving $\langle d\rangle \subseteq \langle a, b\rangle$ and $\langle a, b\rangle \subseteq \langle d\rangle$, naming the property of R used for each inclusion.

2. In $\mathbb{Z}[i]$, with $a = 2 + 2i$ and $b = 5 + i$, compute a gcd d and fill in d to make the diagram

$$\langle 2 + 2i,\ 5 + i\rangle \quad = \quad \langle d\rangle$$

an honest equality of ideals; verify that your d divides both generators and is a $\mathbb{Z}[i]$-linear combination of them.

3. Diagram the halting of the Euclidean algorithm in $\mathbb{Z}$ for $a = 803$, $b = 154$: draw one arrow per division step

$$(803,\ 154) \longrightarrow (154,\ 33) \longrightarrow (33,\ 22) \longrightarrow (22,\ 11) \longrightarrow (11,\ 0)$$

labelling each arrow with its (q, r) and confirming $\mathrm{N}(r) < \mathrm{N}(b)$ at every step. Read off the generator of $\langle 803, 154\rangle$ from the last nonzero remainder, and explain how the strictly decreasing norms force the process to halt.

4. Draw the one-arrow refinement ladder

$$\text{field} \xRightarrow{\text{trivially Euclidean}} \text{ED}$$

and locate on it a field, $\mathbb{Z}$, and $\mathbb{Z}[i]$, indicating for each which side of the arrow it sits on. Explain, via the universal-side-divisor proposition, why "ED" is the relevant rung for the Division Algorithm: every non-field ED has a universal side divisor (e.g. 2 in $\mathbb{Z}$, x in $\mathbb{Q}[x]$), a norm-free certificate that a generic domain need not possess. Note also why the arrow does not reverse, citing $\mathbb{Z}$ as an ED that is not a field.

8.2 Principal Ideal Domains

Principal ideal domains

Recall (8.1) that a *Euclidean domain* (ED) is an integral domain R equipped with a norm $N\colon R \to \mathbb{Z}_{\geq 0}$ (with $N(0) = 0$) such that for all $a, b \in R$ with $b \neq 0$ there exist $q, r \in R$ with

$$a = qb + r, \qquad r = 0 \ \text{ or } \ N(r) < N(b).$$

The division algorithm is exactly what lets us run the Euclidean algorithm to compute gcds. We now isolate the purely ideal-theoretic consequence that makes the machinery work, and find that it is strictly weaker than possessing a division algorithm.

Definition 8.2.1 (Principal ideal, principal ideal domain)**.** Let R be a commutative ring. An ideal $I \subseteq R$ is *principal* if $I = \langle a\rangle = aR$ for some single element $a \in R$. A *principal ideal domain* (PID) is an integral domain in which *every* ideal is principal.

Theorem 8.2.2 (ED $\implies$ PID)**.** *Every Euclidean domain is a principal ideal domain.*

Proof. Let R be a Euclidean domain with norm N, and let $I \subseteq R$ be an ideal. If $I = \langle 0\rangle$ it is principal, so assume $I \neq \langle 0\rangle$. Among the nonzero elements of I, choose $d \in I$ of *minimal* norm $N(d)$ (possible since N takes values in $\mathbb{Z}_{\geq 0}$, a well-ordered set). Clearly $\langle d\rangle \subseteq I$. Conversely take any $a \in I$ and divide: write $a = qd + r$ with $r = 0$ or $N(r) < N(d)$. Then $r = a - qd \in I$. If $r \neq 0$ then $N(r) < N(d)$ contradicts the minimality of $N(d)$ among nonzero elements of I. Hence $r = 0$, so $a = qd \in \langle d\rangle$. Therefore $I = \langle d\rangle$ is principal. □

Method (Proving a specific ring is a PID)**.** *Trigger.* You must show *every* ideal of an integral domain R is principal, or you are handed a familiar ring ($\mathbb{F}[x]$, $\mathbb{Z}$, $\mathbb{Z}[i]$).

1. **Cheapest route:** exhibit a Euclidean norm N on R (a degree function, absolute value, complex norm). Then ED $\implies$ PID is automatic. This handles $\mathbb{Z}$ ($N = |\cdot|$), $\mathbb{F}[x]$ ($N = \deg$), $\mathbb{Z}[i]$ ($N = \mathrm{N}$), $\mathbb{F}$ a field (every nonzero ideal is R).

2. **No obvious norm:** take an arbitrary ideal $I \neq \langle 0\rangle$, choose a "smallest" nonzero element by some size measure, and prove every other element is a multiple of it (mimic the ED proof). This is how one shows $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a PID with *no* Euclidean norm.

3. **To DISPROVE PID:** produce one ideal that is provably not principal (see the $\mathbb{Z}[x]$ method below).

Worked Example 8.2.3 ($\mathbb{F}[x]$ is a PID)**.** Let $\mathbb{F}$ be a field. Show $\mathbb{F}[x]$ is a PID and identify the generator of an arbitrary nonzero ideal.

Recognition. ED $\implies$ PID: $\mathbb{F}[x]$ carries the degree norm, so it is Euclidean, hence a PID. The generator-of-minimal-norm in the proof becomes the monic polynomial of least degree.

Solution. The map $N(f) = \deg f$ (for $f \neq 0$) makes $\mathbb{F}[x]$ Euclidean: polynomial long division over a field gives $f = qg + r$ with $r = 0$ or $\deg r < \deg g$ (the leading coefficient of g is a unit, so division never stalls). Hence $\mathbb{F}[x]$ is a PID by the theorem. Concretely, given an ideal $I \neq \langle 0\rangle$, pick $d \in I$ of least degree; rescaling by the inverse of its leading coefficient we may take d monic, and the ED proof gives $I = \langle d\rangle$ with d the unique monic generator. *Check.* Two monic generators d_1, d_2 of I satisfy $d_1 \mid d_2$ and $d_2 \mid d_1$, so they are associates; the only monic associate of a monic polynomial is itself, so the monic generator is unique.

Worked Example 8.2.4 (Generator of (f, g) in $\mathbb{Q}[x]$)**.** In $R = \mathbb{Q}[x]$ find a generator of $I = \langle f, g\rangle$ with $f = x^3 - 1$, $g = x^2 - 1$.

Recognition. In a PID $\langle f, g\rangle = \langle d\rangle$ where $d = \gcd(f, g)$, computed by the Euclidean algorithm (the division algorithm of the ED).

Solution. Run the Euclidean algorithm. Divide f by g:

$$x^3 - 1 = x\,(x^2 - 1) + (x - 1), \qquad r_1 = x - 1.$$

Divide g by r_1:

$$x^2 - 1 = (x + 1)(x - 1) + 0, \qquad r_2 = 0.$$

The last nonzero remainder is $x-1$, so $\gcd(f, g) = x-1$ (already monic) and $I = \langle x-1\rangle$. *Check.* $x-1 \mid x^3-1$ since $x = 1$ is a root of $x^3 - 1$, and $x - 1 \mid x^2 - 1 = (x-1)(x+1)$. And $x - 1$ is a $\mathbb{Q}[x]$-combination: from the first equation $x - 1 = (x^3 - 1) - x(x^2 - 1)$, so $x - 1 \in I$. Both inclusions hold, confirming $\langle f, g\rangle = \langle x - 1\rangle$.

Worked Example 8.2.5 (Generator of (a, b) in $\mathbb{Z}$)**.** In $\mathbb{Z}$ find a generator of $I = \langle 1755, 1599\rangle$.

Recognition. $\mathbb{Z}$ is Euclidean (norm $|\cdot|$), hence a PID; $\langle a, b\rangle = \langle \gcd(a, b)\rangle$, and the gcd is a $\mathbb{Z}$-linear combination (Bezout).

Solution. Euclidean algorithm:

$$1755 = 1 \cdot 1599 + 156, \quad 1599 = 10 \cdot 156 + 39, \quad 156 = 4 \cdot 39 + 0.$$

Last nonzero remainder 39, so gcd = 39 and $I = \langle 39\rangle$. *Check.* $1755 = 39 \cdot 45$, $1599 = 39 \cdot 41$, so 39 divides both. Back-substitute for Bezout: $39 = 1599 - 10 \cdot 156 = 1599 - 10(1755 - 1599) = 11 \cdot 1599 - 10 \cdot 1755$. Indeed $11 \cdot 1599 - 10 \cdot 1755 = 17589 - 17550 = 39$. Thus $39 \in I$ and $I = \langle 39\rangle$.

Gcds in a PID and the structure of ideals

Theorem 8.2.6 (gcd as ideal generator)**.** *Let R be a PID and $a, b \in R$ not both zero. Write $\langle a, b\rangle = \langle d\rangle$ (possible since R is a PID). Then:*

1. *d is a* greatest common divisor *of a and b: $d \mid a$, $d \mid b$, and if $e \mid a$ and $e \mid b$ then $e \mid d$.*

2. *$d = ax + by$ for some $x, y \in R$ (a linear combination of a, b).*

3. *d is unique up to multiplication by a unit (i.e. up to associates).*

Proof. Since $a, b \in \langle a, b\rangle = \langle d\rangle$ we have $d \mid a$ and $d \mid b$. Since $d \in \langle a, b\rangle = aR + bR$, there are $x, y \in R$ with $d = ax + by$, giving (2). If $e \mid a$ and $e \mid b$ then e divides $ax + by = d$, proving d is *greatest* and giving (1). For (3): if $\langle d\rangle = \langle d'\rangle$ then $d \mid d'$ and $d' \mid d$, so $d' = ud$ with $u \in R^\times$. In a domain such d, d' are associates. □

Remark 8.2.1. The equality $\langle a, b\rangle = \langle d\rangle$ packages two facts at once: *existence* of a gcd (some rings, like $\mathbb{Z}[\sqrt{-5}]$, have pairs with no gcd) and the *Bezout identity* $d = ax + by$. In a general UFD gcds exist but need *not* be linear combinations; the linear-combination property is special to PIDs (it is equivalent to being a Bezout domain).

Method (Finding the generator of a sum of ideals $\langle a\rangle + \langle b\rangle$)**.** *Trigger.* You see $\langle a, b\rangle$, $\langle a\rangle + \langle b\rangle$, or "the ideal generated by a and b" in a PID and want a single generator.

1. Compute $d = \gcd(a, b)$ (Euclidean algorithm if a norm is available).
2. Then $\langle a, b\rangle = \langle d\rangle$. Dually, $\langle a\rangle \cap \langle b\rangle = \langle \operatorname{lcm}(a, b)\rangle$.
3. Normalize: in $\mathbb{Z}$ take $d > 0$; in $\mathbb{F}[x]$ take d monic. This pins down the generator exactly.
4. Sanity check by back-substitution: write $d = ax + by$ to confirm $d \in \langle a, b\rangle$, and check $d \mid a,\ d \mid b$ to confirm $\langle a, b\rangle \subseteq \langle d\rangle$.

Theorem 8.2.7 (Nonzero prime ideals are maximal in a PID)**.** *Let R be a principal ideal domain. Then every nonzero prime ideal of R is maximal.*

Proof. Let $\langle p\rangle$ be a nonzero prime ideal of R (every ideal is principal). Suppose $\langle p\rangle \subseteq M$ for some ideal M; write $M = \langle m\rangle$. From $\langle p\rangle \subseteq \langle m\rangle$ we get $p \in \langle m\rangle$, so $p = mr$ for some $r \in R$. Since $\langle p\rangle$ is prime, p is a prime element, hence $p \mid m$ or $p \mid r$; that is, either $m \in \langle p\rangle$ or $r \in \langle p\rangle$.

- If $m \in \langle p\rangle$, then $\langle m\rangle \subseteq \langle p\rangle$, so $M = \langle m\rangle = \langle p\rangle$.
- If $r \in \langle p\rangle$, write $r = ps$. Then $p = mr = mps$, so $p(1 - ms) = 0$. As R is a domain and $p \neq 0$, $1 = ms$, so $m \in R^\times$ and $M = \langle m\rangle = R$.

Thus the only ideals containing $\langle p\rangle$ are $\langle p\rangle$ and R, i.e. $\langle p\rangle$ is maximal. □

Corollary 8.2.8. *In a PID R, a nonzero element p is prime if and only if it is irreducible, and the quotient $R/\langle p\rangle$ is a field for every irreducible p.*

Proof. p prime $\iff$ $\langle p\rangle$ nonzero prime $\iff$ (by the theorem) $\langle p\rangle$ maximal $\iff$ $R/\langle p\rangle$ a field. In any domain prime $\implies$ irreducible. For the reverse, let p be irreducible. Then $\langle p\rangle \neq \langle 0\rangle$ and $\langle p\rangle \neq R$, and $\langle p\rangle$ is contained in some maximal ideal $\langle m\rangle$. From $\langle p\rangle \subseteq \langle m\rangle$ we get $p = mr$; irreducibility forces m or r to be a unit, and m is not a unit (else $\langle m\rangle = R$), so $r \in R^\times$ and $\langle p\rangle = \langle m\rangle$ is maximal, hence prime. □

Worked Example 8.2.9 (Prime = maximal applied to $\mathbb{Z}$)**.** Show that in $\mathbb{Z}$ the nonzero prime ideals are precisely the maximal ideals, and list both.

Recognition. $\mathbb{Z}$ is a PID, so the theorem applies: every nonzero prime ideal is maximal.

Solution. The ideals of $\mathbb{Z}$ are $\langle n\rangle$, $n \geq 0$. The ideal $\langle n\rangle$ is prime iff $n = 0$ or $n = p$ prime. The *nonzero* primes are exactly $\langle p\rangle$ for p a rational prime, and each is maximal because $\mathbb{Z}/\langle p\rangle = \mathbb{F}_p$ is a field. The ideal $\langle 0\rangle$ is prime (since $\mathbb{Z}$ is a domain) but *not* maximal — this is the unique nonmaximal prime, and the theorem only claims maximality for *nonzero* primes. *Check.* $\langle 6\rangle$ is not prime ($2 \cdot 3 \in \langle 6\rangle$ but $2, 3 \notin \langle 6\rangle$), consistent with 6 not being a rational prime; $\mathbb{Z}/\langle 6\rangle \cong \mathbb{Z}/2 \times \mathbb{Z}/3$ is not a field.

Worked Example 8.2.10 (Prime = maximal applied to $\mathbb{F}[x]$)**.** Show every nonzero prime ideal of $\mathbb{Q}[x]$ is maximal, and decide whether $\langle x^2 + 1\rangle$ and $\langle x^2 - 1\rangle$ are maximal.

Recognition. $\mathbb{Q}[x]$ is a PID, so nonzero primes are maximal; primality of $\langle f\rangle$ is irreducibility of f.

Solution. Nonzero prime ideals of $\mathbb{Q}[x]$ are $\langle p(x)\rangle$ with p irreducible, and each is maximal with $\mathbb{Q}[x]/\langle p\rangle$ a field. Now $x^2 + 1$ is irreducible over $\mathbb{Q}$ (no rational root, degree 2), so $\langle x^2 + 1\rangle$ is maximal and $\mathbb{Q}[x]/\langle x^2 + 1\rangle \cong \mathbb{Q}(i)$, a field. But $x^2 - 1 = (x - 1)(x + 1)$ is reducible, so $\langle x^2 - 1\rangle$ is *not* prime, hence not maximal. *Check.* $\mathbb{Q}[x]/\langle x^2 - 1\rangle \cong \mathbb{Q}[x]/\langle x - 1\rangle \times \mathbb{Q}[x]/\langle x + 1\rangle \cong \mathbb{Q} \times \mathbb{Q}$ by CRT — a product of two fields, not a field, so indeed not maximal.

Worked Example 8.2.11 (The zero ideal can be a nonmaximal prime)**.** In $R = \mathbb{Q}[x]$, is $\langle 0 \rangle$ prime? Maximal? Reconcile with the theorem.

Recognition. The theorem restricts to *nonzero* prime ideals; $\langle 0 \rangle$ is exempt.

Solution. $\langle 0 \rangle$ is prime since R is a domain ($fg = 0 \implies f = 0$ or $g = 0$). It is not maximal: $\langle 0 \rangle \subsetneq \langle x \rangle \subsetneq R$. So $\langle 0 \rangle$ is a prime that is not maximal, and there is no contradiction — the theorem only promotes *nonzero* primes to maximal. *Check.* $R/\langle 0 \rangle = R = \mathbb{Q}[x]$ is a domain but not a field (x has no inverse), confirming $\langle 0 \rangle$ is prime but not maximal.

Noetherian: the ascending chain condition

Theorem 8.2.12 (PID $\implies$ Noetherian)**.** *Let R be a principal ideal domain. Then R satisfies the* ascending chain condition *(ACC) on ideals: every chain*

$$I_1 \subseteq I_2 \subseteq I_3 \subseteq \cdots$$

of ideals stabilizes, i.e. there is n with $I_n = I_{n+1} = \cdots$. Equivalently, every nonempty collection of ideals has a maximal element. (Such a ring is called Noetherian*.)*

Proof. Let $I_1 \subseteq I_2 \subseteq \cdots$ be an ascending chain. Put $I = \bigcup_{k \geq 1} I_k$. This is an ideal: if $a, b \in I$ then $a \in I_j$, $b \in I_k$ for some j, k, so both lie in $I_{\max(j,k)}$ (the chain is nested), hence $a - b \in I$ and $ra \in I$ for all $r \in R$. Since R is a PID, $I = \langle d \rangle$ for some d. Now $d \in I = \bigcup_k I_k$, so $d \in I_n$ for some n. Then

$$\langle d \rangle \subseteq I_n \subseteq I_{n+1} \subseteq \cdots \subseteq I = \langle d \rangle,$$

forcing $I_n = I_{n+1} = \cdots = \langle d \rangle$. The chain stabilizes at stage n. □

Remark 8.2.2. ACC is exactly the finiteness needed to prove existence of irreducible factorizations: if some element had no factorization into irreducibles, one could build a strictly ascending chain of ideals, contradicting ACC. This is the first half of "PID $\implies$ UFD" (the second half, uniqueness, uses prime = irreducible). We record the implication chain below.

Worked Example 8.2.13 (ACC fails in a non-PID)**.** Exhibit an ascending chain in $R = \mathbb{Q}[x_1, x_2, x_3, \dots]$ (infinitely many variables) that never stabilizes, illustrating that non-PIDs can fail ACC.

Recognition. ACC is a *theorem* for PIDs; a ring that violates ACC therefore cannot be a PID. We build a strictly increasing chain.

Solution. Let $I_k = \langle x_1, x_2, \dots, x_k \rangle$. Then $I_1 \subsetneq I_2 \subsetneq I_3 \subsetneq \cdots$ since $x_{k+1} \in I_{k+1} \setminus I_k$ (no R-combination of $x_1, \dots, x_k$ produces x_{k+1}: evaluate at $x_1 = \cdots = x_k = 0$, $x_{k+1} = 1$, which kills every element of I_k but sends x_{k+1} to 1). This chain never stabilizes, so R is not Noetherian and a fortiori not a PID. *Check.* Indeed $I_k = \langle x_1, \dots, x_k \rangle$ needs k generators and is not principal for $k \geq 2$, consistent with R failing to be a PID.

$\mathbb{Z}[x]$ is not a PID

Proposition 8.2.14 ($\mathbb{Z}[x]$ is not a PID)**.** *The ideal $I = \langle 2, x \rangle \subseteq \mathbb{Z}[x]$ is not principal. Hence $\mathbb{Z}[x]$ is an integral domain that is* not *a PID. (More generally, if R is not a field then $R[x]$ is not a PID.)*

Proof. First identify I concretely: $\langle 2, x \rangle = \{\, f \in \mathbb{Z}[x] : f(0) \text{ is even} \,\}$. Indeed every element $2g + xh$ has constant term $2g(0)$, which is even; conversely if $f(0) = 2c$ then $f = 2c + (f - 2c)$ where $f - 2c$ has zero constant term, hence is $x \cdot (\text{poly}) \in \langle x \rangle$, so $f \in \langle 2, x \rangle$. In particular $I \neq \mathbb{Z}[x]$ because $1 \notin I$ ($1(0) = 1$ is odd).

Suppose for contradiction $I = \langle p \rangle$ for some $p \in \mathbb{Z}[x]$. Since $2 \in I = \langle p \rangle$, we have $p \mid 2$ in $\mathbb{Z}[x]$. The divisors of the constant 2 in $\mathbb{Z}[x]$ are units ± 1 and ± 2 (a degree argument: $2 = pq$ forces $\deg p = \deg q = 0$, so $p \in \mathbb{Z}$ and $p \mid 2$ in $\mathbb{Z}$).

- If $p = \pm 1$ then $\langle p \rangle = \mathbb{Z}[x] \neq I$ (we showed $1 \notin I$). Contradiction.
- If $p = \pm 2$ then $\langle p \rangle = \langle 2 \rangle$ consists of polynomials with all coefficients even; but $x \in I$ has an odd coefficient, so $x \notin \langle 2 \rangle = \langle p \rangle$, contradicting $x \in I$.

No choice of p works, so I is not principal and $\mathbb{Z}[x]$ is not a PID. $\square$

Worked Example 8.2.15 (Why non-principal $\langle 2, x\rangle$ kills PID)**.** Spell out the logical step: how does $\langle 2, x\rangle$ not being principal prove $\mathbb{Z}[x]$ is not a PID?

Recognition. Definition unpacking: a PID requires *every* ideal principal, so one non-principal ideal is a counterexample.

Solution. A PID is defined as an integral domain in which *every* ideal is principal. $\mathbb{Z}[x]$ is an integral domain (it is a subring of $\mathbb{Q}[x]$, itself a domain; equivalently the product of two nonzero polynomials is nonzero by adding leading degrees). The previous proposition exhibits a single ideal, $\langle 2, x\rangle$, that is *not* principal. The universal quantifier "every ideal is principal" is therefore false for $\mathbb{Z}[x]$, so $\mathbb{Z}[x]$ fails the definition of PID. *Check.* No contradiction with $\mathbb{Z}[x]$ being a UFD — being a UFD does *not* require all ideals principal; indeed $\mathbb{Z}[x]$ is a UFD but not a PID, so the inclusion PID $\subset$ UFD is strict, witnessed precisely by $\mathbb{Z}[x]$.

Worked Example 8.2.16 ($\langle 2, x\rangle$ has no gcd-style single generator)**.** Confirm directly that 2 and x have gcd 1 in $\mathbb{Z}[x]$ yet $\langle 2, x\rangle \neq \langle 1\rangle$, so the "gcd generates" theorem really needs the PID hypothesis.

Recognition. Contrast with the PID gcd theorem: there $\langle a, b\rangle = \langle \gcd(a, b)\rangle$. Failure here pinpoints why $\mathbb{Z}[x]$ is not a PID.

Solution. In $\mathbb{Z}[x]$ the only common divisors of 2 and x are units ± 1 (a divisor of x is ± 1 or $\pm x$ up to units; $\pm x \nmid 2$), so $\gcd(2, x) = 1$. If $\mathbb{Z}[x]$ were a PID we would get $\langle 2, x\rangle = \langle \gcd(2, x)\rangle = \langle 1\rangle = \mathbb{Z}[x]$, i.e. $1 = 2f + xg$ for some $f, g \in \mathbb{Z}[x]$. Evaluate at $x = 0$: $1 = 2f(0)$, impossible in $\mathbb{Z}$ (left side odd, right side even). *Check.* So $1 \notin \langle 2, x\rangle$, $\langle 2, x\rangle \subsetneq \mathbb{Z}[x]$, and the gcd 1 fails to generate the ideal — exactly the PID property that breaks. This is the same obstruction as the non-principality computation, viewed through Bezout.

Worked Example 8.2.17 ($\mathbb{F}[x, y]$ is not a PID)**.** Show $R = \mathbb{Q}[x, y]$ is not a PID using the ideal $\langle x, y\rangle$.

Recognition. Same non-principal-ideal strategy; $\langle x, y\rangle$ is the "functions vanishing at the origin" ideal and needs two generators.

Solution. $\langle x, y\rangle = \{f \in \mathbb{Q}[x, y] : f(0, 0) = 0\}$, a maximal ideal with $R/\langle x, y\rangle \cong \mathbb{Q}$. Suppose $\langle x, y\rangle = \langle p\rangle$. Then $p \mid x$ and $p \mid y$. Divisors of x in $\mathbb{Q}[x, y]$ are (up to units) 1 and x; the only common divisor of x and y is a unit, so $p \in \mathbb{Q}^\times$, giving $\langle p\rangle = R$. But $\langle x, y\rangle \neq R$ since $1 \notin \langle x, y\rangle$ ($1(0, 0) = 1 \neq 0$). Contradiction, so R is not a PID. *Check.* Consistent with $\mathbb{Q}[x, y] = \mathbb{Q}[x][y]$ being $S[y]$ for $S = \mathbb{Q}[x]$ a non-field, so $\langle x, y\rangle$ behaves just like $\langle 2, x\rangle$ did in $\mathbb{Z}[x]$; and $\mathbb{Q}[x, y]$ is still a UFD.

Caution. **Two generators does not mean non-principal.** Writing an ideal as $\langle a, b\rangle$ does not by itself prove it is non-principal — in a PID *every* $\langle a, b\rangle$ collapses to $\langle d\rangle$. E.g. $\langle 6, 9\rangle = \langle 3\rangle$ in $\mathbb{Z}$. To prove non-principality you must show *no* single element generates it, as in $\langle 2, x\rangle$. Conversely, do not conclude $\mathbb{Z}[x]$ is "not a UFD" from this; it is a UFD. Only the *PID* property fails.

Caution. **"Prime ideal is maximal" needs nonzero AND PID.** The theorem is false without both hypotheses. In $\mathbb{Z}$, $\langle 0\rangle$ is prime but not maximal (the nonzero hypothesis matters). In $\mathbb{Z}[x]$ (not a PID), $\langle x\rangle$ is prime ($\mathbb{Z}[x]/\langle x\rangle \cong \mathbb{Z}$ is a domain) but *not* maximal, since $\langle x\rangle \subsetneq \langle 2, x\rangle \subsetneq \mathbb{Z}[x]$. So $\mathbb{Z}[x]/\langle x\rangle \cong \mathbb{Z}$ is a domain that is not a field — exactly the failure of "prime = maximal" in a non-PID.

ED $\subset$ PID is strict: $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$

Theorem 8.2.18 (A PID that is not Euclidean)**.** *Let $\omega = \frac{1+\sqrt{-19}}{2}$ and $R = \mathbb{Z}[\omega]$, the ring of integers of $\mathbb{Q}(\sqrt{-19})$, with field norm $\mathrm{N}(a + b\omega) = a^2 + ab + 5b^2$. Then R is a principal ideal domain, but R is* not *a Euclidean domain (for any norm whatsoever). Hence the inclusion $\{ED\} \subsetneq \{PID\}$ is strict.*

Indication. **Not Euclidean.** The key is the notion of a *universal side divisor*: in any Euclidean domain that is not a field, there exists a nonzero nonunit u such that for every $x \in R$ there is $z \in \{0\} \cup R^\times$ with $u \mid (x - z)$ — equivalently every residue class of $R/\langle u\rangle$ is represented by $\{0\} \cup R^\times$. For $R = \mathbb{Z}[\omega]$ one checks $R^\times = \{\pm 1\}$ (the norm form $a^2 + ab + 5b^2$ equals 1 only at $(\pm 1, 0)$). Taking $x = 2$, a universal side divisor u divides $2 - 0$, $2 - 1$ or $2 + 1$, i.e. 2, 1 or 3, and $u \nmid 1$ since u is not a unit. For $b \neq 0$ the norm form equals $(a + \frac{b}{2})^2 + \frac{19}{4}b^2 \geq 5$, and for $b = 0$ it is a^2, so it never takes the values 2 or 3; hence 2 and 3 are irreducible in R and the only candidates are $u = \pm 2$ and $u = \pm 3$. Testing them shows neither is a universal side divisor:

$R/\langle 2\rangle$ and $R/\langle 3\rangle$ have order $\mathrm{N}(2) = 4$ and $\mathrm{N}(3) = 9$ respectively, too large to be covered by the three residues $\{0, \pm 1\}$. Hence R has no universal side divisor, so R is not Euclidean for *any* norm.

Is a PID. One uses the *Dedekind–Hasse* criterion: an integral domain R is a PID iff there is a function $N\colon R \to \mathbb{Z}_{\geq 0}$ (a Dedekind–Hasse norm) with $N(a) > 0$ for $a \neq 0$ such that for all nonzero $a, b \in R$, either $a \in \langle b\rangle$ or there is a nonzero $r \in \langle a, b\rangle$ with $N(r) < N(b)$. The field norm N is shown to be a Dedekind–Hasse norm on $\mathbb{Z}[\omega]$ by a direct (case) verification: given a, b, the quotient $a/b \in \mathbb{Q}(\sqrt{-19})$ can be approximated by an element of R closely enough (or, when it cannot, one multiplies by a small element) to produce such an r. This makes every ideal principal, so R is a PID. Full details are in Dummit & Foote, §8.1–8.2. □

Corollary 8.2.19 (The strict hierarchy)**.** *We have proper containments*

$$\{\textit{fields}\} \subsetneq \{\textit{Euclidean domains}\} \subsetneq \{\textit{PIDs}\} \subsetneq \{\textit{UFDs}\} \subsetneq \{\textit{integral domains}\}.$$

Witnesses for strictness: $\mathbb{Z}$ is a non-field ED; $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a non-Euclidean PID; $\mathbb{Z}[x]$ is a non-PID UFD; $\mathbb{Z}[\sqrt{-5}]$ is a non-UFD domain (e.g. $6 = 2\cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$ are two essentially different factorizations into irreducibles).

$$\text{fields} \Longrightarrow \text{ED} \Longrightarrow \text{PID} \Longrightarrow \text{UFD} \Longrightarrow \text{domain}$$

Diagram explanation. Objects: Each node is a class of commutative rings (or integral domains): fields, Euclidean domains (ED), principal ideal domains (PID), unique factorization domains (UFD), and general integral domains. The arrow direction runs from more structured to less structured.

Arrows: Each double arrow ($\Rightarrow$) is a logical implication between ring classes: fields $\Rightarrow$ ED means every field is a Euclidean domain (the trivial norm $N(a) = 0$ for all $a \neq 0$ works, or simply every nonzero ideal is R so division is trivial); ED $\Rightarrow$ PID is the theorem proved in this section; PID $\Rightarrow$ UFD is stated in the remark and proved in the next section; UFD $\Rightarrow$ domain is definitional (UFDs are defined to be integral domains).

What commutes: The chain is a transitive sequence: fields $\Rightarrow$ ED $\Rightarrow$ PID $\Rightarrow$ UFD $\Rightarrow$ domain. By transitivity, fields $\Rightarrow$ domain (every field is an integral domain), and every ED is a UFD, etc. All six composite implications hold (ten implications in all, counting the four arrows).

Why it commutes: Each implication is strict one-way. The chain is linear, not a square, so "commutativity" here means transitivity: if $A \Rightarrow B$ and $B \Rightarrow C$ then $A \Rightarrow C$ by chaining. No nontrivial reverse implication holds, as the witnesses in the corollary show.

Why this matters here: This diagram crystallizes the cumulative work of Section 8.2: every theorem in this section either proves one of the forward arrows (ED $\Rightarrow$ PID was the first theorem) or exhibits a witness showing the arrow cannot be reversed. It is the organizing spine of the section.

Concrete example: $\mathbb{Z}$ is an ED (norm $|\cdot|$) but not a field (2 is not invertible). $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a PID but not an ED (no universal side divisor). $\mathbb{Z}[x]$ is a UFD but not a PID ($\langle 2, x\rangle$ is non-principal). $\mathbb{Z}[\sqrt{-5}]$ is a domain but not a UFD ($6 = 2\cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$).

Common pitfall: Students sometimes read $\Rightarrow$ as $\Leftrightarrow$, concluding, e.g., that every PID must be Euclidean. The corollary's list of witnesses is precisely to block this: each arrow is strict, so the reverse implication fails for an explicit ring.

Takeaway: The point of this diagram is that the five standard classes of integral domains form a strict linear hierarchy of inclusions, with each arrow forward proved and each reversal blocked by a concrete example.

The next diagram records, inside a PID, the coincidence of nonzero primes with maximal ideals and the gcd computation $\langle a, b\rangle = \langle d\rangle$:

$$\begin{array}{ccc} \langle a\rangle & & \langle b\rangle \\ & \subseteq \quad \supseteq & \\ & \langle a, b\rangle = \langle d\rangle = \langle \gcd(a, b)\rangle & \\ & \Big\downarrow \text{if } d \text{ prime} & \\ & \langle d\rangle \text{ maximal} & \end{array}$$

Diagram explanation. Objects: Four ideal-nodes inside a fixed PID R. Top row: $\langle a\rangle$ and $\langle b\rangle$, the principal ideals generated by individual elements $a, b \in R$. Middle: $\langle a, b\rangle = \langle d\rangle = \langle \gcd(a, b)\rangle$, the sum of those two ideals, which collapses to a single principal ideal because R is a PID; d is the gcd, well-defined up to a unit. Bottom: $\langle d\rangle$ labeled maximal, active only when d is a prime element.

Arrows: The phantom arrows from $\langle a\rangle$ and $\langle b\rangle$, labeled $\subseteq$ and $\supseteq$ (each symbol opens toward the larger ideal), record containments: $\langle a\rangle \subseteq \langle a, b\rangle$ and $\langle b\rangle \subseteq \langle a, b\rangle$ (each generator belongs to the larger ideal). The vertical arrow from $\langle a, b\rangle = \langle d\rangle$ to $\langle d\rangle$ maximal is a conditional logical step: when d is a prime element, the theorem "nonzero prime ideals are maximal in a PID" promotes $\langle d\rangle$ from merely principal to maximal.

What commutes: No closed square, so the relevant equalities are: (1) $\langle a, b\rangle = \langle d\rangle$ as ideals (PID gives every two-generator ideal a single generator, namely the gcd); (2) $\langle d\rangle = \langle \gcd(a, b)\rangle$ names that generator as the gcd; (3) when d is prime, $\langle d\rangle$ is maximal (the nonzero-prime-is-maximal theorem).

Why it commutes: Well-definedness of d: different choices of gcd are associates ($d' = ud$, $u \in R^\times$), so $\langle d'\rangle = \langle d\rangle$; the ideal is independent of the choice of associate. The equality $\langle a, b\rangle = \langle d\rangle$ follows because $d \mid a$ and $d \mid b$ give $\langle a\rangle \subseteq \langle d\rangle$ and $\langle b\rangle \subseteq \langle d\rangle$, hence $\langle a, b\rangle \subseteq \langle d\rangle$; and $d = ax + by \in \langle a, b\rangle$ gives the reverse.

Why this matters here: The diagram is a visual summary of two payoffs of the PID axiom proved in this section: ideal-sums compress to a gcd generator, and prime generators produce maximal ideals (hence fields as quotients). It shows the student what "every ideal is principal" buys in one picture.

Concrete example: In $\mathbb{Z}$: $a = 12$, $b = 8$, $d = \gcd(12, 8) = 4$, so $\langle 12, 8\rangle = \langle 4\rangle$. If $d = 5$ (prime), $\langle 5\rangle$ is maximal and $\mathbb{Z}/\langle 5\rangle = \mathbb{F}_5$ is a field. In $\mathbb{Q}[x]$: $a = x^3 - 1$, $b = x^2 - 1$, $d = x - 1$, $\langle x^3 - 1, x^2 - 1\rangle = \langle x - 1\rangle$; since $x - 1$ is irreducible (prime in a PID), $\langle x - 1\rangle$ is maximal and $\mathbb{Q}[x]/\langle x - 1\rangle \cong \mathbb{Q}$.

Common pitfall: Students sometimes read the middle equality $\langle a, b\rangle = \langle d\rangle$ as saying $a = d$ or $b = d$; in fact d is a new element (the gcd), generally different from a and b, and the equality is of ideals, not elements. Also, the bottom node $\langle d\rangle$ maximal applies only when d is prime; if $d = 4$ in $\mathbb{Z}$, $\langle 4\rangle$ is not maximal ($\langle 4\rangle \subsetneq \langle 2\rangle \subsetneq \mathbb{Z}$).

Takeaway: The point of this diagram is that in a PID the two-generator ideal $\langle a, b\rangle$ automatically collapses to the principal ideal $\langle \gcd(a, b)\rangle$, and if that gcd happens to be prime the ideal is moreover maximal, linking the gcd computation directly to the prime-equals-maximal theorem.

Remark 8.2.3 (Summary of what the PID axiom buys). Every ideal principal $\Longrightarrow$ (i) gcds exist and are Bezout combinations $d = ax + by$; (ii) every nonzero prime ideal is maximal, and prime = irreducible; (iii) ACC holds, so factorizations into irreducibles exist. Together (ii) and (iii) give the next section's theorem PID $\Longrightarrow$ UFD. None of these uses a division algorithm directly — which is why a non-Euclidean ring like $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ can still enjoy all of them.

Exercises (from the text).

1. Prove that in a Principal Ideal Domain two ideals (a) and (b) are comaximal (cf. Section 7.6) if and only if a greatest common divisor of a and b is 1 (in which case a and b are said to be *coprime* or *relatively prime*).

2. Prove that any two nonzero elements a, b of a P.I.D. have a least common multiple, i.e., an element e with $a \mid e$ and $b \mid e$ such that $e \mid e'$ whenever $a \mid e'$ and $b \mid e'$ (cf. D&F, Exercise 11 of Section 8.1).

3. Prove that a quotient of a P.I.D. by a prime ideal is again a P.I.D.

4. Let R be an integral domain. Prove that if the following two conditions hold then R is a Principal Ideal Domain:

   (i) any two nonzero elements a and b in R have a greatest common divisor which can be written in the form $ra + sb$ for some $r, s \in R$, and

   (ii) if $a_1, a_2, a_3, \ldots$ are nonzero elements of R such that $a_{i+1} \mid a_i$ for all i, then there is a positive integer N such that a_n is a unit times a_N for all $n \geq N$.

5. Let R be the quadratic integer ring $\mathbb{Z}[\sqrt{-5}]$. Define the ideals $I_2 = (2, 1 + \sqrt{-5})$, $I_3 = (3, 2 + \sqrt{-5})$, and $I_3' = (3, 2 - \sqrt{-5})$.

   (a) Prove that I_2, I_3, and I_3' are nonprincipal ideals in R. [D&F prove this for I_3 in Section 8.1 (Example 2 following Proposition 1) by comparing norms.]

(b) Prove that the product of two nonprincipal ideals can be principal by showing that I_2^2 is the principal ideal generated by 2, i.e., $I_2^2 = (2)$.

(c) Prove similarly that $I_2 I_3 = (1 - \sqrt{-5})$ and $I_2 I_3' = (1 + \sqrt{-5})$ are principal. Conclude that the principal ideal (6) is the product of 4 ideals: $(6) = I_2^2 I_3 I_3'$.

6. Let R be an integral domain and suppose that every prime ideal in R is principal. This exercise proves that every ideal of R is principal, i.e., R is a P.I.D.

(a) Assume that the set of ideals of R that are not principal is nonempty and prove that this set has a maximal element under inclusion (which, by hypothesis, is not prime). [Use Zorn's Lemma.]

(b) Let I be an ideal which is maximal with respect to being nonprincipal, and let $a, b \in R$ with $ab \in I$ but $a \notin I$ and $b \notin I$. Let $I_a = (I, a)$ be the ideal generated by I and a, let $I_b = (I, b)$ be the ideal generated by I and b, and define $J = \{r \in R \mid rI_a \subseteq I\}$. Prove that $I_a = (\alpha)$ and $J = (\beta)$ are principal ideals in R with $I \subseteq I_b \subseteq J$ and $I_a J = (\alpha\beta) \subseteq I$.

(c) If $x \in I$ show that $x = s\alpha$ for some $s \in J$. Deduce that $I = I_a J$ is principal, a contradiction, and conclude that R is a P.I.D.

7. An integral domain R in which every ideal generated by two elements is principal (i.e., for every $a, b \in R$, $(a, b) = (d)$ for some $d \in R$) is called a *Bezout Domain*. [cf. also Exercise 11 in Section 3.]

(a) Prove that the integral domain R is a Bezout Domain if and only if every pair of elements a, b of R has a g.c.d. d that can be written as an R-linear combination of a and b, i.e., $d = ra + sb$ for some $r, s \in R$.

(b) Prove that every finitely generated ideal of a Bezout Domain is principal. [cf. the exercises in Sections 9.2 and 9.3 for Bezout Domains in which not every ideal is principal.]

(c) Let F be the fraction field of the Bezout Domain R. Prove that every element of F can be written in the form a/b with a and b relatively prime elements of R (cf. Exercise 1).

8. Prove that if R is a Principal Ideal Domain and D is a multiplicatively closed subset of R with $0 \notin D$, then $D^{-1}R$ is also a P.I.D. (cf. Section 7.5).

Practice problems.

1. Show directly that every ideal of $\mathbb{Z}$ is principal: given a nonzero ideal $I \subseteq \mathbb{Z}$, prove that $I = \langle d \rangle$, where d is the least positive element of I. (Hint: well-ordering produces d; for $a \in I$ divide $a = qd + r$ with $0 \le r < d$ and rule out $r > 0$.)

2. In a PID, prove that a nonzero element p is prime if and only if it is irreducible. (You may use: every proper ideal lies in a maximal ideal, and in a PID nonzero primes are maximal.)

3. In a PID R, suppose $\langle a \rangle + \langle b \rangle = R$ (so a, b are comaximal). Prove the Chinese Remainder Theorem in this setting: the natural map

$$R/\langle ab \rangle \longrightarrow R/\langle a \rangle \times R/\langle b \rangle, \qquad x + \langle ab \rangle \mapsto \big(x + \langle a \rangle,\, x + \langle b \rangle\big),$$

is a ring isomorphism. (Hint: surjectivity uses $1 = ax + by$; for injectivity show $\langle a \rangle \cap \langle b \rangle = \langle ab \rangle$ when a, b are comaximal.)

4. Use the ascending chain condition in a PID to prove existence of factorizations: every nonzero nonunit of a PID is a finite product of irreducible elements. (Hint: if some a had no such factorization, build a strictly ascending chain $\langle a \rangle \subsetneq \langle a_1 \rangle \subsetneq \langle a_2 \rangle \subsetneq \cdots$ of ideals by repeatedly splitting off a proper non-unit factor, contradicting ACC.)

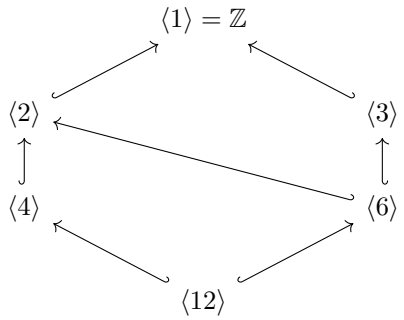
5. Prove that a PID satisfies the ascending chain condition on ideals (so PID $\implies$ Noetherian): every chain $I_1 \subseteq I_2 \subseteq I_3 \subseteq \cdots$ of ideals stabilizes. (Hint: the union $I = \bigcup_k I_k$ is an ideal, hence $I = \langle d \rangle$; locate d in some I_n.)

6. In $\mathbb{Z}$ compute $\gcd(85, 49)$ by the Euclidean algorithm, and then either find the inverse of 49 in $\mathbb{Z}/85\mathbb{Z}$ using Bezout or show no inverse exists.

7. Determine, with proof, whether $\langle 7,\ 3+\sqrt{-5}\rangle$ is a principal ideal in $\mathbb{Z}[\sqrt{-5}]$, where $\mathrm{N}(a+b\sqrt{-5}) = a^2+5b^2$. (Hint: if the ideal were $\langle d\rangle$, then $\mathrm{N}(d)$ divides both $\mathrm{N}(7) = 49$ and $\mathrm{N}(3+\sqrt{-5}) = 14$; rule out $\mathrm{N}(d) = 7$ by checking $a^2 + 5b^2 = 7$ has no solution, and show 1 is not in the ideal.)

Additional exercises.

1. Prove that in a PID every nonzero prime ideal is maximal. Then give an integral domain having a nonzero prime ideal that is *not* maximal, exhibiting where the PID hypothesis is needed. (Hint: in $\mathbb{Z}[x]$, the ideal $\langle x\rangle$ is prime since $\mathbb{Z}[x]/\langle x\rangle \cong \mathbb{Z}$ is a domain, but $\langle x\rangle \subsetneq \langle 2, x\rangle \subsetneq \mathbb{Z}[x]$.)



2. Let R be a PID and $p \in R$ irreducible. Prove that the only ideals of R containing $\langle p^2\rangle$ are $\langle 1\rangle = R$, $\langle p\rangle$, and $\langle p^2\rangle$, and deduce that $R/\langle p^2\rangle$ is a local ring whose unique maximal ideal is $\langle p\rangle/\langle p^2\rangle$. (Hint: an ideal containing $\langle p^2\rangle$ is $\langle d\rangle$ with $d \mid p^2$; the divisors of p^2 up to units are $1, p, p^2$.)

3. Let $\omega = \frac{1+\sqrt{-19}}{2}$ and $R = \mathbb{Z}[\omega]$, with field norm $\mathrm{N}(a+b\omega) = a^2+ab+5b^2$. Prove that R has no universal side divisor, hence is *not* a Euclidean domain for any norm; you may use that $R^\times = \{\pm 1\}$ and that R is a PID (via the Dedekind–Hasse criterion). Conclude that $\{\text{ED}\} \subsetneq \{\text{PID}\}$ is strict. (Hint: taking $x = 2$ shows that a universal side divisor divides 2 or 3; since $a^2+ab+5b^2$ never equals 2 or 3, it must be ± 2 or ± 3. But $|R/\langle 2\rangle| = \mathrm{N}(2) = 4$ and $|R/\langle 3\rangle| = \mathrm{N}(3) = 9$ exceed the three residues $\{0, \pm 1\}$.)

4. Let $\mathbb{F}$ be a field. Show that the formal power series ring $\mathbb{F}[[x]]$ is a PID whose only nonzero proper ideals are $\langle x^n\rangle$ for $n \geq 1$, and identify $\mathbb{F}[[x]]^\times$. (Hint: a power series is a unit iff its constant term is nonzero; for a nonzero ideal let n be the minimal order of its elements and show the ideal equals $\langle x^n\rangle$.)

Commutative-diagram exercises.

1. In $\mathbb{Z}$, consider the divisor lattice of 12 under *reverse* divisibility ($\langle a\rangle \subseteq \langle b\rangle$ iff $b \mid a$):

   Interpret each edge as a divisibility relation, identify which of $\langle 2\rangle, \langle 3\rangle, \langle 4\rangle, \langle 6\rangle, \langle 12\rangle$ are prime (hence maximal in $\mathbb{Z}$), and state $\langle 2\rangle \cap \langle 3\rangle$ and $\langle 2\rangle + \langle 3\rangle$ as principal ideals.

2. In $\mathbb{Z}$, fill in the PID gcd diagram

$$\langle a\rangle \hookrightarrow \langle a, b\rangle = \langle d\rangle \hookleftarrow \langle b\rangle$$

   for $a = 1240$, $b = 962$: compute $d = \gcd(a, b)$ by the Euclidean algorithm, exhibit Bezout coefficients x, y with $d = ax + by$, and verify both inclusions $\langle a\rangle \subseteq \langle d\rangle$ and $\langle b\rangle \subseteq \langle d\rangle$.

3. Let R be a PID and $p \in R$ irreducible. Using that $\langle p\rangle$ is maximal, explain why in the diagram

$$R \xrightarrow{\ \pi\ } R/\langle p\rangle$$

   the surjection π has $\ker \pi = \langle p\rangle$ and the target $R/\langle p\rangle$ is a field. Then specialize to $R = \mathbb{Q}[x]$, $p = x^2+1$, and identify the field $\mathbb{Q}[x]/\langle x^2+1\rangle$.

4. In $R = \mathbb{Z}$, complete the gcd–lcm diamond

for $a = 12$, $b = 18$: fill in $d = \gcd(a, b)$ and $m = \operatorname{lcm}(a, b)$, label each edge with the divisibility it encodes, state $\langle a \rangle + \langle b \rangle$ and $\langle a \rangle \cap \langle b \rangle$ as principal ideals, and verify $\langle d \rangle \langle m \rangle = \langle ab \rangle$ (i.e. dm and ab are associates).

8.3 Unique Factorization Domains

Associates, irreducibles, primes, and unique factorization

Throughout this section R is an integral domain (commutative, $1 \neq 0$, no zero divisors). We measure factorization up to multiplication by units, so the first notion we need is that of an associate.

Definition 8.3.1 (Associates)**.** Two elements $a, b \in R$ are *associates*, written $a \sim b$, if $a = ub$ for some unit $u \in R^\times$. Equivalently (in a domain), $a \sim b$ iff $a \mid b$ and $b \mid a$, iff $\langle a \rangle = \langle b \rangle$ as principal ideals.

Proposition 8.3.2 (Characterizations of associates)**.** *In an integral domain, for $a, b \in R$ the following are equivalent: (i) $a = ub$ for a unit u; (ii) $a \mid b$ and $b \mid a$; (iii) $\langle a \rangle = \langle b \rangle$.*

Proof. We verify the three characterizations agree. If $a = ub$ with u a unit, then $b \mid a$, and $b = u^{-1}a$ gives $a \mid b$; conversely $\langle a \rangle \subseteq \langle b \rangle$ and $\langle b \rangle \subseteq \langle a \rangle$, so $\langle a \rangle = \langle b \rangle$. If instead $a \mid b$ and $b \mid a$, write $b = xa$ and $a = yb$. Then $a = yxa$, so $a(1 - yx) = 0$. If $a = 0$ then $b = 0$ and they are trivially associates; if $a \neq 0$, since R is a domain $1 = yx$, so y is a unit and $a = yb$. Finally $\langle a \rangle = \langle b \rangle \implies a \mid b$ and $b \mid a$ directly. So all three are equivalent. □

Remark 8.3.1. Associate is an equivalence relation. In $\mathbb{Z}$ the units are $\{\pm 1\}$, so $a \sim b \iff b = \pm a$; the associate classes of nonzero elements are $\{n, -n\}$. In a field every nonzero element is a unit, so all nonzero elements are associates of 1. In $\mathbb{Z}[i]$ the units are $\{\pm 1, \pm i\}$, so each nonzero α has four associates $\pm\alpha, \pm i\alpha$.

Definition 8.3.3 (Irreducible, prime)**.** Let $r \in R$ be nonzero and not a unit.

(i) r is *irreducible* if whenever $r = ab$ with $a, b \in R$, then a or b is a unit. (It cannot be written as a product of two nonunits.)

(ii) r is *prime* if the ideal $\langle r \rangle$ is a nonzero prime ideal; equivalently, $r \neq 0$, r is not a unit, and $r \mid ab \implies r \mid a$ or $r \mid b$.

An element with a nontrivial factorization $r = ab$ (both nonunits) is *reducible*.

Method (Deciding irreducible vs. reducible, and prime)**.** *Trigger.* You are handed a specific nonzero nonunit r in a concrete domain and asked whether it is irreducible and/or prime.

1. **Irreducible test (norm method).** If a multiplicative norm $\mathrm{N}\colon R \to \mathbb{Z}_{\geq 0}$ is available with $\mathrm{N}(\alpha\beta) = \mathrm{N}(\alpha)\,\mathrm{N}(\beta)$ and $\mathrm{N}(\alpha) = 1 \iff \alpha \in R^\times$, then in any factorization $r = ab$ we get $\mathrm{N}(r) = \mathrm{N}(a)\,\mathrm{N}(b)$. If $\mathrm{N}(r)$ is prime in $\mathbb{Z}$, one factor has norm 1 and is a unit, so r is irreducible. (The converse can fail.)
2. **Reducible.** Exhibit one factorization $r = ab$ with $\mathrm{N}(a), \mathrm{N}(b) > 1$.
3. **Prime test.** Find a, b with $r \mid ab$ but $r \nmid a$ and $r \nmid b$ to show *not* prime; or prove $R/\langle r \rangle$ is a domain to show prime.
4. *Shortcut.* Prime always implies irreducible (Proposition below). In a UFD the two notions coincide, so the norm test settles both.

Proposition 8.3.4 (Prime $\implies$ irreducible)**.** *In an integral domain, every prime element is irreducible.*

Proof. Let p be prime and suppose $p = ab$. Then $p \mid ab$, so by primality $p \mid a$ or $p \mid b$; say $p \mid a$, write $a = px$. Then $p = ab = pxb$, so $p(1 - xb) = 0$; since $p \neq 0$ and R is a domain, $xb = 1$, so b is a unit. Thus in any factorization $p = ab$ one factor is a unit, i.e. p is irreducible. □

Caution. The converse fails in general: *irreducible does not imply prime* in an arbitrary domain. The standard counterexample is $\mathbb{Z}[\sqrt{-5}]$ (worked below), where 2 is irreducible but $2 \mid (1+\sqrt{-5})(1-\sqrt{-5})$ while 2 divides neither factor. The notions coincide in every UFD; conversely, a domain in which every nonzero nonunit is a product of irreducibles and every irreducible is prime is a UFD (see the additional exercises).

Worked Example 8.3.5 (Prime implies irreducible, by hand in $\mathbb{Z}$)**.** *Recognition.* In $\mathbb{Z}$, verify directly that the prime 5 is irreducible using only the definition, to see the general proof concretely.

Solution. Suppose $5 = ab$ with $a, b \in \mathbb{Z}$. Then $5 \mid ab$; since 5 is prime in the usual sense, $5 \mid a$ or $5 \mid b$, say $5 \mid a$, so $a = 5x$. Then $5 = 5xb \implies xb = 1 \implies b \in \{\pm 1\} = \mathbb{Z}^\times$. So one factor is a unit and 5 is irreducible. *Check.* The only factorizations of 5 are $5 = 1 \cdot 5 = (-1)(-5)$, each with a unit factor; consistent.

Worked Example 8.3.6 (An irreducible that is not prime in $\mathbb{Z}[\sqrt{-5}]$)**.** *Recognition.* We want a domain where unique factorization fails; the norm $\mathrm{N}(a+b\sqrt{-5}) = a^2+5b^2$ flags two genuinely different factorizations of the same element.

Solution. In $R = \mathbb{Z}[\sqrt{-5}]$ the norm $\mathrm{N}(a + b\sqrt{-5}) = a^2 + 5b^2$ is multiplicative, and $R^\times = \{\pm 1\}$ since $\mathrm{N}(\alpha) = 1 \implies a^2 + 5b^2 = 1 \implies b = 0,\ a = \pm 1$. Consider

$$6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5}).$$

2 **is irreducible:** $\mathrm{N}(2) = 4$. If $2 = \alpha\beta$ with both nonunits then $\mathrm{N}(\alpha) = \mathrm{N}(\beta) = 2$, but $a^2 + 5b^2 = 2$ has no integer solution. So no such factorization exists; 2 is irreducible. (Same argument: 3 has $\mathrm{N} = 9$, and $a^2 + 5b^2 = 3$ is unsolvable, so 3 is irreducible; $1 \pm \sqrt{-5}$ each have $\mathrm{N} = 6$, and $\mathrm{N} = 2$ or 3 are both unsolvable, so they are irreducible too.) 2 **is not prime:** $2 \mid 6 = (1 + \sqrt{-5})(1 - \sqrt{-5})$. But $2 \nmid (1 \pm \sqrt{-5})$: if $1 + \sqrt{-5} = 2(a + b\sqrt{-5})$ then $2b = 1$, impossible in $\mathbb{Z}$. So 2 divides the product but neither factor: 2 is irreducible but not prime. *Check.* The two factorizations of 6 use irreducibles $\{2, 3\}$ versus $\{1+\sqrt{-5}, 1-\sqrt{-5}\}$, and $2 \not\sim 1 \pm \sqrt{-5}$ (different norms 4 vs 6), so factorization into irreducibles is *not* unique. Hence $\mathbb{Z}[\sqrt{-5}]$ is not a UFD.

Worked Example 8.3.7 (Irreducibility via prime norm in $\mathbb{Z}[i]$)**.** *Recognition.* Whenever $\mathrm{N}(\alpha)$ is a rational prime, the norm test instantly forces α irreducible.

Solution. In $\mathbb{Z}[i]$, $\mathrm{N}(a + bi) = a^2 + b^2$ is multiplicative and $\mathbb{Z}[i]^\times = \{\pm 1, \pm i\}$ (the norm-1 elements). Take $\alpha = 2 + i$: $\mathrm{N}(2 + i) = 4 + 1 = 5$, a prime. If $2 + i = \beta\gamma$ then $5 = \mathrm{N}(\beta)\,\mathrm{N}(\gamma)$, so one of $\mathrm{N}(\beta), \mathrm{N}(\gamma)$ equals 1, i.e. is a unit. Hence $2 + i$ is irreducible. Likewise $2 - i$ ($\mathrm{N} = 5$), $1 + i$ ($\mathrm{N} = 2$), and 3 ($\mathrm{N} = 9$, but $a^2 + b^2 = 3$ unsolvable, so 3 stays irreducible in $\mathbb{Z}[i]$) are all irreducible. *Check.* The splitting $5 = (2 + i)(2 - i)$ has consistent norms, since $\mathrm{N}(2 + i)\,\mathrm{N}(2 - i) = 5 \cdot 5 = 25 = \mathrm{N}(5)$, matching $\mathrm{N}(5) = 5^2 = 25$. Consistent.

Worked Example 8.3.8 (Factoring rational primes in $\mathbb{Z}[i]$)**.** *Recognition.* $\mathbb{Z}[i]$ is a UFD (it is Euclidean), so each integer prime p either stays irreducible or splits; the splitting is governed by p mod 4 and read off the norm.

Solution. (a) 5 splits. $5 = (2 + i)(2 - i)$. Check: $(2 + i)(2 - i) = 4 - i^2 = 4 + 1 = 5$. Both factors have norm 5 (prime), hence irreducible; 5 is a product of two nonassociate irreducibles. *(b) 2 ramifies.* $2 = -i(1 + i)^2$. Check: $(1 + i)^2 = 1 + 2i + i^2 = 2i$, and $-i \cdot 2i = -2i^2 = 2$. Here $1 + i$ is irreducible ($\mathrm{N} = 2$) and $-i$ is a unit, so 2 is (a unit times) the square of one irreducible. *(c) 3 is inert.* $\mathrm{N}(3) = 9$; a proper factor would need norm 3, but $a^2 + b^2 = 3$ has no integer solution, so 3 remains irreducible in $\mathbb{Z}[i]$. *Check.* Norms multiply correctly: (a) $5 \cdot 5 = 25 = \mathrm{N}(5)$; (b) $\mathrm{N}((1 + i)^2) = 2^2 = 4 = \mathrm{N}(2)$ and the unit $-i$ has norm 1; (c) 9 has no factorization $9 = 3 \cdot 3$ realized by norm-3 Gaussian integers. All consistent with $\mathbb{Z}[i]$ being a UFD.

Unique factorization domains

Definition 8.3.9 (UFD)**.** An integral domain R is a *unique factorization domain* (UFD) if every nonzero nonunit $r \in R$ satisfies:

(1) **Existence.** $r = p_1 p_2 \cdots p_n$ for some irreducibles p_i (not necessarily distinct);

(2) **Uniqueness.** if also $r = q_1 q_2 \cdots q_m$ with each q_j irreducible, then $m = n$ and after reordering $p_i \sim q_i$ for all i.

Method (Showing a domain is, or is not, a UFD)**.** *Trigger.* Asked to decide whether a given domain has unique factorization.

1. **To prove it fails (norm method).** Exhibit one element with two factorizations into irreducibles whose multisets of associate-classes differ. Use a multiplicative norm to (a) prove the factors are irreducible by ruling out intermediate norms, and (b) show the factors across the two factorizations are non-associate (different norms, or not unit multiples). Example: 6 in $\mathbb{Z}[\sqrt{-5}]$.

2. **To prove it holds (structure method).** Show R is a PID (or Euclidean), then invoke "PID $\implies$ UFD." Or verify both axioms directly: ACC on principal ideals gives existence, and "irreducible $\implies$ prime" gives uniqueness.

3. **Inheriting.** If R is a UFD then so is $R[x]$ (stated below), so $\mathbb{Z}[x]$ and $\mathbb{F}[x_1, \ldots, x_n]$ are UFDs.

Theorem 8.3.10 (In a UFD, irreducible $\iff$ prime)**.** *In a unique factorization domain R, an element is prime if and only if it is irreducible.*

Proof. Prime $\implies$ irreducible holds in any domain. For the converse, let p be irreducible and suppose $p \mid ab$, say $ab = pc$. If a is a unit then $b = a^{-1}pc$, so $p \mid b$; symmetrically if b is a unit then $p \mid a$. So assume a and b are nonzero nonunits (if $a = 0$ then $p \mid a$ trivially, similarly for b). Factor $a = \prod_i p_i$ and $b = \prod_j q_j$ into irreducibles, and factor c into irreducibles (absorbing any unit). Then

$$\Big(\prod_i p_i\Big)\Big(\prod_j q_j\Big) = p \cdot \prod_k r_k$$

are two factorizations of ab into irreducibles. By uniqueness, the irreducible p on the right is an associate of some factor on the left, i.e. $p \sim p_i$ for some i (so $p \mid a$) or $p \sim q_j$ for some j (so $p \mid b$). Hence $p \mid a$ or $p \mid b$, and p is prime. □

Worked Example 8.3.11 (Using uniqueness to prove irreducible $\implies$ prime)**.** *Recognition.* In a UFD the only way an irreducible can divide a product is to appear (up to associates) in the factorization of one of the factors.

Solution. Work in $\mathbb{Z}$ (a UFD). Let $p = 7$ (irreducible) and suppose $7 \mid ab$ with $a = 2^2 \cdot 7 = 28$, $b = 15 = 3 \cdot 5$. Then $ab = 2^2 \cdot 3 \cdot 5 \cdot 7$. The irreducible 7 appears in this unique factorization; tracing it back, 7 came from $a = 28$, so $7 \mid a$. In general the prime 7 must show up in the merged factorization of ab, and uniqueness pins it to a factor of a or of b. *Check.* Indeed $7 \mid 28 = a$, and $7 \nmid 15 = b$; the conclusion "$7 \mid a$" is exactly what primality predicts.

Theorem 8.3.12 (gcds exist in a UFD)**.** *Let R be a UFD. Write the distinct irreducibles (up to associates) appearing in a and b as $p_1, \ldots, p_k$, so*

$$a = u \prod_{i=1}^{k} p_i^{e_i}, \qquad b = v \prod_{i=1}^{k} p_i^{f_i} \qquad (u, v \in R^\times,\ e_i, f_i \geq 0).$$

Then $d = \prod_{i=1}^{k} p_i^{\min(e_i, f_i)}$ is a greatest common divisor of a and b (unique up to associates), and $\ell = \prod_i p_i^{\max(e_i, f_i)}$ is a least common multiple.

Proof. $d \mid a$ since $\min(e_i, f_i) \le e_i$, and likewise $d \mid b$. If $c \mid a$ and $c \mid b$, then in the factorization of c each irreducible (an associate of some p_i, since c divides a) appears to a power $\le e_i$ and $\le f_i$, hence $\le \min(e_i, f_i)$; so $c \mid d$. Thus d is a gcd. Uniqueness up to associates follows because any two gcds divide each other. The lcm statement is dual. □

Worked Example 8.3.13 (gcd via factorizations in $\mathbb{Z}$)**.** *Recognition.* Both numbers factor into the same set of primes; take the minimum exponent prime-by-prime.

Solution. $a = 360 = 2^3 \cdot 3^2 \cdot 5$, $b = 84 = 2^2 \cdot 3 \cdot 7$. Common primes $2, 3$ (and $5, 7$ with exponent 0 in the other). Minima: $2^{\min(3,2)} = 2^2$, $3^{\min(2,1)} = 3^1$, $5^{\min(1,0)} = 5^0$, $7^{\min(0,1)} = 7^0$. So $\gcd = 2^2 \cdot 3 = 12$. *Check.* $12 \mid 360$ ($360/12 = 30$) and $12 \mid 84$ ($84/12 = 7$), and $\gcd(30, 7) = 1$, so 12 is greatest. Also $\text{lcm} = 2^3 \cdot 3^2 \cdot 5 \cdot 7 = 2520$, and $12 \cdot 2520 = 30240 = 360 \cdot 84$. Consistent.

Worked Example 8.3.14 (gcd via factorizations in $\mathbb{Z}[i]$)**.** *Recognition.* $\mathbb{Z}[i]$ is a UFD, so the same min-exponent recipe works once we factor into Gaussian irreducibles.

Solution. Compute $\gcd(2 + i, 5)$ in $\mathbb{Z}[i]$. Factor: $5 = (2 + i)(2 - i)$ and $2 + i$ is irreducible ($\mathrm{N} = 5$). Writing both over the irreducibles $\{2 + i, 2 - i\}$: $2 + i = (2 + i)^1(2 - i)^0$, $5 = (2 + i)^1(2 - i)^1$. Minima: $(2 + i)^{\min(1,1)}(2 - i)^{\min(0,1)} = (2 + i)^1$. So $\gcd(2 + i, 5) = 2 + i$ (up to a unit). *Check.* $2 + i \mid 5$ since $5/(2 + i) = 5(2 - i)/\mathrm{N}(2 + i) = 5(2 - i)/5 = 2 - i \in \mathbb{Z}[i]$, and $2 + i \mid 2 + i$ trivially; nothing of larger norm divides $2 + i$, so $2 + i$ is the gcd. Consistent.

The implication chain: ED $\Longrightarrow$ PID $\Longrightarrow$ UFD

Theorem 8.3.15 (Every PID is a UFD)**.** *Every principal ideal domain is a unique factorization domain. Consequently*

$$\textit{Euclidean domain} \implies \textit{PID} \implies \textit{UFD} \implies \textit{integral domain},$$

and all inclusions are strict.

Proof sketch. Two ingredients. *Existence:* a PID is Noetherian, so the ascending chain condition holds on (principal) ideals. If some nonzero nonunit had no factorization into irreducibles, one builds a strictly increasing chain $\langle a_1 \rangle \subsetneq \langle a_2 \rangle \subsetneq \cdots$ by repeatedly splitting a non-factorable factor, contradicting ACC; hence every element factors into irreducibles. *Uniqueness:* in a PID every irreducible p is prime, because $\langle p \rangle$ is maximal (if $\langle p \rangle \subseteq \langle m \rangle \subseteq R$ then $p = mb$, and irreducibility forces m a unit or b a unit, i.e. $\langle m \rangle = R$ or $\langle m \rangle = \langle p \rangle$), and maximal ideals are prime. With "irreducible $\implies$ prime" available, the standard cancellation argument shows any two irreducible factorizations match up to order and associates. The strictness of the inclusions: $\mathbb{Z}[i]$ is Euclidean; $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a PID that is not Euclidean (next box); $\mathbb{Z}[x]$ is a UFD that is not a PID (e.g. $\langle 2, x \rangle$ is not principal); $\mathbb{Z}[\sqrt{-5}]$ is a domain that is not a UFD. □

$$\text{ED} \Longrightarrow \text{PID} \Longrightarrow \text{UFD} \Longrightarrow \text{domain}$$

Diagram explanation. Objects: Four classes of integral domains, listed left to right in strictly increasing generality: Euclidean domains (ED), principal ideal domains (PID), unique factorization domains (UFD), and arbitrary integral domains (domain). Each node represents a class of rings, not a single ring.

Arrows: Each double arrow $\Rightarrow$ is a class inclusion: every ED is a PID, every PID is a UFD, every UFD is an integral domain. There are no arrows going right to left, signalling that each inclusion is strict.

What commutes: The chain is a linear sequence, not a square, so commutativity is trivial: the unique path from ED to domain passes through PID and UFD. What matters is the direction and the absence of reverse arrows.

Why it commutes: ED $\Rightarrow$ PID: in a nonzero ideal I a nonzero element d of minimal norm generates I (dividing $a \in I$ by d leaves a remainder in I of smaller norm, hence 0). PID $\Rightarrow$ UFD: in a PID, ACC on principal ideals gives existence of irreducible factorizations, and every irreducible is prime (because $\langle p \rangle$ is maximal hence prime), giving uniqueness. UFD $\Rightarrow$ domain: a UFD is by definition a domain.

Why this matters here: This diagram is the structural punchline of the section. After proving prime $\Rightarrow$ irreducible (always), irreducible $\Rightarrow$ prime (in a UFD), and every PID is a UFD, the diagram collects those implications into a single memorable hierarchy, and the proof-sketch above has just verified each implication.

Concrete example: $\mathbb{Z}[i]$ (Gaussian integers) is Euclidean via the norm, hence a PID, hence a UFD. $\mathbb{Z}[\frac{1+\sqrt{-19}}{2}]$ is a PID but not Euclidean (no Euclidean function). $\mathbb{Z}[x]$ is a UFD (since $\mathbb{Z}$ is) but not a PID ($\langle 2, x\rangle$ is not principal). $\mathbb{Z}[\sqrt{-5}]$ is a domain but not a UFD (the element 6 has two genuinely different irreducible factorizations).

Common pitfall: Students sometimes read the implication chain as "every UFD has a Euclidean algorithm" or conflate PID and UFD. Neither reverse arrow exists: each class is genuinely more restrictive than the one to its right. In particular, having unique factorization does not by itself guarantee that every ideal is principal.

Takeaway: The point of this diagram is that the standard classes of "nice" domains form a strict linear hierarchy, and each step genuinely loses structure, as witnessed by concrete examples sitting in each gap.

Inside the world of elements, the dual picture is the relation between prime and irreducible:

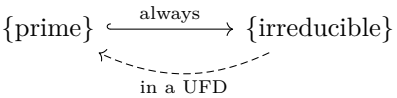


Diagram explanation. Objects: Two subsets of the nonzero nonunits of an integral domain R: the set of prime elements {prime} and the set of irreducible elements {irreducible}. Both live inside the same domain; the diagram compares them as subsets.

Arrows: The solid hooked arrow $\hookrightarrow$ labelled "always" is a set inclusion: every prime element is irreducible, in any integral domain, with no extra hypotheses. The dashed arrow going back, labelled "in a UFD," is a conditional inclusion: in a UFD (and only in a UFD, among the named classes) every irreducible is also prime, so the two sets coincide. The dashed style signals that this reverse arrow does not exist in general.

What commutes: There is no square to commute; the diagram expresses set-containment. The solid arrow means {prime} $\subseteq$ {irreducible} in every domain. Together with the dashed arrow in a UFD, the conclusion is {prime} = {irreducible} inside any UFD.

Why it commutes: Solid arrow: if p is prime and $p = ab$, then $p \mid ab$, so $p \mid a$ or $p \mid b$; say $p \mid a$, write $a = px$; then $p(1 - xb) = 0$ and $p \neq 0$ forces $xb = 1$, so b is a unit. Dashed arrow (in a UFD only): if p is irreducible and $p \mid ab$, factor a and b into irreducibles; unique factorization forces p to be an associate of some factor in a or in b, giving $p \mid a$ or $p \mid b$.

Why this matters here: The two diagrams together (the domain-class chain and this element-level diagram) explain *why* UFDs are the right setting for unique factorization: uniqueness requires cancellation, which requires that irreducibles generate prime ideals, which is exactly the dashed arrow. The failure of the dashed arrow in $\mathbb{Z}[\sqrt{-5}]$ (where 2 is irreducible but not prime) is what breaks unique factorization there.

Concrete example: In $\mathbb{Z}$ (a UFD) every irreducible is $\pm p$ for a rational prime p, and every such p is prime: both arrows hold and the sets are equal. In $\mathbb{Z}[\sqrt{-5}]$ (not a UFD) the element 2 is irreducible but $2 \mid (1 + \sqrt{-5})(1 - \sqrt{-5}) = 6$ while 2 divides neither factor, so 2 is not prime: the dashed reverse arrow fails.

Common pitfall: Students often assume the dashed arrow is "obvious" and apply it outside UFDs. Checking that an element is irreducible (no factorization into nonunits) does not automatically make it prime (divides a product implies divides a factor); the extra hypothesis of unique factorization is essential and cannot be dropped.

Takeaway: The point of this diagram is that prime and irreducible coincide in every UFD, and that in a domain where factorizations into irreducibles exist (such as $\mathbb{Z}[\sqrt{-5}]$) the failure of this coincidence is exactly what makes it not a UFD: it is the mechanism by which unique factorization breaks down.

Remark 8.3.2 (The PID-not-Euclidean example, stated). The ring $R = \mathbb{Z}\left[\frac{1+\sqrt{-19}}{2}\right]$ (the ring of integers of $\mathbb{Q}(\sqrt{-19})$) is a principal ideal domain but admits *no* Euclidean function whatsoever. D&F prove it is not Euclidean by showing it has no "universal side divisor" (the field norm rules out small remainders), yet a careful argument with the Dedekind–Hasse criterion shows every ideal is principal. So the inclusion ED $\subsetneq$ PID is strict.

Gauss's lemma and polynomials over a UFD

Definition 8.3.16 (Content, primitive)**.** Let R be a UFD with fraction field $\mathrm{Frac}(R)$. For a nonzero $f = \sum a_i x^i \in R[x]$, the *content* $\mathrm{cont}(f)$ is a gcd of the coefficients $a_0, \ldots, a_n$ (well-defined up to a unit). Call f *primitive* if $\mathrm{cont}(f)$ is a unit, i.e. the coefficients have no common irreducible factor.

Theorem 8.3.17 (Gauss's Lemma, stated)**.** *Let R be a UFD with fraction field $F = \mathrm{Frac}(R)$.*

(i) The product of two primitive polynomials in $R[x]$ is primitive; more generally $\mathrm{cont}(fg) \sim \mathrm{cont}(f)\,\mathrm{cont}(g)$.

(ii) If $f \in R[x]$ factors as $f = AB$ with $A, B \in F[x]$ nonconstant, then $f = ab$ for some $a, b \in R[x]$ with $\deg a = \deg A$, $\deg b = \deg B$. Hence a nonconstant $f \in R[x]$ is irreducible in $R[x]$ iff it is primitive and irreducible in $F[x]$.

Sketch. (i) Suppose f, g primitive but fg not, so some irreducible (hence prime, R a UFD) p divides every coefficient of fg. Reduce mod p: in the domain $(R/\langle p\rangle)[x]$ we get $\bar{f}\bar{g} = 0$, forcing $\bar{f} = 0$ or $\bar{g} = 0$, i.e. $p \mid \mathrm{cont}(f)$ or $p \mid \mathrm{cont}(g)$, contradicting primitivity. The content formula follows by pulling out contents. (ii) Clear denominators and contents from an $F[x]$-factorization and apply (i) to descend the factorization to $R[x]$. □

Theorem 8.3.18 (R a UFD $\implies$ $R[x]$ a UFD, stated)**.** *If R is a UFD then the polynomial ring $R[x]$ is a UFD. By induction $R[x_1, \ldots, x_n]$ is a UFD; in particular $\mathbb{Z}[x_1, \ldots, x_n]$ and $\mathbb{F}[x_1, \ldots, x_n]$ are UFDs.*

Sketch. The irreducibles of $R[x]$ are exactly (a) the irreducibles of R (as constant polynomials) and (b) primitive polynomials that are irreducible in $F[x]$, where $F = \mathrm{Frac}(R)$. Existence of factorizations: split off the content (factored in the UFD R) and factor the primitive part using that $F[x]$ is a PID, hence a UFD, then descend via Gauss's Lemma. Uniqueness: Gauss's Lemma transfers the unique factorization in $F[x]$ back to $R[x]$, matched with unique factorization of the content in R. □

Worked Example 8.3.19 ($\mathbb{Z}[x]$ is a UFD but not a PID)**.** *Recognition.* Inheritance gives the UFD property; a single non-principal ideal blocks the PID property, witnessing strictness of PID $\subsetneq$ UFD.

Solution. Since $\mathbb{Z}$ is a UFD, $\mathbb{Z}[x]$ is a UFD by the theorem above. But $\mathbb{Z}[x]$ is not a PID: the ideal $\langle 2, x\rangle$ (all polynomials with even constant term) is not principal. If $\langle 2, x\rangle = \langle d\rangle$, then $d \mid 2$ forces $d \in \{\pm 1, \pm 2\}$, and $d \mid x$ forces $\deg d = 0$ with d dividing the leading coefficient 1, so $d \in \{\pm 1\}$; but then $\langle d\rangle = \mathbb{Z}[x] \neq \langle 2, x\rangle$ (the constant $1 \notin \langle 2, x\rangle$). Contradiction. *Check.* $\langle 2, x\rangle$ is a maximal ideal with $\mathbb{Z}[x]/\langle 2, x\rangle \cong \mathbb{F}_2$, yet it needs two generators, confirming $\mathbb{Z}[x]$ is a UFD that is not a PID.

Worked Example 8.3.20 (Irreducibility in $\mathbb{Z}[x]$ via Gauss's Lemma)**.** *Recognition.* Gauss's Lemma reduces irreducibility over $\mathbb{Z}$ to: primitive plus irreducible over $\mathbb{Q}$.

Solution. Let $f(x) = x^2 - 2 \in \mathbb{Z}[x]$. Content: $\gcd(1, 0, -2) = 1$, so f is primitive. Over $\mathbb{Q}$, f has no rational root ($\sqrt{2} \notin \mathbb{Q}$, and a degree-2 polynomial with no root in a field is irreducible there), so f is irreducible in $\mathbb{Q}[x]$. By Gauss's Lemma (ii), f is irreducible in $\mathbb{Z}[x]$. *Check.* Any factorization $x^2 - 2 = (ax + b)(cx + d)$ over $\mathbb{Z}$ needs $ac = 1$, $bd = -2$, $ad + bc = 0$; $a = c = 1$ forces $b + d = 0$ and $bd = -2$, so $b, -b$ with $-b^2 = -2$, i.e. $b^2 = 2$, impossible in $\mathbb{Z}$. Irreducible, as predicted.

Caution. "Irreducible over $\mathbb{Z}$" is not the same as "irreducible over $\mathbb{Q}$" for *imprimitive* polynomials. The polynomial $2x + 4 = 2(x + 2)$ is reducible in $\mathbb{Z}[x]$ (the constant 2 is a nonunit irreducible factor) but is a unit times an irreducible in $\mathbb{Q}[x]$, where 2 is a unit. Gauss's Lemma compares the two worlds only after you strip the content, i.e. for primitive polynomials.

Remark 8.3.3 (Summary of the logic). The whole section threads one chain of implications: a multiplicative norm certifies irreducibles; *prime* $\implies$ *irreducible* always; the reverse *irreducible* $\implies$ *prime* is exactly the property that makes factorizations unique, and it holds in every PID (because irreducibles generate maximal ideals there). Thus ED $\implies$ PID $\implies$ UFD, while $\mathbb{Z}[\sqrt{-5}]$ shows a domain can fail to be a UFD precisely by having an irreducible that is not prime.

Exercises (from the text).

1. Let $G = \mathbb{Q}^\times$ be the multiplicative group of nonzero rational numbers. If $a = p/q \in G$, where p and q are relatively prime integers, let $\varphi : G \to G$ be the map which interchanges the primes 2 and 3 in the prime factorizations of p and q (so, for example, $\varphi(2^4 3^{11} 5^1 13^2) = 3^4 2^{11} 5^1 13^2$, $\varphi(3/16) = \varphi(3/2^4) = 2/3^4 = 2/81$, and φ is the identity on all rational numbers with numerators and denominators relatively prime to 2 and to 3).

   (a) Prove that φ is a group isomorphism.

   (b) Prove that there are infinitely many isomorphisms of the group G to itself.

2. Let a and b be nonzero elements of the Unique Factorization Domain R. Prove that a and b have a least common multiple (cf. Exercise 11 of Section 1) and describe it in terms of the prime factorizations of a and b in the same fashion that Proposition 13 describes their greatest common divisor.

3. Determine all the representations of the integer $2130797 = 17^2 \cdot 73 \cdot 101$ as a sum of two squares.

4. Prove that if an integer is the sum of two rational squares, then it is the sum of two integer squares (for example, $13 = (1/5)^2 + (18/5)^2 = 2^2 + 3^2$).

5. Let $R = \mathbb{Z}[\sqrt{-n}]$ where n is a squarefree integer greater than 3.

   (a) Prove that 2, $\sqrt{-n}$ and $1 + \sqrt{-n}$ are irreducibles in R.

   (b) Prove that R is not a U.F.D. Conclude that the quadratic integer ring $\mathcal{O}$ is not a U.F.D. for $D \equiv 2, 3 \bmod 4$, $D < -3$ (so also not Euclidean and not a P.I.D.). [Show that either $\sqrt{-n}$ or $1+\sqrt{-n}$ is not prime.]

   (c) Give an explicit ideal in R that is not principal. [Using (b) consider a maximal ideal containing the nonprime ideal $(\sqrt{-n})$ or $(1 + \sqrt{-n})$.]

6. (a) Prove that the quotient ring $\mathbb{Z}[i]/(1 + i)$ is a field of order 2.

   (b) Let $q \in \mathbb{Z}$ be a prime with $q \equiv 3 \bmod 4$. Prove that the quotient ring $\mathbb{Z}[i]/(q)$ is a field with q^2 elements.

   (c) Let $p \in \mathbb{Z}$ be a prime with $p \equiv 1 \bmod 4$ and write $p = \pi\overline{\pi}$ as in Proposition 18. Show that the hypotheses for the Chinese Remainder Theorem (Theorem 17 in Section 7.6) are satisfied and that $\mathbb{Z}[i]/(p) \cong \mathbb{Z}[i]/(\pi) \times \mathbb{Z}[i]/(\overline{\pi})$ as rings. Show that the quotient ring $\mathbb{Z}[i]/(p)$ has order p^2 and conclude that $\mathbb{Z}[i]/(\pi)$ and $\mathbb{Z}[i]/(\overline{\pi})$ are both fields of order p.

7. Let π be an irreducible element in $\mathbb{Z}[i]$.

   (a) For any integer $n \geq 0$, prove that $(\pi^{n+1}) = \pi^{n+1}\mathbb{Z}[i]$ is an ideal in $(\pi^n) = \pi^n\mathbb{Z}[i]$ and that multiplication by π^n induces an isomorphism $\mathbb{Z}[i]/(\pi) \cong (\pi^n)/(\pi^{n+1})$ as additive abelian groups.

   (b) Prove that $|\mathbb{Z}[i]/(\pi^n)| = |\mathbb{Z}[i]/(\pi)|^n$.

   (c) Prove for any nonzero α in $\mathbb{Z}[i]$ that the quotient ring $\mathbb{Z}[i]/(\alpha)$ has order equal to $N(\alpha)$. [Use (b) together with the Chinese Remainder Theorem and the results of the previous exercise.]

8. Let R be the quadratic integer ring $\mathbb{Z}[\sqrt{-5}]$ and define the ideals $I_2 = (2, 1 + \sqrt{-5})$, $I_3 = (3, 2 + \sqrt{-5})$, and $I_3' = (3, 2 - \sqrt{-5})$.

   (a) Prove that 2, 3, $1 + \sqrt{-5}$ and $1 - \sqrt{-5}$ are irreducibles in R, no two of which are associate in R, and that $6 = 2 \cdot 3 = (1 + \sqrt{-5}) \cdot (1 - \sqrt{-5})$ are two distinct factorizations of 6 into irreducibles in R.

   (b) Prove that I_2, I_3, and I_3' are prime ideals in R. [One approach: for I_3, observe that $R/I_3 \cong (R/(3))/(I_3/(3))$ by the Third Isomorphism Theorem for Rings. Show that $R/(3)$ has 9 elements, $(I_3/(3))$ has 3 elements, and $R/I_3 \cong \mathbb{Z}/3\mathbb{Z}$ as an additive abelian group. Conclude that I_3 is a maximal (hence prime) ideal and that $R/I_3 \cong \mathbb{Z}/3\mathbb{Z}$ as rings.]

   (c) Show that the factorizations in (a) imply the equality of ideals $(6) = (2)(3)$ and $(6) = (1 + \sqrt{-5})(1 - \sqrt{-5})$. Show that these two ideal factorizations give the same factorization of the ideal (6) as the product of prime ideals (cf. Exercise 5 in Section 2).

9. Suppose that the quadratic integer ring $\mathcal{O}$ is a P.I.D. Prove that the absolute value of the field norm N on $\mathcal{O}$ (here $D \neq 0, 1$ is a squarefree integer, $\mathcal{O} = \mathbb{Z}[\omega]$, where $\omega = \sqrt{D}$ if $D \equiv 2, 3 \pmod 4$ and $\omega = \frac{1+\sqrt{D}}{2}$ if $D \equiv 1 \pmod 4$, and $N(a+b\sqrt{D}) = (a+b\sqrt{D})(a-b\sqrt{D}) = a^2 - Db^2$ for $a, b \in \mathbb{Q}$, as in D&F, Section 7.1) is a Dedekind–Hasse norm on $\mathcal{O}$. Conclude that if the quadratic integer ring $\mathcal{O}$ possesses any Dedekind–Hasse norm, then in fact the absolute value of the field norm on $\mathcal{O}$ already provides a Dedekind–Hasse norm on $\mathcal{O}$. [If $\alpha, \beta \in \mathcal{O}$ then $(\alpha, \beta) = (\gamma)$ for some $\gamma \in \mathcal{O}$. Show that if β does not divide α then $0 < |N(\gamma)| < |N(\beta)|$ — use the fact that the units in $\mathcal{O}$ are precisely the elements whose norm is ± 1.]

10. (k-stage Euclidean Domains) Let R be an integral domain and let $N : R \to \mathbb{Z}^+ \cup \{0\}$ be a norm on R. The ring R is Euclidean with respect to N if for any $a, b \in R$ with $b \neq 0$ there exist elements q and r in R with

$$a = qb + r \qquad \text{with } r = 0 \text{ or } N(r) < N(b).$$

Suppose now that this condition is weakened, namely that for any $a, b \in R$ with $b \neq 0$ there exist elements q, q' and r, r' in R with

$$a = qb + r, \qquad b = q'r + r' \qquad \text{with } r' = 0 \text{ or } N(r') < N(b),$$

i.e., the remainder after two divisions is smaller. Call such a domain a 2-*stage Euclidean Domain*.

(a) Prove that iterating the divisions in a 2-stage Euclidean Domain produces a greatest common divisor of a and b which is a linear combination of a and b. Conclude that every *finitely generated* ideal of a 2-stage Euclidean Domain is principal. (There are 2-stage Euclidean Domains that are *not* P.I.D.s, however.) [Imitate the proof of Theorem 4.]

(b) Prove that a 2-stage Euclidean Domain in which every nonzero nonunit can be factored into a finite number of irreducibles is a Unique Factorization Domain. [Prove first that irreducible elements are prime, as follows: If p is irreducible and $p \mid ab$ with p not dividing a, use part (a) to write $px + ay = 1$ for some x, y. Multiply through by b to conclude that $p \mid b$, so p is prime. Now follow the proof of uniqueness in Theorem 14.]

(c) Make the obvious generalization to define the notion of a k-stage Euclidean Domain for any integer $k \geq 1$. Prove that statements (a) and (b) remain valid if "2-stage Euclidean" is replaced by "k-stage Euclidean."

11. (Characterization of P.I.D.s) Prove that R is a P.I.D. if and only if R is a U.F.D. that is also a Bezout Domain (cf. Exercise 7 in Section 2). [One direction is given by Theorem 14. For the converse, let a be a nonzero element of the ideal I with a minimal number of irreducible factors. Prove that $I = (a)$ by showing that if there is an element $b \in I$ that is not in (a) then $(a, b) = (d)$ leads to a contradiction.]

Practice problems.

1. Factor 85 into irreducibles in $\mathbb{Z}[i]$, using the norm $\mathrm{N}(a + bi) = a^2 + b^2$. (Hint: $85 = 5 \cdot 17$.)

Answer. Both 5 and 17 are $\equiv 1 \bmod 4$, hence split: $5 = (2 + i)(2 - i)$ and $17 = (4 + i)(4 - i)$. Each factor has prime norm ($\mathrm{N}(2 \pm i) = 5$, $\mathrm{N}(4 \pm i) = 17$), so each is irreducible. Thus, up to units,

$$85 = (2 + i)(2 - i)(4 + i)(4 - i).$$

Check. $\mathrm{N}(2 + i)\,\mathrm{N}(2 - i)\,\mathrm{N}(4 + i)\,\mathrm{N}(4 - i) = 5 \cdot 5 \cdot 17 \cdot 17 = 25 \cdot 289 = 7225 = 85^2 = \mathrm{N}(85)$. Consistent.

2. Determine whether $1 + 3i$ is irreducible in $\mathbb{Z}[i]$, using the norm $\mathrm{N}(a + bi) = a^2 + b^2$.

Answer. $\mathrm{N}(1 + 3i) = 1 + 9 = 10 = 2 \cdot 5$, which is *not* a rational prime, so the prime-norm shortcut does not apply and $1 + 3i$ may well be reducible. Seek a factor of norm 2 or 5: the norm-2 element $1 + i$ divides $1 + 3i$, since

$$(1 + i)(2 + i) = 2 + i + 2i + i^2 = 1 + 3i.$$

Both $1+i$ ($\mathrm{N} = 2$) and $2+i$ ($\mathrm{N} = 5$) have prime norm, hence are irreducible nonunits. So $1+3i = (1+i)(2+i)$ is reducible. *Check.* $\mathrm{N}(1 + i)\,\mathrm{N}(2 + i) = 2 \cdot 5 = 10 = \mathrm{N}(1 + 3i)$. Consistent. (Contrast: a Gaussian integer of *prime* norm is forced to be irreducible; composite norm leaves the question open until you exhibit a proper factor.)

3. Prove that in any integral domain every prime element is irreducible. (Reproduce the one-line argument.)

   Answer. Let p be prime and write $p = ab$. Then $p \mid ab$, so $p \mid a$ or $p \mid b$; say $p \mid a$, $a = px$. Then $p = pxb$, so $p(1 - xb) = 0$. Since R is a domain and $p \neq 0$, $xb = 1$, so b is a unit. Thus in any factorization one factor is a unit, and p is irreducible.

4. Show that 3 is irreducible but not prime in $\mathbb{Z}[\sqrt{-5}]$ by exhibiting two factorizations of 9. (Use $\mathrm{N}(a + b\sqrt{-5}) = a^2 + 5b^2$.)

   Answer. Two factorizations:

$$9 = 3 \cdot 3 = (2 + \sqrt{-5})(2 - \sqrt{-5}), \qquad \mathrm{N}(2 \pm \sqrt{-5}) = 4 + 5 = 9.$$

   3 *irreducible:* $\mathrm{N}(3) = 9$, so a proper factor would have norm 3, but $a^2 + 5b^2 = 3$ has no integer solution; hence 3 is irreducible. 3 *not prime:* $3 \mid 9 = (2 + \sqrt{-5})(2 - \sqrt{-5})$, but $3 \nmid 2 + \sqrt{-5}$ (would force $3 \mid 2$ in $\mathbb{Z}$) and $3 \nmid 2 - \sqrt{-5}$. So 3 is irreducible but not prime, and $\mathbb{Z}[\sqrt{-5}]$ is not a UFD.

5. In $\mathbb{F}_3[x]$, decide whether $x^2 + 1$ is irreducible; if reducible, factor it.

   Answer. Test for roots in $\mathbb{F}_3$: $0^2 + 1 = 1$, $1^2 + 1 = 2$, $2^2 + 1 = 5 \equiv 2 \pmod 3$. No root, and a degree-2 polynomial over a field with no root is irreducible. So $x^2 + 1$ is irreducible in $\mathbb{F}_3[x]$. (Contrast: over $\mathbb{F}_2$, $x^2 + 1 = (x + 1)^2$; over $\mathbb{F}_5$, $x^2 + 1 = (x + 2)(x - 2)$. The $\mathbb{F}_3$ case is inert.)

6. In $\mathbb{Z}$, factor $a = 2^3 \cdot 3 \cdot 5^2$ and $b = 2 \cdot 3^2 \cdot 5 \cdot 7$, and read off gcd and lcm by taking min / max exponents.

   Answer. Here $a = 600$, $b = 630$.

$$\gcd(a, b) = 2^{\min(3,1)} 3^{\min(1,2)} 5^{\min(2,1)} 7^{\min(0,1)} = 2 \cdot 3 \cdot 5 = 30,$$

$$\mathrm{lcm}(a, b) = 2^3 3^2 5^2 7^1 = 8 \cdot 9 \cdot 25 \cdot 7 = 12600.$$

   Check. $\gcd \cdot \mathrm{lcm} = 30 \cdot 12600 = 378000 = 600 \cdot 630 = ab$. Consistent.

7. Suppose R is a UFD and p is irreducible. Prove p is prime, appealing to uniqueness of factorization.

   Answer. Suppose $p \mid ab$, say $ab = pc$. If a or b is 0 or a unit, then p divides a or b directly (e.g. $b = a^{-1}pc$ if a is a unit). Otherwise factor a, b, and c into irreducibles, absorbing c into p if c is a unit. Then

$$\Big(\prod_i p_i\Big)\Big(\prod_j q_j\Big) = p \cdot \prod_k r_k$$

   are two irreducible factorizations of ab. By uniqueness the irreducible p on the right is an associate of some factor on the left, so $p \sim p_i$ for some i (whence $p \mid a$) or $p \sim q_j$ for some j (whence $p \mid b$). Hence p is prime.

8. In $\mathbb{Z}[i]$, list the associates of $1 + i$, show $1 - i$ is among them, and deduce $2 = -i(1 + i)^2$.

   Answer. $\mathbb{Z}[i]^\times = \{1, -1, i, -i\}$, so the associates of $1 + i$ are

$$1 + i, \quad -(1 + i) = -1 - i, \quad i(1 + i) = -1 + i, \quad -i(1 + i) = 1 - i.$$

   Thus $1 - i = -i(1 + i)$ is an associate of $1 + i$. Then

$$2 = (1 + i)(1 - i) = (1 + i)\big(-i(1 + i)\big) = -i(1 + i)^2,$$

   with $1 + i$ irreducible ($\mathrm{N}(1 + i) = 2$), so 2 ramifies. *Check.* $(1 + i)^2 = 2i$ and $-i \cdot 2i = 2$. Consistent.

Additional exercises.

1. Prove that an integral domain R is a UFD if and only if every nonzero nonunit is a product of irreducibles *and* every irreducible element of R is prime.

   Answer. ($\Rightarrow$) In a UFD factorizations exist by definition, and irreducible $\Longrightarrow$ prime holds (the uniqueness axiom forces it). ($\Leftarrow$) Existence is the first hypothesis. For uniqueness, suppose $p_1 \cdots p_n = q_1 \cdots q_m$ with all factors irreducible, hence prime. Then $p_1 \mid q_1 \cdots q_m$, so $p_1 \mid q_j$ for some j; since q_j is irreducible, $q_j \sim p_1$. Cancel (valid in a domain) and induct on n. Thus $n = m$ and the factors match up to associates and order, so R is a UFD.

2. Show $\mathbb{Z}[\sqrt{-5}]$ is not a UFD by exhibiting an element with two essentially different irreducible factorizations, proving each factor irreducible by the norm.

   Answer. Take
   $$21 = 3 \cdot 7 = (1 + 2\sqrt{-5})(1 - 2\sqrt{-5}),$$
   with $\mathrm{N}(3) = 9$, $\mathrm{N}(7) = 49$, $\mathrm{N}(1 \pm 2\sqrt{-5}) = 1 + 20 = 21$. Each factor is irreducible: $a^2 + 5b^2 = 3$ and $a^2 + 5b^2 = 7$ are unsolvable in $\mathbb{Z}$, so 3 and 7 are irreducible; a proper factor of $1 \pm 2\sqrt{-5}$ would have norm 3 or 7, impossible, so $1 \pm 2\sqrt{-5}$ are irreducible. No factor on the left is an associate of one on the right: the units are only ± 1, and the norms $9, 49$ on the left differ from $21, 21$ on the right. Hence the two factorizations of 21 are essentially different, and $\mathbb{Z}[\sqrt{-5}]$ is not a UFD.

3. Prove Gauss's Lemma: with R a UFD, the product of two primitive polynomials in $R[x]$ is primitive (so $\mathrm{cont}(fg) \sim \mathrm{cont}(f)\,\mathrm{cont}(g)$). State where content is used.

   Answer. Let $f, g \in R[x]$ be primitive. If fg were not primitive, some irreducible p (hence prime, since R is a UFD) would divide every coefficient of fg. Reduce mod p: in $(R/\langle p\rangle)[x]$, an integral domain, $\bar{f}\,\bar{g} = 0$, so $\bar{f} = 0$ or $\bar{g} = 0$, i.e. $p \mid \mathrm{cont}(f)$ or $p \mid \mathrm{cont}(g)$, contradicting primitivity. For the general formula, write $f = \mathrm{cont}(f) f_0$, $g = \mathrm{cont}(g) g_0$ with f_0, g_0 primitive; then $fg = \mathrm{cont}(f)\,\mathrm{cont}(g)\, f_0 g_0$ with $f_0 g_0$ primitive by the first part, so $\mathrm{cont}(fg) \sim \mathrm{cont}(f)\,\mathrm{cont}(g)$. Content enters twice: to reduce the general claim to the primitive case, and to make $R/\langle p\rangle$ a domain by invoking the primality of the irreducible p.

4. Let p be a rational prime with $p \equiv 1 \bmod 4$. Using that p is a sum of two squares, show p is reducible in $\mathbb{Z}[i]$ and describe its factorization up to units.

   Answer. Since $p \equiv 1 \bmod 4$, $p = a^2 + b^2 = (a + bi)(a - bi)$. Now $\mathrm{N}(a + bi) = p$ is prime, so $a + bi$ and $a - bi$ are irreducible; they are non-associate, since their ratio is not a unit (a unit multiple would force $a = \pm b$ or $ab = 0$, making $p = a^2 + b^2$ degenerate, not an odd prime). Thus p splits into two non-associate irreducibles, hence is reducible in $\mathbb{Z}[i]$, with $p = \pi\overline{\pi}$ up to units. **Example:** $13 = 3^2 + 2^2 = (3 + 2i)(3 - 2i)$.

5. Give a domain with a nonzero nonunit having *no* factorization into irreducibles, showing existence can fail without an ascending-chain hypothesis. Use $R = \mathbb{Z} + x\mathbb{Q}[x]$.

   Answer. Let $R = \mathbb{Z} + x\mathbb{Q}[x]$ (polynomials with integer constant term and rational higher coefficients). The element x is a nonzero nonunit. But $x = 2 \cdot \frac{x}{2}$ with $\frac{x}{2} \in R$, and $\frac{x}{2} = 2 \cdot \frac{x}{4}$, etc., giving an infinite chain of proper divisors $x, \frac{x}{2}, \frac{x}{4}, \ldots$. Equivalently the principal ideals ascend without stabilizing,
   $$\langle x\rangle \subsetneq \langle \tfrac{x}{2}\rangle \subsetneq \langle \tfrac{x}{4}\rangle \subsetneq \cdots,$$
   so ACC on principal ideals fails. This chain alone does not rule out a factorization of x, so argue directly: the units of R are ± 1, and a nonzero $f \in R$ with constant term 0 is never irreducible, since $f = 2 \cdot \frac{f}{2}$ with 2 and $\frac{f}{2}$ nonunits of R. So every irreducible of R has nonzero constant term, hence so does every product of irreducibles, while x has constant term 0. Hence x admits no finite factorization into irreducibles, and existence of irreducible factorizations is not automatic in a domain; UFDs must assume it.

Commutative-diagram exercises.

1. Draw the strict implication chain ED $\Longrightarrow$ PID $\Longrightarrow$ UFD $\Longrightarrow$ domain and give a one-line witness ring for the failure of each reverse arrow.
   $$\text{ED} \Longrightarrow \text{PID} \Longrightarrow \text{UFD} \Longrightarrow \text{domain}$$
   Answer (reverse arrows all fail).

   - PID $\not\Longrightarrow$ ED: witness $\mathbb{Z}\left[\frac{1+\sqrt{-19}}{2}\right]$, a PID with no Euclidean function.
   - UFD $\not\Longrightarrow$ PID: witness $\mathbb{Z}[x]$, a UFD where $\langle 2, x\rangle$ is not principal.
   - domain $\not\Longrightarrow$ UFD: witness $\mathbb{Z}[\sqrt{-5}]$, a domain with $6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$.

2. For a UFD R and a prime p, draw the quotient map $R \twoheadrightarrow R/\langle p\rangle$ and explain, via primeness (not mere irreducibility), why the target is an integral domain.

$$R \xrightarrow{\ \pi\ } R/\langle p\rangle \qquad \ker\pi = \langle p\rangle, \quad R/\langle p\rangle \text{ a domain}$$

Answer. p prime $\iff$ $\langle p\rangle$ a prime ideal $\iff$ $R/\langle p\rangle$ an integral domain. The map π is surjective with kernel $\langle p\rangle$; the target is a domain precisely because p is *prime*. Irreducibility alone would not suffice in a non-UFD: in $\mathbb{Z}[\sqrt{-5}]$, 2 is irreducible but $\mathbb{Z}[\sqrt{-5}]/\langle 2\rangle$ has zero divisors (the image of $1+\sqrt{-5}$ is a nonzero nilpotent). In a UFD irreducible = prime, so for irreducible p the quotient is a domain. (Contrast the PID case, where $\langle p\rangle$ is maximal and $R/\langle p\rangle$ is a *field*.)

3. Draw the relationship {prime} $\hookrightarrow$ {irreducible} (always), with a dashed reverse arrow labeled "in a UFD," and instantiate the failure of the reverse arrow in $\mathbb{Z}[\sqrt{-5}]$.

$$\{\text{prime}\} \xhookrightarrow{\ \text{always}\ } \{\text{irreducible}\}$$
$$\text{in a UFD}\ \dashleftarrow$$

Answer. The solid hook is the body's "prime $\implies$ irreducible," valid in any domain. The dashed back-arrow "irreducible $\implies$ prime" holds in every UFD, but not in every domain. Failure in $\mathbb{Z}[\sqrt{-5}]$: 2 is irreducible but not prime, since $2 \mid 6 = (1+\sqrt{-5})(1-\sqrt{-5})$ while $2 \nmid 1+\sqrt{-5}$ and $2 \nmid 1-\sqrt{-5}$. So the dashed arrow is absent there, which is exactly why $\mathbb{Z}[\sqrt{-5}]$ is not a UFD.

4. For R a UFD with $F = \mathrm{Frac}(R)$, draw the content factorization $f \mapsto \mathrm{cont}(f)\cdot f_0$ (with f_0 primitive) and relate irreducibility in $R[x]$ to $F[x]$ via Gauss's Lemma.

$$R[x] \ni f \xmapsto{\ \text{cont}\ } \mathrm{cont}(f)\cdot f_0 \qquad\qquad f_0 \text{ irred. in } R[x] \xLeftrightarrow{\ \text{Gauss}\ } f_0 \text{ irred. in } F[x]$$

Answer. Every nonzero $f \in R[x]$ factors as $f = \mathrm{cont}(f) f_0$ with f_0 primitive. The irreducibles of $R[x]$ are (a) the irreducibles of R (constants) and (b) primitive polynomials irreducible in $F[x]$. Gauss's Lemma is the bridge: a primitive f_0 is irreducible in $R[x]$ iff it is irreducible in $F[x]$. **Instantiate:** $x^2 - 2 \in \mathbb{Z}[x]$ is primitive and irreducible over $\mathbb{Q}$, hence irreducible in $\mathbb{Z}[x]$; whereas $2x + 4 = 2(x+2)$ is reducible in $\mathbb{Z}[x]$ (content 2 a nonunit) but a unit times an irreducible in $\mathbb{Q}[x]$, where 2 is a unit.

8.4 Gauss Primes and Sums of Two Squares

Gauss primes and sums of two squares

We have seen that the ring of Gauss integers $\mathbb{Z}[i] = \{\, a + bi \mid a, b \in \mathbb{Z} \,\}$ is a Euclidean domain, hence a PID and a UFD: every nonzero nonunit is a product of prime elements, called *Gauss primes*, unique up to units and order. The units are $\{\pm 1, \pm i\}$. Our goal is to *classify* the Gauss primes by relating them to the rational primes $2, 3, 5, 7, \ldots$ of $\mathbb{Z}$, and to harvest from that classification Fermat's theorem on sums of two squares.

The whole story is governed by the multiplicative *norm*

$$\mathrm{N}(a+bi) = (a+bi)(a-bi) = a^2 + b^2 = |a+bi|^2 \in \mathbb{Z}_{\geq 0},$$

which satisfies $\mathrm{N}(\alpha\beta) = \mathrm{N}(\alpha)\,\mathrm{N}(\beta)$. A Gauss integer α is a unit iff $\mathrm{N}(\alpha) = 1$. We write $\overline{\alpha} = a - bi$ for the complex conjugate, so $\mathrm{N}(\alpha) = \alpha\overline{\alpha}$.

Lemma 8.4.1 (Divisibility by rational integers)**.** *Let $d \in \mathbb{Z}$ and $a + bi \in \mathbb{Z}[i]$.*

1. A Gauss integer that is a real number is an ordinary integer.

2. d divides $a + bi$ in $\mathbb{Z}[i]$ if and only if d divides both a and b in $\mathbb{Z}$.

Proof. (1) If $a + bi \in \mathbb{R}$ then $b = 0$, so $a + bi = a \in \mathbb{Z}$. (2) If $a + bi = d(s + ti)$ with $s, t \in \mathbb{Z}$, then $a = ds$ and $b = dt$, so $d \mid a$ and $d \mid b$. Conversely if $a = ds$ and $b = dt$ then $a + bi = d(s + ti)$. □

The classification theorem

The next theorem is the heart of the section. It says a rational prime p behaves in exactly one of three ways inside $\mathbb{Z}[i]$, and pins down which by the residue of p modulo 4.

Theorem 8.4.2 (Classification of Gauss primes)**.** *1. Let π be a Gauss prime and $\overline{\pi}$ its complex conjugate. Then $\mathrm{N}(\pi) = \pi\overline{\pi}$ is either a rational prime or the square of a rational prime.*

2. Let p be a rational prime. Then p is either a Gauss prime, or the product $\pi\overline{\pi}$ of a Gauss prime and its conjugate.

3. The rational primes p that remain Gauss primes (are inert*) are exactly those with $p \equiv 3 \pmod 4$, namely $3, 7, 11, 19, 23, \ldots$*

4. For a rational prime p the following are equivalent:

(a) p is a product of complex-conjugate Gauss primes (is split*, or for $p = 2$* ramified*);*

(b) $p = 2$ or $p \equiv 1 \pmod 4$ (so $p = 2, 5, 13, 17, 29, \ldots$);

(c) $p = a^2 + b^2$ is a sum of two integer squares;

(d) the residue of -1 is a square modulo p (i.e. -1 is a quadratic residue).

Proof. **(a)** Let $\pi = a + bi$ and factor the positive integer $\mathrm{N}(\pi) = a^2 + b^2 = p_1 \cdots p_k$ into rational primes. This same equation $\pi\overline{\pi} = p_1 \cdots p_k$ holds in $\mathbb{Z}[i]$, but the right side need not be a prime factorization there. Continue factoring each p_j in $\mathbb{Z}[i]$ to reach a Gauss-prime factorization. By unique factorization in $\mathbb{Z}[i]$, the Gauss primes obtained must be associates of the two factors π and $\overline{\pi}$. Hence at most two prime factors occur, so $\mathrm{N}(\pi)$ is either a rational prime or a product of two rational primes; in the latter case matching $\pi, \overline{\pi}$ against the factors forces the two to be equal, so $\mathrm{N}(\pi) = p^2$.

(b) A rational prime p is not a unit of $\mathbb{Z}[i]$, so some Gauss prime π divides p. Then $\overline{\pi}$ divides $\overline{p} = p$ as well, so $\mathrm{N}(\pi) = \pi\overline{\pi}$ divides p^2 in $\mathbb{Z}[i]$ and (being a positive integer) in $\mathbb{Z}$. Thus $\mathrm{N}(\pi) \in \{p, p^2\}$. If $\mathrm{N}(\pi) = p^2$ then π and p are associates and p is itself a Gauss prime; if $\mathrm{N}(\pi) = p$ then $p = \pi\overline{\pi}$ splits.

(d) We show (i) $\Longleftrightarrow$ (iii), (i) $\Longleftrightarrow$ (iv), and (ii) $\Longleftrightarrow$ (iv); part (c) then follows since the inert primes are precisely those that are *not* of the split type.

(i) $\Longleftrightarrow$ (iii). If $p = \pi\overline{\pi}$ with $\pi = a + bi$ a Gauss prime, then $p = a^2 + b^2$ is a sum of two squares. Conversely if $p = a^2 + b^2$, then $p = (a - bi)(a + bi)$ factors in $\mathbb{Z}[i]$, and by (a) each factor has norm p, hence is a Gauss prime; so p is a product of conjugate Gauss primes.

(i) $\Longleftrightarrow$ (iv). The quotient $R = \mathbb{Z}[i]/(p)$ may be built in two steps from $\mathbb{Z}[x]$. Killing $x^2 + 1$ first yields $\mathbb{Z}[i]$, then killing p yields R; killing p first yields $\mathbb{F}_p[x]$, then killing $x^2 + 1$ yields R again. So $R \cong \mathbb{F}_p[x]/(x^2 + 1)$. Now (p) is a maximal ideal of $\mathbb{Z}[i]$ iff p is a Gauss prime; equivalently R is a field iff $x^2 + 1$ is irreducible in $\mathbb{F}_p[x]$. Thus p is *inert* iff $x^2 + 1$ is irreducible mod p, i.e. iff -1 is *not* a square mod p. Negating, p splits iff -1 is a square mod p, which is (iv). (For $p = 2$, $x^2 + 1 = (x + 1)^2$ in $\mathbb{F}_2[x]$ and $-1 \equiv 1$ is a square; $2 = -i(1 + i)^2$ is ramified.)

(ii) $\Longleftrightarrow$ (iv). It is clear that -1 is a square modulo 2. For odd p, the multiplicative group $\mathbb{F}_p^\times$ is cyclic of order $p - 1$. An element $\overline{a}$ solves $x^2 \equiv -1$ iff $\overline{a}$ has order 4 (its square then has order 2, and -1 is the unique element of order 2). And $\mathbb{F}_p^\times$ contains an element of order 4 iff $4 \mid p - 1$, i.e. iff $p \equiv 1 \pmod 4$. Hence -1 is a square mod p iff $p \equiv 1 \pmod 4$ (or $p = 2$), which is (ii). □

Corollary 8.4.3 (Fermat's two-squares theorem)**.** *A rational prime p is a sum of two integer squares, $p = a^2 + b^2$, if and only if $p = 2$ or $p \equiv 1 \pmod 4$. No prime $p \equiv 3 \pmod 4$ is a sum of two squares.*

Proof. Immediate from the equivalence (ii) $\Longleftrightarrow$ (iii) of Theorem 8.4.2(d). The last clause is the contrapositive: a prime that is a sum of two squares cannot be $\equiv 3 \pmod 4$. □

Remark 8.4.1. The arithmetic obstruction for $p \equiv 3 \pmod 4$ is visible mod 4 directly: every square is $\equiv 0$ or $1 \pmod 4$, so $a^2 + b^2 \in \{0, 1, 2\} \pmod 4$ and can never be $\equiv 3$. The deeper content of the theorem is the *converse* — that $p \equiv 1 \pmod 4$ *always* is a sum of two squares — which is exactly the splitting of p in the UFD $\mathbb{Z}[i]$.

Method (Deciding how a rational prime p factors in $\mathbb{Z}[i]$)**.** *Trigger.* You must factor a rational prime in the Gauss integers, or test whether x^2+1 factors mod p.

1. Reduce p modulo 4.
2. If $p=2$: *ramified*, $2=-i(1+i)^2$, with $\mathrm{N}(1+i)=2$.
3. If $p\equiv 1 \pmod 4$: *split*. Solve $a^2+b^2=p$ (equivalently find c with $c^2\equiv -1 \bmod p$, then $\gcd_{\mathbb{Z}[i]}(p,\, c+i)$ gives the factor). Then $p=(a+bi)(a-bi)$ with both factors Gauss primes of norm p.
4. If $p\equiv 3 \pmod 4$: *inert*, p stays a Gauss prime, $\mathrm{N}(p)=p^2$.

Worked Example 8.4.4 (The split primes $5, 13, 17$)**.** Factor 5, 13, and 17 into Gauss primes.

Recognition. All three are $\equiv 1 \pmod 4$ $(5, 13, 17)$, so by Theorem 8.4.2(d) each splits as a product of conjugate Gauss primes; find a, b with $a^2+b^2=p$.

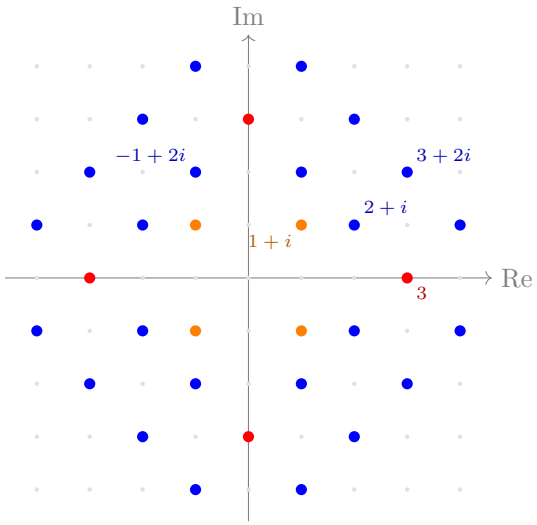
Solution. $5=4+1=2^2+1^2$, so $5=(2+i)(2-i)$. $13=9+4=3^2+2^2$, so $13=(3+2i)(3-2i)$. $17=16+1=4^2+1^2$, so $17=(4+i)(4-i)$. In each case both factors have norm p (a rational prime), hence are Gauss primes by part (a). *Check.* $(2+i)(2-i)=4-i^2=5$; $(3+2i)(3-2i)=9-4i^2=13$; $(4+i)(4-i)=16-i^2=17$. Correspondingly -1 is a QR: $2^2\equiv -1$ (5), $5^2=25\equiv -1$ (13), $4^2=16\equiv -1$ (17).

Worked Example 8.4.5 (The ramified prime 2)**.** Factor 2 in $\mathbb{Z}[i]$ and explain why it is special.

Recognition. 2 is the unique prime where the two conjugate factors are *associates* rather than distinct — the ramified case.

Solution. $2=1+1=1^2+1^2=(1+i)(1-i)$. Here $1-i=-i(1+i)$ (since $-i(1+i)=-i-i^2=1-i$), so the two factors are associates of the single Gauss prime $\pi=1+i$, with $\mathrm{N}(1+i)=2$. Thus $2=(1+i)(1-i)=-i(1+i)^2$ is, up to a unit, the *square* of one Gauss prime. *Check.* $-i(1+i)^2=-i(1+2i+i^2)=-i(2i)=-2i^2=2$. Unlike $5=(2+i)(2-i)$ where $2+i$ and $2-i$ are non-associate, here both "factors" are $\pm i$-multiples of $1+i$, which is what *ramified* means.

Worked Example 8.4.6 (The inert primes $3, 7, 11$)**.** Show 3, 7, and 11 remain prime in $\mathbb{Z}[i]$, and connect to $x^2+1 \bmod p$.



Recognition. All are $\equiv 3 \pmod 4$ $(3, 7, 11)$, so by Theorem 8.4.2(c) they are inert: p stays a Gauss prime, equivalently x^2+1 is irreducible mod p and -1 is a non-residue.

Solution. Suppose $3=\alpha\beta$ with neither a unit. Taking norms, $9=\mathrm{N}(\alpha)\,\mathrm{N}(\beta)$ with $\mathrm{N}(\alpha), \mathrm{N}(\beta)>1$, forcing $\mathrm{N}(\alpha)=3$. But $\mathrm{N}(a+bi)=a^2+b^2=3$ has no integer solution (squares are $0, 1, 4, 9, \ldots$; no two sum to 3). So 3 has no proper factor and is a Gauss prime. The same norm argument kills 7 ($a^2+b^2=7$ unsolvable: $0, 1, 4$ give sums $0, 1, 2, 4, 5, 8$, never 7) and 11 ($a^2+b^2=11$ unsolvable). *Check.* Consistently, -1 is a non-residue: mod 3 the squares are $\{0, 1\}$, mod 7 they are $\{0, 1, 2, 4\}$, mod 11 they are $\{0, 1, 3, 4, 5, 9\}$ — none contains $p-1\equiv -1$. So x^2+1 is irreducible in each $\mathbb{F}_p[x]$ and $\mathbb{F}_p[x]/(x^2+1)=\mathbb{F}_{p^2}$ is a field, matching $\mathbb{Z}[i]/(p)$ being a field.

Caution. **Split factors are not always associates — only 2 ramifies.** For $p\equiv 1 \pmod 4$ the conjugates $a+bi$ and $a-bi$ are *non-associate* Gauss primes (e.g. $2+i$ and $2-i$ are not $\pm 1, \pm i$ multiples of each other). Only $p=2$ has its two factors associate, because $(1+i)/(1-i)=i$ is a unit. Calling $5=(2+i)(2-i)$ "ramified" is the common slip; 5 is *split*, 2 is ramified.

The Gauss-prime lattice in the plane

Plotting the Gauss primes of small norm reveals the trichotomy geometrically: inert primes sit on the real and imaginary axes (the rational primes $3, 7, 11, \ldots$ and their i-multiples), while split primes come in conjugate pairs reflected across the real axis, and $1+i$ sits on the diagonal closest to the origin.

p mod 4	type	N pattern	Gauss primes above p
2	ramified	$2 = \mathrm{N}(1+i)$	$1+i$ (up to units)
1	split	$p = a^2+b^2$	$a+bi,\ a-bi$ (non-associate)
3	inert	$p^2 = \mathrm{N}(p)$	p itself

Remark 8.4.2. Reading the diagram: the orange point $1+i$ (and its three unit-multiples) is the lone ramified prime, nearest the origin off the axes. The blue points are split primes, each appearing as a conjugate pair $a \pm bi$ symmetric across the real axis, together with their i-rotations — e.g. $2 \pm i$, $1 \pm 2i$ above 5, and $3 \pm 2i$, $2 \pm 3i$ above 13. The red points $\pm 3, \pm 3i$ are inert: the rational prime 3 and its unit multiples, sitting squarely on the axes because $\mathrm{N} = 9$ cannot be written a^2+b^2 with both a, b nonzero small. The eightfold symmetry of the whole picture is the action of the units $\{\pm 1, \pm i\}$ together with complex conjugation.

8.5 Graded Problem Bank

Easy

DF 8.1.1 For each pair of integers a, b (e.g. $a = 20, b = 13$ and four further pairs), compute $d = \gcd(a,b)$ by the Euclidean Algorithm and write $d = ax + by$.

DF 8.1.2 For each pair a, n (e.g. $a = 13, n = 20$ and three more), show a is relatively prime to n and find the inverse of a mod n.

DF 8.1.5 Determine all integer solutions of $2x + 4y = 5$, of $17x + 29y = 31$, and of $85x + 145y = 505$.

DF 8.1.7 Find a generator (a gcd) for the ideal $(85, 1+13i)$ in $\mathbb{Z}[i]$ by the Euclidean Algorithm; do the same for $(47-13i, 53+56i)$.

DF 8.3.3 Determine all representations of $2130797 = 17^2 \cdot 73 \cdot 101$ as a sum of two squares.

Artin 1.2 Write $7/24$ as $a/8 + b/3$.

Artin 1.4 Solve the simultaneous congruences (a) $x \equiv 3\ (8),\ x \equiv 2\ (5)$; (b) $x \equiv 3\ (15),\ x \equiv 5\ (8),\ x \equiv 2\ (7)$; (c) $x \equiv 13\ (43),\ x \equiv 7\ (71)$.

Artin 2.1 Factor into irreducibles in $\mathbb{F}_p[x]$: (a) $x^3 + x^2 + x + 1$, $p = 2$; (b) $x^2 - 3x - 3$, $p = 5$; (c) $x^2 + 1$, $p = 7$.

Artin 2.2 Compute the gcd of $x^6 + x^4 + x^3 + x^2 + x + 1$ and $x^5 + 2x^3 + x^2 + x + 1$ in $\mathbb{Q}[x]$.

Artin 2.3 How many roots does $x^2 - 2$ have modulo 8?

Artin 2.8 Describe a systematic division-with-remainder in $\mathbb{Z}[i]$ and use it to divide $4 + 36i$ by $5 + i$.

Artin 4.1 Factor (a) $x^9 - x$ and $x^9 - 1$ in $\mathbb{F}_3[x]$; (b) $x^{16} - x$ in $\mathbb{F}_2[x]$.

Artin 4.2 Prove irreducible: (a) $x^2 + 1$ in $\mathbb{F}_7[x]$; (b) $x^3 - 9$ in $\mathbb{F}_{31}[x]$.

Artin 4.7 Factor $x^3 + x + 1$ in $\mathbb{F}_p[x]$ for $p = 2, 3, 5$.

Artin 4.10 Factor in $\mathbb{Q}[x]$ the polynomials (a)–(l) listed (e.g. $x^2+2351x+125$, x^3+2x^2+3x+1, $x^4+2x^3+2x^2+2x+2$, ...).

Artin 5.1 Factor into primes in $\mathbb{Z}[i]$: (a) $1 - 3i$; (b) 10; (c) $6 + 9i$; (d) $7 + i$.

Artin 5.2 Find the gcd in $\mathbb{Z}[i]$ of (a) $11 + 7i,\ 4 + 7i$; (b) $11 + 7i,\ 8 + i$; (c) $3 + 4i,\ 18 - i$.

Artin 5.3 Find a generator for the ideal of $\mathbb{Z}[i]$ generated by $3 + 4i$ and $4 + 7i$.

Artin 5.7 Describe the residue ring $\mathbb{Z}[i]/(p)$ for each prime p.

Fraleigh 34.1 Is 5 an irreducible of $\mathbb{Z}$?

Fraleigh 34.2 Is -17 an irreducible of $\mathbb{Z}$?

Fraleigh 34.3 Is 14 an irreducible of $\mathbb{Z}$?

Fraleigh 34.4 Is $2x - 3$ an irreducible of $\mathbb{Z}[x]$?

Fraleigh 34.5 Is $2x - 10$ an irreducible of $\mathbb{Z}[x]$?

Fraleigh 34.6 Is $2x - 3$ an irreducible of $\mathbb{Q}[x]$?

Fraleigh 34.7 Is $2x - 10$ an irreducible of $\mathbb{Q}[x]$?

Fraleigh 34.8 Is $2x - 10$ an irreducible of $\mathbb{Z}_{11}[x]$?

Fraleigh 34.9 If possible, give four different associates of $2x - 7$ as an element of $\mathbb{Z}[x]$; of $\mathbb{Q}[x]$; of $\mathbb{Z}_{11}[x]$.

Fraleigh 34.10 Factor $4x^2 - 4x + 8$ into irreducibles in $\mathbb{Z}[x]$, in $\mathbb{Q}[x]$, and in $\mathbb{Z}_{11}[x]$.

Fraleigh 34.11 Find all gcd's of $234, 3250, 1690$ in $\mathbb{Z}$.

Fraleigh 34.12 Find all gcd's of $784, -1960, 448$ in $\mathbb{Z}$.

Fraleigh 34.13 Find all gcd's of $2178, 396, 792, 594$ in $\mathbb{Z}$.

Fraleigh 34.14 Write $18x^2 - 12x + 48$ in $\mathbb{Z}[x]$ as content times a primitive polynomial.

Fraleigh 34.15 Write $18x^2 - 12x + 48$ in $\mathbb{Q}[x]$ as content times a primitive polynomial.

Fraleigh 34.16 Write $2x^2 - 3x + 6$ in $\mathbb{Z}[x]$ as content times a primitive polynomial.

Fraleigh 34.17 Write $2x^2 - 3x + 6$ in $\mathbb{Z}_7[x]$ as content times a primitive polynomial.

Fraleigh 34.21 Decide true/false: every field is a UFD; every field is a PID; every PID is a UFD; every UFD is a PID; $\mathbb{Z}[x]$ is a UFD; etc.

Fraleigh 35.1 Is $\nu(n) = n^2$ a Euclidean norm for $\mathbb{Z}$?

Fraleigh 35.2 Is $\nu(f) = \deg f$ a Euclidean norm for $\mathbb{Z}[x]$?

Fraleigh 35.3 Is $\nu(f) =$ (absolute value of the leading coefficient of f) a Euclidean norm for $\mathbb{Z}[x]$?

Fraleigh 35.4 Is $\nu(a) = a^2$ a Euclidean norm for $\mathbb{Q}$?

Fraleigh 35.5 Is $\nu(a) = 50$ a Euclidean norm for $\mathbb{Q}$?

Fraleigh 35.6 Express the gcd 23 in the form $\lambda(22471) + \mu(3266)$ with $\lambda, \mu \in \mathbb{Z}$.

Fraleigh 35.7 Find a gcd of 49349 and 15555 in $\mathbb{Z}$.

Fraleigh 35.8 Express the positive gcd of 49349 and 15555 as $\lambda(49349) + \mu(15555)$ with $\lambda, \mu \in \mathbb{Z}$.

Fraleigh 35.9 Find a gcd of $x^{10} - 3x^9 + 3x^8 - 11x^7 + 11x^6 - 11x^5 + 19x^4 - 13x^3 + 8x^2 - 9x + 3$ and $x^6 - 3x^5 + 3x^4 - 9x^3 + 5x^2 - 5x + 2$ in $\mathbb{Q}[x]$.

Fraleigh 35.11 Find the gcd of $2178, 396, 792, 726$ in $\mathbb{Z}$.

Fraleigh 35.13 Decide true/false: every Euclidean domain is a PID; every PID is a Euclidean domain; every Euclidean domain is a UFD; for any field F, $F[x]$ is a Euclidean domain; etc.

Fraleigh 36.1 Factor the Gaussian integer 5 into irreducibles in $\mathbb{Z}[i]$.

Fraleigh 36.2 Factor 7 into irreducibles in $\mathbb{Z}[i]$.

Fraleigh 36.3 Factor $4 + 3i$ into irreducibles in $\mathbb{Z}[i]$.

Fraleigh 36.4 Factor $6 - 7i$ into irreducibles in $\mathbb{Z}[i]$.

Fraleigh 36.6 For $\alpha = 7 + 2i$, $\beta = 3 - 4i$ in $\mathbb{Z}[i]$, find σ, ρ with $\alpha = \beta\sigma + \rho$ and $\mathrm{N}(\rho) < \mathrm{N}(\beta)$.

Fraleigh 36.7 Use a Euclidean algorithm in $\mathbb{Z}[i]$ to find a gcd of $8 + 6i$ and $5 - 15i$.

Fraleigh 36.8 Decide true/false statements about $\mathbb{Z}[i]$ (PID, Euclidean domain, multiplicative norm, units, $\mathbb{Z}[\sqrt{-5}]$ not a UFD, etc.).

Medium

DF 8.1.3 Let R be a Euclidean Domain and m the minimum norm of a nonzero element. Prove every nonzero element of norm m is a unit, and deduce a nonzero element of norm zero (if any) is a unit.

DF 8.1.4 In a Euclidean Domain: (a) if $(a, b) = 1$ and $a \mid bc$ then $a \mid c$, and more generally $\frac{a}{(a,b)} \mid c$; (b) describe the full solution set of $ax + by = N$ given one solution.

DF 8.1.9 Prove the ring of integers $\mathcal{O}$ in $\mathbb{Q}(\sqrt{2})$ is a Euclidean Domain with respect to the absolute value of the field norm.

DF 8.1.10 Prove $\mathbb{Z}[i]/I$ is finite for any nonzero ideal I of $\mathbb{Z}[i]$, using $I = (\alpha)$ and the Division Algorithm.

DF 8.2.1 Prove that in a PID two ideals $(a), (b)$ are comaximal iff a gcd of a and b is 1.

DF 8.2.2 Prove any two nonzero elements of a PID have a least common multiple.

DF 8.2.3 Prove that a quotient of a PID by a prime ideal is again a PID.

DF 8.2.7 (Bezout Domains) Prove an integral domain R is a Bezout Domain iff every pair a, b has a gcd of the form $ra + sb$; that every finitely generated ideal is principal; and that every element of $\mathrm{Frac}(R)$ is a/b with a, b coprime.

DF 8.2.8 Prove that if R is a PID and D a multiplicatively closed subset with $0 \notin D$, then $D^{-1}R$ is a PID.

DF 8.3.1 For $G = \mathbb{Q}^\times$ and the map φ swapping the primes $2, 3$ in prime factorizations: (a) prove φ is a group isomorphism; (b) prove there are infinitely many isomorphisms $G \to G$.

DF 8.3.2 For nonzero a, b in a UFD R, prove they have an lcm and describe it via the prime factorizations of a, b.

DF 8.3.4 Prove that if an integer is a sum of two rational squares, then it is a sum of two integer squares.

DF 8.3.6 (a) Prove $\mathbb{Z}[i]/(1+i)$ is a field of order 2; (b) for a prime $q \equiv 3\ (4)$ prove $\mathbb{Z}[i]/(q)$ is a field with q^2 elements; (c) for $p \equiv 1\ (4)$ with $p = \pi\overline{\pi}$, apply CRT to show $\mathbb{Z}[i]/(p) \cong \mathbb{Z}[i]/(\pi) \times \mathbb{Z}[i]/(\overline{\pi})$ and each factor is a field of order p.

Artin 1.1 Prove a positive integer that is not a perfect square is not the square of a rational number.

Artin 1.3 (CRT) For coprime n, m and arbitrary a, b, prove $x \equiv a\ (m)$, $x \equiv b\ (n)$ has a solution, and determine all solutions.

Artin 1.5 For coprime integers a, b, prove there are integers m, n with $a^m + b^n \equiv 1\ (ab)$.

Artin 2.4 Adapt Euclid's argument to prove that for any field F there are infinitely many monic irreducible polynomials in $F[x]$.

Artin 2.6 Prove the rings (a) $\mathbb{Z}[\omega]$, $\omega = e^{2\pi i/3}$, and (b) $\mathbb{Z}[\sqrt{-2}]$ are Euclidean domains.

Artin 2.7 Prove the gcd of two integers in $\mathbb{Z}$ equals their gcd in the ring of Gauss integers.

Artin 2.9 Prove the ring $F[x, x^{-1}]$ of Laurent polynomials over a field F is a PID.

Artin 2.10 Prove the ring $\mathbb{R}[[t]]$ of formal power series is a UFD.

Artin 3.1 For $\varphi : \mathbb{Z}[x] \to \mathbb{C}$ with (a) $\varphi(x) = 1 + \sqrt{2}$, (b) $\varphi(x) = \frac{1}{2} + \sqrt{2}$: is $\ker \varphi$ principal, and if so find a generator.

Artin 3.2 Prove two integer polynomials are relatively prime in $\mathbb{Q}[x]$ iff the ideal they generate in $\mathbb{Z}[x]$ contains a nonzero integer.

Artin 3.6 For $\alpha \in \mathbb{C}$, prove the kernel of the substitution map $\mathbb{Z}[x] \to \mathbb{C}$, $x \mapsto \alpha$, is a principal ideal and describe its generator.

Artin 4.3 Decide whether $x^4 + 6x^3 + 9x + 3$ generates a maximal ideal in $\mathbb{Q}[x]$.

Artin 4.4 Factor $x^5 + 2x^4 + 3x^3 + 3x + 5$ modulo 2, modulo 3, and in $\mathbb{Q}$.

Artin 4.5 Which of $x^2 + 27x + 213$, $8x^3 - 6x + 1$, $x^3 + 6x^2 + 1$, $x^5 - 3x^4 + 3$ are irreducible in $\mathbb{Q}[x]$?

Artin 4.6 Factor $x^5 + 5x + 5$ into irreducibles in $\mathbb{Q}[x]$ and in $\mathbb{F}_2[x]$.

Artin 4.8 How can $f(x) = x^4 + bx^2 + c$ factor over a field F? Illustrate with $x^4 + 4x^2 + 4$ and $x^4 + 3x^2 + 4$.

Artin 4.9 For which primes p and integers n is $x^n - p$ irreducible in $\mathbb{Q}[x]$?

Artin 4.12 Determine (a) the monic irreducible cubics over $\mathbb{F}_3$; (b) the monic irreducible quadratics over $\mathbb{F}_5$; (c) the number of irreducible cubics over $\mathbb{F}_5$.

Artin 4.15 With reference to the Eisenstein criterion, what can one say when (a) f is constant, (b) $f = x^n + bx^{n-1}$?

Artin 4.16 Factor $x^{14} + 8x^{13} + 3$ in $\mathbb{Q}[x]$, using reduction modulo 3 as a guide.

Artin 4.17 Using congruence modulo 4 as an aid, factor $x^4 + 6x^3 + 7x^2 + 8x + 9$ in $\mathbb{Q}[x]$.

Artin 4.19 Factor $x^5 - x^4 - x^2 - 1$ modulo 2, modulo 16, and over $\mathbb{Q}$.

Artin 5.5 For a Gauss prime π, prove π and $\overline{\pi}$ are associates iff π is an associate of an integer prime or $\pi\overline{\pi} = 2$.

Artin 5.6 For $R = \mathbb{Z}[\sqrt{-3}]$, prove an integer prime p is prime in R iff $x^2 + 3$ is irreducible in $\mathbb{F}_p[x]$.

Artin M.5 For which integers n does the circle $x^2 + y^2 = n$ contain a point with integer coordinates?

Fraleigh 34.18 Correct, if needed, the definition: a, b in a domain D are associates iff their quotient a/b in D is a unit.

Fraleigh 34.19 Correct, if needed, the definition: an element of a domain is irreducible iff it cannot be factored into a product of two elements.

Fraleigh 34.20 Correct, if needed, the definition: an element of a domain is prime iff it cannot be factored into a product of two smaller elements.

Fraleigh 34.22 For a UFD D, describe the irreducibles of $D[x]$ in terms of the irreducibles of D and those of $F[x]$, F a field of quotients.

Fraleigh 34.23 Give an example of $g(x) \in D[x]$ that is irreducible in $F[x]$ but not in $D[x]$.

Fraleigh 34.24 In $\mathbb{Z} \times \mathbb{Z}$ (a commutative ring with unity, not a domain), discuss factorization into irreducibles; consider $(1, 0)$ in particular.

Fraleigh 34.25 Prove that if p is a prime in an integral domain D, then p is an irreducible.

Fraleigh 34.27 Show $a \sim b$ iff $a = bu$ for a unit u is an equivalence relation on a commutative ring with unity.

Fraleigh 34.28 For a domain D with unit group U, show $D^* - U$ (nonzero nonunits) is closed under multiplication; is it a group?

Fraleigh 35.10 Describe how the Euclidean Algorithm finds the gcd of n elements $a_1, \ldots, a_n$ of a Euclidean domain.

Fraleigh 35.12 For $\mathbb{Z}[x]$: is it a UFD? show $\{a+xf(x) \mid a \in 2\mathbb{Z},\ f \in \mathbb{Z}[x]\}$ is an ideal; is $\mathbb{Z}[x]$ a PID? a Euclidean domain?

Fraleigh 35.14 Does the choice of a particular Euclidean norm ν on a Euclidean domain D influence the arithmetic structure of D? Explain.

Fraleigh 35.15 For a Euclidean norm ν, show that if a, b are associates in D then $\nu(a) = \nu(b)$.

Fraleigh 35.18 Show that every field is a Euclidean domain.

Fraleigh 35.21 Show nonzero $r, s \in \mathbb{Z}$ generate $\langle \mathbb{Z}, + \rangle$ iff r, s are relatively prime.

Fraleigh 35.22 Show for nonzero $a, b, n \in \mathbb{Z}$ that $ax \equiv b\ (n)$ has a solution if a, n are relatively prime.

Fraleigh 35.24 Outline a constructive method to solve $ax \equiv b\ (n)$ when solvable, and use it to solve $22x \equiv 18\ (42)$.

Fraleigh 36.5 Show 6 does not factor uniquely into irreducibles in $\mathbb{Z}[\sqrt{-5}]$; exhibit two factorizations.

Fraleigh 36.9 For a domain D with multiplicative norm N where $|N(\alpha)| = 1$ iff α is a unit, and π of minimal $|N| > 1$, show π is irreducible.

Hard

DF 8.1.6 (Postage Stamp Problem) For coprime positive a, b, prove every sufficiently large N is a nonnegative combination $ax + by$; prove $ab - a - b$ is not, but every integer greater than $ab - a - b$ is.

DF 8.1.8 For $F = \mathbb{Q}(\sqrt{D})$ with quadratic integer ring $\mathcal{O}$: (a) for $D = -1, -2, -3, -7, -11$ prove $\mathcal{O}$ is Euclidean with respect to N; (b) for $D = -43, -67, -163$ prove $\mathcal{O}$ is not Euclidean with respect to any norm.

DF 8.2.5 For $R = \mathbb{Z}[\sqrt{-5}]$ with $I_2 = (2, 1+\sqrt{-5})$, $I_3 = (3, 2+\sqrt{-5})$, $I_3' = (3, 2-\sqrt{-5})$: (a) prove I_2, I_3, I_3' are nonprincipal; (b) prove $I_2^2 = (2)$; (c) prove $I_2 I_3 = (1-\sqrt{-5})$, $I_2 I_3' = (1+\sqrt{-5})$, so $(6) = I_2^2 I_3 I_3'$.

DF 8.2.4 Prove an integral domain R is a PID if (i) any two nonzero a, b have a gcd of the form $ra + sb$, and (ii) every chain $a_{i+1} \mid a_i$ stabilizes up to units.

DF 8.2.6 If every prime ideal of a domain R is principal, prove every ideal is principal (so R is a PID), via a Zorn's-Lemma maximal nonprincipal ideal argument.

DF 8.3.5 For $R = \mathbb{Z}[\sqrt{-n}]$, $n > 3$ squarefree: (a) prove $2, \sqrt{-n}, 1+\sqrt{-n}$ are irreducible; (b) prove R is not a UFD; (c) exhibit an explicit nonprincipal ideal.

DF 8.3.7 For an irreducible $\pi \in \mathbb{Z}[i]$: (a) prove multiplication by π^n induces $\mathbb{Z}[i]/(\pi) \cong (\pi^n)/(\pi^{n+1})$ as additive groups; (b) prove $|\mathbb{Z}[i]/(\pi^n)| = |\mathbb{Z}[i]/(\pi)|^n$; (c) prove $|\mathbb{Z}[i]/(\alpha)| = N(\alpha)$ for nonzero α.

DF 8.3.8 For $R = \mathbb{Z}[\sqrt{-5}]$ with I_2, I_3, I_3': (a) prove $2, 3, 1 \pm \sqrt{-5}$ are non-associate irreducibles giving two factorizations of 6; (b) prove I_2, I_3, I_3' are prime ideals; (c) reconcile the two ideal factorizations of (6) into primes.

DF 8.3.9 If the quadratic integer ring $\mathcal{O}$ is a PID, prove the absolute value of the field norm is a Dedekind–Hasse norm on $\mathcal{O}$.

DF 8.3.10 (k-stage Euclidean Domains) (a) Prove iterated two-step division yields a gcd that is a linear combination, so finitely generated ideals are principal; (b) prove such a domain with factorization into irreducibles is a UFD; (c) generalize to k-stage.

DF 8.3.11 (Characterization of PIDs) Prove R is a PID iff R is a UFD that is also a Bezout Domain.

Artin 2.5 (a) Prove every element of $\mathbb{C}(x)$ is a sum of a polynomial and a combination of functions $1/(x-a)^i$; (b) exhibit a basis for $\mathbb{C}(x)$ over $\mathbb{C}$.

Artin 3.3 State and prove a version of Gauss's Lemma for Euclidean domains.

Artin 3.4 Prove $xy - zw$, the determinant of a variable 2×2 matrix, is an irreducible element of $\mathbb{C}[x, y, z, w]$.

Artin 3.5 (a) For $\psi : \mathbb{C}[x, y] \to \mathbb{C}[t]$, $f(x, y) \mapsto f(t^2, t^3)$, prove the image is the polynomials p with $p'(0) = 0$; (b) for $\varphi : f \mapsto f(t^2 - t, t^3 - t^2)$, prove $\ker \varphi$ is principal, find a generator, and describe the image.

Artin 4.11 Use the sieve method to determine the primes < 100 and discuss its efficiency.

Artin 4.13 (Lagrange interpolation) (a) Build a degree-n polynomial with prescribed roots and value 1 at a_0; (b) determine the unique g of degree $\le d$ with $g(a_i) = b_i$ explicitly.

Artin 4.14 By analyzing the locus $x^2 + y^2 = 1$, prove $x^2 + y^2 - 1$ is irreducible in $\mathbb{C}[x, y]$.

Artin 4.18* For $q = p^e$ and $r = p^{e-1}$, prove the cyclotomic polynomial $(x^q - 1)/(x^r - 1)$ is irreducible.

Artin 5.4 Make a neat drawing of the primes in $\mathbb{Z}[i]$ in a reasonable size range.

Artin 5.8 For $R = \mathbb{Z}[\omega]$, $\omega = e^{2\pi i/3}$, draw the prime elements of absolute value ≤ 10.

Artin 5.9* For $R = \mathbb{Z}[\omega]$ and integer prime $p \neq 3$, prove: (a) $x^2 + x + 1$ has a root in $\mathbb{F}_p$ iff $p \equiv 1$ (3); (b) (p) is maximal iff $p \equiv -1$ (3); (c) p factors in R iff $p = a^2 + ab + b^2$.

Artin 5.10 (a) For a Gauss integer α with no integer factor and $\alpha\overline{\alpha}$ a perfect square, prove α or $i\alpha$ is a square in $\mathbb{Z}[i]$; (b) parametrize primitive Pythagorean triples via $a = m^2 - n^2,\ b = 2mn,\ c = m^2 + n^2$.

Artin M.1 For a commutative cancellation semigroup S with identity, make the right definitions and extend Proposition 12.2.14(a) to this setting.

Artin M.2 For the semigroup of nonnegative integer combinations of vectors $v_1, \ldots, v_n \in \mathbb{Z}^2$, determine which have unique factorization (a) with nonnegative coordinates, (b) in general.

Artin M.3 For an integer prime p and an $n \times n$ integer matrix A with $A^p = I$ but $A \neq I$, prove $n \ge p - 1$; give an example with $n = p - 1$.

Artin M.4* For $R =$ real polynomials in $\cos t, \sin t$: (a) prove $R \cong \mathbb{R}[x, y]/(x^2 + y^2 - 1)$; (b) prove R is not a UFD; (c) prove $S = \mathbb{C}[x, y]/(x^2 + y^2 - 1)$ is a PID; (d) determine the units of S and R.

Artin M.6 In a domain, if an ideal I is a product of distinct maximal ideals in two ways, prove the two factorizations agree up to order.

Artin M.7 For $R = \mathbb{Z}[x]$: (a) prove every maximal ideal has the form (p, f) with p prime and f irreducible mod p; (b) if $I = (f, g)$ with f, g having no common factor, prove R/I is finite.

Artin M.8 For coprime integers u, v and $R' = \mathbb{Z}$ with an adjoined α satisfying $v\alpha = u$, prove $R' \cong \mathbb{Z}[1/v]$ (and the analogous description).

Artin M.9 For $R = \mathbb{Z}[i]$ and $W \subseteq V = R^2$ the submodule generated by the columns of a 2×2 matrix over R, explain how to determine the index $[V : W]$.

Artin M.10 For $f, g \in \mathbb{C}[x, y]$ with no common factor, prove $R = \mathbb{C}[x, y]/(f, g)$ is finite-dimensional over $\mathbb{C}$.

Artin M.11 (Berlekamp's method) For factoring in $\mathbb{F}_2[x]$: (a) characterize square factors via $\gcd(f, f')$; (b) split into relatively prime factors via the CRT; (c) factor $x^9 + x^6 + x^4 + 1$.

Fraleigh 34.26 Prove that if p is an irreducible in a UFD, then p is a prime.

Fraleigh 34.29 In a UFD D, prove that a nonconstant divisor of a primitive polynomial in $D[x]$ is again primitive.

Fraleigh 34.30 Prove that in a PID every proper ideal is contained in a maximal ideal.

Fraleigh 34.31 Factor $x^3 - y^3$ into irreducibles in $\mathbb{Q}[x, y]$ and prove each factor is irreducible.

Fraleigh 35.16 For a Euclidean norm ν and nonzero a, b, prove $\nu(a) < \nu(ab)$ iff b is not a unit.

Fraleigh 35.17 Prove or disprove: for a Euclidean norm ν, the set $\{a \mid \nu(a) > \nu(1)\} \cup \{0\}$ is an ideal of D.

Fraleigh 35.19 For a Euclidean norm ν: (a) show $\eta(a) = \nu(a) + s$ is a Euclidean norm when $s + \nu(1) > 0$; (b) show $\lambda(a) = t \cdot \nu(a)$ is one for $t \in \mathbb{Z}^+$; (c) build a Euclidean norm μ with $\mu(1) = 1$ and $\mu(a) > 100$ for all nonzero nonunits.

Fraleigh 35.20 In a UFD D, prove every two nonzero elements have an lcm (show the common multiples form an ideal in a Euclidean domain).

Fraleigh 35.23 Prove $ax \equiv b$ (n) has a solution iff the positive gcd of a, n divides b, and interpret in $\mathbb{Z}_n$.

Chapter 9

Polynomial Rings

9.1 Definitions and Basic Properties

The polynomial ring $R[x]$

Throughout, R is a commutative ring with $1 \neq 0$.

Definition 9.1.1 (The polynomial ring in one variable)**.** Let R be a commutative ring. The *polynomial ring* $R[x]$ is the set of all formal finite sums

$$f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0, \qquad a_i \in R,$$

where the *coefficient* a_i lies in R for each i and only finitely many are nonzero. If $a_n \neq 0$ we call $n = \deg f$ the *degree* of f, a_n the *leading coefficient* $\mathrm{LC}(f)$, and $a_n x^n$ the *leading term*. A polynomial is *monic* if $\mathrm{LC}(f) = 1$. The zero polynomial has, by convention, $\deg 0 = -\infty$ (equivalently, undefined); it has no leading term. Polynomials of degree 0 together with 0 are the *constants* $R \subseteq R[x]$.

Addition and multiplication are: with $f = \sum_i a_i x^i$ and $g = \sum_j b_j x^j$,

$$f + g = \sum_k (a_k + b_k)\, x^k, \qquad fg = \sum_k \Big(\textstyle\sum_{i+j=k} a_i b_j \Big) x^k.$$

Remark 9.1.1. The coefficient of x^k in fg is the *convolution* $c_k = \sum_{i+j=k} a_i b_j$. Two polynomials are equal iff all corresponding coefficients are equal; $R[x]$ is a commutative ring with identity $1 \in R$, and $R \hookrightarrow R[x]$ as the constants makes R a subring.

Method (Computing $f + g$ and fg by hand)**.** *Trigger.* You must add or multiply concrete polynomials, possibly over a ring with zero divisors or characteristic n.
Recipe.

1. **Align by power.** Write each polynomial with explicit x^k slots; treat missing powers as coefficient 0.
2. **Add:** add coefficients slot by slot *in* R (reduce mod n in $\mathbb{Z}/n\mathbb{Z}$).
3. **Multiply:** for each output power k, sum $a_i b_j$ over all $i + j = k$ (convolution); reduce each coefficient in R.
4. **Read off** the leading term last; in $\mathbb{Z}/n\mathbb{Z}$ a top coefficient can vanish, so recompute deg *after* reducing.

Worked Example 9.1.2 (Multiplying in $\mathbb{Z}/3\mathbb{Z}[x]$)**.** Compute $(2x^2 + x + 1)(x + 2)$ in $\mathbb{Z}/3\mathbb{Z}[x]$.
Recognition. Convolution multiplication with coefficient arithmetic done mod 3.
Solution. Expand, then reduce each coefficient mod 3:

$$(2x^2 + x + 1)(x + 2) = 2x^3 + 4x^2 + x^2 + 2x + x + 2 = 2x^3 + 5x^2 + 3x + 2.$$

Reduce mod 3: $5 \equiv 2$, $3 \equiv 0$, so

$$(2x^2 + x + 1)(x + 2) = 2x^3 + 2x^2 + 2 \in \mathbb{Z}/3\mathbb{Z}[x].$$

Check (convolution by slots). $a = (1, 1, 2)$ for (a_0, a_1, a_2), $b = (2, 1)$. $c_0 = 1 \cdot 2 = 2$; $c_1 = 1 \cdot 2 + 1 \cdot 1 = 3 \equiv 0$; $c_2 = 2 \cdot 2 + 1 \cdot 1 = 5 \equiv 2$; $c_3 = 2 \cdot 1 = 2$. Coefficients $(2, 0, 2, 2)$ match. $\deg = 3 = 2 + 1$, as expected since $\mathbb{Z}/3\mathbb{Z}$ is a field (a domain), so no degree drop. ■

Worked Example 9.1.3 (Degree can drop in $\mathbb{Z}/4\mathbb{Z}[x]$)**.** In $\mathbb{Z}/4\mathbb{Z}[x]$ compute $(2x + 1)^2$ and report its degree.

Recognition. $\mathbb{Z}/4\mathbb{Z}$ has the zero divisor 2 ($2 \cdot 2 = 4 \equiv 0$); the top coefficient of a product may vanish.

Solution.

$$(2x + 1)^2 = 4x^2 + 4x + 1.$$

Reduce mod 4: $4 \equiv 0$, $4 \equiv 0$, so $(2x + 1)^2 = 1$ in $\mathbb{Z}/4\mathbb{Z}[x]$. *Check.* The leading coefficients multiply to $2 \cdot 2 = 4 \equiv 0$, so the x^2 term dies and the x term dies too. Result is the constant 1, of degree 0, while $\deg(2x + 1) + \deg(2x + 1) = 1 + 1 = 2$. Hence $\deg(fg) < \deg f + \deg g$. This is impossible over an integral domain, but $\mathbb{Z}/4\mathbb{Z}$ is not a domain. As a bonus, $2x + 1$ is a *unit* of $\mathbb{Z}/4\mathbb{Z}[x]$ with inverse itself. ■

Worked Example 9.1.4 (Adding and multiplying in $\mathbb{Z}/5\mathbb{Z}[x]$)**.** In $\mathbb{Z}/5\mathbb{Z}[x]$, let $f = 3x^2 + 4$ and $g = 2x + 3$. Compute $f + g$ and fg.

Recognition. Slot addition and convolution, all coefficients mod 5.

Solution. $f = 3x^2 + 0 \cdot x + 4$, $g = 0 \cdot x^2 + 2x + 3$.

$$f + g = 3x^2 + 2x + 7 \equiv 3x^2 + 2x + 2.$$

For fg: $c_0 = 4 \cdot 3 = 12 \equiv 2$; $c_1 = 4 \cdot 2 = 8 \equiv 3$; $c_2 = 3 \cdot 3 = 9 \equiv 4$; $c_3 = 3 \cdot 2 = 6 \equiv 1$. So

$$fg = x^3 + 4x^2 + 3x + 2 \in \mathbb{Z}/5\mathbb{Z}[x].$$

Check. $\mathbb{Z}/5\mathbb{Z}$ is a field, so $\deg(fg) = 2 + 1 = 3$ and $\mathrm{LC}(fg) = 3 \cdot 2 = 6 \equiv 1$, matching the x^3 coefficient. ■

Worked Example 9.1.5 (A product over $\mathbb{Z}$ with telescoping middle terms)**.** Compute $(x^2 + x + 1)(x - 1)$ in $\mathbb{Z}[x]$.

Recognition. Ordinary convolution over the domain $\mathbb{Z}$; watch cancellation in the interior coefficients.

Solution.

$$(x^2 + x + 1)(x - 1) = x^3 + x^2 + x - x^2 - x - 1 = x^3 - 1.$$

Check. $c_0 = 1 \cdot (-1) = -1$; $c_1 = 1 \cdot (-1) + 1 \cdot 1 = 0$; $c_2 = 1 \cdot (-1) + 1 \cdot 1 = 0$; $c_3 = 1 \cdot 1 = 1$. So $x^3 - 1$. Interior cancellation does *not* lower the degree because the top coefficient $1 \cdot 1 = 1 \neq 0$. ■

Caution. "Degree of a product is the sum of degrees" is only guaranteed when R is an integral domain. Over $\mathbb{Z}/4\mathbb{Z}$, $\mathbb{Z}/6\mathbb{Z}$, or any ring with zero divisors the leading coefficients can multiply to 0 and the degree drops (or the product becomes a unit/constant). Always reduce coefficients *before* reading off the degree.

Multivariate polynomial rings

Definition 9.1.6 (Polynomials in several variables, by iteration)**.** Define $R[x_1, \ldots, x_n]$ recursively by

$$R[x_1, \ldots, x_n] := \big(R[x_1, \ldots, x_{n-1}]\big)[x_n].$$

Concretely an element is a finite sum of *monomials* $a\, x_1^{d_1} x_2^{d_2} \cdots x_n^{d_n}$ with $a \in R$. The (total) *degree* of such a monomial is $d_1 + \cdots + d_n$, and the *total degree* of $f \neq 0$ is the maximum total degree of a monomial appearing with nonzero coefficient. A polynomial is *homogeneous* of degree d if every monomial has total degree d.

Remark 9.1.2. Iteration means a polynomial in $\mathbb{Z}[x, y]$ may be read as a polynomial in y whose coefficients lie in $\mathbb{Z}[x]$, or vice versa. For instance $x^2y + xy + 3y + x^2 = (x^2 + x + 3)\, y + x^2 \in (\mathbb{Z}[x])[y]$, a degree-1 polynomial in y.

Worked Example 9.1.7 ($\mathbb{Z}[x,y]$ and its total degree)**.** Let $f = x^2y + 3xy^2 + y + 5 \in \mathbb{Z}[x,y]$. Find the total degree of f, view f in $(\mathbb{Z}[x])[y]$, and compute $f \cdot y$.

Recognition. Total degree counts the largest $d_x + d_y$; iteration groups by powers of y.

Solution. Monomial total degrees: x^2y : 2+1=3; $3xy^2$: 1+2=3; y : 1; 5 : 0. So $\deg f = 3$. As an element of $(\mathbb{Z}[x])[y]$:

$$f = (3x)\,y^2 + (x^2+1)\,y + 5, \qquad \deg_y f = 2,\ \mathrm{LC}_y(f) = 3x.$$

Multiplying by y shifts every y-power up by one:

$$f \cdot y = x^2y^2 + 3xy^3 + y^2 + 5y, \qquad \deg(f \cdot y) = 4.$$

Check. $3x \cdot y^2 \cdot y = 3xy^3$ has total degree $1 + 3 = 4$, the new maximum; since $\mathbb{Z}$ is a domain, $\deg(f \cdot y) = \deg f + \deg y = 3 + 1 = 4$. ■

Integral domains: $R[x]$ a domain, degree additivity, and units

Proposition 9.1.8 (D&F 7.2, Prop. 4; 9.1, Prop. 1)**.** *Let R be an integral domain and let $f, g \in R[x]$ be nonzero. Then:*

(1) $\deg(fg) = \deg f + \deg g$*;*

(2) $R[x]^\times = R^\times$ *(the units of $R[x]$ are exactly the constant units of R);*

(3) $R[x]$ is an integral domain.

Proof. Write $f = a_m x^m + \cdots$, $g = b_n x^n + \cdots$ with $a_m = \mathrm{LC}(f) \neq 0$, $b_n = \mathrm{LC}(g) \neq 0$. The coefficient of x^{m+n} in fg is $a_m b_n$. Since R is a domain and $a_m, b_n \neq 0$, we have $a_m b_n \neq 0$. No monomial of higher degree can occur, so $fg \neq 0$, $\deg(fg) = m + n$, and $\mathrm{LC}(fg) = a_m b_n$. This proves (1) and shows $R[x]$ has no zero divisors, i.e. (3).

For (2): if $u \in R^\times$ then u is a unit in $R[x]$, so $R^\times \subseteq R[x]^\times$. Conversely, suppose $fg = 1$ in $R[x]$. Taking degrees and using (1), $\deg f + \deg g = \deg 1 = 0$, and since degrees are nonnegative integers, $\deg f = \deg g = 0$. Thus $f, g \in R$ and $fg = 1$ in R, so $f \in R^\times$. Hence $R[x]^\times \subseteq R^\times$. □

Remark 9.1.3. By induction (1)–(3) extend to several variables: if R is an integral domain then so is $R[x_1, \ldots, x_n]$, and $R[x_1, \ldots, x_n]^\times = R^\times$.

Method (Degree arguments)**.** *Trigger.* You must show a product is nonzero, identify the units of $R[x]$, prove an element is irreducible by degree count, or rule out a factorization.

Recipe.

1. **Confirm the base ring is a domain.** Only then is $\deg(fg) = \deg f + \deg g$ and $\mathrm{LC}(fg) = \mathrm{LC}(f)\,\mathrm{LC}(g)$ valid.
2. **Take degrees of the hypothesized identity** (e.g. $fg = 1$, or $fg = h$).
3. **Solve the integer equation** in nonnegative degrees; small/forced solutions pin down $\deg f, \deg g$.
4. **Translate back** to a statement about constants/leading coefficients in R.

Worked Example 9.1.9 (Units of $\mathbb{Z}[x]$ versus $\mathbb{Q}[x]$)**.** Determine $\mathbb{Z}[x]^\times$ and $\mathbb{Q}[x]^\times$.

Recognition. $\mathbb{Z}$ and $\mathbb{Q}$ are integral domains, so $R[x]^\times = R^\times$.

Solution. $\mathbb{Z}$ is a domain with $\mathbb{Z}^\times = \{\pm 1\}$, so by Prop. 4(2), $\mathbb{Z}[x]^\times = \{\,1, -1\,\}$. In particular x, 2, and $x + 1$ are non-units in $\mathbb{Z}[x]$. $\mathbb{Q}$ is a field, so $\mathbb{Q}^\times = \mathbb{Q} \setminus \{0\}$ and $\mathbb{Q}[x]^\times = \mathbb{Q} \setminus \{0\}$, the nonzero constants; e.g. $\frac{1}{2}$ is a unit but x is not. *Check (degree argument).* If $fg = 1$ in $\mathbb{Z}[x]$ then $\deg f = \deg g = 0$, so $f, g \in \mathbb{Z}$ with $fg = 1$, forcing $f = \pm 1$. The same argument over $\mathbb{Q}$ gives nonzero rationals. ■

Worked Example 9.1.10 ($2x+1$ is a unit in $\mathbb{Z}/4\mathbb{Z}[x]$ but the proposition does not apply)**.** Show $2x+1 \in \mathbb{Z}/4\mathbb{Z}[x]^\times$, and explain why this does not contradict Prop. 4(2).

Recognition. A degree-1 unit can only exist when the base ring is *not* a domain.

Solution. $(2x+1)(2x+1) = 4x^2+4x+1 = 1$ in $\mathbb{Z}/4\mathbb{Z}[x]$ (computed earlier), so $2x+1$ is its own inverse, hence a unit of degree 1. *Check.* Prop. 4 requires R to be an integral domain; $\mathbb{Z}/4\mathbb{Z}$ is not ($2 \cdot 2 = 0$), so $\mathbb{Z}/4\mathbb{Z}[x]^\times \neq (\mathbb{Z}/4\mathbb{Z})^\times$. Indeed the nilpotent 2 produces the non-constant unit $1+2x$ (a unit because 2 is nilpotent: $(1+2x)(1-2x) = 1-4x^2 = 1$). ■

Worked Example 9.1.11 (No nontrivial factorization of a linear polynomial over a domain)**.** Over the domain $\mathbb{Z}$, show x cannot be written as a product of two non-units of $\mathbb{Z}[x]$.

Recognition. Pure degree count plus $\mathbb{Z}[x]^\times = \{\pm 1\}$.

Solution. Suppose $x = fg$ with $f, g \in \mathbb{Z}[x]$. By additivity $\deg f + \deg g = \deg x = 1$, so one factor, say g, has degree 0: $g = c \in \mathbb{Z}$. Then $f = ax+b$ and $cf = x$ forces $ca = 1$, $cb = 0$, so $c \in \{\pm 1\}$, i.e. c is a unit. Hence any factorization of x has a unit factor; x is irreducible in $\mathbb{Z}[x]$. *Check.* The leading coefficient equation $\mathrm{LC}(f)\,\mathrm{LC}(g) = 1$ in $\mathbb{Z}$ forces a unit leading coefficient. ■

Worked Example 9.1.12 ($R[x]$ inherits domain-ness, but a quotient need not)**.** Decide whether $\mathbb{Z}[x]$ is a domain and whether $\mathbb{Z}/6\mathbb{Z}[x]$ is a domain.

Recognition. R a domain $\Rightarrow R[x]$ a domain; R with zero divisors $\Rightarrow R[x]$ has them too.

Solution. $\mathbb{Z}$ is a domain, so $\mathbb{Z}[x]$ is a domain by Prop. 4(3). $\mathbb{Z}/6\mathbb{Z}$ is *not* a domain ($2 \cdot 3 = 0$), and these zero divisors persist as constants in $\mathbb{Z}/6\mathbb{Z}[x]$: $\bar{2} \cdot \bar{3} = \bar{0}$ with $\bar{2}, \bar{3} \neq 0$. So $\mathbb{Z}/6\mathbb{Z}[x]$ is not a domain. *Check.* deg additivity fails in $\mathbb{Z}/6\mathbb{Z}[x]$, e.g. $(3x+1)(2x) = 6x^2+2x = 2x$ drops from degree 2 to degree 1. ■

Ideal extension $I[x]$, the quotient $R[x]/I[x]$, and primeness

Proposition 9.1.13 (D&F 9.1, Prop. 2)**.** *Let I be an ideal of the commutative ring R, and let*

$$I[x] := \{\, f \in R[x] \;\mid\; \textit{every coefficient of } f \textit{ lies in } I \,\}.$$

Then:

(1) $I[x]$ is an ideal of $R[x]$;

(2) $R[x]/I[x] \cong (R/I)[x]$;

(3) if I is a prime ideal of R, then $I[x]$ is a prime ideal of $R[x]$.

Proof. Consider the *reduction-of-coefficients* map. Reducing each coefficient mod I via $R \twoheadrightarrow R/I$, $a \mapsto \bar{a}$, induces a ring homomorphism

$$\varphi : R[x] \longrightarrow (R/I)[x], \qquad \varphi\Big(\textstyle\sum_i a_i x^i\Big) = \sum_i \bar{a}_i\, x^i.$$

It is a homomorphism because reduction mod I respects the coefficient formulas for sums ($\overline{a_k + b_k} = \bar{a}_k + \bar{b}_k$) and products ($\overline{\sum_{i+j=k} a_i b_j} = \sum_{i+j=k} \bar{a}_i \bar{b}_j$). It is surjective since any $\sum \bar{c}_i x^i$ is hit by $\sum c_i x^i$. Its kernel is exactly the polynomials all of whose coefficients reduce to 0, i.e. all of whose coefficients lie in I: $\ker\varphi = I[x]$. In particular $I[x]$ is an ideal (a kernel), proving (1), and the First Isomorphism Theorem gives

$$R[x]/I[x] \;\cong\; (R/I)[x],$$

proving (2). For (3): if I is prime then R/I is an integral domain, so by Prop. 4(3) $(R/I)[x]$ is an integral domain; hence $R[x]/I[x] \cong (R/I)[x]$ is a domain, which says exactly that $I[x]$ is a prime ideal of $R[x]$. □

Remark 9.1.4 (The reduction map $\mathbb{Z}[x] \to \mathbb{F}_p[x]$). The most important instance is $R = \mathbb{Z}$, $I = (p)$ for a prime p. Then $\mathbb{Z}/(p) = \mathbb{F}_p$ and Prop. 2 gives the surjective *reduction mod p* homomorphism with kernel $(p)[x] = (p)$ (the polynomials with all coefficients divisible by p):

$$\mathbb{Z}[x] \xrightarrow{\ \text{mod } p\ } \mathbb{F}_p[x]$$

Diagram explanation. Objects: $\mathbb{Z}[x]$ is the polynomial ring over the integers, a commutative domain. $\mathbb{F}_p[x]$ is the polynomial ring over the prime field $\mathbb{F}_p = \mathbb{Z}/(p)$, also a commutative domain (in fact a Euclidean domain, since $\mathbb{F}_p$ is a field).

Arrows: The single arrow is the *reduction-mod-p* ring homomorphism $\varphi : \mathbb{Z}[x] \to \mathbb{F}_p[x]$ defined by $\varphi(\sum_i a_i x^i) = \sum_i \bar{a}_i x^i$, where $\bar{a}_i = a_i \bmod p$. It is surjective (every polynomial in $\mathbb{F}_p[x]$ is hit by any lift of its coefficients to $\mathbb{Z}$), hence the double-head arrow.

What commutes: This is a single arrow, so there is no path equality to verify. The key identity is $\ker \varphi = (p)[x] = (p)$, the set of polynomials all of whose coefficients are divisible by p.

Why it commutes: φ is a ring homomorphism because coefficient-reduction mod p is itself a ring homomorphism $\mathbb{Z} \to \mathbb{F}_p$, and polynomial arithmetic (sum and convolution formulas) is defined coefficient-by-coefficient, so $\varphi(f+g) = \varphi(f) + \varphi(g)$ and $\varphi(fg) = \varphi(f)\varphi(g)$ follow termwise.

Why this matters here: The surjectivity and kernel computation give, by the First Isomorphism Theorem, $\mathbb{Z}[x]/(p) \cong \mathbb{F}_p[x]$. Since $\mathbb{F}_p[x]$ is a domain, (p) is prime in $\mathbb{Z}[x]$. This single arrow *is* the engine of the reduction-mod-p irreducibility test: if f is monic and $\varphi(f)$ is irreducible in $\mathbb{F}_p[x]$, then f is irreducible in $\mathbb{Z}[x]$. (Monic cannot be dropped: $f = 3x + 3 = 3(x+1)$ is reducible in $\mathbb{Z}[x]$, yet $\varphi(f) = x + 1$ is irreducible in $\mathbb{F}_2[x]$.)

Concrete example: With $p = 3$: $\varphi(2x^2 + 3x + 7) = 2x^2 + 0 \cdot x + 1 = 2x^2 + 1 \in \mathbb{F}_3[x]$. The polynomial $3x \in \ker \varphi$ since all coefficients are divisible by 3.

Common pitfall: Students sometimes think φ sends $x \mapsto p$ or changes the variable; it does not. Only the *coefficients* are reduced; the indeterminate x is unchanged. Also, surjectivity does not mean φ has a ring-homomorphism section: the map $\mathbb{F}_p[x] \to \mathbb{Z}[x]$ sending $\bar{a}_i \mapsto a_i$ (any lift) is a set map but not a ring map.

Takeaway: The point of this diagram is that reducing coefficients mod a prime p gives a surjective ring homomorphism from $\mathbb{Z}[x]$ onto the simpler Euclidean domain $\mathbb{F}_p[x]$, whose kernel is exactly the ideal (p), proving (p) prime and enabling the reduction-mod-p irreducibility criterion.

so $\mathbb{Z}[x]/(p) \cong \mathbb{F}_p[x]$. Because (p) is prime in $\mathbb{Z}$, (p) is prime in $\mathbb{Z}[x]$ and $\mathbb{F}_p[x]$ is an integral domain. This is the engine behind the reduction-mod-p irreducibility test of §9.4.

Method (Recognizing and using $I[x]$ / reduction quotients)**.** *Trigger.* You see a quotient $R[x]/J$ where J is "coefficients in some ideal," or you want to reduce a polynomial problem to a simpler ring.

Recipe.

1. **Spot $I[x]$:** J consists of all polynomials whose coefficients lie in an ideal $I \subseteq R$ (e.g. $J = (p)$ in $\mathbb{Z}[x]$ means "all coefficients divisible by p").
2. **Quotient downstairs first:** replace R by R/I coefficientwise; the quotient is $(R/I)[x]$.
3. **Test primeness:** $I[x]$ is prime $\iff$ R/I is a domain $\iff$ I is prime in R.
4. **To kill a variable too**, quotient additionally by (x) (or $(x-a)$): use evaluation $x \mapsto 0$ (or $x \mapsto a$).

Worked Example 9.1.14 ($\mathbb{Z}[x]/(p,x) \cong \mathbb{F}_p$ via a two-step reduction)**.** Show $\mathbb{Z}[x]/(p,x) \cong \mathbb{F}_p$ for a prime p, identifying the maps.

Recognition. The ideal (p, x) kills coefficients mod p and then evaluates at $x = 0$; compose reduction with evaluation.

Solution. Use the evaluation-at-0 homomorphism composed with reduction mod p:

$$\mathbb{Z}[x] \xrightarrow{\bmod p} \mathbb{F}_p[x] \xrightarrow{x \mapsto 0} \mathbb{F}_p$$

Diagram explanation. Objects: $\mathbb{Z}[x]$ is the polynomial ring over $\mathbb{Z}$. $\mathbb{F}_p[x]$ is the Euclidean domain of polynomials over the prime field $\mathbb{F}_p = \mathbb{Z}/(p)$. $\mathbb{F}_p$ is the prime field itself, viewed here as the codomain of evaluation at 0.

Arrows: The left arrow is the surjective reduction-mod-p homomorphism $\varphi : \mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_p[x]$, $\sum a_i x^i \mapsto \sum \bar{a}_i x^i$. The right arrow is the surjective evaluation-at-0 homomorphism $\mathrm{ev}_0 : \mathbb{F}_p[x] \twoheadrightarrow \mathbb{F}_p$, $\sum \bar{a}_i x^i \mapsto \bar{a}_0$. Both are surjective ring homomorphisms.

What commutes: The composite $\Phi = \mathrm{ev}_0 \circ \varphi : \mathbb{Z}[x] \to \mathbb{F}_p$ satisfies $\Phi(\sum a_i x^i) = \bar{a}_0$, the constant term of f reduced mod p. The kernel of the composite is $\ker \Phi = (p, x)$, the ideal generated by p and x in $\mathbb{Z}[x]$.

Why it commutes: A generic $f = \sum a_i x^i$ travels along the top: first reduce coefficients to get $\sum \bar{a}_i x^i$, then evaluate at 0 to get $\bar{a}_0$. The composite sends $f \mapsto \bar{a}_0 \in \mathbb{F}_p$. This is the constant term of f reduced mod p; any f with $p \mid a_0$ or with $a_0 = 0$ lies in $\ker \Phi$, confirming $\ker \Phi = (p) + (x) = (p, x)$.

Why this matters here: This diagram decomposes the maximal ideal $(p, x) \subseteq \mathbb{Z}[x]$ into two successive quotients, making clear why $\mathbb{Z}[x]/(p, x) \cong \mathbb{F}_p$: first kill the prime p from coefficients, then kill the variable x by evaluation. The result is a field, so (p, x) is maximal in $\mathbb{Z}[x]$.

Concrete example: With $p = 3$ and $f = 6x^2+4x+7$: after reduction mod 3, $\varphi(f) = 0 \cdot x^2+x+1 = x+1 \in \mathbb{F}_3[x]$; then $\mathrm{ev}_0(x + 1) = 1 \in \mathbb{F}_3$. So $\Phi(f) = \overline{7} = 1$, which equals $\overline{a_0} = \overline{7} = 1$. ■

Common pitfall: Students sometimes think (p, x) consists only of multiples of p and multiples of x, forgetting that their *sum* $ap + bx$ (with $a, b \in \mathbb{Z}[x]$) is the general element. In particular $f = 7 \in (p, x)$ only when $p \mid 7$; otherwise $7 \notin (3, x)$ even though 7 has no x.

Takeaway: The point of this diagram is that the two-step surjection – reduce mod p, then evaluate at $x = 0$ – decomposes the maximal ideal $(p, x) \subseteq \mathbb{Z}[x]$ into two successive kernels and proves $\mathbb{Z}[x]/(p, x) \cong \mathbb{F}_p$ without needing a separate generator-by-generator argument.

The composite $\Phi : \mathbb{Z}[x] \to \mathbb{F}_p$ sends $f = \sum a_i x^i \mapsto \overline{a_0}$ (the constant term mod p). It is surjective. Its kernel consists of all f with $\overline{a_0} = 0$, i.e. $p \mid a_0$, equivalently $f \in (p) + (x) = (p, x)$:

$$\ker \Phi = (p, x).$$

By the First Isomorphism Theorem,

$$\mathbb{Z}[x]/(p, x) \;\cong\; \mathbb{F}_p.$$

Check. $|\mathbb{F}_p| = p$, finite, and $\mathbb{F}_p$ is a field, so (p, x) is a maximal ideal of $\mathbb{Z}[x]$. Concretely $\bar{f} = \overline{f(0)} = \overline{a_0} \in \{0, 1, \ldots, p - 1\}$. With $p = 3$, $f = 6x^2 + 4x + 7$ maps to $7 \bmod 3 = 1$. ■

Worked Example 9.1.15 ($\mathbb{Z}[x]/(p) \cong \mathbb{F}_p[x]$ explicitly)**.** Identify the quotient $\mathbb{Z}[x]/(p)$ and show (p) is prime in $\mathbb{Z}[x]$.

Recognition. Prop. 2 with $R = \mathbb{Z}$, $I = (p)$: $(p)[x] = (p)$ and the quotient is $(\mathbb{Z}/(p))[x]$.

Solution. Every coefficient is reduced mod p; the reduction map $\varphi : \mathbb{Z}[x] \to \mathbb{F}_p[x]$ has kernel (p), so

$$\mathbb{Z}[x]/(p) \;\cong\; \mathbb{F}_p[x].$$

Since $\mathbb{F}_p$ is a field (hence a domain) and a domain's polynomial ring is a domain, $\mathbb{F}_p[x]$ is a domain; therefore (p) is a *prime* ideal of $\mathbb{Z}[x]$ by Prop. 2(3). *Check.* (p) is not maximal in $\mathbb{Z}[x]$: $\mathbb{F}_p[x]$ is not a field (e.g. x has no inverse), and indeed $(p) \subsetneq (p, x) \subsetneq \mathbb{Z}[x]$ shows a strictly larger proper ideal. ■

Worked Example 9.1.16 (Factoring across the reduction map $\mathbb{Z}[x] \to \mathbb{F}_5[x]$)**.** Reduce $f = x^2+6x+10 \in \mathbb{Z}[x]$ mod 5 and use the quotient $\mathbb{F}_5[x]$ to factor the image.

Recognition. Reduction mod p is a ring homomorphism, so it sends factorizations to factorizations; work in the smaller ring $\mathbb{F}_5[x]$.

Solution. Reduce coefficients mod 5: $6 \equiv 1$, $10 \equiv 0$, so $\bar{f} = x^2 + x = x(x+1)$ in $\mathbb{F}_5[x]$. Thus the image factors. (Over $\mathbb{Z}$ itself $f = x^2 + 6x + 10$ is irreducible by the quadratic formula: discriminant $36 - 40 = -4 < 0$.) *Check.* Evaluate the factorization in $\mathbb{F}_5$ at, say, $x = 2$: $\bar{f}(2) = 4 + 2 = 6 \equiv 1$, and $x(x+1)\big|_2 = 2 \cdot 3 = 6 \equiv 1$; they agree. Reduction is the homomorphism φ of Prop. 2 with $I = (5)$. ■

Worked Example 9.1.17 (I prime $\Rightarrow I[x]$ prime, and I not prime $\Rightarrow I[x]$ not prime)**.** In $R = \mathbb{Z}$ compare $I = (7)$ (prime) with $I = (6)$ (not prime), and decide whether $I[x]$ is prime in $\mathbb{Z}[x]$.

Recognition. Prop. 2(3): primeness of $I[x]$ is controlled by whether R/I is a domain.

Solution. For $I = (7)$: $\mathbb{Z}/(7) = \mathbb{F}_7$ is a domain, so $(7)[x] = (7)$ is a prime ideal of $\mathbb{Z}[x]$, and $\mathbb{Z}[x]/(7) \cong \mathbb{F}_7[x]$, a domain. For $I = (6)$: $\mathbb{Z}/(6) = \mathbb{Z}/6\mathbb{Z}$ is *not* a domain ($\bar{2} \cdot \bar{3} = \bar{0}$). Hence $(6)[x] = (6)$ is *not* prime in $\mathbb{Z}[x]$: the constants $\bar{2}, \bar{3}$ multiply to $\bar{0}$ in $\mathbb{Z}[x]/(6) \cong \mathbb{Z}/6\mathbb{Z}[x]$, i.e. $2 \cdot 3 = 6 \in (6)$ while $2, 3 \notin (6)$. *Check.* The witness $2 \cdot 3 = 6 \in (6)[x]$ with $2 \notin (6)[x]$, $3 \notin (6)[x]$ is exactly a failure of the prime-ideal property. For (7), no such constant witness exists because 7 is prime. ■

Worked Example 9.1.18 (Quotient by (x): evaluation at 0)**.** Identify $R[x]/(x)$ for any commutative ring R, and apply it to $R = \mathbb{Z}[y]$.

Recognition. (x) is generated by the variable; quotienting sets $x = 0$, i.e. keeps only the constant term.

Solution. The evaluation map $\mathrm{ev}_0 : R[x] \to R$, $f \mapsto f(0) = a_0$, is a surjective ring homomorphism with kernel (x) (the polynomials with zero constant term). So

$$R[x]/(x) \cong R.$$

With $R = \mathbb{Z}[y]$: $\mathbb{Z}[y][x] = \mathbb{Z}[x, y]$, and $\mathbb{Z}[x, y]/(x) \cong \mathbb{Z}[y]$. Concretely $\bar{f}$ is f with every x set to 0; e.g. $x^2y + 3x + y^2 + 5 = y^2 + 5$. *Check.* (x) is prime in $\mathbb{Z}[x, y]$ because $\mathbb{Z}[y]$ is a domain (Prop. 2(3) with $R = \mathbb{Z}[x]$ and its prime ideal $I = (x)$ (as $\mathbb{Z}[x]/(x) \cong \mathbb{Z}$), since $I[y] = (x) \subseteq \mathbb{Z}[x][y] = \mathbb{Z}[x, y]$; or directly via the domain quotient). ■

Caution. $I[x]$ prime does not make *$I[x]$ maximal.* Even when I is maximal in R (so R/I is a field), $(R/I)[x]$ is only a domain, never a field. Thus (p) is prime but *not* maximal in $\mathbb{Z}[x]$; to reach a field you must also quotient out a variable, e.g. (p, x) giving $\mathbb{F}_p$, or $(p, f(x))$ with f irreducible mod p giving a finite field.

Remark 9.1.5 (Summary diagram: extend an ideal vs. reduce coefficients). The two viewpoints of Prop. 2 are the two legs of one commutative square. Reducing coefficients of $R[x]$ by $I[x]$ is the same as forming polynomials over the reduced ring R/I:

$$\begin{array}{ccc} R & \hookrightarrow & R[x] \\ {\scriptstyle \bmod I}\downarrow & & \downarrow{\scriptstyle \bmod\ I[x]} \\ R/I & \hookrightarrow & (R/I)[x] \end{array}$$

Diagram explanation. Objects: Top-left: R, a commutative ring. Top-right: $R[x]$, the polynomial ring over R. Bottom-left: R/I, the quotient ring of R by an ideal I. Bottom-right: $(R/I)[x]$, the polynomial ring over the quotient ring R/I.

Arrows: Top horizontal: the canonical inclusion $R \hookrightarrow R[x]$, sending a constant $r \mapsto r$ (the degree-0 polynomial). Left vertical: the surjection $R \twoheadrightarrow R/I$, $r \mapsto r + I = \bar{r}$, the standard quotient map. Right vertical: the surjection $R[x] \twoheadrightarrow (R/I)[x]$, $\sum a_i x^i \mapsto \sum \bar{a}_i x^i$, reducing each coefficient mod I; its kernel is $I[x]$. Bottom horizontal: the canonical inclusion $R/I \hookrightarrow (R/I)[x]$, $\bar{r} \mapsto \bar{r}$ as constant polynomials.

What commutes: Going right-then-down equals going down-then-right: for $r \in R$, the path $r \xrightarrow{\text{incl}} r \xrightarrow{\bmod I[x]} \bar{r}$ equals $r \xrightarrow{\bmod I} \bar{r} \xrightarrow{\text{incl}} \bar{r}$. Both composites send $r \in R$ to the constant polynomial $\bar{r} \in (R/I)[x]$.

Why it commutes: Chase $r \in R$: right-then-down gives $r \mapsto r \in R[x] \mapsto \bar{r} \in (R/I)[x]$. Down-then-right gives $r \mapsto \bar{r} \in R/I \mapsto \bar{r} \in (R/I)[x]$. Both land at the same constant polynomial $\bar{r}$. The right vertical map is well-defined on $R[x]$ coefficientwise; each coefficient's image $a_i + I$ does not depend on the representative a_i chosen from its coset because all representatives differ by an element of I, which maps to 0 in R/I.

Why this matters here: The square encodes the isomorphism $R[x]/I[x] \cong (R/I)[x]$ (Proposition 2(2)) in diagrammatic form. It shows that two operations – extend first then reduce, vs. reduce first then extend – commute: you can reduce coefficients before or after forming the polynomial ring and get the same ring.

Concrete example: Take $R = \mathbb{Z}$, $I = (p)$. The square becomes $\mathbb{Z} \hookrightarrow \mathbb{Z}[x]$, $\mathbb{Z} \twoheadrightarrow \mathbb{F}_p$, $\mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_p[x]$, $\mathbb{F}_p \hookrightarrow \mathbb{F}_p[x]$. For the constant $3 \in \mathbb{Z}$: right-then-down sends $3 \mapsto 3 \in \mathbb{Z}[x] \mapsto \bar{3} \in \mathbb{F}_p[x]$; down-then-right sends $3 \mapsto \bar{3} \in \mathbb{F}_p \mapsto \bar{3} \in \mathbb{F}_p[x]$. Both give the constant polynomial $\bar{3}$. ■

Common pitfall: Students sometimes confuse the inclusion $R \hookrightarrow R[x]$ with an isomorphism; R is a proper subring of $R[x]$. Also, the right vertical arrow $R[x] \twoheadrightarrow (R/I)[x]$ requires checking well-definedness: different lifts a_i vs. $a_i + c_i$ (with $c_i \in I$) give the same image $\bar{a}_i$ in R/I, so the map on polynomials is indeed independent of coefficient representatives.

Takeaway: The point of this diagram is that forming a polynomial ring and quotienting by a coefficient ideal are interchangeable operations – the square commutes – which is precisely the content of $R[x]/I[x] \cong (R/I)[x]$.

Going right-then-down equals going down-then-right; the right vertical map has kernel $I[x]$, which is why $R[x]/I[x] \cong (R/I)[x]$.

Exercises (from the text).

1. Let $p(x,y,z) = 2x^2y - 3xy^3z + 4y^2z^5$ and $q(x,y,z) = 7x^2 + 5x^2y^3z^4 - 3x^2z^3$ be polynomials in $\mathbb{Z}[x,y,z]$.
   (a) Write each of p and q as a polynomial in x with coefficients in $\mathbb{Z}[y,z]$.
   (b) Find the degree of each of p and q.
   (c) Find the degree of p and q in each of the three variables x, y and z.
   (d) Compute pq and find the degree of pq in each of the three variables x, y and z.
   (e) Write pq as a polynomial in the variable z with coefficients in $\mathbb{Z}[x,y]$.
2. Repeat the preceding exercise under the assumption that the coefficients of p and q are in $\mathbb{Z}/3\mathbb{Z}$.
3. If R is a commutative ring and $x_1, x_2, \ldots, x_n$ are independent variables over R, prove that $R[x_{\pi(1)}, x_{\pi(2)}, \ldots, x_{\pi(n)}]$ is isomorphic to $R[x_1, x_2, \ldots, x_n]$ for any permutation π of $\{1, 2, \ldots, n\}$.
4. Prove that the ideals (x) and (x,y) are prime ideals in $\mathbb{Q}[x,y]$ but only the latter ideal is a maximal ideal.
5. Prove that (x,y) and $(2,x,y)$ are prime ideals in $\mathbb{Z}[x,y]$ but only the latter ideal is a maximal ideal.
6. Prove that (x,y) is not a principal ideal in $\mathbb{Q}[x,y]$.
7. Let R be a commutative ring with 1. Prove that a polynomial ring in more than one variable over R is never a Principal Ideal Domain.
8. Let F be a field and let $R = F[x, x^2y, x^3y^2, \ldots, x^ny^{n-1}, \ldots]$ be a subring of the polynomial ring $F[x,y]$.
   (a) Prove that the fields of fractions of R and $F[x,y]$ are the same.
   (b) Prove that R contains an ideal that is not finitely generated.
9. Prove that a polynomial ring in infinitely many variables with coefficients in any commutative ring contains ideals that are not finitely generated.
10. Prove that the ring $\mathbb{Z}[x_1, x_2, x_3, \ldots]/(x_1x_2, x_3x_4, x_5x_6, \ldots)$ contains infinitely many minimal prime ideals (cf. Exercise 36 of Section 7.4).
11. Show that the radical of the ideal $I = (x, y^2)$ in $\mathbb{Q}[x,y]$ is (x,y) (cf. Exercise 30, Section 7.4). Deduce that I is a primary ideal that is not a power of a prime ideal (cf. Exercise 41, Section 7.4).
12. Let $R = \mathbb{Q}[x,y,z]$ and let bars denote passage to $\mathbb{Q}[x,y,z]/(xy - z^2)$. Prove that $\overline{P} = (\overline{x}, \overline{z})$ is a prime ideal. Show that $\overline{x}\overline{y} \in \overline{P}^2$ but no power of $\overline{y}$ lies in $\overline{P}^2$. (This shows $\overline{P}$ is a prime ideal whose square is not a primary ideal – cf. Exercise 41, Section 7.4.)
13. Prove that the rings $F[x,y]/(y^2 - x)$ and $F[x,y]/(y^2 - x^2)$ are not isomorphic for any field F.
14. Let R be an integral domain and let i, j be relatively prime integers. Prove that the ideal $(x^i - y^j)$ is a prime ideal in $R[x,y]$. [Consider the ring homomorphism φ from $R[x,y]$ to $R[t]$ defined by mapping x to t^j and mapping y to t^i. Show that an element of $R[x,y]$ differs from an element in $(x^i - y^j)$ by a polynomial $f(x,y)$ of degree at most $j-1$ in y and observe that the exponents of $\varphi(x^ry^s)$ are distinct for $0 \leq s < j$.]
15. Let $p(x_1, x_2, \ldots, x_n)$ be a homogeneous polynomial of degree k in $R[x_1, \ldots, x_n]$. Prove that for all $\lambda \in R$ we have $p(\lambda x_1, \lambda x_2, \ldots, \lambda x_n) = \lambda^k p(x_1, x_2, \ldots, x_n)$.
16. Prove that the product of two homogeneous polynomials is again homogeneous.
17. An ideal I in $R[x_1, \ldots, x_n]$ is called a *homogeneous ideal* if whenever $p \in I$ then each homogeneous component of p is also in I. Prove that an ideal is a homogeneous ideal if and only if it may be generated by homogeneous polynomials. [Use induction on degrees to show the "if" implication.]

18. Let R be an arbitrary ring and let $\mathrm{Func}(R)$ be the ring of all functions from R to itself. If $p(x) \in R[x]$ is a polynomial, let $f_p \in \mathrm{Func}(R)$ be the function on R defined by $f_p(r) = p(r)$ (the usual way of viewing a polynomial in $R[x]$ as defining a function on R by "evaluating at r").

    (a) For fixed $a \in R$, prove that "evaluation at a" is a ring homomorphism from $\mathrm{Func}(R)$ to R (cf. Example 4 following Theorem 7 in Section 7.3).

    (b) Prove that the map $\varphi : R[x] \to \mathrm{Func}(R)$ defined by $\varphi(p(x)) = f_p$ is not a ring homomorphism in general. Deduce that polynomial identities need not give corresponding identities when the polynomials are viewed as functions. [If $R = \mathbb{H}$ is the ring of real Hamilton Quaternions show that $p(x) = x^2 + 1$ factors as $(x + i)(x - i)$, but that $p(j) = 0$ while $(j + i)(j - i) \neq 0$.]

    (c) For fixed $a \in R$, prove that the composite "evaluation at a" of the maps in (a) and (b) mapping $R[x]$ to R is a ring homomorphism if and only if a is in the center of R.

Practice problems.

1. In $\mathbb{Q}[x]$, divide $f(x) = 2x^4 - 3x^3 + x^2 + 5x - 1$ by $g(x) = x^2 - x + 2$; find the unique quotient q and remainder r with $\deg r < 2$, and verify $f = qg + r$.
2. In $\mathbb{F}_5[x]$, divide $x^4 + 3x^3 + 2x + 4$ by $x^2 + 1$. State q and r with all coefficients reduced mod 5.
3. Compute $\gcd(x^4 - 1,\ x^3 - x^2 + x - 1)$ in $\mathbb{Q}[x]$ by the Euclidean algorithm, and express it as a $\mathbb{Q}[x]$-combination of the two polynomials.
4. Find the content $\mathrm{cont}(f)$ and the primitive part of $f(x) = 18x^3 - 24x^2 + 30x - 12 \in \mathbb{Z}[x]$. Write $f = \mathrm{cont}(f) \cdot f_0$ with f_0 primitive.
5. Show that $g(x) = 3x^2 + 5x - 2$ and $h(x) = 4x^3 - 2x + 6$ are primitive or not, then verify directly that $\mathrm{cont}(gh) = \mathrm{cont}(g)\,\mathrm{cont}(h)$ (Gauss's Lemma) for these two.
6. List all rational roots of $f(x) = 2x^3 - 3x^2 - 8x - 3$ via the Rational Root Theorem, and factor f completely in $\mathbb{Q}[x]$.
7. Determine whether $x^3 - 3x - 1$ has a root in $\mathbb{Q}$. Conclude whether it is irreducible in $\mathbb{Q}[x]$, and justify why "no rational root" suffices here but not for degree 4.
8. Use reduction mod 2 to prove $x^4 + x + 1$ is irreducible in $\mathbb{Z}[x]$ (hence in $\mathbb{Q}[x]$). Explain why reduction mod 3 would not have settled the question.
9. Apply Eisenstein's criterion (choose the prime) to show each is irreducible in $\mathbb{Q}[x]$: (a) $x^5 - 6x + 3$; (b) $\frac{2}{3}x^4 + 2x^2 + 2$; (c) $x^4 + 10x^3 + 20x^2 + 30x + 5$.
10. Show $\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$ is irreducible in $\mathbb{Q}[x]$ by substituting $x \mapsto x + 1$ and applying Eisenstein at $p = 5$.
11. Factor $f(x) = x^4 + 4$ completely in $\mathbb{Z}[x]$ (Sophie Germain identity), and confirm each factor is irreducible in $\mathbb{Q}[x]$.
12. With the lex order $x > y > z$, write the terms of $f = 3x^2yz - 5xy^3 + 7y^2z^2 - 2$ in decreasing order, and give $\mathrm{LT}(f)$, $\mathrm{LM}(f)$, $\mathrm{LC}(f)$, and $\mathrm{multideg}(f)$.
13. For $f = 2x^2y + 3xy^2$ and $g = x^3 - z$, compute the S-polynomial $S(f, g)$ under lex with $x > y > z$.
14. In $\mathbb{Q}[x]$, confirm that $x^2 + x + 1$ is irreducible, and that it remains irreducible in $\mathbb{F}_2[x]$; contrast this with $x^2 + 1$, which is reducible over $\mathbb{F}_2$.
15. Using grlex with $x > y$, divide $f = x^2y + xy^2 + y^2$ by the ordered list $(g_1, g_2) = (xy - 1,\ y^2 - 1)$; record the quotients and remainder.

Additional exercises.

1. Let R be an integral domain. Prove that for $f, g \in R[x]$ with $g \neq 0$ whose leading coefficient is a unit, division with remainder $f = qg + r$, $\deg r < \deg g$, exists and is unique. Where does the unit hypothesis enter?

2. Prove Gauss's Lemma: a product of primitive polynomials in $\mathbb{Z}[x]$ is primitive. Deduce that if a monic $f \in \mathbb{Z}[x]$ factors nontrivially in $\mathbb{Q}[x]$ then it factors nontrivially in $\mathbb{Z}[x]$.

3. Give a polynomial in $\mathbb{Z}[x]$ that is irreducible mod p for no prime p yet is irreducible in $\mathbb{Q}[x]$ (e.g. x^4+1). Verify it factors in $\mathbb{F}_p[x]$ for $p = 2, 3, 5$ but is irreducible over $\mathbb{Q}$.

4. Let p be prime. Prove the reduction map $\mathbb{Z}[x] \to \mathbb{F}_p[x]$ sending $f \mapsto \bar{f}$ is a surjective ring homomorphism, and determine its kernel.

5. Show that $x^4 - 10x^2 + 1$ has no rational roots and no Eisenstein prime, yet is irreducible in $\mathbb{Q}[x]$ (the minimal polynomial of $\sqrt{2}+\sqrt{3}$). Reduce mod p for small p to gather evidence, then argue irreducibility.

6. Prove that if $f \in \mathbb{Z}[x]$ is primitive and irreducible in $\mathbb{Z}[x]$, then f is irreducible in $\mathbb{Q}[x]$; give a counterexample showing primitivity cannot be dropped.

Commutative-diagram exercises.

1. Let p be an irreducible polynomial in $F[x]$ for a field F. Show (p) is a maximal ideal and that

$$F[x] \xrightarrow{\ \pi\ } F[x]/(p)$$

has $F[x]/(p)$ a field. Identify the field for $F = \mathbb{R}$, $p = x^2+1$.

2. Fix a prime p and let $r_p \colon \mathbb{Z}[x] \to \mathbb{F}_p[x]$ be reduction mod p. For $f \in \mathbb{Z}[x]$ monic, show that the diagram

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\ r_p\ } & \mathbb{F}_p[x] \\ \downarrow & & \downarrow \\ \mathbb{Z}[x]/(f) & \xrightarrow{\ \bar{r}_p\ } & \mathbb{F}_p[x]/(\bar{f}) \end{array}$$

commutes, where the vertical maps are the quotient projections. Conclude that if $\bar{f}$ is irreducible in $\mathbb{F}_p[x]$ then f is irreducible in $\mathbb{Q}[x]$.

3. Using the previous diagram with $f = x^3 - x - 1$ and $p = 3$, show $\bar{f}$ is irreducible in $\mathbb{F}_3[x]$ and hence f is irreducible in $\mathbb{Q}[x]$.

4. Let $p = x^2 - 2 \in \mathbb{Q}[x]$. Compare the factorization of p along

$$\mathbb{Q}[x] \xhookrightarrow{\ \iota\ } \mathbb{R}[x]$$

explaining how p irreducible in $\mathbb{Q}[x]$ can become reducible after extending the coefficient field, and relate this to $\mathbb{Q}[x]/(p) \cong \mathbb{Q}(\sqrt{2})$.

5. For the reduction map $\mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_{11}[x]$, take $f = x^4 + x^3 + x^2 + x + 1$. Compute $\bar{f}$, factor it in $\mathbb{F}_{11}[x]$, and explain why this factorization does *not* contradict the irreducibility of f in $\mathbb{Q}[x]$ (cf. Φ_5).

9.2 Polynomial Rings over Fields I

$F[x]$ is a Euclidean domain: division, GCDs, and roots

Throughout this section F denotes a *field*. The single fact that drives everything is that we can divide one polynomial by another and control the size of the remainder by its *degree*. This makes $F[x]$ a Euclidean domain, and Euclidean domains are automatically PIDs and UFDs. We develop the consequences concretely: every ideal is principal (generated by a monic gcd), the Euclidean algorithm computes gcds and Bézout coefficients, roots correspond to linear factors, and a polynomial of degree n has at most n roots in a field.

Theorem 9.2.1 (Division Algorithm in $F[x]$)**.** *Let F be a field and let $f, g \in F[x]$ with $g \neq 0$. Then there exist* unique *polynomials $q, r \in F[x]$ such that*

$$f = qg + r, \qquad \text{with } r = 0 \text{ or } \deg r < \deg g.$$

Proof. Existence. If $f = 0$ or $\deg f < \deg g$ take $q = 0,\ r = f$. Otherwise induct on $\deg f$. Write $\mathrm{LT}(f) = ax^m$ and $\mathrm{LT}(g) = bx^n$ with $m \geq n$. Because F is a field, b is a unit, so we may form

$$f_1 \;=\; f - \frac{a}{b}\,x^{m-n} g.$$

The leading terms cancel by construction, so $f_1 = 0$ or $\deg f_1 < \deg f$. By induction $f_1 = q_1 g + r$ with $r = 0$ or $\deg r < \deg g$, whence $f = \left(\frac{a}{b}x^{m-n} + q_1\right)g + r$.

Uniqueness. If $qg + r = q'g + r'$ with both remainders of degree $< \deg g$ (or zero), then $(q - q')g = r' - r$. If $q \neq q'$ the left side has degree $\geq \deg g$ while the right side has degree $< \deg g$ (or is 0), a contradiction. Hence $q = q'$ and then $r = r'$. □

Remark 9.2.1. The proof uses only that $\mathrm{LC}(g)$ is a unit. Over a general commutative ring R the algorithm still runs when g is *monic* (or has unit leading coefficient). Over a field every nonzero leading coefficient is a unit, so division is unrestricted.

Corollary 9.2.2 ($F[x]$ is a Euclidean domain)**.** *With the norm $N(f) = \deg f$ for $f \neq 0$, $F[x]$ is a Euclidean domain. Consequently $F[x]$ is a PID and a UFD.*

Proof. The Division Algorithm is exactly the Euclidean condition: for $g \neq 0$ we get $f = qg + r$ with $r = 0$ or $N(r) = \deg r < \deg g = N(g)$. Every Euclidean domain is a PID, and every PID is a UFD (D&F 8.1, 8.3). □

Method (Polynomial long division in $F[x]$)**.** *Trigger.* You must compute q, r with $f = qg + r$, $\deg r < \deg g$; or you want to test whether $g \mid f$; or you need a remainder mod g inside $F[x]/(g)$.

Recipe.

1. Arrange f, g in descending degree. Set $r := f$, $q := 0$.
2. While $r \neq 0$ and $\deg r \geq \deg g$: compute the term $t = \dfrac{\mathrm{LC}(r)}{\mathrm{LC}(g)}\,x^{\deg r - \deg g}$, then update $q := q + t$ and $r := r - t\,g$ (this kills $\mathrm{LT}(r)$).
3. Stop when $r = 0$ or $\deg r < \deg g$. Output (q, r).

Check. Expand $qg + r$ and confirm it equals f; confirm $\deg r < \deg g$.

Worked Example 9.2.3 (Long division in $\mathbb{Q}[x]$)**.** Divide $f = 2x^4 - 3x^3 + x - 5$ by $g = x^2 - x + 2$ in $\mathbb{Q}[x]$.

Recognition. Division Algorithm: $g \neq 0$ and $\mathrm{LC}(g) = 1$ is a unit, so a unique (q, r) with $\deg r < 2$ exists. Run the long-division loop.

Solution. Start $r = 2x^4 - 3x^3 + 0x^2 + x - 5$.

Step 1. $\mathrm{LT}(r) = 2x^4$, $\mathrm{LT}(g) = x^2$, so $t_1 = 2x^2$.

$$r - 2x^2 g = (2x^4 - 3x^3 + x - 5) - (2x^4 - 2x^3 + 4x^2) = -x^3 - 4x^2 + x - 5.$$

Step 2. $\mathrm{LT}(r) = -x^3$, so $t_2 = -x$.

$$r - (-x)g = (-x^3 - 4x^2 + x - 5) - (-x^3 + x^2 - 2x) = -5x^2 + 3x - 5.$$

Step 3. $\mathrm{LT}(r) = -5x^2$, so $t_3 = -5$.

$$r - (-5)g = (-5x^2 + 3x - 5) - (-5x^2 + 5x - 10) = -2x + 5.$$

Now $\deg(-2x + 5) = 1 < 2$, stop. Thus

$$q = 2x^2 - x - 5, \qquad r = -2x + 5.$$

Check. Compute qg term by term: $2x^2 \cdot g = 2x^4 - 2x^3 + 4x^2$; $-x \cdot g = -x^3 + x^2 - 2x$; $-5 \cdot g = -5x^2 + 5x - 10$. Summing,

$$qg = 2x^4 - 3x^3 + (4 + 1 - 5)x^2 + (-2 + 5)x - 10 = 2x^4 - 3x^3 + 3x - 10.$$

Then $qg + r = (2x^4 - 3x^3 + 3x - 10) + (-2x + 5) = 2x^4 - 3x^3 + x - 5 = f$, and $\deg r = 1 < 2$. ■

Worked Example 9.2.4 (Division forcing fractions)**.** Divide $f = x^3 + 2x + 1$ by $g = 3x - 1$ in $\mathbb{Q}[x]$.

Recognition. $\mathrm{LC}(g) = 3$ is a unit in $\mathbb{Q}$, so division is legal and the remainder is a constant.

Solution. $t_1 = \frac{1}{3}x^2$: $\quad r = f - \frac{1}{3}x^2(3x-1) = x^3 + 2x + 1 - (x^3 - \frac{1}{3}x^2) = \frac{1}{3}x^2 + 2x + 1$.
$t_2 = \frac{1}{9}x$: $\quad r = \frac{1}{3}x^2 + 2x + 1 - \frac{1}{9}x(3x-1) = \frac{1}{3}x^2 + 2x + 1 - (\frac{1}{3}x^2 - \frac{1}{9}x) = \frac{19}{9}x + 1$.
$t_3 = \frac{19}{27}$: $\quad r = \frac{19}{9}x + 1 - \frac{19}{27}(3x-1) = \frac{19}{9}x + 1 - (\frac{19}{9}x - \frac{19}{27}) = 1 + \frac{19}{27} = \frac{46}{27}$. So $q = \frac{1}{3}x^2 + \frac{1}{9}x + \frac{19}{27}$, $r = \frac{46}{27}$.
Check. By the root form, $r = f(\frac{1}{3}) = \frac{1}{27} + \frac{2}{3} + 1 = \frac{1+18+27}{27} = \frac{46}{27}$. ■This shows why we need a field: over $\mathbb{Z}[x]$, $3x - 1$ would not divide with $\mathbb{Z}$ coefficients.

Worked Example 9.2.5 (Division over $\mathbb{F}_5[x]$)**.** Divide $f = x^3 + 2x^2 + 4$ by $g = 2x + 1$ in $\mathbb{F}_5[x]$.

Recognition. In $\mathbb{F}_5$, $\mathrm{LC}(g) = 2$ is a unit ($2^{-1} = 3$ since $2 \cdot 3 = 6 \equiv 1$). Reduce all coefficients mod 5.

Solution. $t_1 = (1)(2^{-1})x^2 = 3x^2$: $\quad 3x^2 g = 3x^2(2x+1) = 6x^3 + 3x^2 = x^3 + 3x^2$. $\quad r = (x^3 + 2x^2 + 4) - (x^3 + 3x^2) = -x^2 + 4 = 4x^2 + 4$.
$t_2 = 4 \cdot 3\, x = 12x = 2x$: $\quad 2x\, g = 2x(2x+1) = 4x^2 + 2x$. $\quad r = (4x^2 + 4) - (4x^2 + 2x) = -2x + 4 = 3x + 4$.
$t_3 = 3 \cdot 3 = 9 = 4$: $\quad 4g = 4(2x+1) = 8x + 4 = 3x + 4$. $\quad r = (3x+4) - (3x+4) = 0$. So $q = 3x^2 + 2x + 4$, $r = 0$, i.e. $2x + 1 \mid f$ in $\mathbb{F}_5[x]$. *Check.* The root of $2x + 1$ is $x = -1 \cdot 2^{-1} = -3 = 2$. Then $f(2) = 8 + 8 + 4 = 20 \equiv 0 \pmod 5$, confirming $r = 0$. ■

Caution. Division is only as forgiving as the coefficient ring. In $\mathbb{Z}[x]$ you may divide by g with $\mathbb{Z}$-coefficient quotient only when $\mathrm{LC}(g)$ is a unit (e.g. g monic); for instance x cannot be divided by $3x - 1$ with remainder in $\mathbb{Z}[x]$ ($x = q(3x-1) + r$ with $r \in \mathbb{Z}$ forces $q \in \mathbb{Z}$ with $3q = 1$), whereas in $\mathbb{Q}[x]$, $x = \frac{1}{3}(3x-1) + \frac{1}{3}$. Over a field F there is never an obstruction: every nonzero element is a unit.

Ideals, GCDs, and the Euclidean algorithm

Theorem 9.2.6 ($F[x]$ is a PID; ideals are generated by gcds)**.** *Every ideal I of $F[x]$ is principal. If $I \neq 0$, then $I = (d)$ where d is the unique* monic *polynomial of least degree in I; moreover $d = \gcd$ of any generating set of I.*

Proof. $I = 0$ is (0). If $I \neq 0$ choose $d \in I \setminus \{0\}$ of minimal degree; scaling by $\mathrm{LC}(d)^{-1}$ (legal since F is a field) we may take d monic. Clearly $(d) \subseteq I$. Conversely take any $f \in I$ and divide: $f = qd + r$ with $r = 0$ or $\deg r < \deg d$. Then $r = f - qd \in I$. Minimality of $\deg d$ forces $r = 0$, so $f \in (d)$. Hence $I = (d)$. Uniqueness of the monic generator: if $(d) = (d')$ with both monic then $d \mid d'$ and $d' \mid d$, so $d' = ud$ with $u \in F^\times$; comparing leading coefficients gives $u = 1$. □

Theorem 9.2.7 (GCD as ideal generator; Bézout)**.** *For $f, g \in F[x]$ not both 0, the ideal (f, g) equals (d) where d is the monic* $\gcd(f, g)$*. Hence there exist $s, t \in F[x]$ with*

$$d = sf + tg \qquad (\textit{Bézout's identity}),$$

and d is characterized by: $d \mid f$, $d \mid g$, and every common divisor of f, g divides d.

Proof. By the previous theorem $(f, g) = (d)$ for a unique monic d. Since $f, g \in (d)$ we get $d \mid f$ and $d \mid g$. Since $d \in (f, g)$ we can write $d = sf + tg$; thus any common divisor of f, g divides d. These two properties are exactly the definition of a greatest common divisor (up to units, pinned down to monic). □

Method (Euclidean algorithm + back-substitution in $F[x]$)**.** *Trigger.* You need $\gcd(f, g)$, a Bézout pair (s, t), the generator of (f, g), or an inverse in $F[x]/(g)$.

Recipe.

1. Set $r_0 = f$, $r_1 = g$ (the larger degree first). Repeatedly divide: $r_{i-1} = q_i r_i + r_{i+1}$ with $\deg r_{i+1} < \deg r_i$.
2. Stop at the last nonzero remainder r_k. Then gcd = monic scaling of r_k: $d = \mathrm{LC}(r_k)^{-1} r_k$.
3. For Bézout, keep coefficient pairs (s_i, t_i) with $r_i = s_i f + t_i g$ via $s_{i+1} = s_{i-1} - q_i s_i$, $t_{i+1} = t_{i-1} - q_i t_i$, starting from $(s_0, t_0) = (1, 0)$, $(s_1, t_1) = (0, 1)$. Scale the final pair by $\mathrm{LC}(r_k)^{-1}$.

Check. Verify $d \mid f$ and $d \mid g$ by division, and recompute $sf + tg = d$.

Worked Example 9.2.8 (GCD and Bézout in $\mathbb{F}_5[x]$)**.** Compute $\gcd(f,g)$ with $f = x^3+2x+1$, $g = x^2+1$ in $\mathbb{F}_5[x]$, and find s, t.

Recognition. Euclidean algorithm in a Euclidean domain; track coefficients for Bézout.

Solution. Step 1. $x^3+2x+1 = (x)(x^2+1)+(x+1)$, since $x(x^2+1) = x^3+x$ and $(x^3+2x+1)-(x^3+x) = x+1$. So $q_1 = x$, $r_2 = x+1$.

Step 2. Divide $r_1 = x^2+1$ by $r_2 = x+1$: $x^2+1 = (x-1)(x+1)+2$, since $(x-1)(x+1) = x^2-1$ and $(x^2+1)-(x^2-1) = 2$. So $q_2 = x-1$, $r_3 = 2$.

Step 3. Divide $r_2 = x+1$ by $r_3 = 2$: $x+1 = (3x+3)\cdot 2 + 0$ (since $2^{-1} = 3$). Remainder 0, so the last nonzero remainder is $r_3 = 2$, a nonzero constant. Hence $\gcd = 2^{-1}\cdot 2 = 1$: f, g are coprime.

Bézout. From Step 2, $2 = (x^2+1)-(x-1)(x+1)$. From Step 1, $x+1 = (x^3+2x+1)-x(x^2+1)$. Substitute:

$$2 = (x^2+1)-(x-1)\big[(x^3+2x+1)-x(x^2+1)\big] = -(x-1)f + \big[1+x(x-1)\big]g.$$

So $2 = -(x-1)f + (x^2-x+1)g$. Multiply by $2^{-1} = 3$:

$$1 = 3(1-x)\,f + 3(x^2-x+1)\,g = (3-3x)f + (3x^2+2x+3)g = (2x+3)f + (3x^2+2x+3)g$$

(using $-3 \equiv 2 \pmod 5$). *Check.* In $(2x+3)f$ the top term is $2x\cdot x^3 = 2x^4$; in $(3x^2)g$ it is $3x^2\cdot x^2 = 3x^4$, and $2+3 = 5 \equiv 0$, so x^4 cancels. Continuing term by term mod 5, all lower-degree terms cancel except the constant $3\cdot 1 + 3\cdot 1 = 6 \equiv 1$, giving 1. ■So $s = 2x+3$, $t = 3x^2+2x+3$, $d = 1$.

Worked Example 9.2.9 (A nontrivial gcd in $\mathbb{Q}[x]$)**.** Find $\gcd(x^4-1,\ x^3-x^2+x-1)$ in $\mathbb{Q}[x]$ and write it as a Bézout combination.

Recognition. Repeated division. Both polynomials vanish at $x = 1$, so $x-1$ is a common factor.

Solution. Step 1. $r_0 = x^4-1$, $r_1 = x^3-x^2+x-1$. Try $x^4-1 = (x+1)\,r_1 + r_2$. Compute $(x+1)r_1 = x^4-x^3+x^2-x+x^3-x^2+x-1 = x^4-1$. So $r_2 = 0$: the division terminates at once and $r_1 \mid r_0$.

Hence gcd is the monic scaling of r_1, and r_1 is already monic. Factoring, $r_1 = x^2(x-1)+(x-1) = (x-1)(x^2+1)$, while $x^4-1 = (x-1)(x+1)(x^2+1)$, confirming $r_1 \mid r_0$. Thus

$$\gcd(x^4-1,\ x^3-x^2+x-1) = x^3-x^2+x-1.$$

Check. $r_1 \mid r_0$ since $x^4-1 = (x+1)r_1$, and $r_1 \mid r_1$; any common divisor divides r_1, so r_1 is the gcd. ■Here Bézout is trivial: $r_1 = 0\cdot r_0 + 1\cdot r_1$.

Worked Example 9.2.10 (Ideal $(f,g) = (\gcd)$ explicitly in $\mathbb{F}_2[x]$)**.** In $\mathbb{F}_2[x]$ let $f = x^3+x+1$, $g = x^2+x$. Identify (f,g) as a principal ideal.

Recognition. $(f,g) = (\gcd(f,g))$; compute the gcd by the Euclidean algorithm over $\mathbb{F}_2$.

Solution. Step 1. $x^3+x+1 = (x+1)(x^2+x)+r_2$. Compute $(x+1)(x^2+x) = x^3+x^2+x^2+x = x^3+x$ (since $2x^2 = 0$). So $r_2 = (x^3+x+1)-(x^3+x) = 1$.

Step 2. Divide $g = x^2+x$ by $r_2 = 1$: remainder 0. Last nonzero remainder is 1. Hence $\gcd = 1$ and

$$(f,g) = (1) = \mathbb{F}_2[x].$$

Check. $1 = (x^3+x+1)-(x+1)(x^2+x) = 1\cdot f + (x+1)g \in (f,g)$, so the ideal contains a unit and is everything. ■Geometrically, $g = x(x+1)$ vanishes at $0, 1$ but $f(0) = 1$, $f(1) = 1$, so f, g share no root and are coprime.

Worked Example 9.2.11 (Reading off the ideal from generators)**.** In $\mathbb{Q}[x]$, simplify the ideal $I = (x^2-1,\ x^2-4x+3,\ x^3-1)$ to a single generator.

Recognition. Each ideal of $F[x]$ is (gcd) of its generators. Compute the gcd of the three.

Solution. Factor: $x^2-1 = (x-1)(x+1)$; $x^2-4x+3 = (x-1)(x-3)$; $x^3-1 = (x-1)(x^2+x+1)$. The only factor common to all three is $(x-1)$ (the cofactors $x+1$, $x-3$, x^2+x+1 share no common root: x^2+x+1 has no rational root, and $x+1, x-3$ differ). Hence

$$I = (x-1).$$

Check. $x-1$ divides all three generators, so $I \subseteq (x-1)$. Conversely $(x^2-1)-(x^2-4x+3) = 4x-4 = 4(x-1)$, so $x-1 = \frac{1}{4}\big[(x^2-1)-(x^2-4x+3)\big] \in I$, giving $(x-1) \subseteq I$. Thus $I = (x-1)$. ■

Roots and factors

Proposition 9.2.12 (Factor Theorem)**.** *Let R be a commutative ring with 1, $f \in R[x]$, and $a \in R$. Then*

$$f(a) = 0 \iff (x - a) \mid f \text{ in } R[x].$$

More precisely, $f(x) = (x - a)\, q(x) + f(a)$ for a unique $q \in R[x]$.

Proof. Divide f by the monic polynomial $x - a$ (legal over any commutative ring since $x - a$ is monic): $f = (x - a)q + r$ with r a constant (degree < 1). Evaluate at $x = a$: $f(a) = 0 \cdot q(a) + r = r$. So $r = f(a)$, giving $f = (x - a)q + f(a)$. Then $(x - a) \mid f$ iff $r = f(a) = 0$. □

Proposition 9.2.13 (At most $\deg f$ roots over a field)**.** *Let F be a field and $f \in F[x]$ nonzero of degree n. Then f has at most n roots in F, counted without multiplicity (and at most n with multiplicity).*

Proof. Induct on n. If $n = 0$, f is a nonzero constant with no roots. If a is a root, the Factor Theorem gives $f = (x - a)q$ with $\deg q = n - 1$. Any root $b \neq a$ satisfies $0 = f(b) = (b - a)q(b)$; since $b - a \neq 0$ and F is an integral domain (no zero divisors), $q(b) = 0$. By induction q has at most $n - 1$ roots, so f has at most $1 + (n - 1) = n$ roots. □

Caution. The integral-domain hypothesis matters (the proof uses nothing more, so the bound holds over any integral domain, e.g. $\mathbb{Z}$). Over $\mathbb{Z}/8\mathbb{Z}$ the polynomial $x^2 - 1$ of degree 2 has *four* roots: $x \in \{1, 3, 5, 7\}$, because $\mathbb{Z}/8\mathbb{Z}$ has zero divisors. The step "$(b - a)q(b) = 0 \implies q(b) = 0$" fails when $b - a$ is a zero divisor. Over a field this never happens.

Method (Root–factor recipe)**.** *Trigger.* You want to factor out known roots, count roots, or test irreducibility of a low-degree polynomial.

1. To remove a root a: confirm $f(a) = 0$, then synthetic-divide by $(x - a)$ to get q with $\deg q = \deg f - 1$; repeat on q.
2. A degree-2 or 3 polynomial over F is irreducible iff it has *no* root in F (a nontrivial factorization must include a linear factor).
3. Rational Root Test in $\mathbb{Q}[x]$: any root p/q (lowest terms) of an integer polynomial has $p \mid a_0$, $q \mid a_n$.

Check. Multiply factors back; verify each claimed root by direct evaluation.

Worked Example 9.2.14 (Factor $x^4 + 1$ over $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, $\mathbb{F}_2$)**.** Factor $f = x^4 + 1$ in each of $\mathbb{Q}[x]$, $\mathbb{R}[x]$, $\mathbb{C}[x]$, $\mathbb{F}_2[x]$.

Recognition. Use roots over $\mathbb{C}$, then group conjugates for $\mathbb{R}$; over $\mathbb{Q}$ show irreducibility; over $\mathbb{F}_2$ note $x^4 + 1 = (x + 1)^4$.

Solution. **Over $\mathbb{C}$:** the roots are the primitive 8th roots of unity $\zeta_k = e^{i\pi(2k+1)/4}$, $k = 0, 1, 2, 3$, i.e. $\frac{\pm 1 \pm i}{\sqrt{2}}$. Thus

$$x^4 + 1 = \prod_{k=0}^{3} \Big(x - \tfrac{\pm 1 \pm i}{\sqrt{2}}\Big).$$

Over $\mathbb{R}$: pair complex-conjugate roots. With $\frac{1 \pm i}{\sqrt{2}}$ giving $x^2 - \sqrt{2}\, x + 1$ and $\frac{-1 \pm i}{\sqrt{2}}$ giving $x^2 + \sqrt{2}\, x + 1$:

$$x^4 + 1 = (x^2 - \sqrt{2}\, x + 1)(x^2 + \sqrt{2}\, x + 1).$$

Check. Product $= (x^2 + 1)^2 - (\sqrt{2}x)^2 = x^4 + 2x^2 + 1 - 2x^2 = x^4 + 1$. ■Each quadratic has discriminant $2 - 4 = -2 < 0$, hence is $\mathbb{R}$-irreducible.

Over $\mathbb{Q}$: f has no rational root (± 1 give 2), so no linear factor. The only possible factorization is into two quadratics. The $\mathbb{R}$-factorization above involves $\sqrt{2} \notin \mathbb{Q}$; one checks no factorization $(x^2 + ax + b)(x^2 + cx + d)$ with $a, b, c, d \in \mathbb{Q}$ exists (matching coefficients gives $c = -a$, $b + d = a^2$, $a(d - b) = 0$, $bd = 1$; $a = 0$ forces $b^2 = -1$, while $a \neq 0$ forces $b = d = \pm 1$ and $a^2 = \pm 2$; all impossible over $\mathbb{Q}$). Hence $x^4 + 1$ is *irreducible over* $\mathbb{Q}$. (It is the 8th cyclotomic polynomial Φ_8.)

Over $\mathbb{F}_2$: here $1 = -1$, so $x^4 + 1 = x^4 - 1 = (x^2 - 1)^2 = (x - 1)^2(x + 1)^2$, but $x - 1 = x + 1$ in $\mathbb{F}_2$, so

$$x^4 + 1 = (x + 1)^4 \quad \text{in } \mathbb{F}_2[x].$$

Check. $(x + 1)^2 = x^2 + 1$ over $\mathbb{F}_2$, and $(x^2 + 1)^2 = x^4 + 1$. ■*Moral.* Irreducibility is not absolute — Φ_8 is irreducible over $\mathbb{Q}$ but splits completely (with multiplicity) over $\mathbb{F}_2$ and into quadratics over $\mathbb{R}$.

Worked Example 9.2.15 (Counting roots and removing them in $\mathbb{F}_7[x]$)**.** Find all roots of $f = x^3 - x$ in $\mathbb{F}_7$ and factor f completely.

Recognition. $\deg f = 3 \implies$ at most 3 roots over a field. Test elements; factor out $(x - a)$.

Solution. $x^3 - x = x(x^2 - 1) = x(x - 1)(x + 1)$, so the roots are $x = 0, 1, -1 = 6$ — exactly 3 roots, meeting the bound. Evaluate to be safe: $f(0) = 0$, $f(1) = 0$, $f(6) = 216 - 6 = 210 = 30 \cdot 7 = 0$. ■No other $a \in \mathbb{F}_7$ is a root (e.g. $f(2) = 6$, $f(3) = 24 = 3$). *Bound check.* A cubic over $\mathbb{F}_7$ has at most 3 roots; we found 3 and the factor form $x(x - 1)(x - 6)$ confirms there are no more. ■

Worked Example 9.2.16 (Finite-field caveat: more roots than degree?)**.** Over $\mathbb{F}_5$, how many roots does $g = x^5 - x$ have, and why is the degree bound not violated?

Recognition. Apply "at most deg roots" (here 5). Fermat's little theorem makes every element a root.

Solution. By Fermat, $a^5 = a$ for all $a \in \mathbb{F}_5$, so every one of the 5 elements $0, 1, 2, 3, 4$ is a root. That is 5 roots for a degree-5 polynomial — exactly the bound, not a violation. Indeed

$$x^5 - x = \prod_{a \in \mathbb{F}_5} (x - a) = x(x - 1)(x - 2)(x - 3)(x - 4).$$

Check. The bound says "at most n roots", and $5 = \deg g$; equality is allowed and here achieved. The point that *can* surprise: a nonzero polynomial like $x^5 - x$ vanishes on *all* of $\mathbb{F}_5$ yet is not the zero polynomial. Polynomial functions on a finite field are not the same as polynomials. ■

Worked Example 9.2.17 (Rational Root Test then degree bound in $\mathbb{Q}[x]$)**.** Factor $f = 2x^3 - 3x^2 - 3x + 2$ in $\mathbb{Q}[x]$.

Recognition. Rational Root Test gives candidate roots; each found root peels off a linear factor; a cubic has ≤ 3 roots.

Solution. Candidates p/q with $p \mid 2$, $q \mid 2$: $\pm 1, \pm 2, \pm \frac{1}{2}$. $f(2) = 16 - 12 - 6 + 2 = 0$, so $(x - 2)$ is a factor. Divide: $2x^3 - 3x^2 - 3x + 2 = (x - 2)(2x^2 + x - 1)$. Then $2x^2 + x - 1 = (2x - 1)(x + 1)$. Hence

$$f = (x - 2)(2x - 1)(x + 1),$$

with roots $2, \frac{1}{2}, -1$ — exactly 3, meeting the bound for a cubic. *Check.* Expand: $(2x-1)(x+1) = 2x^2+x-1$; times $(x - 2)$: $2x^3 + x^2 - x - 4x^2 - 2x + 2 = 2x^3 - 3x^2 - 3x + 2 = f$. ■

The quotient $F[x]/(f)$

For irreducible p, the quotient $F[x]/(p)$ is a field — the engine of field theory. The Euclidean structure lets us compute in it explicitly: every nonzero class has a representative of degree $< \deg p$, and inverses come from Bézout.

Theorem 9.2.18 ($F[x]/(p)$ is a field iff p is irreducible)**.** *Let F be a field and $p \in F[x]$ nonconstant. Then (p) is a maximal ideal of $F[x]$ iff p is irreducible; equivalently $F[x]/(p)$ is a field iff p is irreducible.*

Proof. In a PID that is not a field (such as $F[x]$), the nonzero prime ideals are exactly the maximal ideals, and (p) is prime iff p is irreducible (D&F 8.2). Concretely: if p is irreducible and $\bar{f} \neq 0$ in $F[x]/(p)$, then $p \nmid f$, so $\gcd(f, p) = 1$; Bézout gives $sf + tp = 1$, hence $\bar{s}\,\bar{f} = \bar{1}$ and $\bar{f}$ is invertible. If $p = ab$ is a proper factorization, then $\bar{a}\bar{b} = 0$ with $\bar{a}, \bar{b} \neq 0$, so there are zero divisors and $F[x]/(p)$ is not even a domain. □

The structure is summarized by the diagram below: the quotient map collapses $F[x]$ onto a ring built from remainders mod p, and the field F embeds as the constants.

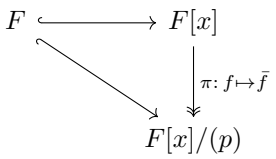


Diagram explanation. Objects: Three rings arranged at the vertices. F (upper-left) is the base field — a commutative ring in which every nonzero element is a unit. $F[x]$ (upper-right) is the polynomial ring over F, a Euclidean domain and PID. $F[x]/(p)$ (lower-right) is the quotient ring by the ideal (p); when p is irreducible it is itself a field.

Arrows: The horizontal hooked arrow $F \hookrightarrow F[x]$ is the *constant embedding*: it sends $a \in F$ to the degree-0 polynomial $a \in F[x]$. The vertical double-headed arrow $\pi\colon F[x] \twoheadrightarrow F[x]/(p)$ is the *canonical quotient map*: it sends $f \mapsto \bar{f} = f + (p)$, and is surjective by definition of the quotient ring. The diagonal hooked arrow $F \hookrightarrow F[x]/(p)$ sends $a \mapsto \bar{a}$, the class of the constant polynomial; it is the composite $\pi \circ \iota$ where ι is the horizontal inclusion.

What commutes: The triangle commutes: the two paths from F to $F[x]/(p)$ are equal. Path 1 (right then down): $a \overset{\iota}{\mapsto} a \overset{\pi}{\mapsto} \bar{a}$. Path 2 (diagonal directly): $a \mapsto \bar{a}$. So $\pi \circ \iota =$ the diagonal map.

Why it commutes: Chase the element $a \in F$. Along the top-right path, ι sends a to the constant polynomial $a \in F[x]$; then π sends it to its coset $a + (p) = \bar{a}$. Along the diagonal, the map is defined as $a \mapsto \bar{a}$ directly. Both outputs are the same coset $\bar{a}$. Well-definedness of π: two polynomials f and $f + hp$ (same coset) both map to $\bar{f}$ because $(f + hp) + (p) = f + (p)$; the ideal (p) absorbs hp. The constant map ι is well-defined trivially (it is a ring homomorphism).

Why this matters here: This diagram appears immediately after the theorem that $F[x]/(p)$ is a field if and only if p is irreducible. Its purpose is to record that the field F does not disappear in the quotient: every scalar $a \in F$ survives as the nonzero class $\bar{a}$ (the composite diagonal map is injective since $\ker(\pi \circ \iota)$ can only contain a with $p \mid a$, impossible for a constant $a \neq 0$). This injectivity is what lets us regard $F[x]/(p)$ as a field *extension* of F.

Concrete example: Take $F = \mathbb{R}$ and $p = x^2 + 1$ (irreducible over $\mathbb{R}$). The horizontal embedding sends $a \in \mathbb{R}$ to the constant polynomial a. The quotient map π sends $a + bx \mapsto \overline{a + bx}$. The diagonal sends $a \mapsto \bar{a}$. Under the identification $\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$ (with $\bar{x} \leftrightarrow i$), the scalar a maps to $a + 0i \in \mathbb{C}$, confirming that $\mathbb{R}$ embeds as the real axis of $\mathbb{C}$.

Common pitfall: Students sometimes read the diagonal arrow as a *different* embedding of F into $F[x]/(p)$ that is independent of π. In fact the diagonal is *defined* as $\pi \circ \iota$; the diagram is recording that this composite is injective (a hook), not introducing a new map. Forgetting that $\iota(a)$ is the *constant* polynomial a (not the indeterminate x) is a related error.

Takeaway: The point of this diagram is that F embeds injectively into the quotient $F[x]/(p)$ via constant polynomials, so $F[x]/(p)$ is always a field extension of F (not just a field in the abstract) whenever p is irreducible.

Worked Example 9.2.19 (Inverse in $\mathbb{F}_2[x]/(x^2+x+1)$)**.** In $K = \mathbb{F}_2[x]/(p)$ with $p = x^2 + x + 1$ (irreducible over $\mathbb{F}_2$, no root since $p(0) = p(1) = 1$), compute $\bar{x}^{-1}$.

Recognition. K is a field of 4 elements; invert via Bézout against p.

Solution. $\gcd(x, x^2+x+1)$: $x^2 + x + 1 = (x+1) \cdot x + 1$, so $1 = (x^2+x+1) - (x+1)x$, giving $-(x+1)x \equiv 1 \pmod{p}$, i.e. $(x+1)\bar{x} = 1$ in K (where $-1 = 1$). Thus $\bar{x}^{-1} = \bar{x} + 1$. *Check.* $\bar{x}(\bar{x}+1) = \bar{x}^2 + \bar{x} = (\bar{x}+1) + \bar{x}$ using $\bar{x}^2 = \bar{x} + 1$ (from $x^2 \equiv x + 1$, since $-1 = 1$); that is $(\bar{x}+1) + \bar{x} = 2\bar{x} + 1 = 1$. ■The four elements of K are $0, 1, \bar{x}, \bar{x}+1$.

Worked Example 9.2.20 ($\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$)**.** Show the evaluation-style map exhibits $\mathbb{R}[x]/(x^2+1)$ as $\mathbb{C}$.

Recognition. $x^2 + 1$ is irreducible over $\mathbb{R}$ (no real root), so the quotient is a field; the class $\bar{x}$ behaves like i.

Solution. Every class has a unique representative $a+b\bar{x}$ with $a, b \in \mathbb{R}$ (remainders mod a degree-2 polynomial). Multiplication uses $\bar{x}^2 = -1$:

$$(a + b\bar{x})(c + d\bar{x}) = ac + (ad + bc)\bar{x} + bd\,\bar{x}^2 = (ac - bd) + (ad + bc)\bar{x},$$

identical to complex multiplication under $\bar{x} \leftrightarrow i$. The map $a + b\bar{x} \mapsto a + bi$ is a ring isomorphism onto $\mathbb{C}$. *Check.* $\bar{x}^2 + 1 = -1 + 1 = 0$ in the quotient, matching $i^2 + 1 = 0$. ■

Caution. $F[x]/(f)$ is a field *only* when f is irreducible. For $f = x^2 - 1 = (x - 1)(x + 1)$ over $\mathbb{Q}$, the quotient $\mathbb{Q}[x]/(x^2 - 1)$ has zero divisors $(\bar{x} - 1)(\bar{x} + 1) = 0$ with both factors nonzero; by CRT it is $\mathbb{Q} \times \mathbb{Q}$, a ring but not a field. Always check irreducibility before claiming a field.

Exercises (from the text).

1. Let $f(x) \in F[x]$ be a polynomial of degree $n \geq 1$ and let bars denote passage to the quotient $F[x]/(f(x))$. Prove that for each $g(x)$ there is a unique polynomial $g_0(x)$ of degree $\leq n - 1$ such that $\overline{g(x)} = \overline{g_0(x)}$ (equivalently, the elements $\overline{1}, \overline{x}, \ldots, \overline{x^{n-1}}$ are a basis of the vector space $F[x]/(f(x))$ over F — in particular, the dimension of this space is n). [Use the Division Algorithm.]

2. Let F be a finite field of order q and let $f(x)$ be a polynomial in $F[x]$ of degree $n \geq 1$. Prove that $F[x]/(f(x))$ has q^n elements. [Use the preceding exercise.]

3. Let $f(x)$ be a polynomial in $F[x]$. Prove that $F[x]/(f(x))$ is a field if and only if $f(x)$ is irreducible. [Use Proposition 7, Section 8.2.]

4. Let F be a field and let $f(x), g(x) \in F[x]$. Suppose $f(x)$ is the polynomial obtained from $g(x)$ by multiplying each of its coefficients by some fixed nonzero element of F. Prove that the greatest common divisor of $f(x)$ and $g(x)$ is the same as the greatest common divisor obtained by replacing $f(x)$ with any of its associates.

5. Exhibit all the ideals in the ring $F[x]/(p(x))$, where F is a field and $p(x)$ is a polynomial in $F[x]$ (describe them in terms of the factorization of $p(x)$).

6. Describe (briefly) the ring structure of the following rings: $\mathbb{Z}[x]/(2)$, $\mathbb{Z}[x]/(x)$, $\mathbb{Z}[x]/(x^2)$, $\mathbb{Z}[x]/(2, x)$, $\mathbb{Z}[x]/(2, x^2)$, showing $a^2 = 0$ or 1 for every a in the last ring and determining those a with $a^2 = 0$. Determine the characteristics of each of these rings (cf. Exercise 26, Section 7.3).

7. Determine all the ideals of the ring $\mathbb{Z}[x]/(2, x^3 + 1)$.

8. Determine the greatest common divisor of $a(x) = x^3 - 2$ and $b(x) = x + 1$ in $\mathbb{Q}[x]$ and write it as a linear combination (in $\mathbb{Q}[x]$) of $a(x)$ and $b(x)$.

9. Determine the greatest common divisor of $a(x) = x^5 + 2x^3 + x^2 + x + 1$ and the polynomial $b(x) = x^4 + 2x^3 + x^2 - 1$ in $\mathbb{Q}[x]$ and write it as a linear combination (in $\mathbb{Q}[x]$) of $a(x)$ and $b(x)$.

10. Determine the greatest common divisor of $a(x) = x^3 + 4x^2 + x - 6$ and $b(x) = x^5 - 6x + 5$ in $\mathbb{Q}[x]$ and write it as a linear combination (in $\mathbb{Q}[x]$) of $a(x)$ and $b(x)$.

11. Suppose $f(x)$ and $g(x)$ are two nonzero polynomials in $\mathbb{Q}[x]$ with greatest common divisor $d(x)$.
(a) Given $h(x) \in \mathbb{Q}[x]$, show that there are polynomials $a(x), b(x) \in \mathbb{Q}[x]$ satisfying the equation $a(x)f(x) + b(x)g(x) = h(x)$ if and only if $h(x)$ is divisible by $d(x)$.
(b) If $a_0(x), b_0(x) \in \mathbb{Q}[x]$ are particular solutions to the equation in (a), show that the full set of solutions to this equation is given by

$$a(x) = a_0(x) + m(x)\frac{g(x)}{d(x)}$$

$$b(x) = b_0(x) - m(x)\frac{f(x)}{d(x)}$$

as $m(x)$ ranges over the polynomials in $\mathbb{Q}[x]$ [cf. Exercise 4 in Section 8.1].

12. Let $F[x_1, x_2, x_3, \dots]$ be the polynomial ring in the infinite set of variables $x_1, x_2, x_3, \dots$ over the field F, and let I be the ideal $(x_1 - x_2^2, x_2 - x_3^2, \dots, x_i - x_{i+1}^2, \dots)$ in this ring. Define R to be the quotient ring $F[x_1, x_2, x_3, \dots]/I$, so that in R the square of each x_{i+1} is x_i. Denote the image of x_i in R also by x_i and let $x_0 = x_1^2$ (so that x_0 may be thought of as $x^{1/2^0}$, x_1 as $x^{1/2}$, etc., where $x = x_0$). Let R_n be the subring of R generated by F and x_n.
(a) Prove that $R_0 \subseteq R_1 \subseteq R_2 \subseteq \dots$ and that R is the union of all the R_n.
(b) Prove that R_n is isomorphic to a polynomial ring in one variable over F, so that R_n is a P.I.D. Deduce that R is a Bezout Domain (cf. Exercise 7 in Section 8.2). [First show that the ring $S_n = F[x_1, \dots, x_n]/(x_1 - x_2^2, \dots, x_{n-1} - x_n^2)$ is isomorphic to the polynomial ring $F[x_n]$. Then show that any polynomial relation x_n satisfies in R gives a corresponding relation in S_N for some $N \geq n$.]
(c) Prove that the ideal generated by $x_0, x_1, x_2, \dots$ in R is not finitely generated (so R is not a P.I.D.).

13. This exercise introduces a noncommutative ring which is a "right" Euclidean Domain (and a "left" Principal Ideal Domain) but is not a "left" Euclidean Domain (and not a "right" Principal Ideal Domain). Let F be a field of characteristic p in which not every element is a pth power. If $F = \mathbb{F}_p(t)$ is the field of rational functions in the variable t with coefficients in $\mathbb{F}_p$, for example, then t is not a pth power in F. Let R be the ring of polynomials in the variable x with coefficients in F with the usual addition of polynomials $\sum_{i=0}^{n} a_i x^i$ but with a noncommutative multiplication defined by

$$\left(\sum_{i=0}^{n} a_i x^i\right)\left(\sum_{j=0}^{m} b_j x^j\right) = \sum_{i,j} a_i b_j^{p^i} x^{i+j}.$$

This multiplication arises from defining $xa = a^p x$ for every $a \in F$ and extending in a natural way to all of R. Let N be the function on the nonzero elements of R given by $N(f) = \deg f$.
(a) Show that $x^i a = a^{p^i} x^i$ for every $a \in F$ and every integer $i \geq 0$ and that R is a ring with this definition of multiplication. [Use the fact that $a \to a^p$ is an injective ring homomorphism to prove associativity of multiplication; note also that $x^i x^j = x^{i+j}$ and $x^0 = 1$, from which it follows that the associative law holds on monomials $a_i x^i$.]
(b) Prove that if a and b are any two elements of R with b nonzero then there are unique elements q and r of R such that $a = qb + r$ with $r = 0$ or $\deg(r) < \deg(b)$. Prove that R has no zero divisors.
(c) Prove that R is "right Euclidean" with respect to N. Prove that every left ideal of R is principal (so R is a "left Principal Ideal Domain").
(d) Let $f = cx$ for some $c \in F$ that is not a pth power in F, and let $g = x$. Prove that there are no $q, r \in R$ with $f = gq + r$ and $r = 0$ or $\deg(r) < \deg(g)$, so R is not "left Euclidean" with respect to N. Prove that the right ideal of R generated by x and cx is not principal. Conclude that R is not "left Euclidean" with respect to any norm.

Practice problems.

1. In $\mathbb{Q}[x]$, divide $f(x) = 2x^4 - 3x^3 + x^2 - 5x + 7$ by $g(x) = x^2 - x + 1$ to find $q(x)$ and $r(x)$ with $f = qg + r$ and $\deg r < 2$.
2. In $\mathbb{F}_5[x]$, perform the division of $f(x) = x^4 + 3x^2 + 2$ by $g(x) = x^2 + x + 1$, working with all coefficients reduced mod 5.
3. Use the Euclidean algorithm in $\mathbb{Q}[x]$ to compute $\gcd(x^4 - 1,\ x^3 - 1)$, and express it as $a(x)(x^4 - 1) + b(x)(x^3 - 1)$.
4. Compute $\gcd(x^3 + x + 1,\ x^2 + 1)$ in $\mathbb{F}_2[x]$.
5. Compute the content $\text{cont}(f)$ and the primitive part of $f(x) = 18x^3 - 12x^2 + 30x - 6$ in $\mathbb{Z}[x]$.
6. Factor $6x^2 + x - 2$ in $\mathbb{Z}[x]$ into a product of irreducibles, and verify your factorization is consistent with Gauss's Lemma (i.e. the factors are primitive up to units).
7. Determine all rational roots of $f(x) = 2x^3 - 3x^2 - 8x - 3$ using the Rational Root Theorem, then factor f completely in $\mathbb{Q}[x]$.
8. Show that $x^3 - 3x - 1$ has no rational roots, and conclude it is irreducible in $\mathbb{Q}[x]$.

9. Use Eisenstein's criterion to prove that $x^4 - 6x^3 + 12x^2 - 18x + 24$ is irreducible in $\mathbb{Q}[x]$. State the prime you use.
10. Prove that $f(x) = x^4 + x^3 + x^2 + x + 1$ is irreducible in $\mathbb{Q}[x]$ by substituting $x \mapsto x + 1$ and applying Eisenstein at $p = 5$.
11. Show that $x^4 + 1$ is irreducible in $\mathbb{Q}[x]$ but reducible in $\mathbb{F}_2[x]$; factor it in $\mathbb{F}_2[x]$.
12. Use reduction mod 2 to prove that $f(x) = x^4 + x + 1 \in \mathbb{Z}[x]$ is irreducible in $\mathbb{Q}[x]$. (First check it is irreducible in $\mathbb{F}_2[x]$.)
13. Decide whether $x^3 + x^2 + x + 1$ is irreducible in $\mathbb{Q}[x]$. If reducible, give its factorization into irreducibles.
14. In $\mathbb{F}_3[x]$, list all monic irreducible polynomials of degree 2.
15. Using the lex order with $x > y$, identify $\mathrm{LT}(f)$, $\mathrm{LM}(f)$, $\mathrm{LC}(f)$, and $\mathrm{multideg}(f)$ for $f = 3x^2y - 5xy^3 + x^3 + 2y^2$.
16. With respect to grlex with $x > y > z$, order the monomials of $g = x^2yz + xy^2z^2 + x^3 + z^4$ from largest to smallest and give $\mathrm{LM}(g)$.
17. Let $f = x^2 - 1$ and $g = xy - 1$ in $\mathbb{Q}[x, y]$ with lex order $x > y$. Compute the S-polynomial $S(f, g)$.

Additional exercises.

1. Let F be a field. Prove that $f \in F[x]$ of degree 2 or 3 is irreducible in $F[x]$ if and only if it has no root in F. Give an explicit degree-4 counterexample over $\mathbb{Q}$ showing the statement fails for higher degree.
2. (Gauss's Lemma, application.) Suppose $f(x) \in \mathbb{Z}[x]$ is monic and factors as $f = g \cdot h$ with $g, h \in \mathbb{Q}[x]$ monic of positive degree. Prove that in fact $g, h \in \mathbb{Z}[x]$.
3. For which primes p is $x^2 + 1$ irreducible in $\mathbb{F}_p[x]$? Prove your answer for $p = 2, 3, 5, 7, 11, 13$ and conjecture the general criterion.
4. Prove that for every $n \geq 1$ there exists an irreducible polynomial of degree n in $\mathbb{Q}[x]$, using Eisenstein with the prime 2 on a polynomial of the form $x^n - 2$.
5. Run Buchberger's algorithm on the ideal $I = (x^2 - y,\ x^3 - z) \subseteq \mathbb{Q}[x, y, z]$ under lex with $x > y > z$ to compute a Grobner basis of I.
6. Let ζ be a primitive 7th root of unity. Prove that the cyclotomic polynomial $\Phi_7(x) = x^6 + x^5 + x^4 + x^3 + x^2 + x + 1$ is irreducible in $\mathbb{Q}[x]$, and deduce $[\mathbb{Q}(\zeta) : \mathbb{Q}] = 6$.

Commutative-diagram exercises.

1. Consider the reduction-mod-p ring homomorphism in the diagram

$$\mathbb{Z}[x] \xrightarrow{\ \bmod p\ } \mathbb{F}_p[x]$$

   Prove this map is a surjective ring homomorphism, describe its kernel, and use it to explain why if the reduction $\overline{f} \in \mathbb{F}_p[x]$ of a monic $f \in \mathbb{Z}[x]$ is irreducible then f is irreducible in $\mathbb{Q}[x]$.
2. Let $p(x) = x^2 + 1 \in \mathbb{R}[x]$. Show p is irreducible, so $\mathbb{R}[x]/(p)$ is a field, and prove there is an isomorphism

$$\mathbb{R}[x]/(x^2 + 1) \xrightarrow{\ \sim\ } \mathbb{C}$$

   sending $\overline{x} \mapsto i$. Identify the image of $\overline{x^2 + x + 1}$.
3. Take $f(x) = x^2 + 1 \in \mathbb{Z}[x]$. Fill in the commuting square

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\ \bmod 2\ } & \mathbb{F}_2[x] \\ \downarrow & & \downarrow \\ \mathbb{Z}[x]/(x^2+1) & \xrightarrow{\ \overline{\bmod 2}\ } & \mathbb{F}_2[x]/(\overline{x^2+1}) \end{array}$$

Determine whether the bottom-right ring is a field, and explain how the square reflects the fact that $x^2+1=(x+1)^2$ in $\mathbb{F}_2[x]$.

4. Let p be irreducible in $F[x]$ and consider the quotient map $\pi\colon F[x] \twoheadrightarrow F[x]/(p)$ shown by

$$F[x] \xrightarrow{\ \pi\ } F[x]/(p)$$

Prove $F[x]/(p)$ is a field, and that the composite $F \hookrightarrow F[x] \xrightarrow{\pi} F[x]/(p)$ embeds F as a subfield.

5. Consider a monic $f \in \mathbb{Z}[x]$ and its factorization viewed in two rings via

$$\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$$

Using Gauss's Lemma, prove that f is irreducible in $\mathbb{Z}[x]$ if and only if it is irreducible in $\mathbb{Q}[x]$, and give an example of a non-monic $g \in \mathbb{Z}[x]$ that is irreducible in $\mathbb{Q}[x]$ but not in $\mathbb{Z}[x]$.

9.3 Polynomial Rings that are Unique Factorization Domains

Content, primitive polynomials, and Gauss's lemma

Throughout this section R is a *unique factorization domain* (UFD) with field of fractions $F = \mathrm{Frac}(R)$. The two model cases to keep in mind are

$$R=\mathbb{Z},\quad F=\mathbb{Q}, \qquad \text{and} \qquad R=k[t]\ (k \text{ a field}),\quad F=k(t).$$

The whole point of the section is to relate factoring in $R[x]$ to the (much easier) factoring in $F[x]$, where $F[x]$ is a Euclidean domain. The bridge is the inclusion

$$R[x] \hookrightarrow F[x] \qquad F=\mathrm{Frac}(R),$$

Diagram explanation. Objects: Two polynomial rings: $R[x]$, where R is a UFD (e.g. $\mathbb{Z}$ or $k[t]$), and $F[x]$, where $F=\mathrm{Frac}(R)$ is the fraction field of R (e.g. $\mathbb{Q}$ or $k(t)$). Both are integral domains; $F[x]$ is additionally a Euclidean domain, so it has a division algorithm that $R[x]$ may lack.

Arrows: A single hooked arrow $R[x] \hookrightarrow F[x]$ is the natural inclusion/embedding: a polynomial $a_nx^n+\cdots+a_0 \in R[x]$ is sent to itself, now viewed with coefficients in F (each $a_i \in R$ maps to $a_i/1 \in F$). The hook signals it is injective: if two polynomials in $R[x]$ are equal as elements of $F[x]$, they are equal in $R[x]$.

What commutes: This is a single arrow, so there is no composite path to equate. The relevant property is that the inclusion is a *ring homomorphism*: it respects addition and multiplication. In particular, if $f=gh$ in $R[x]$, then $f=gh$ holds in $F[x]$ too (the factorization is visible upstairs).

Why it commutes: The ring operations in $R[x]$ are inherited from those in $F[x]$ because $R \subset F$ is a subring inclusion and $R[x] \subset F[x]$ appends the same indeterminate. Adding or multiplying polynomials coefficient-by-coefficient works identically in R and in F since the ring operations of R are the restrictions of those of F.

Why this matters here: The author draws this map to justify the *bridge* strategy of the entire section: factoring in $R[x]$ is hard (no division algorithm), but $R[x]$ sits inside the Euclidean domain $F[x]$, so one can attempt factorization over F and then pull results back. Gauss's Lemma is precisely the theorem that makes the return trip possible.

Concrete example: Take $R=\mathbb{Z}$, $F=\mathbb{Q}$. The polynomial $2x^2-x-6 \in \mathbb{Z}[x]$ maps to $2x^2-x-6 \in \mathbb{Q}[x]$. Over $\mathbb{Q}$ it factors as $(x-2)(2x+3)$ (easy: quadratic formula), and that same factorization witnesses $2x^2-x-6=(x-2)(2x+3)$ in $\mathbb{Z}[x]$.

Common pitfall: Students sometimes think the inclusion is also *surjective* or that every $F[x]$-factorization automatically gives an $R[x]$-factorization without adjustment. It does not: $2x^2-x-6=2(x-2)(x+\frac{3}{2})$ over $\mathbb{Q}$ has a non-integer coefficient; Gauss's Lemma (not the inclusion alone) is what lets you redistribute the scalar 2 to clear the denominator.

Takeaway: The point of this diagram is that $R[x]$ embeds into the better-behaved ring $F[x]$, and the rest of the section (Gauss's Lemma) is the machinery for making the round trip between the two rings productive.

which lets us clear denominators back and forth. The measure of "how much of R" a polynomial carries is its content.

Definition 9.3.1 (Content and primitive polynomials)**.** Let R be a UFD and let

$$f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \in R[x], \qquad f \neq 0.$$

A *content* of f, written $\operatorname{cont}(f)$, is a greatest common divisor of its coefficients:

$$\operatorname{cont}(f) = \gcd(a_0, a_1, \ldots, a_n),$$

defined up to multiplication by a unit of R. We call f *primitive* if $\operatorname{cont}(f)$ is a unit, i.e. $\gcd(a_0, \ldots, a_n) = 1$ (no irreducible of R divides every coefficient). Writing $f = \operatorname{cont}(f) \cdot f_1$ exhibits $f_1 \in R[x]$, the *primitive part* of f, which is primitive.

Remark 9.3.1. Because R is a UFD, gcd's exist and are well defined up to units, so $\operatorname{cont}(f)$ makes sense. In $R = \mathbb{Z}$ we normalize $\operatorname{cont}(f) > 0$ and the primitive part has positive leading coefficient when convenient. The factorization $f = c\, f_1$ with $c = \operatorname{cont}(f)$ and f_1 primitive is unique up to a unit of R. Constants count too: $\operatorname{cont}(6) = 6$ in $\mathbb{Z}[x]$, and a nonzero constant is primitive iff it is a unit.

Method (Computing $\operatorname{cont}(f)$ and the primitive part)**.** *Trigger.* You are handed $f \in R[x]$ and want to strip off the "R-part," or you need a primitive polynomial to feed into Gauss's Lemma.

1. List all coefficients $a_0, \ldots, a_n$ (include the constant term, even if 0 is present in the middle).
2. Compute $c = \gcd(a_0, \ldots, a_n)$ in R (in $\mathbb{Z}$: factor each $|a_i|$, take the min power of each prime; or run the Euclidean algorithm pairwise).
3. Divide: $f_1 = f/c$. Then $f = c\, f_1$ with f_1 *primitive.*
4. *Check.* Verify gcd of the coefficients of f_1 is 1 (every prime fails to divide *some* coefficient, i.e. no prime divides all of them).

Worked Example 9.3.2 (Content and primitive part in $\mathbb{Z}[x]$)**.** Compute the content and primitive part of $f(x) = 12x^3 - 30x^2 + 0 \cdot x + 18 \in \mathbb{Z}[x]$.

Recognition. This is a direct gcd-of-coefficients computation (Definition of content); the primitive part is $f/\operatorname{cont}(f)$.

Solution. Coefficients are $12, -30, 0, 18$. We have $\gcd(12, 30, 18)$ (the 0 contributes nothing since $\gcd(a, 0) = a$). Factor: $12 = 2^2 \cdot 3$, $30 = 2 \cdot 3 \cdot 5$, $18 = 2 \cdot 3^2$. The common primes are 2^1 and 3^1, so $\operatorname{cont}(f) = 2 \cdot 3 = 6$. Hence

$$f(x) = 6\big(2x^3 - 5x^2 + 3\big), \qquad f_1(x) = 2x^3 - 5x^2 + 3.$$

Check. Coefficients of f_1 are $2, -5, 0, 3$; $\gcd(2, 5, 3) = 1$ (e.g. 5 is odd, so $2 \nmid$ all; $3 \nmid 2$), so f_1 is primitive. And $6 \cdot f_1 = 12x^3 - 30x^2 + 18 = f$. Good.

Worked Example 9.3.3 (Content over $\mathbb{Q}$ first, then $\mathbb{Z}$)**.** Find the content and primitive part of $g(x) = \frac{2}{3}x^2 - \frac{4}{9}x + \frac{10}{9} \in \mathbb{Q}[x]$, viewed via clearing denominators.

Recognition. g has coefficients in $F = \mathbb{Q}$, not in $R = \mathbb{Z}$. To talk about content we first scale by a unit of $\mathbb{Q}$ to land in $\mathbb{Z}[x]$, then take the $\mathbb{Z}$-content. (This is the standard "clear denominators, then extract content" move; see the Method "Reduce $\mathbb{Z}[x]$ to $\mathbb{Q}[x]$" below.)

Solution. Multiply by 9 (a unit in $\mathbb{Q}$): $9g = 6x^2 - 4x + 10 \in \mathbb{Z}[x]$. Now $\gcd(6, 4, 10) = 2$, so $9g = 2(3x^2 - 2x + 5)$ and

$$g(x) = \frac{2}{9}\big(3x^2 - 2x + 5\big).$$

The primitive part is $3x^2 - 2x + 5$, and the "$\mathbb{Q}$-content" is $\frac{2}{9}$ (well defined up to a unit of $\mathbb{Z}$, i.e. up to sign). *Check.* $\gcd(3, 2, 5) = 1$, primitive. And $\frac{2}{9}(3x^2 - 2x + 5) = \frac{6}{9}x^2 - \frac{4}{9}x + \frac{10}{9} = \frac{2}{3}x^2 - \frac{4}{9}x + \frac{10}{9} = g$. Good.

Theorem 9.3.4 (Gauss's Lemma)**.** *Let R be a UFD with fraction field F.*

(a) If $p(x), q(x) \in R[x]$ are primitive, then their product $p(x)q(x)$ is primitive.

(b) More generally $\operatorname{cont}(pq) = \operatorname{cont}(p)\operatorname{cont}(q)$ *up to a unit of R.*

(c) If $f(x) \in R[x]$ factors as $f = AB$ with $A, B \in F[x]$ nonconstant, then there exist $\alpha, \beta \in F^\times$ with $\alpha A,\ \beta B \in R[x]$ and $f = (\alpha A)(\beta B)$; in particular f factors in $R[x]$ into two factors of the same degrees *as A, B.*

Proof. (a) Suppose pq is not primitive. Then some irreducible $\pi \in R$ divides every coefficient of pq. Since R is a UFD, π is prime, so $R/(\pi)$ is an integral domain and hence so is $(R/(\pi))[x]$. Reduction mod π gives a ring homomorphism

$$R[x] \xrightarrow{\bmod \pi} (R/(\pi))[x], \qquad f \mapsto \bar{f}.$$

Diagram explanation. Objects: Two polynomial rings. The domain is $R[x]$, where R is a UFD and $\pi \in R$ is a fixed irreducible (hence prime, since R is a UFD). The codomain is $(R/(\pi))[x]$, the polynomial ring over the quotient ring $R/(\pi)$; because π is prime, $R/(\pi)$ is an integral domain, so $(R/(\pi))[x]$ is also an integral domain (no zero-divisors).

Arrows: The double-headed arrow labelled $\bmod \pi$ is the *reduction map* (surjective ring homomorphism): it sends $f = \sum a_i x^i \in R[x]$ to $\bar{f} = \sum \bar{a}_i x^i \in (R/(\pi))[x]$ by reducing each coefficient modulo (π). Well-definedness: $a_i \mapsto a_i + (\pi)$ is the canonical quotient map on R, so mapping coefficient-by-coefficient is a well-defined ring homomorphism, and extending to polynomials is standard. Surjectivity: given any $\sum \bar{b}_i x^i$, lift each $\bar{b}_i$ to $b_i \in R$ and take $\sum b_i x^i \in R[x]$.

What commutes: As a single arrow there is no square to commute. The relevant multiplicativity is: $\overline{fg} = \bar{f} \cdot \bar{g}$ for all $f, g \in R[x]$. This is the ring-homomorphism property applied to multiplication.

Why it commutes: Chase coefficients: the k-th coefficient of fg is $\sum_{i+j=k} a_i b_j$, which maps to $\sum_{i+j=k} \bar{a}_i \bar{b}_j$, the k-th coefficient of $\bar{f} \cdot \bar{g}$. This works in any quotient ring because the quotient map $R \to R/(\pi)$ is itself a ring homomorphism.

Why this matters here: This map is the engine of the proof that the product of two primitive polynomials is primitive. The argument is by contradiction: if π killed all coefficients of pq, then $\overline{pq} = \bar{p}\bar{q} = 0$ in the *integral domain* $(R/(\pi))[x]$, forcing $\bar{p} = 0$ or $\bar{q} = 0$, contradicting the primitivity of p or q. The domain property of $(R/(\pi))[x]$ is indispensable, which is why the UFD hypothesis (π prime $\Rightarrow R/(\pi)$ a domain) is needed.

Concrete example: $R = \mathbb{Z}$, $\pi = 2$. Take $p = 2x + 1$, $q = 3x + 2$, both primitive. Mod 2: $\bar{p} = 1 \neq 0$, $\bar{q} = x \neq 0$ in $\mathbb{F}_2[x]$, so $\overline{pq} = x \neq 0$, confirming 2 does not divide all coefficients of $pq = 6x^2 + 7x + 2$.

Common pitfall: Students sometimes forget that the codomain $(R/(\pi))[x]$ must be a *domain* for the zero-product argument to work. If R were merely a commutative ring and π not prime, $(R/(\pi))[x]$ could have zero-divisors, and $\bar{p}\bar{q} = 0$ would not force $\bar{p} = 0$ or $\bar{q} = 0$. The primeness of π (not just irreducibility in a general domain) is what gives the integral domain property here.

Takeaway: The point of this diagram is that reducing mod an irreducible π turns the content question into a zero-divisor question in an integral domain, making the contradiction immediate from the domain axiom.

By hypothesis $\overline{pq} = \bar{p}\,\bar{q} = 0$ in the domain $(R/(\pi))[x]$, so $\bar{p} = 0$ or $\bar{q} = 0$, i.e. π divides all coefficients of p or of q. This contradicts primitivity of p or q. Hence pq is primitive.

(b) Write $p = \operatorname{cont}(p)\, p_1$, $q = \operatorname{cont}(q)\, q_1$ with p_1, q_1 primitive. Then $pq = \operatorname{cont}(p)\operatorname{cont}(q)\,(p_1 q_1)$ and $p_1 q_1$ is primitive by (a). Uniqueness of the content $\cdot$ primitive decomposition gives $\operatorname{cont}(pq) = \operatorname{cont}(p)\operatorname{cont}(q)$ up to a unit.

(c) Write $A = \frac{a}{b} A_1$, $B = \frac{c}{d} B_1$ with $A_1, B_1 \in R[x]$ primitive and $a, b, c, d \in R$ (clear denominators, then pull out content). Then $f = \frac{ac}{bd} A_1 B_1$, and $A_1 B_1$ is primitive by (a). Comparing contents: $bd \operatorname{cont}(f) = ac \cdot (\text{unit})$, so $\frac{ac}{bd} = \operatorname{cont}(f) \cdot (\text{unit}) \in R$. Absorbing this element of R into one factor, $f = (\alpha A)(\beta B)$ with both factors in $R[x]$ of degrees $\deg A, \deg B$. □

Remark 9.3.2. The heart of the proof is: *π prime $\Rightarrow (R/(\pi))[x]$ a domain.* This is exactly where "R a UFD" is used. Part (c) is the practically useful form: it says a factorization over the field F can always be "cleared" to a factorization over R with the same degree pattern.

Method (Reduce $\mathbb{Z}[x]$-factoring to $\mathbb{Q}[x]$-factoring (Gauss))**.** *Trigger.* You must decide whether a primitive $f \in \mathbb{Z}[x]$ is irreducible, or factor it over $\mathbb{Z}$, and factoring over a field is easier.

1. Make f primitive (divide out $\operatorname{cont}(f)$); the constant content factors separately.
2. Try to factor the primitive f over $\mathbb{Q}$ (rational root test for linear factors; quadratic formula; known irreducibility criteria).
3. If f is irreducible over $\mathbb{Q}$, then (being primitive) it is irreducible in $\mathbb{Z}[x]$ (a nonunit constant cannot divide the primitive f, so a factorization into nonunits of $\mathbb{Z}[x]$ has two nonconstant factors and is already one over $\mathbb{Q}$). If $f = AB$ over $\mathbb{Q}$, use Gauss (c): clear denominators and rescale to get $f = A'B'$ over $\mathbb{Z}$ with $\deg A' = \deg A$, $\deg B' = \deg B$.
4. *Check.* Multiply the $\mathbb{Z}$-factors back out and confirm you recover f.

Worked Example 9.3.5 (Factor over $\mathbb{Z}$ by factoring over $\mathbb{Q}$)**.** Factor $f(x) = 2x^2 - x - 6 \in \mathbb{Z}[x]$ using Gauss's Lemma.

Recognition. f is primitive ($\gcd(2,1,6) = 1$); factor it over $\mathbb{Q}$ first, then Gauss (c) guarantees a same-degree factorization over $\mathbb{Z}$.

Solution. Over $\mathbb{Q}$ use the quadratic formula: roots of $2x^2 - x - 6 = 0$ are

$$x = \frac{1 \pm \sqrt{1+48}}{4} = \frac{1 \pm 7}{4} \in \{2,\ -\tfrac{3}{2}\}.$$

So over $\mathbb{Q}$, $f = 2(x-2)(x+\frac{3}{2})$. Clear the denominator on the second factor by moving the 2: $f = (x-2)(2x+3)$. Both factors are in $\mathbb{Z}[x]$, with degrees $1, 1$ matching the $\mathbb{Q}$-factorization. *Check.* $(x-2)(2x+3) = 2x^2 + 3x - 4x - 6 = 2x^2 - x - 6 = f$. Good. (Note $2x+3$ is primitive and irreducible; $x-2$ is primitive and irreducible.)

Worked Example 9.3.6 (Irreducibility transfers: primitive + irreducible over $\mathbb{Q}$)**.** Show $f(x) = x^3 - 3x - 1 \in \mathbb{Z}[x]$ is irreducible in $\mathbb{Z}[x]$.

Recognition. f is primitive (leading coeff 1). Hence it suffices to show f is irreducible over $\mathbb{Q}$ (Corollary "Irreducibles of $R[x]$" below); for a cubic, irreducibility over $\mathbb{Q}$ is equivalent to having no rational root.

Solution. Rational root test: any rational root is an integer dividing the constant term -1, so ± 1. Compute $f(1) = 1 - 3 - 1 = -3 \neq 0$, $f(-1) = -1 + 3 - 1 = 1 \neq 0$. No rational root, so the cubic f has no linear factor over $\mathbb{Q}$; a cubic with no linear factor is irreducible over $\mathbb{Q}$. Since f is primitive, it is irreducible in $\mathbb{Z}[x]$: a nonunit constant cannot divide f, so a factorization of f into nonunits of $\mathbb{Z}[x]$ would have two nonconstant factors, i.e. would be a factorization over $\mathbb{Q}$. *Check.* If f factored in $\mathbb{Z}[x]$ it would be (degree)$1 + 2$ or 3 with a unit; the degree-1 factor would force an integer root ± 1, already ruled out. Consistent.

Worked Example 9.3.7 (Product of primitives is primitive (verify (a) directly))**.** Verify Gauss (a) for $p(x) = 2x + 1$ and $q(x) = 3x + 2$ in $\mathbb{Z}[x]$.

Recognition. Both p, q are primitive; Theorem (a) predicts pq is primitive. We confirm by computing $\operatorname{cont}(pq)$.

Solution. $\gcd(2,1) = 1$ so p is primitive; $\gcd(3,2) = 1$ so q is primitive. Multiply:

$$pq = (2x+1)(3x+2) = 6x^2 + 4x + 3x + 2 = 6x^2 + 7x + 2.$$

Coefficients $6, 7, 2$: check primes. $2 \mid 6$, $2 \nmid 7$, so 2 fails; $3 \mid 6$, $3 \nmid 7$, so 3 fails; any prime dividing all three must divide $\gcd(6,7,2) = 1$. Hence $\operatorname{cont}(pq) = 1$, so pq is primitive, confirming (a). *Cross-check via mod π:* mod 2, $\bar{p} = 1 \neq 0$ and $\bar{q} = x \neq 0$ in $\mathbb{F}_2[x]$, so $\overline{pq} = x \neq 0$; mod 3, $\bar{p} = 2x + 1 \neq 0$, $\bar{q} = 2 \neq 0$, so $\overline{pq} \neq 0$. No prime kills pq. Good.

Worked Example 9.3.8 (Content is multiplicative (verify (b)))**.** Verify $\operatorname{cont}(fg) = \operatorname{cont}(f)\operatorname{cont}(g)$ for $f = 4x + 6$, $g = 9x - 15$ in $\mathbb{Z}[x]$.

Recognition. Direct check of Theorem (b): extract contents, multiply primitive parts, compare.

Solution. $\operatorname{cont}(f) = \gcd(4,6) = 2$, $f = 2(2x+3)$; $\operatorname{cont}(g) = \gcd(9,15) = 3$, $g = 3(3x-5)$. Then

$$fg = 2\cdot 3\,(2x+3)(3x-5) = 6\big(6x^2 - 10x + 9x - 15\big) = 6\big(6x^2 - x - 15\big).$$

Now $6x^2 - x - 15$ has coefficients $6, -1, -15$, $\gcd(6,1,15) = 1$, primitive. So $\operatorname{cont}(fg) = 6 = 2\cdot 3 = \operatorname{cont}(f)\operatorname{cont}(g)$. *Check directly:* $fg = (4x+6)(9x-15) = 36x^2 - 60x + 54x - 90 = 36x^2 - 6x - 90$; $\gcd(36,6,90) = 6$. Matches. Good.

Theorem 9.3.9 (R a UFD $\Rightarrow$ $R[x]$ a UFD)**.** *If R is a unique factorization domain, then so is $R[x]$. Consequently, by induction, $R[x_1,\dots,x_n]$ is a UFD; in particular $\mathbb{Z}[x_1,\dots,x_n]$ and $F[x_1,\dots,x_n]$ (for a field F) are UFDs.*

Proof sketch. Let $f \in R[x]$ be nonzero, nonunit. Write $f = \operatorname{cont}(f)\, f_1$ with f_1 primitive. Factor $\operatorname{cont}(f)$ uniquely into irreducibles of R (possible since R is a UFD). For f_1: working in the Euclidean (hence UFD) ring $F[x]$, factor $f_1 = q_1 \cdots q_r$ into irreducibles over F. By Gauss (c), rescale each q_i to a primitive $p_i \in R[x]$ with $f_1 = u\, p_1 \cdots p_r$, $u \in R^\times$; each p_i is irreducible in $R[x]$ (it is primitive and irreducible over F). This proves *existence* of a factorization of f into irreducibles of R and primitive irreducibles. *Uniqueness* follows from uniqueness in R (for the content part) and uniqueness in $F[x]$ together with Gauss's Lemma (for the primitive part: two primitive associates over F are associates over R). □

Corollary 9.3.10 (Irreducibles of $R[x]$)**.** *Let R be a UFD with fraction field F. The irreducible elements of $R[x]$ are exactly:*

1. *the irreducible elements of R (the* constant *irreducibles), and*
2. *the* primitive *polynomials $p(x) \in R[x]$ of degree ≥ 1 that are irreducible in $F[x]$.*

A nonconstant $f \in R[x]$ is irreducible iff f is primitive and irreducible over F.

Proof. A constant $c \in R[x]$ is irreducible in $R[x]$ iff irreducible in R (degree forces any factorization to be by constants). For nonconstant f: if $f = cg$ with $c = \operatorname{cont}(f)$ a nonunit, that is a nontrivial factorization, so irreducible $\Rightarrow$ primitive. Given f primitive, any factorization $f = AB$ in $R[x]$ has A, B of degrees summing to $\deg f$; by Gauss (a) neither can be a nonunit constant (that would divide the content), so a nontrivial $R[x]$-factorization is a nontrivial $F[x]$-factorization, and conversely by Gauss (c). Hence primitive f is irreducible in $R[x]$ iff irreducible in $F[x]$. □

Method (Classify an irreducible of $R[x]$)**.** *Trigger.* "Is $f \in R[x]$ irreducible?"

1. If $\deg f = 0$: f is irreducible iff it is an irreducible of R (e.g. a prime in $\mathbb{Z}$).
2. If $\deg f \geq 1$: first check f is *primitive* (else $\operatorname{cont}(f)$ splits off a nonunit factor $\Rightarrow$ reducible).
3. Then check irreducibility over F (rational roots, Eisenstein, mod-p reduction, degree arguments).
4. *Check.* Primitive + irreducible over F is equivalent to irreducible in $R[x]$.

Worked Example 9.3.11 (A primitive irreducible of $\mathbb{Z}[x]$)**.** Show $f(x) = 2x^2 + 2x + 1$ is irreducible in $\mathbb{Z}[x]$, and identify which "type" of irreducible it is.

Recognition. Nonconstant, so test primitivity then irreducibility over $\mathbb{Q}$ (Corollary).

Solution. Primitive? $\gcd(2,2,1) = 1$, yes. Irreducible over $\mathbb{Q}$? A quadratic is reducible over $\mathbb{Q}$ iff it has a rational root iff its discriminant is a perfect square (in $\mathbb{Q}$). Here $\Delta = 2^2 - 4\cdot 2\cdot 1 = 4 - 8 = -4 < 0$, so there are no real roots, hence no rational root, hence f is irreducible over $\mathbb{Q}$. Being primitive and irreducible over $\mathbb{Q}$, f is irreducible in $\mathbb{Z}[x]$ — of *type (2)* in the Corollary (a primitive nonconstant irreducible). *Check.* A factorization in $\mathbb{Z}[x]$ would be $(ax+b)(cx+d)$ with $ac = 2$, $bd = 1$, and this forces an integer root dividing 1, i.e. ± 1; $f(1) = 5$, $f(-1) = 1$, neither 0. Consistent.

Worked Example 9.3.12 (Same polynomial, two factorization patterns)**.** Factor $h(x) = 6x^2 - x - 2 \in \mathbb{Z}[x]$ completely into irreducibles of $\mathbb{Z}[x]$.

Recognition. Strip content, factor over $\mathbb{Q}$ via roots, then Gauss (c) clears to $\mathbb{Z}$; finally read off irreducible types.

Solution. $\text{cont}(h) = \gcd(6, 1, 2) = 1$, primitive. Roots of $6x^2 - x - 2 = 0$:

$$x = \frac{1 \pm \sqrt{1 + 48}}{12} = \frac{1 \pm 7}{12} \in \{\tfrac{2}{3},\ -\tfrac{1}{2}\}.$$

Over $\mathbb{Q}$: $h = 6(x - \frac{2}{3})(x + \frac{1}{2})$. Clear denominators by distributing the 6 as $3 \cdot 2$: $h = (3x - 2)(2x + 1)$. *Check.* $(3x - 2)(2x + 1) = 6x^2 + 3x - 4x - 2 = 6x^2 - x - 2 = h$. Good. Both $3x - 2$ and $2x + 1$ are primitive and linear (hence irreducible over $\mathbb{Q}$), so each is a type-(2) irreducible of $\mathbb{Z}[x]$; the content contributes no constant irreducible.

$\mathbb{Z}[x]$ is a UFD but not a PID: the ideal $(2, x)$

Proposition 9.3.13 ($\mathbb{Z}[x]$ is not a PID)**.** *The ideal $I = (2, x) \subseteq \mathbb{Z}[x]$ is not principal. Hence $\mathbb{Z}[x]$ is a UFD that is* not *a principal ideal domain. (More generally $R[x]$ is a PID iff R is a field.)*

Proof. First, $I = \{f \in \mathbb{Z}[x] :\ f(0) \text{ is even}\}$: indeed 2 and x both lie in this set, and the set is an ideal; conversely $f = a_0 + a_1 x + \cdots$ with a_0 even equals $a_0 + x(a_1 + a_2 x + \cdots) \in (2, x)$. Note $\mathbb{Z}[x]/I \cong \mathbb{F}_2$ via $f \mapsto f(0) \bmod 2$, a field, so I is maximal.

Suppose $I = (d)$ for some $d \in \mathbb{Z}[x]$. From $2 \in (d)$ we get $d \mid 2$ in $\mathbb{Z}[x]$; comparing degrees, d is a constant dividing 2, so $d \in \{\pm 1, \pm 2\}$. If $d = \pm 1$ then $I = \mathbb{Z}[x]$, false ($1 \notin I$ since 1 is odd at 0). If $d = \pm 2$ then $x \in (2)$ would give $x = 2g(x)$, impossible (the coefficient 1 of x is not even). Contradiction, so I is not principal. □

Remark 9.3.3. This is the cleanest demonstration that "UFD" is strictly weaker than "PID." The diagram of implications is

$$\text{Euclidean} \Longrightarrow \text{PID} \Longrightarrow \text{UFD}$$

Diagram explanation. Objects: Three *classes* of commutative rings (not individual rings): Euclidean domains (rings with a Euclidean algorithm, e.g. $\mathbb{Z}$ and $F[x]$), principal ideal domains (PIDs: every ideal is principal, e.g. $\mathbb{Z}$ and $\mathbb{Z}[i]$), and unique factorization domains (UFDs: every nonzero nonunit factors uniquely into irreducibles, e.g. $\mathbb{Z}$, $\mathbb{Z}[x]$, $F[x_1, \ldots, x_n]$). Each node is a property of a ring.

Arrows: Two double-line implication arrows ($\Rightarrow$) encode strict implications (not reversible). The first says every Euclidean domain is a PID (the Euclidean algorithm produces a gcd, which generates any ideal). The second says every PID is a UFD (by the ascending-chain/divisibility argument). Both are one-way: neither arrow reverses.

What commutes: There is no composite path creating a loop, so "commuting" is not the relevant notion. Instead the chain records: Euclidean $\Rightarrow$ PID $\Rightarrow$ UFD, and both implications are strict (proper containments of classes). The chain of composites gives Euclidean $\Rightarrow$ UFD by transitivity.

Why it commutes: Euclidean $\Rightarrow$ PID: given an ideal I in a Euclidean domain, take the element $d \in I$ with smallest Euclidean norm; every other element of I is a multiple of d by the division algorithm, so $I = (d)$. PID $\Rightarrow$ UFD: in a PID, irreducible equals prime (since (p) is maximal, hence prime), so the standard proof of unique factorization via prime chains applies.

Why this matters here: The diagram appears right after proving $\mathbb{Z}[x]$ is not a PID (the ideal $(2, x)$ is not principal). Its purpose is to locate $\mathbb{Z}[x]$ precisely in the hierarchy: $\mathbb{Z}[x]$ is a UFD (just proved by the theorem) but not a PID, so it witnesses that the second implication is strict. The remark also explains why factoring is pushed to $F[x]$: $F[x]$ is Euclidean, making it maximally well-behaved.

Concrete example: $\mathbb{Z}$ is Euclidean (ordinary division algorithm), hence a PID, hence a UFD. $\mathbb{Z}[x]$ is a UFD but not a PID ($(2, x)$ is not principal). $\mathbb{Q}[x]$ is Euclidean (polynomial division). The Gaussian integers $\mathbb{Z}[i]$ are Euclidean, so a PID, so a UFD. The ring $\mathbb{Z}[\sqrt{-5}]$ fails even to be a UFD ($6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$).

Common pitfall: Students sometimes read the double-arrow as a two-way implication (an "iff"). It is not: the arrows go only left-to-right. Seeing $\mathbb{Z}[x]$ in UFD is often mistakenly used to claim it is a PID; the very point of the preceding proposition is that the second implication is strict.

Takeaway: The point of this diagram is that the ring-class hierarchy has exactly these implications and no more, and $\mathbb{Z}[x]$ is the canonical example showing UFD does not imply PID.

and $\mathbb{Z}[x]$ sits in UFD $\setminus$ PID. By contrast $\mathbb{Q}[x]$ *is* Euclidean (a field times $[x]$), which is exactly why factoring over F is easy and we push problems there via Gauss.

Worked Example 9.3.14 ($(2, x)$ is maximal but not principal)**.** Confirm $\mathbb{Z}[x]/(2, x) \cong \mathbb{F}_2$ and use it to re-derive non-principality.

Recognition. Compute the quotient via evaluation/reduction (First Isomorphism Theorem), then note a principal generator would have to be a constant.

Solution. Define $\varphi : \mathbb{Z}[x] \to \mathbb{F}_2$, $\varphi(f) = f(0) \bmod 2$. This is a surjective ring homomorphism with $\ker \varphi = \{f : \ f(0) \equiv 0\} = (2, x)$ (shown above). So $\mathbb{Z}[x]/(2, x) \cong \mathbb{F}_2$, a field $\Rightarrow (2, x)$ maximal. If $(2, x) = (d)$, then $d \mid 2$ forces d constant, and a single constant d generates either all of $\mathbb{Z}[x]$ ($d = \pm 1$) or the multiples of 2 ($d = \pm 2$), and $\{\text{multiples of } 2\} \neq (2, x)$ since $x \notin (2)$. *Check.* $x \in (2)$ would say every coefficient of x is even; but the coefficient is 1. So no constant generates $(2, x)$; not principal. Good.

Worked Example 9.3.15 (Gauss in a polynomial-coefficient UFD)**.** In $R = \mathbb{Q}[t]$ (a UFD, $F = \mathbb{Q}(t)$), show $f(x) = t\,x^2 - (t^2 + 1)x + t \in R[x]$ factors, and find the factorization.

Recognition. $R[x] = \mathbb{Q}[t][x]$ with R a UFD; factor over $F = \mathbb{Q}(t)$ then clear by Gauss (c). $\operatorname{cont}(f) = \gcd(t, t^2 + 1, t) = 1$ since $\gcd(t, t^2 + 1) = 1$ in $\mathbb{Q}[t]$, so f is primitive.

Solution. Treat f as a quadratic in x over $F = \mathbb{Q}(t)$. Discriminant:

$$\Delta = (t^2 + 1)^2 - 4t \cdot t = (t^2 + 1)^2 - 4t^2 = t^4 - 2t^2 + 1 = (t^2 - 1)^2.$$

Roots: $x = \dfrac{(t^2 + 1) \pm (t^2 - 1)}{2t} \in \left\{ \dfrac{2t^2}{2t},\ \dfrac{2}{2t} \right\} = \left\{ t,\ \dfrac{1}{t} \right\}$. So over F, $f = t\,(x - t)\big(x - \frac{1}{t}\big)$. Distribute the leading t onto the second factor:

$$f = (x - t)\big(tx - 1\big).$$

Both factors lie in $R[x] = \mathbb{Q}[t][x]$, matching degrees $1, 1$. *Check.* $(x - t)(tx - 1) = tx^2 - x - t^2x + t = tx^2 - (t^2 + 1)x + t = f$. Good. Each linear factor is primitive in $\mathbb{Q}[t][x]$, so they are type-(2) irreducibles, and $\operatorname{cont}(f) = 1$ contributes no constant irreducible — consistent with the multiplicativity $\operatorname{cont}(f) = \operatorname{cont}(x - t)\operatorname{cont}(tx - 1) = 1 \cdot 1$.

Caution. **"Irreducible over $\mathbb{Q}$" is not the same as "irreducible over $\mathbb{Z}$" without primitivity.** Example: $2x + 4 = 2(x + 2)$ is irreducible *over* $\mathbb{Q}$ (it is a unit times a linear factor, and units in $\mathbb{Q}[x]$ are nonzero constants, so $x + 2$ is a unit-multiple) — but in $\mathbb{Z}[x]$ it is *reducible*, $2x + 4 = 2 \cdot (x + 2)$, because 2 is not a unit in $\mathbb{Z}$. Irreducibility passes from $\mathbb{Q}[x]$ to $\mathbb{Z}[x]$ only for *primitive* polynomials (Corollary "Irreducibles of $R[x]$"). Always extract the content first.

Caution. **Content lives up to units only.** In $\mathbb{Z}[x]$, $\operatorname{cont}(f)$ is determined up to sign; in $k[t][x]$, up to a nonzero scalar in k. Do not assert "$\operatorname{cont}(f) = 6$" as if it were canonical without fixing the normalization (cont > 0 in $\mathbb{Z}$, or monic in $k[t]$). Likewise "$\operatorname{cont}(fg) = \operatorname{cont}(f)\operatorname{cont}(g)$" is an equality *of associates*.

Caution. **Gauss needs R to be a UFD, not merely a domain.** The proof of (a) uses that an irreducible π is *prime* so that $(R/(\pi))[x]$ is a domain. In a non-UFD like $\mathbb{Z}[\sqrt{-5}]$ irreducibles need not be prime, and the clean content theory fails. The chain $\mathbb{Z} \Rightarrow \mathbb{Z}[x] \Rightarrow \mathbb{Z}[x, y] \Rightarrow \cdots$ being UFDs rests entirely on this.

Exercises (from the text).

1. Let R be an integral domain with quotient field F and let $p(x)$ be a monic polynomial in $R[x]$. Assume that $p(x) = a(x)b(x)$ where $a(x)$ and $b(x)$ are monic polynomials in $F[x]$ of smaller degree than $p(x)$. Prove that if $a(x) \notin R[x]$ then R is not a Unique Factorization Domain. Deduce that $\mathbb{Z}[2\sqrt{2}]$ is not a U.F.D.

2. Prove that if $f(x)$ and $g(x)$ are polynomials with rational coefficients whose product $f(x)g(x)$ has integer coefficients, then the product of any coefficient of $g(x)$ with any coefficient of $f(x)$ is an integer.

3. Let F be a field. Prove that the set R of polynomials in $F[x]$ whose coefficient of x is equal to 0 is a subring of $F[x]$ and that R is not a U.F.D. [Show that $x^6 = (x^2)^3 = (x^3)^2$ gives two distinct factorizations of x^6 into irreducibles.]

4. Let $R = \mathbb{Z} + x\mathbb{Q}[x] \subset \mathbb{Q}[x]$ be the set of polynomials in x with rational coefficients whose constant term is an integer.

   (a) Prove that R is an integral domain and its units are ± 1.

   (b) Show that the irreducibles in R are $\pm p$ where p is a prime in $\mathbb{Z}$ and the polynomials $f(x)$ that are irreducible in $\mathbb{Q}[x]$ and have constant term ± 1. Prove that these irreducibles are prime in R.

   (c) Show that x cannot be written as the product of irreducibles in R (in particular, x is not irreducible) and conclude that R is not a U.F.D.

   (d) Show that x is not a prime in R and describe the quotient ring $R/(x)$.

5. Let $R = \mathbb{Z} + x\mathbb{Q}[x] \subset \mathbb{Q}[x]$ be the ring considered in the previous exercise.

   (a) Suppose that $f(x), g(x) \in \mathbb{Q}[x]$ are two nonzero polynomials with rational coefficients and that x^r is the largest power of x dividing both $f(x)$ and $g(x)$ in $\mathbb{Q}[x]$, i.e., r is the degree of the lowest order term appearing in either $f(x)$ or $g(x)$. Let f_r and g_r be the coefficients of x^r in $f(x)$ and $g(x)$, respectively (one of which is nonzero by definition of r). Then $\mathbb{Z}f_r + \mathbb{Z}g_r = \mathbb{Z}d_r$ for some nonzero $d_r \in \mathbb{Q}$ (cf. Exercise 14 in Section 2.4). Prove that there is a polynomial $d(x) \in \mathbb{Q}[x]$ that is a g.c.d. of $f(x)$ and $g(x)$ in $\mathbb{Q}[x]$ and whose term of minimal degree is $d_r x^r$.

   (b) Prove that $f(x) = d(x)q_1(x)$ and $g(x) = d(x)q_2(x)$ where $q_1(x)$ and $q_2(x)$ are elements of the subring R of $\mathbb{Q}[x]$.

   (c) Prove that $d(x) = a(x)f(x) + b(x)g(x)$ for polynomials $a(x), b(x)$ in R. [The existence of $a(x), b(x)$ in the Euclidean Domain $\mathbb{Q}[x]$ is immediate. Use Exercise 11 in Section 2 to show that $a(x)$ and $b(x)$ can be chosen to lie in R.]

   (d) Conclude from (b) and (c) that $Rf(x) + Rg(x) = Rd(x)$ in $\mathbb{Q}[x]$ and use this to prove that R is a Bezout Domain (cf. Exercise 7 in Section 8.2).

   (e) Show that (d), the results of the previous exercise, and Exercise 11 of Section 8.3 imply that R must contain ideals that are not principal (hence not finitely generated). Prove that in fact $I = x\mathbb{Q}[x]$ is an ideal of R that is not finitely generated.

Practice problems.

1. Divide $f(x) = 2x^4 - 3x^3 + x - 5$ by $g(x) = x^2 - 2x + 1$ in $\mathbb{Q}[x]$, finding q, r with $f = qg + r$ and $\deg r < 2$.

2. In $\mathbb{F}_5[x]$, divide $x^4 + x^3 + x + 1$ by $x^2 + 1$ and exhibit the quotient and remainder.

3. Compute $\gcd(x^4-1,\ x^3-x^2+x-1)$ in $\mathbb{Q}[x]$ by the Euclidean algorithm, and express it as a $\mathbb{Q}[x]$-combination of the two polynomials.

4. Find the content $\mathrm{cont}(f)$ and the primitive part of $f(x) = 6x^3 - 15x^2 + 9x - 24 \in \mathbb{Z}[x]$.

5. Let $f(x) = 2x^2 + 3x + 4$ and $g(x) = 6x^2 - x + 10$ in $\mathbb{Z}[x]$. Verify Gauss's Lemma directly: compute $\mathrm{cont}(fg)$ and confirm $\mathrm{cont}(fg) = \mathrm{cont}(f)\,\mathrm{cont}(g)$.

6. Determine all rational roots of $f(x) = 2x^3 - 3x^2 - 8x + 12$, and factor f completely in $\mathbb{Q}[x]$.

7. Show $f(x) = x^4 + x^3 + x^2 + x + 1$ has no rational roots, and decide whether it is irreducible in $\mathbb{Q}[x]$.

8. Use reduction mod 2 to prove $f(x) = x^4 + x + 1 \in \mathbb{Z}[x]$ is irreducible in $\mathbb{Q}[x]$.

9. Apply Eisenstein's criterion at a suitable prime to show $f(x) = x^5 - 6x^3 + 12x - 15$ is irreducible in $\mathbb{Q}[x]$.

10. Using the substitution $x \mapsto x + 1$ and Eisenstein at $p = 5$, prove the cyclotomic polynomial $\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$ is irreducible in $\mathbb{Q}[x]$.

11. Factor $f(x) = x^4 + 4$ completely in $\mathbb{Z}[x]$.
12. Decide, with proof, whether $f(x) = x^3 - 3x - 1$ is irreducible in $\mathbb{Q}[x]$.
13. Order the monomials of $f(x, y, z) = 4x^2yz + 7y^3z^2 - x^3 + 2xz^4$ under the lex order ($x > y > z$), and identify $\mathrm{LM}(f)$, $\mathrm{LT}(f)$, and $\mathrm{multideg}(f)$.
14. For the same f, give $\mathrm{LT}(f)$ under grlex and under grevlex (with $x > y > z$).
15. Compute the S-polynomial $S(f, g)$ for $f = x^2y - 1$, $g = xy^2 - x$ in $\mathbb{Q}[x, y]$ under lex with $x > y$.

Additional exercises.

1. Let R be a UFD with field of fractions F, and let $f \in R[x]$ be primitive of positive degree. Prove that f is irreducible in $R[x]$ if and only if it is irreducible in $F[x]$.
2. Show that $f(x, y) = x^2 + y^2 - 1 \in \mathbb{Q}[x, y]$ is irreducible. (Hint: view it in $(\mathbb{Q}[y])[x]$ and use that $\mathbb{Q}[y]$ is a UFD.)
3. Let p be prime. Prove that $f(x) = x^p - x - 1$ is irreducible in $\mathbb{F}_p[x]$, and deduce it is irreducible in $\mathbb{Q}[x]$.
4. Give an example of a polynomial $f \in \mathbb{Z}[x]$ that is irreducible mod p for no prime p yet is irreducible in $\mathbb{Q}[x]$; justify both claims for $f(x) = x^4 + 1$.
5. Run the Buchberger criterion on the ideal $I = \langle x^2 - y,\ xy - z \rangle \subseteq \mathbb{Q}[x, y, z]$ under lex ($x > y > z$): compute the relevant S-polynomials and decide whether the given generators form a Grobner basis; if not, extend to one.
6. Prove that if $f \in \mathbb{Z}[x]$ is monic and has a root in $\mathbb{Q}$, then that root lies in $\mathbb{Z}$. Use this to show $x^3 + x + 1$ has no rational root.

Commutative-diagram exercises.

1. Consider the reduction-mod-p ring homomorphism

$$\mathbb{Z}[x] \xrightarrow{\ \mathrm{mod}\ p\ } \mathbb{F}_p[x]$$

   Prove it is a surjective ring homomorphism, and show by example that the image of an irreducible polynomial in $\mathbb{Z}[x]$ need not be irreducible in $\mathbb{F}_p[x]$.
2. Let $p(x) \in \mathbb{F}_3[x]$ be an irreducible quadratic. Show that $\mathbb{F}_3[x]/(p(x))$ is a field, determine its order, and exhibit such a $p(x)$ explicitly.
3. For the map in problem 1, suppose $f \in \mathbb{Z}[x]$ is monic with $\deg f = n$ and $\overline{f} \in \mathbb{F}_p[x]$ is irreducible of degree n. Prove f is irreducible in $\mathbb{Q}[x]$, and explain via the diagram why the converse fails.
4. Let F be a field and $p(x) \in F[x]$ irreducible. Show $F[x]/(p)$ is a field and that the composite

$$F \hookrightarrow F[x] \xrightarrow{\ \mathrm{mod}\ p\ } F[x]/(p)$$

   is an injective ring homomorphism, so $F[x]/(p)$ is naturally an extension field of F.
5. Consider factoring $f(x) = 2x^2 + 3$ in $\mathbb{Z}[x]$ versus in $\mathbb{Q}[x] = \mathrm{Frac}(\mathbb{Z})[x]$. Explain, using Gauss's Lemma, why f is irreducible in both, and contrast with $g(x) = 2x^2 + 2 = 2(x^2 + 1)$, which is reducible in $\mathbb{Z}[x]$ but, up to a unit, irreducible in $\mathbb{Q}[x]$.

9.4 Irreducibility Criteria

Tests for irreducibility of polynomials

Throughout, R is an integral domain and $F = \mathrm{Frac}(R)$ its field of fractions; the running cases are $R = \mathbb{Z}$, $F = \mathbb{Q}$, and reduction maps $\mathbb{Z}[x] \to \mathbb{F}_p[x]$. By Gauss's Lemma a primitive nonconstant polynomial $f \in \mathbb{Z}[x]$

is irreducible in $\mathbb{Z}[x]$ iff it is irreducible in $\mathbb{Q}[x]$, so every test below transfers between $\mathbb{Z}[x]$ and $\mathbb{Q}[x]$ up to a rational constant. We collect the four standard tests: rational roots, the degree-2/3 root criterion, reduction mod p, and Eisenstein.

The single most important picture is the reduction homomorphism $\mathbb{Z}[x] \to \mathbb{F}_p[x]$, which turns a hard question over $\mathbb{Q}$ into a finite question over $\mathbb{F}_p$:

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\bmod p} & \mathbb{F}_p[x] \\ \big\downarrow & & \\ \mathbb{Q}[x] & & \end{array} \qquad\qquad f \xmapsto{\bmod p} \bar{f}$$

Diagram explanation. Objects: The left diagram has three nodes: $\mathbb{Z}[x]$, the polynomial ring over the integers (upper left); $\mathbb{F}_p[x]$, the polynomial ring over the field with p elements (upper right); and $\mathbb{Q}[x]$, the polynomial ring over the rationals (lower left). The right diagram tracks a single polynomial $f \in \mathbb{Z}[x]$ and its residue $\bar{f} \in \mathbb{F}_p[x]$.

Arrows: The horizontal arrow $\bmod p : \mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_p[x]$ is the surjective ring homomorphism reducing every coefficient modulo p: it sends $a_n x^n + \cdots + a_0$ to $\bar{a}_n x^n + \cdots + \bar{a}_0$. The vertical arrow $\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$ is the natural inclusion (every integer polynomial is a rational polynomial), an injective ring homomorphism. The missing bottom-right arrow indicates there is NO natural map from $\mathbb{Q}[x]$ to $\mathbb{F}_p[x]$ that makes this square commute, which is why the diagram is an L-shape rather than a full square. The element diagram on the right simply names the action of the horizontal arrow on a specific polynomial.

What commutes: The diagram is not presented as a commutative square; it is an inclusion plus a surjection meeting at $\mathbb{Z}[x]$. The key compatibility is that $\bmod p$ is a ring homomorphism: $\overline{f+g} = \bar{f} + \bar{g}$ and $\overline{f \cdot g} = \bar{f} \cdot \bar{g}$ for all $f, g \in \mathbb{Z}[x]$.

Why it commutes: The multiplicativity $\overline{f \cdot g} = \bar{f} \cdot \bar{g}$ follows by reducing coefficients mod p and noting that the product formula for polynomial coefficients is a sum of products of integer coefficients: reducing each integer mod p commutes with addition and multiplication in $\mathbb{Z}$, since $\mathbb{Z} \to \mathbb{F}_p$ (the natural quotient $\mathbb{Z} \to \mathbb{Z}/p\mathbb{Z}$) is a ring homomorphism. Concretely, if $f = \sum a_i x^i$ and $g = \sum b_j x^j$ then the k-th coefficient of fg is $\sum_{i+j=k} a_i b_j$; reducing mod p gives $\sum_{i+j=k} \bar{a}_i \bar{b}_j$, which is the k-th coefficient of $\bar{f}\bar{g}$.

Why this matters here: This diagram is the conceptual engine behind every irreducibility test in this section. Gauss's Lemma licenses moving between $\mathbb{Z}[x]$ and $\mathbb{Q}[x]$; the surjection $\bmod p$ then converts a potentially hard question over $\mathbb{Q}$ into a finite computation over $\mathbb{F}_p$. The multiplicativity means a factorization $f = gh$ in $\mathbb{Z}[x]$ produces a factorization $\bar{f} = \bar{g}\bar{h}$ in $\mathbb{F}_p[x]$, so irreducibility of $\bar{f}$ (checkable by finite search) certifies irreducibility of f over $\mathbb{Q}$, provided $\deg \bar{f} = \deg f$.

Concrete example: Take $f = x^3 - 3x - 1 \in \mathbb{Z}[x]$ and $p = 2$. Then $\bar{f} = x^3 + x + 1 \in \mathbb{F}_2[x]$; testing both elements of $\mathbb{F}_2$ shows $\bar{f}$ has no root, so $\bar{f}$ is irreducible over $\mathbb{F}_2$, and the inclusion $\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$ together with Gauss's Lemma then yields: f is irreducible over $\mathbb{Q}$.

Common pitfall: Students sometimes treat the diagram as a full commutative square and seek a map $\mathbb{Q}[x] \to \mathbb{F}_p[x]$. No ring homomorphism $\mathbb{Q}[x] \to \mathbb{F}_p[x]$ extends $\bmod p$, because $p \cdot 1 = 0$ in $\mathbb{F}_p$ while p is a unit in $\mathbb{Q}$ (such a map would send $1 = p \cdot p^{-1}$ to 0, not to 1); the lower-right corner is intentionally absent. The diagram records only the two maps that genuinely exist and interact at $\mathbb{Z}[x]$.

Takeaway: The point of this diagram is that the reduction map $\bmod p$ is a ring homomorphism, so it converts any factorization of f in $\mathbb{Z}[x]$ into a factorization of $\bar{f}$ in $\mathbb{F}_p[x]$, turning an infinite problem over $\mathbb{Q}$ into a finite one over $\mathbb{F}_p$.

The map $\bmod p : \mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_p[x]$ is a surjective ring homomorphism sending $a_n x^n + \cdots + a_0$ to $\bar{a}_n x^n + \cdots + \bar{a}_0$ with $\bar{a}_i = a_i \bmod p$. A factor of f in $\mathbb{Z}[x]$ maps to a factor of $\bar{f}$; if $\bar{f}$ refuses to factor (with degree preserved), then f could not have factored either.

The rational root theorem

Proposition 9.4.1 (Rational roots, D&F 9.4.11)**.** *Let $f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0 \in \mathbb{Z}[x]$ with $a_n \neq 0$ and $a_0 \neq 0$. If $\alpha = p/q \in \mathbb{Q}$ is a root of f, written in lowest terms with $\gcd(p, q) = 1$, then $p \mid a_0$ and*

$q \mid a_n$. *In particular, if f is monic then every rational root is an integer dividing a_0.*

Proof. Substitute $\alpha = p/q$ and clear denominators by multiplying by q^n:

$$a_n p^n + a_{n-1} p^{n-1} q + \cdots + a_1 p q^{n-1} + a_0 q^n = 0.$$

All terms except $a_n p^n$ carry a factor of q, so $q \mid a_n p^n$. Since $\gcd(p, q) = 1$ gives $\gcd(p^n, q) = 1$, we get $q \mid a_n$. Likewise all terms except $a_0 q^n$ carry a factor of p, so $p \mid a_0 q^n$, and $\gcd(q^n, p) = 1$ forces $p \mid a_0$. □

Method (Hunting rational roots (and using them))**.** *Trigger.* You want a root, or you want to test irreducibility of a degree-2 or degree-3 polynomial in $\mathbb{Q}[x]$ (Proposition below).

1. Clear denominators so $f \in \mathbb{Z}[x]$; record a_0 (constant) and a_n (leading).
2. List candidate roots $\pm p/q$ with $p \mid a_0$, $q \mid a_n$, in lowest terms.
3. Evaluate f at each candidate (Horner's scheme is fastest); a candidate α is a root iff $f(\alpha) = 0$, equivalently $(x - \alpha) \mid f$.
4. If f is monic, only integer divisors of a_0 need testing.

Caveat: once $\deg f \geq 4$, the *absence* of a rational root proves nothing about irreducibility (a quartic can split into two irreducible quadratics with no roots).

Worked Example 9.4.2 (Rational roots of a cubic)**.** Find all rational roots of $f(x) = 2x^3 - 3x^2 - 8x + 3$, and decide irreducibility over $\mathbb{Q}$.

Recognition. Rational Root Theorem: $f \in \mathbb{Z}[x]$, $a_0 = 3$, $a_3 = 2$, so any root p/q has $p \mid 3$, $q \mid 2$.

Solution. Candidates p/q with $p \in \{\pm 1, \pm 3\}$, $q \in \{1, 2\}$:

$$\pm 1,\ \pm 3,\ \pm\tfrac{1}{2},\ \pm\tfrac{3}{2}.$$

Evaluate each:

$$\begin{aligned} f(1) &= 2 - 3 - 8 + 3 = -6, & f(-1) &= -2 - 3 + 8 + 3 = 6, \\ f(3) &= 54 - 27 - 24 + 3 = 6, & f(-3) &= -54 - 27 + 24 + 3 = -54, \\ f(\tfrac{1}{2}) &= \tfrac{1}{4} - \tfrac{3}{4} - 4 + 3 = -\tfrac{3}{2}, & f(-\tfrac{1}{2}) &= -\tfrac{1}{4} - \tfrac{3}{4} + 4 + 3 = 6, \\ f(\tfrac{3}{2}) &= \tfrac{27}{4} - \tfrac{27}{4} - 12 + 3 = -9, & f(-\tfrac{3}{2}) &= -\tfrac{27}{4} - \tfrac{27}{4} + 12 + 3 = \tfrac{3}{2}. \end{aligned}$$

No candidate vanishes, so f has **no rational root**. Since $\deg f = 3$, by the Proposition below f is irreducible over $\mathbb{Q}$. *Sanity check.* Mod 5, $\bar{f} = 2x^3 + 2x^2 + 2x + 3$ (as $-3 \equiv 2$, $-8 \equiv 2$), with

$$\bar{f}(0) = 3,\ \bar{f}(1) = 9 \equiv 4,\ \bar{f}(2) = 31 \equiv 1,\ \bar{f}(3) = 81 \equiv 1,\ \bar{f}(4) = 171 \equiv 1$$

in $\mathbb{F}_5$ — no root in $\mathbb{F}_5$ either, consistent with having no rational root.

Worked Example 9.4.3 (A monic cubic with an integer root)**.** Find the rational roots of $g(x) = x^3 - 4x^2 + x + 6$ and factor it over $\mathbb{Q}$.

Recognition. Monic, so rational roots are integer divisors of $a_0 = 6$: $\pm 1, \pm 2, \pm 3, \pm 6$.

Solution. Horner at $x = -1$: $1,\ -5,\ 6,\ 0$. Root! So $(x + 1) \mid g$ and

$$g(x) = (x + 1)(x^2 - 5x + 6) = (x + 1)(x - 2)(x - 3).$$

Check. $(x + 1)(x - 2)(x - 3)$ has constant term $(1)(-2)(-3) = 6$ and the x^2 coefficient $1 - 2 - 3 = -4$, matching g. All three roots $-1, 2, 3$ divide 6, as the theorem demands.

Worked Example 9.4.4 (Constraining the denominator)**.** Show $h(x) = 3x^3 + x^2 + x - 2$ has exactly one rational root and find it.

Recognition. Rational Root Theorem: $a_0 = -2$, $a_3 = 3$, so $p \mid 2$, $q \mid 3$.

Solution. Candidates: $\pm 1, \pm 2, \pm\frac{1}{3}, \pm\frac{2}{3}$. At $x = \frac{2}{3}$: $3(\frac{8}{27}) + \frac{4}{9} + \frac{2}{3} - 2 = \frac{8}{9} + \frac{4}{9} + \frac{6}{9} - 2 = \frac{18}{9} - 2 = 0$. Root $x = \frac{2}{3}$. Divide: $h(x) = (3x-2)(x^2 + x + 1)$. The quotient $x^2 + x + 1$ has discriminant $1 - 4 = -3 < 0$, so no further rational (or real) roots. *Check.* $(3x-2)(x^2+x+1) = 3x^3 + 3x^2 + 3x - 2x^2 - 2x - 2 = 3x^3 + x^2 + x - 2$. Matches. The root $\frac{2}{3}$ indeed has numerator $\mid 2$ and denominator $\mid 3$.

Worked Example 9.4.5 (No rational root despite small coefficients)**.** Does $f(x) = x^4 + x + 1$ have a rational root?

Recognition. Monic; candidates are integer divisors of $a_0 = 1$, i.e. ± 1.

Solution. $f(1) = 1 + 1 + 1 = 3 \neq 0$ and $f(-1) = 1 - 1 + 1 = 1 \neq 0$. No rational root. *Check / warning.* This does *not* prove $x^4 + x + 1$ irreducible over $\mathbb{Q}$; a quartic can be a product of two quadratics with no roots. (In fact $x^4 + x + 1$ *is* irreducible over $\mathbb{Q}$ — proven by reduction mod 2 below — but the rational-root test alone is silent here.)

Worked Example 9.4.6 (Using a root to certify reducibility)**.** Prove $f(x) = 5x^3 + x^2 - 5x - 1 \in \mathbb{Q}[x]$ is reducible by exhibiting a rational root.

Recognition. Rational Root Theorem: $a_0 = -1$, $a_3 = 5$, candidates $\pm 1, \pm\frac{1}{5}$.

Solution. At $x = 1$: $5 + 1 - 5 - 1 = 0$. A root! So $(x - 1) \mid f$. Better, group to factor fully:

$$5x^3 + x^2 - 5x - 1 = x^2(5x + 1) - (5x + 1) = (5x + 1)(x^2 - 1) = (5x + 1)(x - 1)(x + 1).$$

So f is reducible over $\mathbb{Q}$ (indeed over $\mathbb{Z}$), with rational roots $1, -1, -\frac{1}{5}$. *Check.* Expand back: $(5x+1)(x^2-1) = 5x^3 - 5x + x^2 - 1 = 5x^3 + x^2 - 5x - 1$. Confirmed. Each root satisfies the theorem: ± 1 have numerator $\mid 1$ and denominator $1 \mid 5$, while $-\frac{1}{5}$ has numerator $\mid 1$ and denominator $5 \mid 5$. The lesson: **always verify a claimed factor by multiplying back** — had we instead written down $5x^3 + x^2 - x - 1$, the same grouping would fail ($f(1) = 4 \neq 0$), since that polynomial has no rational root and is in fact irreducible.

Caution. A successful grouping/factoring *must* be confirmed by expansion. If f has no rational root but you "find" a linear factor, you made an arithmetic slip. Conversely, for $\deg f \geq 4$, absence of rational roots is *not* irreducibility.

Reducibility of degree 2 and 3 over a field

Proposition 9.4.7 (Roots vs. factors, D&F 9.4.10)**.** *Let F be a field and $f \in F[x]$ with $\deg f \in \{2, 3\}$. Then f is reducible over F if and only if f has a root in F.*

Proof. If f has a root $\alpha \in F$, then by the division algorithm $f(x) = (x - \alpha)q(x)$ with $\deg q = \deg f - 1 \geq 1$, a nontrivial factorization, so f is reducible. Conversely, if f is reducible, $f = gh$ with $1 \leq \deg g \leq \deg h$ and $\deg g + \deg h = \deg f \leq 3$. If $\deg g \geq 2$ then $\deg h \geq 2$ and $\deg f \geq 4$, a contradiction; so $\deg g = 1$, say $g = ax + b$ with $a \neq 0$, and then $\alpha = -b/a \in F$ is a root of g, hence of f. □

Remark 9.4.1. The hypothesis $\deg f \leq 3$ is essential: a degree-2 or degree-3 reducible polynomial *must* shed a linear factor, but a degree-4 polynomial can factor as (irreducible quadratic)×(irreducible quadratic) with no root at all (e.g. $x^4 + 1 = (x^2 + x + 2)(x^2 + 2x + 2)$ over $\mathbb{F}_3$, which has no root in $\mathbb{F}_3$ — see below).

Method (Degree 2 or 3 irreducibility over F)**.** *Trigger.* $\deg f \in \{2, 3\}$ over a field F (e.g. $\mathbb{Q}$, $\mathbb{F}_p$).

1. Search for a root in F. Over $\mathbb{Q}$ use the Rational Root Theorem; over $\mathbb{F}_p$ just test all p elements.
2. If a root exists, f is reducible; otherwise f is irreducible.

This is the only test where "no root" immediately gives irreducibility.

Worked Example 9.4.8 (Irreducible cubic over $\mathbb{Q}$)**.** Show $x^3 - 3x - 1$ is irreducible over $\mathbb{Q}$.

Recognition. Degree 3 over the field $\mathbb{Q}$: reducible iff it has a rational root.

Solution. Monic, $a_0 = -1$, candidates ± 1. $f(1) = 1-3-1 = -3 \neq 0$, $f(-1) = -1+3-1 = 1 \neq 0$. No rational root, so by the Proposition f is irreducible over $\mathbb{Q}$. *Check.* Mod 2, $\bar{f} = x^3 + x + 1$, and $\bar{f}(0) = 1, \bar{f}(1) = 1$ in $\mathbb{F}_2$ — no root, so $\bar{f}$ is irreducible in $\mathbb{F}_2[x]$, independently confirming irreducibility over $\mathbb{Q}$.

Worked Example 9.4.9 (A quadratic over $\mathbb{F}_5$)**.** Is $x^2 + 2 \in \mathbb{F}_5[x]$ irreducible?

Recognition. Degree 2 over the field $\mathbb{F}_5$: reducible iff it has a root in $\mathbb{F}_5$.

Solution. Compute squares in $\mathbb{F}_5$: $0^2 = 0, 1^2 = 1, 2^2 = 4, 3^2 = 4, 4^2 = 1$. We need $x^2 = -2 = 3$. Since 3 is not a square mod 5, there is no root, so $x^2 + 2$ is irreducible over $\mathbb{F}_5$. *Check.* The squares are $\{0, 1, 4\}$, missing $\{2, 3\}$; $-2 \equiv 3$ is a nonsquare, confirming no root.

Worked Example 9.4.10 (A quadratic that stays irreducible over $\mathbb{F}_7$)**.** Is $x^2 + 1 \in \mathbb{F}_7[x]$ irreducible?

Recognition. Degree 2 over $\mathbb{F}_7$: reducible iff -1 is a square mod 7.

Solution. Squares mod 7: $1, 4, 2, 2, 4, 1$ for $x = 1, \ldots, 6$, i.e. $\{1, 2, 4\}$. We need $x^2 = -1 = 6$; $6 \notin \{1, 2, 4\}$, so *no* root and $x^2 + 1$ is irreducible over $\mathbb{F}_7$. *Check.* Since $7 \equiv 3 \pmod 4$, -1 is a nonsquare mod 7, matching. (Contrast $\mathbb{F}_5$: $2^2 = 4 \equiv -1$, so $x^2 + 1 = (x - 2)(x + 2)$ splits there.)

Worked Example 9.4.11 (Degree-3 over $\mathbb{F}_2$)**.** List the irreducible cubics over $\mathbb{F}_2$.

Recognition. Degree 3 over $\mathbb{F}_2$: irreducible iff no root in $\mathbb{F}_2$ (no factor x or $x + 1$).

Solution. A cubic over $\mathbb{F}_2$ has the form $x^3 + ax^2 + bx + c$. "No root" means $f(0) = c = 1$ and $f(1) = 1 + a + b + c = 0$, i.e. $a + b + c = 1$ so $a + b = 0$, giving $a = b$. With $c = 1$ and $a = b$: the two choices $a = b = 0$ and $a = b = 1$ yield

$$x^3 + x + 1 \quad \text{and} \quad x^3 + x^2 + 1.$$

Check. Each has $f(0) = 1$ and $f(1) = 1 + 1 + 1 = 1$ in $\mathbb{F}_2$ — no roots, so both are irreducible; these are the only two irreducible cubics over $\mathbb{F}_2$.

Worked Example 9.4.12 (Why degree 4 needs more than the root test)**.** Show $x^4 + 1$ has no root in $\mathbb{F}_3$ but is reducible over $\mathbb{F}_3$, illustrating the degree bound.

Recognition. Root test is decisive only for degree ≤ 3; for degree 4 we must factor.

Solution. Over $\mathbb{F}_3$: $0^4 + 1 = 1$, $1^4 + 1 = 2$, $2^4 + 1 = 17 \equiv 2$, so no root in $\mathbb{F}_3$. But over $\mathbb{F}_3$, $x^4 + 1 = (x^2 + x + 2)(x^2 + 2x + 2)$, and neither quadratic has a root in $\mathbb{F}_3$. So $x^4 + 1$ is *reducible* over $\mathbb{F}_3$ despite having no root there. *Check.* $(x^2 + x + 2)(x^2 + 2x + 2) = x^4 + 3x^3 + 6x^2 + 6x + 4 \equiv x^4 + 1 \pmod 3$. (Over $\mathbb{Q}$, $x^4 + 1$ is nonetheless irreducible — see the cyclotomic example Φ_8 — so 3 being a bad prime here does not contradict that.)

Caution. Reduction mod a *single* prime can give a factorization that does not lift: $x^4 + 1$ is irreducible over $\mathbb{Q}$ yet factors mod every prime. Reduction proves irreducibility only when $\bar{f}$ is irreducible; a factorization of $\bar{f}$ does not show that f factors (it only limits the degrees of possible factors of f).

Reduction mod p

Proposition 9.4.13 (Reduction mod p criterion, D&F 9.4.12)**.** *Let $f \in \mathbb{Z}[x]$ be monic of degree $n \geq 1$ and let p be a prime. Let $\bar{f} \in \mathbb{F}_p[x]$ be the reduction of f mod p. If $\bar{f}$ is irreducible in $\mathbb{F}_p[x]$ (and $\deg \bar{f} = n$, automatic since f is monic, as $p \nmid 1$), then f is irreducible in $\mathbb{Z}[x]$, hence in $\mathbb{Q}[x]$.*

Proof. Suppose, for contradiction, $f = gh$ in $\mathbb{Z}[x]$ with $\deg g, \deg h \geq 1$. Since f is monic we may take g, h monic (the leading coefficients of g, h multiply to 1, so are ± 1; absorb signs). Apply the ring homomorphism $\bmod p : \mathbb{Z}[x] \to \mathbb{F}_p[x]$, which is multiplicative: $\bar{f} = \bar{g}\,\bar{h}$. Because g, h are monic, $\deg \bar{g} = \deg g$ and $\deg \bar{h} = \deg h$, so both factors are nonconstant. This contradicts the irreducibility of $\bar{f}$ in $\mathbb{F}_p[x]$. Hence f is irreducible in $\mathbb{Z}[x]$; as a monic (so primitive) polynomial it is then irreducible in $\mathbb{Q}[x]$ by Gauss's Lemma. $\square$

Remark 9.4.2. If f is not monic, pick a prime $p \nmid a_n$ (the leading coefficient), so that $\deg \bar{f} = \deg f$; the same argument (with $\deg \bar{g} \le \deg g$, $\deg \bar{h} \le \deg h$ and $\deg \bar{g} + \deg \bar{h} = \deg f$ in place of monicity) shows that f is irreducible in $\mathbb{Q}[x]$, and in $\mathbb{Z}[x]$ if f is primitive (e.g. $2x^2 + 2 = 2(x^2 + 1)$ is reducible in $\mathbb{Z}[x]$ although its reduction mod 3 is irreducible). Picking $p \mid a_n$ drops the degree and the criterion fails — for example $\bar{f}$ could become a constant.

$$f = gh \in \mathbb{Z}[x] \xmapsto{\quad \bmod p \quad} \bar{f} = \bar{g}\,\bar{h} \in \mathbb{F}_p[x]$$

(nontrivial if reducible) (forces $\bar{f}$ reducible)

Diagram explanation. Objects: Upper left: $f = gh \in \mathbb{Z}[x]$, a monic polynomial hypothetically admitting a nontrivial factorization (each of g, h monic with degree ≥ 1) — the assumption for contradiction. Upper right: $\bar{f} = \bar{g}\bar{h} \in \mathbb{F}_p[x]$, the reductions mod p, which form a factorization in $\mathbb{F}_p[x]$. The lower row labels clarify the logical status: on the left, the factorization is nontrivial by hypothesis; on the right, it witnesses that $\bar{f}$ is reducible.

Arrows: The horizontal arrow ($\mapsto$) sends the factorization $f = gh$ to its image under the surjective ring homomorphism $\mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_p[x]$ that reduces each coefficient mod p. There are no vertical arrows: each entry of the bottom row only annotates the node above it. The diagram records the functorial action: the ring homomorphism sends the triple (f, g, h) to $(\bar{f}, \bar{g}, \bar{h})$ preserving the multiplication.

What commutes: The central equality is $\overline{gh} = \bar{g}\bar{h}$, i.e., the reduction homomorphism commutes with multiplication: applying mod$p$ to the product gh gives the same result as reducing g and h separately and then multiplying in $\mathbb{F}_p[x]$.

Why it commutes: Because mod$p : \mathbb{Z}[x] \to \mathbb{F}_p[x]$ is a ring homomorphism (proved by the coefficient-level observation: the k-th coefficient of gh is $\sum_{i+j=k} g_i h_j$, and reducing mod p distributes over this finite sum and each product $g_i h_j$ because $\mathbb{Z} \to \mathbb{F}_p$ is a ring homomorphism). Since g and h are monic, $\deg \bar{g} = \deg g$ and $\deg \bar{h} = \deg h$, so both $\bar{g}$ and $\bar{h}$ are nonconstant.

Why this matters here: This diagram encapsulates the contrapositive proof of the Reduction mod p criterion. If f were reducible in $\mathbb{Z}[x]$, the horizontal arrow would produce a nontrivial factorization $\bar{f} = \bar{g}\bar{h}$ in $\mathbb{F}_p[x]$, contradicting the hypothesis that $\bar{f}$ is irreducible. The diagram makes the logical flow visible: reducible on the left forces reducible on the right, so irreducible on the right blocks reducible on the left.

Concrete example: Take $f = x^3 - x^2 + 2x - 1$; if we assume $f = (x - 1)(x^2 + 1)$ over $\mathbb{Q}$ and reduce mod 2, we get $\bar{f} = x^3 + x^2 + 1$ and $\bar{g} = x + 1$, $\bar{h} = x^2 + 1$, so $\bar{g}\bar{h} = (x + 1)(x^2 + 1) = x^3 + x^2 + x + 1 \neq \bar{f}$, which shows that the assumed factorization is false (indeed $(x - 1)(x^2 + 1) = x^3 - x^2 + x - 1 \neq f$); a genuine factorization always survives reduction, for example $f = x^2 - 3x + 2 = (x - 1)(x - 2)$ reduced mod 5, giving $\bar{f} = (x + 4)(x + 3)$ in $\mathbb{F}_5[x]$.

Common pitfall: Students sometimes read the diagram as saying "if $\bar{f}$ factors, then f factors," which is the wrong direction. The homomorphism sends $\mathbb{Z}[x]$ to $\mathbb{F}_p[x]$, not the other way; a factorization of $\bar{f}$ does NOT imply a factorization of f (as the $x^4 + 1$ example shows, where $\bar{f}$ factors mod every prime yet f is irreducible over $\mathbb{Q}$). The valid implication is: f reducible in $\mathbb{Z}[x]$ implies $\bar{f}$ reducible in $\mathbb{F}_p[x]$, i.e., its contrapositive.

Takeaway: The point of this diagram is that the ring homomorphism mod$p$ is functorial for multiplication, so any factorization of f in $\mathbb{Z}[x]$ descends to a factorization of $\bar{f}$ in $\mathbb{F}_p[x]$, making irreducibility of $\bar{f}$ a sufficient (but not necessary) certificate for irreducibility of f over $\mathbb{Q}$.

Method (Reduction mod p)**.** *Trigger.* $f \in \mathbb{Z}[x]$ (or $\mathbb{Q}[x]$, cleared to $\mathbb{Z}[x]$), no obvious roots, degree ≥ 2, and Eisenstein does not apply.

1. Make f monic if possible; otherwise choose a prime p with $p \nmid a_n$.
2. Reduce: form $\bar{f} \in \mathbb{F}_p[x]$. Try small primes $p = 2, 3, 5$.
3. Test $\bar{f}$ for irreducibility over $\mathbb{F}_p$ (root test if $\deg \le 3$; otherwise trial-divide by all irreducibles of degree $\le \lfloor \deg f/2 \rfloor$).

4. If $\bar{f}$ is irreducible of full degree for *some* prime, conclude f is irreducible over $\mathbb{Q}$. If $\bar{f}$ factors, the test is inconclusive — try another p.

Worked Example 9.4.14 (Reduction mod 2 proves a quartic irreducible)**.** Prove $f(x) = x^4 + x + 1$ is irreducible over $\mathbb{Q}$.

Recognition. Reduction mod p: f monic, reduce mod 2 and show $\bar{f}$ irreducible in $\mathbb{F}_2[x]$.

Solution. $\bar{f} = x^4 + x + 1 \in \mathbb{F}_2[x]$. Roots: $\bar{f}(0) = 1$, $\bar{f}(1) = 1 + 1 + 1 = 1 \neq 0$, so no linear factor. The only irreducible quadratic over $\mathbb{F}_2$ is $x^2 + x + 1$; divide:

$$x^4 + x + 1 = (x^2 + x + 1)(x^2 + x) + 1,$$

since $(x^2+x+1)(x^2+x) = x^4+x^3+x^2+x^3+x^2+x = x^4+x$ in $\mathbb{F}_2$, leaving remainder $x^4+x+1-(x^4+x) = 1 \neq 0$. So $x^2 + x + 1 \nmid \bar{f}$. With no linear and no quadratic factor, $\bar{f}$ is irreducible over $\mathbb{F}_2$, hence f is irreducible over $\mathbb{Q}$. *Check.* A reducible quartic over $\mathbb{F}_2$ with no root would be $(x^2 + x + 1)^2 = x^4 + x^2 + 1 \neq x^4 + x + 1$, confirming $\bar{f}$ does not factor as a square of the quadratic either.

Worked Example 9.4.15 (Reduction mod 2 for a cubic (mod 3 fails))**.** Show $f(x) = x^3 + x^2 - 2x + 1$ is irreducible over $\mathbb{Q}$.

Recognition. Reduction mod p: monic cubic, so $\bar{f}$ irreducible iff it has no root in $\mathbb{F}_p$.

Solution. Try $p = 3$: $\bar{f} = x^3+x^2+x+1 \in \mathbb{F}_3[x]$ (since $-2 \equiv 1$). Test all of $\mathbb{F}_3$: $\bar{f}(0) = 1$, $\bar{f}(1) = 1+1+1+1 = 4 \equiv 1$, $\bar{f}(2) = 8 + 4 + 2 + 1 = 15 \equiv 0$. A root at $x = 2$! So $\bar{f}$ is *reducible* mod 3 — the test is inconclusive at $p = 3$.

Solution. [Retry mod 2] Mod 2, $f = x^3 + x^2 - 2x + 1 \equiv x^3 + x^2 + 1$ (since $-2 \equiv 0$). Roots: $\bar{f}(0) = 1$, $\bar{f}(1) = 1 + 1 + 1 = 1 \neq 0$. No root, and degree 3, so $\bar{f}$ is irreducible over $\mathbb{F}_2$. Therefore f is irreducible over $\mathbb{Q}$. *Check.* f has no rational root either: candidates ± 1 give $f(1) = 1+1-2+1 = 1$, $f(-1) = -1+1+2+1 = 3$, both nonzero — consistent.

Worked Example 9.4.16 (A non-monic polynomial: choose a good prime)**.** Show $f(x) = 6x^3 + 3x^2 - 2x + 5$ is irreducible over $\mathbb{Q}$.

Recognition. Reduction mod p with $p \nmid a_3 = 6$; first try $p = 5$, then $p = 7$.

Solution. Try $p = 5$: $6 \equiv 1,\ 3 \equiv 3,\ -2 \equiv 3,\ 5 \equiv 0$, so $\bar{f} = x^3 + 3x^2 + 3x = x(x^2 + 3x + 3)$ — this has the root 0, reducible mod 5. Inconclusive.

Solution. [Retry $p = 7$] $7 \nmid 6$. With $6 \equiv 6,\ 3 \equiv 3,\ -2 \equiv 5,\ 5 \equiv 5$: $\bar{f} = 6x^3 + 3x^2 + 5x + 5 \in \mathbb{F}_7[x]$. Monicize by $6^{-1} = 6$ (since $6 \cdot 6 = 36 \equiv 1$): $6\bar{f} \equiv x^3 + 4x^2 + 2x + 2 =: g$ (as $6 \cdot 3 \equiv 4$, $6 \cdot 5 \equiv 2$). Test roots in $\mathbb{F}_7$:

$$g(0) = 2,\ g(1) = 9 \equiv 2,\ g(2) = 30 \equiv 2,\ g(3) = 71 \equiv 1,\ g(4) = 138 \equiv 5,\ g(5) = 237 \equiv 6,\ g(6) = 374 \equiv 3.$$

No root, degree 3, so g (hence $\bar{f}$) is irreducible over $\mathbb{F}_7$. Therefore f is irreducible over $\mathbb{Q}$. *Check.* $138 = 7 \cdot 19 + 5$, $237 = 7 \cdot 33 + 6$, $374 = 7 \cdot 53 + 3$ — arithmetic confirmed; no value is 0 mod 7.

Worked Example 9.4.17 (When every small prime fails but f is still irreducible)**.** For $f(x) = x^4 + 1$, show reduction mod p never proves irreducibility, yet f is irreducible over $\mathbb{Q}$ (anticipating the cyclotomic argument).

Recognition. Reduction mod p: try several primes; observe each $\bar{f}$ factors.

Solution. Mod 2: $x^4 + 1 = (x + 1)^4$. Mod 3: test roots — $0^4 + 1 = 1,\ 1^4 + 1 = 2,\ 2^4 + 1 = 17 \equiv 2$, no root, but $x^4 + 1 = (x^2 + x + 2)(x^2 + 2x + 2)$ over $\mathbb{F}_3$, since

$$(x^2 + x + 2)(x^2 + 2x + 2) = x^4 + 3x^3 + 6x^2 + 6x + 4 \equiv x^4 + 1.$$

Mod 5: $x^4 + 1 = (x^2 + 2)(x^2 + 3)$ since $(x^2 + 2)(x^2 + 3) = x^4 + 5x^2 + 6 \equiv x^4 + 1$. So $\bar{f}$ is reducible for $p = 2, 3, 5$ — reduction is hopeless here. *Conclusion.* A different tool is needed; $x^4 + 1 = \Phi_8(x)$ is irreducible over $\mathbb{Q}$ (proved via Eisenstein after $x \mapsto x + 1$ below).

Worked Example 9.4.18 (Reduction mod 2 on a quintic)**.** Prove $f(x) = x^5 + x^2 + 1$ is irreducible over $\mathbb{Q}$.

Recognition. Reduction mod 2: monic quintic; show $\bar{f}$ irreducible over $\mathbb{F}_2$.

Solution. $\bar{f} = x^5 + x^2 + 1$. No root: $\bar{f}(0) = 1, \bar{f}(1) = 1 + 1 + 1 = 1$. So no linear factor; a factorization must be (quadratic)(cubic). The only irreducible quadratic is $q = x^2 + x + 1$. Divide $\bar{f}$ by q in $\mathbb{F}_2[x]$:

$$x^5 + x^2 + 1 = q \cdot (x^3 + x^2) + 1,$$

because $q(x^3+x^2) = x^5+x^4+x^3+x^4+x^3+x^2 = x^5+x^2$ in $\mathbb{F}_2$, with remainder $x^5+x^2+1-(x^5+x^2) = 1 \neq 0$; so $q \nmid \bar{f}$. Since the only possible nontrivial factorization (no linear factor, only one irreducible quadratic) is excluded, $\bar{f}$ is irreducible over $\mathbb{F}_2$, hence f is irreducible over $\mathbb{Q}$. *Check.* The irreducible quadratic times either irreducible cubic $x^3 + x + 1$, $x^3 + x^2 + 1$ gives a degree-5 product $\neq \bar{f}$ (matching the constant term 1 but differing in the middle coefficients), confirming $\bar{f}$ is irreducible.

Eisenstein's criterion

Theorem 9.4.19 (Eisenstein's Criterion, D&F 9.4.13)**.** *Let $f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \in \mathbb{Z}[x]$ with $n \geq 1$. Suppose there is a prime p such that*

$$p \mid a_i \text{ for all } 0 \leq i \leq n-1, \qquad p \nmid a_n, \qquad p^2 \nmid a_0.$$

Then f is irreducible in $\mathbb{Q}[x]$. If moreover f is primitive, f is irreducible in $\mathbb{Z}[x]$.

Proof sketch. Suppose $f = gh$ in $\mathbb{Z}[x]$ (Gauss reduces the $\mathbb{Q}$-statement to this) with $g = b_r x^r + \cdots + b_0$, $h = c_s x^s + \cdots + c_0$, $r, s \geq 1$, $r + s = n$. Reduce mod p. Since $p \mid a_i$ for $i < n$ and $p \nmid a_n$, we have $\bar{f} = \bar{a}_n x^n$ in $\mathbb{F}_p[x]$. As $\mathbb{F}_p[x]$ is a UFD with x prime, $\bar{g}\,\bar{h} = \bar{a}_n x^n$ forces $\bar{g} = \bar{b}_r x^r$ and $\bar{h} = \bar{c}_s x^s$ with $r, s \geq 1$. In particular $p \mid b_0$ and $p \mid c_0$, so $p^2 \mid b_0 c_0 = a_0$, contradicting $p^2 \nmid a_0$. Hence no such factorization exists. □

Method (Eisenstein's criterion)**.** *Trigger.* Integer coefficients with a prime p dividing every coefficient except the leading one, p^2 *not* dividing the constant term. Watch for "shift" variants.

1. Identify a candidate prime p (often a prime dividing a_0).
2. Verify the three conditions: $p \mid a_i$ $(i < n)$, $p \nmid a_n$, $p^2 \nmid a_0$.
3. If they hold, f is irreducible over $\mathbb{Q}$. If not, try a substitution $x \mapsto x + c$ (irreducibility is preserved by $x \mapsto x + c$, an automorphism of $\mathbb{Q}[x]$) and re-test.

Worked Example 9.4.20 (Direct Eisenstein)**.** Show $f(x) = x^4 + 10x + 5$ is irreducible over $\mathbb{Q}$.

Recognition. Eisenstein with $p = 5$: check 5 | middle coefficients, $5 \nmid$ leading, $25 \nmid$ constant.

Solution. Coefficients: $a_4 = 1, a_3 = 0, a_2 = 0, a_1 = 10, a_0 = 5$. With $p = 5$: $5 \mid 0, 5 \mid 0, 5 \mid 10, 5 \mid 5$ (all $a_i, i < 4$); $5 \nmid a_4 = 1$; $25 \nmid 5$. All conditions hold, so f is irreducible over $\mathbb{Q}$. *Check.* $a_0 = 5$ and $5^2 = 25 \nmid 5$, the crucial last condition; f has no rational root anyway ($f(1) = 16$, $f(-1) = -4$), consistent.

Worked Example 9.4.21 (Eisenstein on a cubic)**.** Show $2x^3 + 9x^2 + 6x + 3$ is irreducible over $\mathbb{Q}$.

Recognition. Eisenstein with $p = 3$: 3 | all but leading, $3 \nmid 2$, $9 \nmid 3$.

Solution. $a_3 = 2, a_2 = 9, a_1 = 6, a_0 = 3$. With $p = 3$: $3 \mid 9, 3 \mid 6, 3 \mid 3$; $3 \nmid 2$; $9 \nmid 3$. Eisenstein applies, so the polynomial is irreducible over $\mathbb{Q}$. *Check.* It is primitive ($\gcd(2, 9, 6, 3) = 1$), so it is also irreducible in $\mathbb{Z}[x]$; no rational root ($\pm 1, \pm 3, \pm\frac{1}{2}, \pm\frac{3}{2}$ all fail), consistent.

Worked Example 9.4.22 (Eisenstein after a shift)**.** Show $f(x) = x^2 + x + 2$ is irreducible over $\mathbb{Q}$.

Recognition. Eisenstein fails directly (no prime divides $a_1 = 1$); fall back to the root test, and illustrate the shift idea.

Solution. Degree 2, so the cleanest route is the root test: discriminant $1 - 8 = -7 < 0$, no real (hence no rational) root, so irreducible over $\mathbb{Q}$. To see why the shift trick is not magic, substitute $x \mapsto x - 1$: $f(x-1) = (x-1)^2 + (x-1) + 2 = x^2 - 2x + 1 + x - 1 + 2 = x^2 - x + 2$. No prime works on this shifted form either — for genuine degree-2 problems the root/discriminant test is the tool. *Check.* -7 is the discriminant; a negative discriminant guarantees no real root and hence no rational root, matching the irreducibility conclusion.

Worked Example 9.4.23 (The cyclotomic polynomial Φ_p)**.** For p prime, show $\Phi_p(x) = x^{p-1} + x^{p-2} + \cdots + x + 1 = \dfrac{x^p - 1}{x - 1}$ is irreducible over $\mathbb{Q}$.

Recognition. Eisenstein after the shift $x \mapsto x + 1$ with the prime p.

Solution. Since $\Phi_p(x) = \dfrac{x^p - 1}{x - 1}$, substitute $x \mapsto x + 1$:

$$\Phi_p(x+1) = \frac{(x+1)^p - 1}{(x+1) - 1} = \frac{1}{x}\Big(\sum_{k=0}^{p} \binom{p}{k} x^k - 1\Big) = \frac{1}{x}\sum_{k=1}^{p} \binom{p}{k} x^k = \sum_{k=1}^{p} \binom{p}{k} x^{k-1}.$$

Thus

$$\Phi_p(x+1) = x^{p-1} + \binom{p}{p-1} x^{p-2} + \cdots + \binom{p}{2} x + \binom{p}{1} = x^{p-1} + \binom{p}{p-1} x^{p-2} + \cdots + \binom{p}{2} x + p.$$

Apply Eisenstein with the prime p: the leading coefficient is 1 (so $p \nmid$ it); for $1 \le k \le p-1$, $p \mid \binom{p}{k}$ because $\binom{p}{k} = \frac{p!}{k!(p-k)!}$ has a factor p in the numerator not cancelled by $k!(p-k)!$ (all factors $< p$); and the constant term is $\binom{p}{1} = p$, with $p^2 \nmid p$. Eisenstein gives $\Phi_p(x+1)$ irreducible over $\mathbb{Q}$, hence $\Phi_p(x)$ is irreducible over $\mathbb{Q}$ (the shift $x \mapsto x+1$ is an automorphism of $\mathbb{Q}[x]$). *Check ($p = 5$).* $\Phi_5(x+1) = x^4 + 5x^3 + 10x^2 + 10x + 5$; with $p = 5$, 5 divides $5, 10, 10, 5$ but $25 \nmid 5$ — Eisenstein confirmed, so $\Phi_5 = x^4 + x^3 + x^2 + x + 1$ is irreducible.

Worked Example 9.4.24 (Shift to make Eisenstein work: $x^4 + 1$)**.** Show $\Phi_8(x) = x^4 + 1$ is irreducible over $\mathbb{Q}$.

Recognition. No prime fits $x^4 + 1$ directly (every prime divides the middle coefficients, which are all 0, but no prime divides the constant term $a_0 = 1$); shift $x \mapsto x + 1$ and use $p = 2$.

Solution. Substitute:

$$(x+1)^4 + 1 = x^4 + 4x^3 + 6x^2 + 4x + 1 + 1 = x^4 + 4x^3 + 6x^2 + 4x + 2.$$

Apply Eisenstein with $p = 2$: $2 \mid 4, 2 \mid 6, 2 \mid 4, 2 \mid 2$ (all lower coefficients); $2 \nmid 1$ (leading); and $4 \nmid 2$ (constant). Eisenstein applies, so $(x+1)^4 + 1$ is irreducible over $\mathbb{Q}$, hence so is $x^4 + 1$. *Check.* This resolves the earlier puzzle where $x^4 + 1$ factored modulo every prime — those factorizations did not lift, and the shifted Eisenstein argument settles irreducibility over $\mathbb{Q}$.

Worked Example 9.4.25 (An Eisenstein-looking polynomial that actually factors)**.** Decide whether $f(x) = x^4 + 4$ is irreducible over $\mathbb{Q}$. (It looks Eisenstein-friendly with $p = 2$, but $4 \mid a_0$.)

Recognition. Eisenstein's $p^2 \nmid a_0$ condition fails for $p = 2$ ($a_0 = 4$, $4 \mid 4$); so *Eisenstein does not apply* — do not conclude irreducibility. Factor instead.

Solution. The Sophie Germain identity gives

$$x^4 + 4 = x^4 + 4x^2 + 4 - 4x^2 = (x^2 + 2)^2 - (2x)^2 = (x^2 + 2x + 2)(x^2 - 2x + 2).$$

So f is *reducible* over $\mathbb{Q}$ (indeed over $\mathbb{Z}$). Each quadratic factor has discriminant $4 - 8 = -4 < 0$, so the factorization is into two irreducible quadratics; f has no rational root, which is exactly why a careless reader might wrongly invoke Eisenstein. *Check.* $(x^2+2x+2)(x^2-2x+2) = x^4 - 2x^3 + 2x^2 + 2x^3 - 4x^2 + 4x + 2x^2 - 4x + 4 = x^4 + 4$. Confirmed. The lesson: $p^2 \mid a_0$ kills Eisenstein, and the polynomial may genuinely factor.

Caution. Eisenstein is *sufficient*, never necessary. Failure of the criterion (for every prime, even after the shifts you tried) does *not* imply reducibility — e.g. $x^4 + x + 1$ is irreducible (shown by reduction mod 2) but no Eisenstein prime exists. Conversely, the $p^2 \nmid a_0$ clause is essential: $x^4 + 4$ passes "$p \mid$ all lower coefficients" for $p = 2$ yet factors, precisely because $4 \mid a_0$.

Choosing the right test

Method (Which irreducibility test to apply)**.** Given $f \in \mathbb{Q}[x]$, clear denominators to land in $\mathbb{Z}[x]$ and proceed:

1. **Eisenstein first** (cheapest win): scan primes $p \mid a_0$; if some p satisfies all three conditions, done. If not, try the shift $x \mapsto x+1$ (and $x \mapsto x-1$, $x+2, \dots$) and rescan — especially for "$x^n + \cdots$" with sparse coefficients or cyclotomic shape.

2. **Degree ≤ 3:** use the root test (Rational Root Theorem over $\mathbb{Q}$, or exhaustive search over $\mathbb{F}_p$). No root $\Rightarrow$ irreducible.

3. **Degree ≥ 4, Eisenstein failed:** reduction mod p. Try $p = 2, 3, 5$; if $\bar{f}$ is irreducible of full degree for some p, conclude f irreducible. (If $\bar{f}$ factors for all small p, neither confirm nor deny — switch tools or factor by hand.)

4. **Suspect reducibility:** look for explicit factorizations — rational roots (linear factors), or algebraic identities like Sophie Germain ($x^4 + 4a^4$) and difference/sum patterns.

Remark 9.4.3. The four tests sit in a hierarchy of *conclusiveness*. The root test is an iff for degree 2 and 3. Eisenstein and reduction-mod-p are one-directional (success proves irreducibility; failure proves nothing). All of them live downstream of Gauss's Lemma, which licenses moving freely between $\mathbb{Z}[x]$ and $\mathbb{Q}[x]$, and downstream of the reduction homomorphism $\mathbb{Z}[x] \twoheadrightarrow \mathbb{F}_p[x]$, the engine behind both Eisenstein's proof and the mod-p criterion.

Exercises (from the text).

1. Determine whether the following polynomials are irreducible in the indicated rings. For those that are reducible, determine their factorization into irreducibles. The notation $\mathbb{F}_p$ denotes the finite field $\mathbb{Z}/p\mathbb{Z}$, p a prime. (a) $x^2 + x + 1$ in $\mathbb{F}_2[x]$. (b) $x^3 + x + 1$ in $\mathbb{F}_3[x]$. (c) $x^4 + 1$ in $\mathbb{F}_5[x]$. (d) $x^4 + 10x^2 + 1$ in $\mathbb{Z}[x]$.
2. Prove that the following polynomials are irreducible in $\mathbb{Z}[x]$: (a) $x^4 - 4x^3 + 6$ (b) $x^6 + 30x^5 - 15x^3 + 6x - 120$ (c) $x^4 + 4x^3 + 6x^2 + 2x + 1$ [Substitute $x - 1$ for x.] (d) $\dfrac{(x+2)^p - 2^p}{x}$, where p is an odd prime.
3. Show that the polynomial $(x-1)(x-2)\cdots(x-n) - 1$ is irreducible over $\mathbb{Z}$ for all $n \geq 1$. [If the polynomial factors consider the values of the factors at $x = 1, 2, \dots, n$.]
4. Show that the polynomial $(x-1)(x-2)\cdots(x-n) + 1$ is irreducible over $\mathbb{Z}$ for all $n \geq 1$, $n \neq 4$.
5. Find all the monic irreducible polynomials of degree ≤ 3 in $\mathbb{F}_2[x]$, and the same in $\mathbb{F}_3[x]$.
6. Construct fields of each of the following orders: (a) 9, (b) 49, (c) 8, (d) 81 (you may exhibit these as $F[x]/(f(x))$ for some F and f). [Use Exercises 2 and 3 in Section 2.]
7. Prove that $\mathbb{R}[x]/(x^2+1)$ is a field which is isomorphic to the complex numbers.
8. Prove that $K_1 = \mathbb{F}_{11}[x]/(x^2+1)$ and $K_2 = \mathbb{F}_{11}[y]/(y^2+2y+2)$ are both fields with 121 elements. Prove that the map which sends the element $p(\bar{x})$ of K_1 to the element $p(\bar{y}+1)$ of K_2 (where p is any polynomial with coefficients in $\mathbb{F}_{11}$) is well defined and gives a ring isomorphism from K_1 to K_2.
9. Prove that the polynomial $p(x) = x^2 - \sqrt{2}$ is irreducible over $\mathbb{Z}[\sqrt{2}]$. [You may use the fact that $\mathbb{Z}[\sqrt{2}]$ is a U.F.D. — cf. Exercise 9 of Section 8.1.]
10. Prove that the polynomial $p(x) = x^4 - 4x^2 + 8x + 2$ is irreducible over the quadratic field $F = \mathbb{Q}(\sqrt{-2})$. [First use the method of Proposition 11 for the Unique Factorization Domain $\mathbb{Z}[\sqrt{-2}]$ (cf. Exercise 8, Section 8.1) to show that if $\alpha \in \mathbb{Z}[\sqrt{-2}]$ is a root of $p(x)$ then α is a divisor of 2 in $\mathbb{Z}[\sqrt{-2}]$. Conclude that α must be ± 1, $\pm\sqrt{-2}$ or ± 2, and hence show $p(x)$ has no linear factor over F. Show similarly that $p(x)$ is not the product of two quadratics with coefficients in F.]
11. Prove that $x^2 + y^2 - 1$ is irreducible in $\mathbb{Q}[x, y]$.
12. Prove that $x^{n-1} + x^{n-2} + \cdots + x + 1$ is irreducible over $\mathbb{Z}$ if and only if n is a prime.

13. Prove that $x^3 + nx + 2$ is irreducible over $\mathbb{Z}$ for all integers $n \neq 1, -3, -5$.

14. Factor each of the two polynomials: $x^8 - 1$ and $x^6 - 1$ into irreducibles over each of the following rings: (a) $\mathbb{Z}$, (b) $\mathbb{Z}/2\mathbb{Z}$, (c) $\mathbb{Z}/3\mathbb{Z}$.

15. Prove that if F is a field then the polynomial $X^n - x$ which has coefficients in the ring $F[[x]]$ of formal power series (cf. Exercise 3 of Section 7.2) is irreducible over $F[[x]]$. [Recall that $F[[x]]$ is a Euclidean Domain — cf. Exercise 5, Section 7.2 and Example 4, Section 8.1.]

16. Let F be a field and let $f(x)$ be a polynomial of degree n in $F[x]$. The polynomial $g(x) = x^n f(1/x)$ is called the reverse of $f(x)$. (a) Describe the coefficients of g in terms of the coefficients of f. (b) If $f(0) \neq 0$, prove that f is irreducible if and only if g is irreducible.

17. Prove the following variant of Eisenstein's Criterion: let P be a prime ideal of the Unique Factorization Domain R and let $f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ be a polynomial in $R[x]$, $n \geq 1$. Suppose $a_n \notin P$, $a_{n-1}, \ldots, a_0$ are all elements of P and $a_0 \notin P^2$. Prove that $f(x)$ is irreducible in $F[x]$, where F is the quotient field of R.

18. Show that $6x^5 + 14x^3 - 21x + 35$ and $18x^5 - 30x^2 + 120x + 360$ are irreducible in $\mathbb{Q}[x]$.

19. Let F be a field and let $f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_0 \in F[x]$. The derivative, $D_x(f(x))$, of $f(x)$ is defined by
$$D_x(f(x)) = na_n x^{n-1} + (n-1)a_{n-1}x^{n-2} + \cdots + a_1$$
where, as usual, $na = a + a + \cdots + a$ (n times). Note that $D_x(f(x))$ is again a polynomial with coefficients in F. The polynomial $f(x)$ is said to have a multiple root if there is some field E containing F and some $\alpha \in E$ such that $(x - \alpha)^2$ divides $f(x)$ in $E[x]$. For example, the polynomial $f(x) = (x-1)^2(x-2) \in \mathbb{Q}[x]$ has $\alpha = 1$ as a multiple root and the polynomial $g(x) = x^4 + 2x^2 + 1 = (x^2+1)^2 \in \mathbb{R}[x]$ has no roots in $\mathbb{R}$ but has $\alpha = \pm i \in \mathbb{C}$ as multiple roots. We shall prove in Section 13.5 that a nonconstant polynomial $f(x)$ has a multiple root if and only if $f(x)$ is not relatively prime to its derivative (which can be detected by the Euclidean Algorithm in $F[x]$). Use this criterion to determine whether the following polynomials have multiple roots: (a) $x^3 - 3x - 2 \in \mathbb{Q}[x]$ (b) $x^3 + 3x + 2 \in \mathbb{Q}[x]$ (c) $x^6 - 4x^4 + 6x^3 + 4x^2 - 12x + 9 \in \mathbb{Q}[x]$ (d) Show for any prime p and any $a \in \mathbb{F}_p$ that the polynomial $x^p - a$ has a multiple root.

20. Show that the polynomial $f(x) = x$ in $\mathbb{Z}/6\mathbb{Z}[x]$ factors as $(3x+4)(4x+3)$, hence is not an irreducible polynomial. (a) Show that the reduction of $f(x)$ modulo both of the nontrivial ideals (2) and (3) of $\mathbb{Z}/6\mathbb{Z}$ is an irreducible polynomial, showing that the condition that R be an integral domain in Proposition 12 is necessary. (b) Show that in any factorization $f(x) = g(x)h(x)$ in $\mathbb{Z}/6\mathbb{Z}[x]$ the reduction of $g(x)$ modulo (2) is either 1 or x and the reduction of $h(x)$ modulo (2) is then either x or 1, and similarly for the reductions modulo (3). Determine all the factorizations of $f(x)$ in $\mathbb{Z}/6\mathbb{Z}[x]$. [Use the Chinese Remainder Theorem.] (c) Show that the ideal $(3, x)$ is a principal ideal in $\mathbb{Z}/6\mathbb{Z}[x]$. (d) Show that over the ring $\mathbb{Z}/30\mathbb{Z}[x]$ the polynomial $f(x) = x$ has the factorization $f(x) = (10x+21)(15x+16)(6x+25)$. Prove that the product of any of these factors is again of degree 1. Prove that the reduction of $f(x)$ modulo any prime in $\mathbb{Z}/30\mathbb{Z}$ is an irreducible polynomial. Determine all the factorizations of $f(x)$ in $\mathbb{Z}/30\mathbb{Z}[x]$. [Consider the reductions modulo (2), (3) and (5) and use the Chinese Remainder Theorem.] (e) Generalize part (d) to $\mathbb{Z}/n\mathbb{Z}[x]$ where n is the product of k distinct primes.

Practice problems.

1. In $\mathbb{Q}[x]$, perform the division algorithm to write $x^4 - 3x^2 + 5x - 1 = q(x)(x^2 + x + 1) + r(x)$ with $\deg r < 2$. Find q and r.

2. Compute $\gcd(x^4 - 1,\ x^3 - 1)$ in $\mathbb{Q}[x]$ using the Euclidean algorithm, and express it as a $\mathbb{Q}[x]$-combination of the two polynomials.

3. Find the content $\mathrm{cont}(f)$ and the primitive part of $f(x) = 6x^3 - 15x^2 + 9x - 21 \in \mathbb{Z}[x]$.

4. State Gauss's Lemma. Use it to explain why, if a monic $f \in \mathbb{Z}[x]$ factors as $f = gh$ with $g, h \in \mathbb{Q}[x]$ monic of positive degree, then in fact $g, h \in \mathbb{Z}[x]$.

5. List all candidate rational roots of $f(x) = 2x^3 + 3x^2 - 8x + 3$ given by the Rational Root Theorem, then determine the actual rational roots.

6. Factor $f(x) = x^4 - 1$ completely into irreducibles in (a) $\mathbb{Q}[x]$, (b) $\mathbb{R}[x]$, (c) $\mathbb{C}[x]$.

7. Show that $f(x) = x^3 - 3x - 1$ is irreducible in $\mathbb{Q}[x]$ by checking it has no rational root (and explaining why that suffices for degree 3).

8. Use reduction mod 2 to prove that $f(x) = x^4 + x + 1 \in \mathbb{Z}[x]$ is irreducible in $\mathbb{Q}[x]$. (First show f has no root in $\mathbb{F}_2$, then rule out a factorization into two quadratics over $\mathbb{F}_2$.)

9. Apply Eisenstein's Criterion at a suitable prime to prove each is irreducible in $\mathbb{Q}[x]$: (a) $x^5 - 6x + 12$; (b) $2x^4 + 6x^3 - 9x^2 + 15$; (c) $x^3 + 9x^2 + 3x + 6$.

10. Prove that $\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$ is irreducible in $\mathbb{Q}[x]$ by substituting $x \mapsto x + 1$ and applying Eisenstein at $p = 5$.

11. Determine whether $f(x) = x^4 + 4 \in \mathbb{Q}[x]$ is irreducible. (Try the Sophie Germain identity $x^4 + 4 = (x^2 - 2x + 2)(x^2 + 2x + 2)$.)

12. Show that reduction mod p is inconclusive for $f(x) = x^4 + 1$ at every prime p (i.e. f is reducible in $\mathbb{F}_p[x]$ for all p), even though f is irreducible in $\mathbb{Q}[x]$. Verify reducibility explicitly mod 2 and mod 3.

13. Fix the lex monomial order with $x > y$ on $\mathbb{F}_2[x, y]$ (or $\mathbb{Q}[x, y]$). For $f = x^2y + xy^2 + y^2$, identify $\mathrm{LT}(f)$, $\mathrm{LM}(f)$, $\mathrm{LC}(f)$, and $\mathrm{multideg}(f)$.

14. With grlex on $\mathbb{Q}[x, y, z]$ $(x > y > z)$, order the monomials of $g = 4xyz^2 + 3x^2y - 5y^3z + 7$ from largest to smallest and give $\mathrm{LT}(g)$.

15. Let $f = x^3 - 2xy$ and $g = x^2y - 2y^2 + x$ in $\mathbb{Q}[x, y]$ with lex order $x > y$. Compute the S-polynomial $S(f, g)$.

Additional exercises.

1. Prove the converse direction of Gauss's Lemma fails to extend naively: give a polynomial in $\mathbb{Z}[x]$ that is irreducible in $\mathbb{Q}[x]$ but reducible in $\mathbb{Z}[x]$, and explain the role of the content.

2. Let p be prime. Prove that $f(x) = x^{p-1} + x^{p-2} + \cdots + x + 1$ (the p-th cyclotomic polynomial Φ_p) is irreducible in $\mathbb{Q}[x]$. (Compute $f(x + 1)$ using $\Phi_p(x) = \frac{x^p - 1}{x - 1}$ and apply Eisenstein at p.)

3. Let $f(x) = x^4 + 1$. Show f is irreducible over $\mathbb{Q}$ but factors into two quadratics over $\mathbb{R}$, and exhibit the factorization. Then describe its splitting behavior over $\mathbb{F}_p$ in terms of whether -1, 2, or -2 is a square mod p.

4. Suppose $f \in \mathbb{Z}[x]$ and $\bar{f} \in \mathbb{F}_p[x]$ is irreducible for some prime p with $\deg \bar{f} = \deg f$. Prove f is irreducible in $\mathbb{Q}[x]$. Then show by example (necessarily with f not monic) that the hypothesis $\deg \bar{f} = \deg f$ cannot be dropped.

5. Prove that $f(x, y) = y^3 + x^2y - x^3 + x \in \mathbb{Q}[x][y]$ is irreducible by viewing it as a polynomial in y over the UFD $\mathbb{Q}[x]$ and applying Eisenstein at the prime $x \in \mathbb{Q}[x]$.

6. Let $f(x) = x^n - p$ for a prime p and $n \geq 1$. Prove f is irreducible in $\mathbb{Q}[x]$, and conclude that $\sqrt[n]{p}$ has degree n over $\mathbb{Q}$.

Commutative-diagram exercises.

1. Consider the reduction-mod-p ring homomorphism in the diagram

$$\mathbb{Z}[x] \xrightarrow{\bmod p} \mathbb{F}_p[x]$$

   For $p = 3$ and $f(x) = x^2 + 6x + 4$, compute the image $\bar{f}$, and explain why irreducibility of $\bar{f}$ in $\mathbb{F}_3[x]$ forces irreducibility of f in $\mathbb{Q}[x]$ while reducibility of $\bar{f}$ tells you nothing.

2. Let $p(x) = x^2 + 1 \in \mathbb{F}_3[x]$. Show p is irreducible, so that $\mathbb{F}_3[x]/(p)$ is a field; identify how many elements it has and describe its elements as cosets $a + bx + (p)$. Draw the quotient as

$$\mathbb{F}_3[x] \xrightarrow{\bmod (p)} \mathbb{F}_3[x]/(p)$$

and state the image of x^2 under this map.

3. Show x^2+1 is *reducible* in $\mathbb{F}_2[x]$ and in $\mathbb{F}_5[x]$ but irreducible in $\mathbb{F}_3[x]$. Conclude that whether $F[x]/(x^2+1)$ is a field depends on F, and indicate the diagram

$$F[x] \xrightarrow{\text{mod } (x^2+1)} F[x]/(x^2+1)$$

in each case, saying whether the target is a field.

4. The factorization $f = gh$ in $\mathbb{Z}[x]$ should be compatible with reduction. Verify commutativity of

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\text{mod } p} & \mathbb{F}_p[x] \\ {\scriptstyle h\mapsto gh}\downarrow & & \downarrow{\scriptstyle u\mapsto \bar{g}u} \\ \mathbb{Z}[x] & \xrightarrow[\text{mod } p]{} & \mathbb{F}_p[x] \end{array}$$

concretely for $g = x+1$, $h = x+3$ (so $f = gh = x^2+4x+3$) and $p = 2$: reduce first then multiply, and multiply first then reduce, and check the two results agree.

5. Relate factoring over $\mathbb{Z}$ and over $\mathbb{Q} = \mathrm{Frac}(\mathbb{Z})$ via the inclusion $\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$. For $f(x) = 2x^2+4x+2$, exhibit its factorization in $\mathbb{Z}[x]$ and in $\mathbb{Q}[x]$, and use Gauss's Lemma to explain the relation between the two along

$$\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$$

9.5 Polynomial Rings over Fields II

Deeper structure of $F[x]$: maximal ideals, prime ideals, and field extensions

Throughout, F is a field and $F[x]$ is the (commutative, with 1) ring of polynomials in one variable over F. Recall from D&F 9.2 that $F[x]$ is a *Principal Ideal Domain*: every ideal is $(a(x))$ for a single generator, and $F[x]$ is a UFD. We now read off the deeper consequences of this for the quotient rings $F[x]/(p(x))$. The slogan: *in a PID that is not a field (such as $F[x]$), nonzero prime ideals are exactly the maximal ideals, and they are generated by irreducible elements.*

The central picture is the following: for any $p(x) \in F[x]$ the natural inclusion and quotient fit together as

$$F \hookrightarrow F[x] \xrightarrow{\text{mod } p} F[x]/(p)$$

where the first map is $c \mapsto c$ (constants) and the second is $a(x) \mapsto a(x)+(p)$. When p is irreducible the right-hand object is a *field*, and the composite $F \to F[x]/(p)$ is an injective ring homomorphism, so $F[x]/(p)$ is a field *containing (a copy of) F* — an *extension field* of F.

Diagram explanation. Objects: Three rings arranged left to right. F is a field (the coefficient field). $F[x]$ is the polynomial ring over F; it is a commutative ring with 1 and, since F is a field, a Principal Ideal Domain. $F[x]/(p)$ is the quotient ring by the principal ideal $(p) = p(x)F[x]$; it is a commutative ring with 1, and is a field exactly when p is irreducible.

Arrows: The hooked arrow $F \hookrightarrow F[x]$ is the *inclusion of constants*: $c \mapsto c$ (viewing a field element as a degree-0 polynomial). It is an injective ring homomorphism. The double-headed arrow $F[x] \twoheadrightarrow F[x]/(p)$ is the *canonical quotient map*: $a(x) \mapsto a(x)+(p)$. It is a surjective ring homomorphism. Well-definedness: the quotient map sends $a(x)$ to its coset; since every element has a unique coset, the map is defined. If $a(x) = b(x)$ then $a(x) - (b(x)) = 0 \in (p)$, so $a(x)+(p) = b(x)+(p)$: the map respects equality. Ring-homomorphism properties follow from how coset addition and multiplication are defined in $F[x]/(p)$.

What commutes: The diagram is a composable row, not a square. The relevant path equality is: the composite $F \to F[x] \to F[x]/(p)$ sends $c \mapsto c \mapsto c+(p)$, which is exactly the canonical embedding $F \to F[x]/(p)$, $c \mapsto c+(p)$.

Why it commutes: Chase $c \in F$. Via the inclusion it becomes the constant polynomial $c \in F[x]$. Via the quotient map that becomes $c+(p) \in F[x]/(p)$. Directly, the composite sends c to $c+(p)$. These agree because the inclusion produces the constant polynomial c, and $c+(p)$ is exactly its coset in $F[x]/(p)$. Injectivity of the composite: since F is a field, any ring homomorphism from F is either the zero map or injective; since $1 \mapsto 1+(p) \neq 0+(p)$ (as $1 \notin (p)$ when p is nonconstant), the composite is injective.

Why this matters here: This diagram organizes the two-stage relationship between F and the quotient field $F[x]/(p)$. The section will prove that (p) is maximal iff p is irreducible; this diagram makes visible that once the quotient is a field, F embeds into it as a subfield via the composite map, so $F[x]/(p)$ is literally a field extension of F. It justifies the language "$F[x]/(p)$ is a field containing F" used throughout the section.

Concrete example: Take $F = \mathbb{Q}$ and $p = x^2 - 2$. Then $\mathbb{Q} \hookrightarrow \mathbb{Q}[x] \twoheadrightarrow \mathbb{Q}[x]/(x^2-2)$. The composite sends $r \in \mathbb{Q}$ to $r + (x^2-2)$. Since $x^2 - 2$ is irreducible over $\mathbb{Q}$ (no rational root), the quotient is a field isomorphic to $\mathbb{Q}(\sqrt{2})$, with the composite embedding $\mathbb{Q}$ as the constants $\{r + 0 \cdot \bar{x}\} \subset \mathbb{Q}(\sqrt{2})$.

Common pitfall: Students sometimes read the surjective (double-headed) arrow $F[x] \twoheadrightarrow F[x]/(p)$ as an isomorphism. It is not: it has kernel $(p) \neq (0)$ whenever p is nonconstant, so it is not injective. A separate, subtler error is to assume the composite $F \to F[x]/(p)$ is automatically surjective; it is not (its image is just the copy of F inside the quotient), and elements like $\bar{x}$ are genuinely new.

Takeaway: The point of this diagram is that $F[x]/(p)$ receives F as a subfield via a two-step factorization — inclusion of constants followed by the quotient map — making precise why $F[x]/(p)$ (when p is irreducible) is a field extension and not merely an abstract quotient ring.

Theorem 9.5.1 (Maximal ideals of $F[x]$)**.** *Let F be a field and let $p(x) \in F[x]$. The ideal $(p(x))$ is a maximal ideal of $F[x]$ if and only if $p(x)$ is irreducible in $F[x]$. In that case the quotient ring $F[x]/(p(x))$ is a field.*

Proof. Since $F[x]$ is a commutative ring with 1, an ideal M is maximal iff $F[x]/M$ is a field. We show (p) is maximal $\iff$ p is irreducible.

($\Leftarrow$) Suppose p is irreducible. Then p is nonzero and nonunit, so $(p) \neq F[x]$ and $(p) \neq (0)$. Let I be an ideal with $(p) \subseteq I \subseteq F[x]$. Because $F[x]$ is a PID, $I = (a(x))$ for some a. From $(p) \subseteq (a)$ we get $a \mid p$, say $p = ab$. Irreducibility of p forces a or b to be a unit. If a is a unit then $I = (a) = F[x]$; if b is a unit then $a = pb^{-1}$, so $(a) = (p)$, i.e. $I = (p)$. Thus no ideal lies strictly between (p) and $F[x]$, so (p) is maximal.

($\Rightarrow$) Suppose (p) is maximal. Then $(p) \neq F[x]$, so p is not a unit, and $(p) \neq (0)$ (the zero ideal is not maximal in $F[x]$, since $(0) \subsetneq (x) \subsetneq F[x]$), so $p \neq 0$. If $p = ab$ with neither a unit, then $(p) \subseteq (a) \subseteq F[x]$. We cannot have $(a) = F[x]$ (that would make a a unit), so maximality forces $(a) = (p)$, hence a and p are associates and b is a unit — a contradiction. So p is irreducible.

The final clause is the standard fact: M maximal $\Rightarrow$ $F[x]/M$ a field. □

Theorem 9.5.2 (Prime ideals of $F[x]$)**.** *Let F be a field and $p(x) \in F[x]$. The ideal $(p(x))$ is a prime ideal of $F[x]$ if and only if $p(x)$ is irreducible* or *$p(x) = 0$. Equivalently: the prime ideals of $F[x]$ are exactly (0) and the ideals (p) with p irreducible, and every nonzero prime ideal is maximal.*

Proof. (p) is prime iff $F[x]/(p)$ is an integral domain.

If $p = 0$, then $F[x]/(0) \cong F[x]$, which is a domain, so (0) is prime.

If p is a nonzero nonunit: in a PID (indeed any UFD) p is prime as an element iff p is irreducible, and (p) is a prime ideal iff p is a prime element. Directly: if p is irreducible and $p \mid ab$, then since $F[x]$ is a UFD, p (being irreducible) divides a or b, so (p) is prime. Conversely if (p) is prime and $p = ab$ with a, b nonunits, then $ab \in (p)$ forces $a \in (p)$ or $b \in (p)$; say $a = pc$, then $p = pcb$, so $cb = 1$ (cancel p in the domain $F[x]$), making b a unit — contradiction. Hence p is irreducible.

If p is a nonzero unit, $(p) = F[x]$, which is not prime (a prime ideal is proper). This finishes the classification. By the previous theorem each nonzero prime (p) (with p irreducible) is maximal. □

Remark 9.5.1. The chain of implications for the principal ideal (p) in $F[x]$, with $p \neq 0$ nonunit, collapses:

$$(p) \text{ maximal} \iff (p) \text{ prime} \iff p \text{ irreducible}.$$

Compare $\mathbb{Z}[x]$, where this fails: (2) is prime but not maximal (since $\mathbb{Z}[x]/(2) \cong \mathbb{F}_2[x]$ is a domain but not a field), and $(2, x)$ is a non-principal maximal ideal. The reason it works cleanly in $F[x]$ is precisely that $F[x]$ is a *PID*.

Proposition 9.5.3 ($F[x]/(p)$ as an extension of F of degree $\deg p$)**.** *Let $p(x) \in F[x]$ be irreducible of degree $n = \deg p \geq 1$, and write $K = F[x]/(p)$. Let $\bar{x} = x + (p)$ denote the image of x. Then:*

(a) K is a field, and the map $F \to K$, $c \mapsto c + (p)$, is an injective ring homomorphism; identifying F with its image, $F \subseteq K$.

(b) $\bar{x}$ is a root of p in K, i.e. $p(\bar{x}) = 0$ in K.

(c) As an F-vector space, K has basis $\{1, \bar{x}, \bar{x}^2, \ldots, \bar{x}^{\,n-1}\}$; in particular $\dim_F K = n$, so every element of K is uniquely $c_0 + c_1\bar{x} + \cdots + c_{n-1}\bar{x}^{\,n-1}$ with $c_i \in F$.

Proof. (a) K is a field by the Maximal Ideals theorem. A ring homomorphism from a field F is either zero or injective; since $1 \mapsto 1 \neq 0$ in K, it is injective.

(b) Writing $p(x) = \sum a_i x^i$, in K we have $p(\bar{x}) = \sum a_i \bar{x}^{\,i} = \overline{p(x)} = p(x) + (p) = 0$.

(c) By the Division Algorithm in $F[x]$, every $a(x)$ equals $q(x)p(x) + r(x)$ with $r = 0$ or $\deg r < n$. Thus every coset $a + (p)$ has a unique representative r of degree $< n$ (uniqueness: if $r_1 - r_2 \in (p)$ has degree $< n$ then it is 0). The representatives of degree $< n$ are exactly the F-linear combinations $c_0 + c_1 x + \cdots + c_{n-1}x^{n-1}$, so $\{1, \bar{x}, \ldots, \bar{x}^{\,n-1}\}$ spans K over F and is linearly independent, hence a basis. Therefore $\dim_F K = n$. □

Method (Building a field extension as $F[x]/(p)$)**. Goal:** produce a field $K \supseteq F$ in which a given irreducible p acquires a root, or recognize a known field as such a quotient.

1. **Check p is irreducible over F.** For $\deg p \in \{2, 3\}$ it suffices that p has *no root in F* (rational root test, or check all elements when F is finite). For higher degree use D&F 9.4 tools (Gauss, Eisenstein, reduction mod p).

2. **Form $K = F[x]/(p)$.** By the theorem K is a field, $[K : F] = \deg p$, with F-basis $1, \bar{x}, \ldots, \bar{x}^{\,n-1}$.

3. **Set the multiplication rule.** The single relation $p(\bar{x}) = 0$ lets you rewrite $\bar{x}^{\,n}$ (and higher powers) in terms of lower ones. Multiply representatives in $F[x]$, then *reduce mod p* (Division Algorithm) to land back in degree $< n$.

4. **Find inverses** via the Extended Euclidean Algorithm: for $a(x)$ with $\gcd(a, p) = 1$ solve $au + pv = 1$; then $a^{-1} = \bar{u}$ in K.

5. **Identify K with a familiar field** by sending $\bar{x}$ to an actual root (e.g. $\sqrt{2}$, i) and checking the relation holds; the resulting map is an isomorphism by the First Isomorphism Theorem.

Worked Example 9.5.4 ($\mathbb{Q}[x]/(x^2 - 2) \cong \mathbb{Q}(\sqrt{2})$)**.** Show $\mathbb{Q}[x]/(x^2 - 2)$ is a field and is isomorphic to $\mathbb{Q}(\sqrt{2}) = \{a + b\sqrt{2} : a, b \in \mathbb{Q}\}$.

Recognition. $x^2 - 2$ is degree 2 with no rational root (if $(p/q)^2 = 2$ then 2 is a rational square, false), so it is irreducible over $\mathbb{Q}$; hence $(x^2 - 2)$ is maximal and the quotient is a field. To name the field, use the evaluation homomorphism $\mathbb{Q}[x] \to \mathbb{R}$ at $\sqrt{2}$ and the First Isomorphism Theorem.

Solution. Irreducibility. A degree-2 polynomial over a field is reducible iff it has a root in the field. $\sqrt{2} \notin \mathbb{Q}$, so $x^2 - 2$ is irreducible over $\mathbb{Q}$; thus $(x^2 - 2)$ is maximal and $K = \mathbb{Q}[x]/(x^2 - 2)$ is a field.

The isomorphism. Define $\varphi : \mathbb{Q}[x] \to \mathbb{R}$ by $\varphi(a(x)) = a(\sqrt{2})$ (evaluation at $\sqrt{2}$). This is a ring homomorphism. Its image is $\{a + b\sqrt{2} : a, b \in \mathbb{Q}\} = \mathbb{Q}(\sqrt{2})$, because every $a(\sqrt{2})$ reduces using $(\sqrt{2})^2 = 2$ to a $\mathbb{Q}$-linear combination of 1 and $\sqrt{2}$. Its kernel is $\{a(x) : a(\sqrt{2}) = 0\}$. Now $\ker\varphi$ is an ideal of the PID $\mathbb{Q}[x]$ containing $x^2 - 2$; since $(x^2 - 2)$ is maximal and $\ker\varphi \neq \mathbb{Q}[x]$ (as $1 \mapsto 1 \neq 0$), we get $\ker\varphi = (x^2 - 2)$. By the First Isomorphism Theorem,

$$\mathbb{Q}[x]/(x^2 - 2) \cong \operatorname{im}\varphi = \mathbb{Q}(\sqrt{2}).$$

Under this map $\bar{x} \mapsto \sqrt{2}$, and the basis $\{1, \bar{x}\}$ maps to $\{1, \sqrt{2}\}$.

Check. $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2 = \deg(x^2 - 2)$, matching $\dim_{\mathbb{Q}} K = 2$. Sanity inverse: $(\bar{x})^{-1}$? Since $\bar{x}^2 = 2$, we have $\bar{x} \cdot \frac{1}{2}\bar{x} = 1$, so $\bar{x}^{-1} = \frac{1}{2}\bar{x} \leftrightarrow \frac{1}{2}\sqrt{2} = 1/\sqrt{2}$. Correct.

Worked Example 9.5.5 ($\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$)**.** Show $\mathbb{R}[x]/(x^2+1)$ is a field isomorphic to $\mathbb{C}$.

Recognition. x^2+1 has no real root ($r^2 = -1$ impossible in $\mathbb{R}$), so it is irreducible over $\mathbb{R}$; the quotient is a field. Evaluation at i plus the First Isomorphism Theorem names it.

Solution. Irreducibility. Degree 2, no root in $\mathbb{R}$, so x^2+1 is irreducible over $\mathbb{R}$ and $K = \mathbb{R}[x]/(x^2+1)$ is a field with $\mathbb{R}$-basis $\{1, \bar{x}\}$, where $\bar{x}^2 = -1$.

The isomorphism. Define $\varphi : \mathbb{R}[x] \to \mathbb{C}$ by $\varphi(a(x)) = a(i)$. This is a surjective ring homomorphism: any $z = c + di \in \mathbb{C}$ is $\varphi(c + dx)$. The kernel is an ideal of $\mathbb{R}[x]$ containing x^2+1 (since $i^2+1=0$); (x^2+1) is maximal and $\ker\varphi \neq \mathbb{R}[x]$, so $\ker\varphi = (x^2+1)$. By the First Isomorphism Theorem

$$\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}, \qquad \bar{x} \mapsto i.$$

Check. Multiplication matches: $(a+b\bar{x})(c+d\bar{x}) = ac + (ad+bc)\bar{x} + bd\,\bar{x}^2 = (ac-bd) + (ad+bc)\bar{x}$, exactly the rule $(a+bi)(c+di) = (ac-bd) + (ad+bc)i$. And $\dim_{\mathbb{R}} K = 2 = \dim_{\mathbb{R}} \mathbb{C}$. Correct.

Worked Example 9.5.6 ($\mathbb{F}_2[x]/(x^2+x+1) \cong \mathbb{F}_4$, with full tables)**.** Let $p(x) = x^2+x+1 \in \mathbb{F}_2[x]$. Show $K = \mathbb{F}_2[x]/(p)$ is a field with 4 elements and write out its addition and multiplication tables.

Recognition. Over $\mathbb{F}_2$, a quadratic is irreducible iff it has no root in $\mathbb{F}_2$. Test $x = 0, 1$: $p(0) = 1$, $p(1) = 1+1+1 = 1 \neq 0$. No roots, so p is irreducible; quotient is a field of size $2^{\deg p} = 4$.

Solution. Elements. By the basis theorem, $K = \{a + b\bar{x} : a, b \in \mathbb{F}_2\}$, four elements. Write $\alpha = \bar{x}$. So

$$K = \{0,\ 1,\ \alpha,\ \alpha+1\}, \qquad \alpha^2 = -\alpha - 1 = \alpha + 1 \quad (\text{since } -1 = 1 \text{ in } \mathbb{F}_2).$$

Addition (coordinatewise mod 2 on (a, b)):

$+$	0	1	α	$\alpha+1$
0	0	1	α	$\alpha+1$
1	1	0	$\alpha+1$	α
α	α	$\alpha+1$	0	1
$\alpha+1$	$\alpha+1$	α	1	0

Multiplication (reduce using $\alpha^2 = \alpha + 1$):

- $\alpha \cdot \alpha = \alpha^2 = \alpha + 1$.
- $\alpha(\alpha+1) = \alpha^2 + \alpha = (\alpha+1) + \alpha = 2\alpha + 1 = 1$.
- $(\alpha+1)(\alpha+1) = \alpha^2 + 2\alpha + 1 = (\alpha+1) + 0 + 1 = \alpha$ (as $2\alpha = 0$, $1+1=0$).

$\cdot$	0	1	α	$\alpha+1$
0	0	0	0	0
1	0	1	α	$\alpha+1$
α	0	α	$\alpha+1$	1
$\alpha+1$	0	$\alpha+1$	1	α

Check. Every nonzero row of the multiplication table is a permutation of $\{1, \alpha, \alpha+1\}$, so each nonzero element is invertible: K is a field, $K \cong \mathbb{F}_4$. Note $\alpha^{-1} = \alpha + 1$ and $(\alpha+1)^{-1} = \alpha$. Also $K^\times = \{1, \alpha, \alpha+1\}$ is cyclic of order 3 generated by α: $\alpha^1 = \alpha$, $\alpha^2 = \alpha+1$, $\alpha^3 = \alpha \cdot (\alpha+1) = 1$. Consistent with the next theorem.

Worked Example 9.5.7 ($F[x]/(p)$ a field $\iff$ p irreducible — testing both directions)**.** Decide whether each quotient is a field, using only the criterion "p irreducible $\iff$ (p) maximal $\iff$ quotient is a field." (a) $\mathbb{Q}[x]/(x^2-5x+6)$; (b) $\mathbb{F}_3[x]/(x^2+1)$; (c) $\mathbb{R}[x]/(x^3-1)$; (d) $\mathbb{F}_5[x]/(x^2+2)$.

Recognition. The quotient $F[x]/(p)$ is a field exactly when p is irreducible over F. For degrees 2 and 3, irreducibility $\iff$ no root in F; otherwise look for a factorization.

Solution. (a) $x^2-5x+6 = (x-2)(x-3)$ over $\mathbb{Q}$: reducible. So (p) is not maximal and $\mathbb{Q}[x]/(p)$ is *not* a field. (Indeed it has zero divisors: $\overline{(x-2)} \cdot \overline{(x-3)} = 0$ with both factors nonzero.)

(b) x^2+1 over $\mathbb{F}_3$: test roots $0^2+1 = 1$, $1^2+1 = 2$, $2^2+1 = 4+1 = 5 = 2 \pmod 3$. No root, degree 2, so irreducible. Thus $\mathbb{F}_3[x]/(x^2+1)$ *is* a field, of order $3^2 = 9$.

(c) $x^3-1=(x-1)(x^2+x+1)$ over $\mathbb{R}$: reducible. So $\mathbb{R}[x]/(x^3-1)$ is *not* a field. (In fact $\mathbb{R}[x]/(x^3-1)\cong\mathbb{R}\times\mathbb{C}$ by CRT.)

(d) x^2+2 over $\mathbb{F}_5$: test $0,1,2,3,4$: squares are $0,1,4,4,1$, so $x^2\in\{0,1,4\}$; we need $x^2=-2=3 \pmod 5$, never attained. No root, degree 2, irreducible. So $\mathbb{F}_5[x]/(x^2+2)$ *is* a field, of order 25.

Check. For the field cases, sizes are $|F|^{\deg p}$: 9 and 25, both prime powers, as required for finite fields. For the non-field cases we exhibited zero divisors / a product decomposition, confirming non-maximality.

Worked Example 9.5.8 (A degree-3 field: $\mathbb{F}_2[x]/(x^3+x+1)\cong\mathbb{F}_8$)**.** Show $K=\mathbb{F}_2[x]/(x^3+x+1)$ is a field of order 8 and compute α^{-1} and $(\alpha^2+1)^{-1}$, where $\alpha=\bar{x}$.

Recognition. Degree 3 over $\mathbb{F}_2$: irreducible $\iff$ no root in $\mathbb{F}_2$. Then quotient is a field of order $2^3=8$. Inverses come from $\alpha^3=\alpha+1$ and the Extended Euclidean Algorithm.

Solution. Irreducibility. $p(0)=1$, $p(1)=1+1+1=1\neq 0$; no root, degree 3, so $p=x^3+x+1$ is irreducible over $\mathbb{F}_2$. Hence K is a field with basis $\{1,\alpha,\alpha^2\}$ and relation $\alpha^3=\alpha+1$ (since $-\alpha-1=\alpha+1$ in characteristic 2), so $|K|=8$.

Inverse of α. From $\alpha^3=\alpha+1$ we get $\alpha^3+\alpha=1$, i.e. $\alpha(\alpha^2+1)=1$. Therefore $\alpha^{-1}=\alpha^2+1$.

Inverse of α^2+1. By the line above, $(\alpha^2+1)^{-1}=\alpha$.

Check via Euclid (independent confirmation). Apply the Extended Euclidean Algorithm to $a(x)=x$ and $p(x)=x^3+x+1$ in $\mathbb{F}_2[x]$: $p=x\cdot(x^2+1)+1$, so $1=p-x(x^2+1)$, giving $x\cdot(x^2+1)\equiv 1 \pmod p$ (signs irrelevant mod 2). Thus $\alpha^{-1}=\alpha^2+1$, matching. Sanity multiply: $\alpha(\alpha^2+1)=\alpha^3+\alpha=(\alpha+1)+\alpha=1$. Correct.

Finite multiplicative subgroups of a field are cyclic

Theorem 9.5.9 (Cyclicity of finite subgroups of $F^\times$)**.** *Let F be a field and let G be a finite subgroup of the multiplicative group $F^\times=F\setminus\{0\}$. Then G is cyclic. In particular, for a finite field $\mathbb{F}_q$ (with q elements), the group $\mathbb{F}_q^\times=\mathbb{F}_q^\times$ is cyclic of order $q-1$.*

Proof. Let $|G|=n$ and let m be the exponent of G (the least common multiple of the orders of all elements; equivalently the largest order of an element, since G is abelian). Every $g\in G$ satisfies $g^m=1$, so every element of G is a root of the polynomial $x^m-1\in F[x]$. Over a field, x^m-1 has at most m roots (D&F 9.5: a nonzero polynomial of degree d over a field has at most d roots, because each root a contributes a factor $(x-a)$ and these are coprime). Hence $n=|G|\leq m$.

On the other hand, in a finite abelian group the exponent divides the order: $m\mid n$, so $m\leq n$. Therefore $m=n$. Since the exponent of a finite abelian group equals the maximal element order, there is an element $g\in G$ of order $m=n=|G|$, so $G=\langle g\rangle$ is cyclic. □

Remark 9.5.2. The two inputs are essential and field-specific. (1) "At most deg roots" *fails* over a non-domain: in $\mathbb{Z}/8\mathbb{Z}$ the polynomial x^2-1 has the four roots $1,3,5,7$. (2) The result genuinely uses that F is a field; $(\mathbb{Z}/8\mathbb{Z})^\times\cong(\mathbb{Z}/2)^2$ is *not* cyclic — but $\mathbb{Z}/8\mathbb{Z}$ is not a field. A generator of $\mathbb{F}_q^\times$ is called a *primitive root* (mod p when $q=p$).

Method (Finding a generator of $\mathbb{F}_q^\times$ (a primitive root))**.** *Trigger.* You need a cyclic generator g of $\mathbb{F}_q^\times$, i.e. an element of order $q-1$.

1. Factor $q-1=\prod_i \ell_i^{e_i}$.
2. Pick a candidate $g\in\mathbb{F}_q^\times$ (start with small ones: $2,3,\dots$).
3. For each prime ℓ_i dividing $q-1$, compute $g^{(q-1)/\ell_i}$. If *all* of these are $\neq 1$, then $\operatorname{ord}(g)=q-1$ and g is a generator. If some equals 1, discard g and try the next candidate.
4. (Why it works: $\operatorname{ord}(g)\mid q-1$; it is a proper divisor iff $\operatorname{ord}(g)\mid (q-1)/\ell_i$ for some i, equivalently $g^{(q-1)/\ell_i}=1$.)

Worked Example 9.5.10 ($\mathbb{F}_7^\times$ is cyclic; find a generator)**.** Show $\mathbb{F}_7^\times$ is cyclic of order 6 and find a generator.

Recognition. $\mathbb{F}_7$ is a field, so the finite group $\mathbb{F}_7^\times$ is cyclic by the theorem; $|\mathbb{F}_7^\times|=6$. To find a generator use the primitive-root test: g works iff $g^{6/2}\neq 1$ and $g^{6/3}\neq 1$, i.e. $g^3\neq 1$ and $g^2\neq 1$.

Solution. $q-1=6=2\cdot 3$; the prime divisors are $2,3$, so the proper-divisor exponents to test are $6/2=3$ and $6/3=2$.

Try $g=2$: $2^2=4\neq 1$. $2^3=8=1 \pmod 7$. Since $2^3=1$, $\operatorname{ord}(2)=3\neq 6$; **not** a generator.

Try $g=3$: $3^2=9=2\neq 1$ and $3^3=27=6\neq 1 \pmod 7$. Both nontrivial, so $\operatorname{ord}(3)=6$: 3 **is** a generator.

Check. List the powers of 3 mod 7:

$$3^1=3,\quad 3^2=2,\quad 3^3=6,\quad 3^4=4,\quad 3^5=5,\quad 3^6=1.$$

These hit all of $\{1,2,3,4,5,6\}=\mathbb{F}_7^\times$, confirming $\mathbb{F}_7^\times=\langle 3\rangle$. (There are $\varphi(6)=2$ generators; the other is $3^5=5$.)

Worked Example 9.5.11 (Primitive root mod 11)**.** Find a generator of $\mathbb{F}_{11}^\times$ (order 10).

Recognition. $\mathbb{F}_{11}$ is a field, $\mathbb{F}_{11}^\times$ cyclic of order $10=2\cdot 5$. Test exponents $10/2=5$ and $10/5=2$: g generates iff $g^5\neq 1$ and $g^2\neq 1$.

Solution. Try $g=2$: $2^2=4\neq 1$. $2^5=32=10\neq 1 \pmod{11}$. Both nontrivial, so $\operatorname{ord}(2)=10$: 2 is a generator.

Check. Powers of 2 mod 11: $2,4,8,5,10,9,7,3,6,1$ — all ten nonzero residues, exactly once each. So $\mathbb{F}_{11}^\times=\langle 2\rangle$. (By contrast $\operatorname{ord}(10)=2$ since $10\equiv -1$, and $10^5=(-1)^5=-1=10\neq 1$ but $10^2=1$, so 10 fails the $g^2\neq 1$ test — not a generator, as expected.)

Worked Example 9.5.12 ($\mathbb{F}_9^\times$ is cyclic, exhibited inside $\mathbb{F}_3[x]/(x^2+1)$)**.** Let $K=\mathbb{F}_3[x]/(x^2+1)$, a field of order 9, and $\alpha=\bar{x}$ (so $\alpha^2=-1=2$). Show $K^\times$ is cyclic of order 8 and find a generator.

Recognition. K is a field (Example: x^2+1 irreducible over $\mathbb{F}_3$), so $K^\times$ is cyclic by the theorem; $|K^\times|=8=2^3$. The only prime divisor is 2, so g generates iff $g^{8/2}=g^4\neq 1$.

Solution. Is α itself a generator? Compute its order. $\alpha^2=2=-1$, so $\alpha^4=(\alpha^2)^2=(-1)^2=1$. Thus $\operatorname{ord}(\alpha)=4\neq 8$: α is **not** a generator.

Try $g=\alpha+1$. Compute $g^2=(\alpha+1)^2=\alpha^2+2\alpha+1=(-1)+2\alpha+1=2\alpha$. Then $g^4=(2\alpha)^2=4\alpha^2=4\cdot(-1)=-4=-1=2 \pmod 3$. Since $g^4=2\neq 1$, and 8's only prime factor is 2, we conclude $\operatorname{ord}(\alpha+1)=8$: $\alpha+1$ **generates** $K^\times$.

Check. Continue: $g^4=-1$, so $g^8=(-1)^2=1$ and $g^4\neq 1$, confirming order exactly 8. The powers $g^0,\dots,g^7$ are 8 distinct elements, hence all of $K^\times$. Consistent with $\mathbb{F}_9^\times$ cyclic of order 8.

Caution. **"No root $\Rightarrow$ irreducible" is valid ONLY in degree 2 and 3.** For degree ≥ 4 a polynomial can lack roots yet factor. Over $\mathbb{Q}$, $x^4+4=(x^2-2x+2)(x^2+2x+2)$ has no rational (indeed no real) root but is reducible, so $\mathbb{Q}[x]/(x^4+4)$ is *not* a field. Always factor into lower-degree pieces for deg ≥ 4.

Caution. **(p) prime does not imply (p) maximal in a general $R[x]$.** The clean equivalence "prime $\iff$ maximal $\iff$ irreducible" for nonzero ideals holds in $F[x]$ *because F is a field* (making $F[x]$ a PID). In $\mathbb{Z}[x]$, (x) is prime ($\mathbb{Z}[x]/(x)\cong\mathbb{Z}$, a domain) but not maximal ($\mathbb{Z}$ is not a field); $(2,x)$ is a maximal ideal above it (as is (p,x) for every prime p). Do not transport the $F[x]$ equivalence to $\mathbb{Z}[x]$ or $F[x,y]$.

Caution. **Finite multiplicative groups need not be cyclic outside a field.** The proof needs "a degree-d polynomial has at most d roots," which requires an integral domain. $(\mathbb{Z}/8\mathbb{Z})^\times\cong(\mathbb{Z}/2)\times(\mathbb{Z}/2)$ is not cyclic; $\mathbb{Z}/8\mathbb{Z}$ is not a field. Likewise $(\mathbb{Z}/n\mathbb{Z})^\times$ is cyclic only for $n=1,2,4,p^k,2p^k$ (p an odd prime): e.g. $(\mathbb{Z}/15\mathbb{Z})^\times\cong\mathbb{Z}/2\times\mathbb{Z}/4$ is not cyclic, while $(\mathbb{Z}/9\mathbb{Z})^\times$ is cyclic of order 6 although $\mathbb{Z}/9\mathbb{Z}$ is not a field.

Exercises (from the text).

1. Let F be a field and let $f(x)$ be a nonconstant polynomial in $F[x]$. Describe the nilradical of $F[x]/(f(x))$ in terms of the factorization of $f(x)$ (cf. Exercise 29, Section 7.3).
2. For each of the fields constructed in Exercise 6 of Section 4 exhibit a generator for the (cyclic) multiplicative group of nonzero elements.
3. Let p be an odd prime in $\mathbb{Z}$ and let n be a positive integer. Prove that x^n-p is irreducible over $\mathbb{Z}[i]$. [Use Proposition 18 in Chapter 8 and Eisenstein's Criterion.]
4. Prove that $x^3+12x^2+18x+6$ is irreducible over $\mathbb{Z}[i]$. [Use Proposition 8.18 and Eisenstein's Criterion.]

5. Let φ denote Euler's φ-function. Prove the identity $\sum_{d|n} \varphi(d) = n$, where the sum is extended over all the divisors d of n. [First observe that the identity is valid when $n = p^m$ is the power of a prime p since the sum telescopes. Write $n = p^m n'$ where p does not divide n'. Prove that $\sum_{d|n} \varphi(d) = \sum_{d''|p^m} \varphi(d'') \sum_{d'|n'} \varphi(d')$ by multiplying out the right hand side and using the multiplicativity of $\varphi(ab) = \varphi(a)\varphi(b)$ when a and b are relatively prime. Use induction to complete the proof. This problem may be done alternatively by letting Z be the cyclic group of order n and showing that since Z contains a unique subgroup of order d for each d dividing n, the number of elements of Z of order d is $\varphi(d)$. Then $|Z|$ is the sum of $\varphi(d)$ as d runs over all divisors of n.]

6. Let G be a finite subgroup of order n of the multiplicative group $F^\times$ of nonzero elements of the field F. Let φ denote Euler's φ-function and let $\psi(d)$ denote the number of elements of G of order d. Prove that $\psi(d) = \varphi(d)$ for every divisor d of n. In particular conclude that $\psi(n) \geq 1$, so that G is a cyclic group. [Observe that for any integer $N \geq 1$ the polynomial $x^N - 1$ has at most N roots in F. Conclude that for any integer N we have $\sum_{d|N} \psi(d) \leq N$. Since $\sum_{d|N} \varphi(d) = N$ by the previous exercise, show by induction that $\psi(d) \leq \varphi(d)$ for every divisor d of n. Since $\sum_{d|n} \psi(d) = n = \sum_{d|n} \varphi(d)$ show that this implies $\psi(d) = \varphi(d)$ for every divisor d of n.]

7. Prove that the additive and multiplicative groups of a field are never isomorphic. [Consider three cases: when $|F|$ is finite, when $-1 \neq 1$ in F, and when $-1 = 1$ in F.]

Practice problems.

1. In $\mathbb{Q}[x]$, divide $f(x) = 2x^4 - 3x^3 + x^2 - 5$ by $g(x) = x^2 - x + 1$, finding the quotient and remainder. Verify $f = qg + r$ with $\deg r < 2$.
2. Compute gcd in $\mathbb{Q}[x]$ of $f(x) = x^4 - 1$ and $g(x) = x^3 - x^2 + x - 1$ by the Euclidean algorithm, and express it as $af + bg$ for some $a, b \in \mathbb{Q}[x]$.
3. Determine the content $\mathrm{cont}(f)$ and the primitive part of $f(x) = 6x^3 - 9x^2 + 15x - 3 \in \mathbb{Z}[x]$.
4. Show that $f(x) = x^4 + x^3 + x^2 + x + 1$ has no rational roots, hence no linear factor in $\mathbb{Q}[x]$.
5. Factor $f(x) = x^4 + 4$ completely in $\mathbb{Z}[x]$.
6. Use Eisenstein's criterion (with the prime $p = 3$) to prove $f(x) = x^5 - 6x^3 + 12x^2 - 18x + 24$ is irreducible in $\mathbb{Q}[x]$.
7. Show that $f(x) = x^4 - 10x^2 + 1$ is irreducible in $\mathbb{Q}[x]$, even though it is reducible modulo every prime. (Hint: rule out rational roots and the two quadratic-times-quadratic possibilities over $\mathbb{Z}$.)
8. Apply Eisenstein after a substitution to prove the cyclotomic polynomial $\Phi_7(x) = x^6+x^5+x^4+x^3+x^2+x+1$ is irreducible in $\mathbb{Q}[x]$.
9. Use reduction modulo 2 to prove $f(x) = x^4 + x^2 + x + 1 \in \mathbb{Z}[x]$ is irreducible in $\mathbb{Q}[x]$. (First factor its reduction in $\mathbb{F}_2[x]$ into irreducibles and use the degrees of the factors to rule out a product of two quadratics in $\mathbb{Z}[x]$; then rule out a linear factor with the Rational Root Theorem.)
10. Show that $f(x) = x^3 - 3x - 1$ is irreducible in $\mathbb{Q}[x]$ by checking it has no root in $\mathbb{F}_2$ (after reducing) and no rational root.
11. By Gauss's Lemma, show that if a monic $f \in \mathbb{Z}[x]$ factors as a product of two nonconstant polynomials in $\mathbb{Q}[x]$, then it factors into two monic nonconstant polynomials in $\mathbb{Z}[x]$. Use this to find all factorizations of $f(x) = x^3 - 7x + 6$ in $\mathbb{Z}[x]$.
12. Working in $\mathbb{Z}[x]$, decide whether $f(x) = x^4 + 3x^2 + 2$ is irreducible; if not, factor it.
13. Using the lex order with $x > y > z$, compute the leading term $\mathrm{LT}(f)$, leading monomial $\mathrm{LM}(f)$, leading coefficient $\mathrm{LC}(f)$, and multidegree $\mathrm{multideg}(f)$ of $f = 4xy^2z + 5x^3 - 2y^4 + 7yz^2$.
14. For $f = x^2y + xy^2 + y^2$ and $g = xy - 1$ in $\mathbb{Q}[x, y]$ with lex order $x > y$, compute the S-polynomial $S(f, g)$ and reduce it modulo $\{f, g\}$ to its remainder.

15. Determine whether $\{x^2 - y,\ x^3 - z\}$ is a Grobner basis for the ideal it generates in $\mathbb{Q}[x, y, z]$ under lex order $x > y > z$, by computing the relevant S-polynomial and reducing.

Additional exercises.

1. Prove that $f(x) = x^4 - 5x^2 + 1$ is irreducible in $\mathbb{Q}[x]$. (No rational roots; show no factorization into two monic quadratics over $\mathbb{Z}$ is possible by solving the integer coefficient system.)
2. Let p be prime. Prove Eisenstein's criterion: if $f(x) = a_n x^n + \cdots + a_0 \in \mathbb{Z}[x]$ satisfies $p \mid a_i$ for $i < n$, $p \nmid a_n$, and $p^2 \nmid a_0$, then f has no factorization into two polynomials of smaller degree in $\mathbb{Z}[x]$, hence is irreducible in $\mathbb{Q}[x]$ (and, if f is primitive, in $\mathbb{Z}[x]$). Carry out the argument via reduction mod p in $\mathbb{F}_p[x]$.
3. Show that $f(x, y) = y^3 + x^2y^2 + x^3y + x \in \mathbb{Q}[x][y]$ is irreducible by applying Eisenstein's criterion in the ring $\mathbb{Q}[x][y]$ to the prime x of $\mathbb{Q}[x]$.
4. Let $f(x) = x^p - x - 1 \in \mathbb{F}_p[x]$ for a prime p. Prove that f is irreducible over $\mathbb{F}_p$. (Show that if α is a root then so is $\alpha + 1$, so all roots are $\alpha, \alpha + 1, \ldots, \alpha + p - 1$, and deduce no proper factor can have coefficients in $\mathbb{F}_p$.)
5. Using grlex order with $x > y$, compute a Grobner basis of $I = (x^2 - y,\ x^3 - 2)$ in $\mathbb{Q}[x, y]$ by running Buchberger's algorithm; show your S-polynomial reductions.
6. Let $I = (xy - 1,\ x - y^2) \subseteq \mathbb{Q}[x, y]$ with lex order $x > y$. Compute a Grobner basis and use it to find all common roots of the two generators in $\overline{\mathbb{Q}}^2$.

Commutative-diagram exercises.

1. Let $p(x) = x^2 + 1 \in \mathbb{Q}[x]$, which is irreducible, so that the quotient in the diagram

$$\mathbb{Q}[x] \xrightarrow{\ \bmod p(x)\ } \mathbb{Q}[x]/(p(x))$$

   is a field. Identify this field, exhibit the inverse of the image of x, and describe the kernel of the map.

2. For each prime p, consider the reduction map

$$\mathbb{Z}[x] \xrightarrow{\ \bmod p\ } \mathbb{F}_p[x].$$

   Let $f(x) = x^4 + 1$. Compute the image of f in $\mathbb{F}_2[x]$ and in $\mathbb{F}_3[x]$, and factor each image. Explain why f being irreducible in $\mathbb{Q}[x]$ is consistent with its reduction being reducible mod 2 and mod 3.

3. Consider $f(x) = x^3 + x + 1 \in \mathbb{Z}[x]$ and the square

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\ \bmod 2\ } & \mathbb{F}_2[x] \\ \downarrow & & \downarrow \\ \mathbb{Z}[x]/(f) & \dashrightarrow & \mathbb{F}_2[x]/(\bar{f}) \end{array}$$

   Show $\bar{f}$ is irreducible in $\mathbb{F}_2[x]$, conclude $\mathbb{F}_2[x]/(\bar{f})$ is a field, determine its order, and explain how this forces f to be irreducible in $\mathbb{Q}[x]$.

4. Let $R = \mathbb{Z}[x]$. Here $\mathrm{Frac}(R) = \mathbb{Q}(x)$ is not the relevant field; instead consider the inclusion $\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$ and the factorization of $f(x) = 2x^2 - 2$ in each. Draw the diagram

$$\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$$

   and explain, via Gauss's Lemma and content, why f is reducible in both but its irreducible factorizations differ only by units of $\mathbb{Q}$.

5. Let $p(x) \in \mathbb{F}_2[x]$ be irreducible of degree 3, so $K = \mathbb{F}_2[x]/(p(x))$ is a field with the quotient map

$$\mathbb{F}_2[x] \xrightarrow{\ \bmod p\ } K.$$

   Determine $|K|$, show every nonzero element of K satisfies $t^{|K|-1} = 1$, and give one explicit such $p(x)$ together with the multiplicative order of the image of x in $K^\times$.

9.6 Polynomials in Several Variables and Gröbner Bases

Multivariate polynomial rings, monomial orderings, and Grobner bases

Throughout this section F is a field and $R = F[x_1, \dots, x_n]$. We write a *monomial* as $x^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ for a multi-index $\alpha = (\alpha_1, \dots, \alpha_n) \in \mathbb{Z}_{\geq 0}^n$; its (total) degree is $|\alpha| = \alpha_1 + \cdots + \alpha_n$. Every nonzero $f \in R$ is a unique F-linear combination of monomials. The central problem is that in several variables there is no canonical "leading term" until we fix an ordering of the monomials.

Theorem 9.6.1 (Hilbert's Basis Theorem)**.** *If R is a commutative Noetherian ring, then the polynomial ring $R[x]$ is Noetherian. Consequently, for any field F (or any Noetherian ring F), $F[x_1, \dots, x_n]$ is Noetherian: every ideal $I \subseteq F[x_1, \dots, x_n]$ is finitely generated.*

Sketch. Induction on the number of variables reduces everything to the single statement "R Noetherian $\implies R[x]$ Noetherian," since $F[x_1, \dots, x_n] = F[x_1, \dots, x_{n-1}][x_n]$ and F is Noetherian (a field has only the ideals 0 and F). For the one-variable step, let $I \subseteq R[x]$ be an ideal. For each $d \geq 0$ let

$$L_d = \{\, \mathrm{LC}(f) : f \in I,\ \deg f = d \,\} \cup \{0\} \subseteq R,$$

the set of leading coefficients of degree-d elements of I; each L_d is an ideal of R, and $L_0 \subseteq L_1 \subseteq \cdots$ because multiplying by x raises degree without changing the leading coefficient. As R is Noetherian this chain stabilizes at some N, and each L_d is finitely generated. Choosing finitely many elements of I whose leading coefficients generate $L_0, \dots, L_N$ produces a finite generating set for I (subtract off suitable multiples to lower degree, then induct on degree). Hence I is finitely generated, so $R[x]$ is Noetherian. □

Remark 9.6.1. Hilbert's Basis Theorem guarantees that the ideals we study are finitely generated, but it gives no *algorithm* and no *useful* generating set. Grobner bases supply a particular, computable generating set from which membership, equality of ideals, and elimination can all be decided.

Monomial orderings

Definition 9.6.2. A *monomial ordering* on $F[x_1, \dots, x_n]$ is a total order $>$ on the set of monomials $\{x^\alpha : \alpha \in \mathbb{Z}_{\geq 0}^n\}$ such that

(i) $>$ is a well-ordering (every nonempty set of monomials has a least element), and

(ii) $>$ is compatible with multiplication: if $x^\alpha > x^\beta$ then $x^\gamma x^\alpha > x^\gamma x^\beta$ for every γ, i.e. $\alpha > \beta \implies \alpha + \gamma > \beta + \gamma$.

We identify monomials with their exponent vectors, so a monomial ordering is a total well-order on $\mathbb{Z}_{\geq 0}^n$ respecting addition. Conditions (i) and (ii) together force $x^\alpha \geq 1 = x^0$ for all α: if $x^\alpha < 1$ then (ii) gives $1 > x^\alpha > x^{2\alpha} > x^{3\alpha} > \cdots$, a set of monomials with no least element, contradicting (i).

Definition 9.6.3. Fix the variable order $x_1 > x_2 > \cdots > x_n$. Three standard orderings on $\mathbb{Z}_{\geq 0}^n$:

- **Lexicographic (lex)**: $\alpha >_{\mathrm{lex}} \beta$ iff the leftmost nonzero entry of $\alpha - \beta$ is positive.
- **Graded lex (grlex)**: $\alpha >_{\mathrm{grlex}} \beta$ iff $|\alpha| > |\beta|$, or ($|\alpha| = |\beta|$ and $\alpha >_{\mathrm{lex}} \beta$).
- **Graded reverse lex (grevlex)**: $\alpha >_{\mathrm{grevlex}} \beta$ iff $|\alpha| > |\beta|$, or ($|\alpha| = |\beta|$ and the *rightmost* nonzero entry of $\alpha - \beta$ is *negative*).

Definition 9.6.4. Fix a monomial ordering $>$. For nonzero $f = \sum_\alpha c_\alpha x^\alpha \in F[x_1, \dots, x_n]$:

- the *multidegree* $\mathrm{multideg}(f) = \max_>\{\alpha : c_\alpha \neq 0\}$;
- the *leading coefficient* $\mathrm{LC}(f) = c_{\mathrm{multideg}(f)} \in F \setminus \{0\}$;
- the *leading monomial* $\mathrm{LM}(f) = x^{\mathrm{multideg}(f)}$;

- the *leading term* $\mathrm{LT}(f) = \mathrm{LC}(f)\ \mathrm{LM}(f)$.

Method (Comparing two monomials)**.** To decide x^α vs x^β:

1. **lex**: scan $\alpha - \beta$ left to right; first nonzero entry decides (+ means x^α wins).
2. **grlex**: compare total degrees first; tie $\implies$ break by lex.
3. **grevlex**: compare total degrees first; tie $\implies$ scan $\alpha - \beta$ *right to left*, first nonzero entry decides, but now a *negative* entry means x^α wins.

To find $\mathrm{LT}(f)$: list all monomials of f, pick the largest under $>$.

Worked Example 9.6.5 (Lex vs grlex ordering of a polynomial)**.** Order the monomials of $f = 2x^3 + 3xy^2z + 5y^4 + 7z^2$ in $F[x, y, z]$ (with $x > y > z$) under lex and under grlex, and read off $\mathrm{LT}(f)$ in each.

Recognition. Apply the definition of each monomial ordering to the four exponent vectors, then take the maximum.

Solution. The exponent vectors are

$$x^3 : (3, 0, 0), \quad xy^2z : (1, 2, 1), \quad y^4 : (0, 4, 0), \quad z^2 : (0, 0, 2),$$

with total degrees $3, 4, 4, 2$.

Lex. Compare by first coordinate: $(3, 0, 0)$ has first entry 3, the largest, so x^3 is greatest. Next $(1, 2, 1)$ beats $(0, 4, 0)$ and $(0, 0, 2)$ (first entry $1 > 0$). Between $(0, 4, 0)$ and $(0, 0, 2)$: first entries tie at 0, second entries $4 > 0$, so $y^4 > z^2$. Thus

$$x^3 >_{\mathrm{lex}} xy^2z >_{\mathrm{lex}} y^4 >_{\mathrm{lex}} z^2, \qquad \mathrm{LT}_{\mathrm{lex}}(f) = 2x^3.$$

Grlex. Sort by total degree first: degrees are $4, 4$ for xy^2z, y^4 and $3, 2$ for x^3, z^2. So the two degree-4 monomials come first; break their tie by lex: $(1, 2, 1)$ vs $(0, 4, 0)$ has first entry $1 > 0$, so $xy^2z > y^4$. Then degree 3, then degree 2:

$$xy^2z >_{\mathrm{grlex}} y^4 >_{\mathrm{grlex}} x^3 >_{\mathrm{grlex}} z^2, \qquad \mathrm{LT}_{\mathrm{grlex}}(f) = 3xy^2z.$$

Check. The leading terms differ: lex favors high powers of the first variable, grlex favors high total degree. Both orders are total and each monomial appears exactly once.

Worked Example 9.6.6 (Grlex vs grevlex disagree)**.** In $F[x, y, z]$, $x > y > z$, compare x^2z^2 and xy^3 under grlex and grevlex.

Recognition. Equal total degree forces the grading tie-break, where grlex and grevlex use opposite scanning rules; this is the classic case where they diverge.

Solution. Exponents: $x^2z^2 : (2, 0, 2)$ and $xy^3 : (1, 3, 0)$, both of total degree 4, so the tie-break decides.

Grlex (lex tie-break, scan left to right). $\alpha - \beta = (2, 0, 2) - (1, 3, 0) = (1, -3, 2)$; leftmost nonzero entry is $+1$, so $x^2z^2 >_{\mathrm{grlex}} xy^3$.

Grevlex (scan right to left, negative wins). Same difference $(1, -3, 2)$; rightmost nonzero entry is $+2$ (positive), so x^2z^2 does *not* win; hence $xy^3 >_{\mathrm{grevlex}} x^2z^2$.

Check. The two graded orders give opposite verdicts here, illustrating why grevlex is a genuinely different ordering. (Grevlex tends to prefer monomials in which the *last* variables appear to low degree.)

Worked Example 9.6.7 (Lex is a monomial ordering, the "divisibility" order is not)**.** Verify that $>_{\mathrm{lex}}$ on $\mathbb{Z}^2_{\geq 0}$ satisfies the additive compatibility, and explain why the partial order "$x^\alpha \preceq x^\beta$ iff $x^\alpha \mid x^\beta$" is *not* a monomial ordering.

Recognition. Test the two defining axioms directly.

Solution. Compatibility of lex. Suppose $\alpha >_{\mathrm{lex}} \beta$, i.e. the first nonzero entry of $\alpha - \beta$ is positive. For any γ, $(\alpha + \gamma) - (\beta + \gamma) = \alpha - \beta$, so the first nonzero entry is unchanged; hence $\alpha + \gamma >_{\mathrm{lex}} \beta + \gamma$. Good.

Divisibility fails totality. The monomials x and y are incomparable: neither $x \mid y$ nor $y \mid x$. A monomial ordering must be a *total* order, so divisibility is disqualified (it is, however, a useful partial order, and is contained in every monomial ordering by axiom (ii)).

Check. Lex is total (any two distinct exponent vectors differ somewhere) and a well-ordering on $\mathbb{Z}^n_{\geq 0}$ (Dickson's Lemma); divisibility is neither total nor a well-order on all monomials.

Worked Example 9.6.8 (Sorting a polynomial under all three orders)**.** Write $f = x^2y + xy^2 + y^3 + x^2 + 1$ in $F[x, y]$, $x > y$, in descending order under lex, grlex, and grevlex.

Recognition. Routine application of all three definitions to one polynomial, to see where the three orders agree and where they differ.

Solution. Exponents and degrees: $x^2y : (2,1)|3$, $xy^2 : (1,2)|3$, $y^3 : (0,3)|3$, $x^2 : (2,0)|2$, $1 : (0,0)|0$.

Lex (first coordinate, then second): $x^2y\,(2,1) > x^2\,(2,0) > xy^2\,(1,2) > y^3\,(0,3) > 1$. So $\mathrm{LT}_{\mathrm{lex}} = x^2y$.

Grlex (degree, then lex): degree 3 block $\{(2,1),(1,2),(0,3)\}$ ordered by lex gives $x^2y > xy^2 > y^3$; then degree 2: x^2; then degree 0: 1. So $\mathrm{LT}_{\mathrm{grlex}} = x^2y$.

Grevlex (degree, then right-to-left, negative wins): in the degree-3 block compare with the reversed rule. $(2,1)$ vs $(1,2)$: difference $(1,-1)$, rightmost entry -1 negative, so x^2y wins; $(1,2)$ vs $(0,3)$: difference $(1,-1)$, so xy^2 wins. Thus $x^2y > xy^2 > y^3$; then x^2; then 1. So $\mathrm{LT}_{\mathrm{grevlex}} = x^2y$.

Check. In two variables grevlex coincides with grlex: if $|\alpha| = |\beta|$ and $\alpha \neq \beta$ then $\alpha - \beta = (d, -d)$ with $d \neq 0$, and its rightmost entry $-d$ is negative exactly when its leftmost entry d is positive. The two graded orders first differ in three variables, as in the comparison of x^2z^2 and xy^3 above.

Caution. "Leading term" is meaningless without a stated ordering. Always fix the ordering (and the variable order $x_1 > \cdots > x_n$) *before* writing $\mathrm{LT}(f)$. A computation correct under lex can be wrong under grevlex.

The multivariate division algorithm

Theorem 9.6.9 (Multivariate Division Algorithm)**.** *Fix a monomial ordering $>$ on $F[x_1, \ldots, x_n]$ and an ordered tuple $(g_1, \ldots, g_m)$ of nonzero polynomials. Then every $f \in F[x_1, \ldots, x_n]$ can be written*

$$f = q_1g_1 + \cdots + q_mg_m + r,$$

with $q_i, r \in F[x_1, \ldots, x_n]$, such that:

(a) no monomial of the remainder r is divisible by any of $\mathrm{LT}(g_1), \ldots, \mathrm{LT}(g_m)$ (a reduced *remainder); and*

(b) $\mathrm{multideg}(f) \geq \mathrm{multideg}(q_ig_i)$ *whenever $q_ig_i \neq 0$.*

Sketch. Maintain an intermediate dividend p (initially f) and accumulate r. At each step let $t = \mathrm{LT}(p)$. If some $\mathrm{LT}(g_i) \mid t$, take the *first* such i, subtract $\big(t/\mathrm{LT}(g_i)\big)g_i$ from p (adding $t/\mathrm{LT}(g_i)$ to q_i); this cancels $\mathrm{LT}(p)$, so $\mathrm{multideg}(p)$ strictly decreases. If no $\mathrm{LT}(g_i)$ divides t, move t into r (it can never become divisible later) and delete it from p. Because $>$ is a well-ordering, the strictly decreasing multidegrees cannot continue forever, so the process terminates with $p = 0$. Properties (a)–(b) hold by construction. □

Method (Dividing f by $(g_1, \ldots, g_m)$)**.**

1. Set $p := f$, $r := 0$, all $q_i := 0$. Fix the ordering and the *order* of the divisors.
2. While $p \neq 0$: let $t = \mathrm{LT}(p)$.
3. Scan $i = 1, 2, \ldots, m$ for the first $\mathrm{LT}(g_i)$ dividing t. If found, set $q_i \mathrel{+}= t/\mathrm{LT}(g_i)$ and $p \mathrel{-}= (t/\mathrm{LT}(g_i))g_i$.
4. If no $\mathrm{LT}(g_i)$ divides t: set $r \mathrel{+}= t$ and $p \mathrel{-}= t$ (move the whole leading term to the remainder).
5. Output $f = \sum q_ig_i + r$. Verify by expanding.

Worked Example 9.6.10 (Division in $F[x, y]$ depends on the order of divisors)**.** With lex ($x > y$) divide $f = x^2y + xy^2 + y^2$ by the pair, in both orders: (A) $(g_1, g_2) = (xy - 1,\ y^2 - 1)$ and (B) $(g_1, g_2) = (y^2 - 1,\ xy - 1)$. Show the remainders differ.

Recognition. Two divisors whose leading terms (xy and y^2) both divide some monomial of f: which one is tried first changes the path, so the remainder is order-dependent.

Solution. Lex leading terms: $\mathrm{LT}(g) = xy$ for $xy - 1$, $\mathrm{LT} = y^2$ for $y^2 - 1$, and $\mathrm{LT}(f) = x^2y$.

(A) divisors $(xy - 1,\ y^2 - 1)$**.**

- $\mathrm{LT}(p) = x^2y$; $xy \mid x^2y$, quotient x. Subtract $x(xy - 1) = x^2y - x$: $p = xy^2 + y^2 + x$.

- $\mathrm{LT}(p) = xy^2$; $xy \mid xy^2$, quotient y. Subtract $y(xy-1) = xy^2 - y$: $p = y^2 + x + y$.
- $\mathrm{LT}(p) = x$ (under lex $x = (1,0)$ outranks $y^2 = (0,2)$ and $y = (0,1)$); divisible by neither xy nor y^2, so move x to r: $p = y^2 + y$.
- $\mathrm{LT}(p) = y^2$; $y^2 \mid y^2$, quotient 1. Subtract $(y^2 - 1)$: $p = y + 1$.
- $\mathrm{LT}(p) = y$, then 1: neither divisible, move both to r.

Result: $q_1 = x + y,\ q_2 = 1,\ r_A = x + y + 1$. Check: $(x+y)(xy-1) + 1 \cdot (y^2-1) + (x+y+1) = x^2y + xy^2 - x - y + y^2 - 1 + x + y + 1 = x^2y + xy^2 + y^2 = f$. ■

(B) divisors $(y^2 - 1,\ xy - 1)$**.** Now $g_1 = y^2 - 1$ is tried first.

- $\mathrm{LT}(p) = x^2y$; $y^2 \nmid x^2y$ (only one y), so try g_2: $xy \mid x^2y$, quotient x. Subtract $x(xy-1)$: $p = xy^2 + y^2 + x$.
- $\mathrm{LT}(p) = xy^2$; $y^2 \mid xy^2$, quotient x. Subtract $x(y^2-1) = xy^2 - x$: $p = y^2 + 2x$.
- $\mathrm{LT}(p) = 2x$ (under lex $2x = (1,0)$ outranks $y^2 = (0,2)$): divisible by neither y^2 nor xy, so move $2x$ to r: $p = y^2$.
- $\mathrm{LT}(p) = y^2$; $y^2 \mid y^2$, quotient 1. Subtract (y^2-1): $p = 1$, move to r.

Result: $q_1 = x + 1,\ q_2 = x,\ r_B = 2x + 1$. Check: $(x+1)(y^2-1) + x(xy-1) + (2x+1) = xy^2 - x + y^2 - 1 + x^2y - x + 2x + 1 = x^2y + xy^2 + y^2 = f$. ■

Conclusion. $r_A = x + y + 1 \neq 2x + 1 = r_B$: the remainder genuinely depends on the order of the divisors. This is exactly the defect a Grobner basis cures.

Worked Example 9.6.11 (A division with zero remainder)**.** Lex, $x > y$. Divide $f = x^2 - y^2$ by $(g_1, g_2) = (x - y,\ x + y)$.

Recognition. f factors through the divisors' leading terms; we expect $r = 0$, certifying membership in $(x - y, x + y)$.

Solution. $\mathrm{LT}(g_1) = x$, $\mathrm{LT}(g_2) = x$, $\mathrm{LT}(f) = x^2$.

- $\mathrm{LT}(p) = x^2$; $x \mid x^2$ via g_1 first, quotient x. Subtract $x(x-y) = x^2 - xy$: $p = xy - y^2$.
- $\mathrm{LT}(p) = xy$; $x \mid xy$ via g_1, quotient y. Subtract $y(x-y) = xy - y^2$: $p = 0$.

Result $q_1 = x + y,\ q_2 = 0,\ r = 0$. Check: $(x+y)(x-y) = x^2 - y^2 = f$. ■So $f \in (x - y, x + y)$, and in fact g_2 was never needed.

Worked Example 9.6.12 (Reducing modulo a single divisor)**.** Lex, $x > y > z$. Divide $f = x^3y + x^2z$ by $g = x^2 - y$.

Recognition. One divisor; repeatedly cancel any multiple of $\mathrm{LT}(g) = x^2$.

Solution. $\mathrm{LT}(g) = x^2$, $\mathrm{LT}(f) = x^3y$.

- $\mathrm{LT}(p) = x^3y$; $x^2 \mid x^3y$, quotient xy. Subtract $xy(x^2 - y) = x^3y - xy^2$: $p = x^2z + xy^2$. (Under lex $x^2z = (2,0,1) > xy^2 = (1,2,0)$.)
- $\mathrm{LT}(p) = x^2z$; $x^2 \mid x^2z$, quotient z. Subtract $z(x^2 - y) = x^2z - yz$: $p = xy^2 + yz$.
- $\mathrm{LT}(p) = xy^2$; $x^2 \nmid xy^2$; move to r. Then $\mathrm{LT}(p) = yz$; not divisible; move to r.

Result $q = xy + z,\ r = xy^2 + yz$. Check: $(xy+z)(x^2-y) + xy^2 + yz = x^3y - xy^2 + x^2z - yz + xy^2 + yz = x^3y + x^2z = f$. ■

Worked Example 9.6.13 (Three divisors in $\mathbb{Q}[x,y]$)**.** Grlex, $x > y$. Divide $f = x^3 + x^2y + y^3$ by $(g_1, g_2, g_3) = (x^2,\ xy,\ y^2)$.

Recognition. The monomial-ideal divisors make the remainder the sum of monomials of f divisible by none of x^2, xy, y^2; good practice for "$\mathrm{LT}(I)$" intuition.

Solution. $\mathrm{LT}(g_1) = x^2, \mathrm{LT}(g_2) = xy, \mathrm{LT}(g_3) = y^2$. Grlex: $x^3 > x^2y > y^3$.

- x^3: $x^2 \mid x^3$, $q_1 \mathrel{+}= x$, subtract $x \cdot x^2$: $p = x^2y + y^3$.
- x^2y: $x^2 \mid x^2y$, $q_1 \mathrel{+}= y$, subtract $y \cdot x^2$: $p = y^3$.
- y^3: $x^2 \nmid y^3$, $xy \nmid y^3$, $y^2 \mid y^3$, $q_3 \mathrel{+}= y$, subtract $y \cdot y^2$: $p = 0$.

Result $q_1 = x + y,\ q_2 = 0,\ q_3 = y,\ r = 0$. Check: $(x+y)x^2 + y \cdot y^2 = x^3 + x^2y + y^3 = f$. ■Here $r = 0$, so $f \in (x^2, xy, y^2)$.

Caution. A nonzero remainder does *not* prove $f \notin I = (g_1, \ldots, g_m)$ unless $\{g_i\}$ is a Grobner basis. In the worked example with $(xy - 1, y^2 - 1)$, f might still lie in I even though one division gave $r \neq 0$; only division by a Grobner basis gives a remainder that is 0 *iff* $f \in I$.

Grobner bases

Definition 9.6.14. Fix a monomial ordering. For an ideal $I \subseteq F[x_1, \ldots, x_n]$, the *ideal of leading terms* is

$$\mathrm{LT}(I) = \big(\mathrm{LT}(f) : f \in I,\ f \neq 0\big),$$

the (monomial) ideal generated by the leading terms of *all* nonzero elements of I. A finite subset $G = \{g_1, \ldots, g_m\} \subseteq I$ is a *Grobner basis* of I if

$$\big(\mathrm{LT}(g_1), \ldots, \mathrm{LT}(g_m)\big) = \mathrm{LT}(I),$$

i.e. the leading terms of the g_i generate the whole ideal of leading terms.

Theorem 9.6.15 (Existence and basic properties)**.** *With respect to any fixed monomial ordering, every ideal $I \neq 0$ has a Grobner basis, and any Grobner basis of I generates I. Moreover, if G is a Grobner basis of I, then for every f the remainder r on division of f by G is* uniquely *determined (independent of the order of the g_i), and*

$$f \in I \iff r = 0.$$

Sketch. Existence of a finite generating set of the monomial ideal $\mathrm{LT}(I)$ is Dickson's Lemma (equivalently Hilbert's Basis Theorem); pulling back generators $\mathrm{LT}(g_i)$ to elements $g_i \in I$ gives a Grobner basis. That G generates I: given $f \in I$, divide by G; the remainder $r = f - \sum q_i g_i \in I$ has no monomial divisible by any $\mathrm{LT}(g_i)$, so $\mathrm{LT}(r) \notin \mathrm{LT}(I)$ unless $r = 0$ — forcing $r = 0$, hence $f = \sum q_i g_i$. Uniqueness of r and the membership test follow from the same argument. □

Method (Recognizing / using a Grobner basis)**.**

- **Membership test**: to decide $f \in I$, divide f by a Grobner basis G; then $f \in I \iff$ the remainder is 0 (order of divisors no longer matters).
- **Is G a Grobner basis?** Use Buchberger's Criterion below: compute every S-polynomial $S(g_i, g_j)$ and divide by G; G is a Grobner basis iff every such remainder is 0.
- **To build one**: run Buchberger's algorithm — keep adjoining nonzero S-polynomial remainders until all S-remainders are 0.

Definition 9.6.16. For nonzero f, g let $L = \mathrm{lcm}\big(\mathrm{LM}(f), \mathrm{LM}(g)\big)$ (the least common multiple of the leading monomials, taken exponentwise as the coordinatewise maximum). The *S-polynomial* of f and g is

$$S(f,g) = \frac{L}{\mathrm{LT}(f)}\, f - \frac{L}{\mathrm{LT}(g)}\, g.$$

By design the leading terms of the two products both equal L and cancel, so $\mathrm{multideg}\big(S(f,g)\big)$ is strictly less than the multidegree of either product.

Theorem 9.6.17 (Buchberger's Criterion)**.** *A finite generating set $G = \{g_1, \ldots, g_m\}$ of an ideal I is a Grobner basis (for the fixed ordering) if and only if for every pair $i \neq j$ the remainder of $S(g_i, g_j)$ on division by G (in any order) is zero:*

$$\overline{S(g_i, g_j)}^{\,G} = 0 \quad \textit{for all } i < j.$$

Sketch. ($\Longrightarrow$) If G is a Grobner basis then every element of I, in particular $S(g_i, g_j) \in I$, reduces to 0. ($\Leftarrow$) The content of Buchberger's theorem: the only way the leading term of an arbitrary combination $\sum h_k g_k \in I$ can fail to be divisible by some $\mathrm{LT}(g_k)$ is through cancellation of leading terms among pairs; each such cancellation is governed by a single S-polynomial. If all S-polynomials reduce to 0 over G, one shows by a careful "rewriting" / descending-multidegree argument that no new leading terms can escape $(\mathrm{LT}(g_1), \ldots, \mathrm{LT}(g_m))$, so this set equals $\mathrm{LT}(I)$. □

Theorem 9.6.18 (Buchberger's Algorithm)**.** *Given generators $G = \{g_1, \ldots, g_m\}$ of I:*

1. *For each pair $i < j$ compute $S(g_i, g_j)$ and its remainder $r = \overline{S(g_i, g_j)}^{G}$.*
2. *If some $r \neq 0$, adjoin r to G and repeat (now also pairing r with everything).*
3. *When all S-polynomial remainders are 0, G is a Grobner basis of I.*

The algorithm terminates because each adjoined r has $\mathrm{LT}(r) \notin (\mathrm{LT}(g) : g \in G \text{ so far})$, strictly enlarging the monomial ideal of leading terms; by the ascending chain condition (Noetherian!) this can happen only finitely often.

Worked Example 9.6.19 ($\{x + y,\ x - y\}$ is not yet a Grobner basis (lex))**.** Lex, $x > y$, over a field F with $\mathrm{char}\, F \neq 2$. Show $G = \{g_1, g_2\} = \{x + y,\ x - y\}$ is *not* a Grobner basis of $I = (x + y, x - y)$, and extend it to one.

Recognition. One pair, so Buchberger's Criterion needs a single S-polynomial; compute and reduce it.

Solution. $\mathrm{LT}(g_1) = x = \mathrm{LT}(g_2)$, so $L = \mathrm{lcm}(x, x) = x$.

$$S(g_1, g_2) = \frac{x}{x}(x + y) - \frac{x}{x}(x - y) = (x + y) - (x - y) = 2y.$$

Divide $2y$ by G: $\mathrm{LT}(g_1) = \mathrm{LT}(g_2) = x \nmid y$, so the remainder is $2y \neq 0$. *Not zero*, so as written G is *not* a Grobner basis — we must adjoin $g_3 = 2y$ (or, scaling, y). Recompute the new pairs:

$$S(g_1, g_3) : L = \mathrm{lcm}(x, y) = xy, \quad \frac{xy}{x}(x + y) - \frac{xy}{2y}(2y) = (xy + y^2) - xy = y^2.$$

Reduce y^2: $\mathrm{LT}(g_3) = 2y \mid y^2$, quotient $\frac{1}{2}y$; subtract $\frac{1}{2}y \cdot 2y = y^2$: 0. Similarly $S(g_2, g_3) = (xy - y^2) - xy = -y^2$ reduces to 0. So $G' = \{x + y,\ x - y,\ y\}$ *is* a Grobner basis.

Check. $I = (x + y, x - y) = (x, y)$ since $x = \frac{1}{2}[(x + y) + (x - y)]$ and $y = \frac{1}{2}[(x + y) - (x - y)]$; indeed $\mathrm{LT}(I) = (x, y)$, which is generated by $\mathrm{LT}(x + y) = x$ and $\mathrm{LT}(y) = y$. The original leading terms $\{x, x\}$ generate only $(x) \neq (x, y)$, confirming G alone was not a Grobner basis. ■

Worked Example 9.6.20 (A set that already is a Grobner basis)**.** Lex, $x > y$. Show $G = \{g_1, g_2\} = \{x - y^2,\ y^3 - y\}$ is a Grobner basis of $I = (g_1, g_2)$.

Recognition. Leading monomials x and y^3 involve disjoint variables, so Buchberger's product criterion predicts the S-polynomial reduces to 0 — but we verify by hand.

Solution. $\mathrm{LT}(g_1) = x$, $\mathrm{LT}(g_2) = y^3$, $L = \mathrm{lcm}(x, y^3) = xy^3$.

$$S(g_1, g_2) = \frac{xy^3}{x}(x - y^2) - \frac{xy^3}{y^3}(y^3 - y) = y^3(x - y^2) - x(y^3 - y) = xy^3 - y^5 - xy^3 + xy = xy - y^5.$$

Divide $xy - y^5$ by G (lex: $\mathrm{LT} = xy$, since $xy = (1, 1) > y^5 = (0, 5)$). $\mathrm{LT}(g_1) = x \mid xy$, quotient y; subtract $y(x - y^2) = xy - y^3$: $p = -y^5 + y^3$. Now $\mathrm{LT}(p) = -y^5$; $y^3 \mid y^5$, quotient $-y^2$; subtract $-y^2(y^3 - y) = -y^5 + y^3$: $p = y^3 - y^3 = 0$. Remainder 0.

The only pair reduces to 0, so by Buchberger's Criterion G *is* a Grobner basis. *Check.* $\mathrm{LT}(I) \supseteq (x, y^3)$; the reduction confirms no new leading term escapes. ■

Worked Example 9.6.21 (One step of Buchberger's algorithm)**.** Grlex, $x > y$. Start from $G = \{g_1, g_2\} = \{x^2 - y,\ xy - 1\}$ generating I. Run one Buchberger step.

Recognition. Two generators with overlapping leading monomials x^2, xy; compute their S-polynomial, reduce, and adjoin if nonzero.

Solution. $\mathrm{LT}(g_1) = x^2$, $\mathrm{LT}(g_2) = xy$, $L = \mathrm{lcm}(x^2, xy) = x^2y$.

$$S(g_1, g_2) = \frac{x^2y}{x^2}(x^2 - y) - \frac{x^2y}{xy}(xy - 1) = y(x^2 - y) - x(xy - 1) = x^2y - y^2 - x^2y + x = x - y^2.$$

Divide $x - y^2$ by G. Grlex: $\mathrm{LT}(x - y^2) = -y^2$ (degree $2 > 1$, so $y^2 = (0, 2)$ outranks $x = (1, 0)$). Neither $\mathrm{LT}(g_1) = x^2$ nor $\mathrm{LT}(g_2) = xy$ divides y^2 or x, so nothing reduces: remainder $r = x - y^2 \neq 0$. Adjoin it as $g_3 = x - y^2$.

New basis (one step): $G' = \{\, x^2 - y,\ xy - 1,\ x - y^2 \,\}$. *Check.* $g_3 = S(g_1, g_2) = y\, g_1 - x\, g_2 \in I$, so adjoining it does not change I, and now the ideal generated by the leading terms of the basis has gained the new leading monomial y^2. (Continuing with the pairs $(g_1, g_3), (g_2, g_3)$: $S(g_1, g_3) = x^3 - y^3$ and $S(g_2, g_3) = x^2 - y$ both reduce to 0 over G', so G' is already a grlex Grobner basis; the reduced one is $\{x^2 - y,\ xy - 1,\ y^2 - x\}$.)

Worked Example 9.6.22 (Ideal membership via a Grobner basis)**.** Lex, $x > y$. Let $I = (x^2 - y,\ xy - 1)$. First compute a Grobner basis of I, then test $f = x^2y - x$ for membership.

Recognition. Membership is decided by dividing by a *Grobner* basis and checking remainder 0; first we need G.

Solution. **Find G (lex).** $\mathrm{LT}(x^2 - y) = x^2$, $\mathrm{LT}(xy - 1) = xy$. S-polynomial: $L = x^2y$,

$$S = y(x^2 - y) - x(xy - 1) = -y^2 + x = x - y^2.$$

Reduce by $\{x^2 - y, xy - 1\}$: lex $\mathrm{LT}(x - y^2) = x$, but $x^2 \nmid x$ and $xy \nmid x$; remainder $x - y^2 \neq 0$, adjoin $g_3 = x - y^2$ (lex LT $= x$). Now reduce the older generators against g_3:

$$x^2 - y = x\, g_3 + (xy^2 - y), \qquad xy^2 - y = y^2 g_3 + (y^4 - y),$$

so $x^2 - y$ reduces to $y^4 - y = y(y^3 - 1)$. Likewise $xy - 1 = y\, g_3 + (y^3 - 1)$ reduces to $y^3 - 1 \neq 0$ (this is also the remainder of $S(xy - 1, g_3)$), so we adjoin $g_4 = y^3 - 1$. Then $y^4 - y = y\, g_4$, so $x^2 - y$ and $xy - 1$ both reduce to 0 and are redundant. One checks all S-polynomials now reduce to 0, giving the (reduced) Grobner basis

$$G = \{\, x - y^2,\ \ y^3 - 1 \,\}.$$

Indeed $\mathrm{LT}(G) = (x,\, y^3) = \mathrm{LT}(I)$.

Test $f = x^2y - x$**.** Divide by $G = (x - y^2,\ y^3 - 1)$, lex $\mathrm{LT}(g_1) = x, \mathrm{LT}(g_2) = y^3$, $\mathrm{LT}(f) = x^2y$.

- x^2y: $x \mid x^2y$, quotient xy; subtract $xy(x - y^2) = x^2y - xy^3$: $p = xy^3 - x$.
- xy^3: $x \mid xy^3$, quotient y^3; subtract $y^3(x - y^2) = xy^3 - y^5$: $p = y^5 - x$.
- $\mathrm{LT}(p)$: lex compares $x = (1, 0)$ vs $y^5 = (0, 5)$, and $x >_{\mathrm{lex}} y^5$, so $\mathrm{LT}(p) = -x$. $x \mid x$, quotient -1; subtract $-(x - y^2) = -x + y^2$: $p = y^5 - x + x - y^2 = y^5 - y^2$.
- y^5: $y^3 \mid y^5$, quotient y^2; subtract $y^2(y^3 - 1) = y^5 - y^2$: $p = 0$.

Remainder 0, so $f = x^2y - x \in I$. *Check.* Explicitly $x^2y - x = (xy + y^3 - 1)(x - y^2) + y^2(y^3 - 1)$; expanding: $(xy + y^3 - 1)(x - y^2) = x^2y - xy^3 + xy^3 - y^5 - x + y^2 = x^2y - y^5 - x + y^2$, plus $y^2(y^3 - 1) = y^5 - y^2$ gives $x^2y - x$. ■So membership is confirmed by a zero remainder.

Worked Example 9.6.23 (Elimination: solving a polynomial system with lex)**.** Lex, $x > y$. Solve the system $x^2 + y = 0,\ x + y^2 = 0$ over $\mathbb{C}$ by computing a lex Grobner basis of $I = (x^2 + y,\ x + y^2)$ and using elimination.

Recognition. Lex order "eliminates" the higher variable: the elements of a lex Grobner basis lying in $F[y]$ generate $I \cap F[y]$. When this ideal is nonzero (e.g. when the system has only finitely many solutions over $\mathbb{C}$, as here) the basis contains a polynomial in y alone, which we solve first, then back-substitute.

Solution. $\mathrm{LT}(x^2+y)=x^2$, $\mathrm{LT}(x+y^2)=x$. S-polynomial, $L=\mathrm{lcm}(x^2,x)=x^2$:

$$S=\frac{x^2}{x^2}(x^2+y)-\frac{x^2}{x}(x+y^2)=(x^2+y)-x(x+y^2)=y-xy^2=-xy^2+y.$$

Reduce by $\{x^2+y,\ x+y^2\}$: $\mathrm{LT}(-xy^2+y)=-xy^2$ (lex $xy^2=(1,2)>y=(0,1)$); $\mathrm{LT}(g_2)=x\mid xy^2$, quotient $-y^2$; subtract $-y^2(x+y^2)=-xy^2-y^4$: $p=y^4+y$. No leading term (y^4) is divisible by x^2 or x, so remainder $g_3=y^4+y\neq 0$; adjoin it. Further S-polynomials reduce to 0, so a lex Grobner basis is

$$G=\{\,x+y^2,\quad y^4+y\,\}.$$

(The generator x^2+y reduces: $x^2+y-x(x+y^2)=y-xy^2$, which we just saw reduces to y^4+y over G, hence to 0 modulo G; so it is redundant.)

Solve. The eliminated equation $y^4+y=y(y^3+1)=y(y+1)(y^2-y+1)=0$ gives

$$y\in\left\{\,0,\ -1,\ \tfrac{1\pm\sqrt{-3}}{2}\,\right\}.$$

Back-substitute into $x=-y^2$:

y	$x=-y^2$
0	0
-1	-1
$\omega=\frac{1+\sqrt{-3}}{2}$	$-\omega^2$
$\bar\omega=\frac{1-\sqrt{-3}}{2}$	$-\bar\omega^2$

giving four solutions (x,y). *Check.* For $(0,0)$: $0+0=0$, $0+0=0$. For $(-1,-1)$: $(-1)^2+(-1)=0$, $(-1)+(-1)^2=0$. ■For $y=\omega$, a root of y^2-y+1 with $\omega^3=-1$: then $y^4+y=\omega\cdot\omega^3+\omega=-\omega+\omega=0$, and $x=-\omega^2$ gives $x^2+y=\omega^4+\omega=\omega\cdot\omega^3+\omega=0$. ■The lex Grobner basis converted the 2-variable system into a single one-variable equation plus a back-substitution.

Caution. Buchberger's Criterion requires reducing each S-polynomial by the *whole current* basis G, not just by the two polynomials that produced it. Forgetting to reduce against *all* of G can make you adjoin redundant generators or wrongly conclude G is not a Grobner basis.

Caution. Lex Grobner bases are best for *elimination* (for a system with finitely many solutions they expose a one-variable polynomial) but are often very expensive to compute. Grevlex bases are usually fastest; a common strategy is to compute a grevlex basis and convert to lex. The *ideal* I and its variety are unchanged by the ordering — only the basis presentation changes.

Remark 9.6.2. The reduction map $\mathbb{Z}[x]\twoheadrightarrow\mathbb{F}_p[x]$ from Section 9.4 has a multivariate analogue $\mathbb{Z}[x_1,\dots,x_n]\twoheadrightarrow\mathbb{F}_p[x_1,\dots,x_n]$; Grobner basis computations can be carried out over $\mathbb{F}_p$ to detect membership cheaply, then lifted. Schematically:

$$\mathbb{Z}[x_1,\dots,x_n]\xrightarrow{\bmod p}\!\!\!\!\twoheadrightarrow\ \mathbb{F}_p[x_1,\dots,x_n]$$

and over a field F, ideal membership / consistency of a system is decided entirely by a Grobner basis computation in $F[x_1,\dots,x_n]$.

Diagram explanation. Objects: Two polynomial rings: the domain $\mathbb{Z}[x_1,\dots,x_n]$, the ring of polynomials in n variables with integer coefficients (a Noetherian domain, not a field), and the codomain $\mathbb{F}_p[x_1,\dots,x_n]$, the ring of polynomials with coefficients in the field $\mathbb{F}_p=\mathbb{Z}/p\mathbb{Z}$ for a prime p. Both are commutative Noetherian rings, but $\mathbb{F}_p[x_1,\dots,x_n]$ is an algebra over a field, making Grobner-basis arithmetic decidable and finite.

Arrows: The single arrow $\bmod p$: $\mathbb{Z}[x_1,\dots,x_n]\twoheadrightarrow\mathbb{F}_p[x_1,\dots,x_n]$ is the surjective ring homomorphism that reduces every coefficient modulo p: for $f=\sum_\alpha c_\alpha x^\alpha$ with $c_\alpha\in\mathbb{Z}$, the map sends $f\mapsto\sum_\alpha \bar c_\alpha x^\alpha$ where $\bar c_\alpha=c_\alpha \bmod p\in\mathbb{F}_p$. The double-headed arrowhead records surjectivity: every polynomial over $\mathbb{F}_p$ lifts to one over $\mathbb{Z}$.

What commutes: There is only one arrow, so no commutativity square is present. The diagram is instead a declaration: the map exists and is a surjective ring homomorphism. The relevant algebraic content is that $\bmod p$ is a ring map, i.e. it respects addition and multiplication: $\overline{f+g}=\overline f+\overline g$ and $\overline{fg}=\overline f\,\overline g$ in $\mathbb{F}_p[x_1,\dots,x_n]$.

Why it commutes: Chase a generic element: let $f = \sum_\alpha c_\alpha x^\alpha \in \mathbb{Z}[x_1, \ldots, x_n]$. Reducing first and then multiplying by $g = \sum_\beta d_\beta x^\beta$: $(\sum_\alpha \overline{c}_\alpha x^\alpha)(\sum_\beta \overline{d}_\beta x^\beta) = \sum_{\alpha,\beta} \overline{c_\alpha d_\beta} x^{\alpha+\beta}$. Multiplying first then reducing: $fg = \sum_{\alpha,\beta} c_\alpha d_\beta x^{\alpha+\beta}$, and reducing gives $\sum_{\alpha,\beta} \overline{c_\alpha d_\beta} x^{\alpha+\beta}$. These agree because $\overline{c_\alpha d_\beta} = \overline{c}_\alpha \, \overline{d}_\beta$ in $\mathbb{Z}/p\mathbb{Z}$, since reduction mod p is a ring homomorphism $\mathbb{Z} \to \mathbb{F}_p$.

Why this matters here: The remark motivates why Grobner basis theory over a field F is so powerful: the field hypothesis on the coefficient ring lets every leading coefficient be inverted, so a leading term divisible by some $\mathrm{LT}(g_i)$ can always be cancelled; termination comes from the well-ordering, and when the divisors form a Grobner basis the remainder is unique and the membership test $f \in I \iff r = 0$ works. The diagram records the bridge: one can first compute a Grobner basis in the cheap finite-field model $\mathbb{F}_p[x_1, \ldots, x_n]$ (fast, finite arithmetic) to detect ideal membership, then lift the information to $\mathbb{Z}$ or $\mathbb{Q}$.

Concrete example: In one variable, $\mathrm{mod}2\colon \mathbb{Z}[x] \to \mathbb{F}_2[x]$ sends $f = x^2 + 3x + 2$ to $\overline{f} = x^2 + x \in \mathbb{F}_2[x]$ (since $\overline{3} = 1$ and $\overline{2} = 0$). The Grobner basis of $(x^2 + 3x + 2) = (x+1)(x+2)$ over $\mathbb{Z}$ reduces to $(x^2 + x) = (x)(x+1)$ in $\mathbb{F}_2[x]$. Membership of $x^2 + x$ in the $\mathbb{F}_2$-ideal is confirmed by a cheap remainder computation.

Common pitfall: Students sometimes assume that a Grobner basis $G = \{g_1, \ldots, g_m\}$ over $\mathbb{Z}$ reduces directly to a Grobner basis $\{\overline{g}_1, \ldots, \overline{g}_m\}$ over $\mathbb{F}_p$. This can fail when p divides a leading coefficient $\mathrm{LC}(g_i)$: then $\mathrm{LT}(\overline{g}_i)$ is smaller than $\mathrm{LT}(g_i)$ under the inherited ordering, and the monomial ideals $(\mathrm{LT}(\overline{g}_i))$ and $\overline{(\mathrm{LT}(g_i))}$ need no longer match, which can break the Grobner property.

Takeaway: The point of this diagram is that the coefficient-reduction map $\mathbb{Z}[x_1, \ldots, x_n] \twoheadrightarrow \mathbb{F}_p[x_1, \ldots, x_n]$ is a surjective ring homomorphism that lets one transfer Grobner-basis computations into a field-coefficient setting where the membership criterion $f \in I \iff r = 0$ is available, at the cost of careful tracking of which primes p make leading coefficients vanish.

Notation for the exercises below: $\partial(f)$ denotes multideg(f). A Grobner basis $\{g_1, \ldots, g_m\}$ of I is *minimal* if every $\mathrm{LT}(g_i)$ is monic and $\mathrm{LT}(g_j)$ is not divisible by $\mathrm{LT}(g_i)$ for $i \neq j$, and *reduced* if every $\mathrm{LT}(g_i)$ is monic and no term of g_j is divisible by $\mathrm{LT}(g_i)$ for $i \neq j$; for a fixed monomial ordering every nonzero ideal has a unique reduced Grobner basis. The *ideal quotient* of two ideals I, J of a ring R is $(I : J) = \{r \in R \mid rJ \subseteq I\}$. In Exercises 38–44, M and N are monomial ideals with monomial generators $\{m_i \mid i \in I\}$ and $\{n_j \mid j \in J\}$ for index sets I and J.

Exercises (from the text).

1. Suppose I is an ideal in $F[x_1, \ldots, x_n]$ generated by a (possibly infinite) set $\mathcal{S}$ of polynomials. Prove that a finite subset of the polynomials in $\mathcal{S}$ suffice to generate I. [Use Theorem 21 to write $I = (f_1, \ldots, f_m)$ and then write each $f_i \in I$ using polynomials in $\mathcal{S}$.]

2. Let $\geq$ be any monomial ordering.

   (a) Prove that $LT(fg) = LT(f)LT(g)$ and $\partial(fg) = \partial(f) + \partial(g)$ for any nonzero polynomials f and g.

   (b) Prove that $\partial(f + g) \leq \max(\partial(f), \partial(g))$ with equality if $\partial(f) \neq \partial(g)$.

   (c) Prove that $m \geq 1$ for every monomial m.

   (d) Prove that if m_1 divides m_2 then $m_2 \geq m_1$. Deduce that the leading term of f does not divide any of its lower order terms.

3. Prove that if $\geq$ is any total or partial ordering on a nonempty set then the following are equivalent:

   (i) Every nonempty subset contains a minimal element.

   (ii) There is no infinite strictly decreasing sequence $a_1 > a_2 > a_3 > \cdots$ (this is called the *descending chain condition* or *D.C.C.*).

   Deduce that General Polynomial Division always terminates in finitely many steps.

4. Let $\geq$ be a monomial ordering, and for monomials m_1, m_2 define $m_1 \geq_g m_2$ if either $\deg m_1 > \deg m_2$, or $\deg m_1 = \deg m_2$ and $m_1 \geq m_2$.

   (a) Prove that $\geq_g$ is also a monomial ordering. (The relation $\geq_g$ is called the *grading* of $\geq$. An ordering in which the most important criterion for comparison is degree is sometimes called a *graded* or a *degree* ordering, so this exercise gives a method for constructing graded orderings.)

(b) The grading of the lexicographic ordering $x_1 > \cdots > x_n$ is called the *grlex* monomial ordering. Show that $x_2^4 > x_1^2x_2 > x_1x_2^2 > x_2^2 > x_1$ with respect to the grlex ordering and $x_1^2x_2 > x_1x_2^2 > x_1 > x_2^4 > x_2^2$ with respect to the lexicographic ordering.

5. The *grevlex* monomial ordering is defined by first choosing an ordering of the variables $\{x_1, x_2, \ldots, x_n\}$, then defining $m_1 \geq m_2$ for monomials m_1, m_2 if either $\deg m_1 > \deg m_2$ or $\deg m_1 = \deg m_2$ and the first exponent of $x_n, x_{n-1}, \ldots, x_1$ (in that order) where m_1 and m_2 differ is *smaller* in m_1.

   (a) Prove that grevlex is a monomial ordering that satisfies $x_1 > x_2 > \cdots > x_n$.

   (b) Prove that the grevlex ordering on $F[x_1, x_2]$ with respect to $\{x_1, x_2\}$ is the graded lexicographic ordering with $x_1 > x_2$, but that the grevlex ordering on $F[x_1, x_2, x_3]$ is not the graded lexicographic ordering for any lexicographic ordering of the variables.

   (c) Show that $x_1x_2^2x_3 > x_1^2x_3^2 > x_2^2x_3^2 > x_2x_3^2 > x_1x_2 > x_2^2 > x_1x_3 > x_3^2 > x_1 > x_2$ for the grevlex monomial ordering with respect to $\{x_1, x_2, x_3\}$.

6. Show that $x^3y > x^3z^2 > x^3z > x^2y^2z > x^2y > xz^2 > y^2z^2 > y^2z$ with respect to the lexicographic monomial ordering $x > y > z$. Show that for the corresponding grlex monomial ordering $x^3z^2 > x^2y^2z > x^3y > x^3z > y^2z^2 > x^2y > xz^2 > y^2z$, and that for the grevlex monomial ordering with respect to $\{x, y, z\}$ that $x^2y^2z > x^3z^2 > x^3y > x^3z > y^2z^2 > x^2y > y^2z > xz^2$.

7. Order the monomials x^2z, x^2y^2z, xy^2z, x^3y, x^3z^2, x^7, x^2yz^2, x^7z^2 for the lexicographic monomial ordering $x > y > z$, for the corresponding grlex monomial order, and for the grevlex monomial ordering with respect to $\{x, y, z\}$.

8. Show there are $n!$ distinct lexicographic monomial orderings on $F[x_1, \ldots, x_n]$. Show similarly that there are $n!$ distinct grlex and grevlex monomial orderings.

9. It can be shown that any monomial ordering on $F[x_1, \ldots, x_n]$ may be obtained as follows. For $k \leq n$ let $v_1, v_2, \ldots, v_k$ be nonzero vectors in Euclidean n-space, $\mathbb{R}^n$, that are pairwise orthogonal: $v_i \cdot v_j = 0$ for all $i \neq j$, where $\cdot$ is the usual dot product, and suppose also that all the coordinates of v_1 are nonnegative. Define an order, $\geq$, on monomials by $m_1 > m_2$ if and only if for some $t \leq k$ we have $v_i \cdot \partial(m_1) = v_i \cdot \partial(m_2)$ for all $i \in \{1, 2, \ldots, t-1\}$ and $v_t \cdot \partial(m_1) > v_t \cdot \partial(m_2)$.

   (a) Let $k = n$ and let $v_i = (0, \ldots, 0, 1, 0, \ldots, 0)$ with 1 in the ith position. Show that $\geq$ defines the lexicographic order with $x_1 > x_2 > \cdots > x_n$.

   (b) Let $k = n$ and define $v_1 = (1, 1, \ldots, 1)$ and $v_i = (1, 1, \ldots, 1, -n + i - 1, 0, \ldots, 0)$, where there are $i - 2$ trailing zeros, $2 \leq i \leq n$. Show that $\geq$ defines the grevlex order with respect to $\{x_1, \ldots, x_n\}$.

10. Suppose I is a monomial ideal generated by monomials $m_1, \ldots, m_k$. Prove that the polynomial $f \in F[x_1, \ldots, x_n]$ is in I if and only if every monomial term f_i of f is a multiple of one of the m_j. [For polynomials $a_1, \ldots, a_k \in F[x_1, \ldots, x_n]$ expand the polynomial $a_1m_1 + \cdots + a_km_k$ and note that every monomial term is a multiple of at least one of the m_j.] Show that $x^2yz + 3xy^2$ is an element of the ideal $I = (xyz, y^2) \subset F[x, y, z]$ but is not an element of the ideal $I' = (xz^2, y^2)$.

11. Fix a monomial ordering on $R = F[x_1, \ldots, x_n]$ and suppose $\{g_1, \ldots, g_m\}$ is a Grobner basis for the ideal I in R. Prove that $h \in LT(I)$ if and only if h is a sum of monomial terms each divisible by some $LT(g_i)$, $1 \leq i \leq m$. [Use the previous exercise.]

12. Suppose I is a monomial ideal with monomial generators $g_1, \ldots, g_m$. Use the previous exercise to prove that $\{g_1, \ldots, g_m\}$ is a Grobner basis for I.

13. Suppose I is a monomial ideal with monomial generators $g_1, \ldots, g_m$. Use Buchberger's Criterion to prove that $\{g_1, \ldots, g_m\}$ is a Grobner basis for I.

14. Suppose I is a monomial ideal in $R = F[x_1, \ldots, x_n]$ and suppose $\{m_1, \ldots, m_k\}$ is a minimal set of monomials generating I, i.e., each m_i is a monomial and no proper subset of $\{m_1, \ldots, m_k\}$ generates I. Prove that the m_i, $1 \leq i \leq k$ are unique. [Use Exercise 10.]

15. Fix a monomial ordering on $R = F[x_1, \ldots, x_n]$.

(a) Prove that the subset $\{g_1, \ldots, g_m\}$ of the ideal I in R is a minimal Grobner basis of I if and only if $(LT(g_1), \ldots, LT(g_m))$ is a minimal generating set for $LT(I)$.

(b) Prove that the leading terms of a minimal Grobner basis are uniquely determined and the number of elements in any two minimal Grobner bases for I is the same. [Use (a) and the previous exercise.]

16. Fix a monomial ordering on $F[x_1, \ldots, x_n]$ and suppose $G = \{g_1, \ldots, g_m\}$ is a set of generators for the nonzero ideal I. Show that if $S(g_i, g_j) \equiv r \bmod G$, where $r \neq 0$ is the remainder of $S(g_i, g_j)$ on division by G, then the ideal $(LT(g_1), \ldots, LT(g_m), LT(r))$ is strictly larger than the ideal $(LT(g_1), \ldots, LT(g_m))$. Conclude that the algorithm for computing a Grobner basis described following Proposition 26 terminates after a finite number of steps. [Use Exercise 1.]

17. Fix the lexicographic ordering $x > y$ on $F[x, y]$. Use Buchberger's Criterion to show that $\{x^2y - y^2, x^3 - xy\}$ is a Grobner basis for the ideal $I = (x^2y - y^2, x^3 - xy)$.

18. Show $\{x - y^3, y^6 - y^5\}$ is the reduced Grobner basis for the ideal $I = (x - y^3, -x^2 + xy^2)$ with respect to the lexicographic ordering defined by $x > y$.

19. Fix the lexicographic ordering $x > y$ on $F[x, y]$.

(a) Show that $\{x^3 - y, x^2y - y^2, xy^2 - y^2, y^3 - y^2\}$ is the reduced Grobner basis for the ideal $I = (-x^3 + y, x^2y - y^2)$.

(b) Determine whether the polynomial $f = x^6 - x^5y$ is an element of the ideal I.

20. Fix the lexicographic ordering $x > y > z$ on $F[x, y, z]$. Show that $\{x^2 + xy + z, xyz + z^2, xz^2, z^3\}$ is the reduced Grobner basis for the ideal $I = (x^2 + xy + z, xyz + z^2)$ and in particular conclude that the leading term ideal $LT(I)$ requires four generators.

21. Fix the lexicographic ordering $x > y$ on $F[x, y]$. Use Buchberger's Criterion to show that $\{x^2y - y^2, x^3 - xy\}$ is a Grobner basis for the ideal $I = (x^2y - y^2, x^3 - xy)$.

22. Let $I = (x^2 - y, x^2y - z) \subseteq F[x, y, z]$.

(a) Show that $\{x^2 - y, y^2 - z\}$ is the reduced Grobner basis for I with respect to the lexicographic ordering defined by $x > y > z$.

(b) Show that $\{x^2 - y, z - y^2\}$ is the reduced Grobner basis for I with respect to the lexicographic ordering defined by $z > x > y$ (note these are essentially the same polynomials as in (a)).

(c) Show that $\{y - x^2, z - x^4\}$ is the reduced Grobner basis for I with respect to the lexicographic ordering defined by $z > y > x$.

23. Show that the ideals $I = (x^2y + xy^2 - 2y, x^2 + xy - x + y^2 - 2y, xy^2 - x - y + y^3)$ and $J = (x - y^2, xy - y, x^2 - y)$ in $F[x, y]$ are equal.

24. Use reduced Grobner bases to show that the ideal $I = (x^3 - yz, yz + y)$ and the ideal $J = (x^3z + x^3, x^3 + y)$ in $F[x, y, z]$ are equal.

25. Show that the reduced Grobner basis using the lexicographic ordering $x > y$ for the ideal $I = (x^2 + xy^2, x^2 - y^3, y^3 - y^2)$ is $\{x^2 - y^2, y^3 - y^2, xy^2 + y^2\}$.

26. Show that the reduced Grobner basis for the ideal $I = (xy + y^2, x^2y + xy^2 + x^2)$ is $\{x^2, xy + y^2, y^3\}$ with respect to the lexicographic ordering $x > y$ and is $\{y^2 + yx, x^2\}$ with respect to the lexicographic ordering $y > x$.

27. Show that $\{x^3 - y^3, x^2 + xy^2 + y^4, x^2y + xy^3 + y^2\}$ is a reduced Grobner basis for the ideal I in the example following Corollary 28 with respect to the grlex monomial ordering. (Note that while this gives three generators for I rather than two for the lexicographic ordering as in the example, the degrees are smaller.)

28. Let $I = (x^4 - y^4 + z^3 - 1, x^3 + y^2 + z^2 - 1)$. Show that there are five elements in a reduced Grobner basis for I with respect to the lexicographic ordering with $x > y > z$ (the maximum degree among the five generators is 12 and the maximum number of monomial terms among the five generators is 35), that there are two elements for the lexicographic ordering $y > z > x$ (maximum degree is 6 and maximum number of

terms is 8), and that $\{x^3+y^2+z^2-1, xy^2+xz^2-x+y^4-z^3+1\}$ is the reduced Grobner basis for the grevlex monomial ordering.

29. Solve the system of equations $x^2-yz=3$, $y^2-xz=4$, $z^2-xy=5$ over $\mathbb{C}$.

30. Find a Grobner basis for the ideal $I=(x^2+xy+y^2-1, x^2+4y^2-4)$ for the lexicographic ordering $x>y$ and use it to find the four points of intersection of the ellipse $x^2+xy+y^2=1$ with the ellipse $x^2+4y^2=4$ in $\mathbb{R}^2$.

31. Use Grobner bases to find all six solutions to the system of equations $2x^3+2x^2y^2+3y^3=0$ and $3x^5+2x^3y^3+2y^5=0$ over $\mathbb{C}$.

32. Use Grobner bases to show that $(x,z)\cap(y^2,x-yz)=(xy,x-yz)$ in $F[x,y,z]$.

33. Use Grobner bases to compute the intersection of the ideals $(x^3y-xy^2+1, x^2y^2-y^3-1)$ and (x^2-y^2, x^3+y^3) in $F[x,y]$.

34.

    (a) Suppose R is an integral domain, $0\neq f\in R$ and I is an ideal in R. Show that if $\{g_1,\ldots,g_s\}$ are generators for the ideal $I\cap(f)$, then $\{g_1/f,\ldots,g_s/f\}$ are generators for the ideal quotient $(I:(f))$.

    (b) If I is an ideal in the commutative ring R and $f_1,\ldots,f_s\in R$, show that the ideal quotient $(I:(f_1,\ldots,f_s))$ is the ideal $\cap_{i=1}^s(I:(f_i))$.

35. If $I=(x^2y+z^3, x+y^3-z, 2y^4z-yz^2-z^3)$ and $J=(x^2y^5, x^3z^4, y^3z^7)$ in $\mathbb{Q}[x,y,z]$ show $(I:J)$ is the ideal $(z^2, y+z, x-z)$. [Use the previous exercise and Proposition 30.]

36. Suppose that K is an ideal in R, that I is an ideal containing K, and that J is any ideal. If $\overline{I}$ and $\overline{J}$ denote the images of I and J in the quotient ring R/K, show that $\overline{(I:J)}=(\overline{I}:\overline{J})$ where $\overline{(I:J)}$ is the image in R/K of the ideal quotient $(I:J)$.

37. Let K be the ideal (y^5-z^4) in $R=\mathbb{Q}[y,z]$. For each of the following pairs of ideals I and J, use the previous two exercises together with Proposition 30 to verify the ideal quotients $(\overline{I}:\overline{J})$ in the ring R/K:

    i. $I=(y^3, y^5-z^4)$, $J=(z)$, $(\overline{I}:\overline{J})=(\overline{y}^3,\overline{z}^3)$.

    ii. $I=(y^3, z, y^5-z^4)$, $J=(y)$, $(\overline{I}:\overline{J})=(\overline{y}^2,\overline{z})$.

    iii. $I=(y, y^3, z, y^5-z^4)$, $J=(1)$, $(\overline{I}:\overline{J})=(\overline{y},\overline{z})$.

38. Prove that the sum and product of two monomial ideals is a monomial ideal by showing that $M+N=(m_i, n_j \mid i\in I,\ j\in J)$, and $MN=(m_in_j \mid i\in I,\ j\in J)$.

39. Show that if $\{M_s \mid s\in S\}$ is any nonempty collection of monomial ideals that is totally ordered under inclusion then $\cup_{s\in S}M_s$ is a monomial ideal. (In particular, the union of any increasing sequence of monomial ideals is a monomial ideal, cf. Exercise 19, Section 7.3.)

40. Prove that the intersection of two monomial ideals is a monomial ideal by showing that $M\cap N=(e_{i,j} \mid i\in I,\ j\in J)$, where $e_{i,j}$ is the least common multiple of m_i and n_j. [Use Exercise 10.]

41. Prove that for any monomial n, the ideal quotient $(M:(n))$ is $(m_i/d_i \mid i\in I)$, where d_i is the greatest common divisor of m_i and n (cf. Exercise 34). Show that if N is finitely generated, then the ideal quotient $(M:N)$ of two monomial ideals is a monomial ideal.

42.

    (a) Show that M is a monomial prime ideal if and only if $M=(S)$ for some subset S of $\{x_1,x_2,\ldots,x_n\}$. (In particular, there are only finitely many monomial prime ideals, and each is finitely generated.)

    (b) Show that $(x_1,\ldots,x_n)$ is the only monomial maximal ideal.

43. (*Dickson's Lemma*—a special case of Hilbert's Basis Theorem) Prove that every monomial ideal in $F[x_1,\ldots,x_n]$ is finitely generated as follows. Let $\mathcal{S}=\{N \mid N \text{ is a monomial ideal that is not finitely generated}\}$, and assume by way of contradiction $\mathcal{S}\neq\emptyset$.

(a) Show that $\mathcal{S}$ contains a maximal element M. [Use Exercise 39 and Zorn's Lemma.]

(b) Show that there are monomials x, y not in M with $xy \in M$. [Use Exercise 42(a).]

(c) For x as in (b), show that M contains a finitely generated monomial ideal M_0 such that $M_0 + (x) = M + (x)$ and $M = M_0 + (x)(M : (x))$, where $(M : (x))$ is the (monomial) ideal quotient (cf. Exercise 41), and $(x)(M : (x))$ is the product of these two ideals. Deduce that M is finitely generated, a contradiction which proves $\mathcal{S} = \emptyset$. [Use the maximality of M and previous exercises.]

44. If I is a nonzero ideal in $F[x_1, \ldots, x_n]$, use Dickson's Lemma to prove that $LT(I)$ is finitely generated. Conclude that I has a Grobner basis and deduce Hilbert's Basis Theorem. [cf. Proposition 24.]

45. (*n-colorings of graphs*) A finite *graph* $\mathcal{G}$ of size N is a set of vertices $i \in \{1, 2, \ldots, N\}$ and a collection of *edges* (i, j) connecting vertex i with vertex j. An *n-coloring* of $\mathcal{G}$ is an assignment of one of n colors to each vertex in such a way that vertices connected by an edge have distinct colors. Let F be any field containing at least n elements. If we introduce a variable x_i for each vertex i and represent the n colors by choosing a set S of n distinct elements from F, then an n-coloring of $\mathcal{G}$ is equivalent to assigning a value $x_i = \alpha_i$ for each $i = 1, 2, \ldots, N$ where $\alpha_i \in S$ and $\alpha_i \neq \alpha_j$ if (i, j) is an edge in $\mathcal{G}$. If $f(x) = \prod_{\alpha \in S}(x - \alpha)$ is the polynomial in $F[x]$ of degree n whose roots are the elements in S, then $x_i = \alpha_i$ for some $\alpha_i \in S$ is equivalent to the statement that x_i is a solution to the equation $f(x_i) = 0$. The statement $\alpha_i \neq \alpha_j$ is then the statement that $f(x_i) = f(x_j)$ but $x_i \neq x_j$, so x_i and x_j satisfy the equation $g(x_i, x_j) = 0$, where $g(x_i, x_j)$ is the polynomial $(f(x_i) - f(x_j))/(x_i - x_j)$ in $F[x_i, x_j]$. It follows that finding an *n-coloring* of $\mathcal{G}$ is equivalent to solving the system of equations

$$\begin{cases} f(x_i) = 0, & \text{for } i = 1, 2, \ldots, N, \\ g(x_i, x_j) = 0, & \text{for all edges } (i, j) \text{ in } \mathcal{G} \end{cases}$$

(note also we may use any polynomial g satisfying $\alpha_i \neq \alpha_j$ if $g(\alpha_i, \alpha_j) = 0$). It follows by "Hilbert's Nullstellensatz" (cf. Corollary 33 in Section 15.3) that this system of equations has a solution, hence $\mathcal{G}$ has an n-coloring, unless the ideal I in $F[x_1, x_2, \ldots, x_N]$ generated by the polynomials $f(x_i)$ for $i = 1, 2, \ldots, N$, together with the polynomials $g(x_i, x_j)$ for all the edges (i, j) in the graph $\mathcal{G}$, is not a proper ideal. This in turn is equivalent to the statement that the reduced Grobner basis for I (with respect to any monomial ordering) is simply $\{1\}$. Further, when an n-coloring does exist, solving this system of equations as in the examples following Proposition 29 provides an explicit coloring for $\mathcal{G}$.

There are many possible choices of field F and set S. For example, use any field F containing a set S of distinct n^{th} roots of unity, in which case $f(x) = x^n - 1$ and we may take $g(x_i, x_j) = (x_i^n - x_j^n)/(x_i - x_j) = x_i^{n-1} + x_i^{n-2}x_j + \cdots + x_i x_j^{n-2} + x_j^{n-1}$, or use any subset S of $F = \mathbb{F}_p$ with a prime $p \geq n$ (in the special case $n = p$, then, by Fermat's Little Theorem, we have $f(x) = x^p - x$ and $g(x_i, x_j) = (x_i - x_j)^{p-1} - 1$).

(a) Consider a possible 3-coloring of the graph $\mathcal{G}$ with eight vertices and 14 edges $(1,3)$, $(1,4)$, $(1,5)$, $(2,4)$, $(2,7)$, $(2,8)$, $(3,4)$, $(3,6)$, $(3,8)$, $(4,5)$, $(5,6)$, $(6,7)$, $(6,8)$, $(7,8)$. Take $F = \mathbb{F}_3$ with "colors" $0, 1, 2 \in \mathbb{F}_3$ and suppose vertex 1 is colored by 0. In this case $f(x) = x(x-1)(x-2) = x^3 - x \in \mathbb{F}_3[x]$ and $g(x_i, x_j) = x_i^2 + x_i x_j + x_j^2 - 1$. If I is the ideal generated by x_1, $x_i^3 - x_i$, $2 \leq i \leq 8$ and $g(x_i, x_j)$ for the edges (i, j) in $\mathcal{G}$, show that the reduced Grobner basis for I with respect to the lexicographic monomial ordering $x_1 > x_2 > \cdots > x_8$ is $\{x_1, x_2, x_3 + x_8, x_4 + 2x_8, x_5 + x_8, x_6, x_7 + x_8, x_8^2 + 2\}$. Deduce that $\mathcal{G}$ has two distinct 3-colorings, determined by the coloring of vertex 8 (which must be colored by a nonzero element in $\mathbb{F}_3$), and exhibit the colorings of $\mathcal{G}$. Show that if the edge $(3, 7)$ is added to $\mathcal{G}$ then the graph cannot be 3-colored.

(b) Take $F = \mathbb{F}_5$ with four "colors" $1, 2, 3, 4 \in \mathbb{F}_5$, so $f(x) = x^4 - 1$ and we may use $g(x_i, x_j) = x_i^3 + x_i^2 x_j + x_i x_j^2 + x_j^3$. Show that the graph $\mathcal{G}$ with five vertices having 9 edges $(1,3)$, $(1,4)$, $(1,5)$, $(2,3)$, $(2,4)$, $(2,5)$, $(3,4)$, $(3,5)$, $(4,5)$ (the "complete graph on five vertices" with one edge removed) can be 4-colored but cannot be 3-colored.

(c) Use Grobner bases to show that the graph $\mathcal{G}$ with nine vertices and 22 edges $(1,4)$, $(1,6)$, $(1,7)$, $(1,8)$, $(2,3)$, $(2,4)$, $(2,6)$, $(2,7)$, $(3,5)$, $(3,7)$, $(3,9)$, $(4,5)$, $(4,6)$, $(4,7)$, $(4,9)$, $(5,6)$, $(5,7)$, $(5,8)$, $(5,9)$, $(6,7)$, $(6,9)$, $(7,8)$ has precisely four 4-colorings up to a permutation of the colors (so a total of 96 total 4-colorings). Show that if the edge $(1, 5)$ is added then $\mathcal{G}$ cannot be 4-colored.

Practice problems.

1. For each pair, perform polynomial division in $\mathbb{Q}[x]$, finding q, r with $f = qg + r$ and $\deg r < \deg g$ (or $r = 0$):
   (a) $f = 2x^4 - 3x^3 + x - 5$, $g = x^2 - 1$.
   (b) $f = x^3 + x^2 + x + 1$, $g = 2x + 1$.
2. Compute $\gcd(f, g)$ in $\mathbb{Q}[x]$ by the Euclidean algorithm, and express it as $af + bg$:
$$f = x^4 - 1, \qquad g = x^3 - x^2 + x - 1.$$
3. Compute the content $\operatorname{cont}(f)$ and the primitive part of each $f \in \mathbb{Z}[x]$:
   (a) $f = 6x^3 - 9x^2 + 15x - 3$.
   (b) $f = 10x^4 + 25x^2 - 15$.
4. Verify Gauss's Lemma on a concrete case: let $f = 2x^2 + 4x + 2$ and $g = 3x^2 - 3$ in $\mathbb{Z}[x]$. Compute $\operatorname{cont}(f)$, $\operatorname{cont}(g)$, and $\operatorname{cont}(fg)$, and confirm $\operatorname{cont}(fg) = \operatorname{cont}(f)\operatorname{cont}(g)$.
5. Factor completely into irreducibles in $\mathbb{Z}[x]$:
   (a) $x^4 - 1$.
   (b) $2x^3 - x^2 - 2x + 1$.
   (c) $x^4 + 4$.
6. Use the Rational Root Theorem to list all possible rational roots of $f = 3x^3 - 2x^2 + 6x - 4$, then find all actual rational roots and factor f in $\mathbb{Q}[x]$.
7. Determine whether each polynomial is irreducible in $\mathbb{Q}[x]$ by reducing mod a suitable prime p:
   (a) $x^4 + x + 1$ (try $p = 2$).
   (b) $x^3 - x + 1$ (try $p = 2$).
   (c) $x^4 + x^3 + x^2 + x + 1$ (try $p = 2$ and $p = 3$).
8. Apply the Eisenstein criterion to show each is irreducible in $\mathbb{Q}[x]$, naming the prime used:
   (a) $x^5 - 12x^3 + 18x - 6$.
   (b) $2x^4 + 10x^2 + 5$.
   (c) $x^4 + x^3 + x^2 + x + 1$, by substituting $x \mapsto x + 1$ (cyclotomic Φ_5).
9. Show $x^3 + x + 1$ is irreducible in $\mathbb{F}_2[x]$, and deduce that $\mathbb{F}_2[x]/(x^3 + x + 1)$ is a field. How many elements does it have?
10. Fix the lex monomial order with $x > y > z$. For $f = 3x^2y - 2xy^2 + xz^3 + y^4$, identify $\operatorname{multideg}(f)$, $\operatorname{LM}(f)$, $\operatorname{LC}(f)$, and $\operatorname{LT}(f)$.
11. For $f = 4xy^2z + 4x^2y - 5x^3 + 7x^2z^2$, list the leading term $\operatorname{LT}(f)$ under each of: (a) lex with $x > y > z$; (b) grlex with $x > y > z$; (c) grevlex with $x > y > z$.
12. Compute the S-polynomial $S(f, g)$ in $\mathbb{Q}[x, y]$ under lex with $x > y$ for $f = x^2y - 1$ and $g = xy^2 - x$.
13. Using lex with $x > y$, divide $f = x^2y + xy^2 + y^2$ by the ordered list $(g_1, g_2) = (xy - 1,\ y^2 - 1)$, giving the quotients and the remainder.
14. Let $I = (x^2 - y,\ x^3 - z) \subseteq \mathbb{Q}[x, y, z]$. Using lex with $x > y > z$, compute $S(g_1, g_2)$ for $g_1 = x^2 - y$, $g_2 = x^3 - z$ and reduce it modulo $\{g_1, g_2\}$; state whether you obtained a new generator.
15. Decide, using Eisenstein after a shift if needed, whether $x^4 + 4x^3 + 6x^2 + 4x + 6$ is irreducible in $\mathbb{Q}[x]$.

Additional exercises.

1. Show that $f = x^4 - 10x^2 + 1$ is irreducible in $\mathbb{Q}[x]$ but reducible in $\mathbb{F}_p[x]$ for every prime p. (Hint: its roots are $\pm\sqrt{2} \pm \sqrt{3}$; modulo p, at least one of 2, 3, 6 is a square.)
2. Let R be a UFD with field of fractions F. Prove that a nonconstant $f \in R[x]$ is irreducible in $R[x]$ if and only if it is primitive and irreducible in $F[x]$.
3. Prove that the polynomial $f = x^p - x - 1 \in \mathbb{F}_p[x]$ (for p prime) has no root in $\mathbb{F}_p$, and in fact is irreducible over $\mathbb{F}_p$. (Hint: if α is a root then so is $\alpha + 1$.)
4. Run Buchberger's algorithm on $I = (x^2 - y,\ x^2 - z) \subseteq \mathbb{Q}[x, y, z]$ under lex with $x > y > z$ to produce a Grobner basis. Then use it to decide whether $y - z \in I$ and whether $xy - xz \in I$.
5. Let $G = \{g_1, \ldots, g_t\}$ be a Grobner basis for an ideal I under a fixed monomial order. Prove that $f \in I$ if and only if the remainder of f on division by G is 0, and that this remainder is independent of the order in which the g_i are listed.
6. Determine all primes p for which $x^4 + 1$ factors into two quadratics in $\mathbb{F}_p[x]$, and conclude that $x^4 + 1$ is irreducible in $\mathbb{Q}[x]$ yet reducible modulo every prime p.

Commutative-diagram exercises.

1. Let p be prime and consider the reduction-mod-p ring homomorphism. Identify its kernel and explain why it sends a polynomial to its coefficient-wise reduction:

$$\mathbb{Z}[x] \xrightarrow{\text{mod } p} \mathbb{F}_p[x].$$

   Use it to show that if a monic $f \in \mathbb{Z}[x]$ has irreducible image in $\mathbb{F}_p[x]$ for some p, then f is irreducible in $\mathbb{Q}[x]$. Give a monic example where the image is reducible mod 2 but f is still irreducible over $\mathbb{Q}$.

2. Let $p = x^2 + 1 \in \mathbb{R}[x]$. Show p is irreducible, so the top row below realizes a field, and identify that field with $\mathbb{C}$ via the indicated isomorphism:

$$\mathbb{R}[x] \twoheadrightarrow \mathbb{R}[x]/(x^2 + 1) \xrightarrow{\cong} \mathbb{C}.$$

   Describe the image of $\bar{x}$ and write the inverse map $\mathbb{C} \to \mathbb{R}[x]/(x^2 + 1)$.

3. Let $q = x^2 + x + 1 \in \mathbb{F}_2[x]$. Verify q is irreducible, so $\mathbb{F}_2[x]/(q)$ is a field; determine its order. List its elements and the multiplication table data needed to confirm $\bar{x}$ is a generator of the multiplicative group, summarizing the construction by:

$$\mathbb{F}_2[x] \twoheadrightarrow \mathbb{F}_2[x]/(x^2 + x + 1) \xrightarrow{\cong} \mathbb{F}_4.$$

4. Consider factoring $f = 2x^2 - 4$ in $\mathbb{Z}[x]$ versus in $\mathbb{Q}[x] = \mathrm{Frac}(\mathbb{Z})[x]$. Using the inclusion

$$\mathbb{Z}[x] \hookrightarrow \mathbb{Q}[x]$$

   explain how f is reducible in $\mathbb{Z}[x]$ as $2(x^2 - 2)$ (a product of two nonunits, since 2 is not a unit of $\mathbb{Z}[x]$) while $x^2 - 2$ stays irreducible in $\mathbb{Q}[x]$, and contrast this with the notion of irreducibility used in $\mathbb{Q}[x]$ (where the constant 2 is a unit, so $2(x^2 - 2)$ and $x^2 - 2$ are associates).

5. Let p be an odd prime and $f = x^{p-1} + x^{p-2} + \cdots + x + 1$. Using the substitution isomorphism $\sigma : \mathbb{Z}[x] \to \mathbb{Z}[x]$, $x \mapsto x + 1$, which fits into

$$\mathbb{Z}[x] \xrightarrow[\cong]{\sigma} \mathbb{Z}[x] \xrightarrow{\text{mod } p} \mathbb{F}_p[x],$$

   show $f(x + 1)$ is Eisenstein at p, and conclude f is irreducible in $\mathbb{Q}[x]$. Identify $\overline{f(x + 1)} \in \mathbb{F}_p[x]$ explicitly.

Easy

DF 9.1.1 For $p = 2x^2y - 3xy^3z + 4y^2z^5$ and $q = 7x^2 + 5x^2y^3z^4 - 3x^2z^3$ in $\mathbb{Z}[x, y, z]$: write each as a polynomial in x over $\mathbb{Z}[y, z]$, find total degree and degree in each variable, compute pq with its degrees, and write pq as a polynomial in z over $\mathbb{Z}[x, y]$.

DF 9.1.2 Repeat the preceding computations with the coefficients of p and q taken in $\mathbb{Z}/3\mathbb{Z}$.

DF 9.1.16 If $p(x_1, \ldots, x_n)$ is homogeneous of degree k, prove $p(\lambda x_1, \ldots, \lambda x_n) = \lambda^k p(x_1, \ldots, x_n)$ for all $\lambda \in R$.

DF 9.2.4 If $f(x)$ is obtained from $g(x)$ by multiplying every coefficient by a fixed nonzero element of F, show $\gcd(f, g)$ is unchanged under replacing f by any associate.

DF 9.2.8 Find $\gcd(x^3 - 2,\ x + 1)$ in $\mathbb{Q}[x]$ and write it as a $\mathbb{Q}[x]$-linear combination of the two polynomials.

DF 9.2.9 Find $\gcd(x^5 + 2x^3 + x^2 + x + 1,\ x^4 + 2x^3 + x^2 - 1)$ in $\mathbb{Q}[x]$ and express it as a linear combination of the two.

DF 9.2.10 Find $\gcd(x^3 + 4x^2 + x - 6,\ x^5 - 6x + 5)$ in $\mathbb{Q}[x]$ and express it as a linear combination of the two.

DF 9.4.1 Decide irreducibility (and factor when reducible): (a) $x^2 + x + 1$ in $\mathbb{F}_2[x]$; (b) $x^3 + x + 1$ in $\mathbb{F}_3[x]$; (c) $x^4 + 1$ in $\mathbb{F}_5[x]$; (d) $x^4 + 10x^2 + 1$ in $\mathbb{Z}[x]$.

DF 9.4.5 Find all monic irreducible polynomials of degree ≤ 3 in $\mathbb{F}_2[x]$, and the same in $\mathbb{F}_3[x]$.

DF 9.4.7 Prove that $\mathbb{R}[x]/(x^2 + 1)$ is a field isomorphic to $\mathbb{C}$.

DF 9.4.14 Factor $x^8 - 1$ and $x^6 - 1$ into irreducibles over each of $\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z}$, and $\mathbb{Z}/3\mathbb{Z}$.

Fraleigh 27.1 Find the sum and product of $f(x) = 4x - 5$ and $g(x) = 2x^2 - 4x + 2$ in $\mathbb{Z}_8[x]$.

Fraleigh 27.2 Find the sum and product of $f(x) = x + 1$ and $g(x) = x + 1$ in $\mathbb{Z}_2[x]$.

Fraleigh 27.3 Find the sum and product of $f(x) = 2x^2 + 3x + 4$ and $g(x) = 3x^2 + 2x + 3$ in $\mathbb{Z}_6[x]$.

Fraleigh 27.4 Find the sum and product of $f(x) = 2x^3 + 4x^2 + 3x + 2$ and $g(x) = 3x^4 + 2x + 4$ in $\mathbb{Z}_5[x]$.

Fraleigh 27.5 How many polynomials of degree ≤ 3 are there in $\mathbb{Z}_2[x]$ (include 0)?

Fraleigh 27.6 How many polynomials of degree ≤ 2 are there in $\mathbb{Z}_5[x]$ (include 0)?

Fraleigh 27.7 With $F = E = \mathbb{C}$, compute the evaluation $\varphi_2(x^2 + 3)$.

Fraleigh 27.8 With $F = E = \mathbb{C}$, compute $\varphi_i(2x^3 - x^2 + 3x + 2)$.

Fraleigh 27.9 With $F = E = \mathbb{Z}_7$, compute $\varphi_3[(x^4 + 2x)(x^3 - 3x^2 + 3)]$.

Fraleigh 27.10 With $F = E = \mathbb{Z}_7$, compute $\varphi_5[(x^3 + 2)(4x^2 + 3)(x^7 + 3x^2 + 1)]$.

Fraleigh 27.11 With $F = E = \mathbb{Z}_7$, compute $\varphi_4(3x^{106} + 5x^{99} + 2x^{53})$ using Fermat's theorem.

Fraleigh 27.12 Find all zeros of $x^2 + 1$ in $\mathbb{Z}_2$.

Fraleigh 27.13 Find all zeros of $x^3 + 2x + 2$ in $\mathbb{Z}_7$.

Fraleigh 27.14 Find all zeros of $x^5 + 3x^3 + x^2 + 2x$ in $\mathbb{Z}_5$.

Fraleigh 27.15 Find all zeros of $f(x)g(x)$ in $\mathbb{Z}_7$, where $f(x) = x^3 + 2x^2 + 5$ and $g(x) = 3x^2 + 2x$.

Fraleigh 27.16 Using Fermat's theorem, evaluate $\varphi_3(x^{231} + 3x^{117} - 2x^{53} + 1)$ for $\varphi_3 : \mathbb{Z}_5[x] \to \mathbb{Z}_5$.

Fraleigh 27.17 Using Fermat's theorem, find all zeros in $\mathbb{Z}_5$ of $2x^{219} + 3x^{74} + 2x^{57} + 3x^{44}$.

Fraleigh 27.18 Correct, if needed, the definition: a polynomial with coefficients in a ring R is an infinite formal sum $\sum_{i \geq 0} a_i x^i$ with each $a_i \in R$.

Fraleigh 27.19 Correct, if needed, the definition: a zero of $f(x) \in F[x]$ is an $\alpha \in F$ with $\varphi_\alpha(f(x)) = 0$, where φ_α is evaluation at α.

Fraleigh 27.20 Rewrite $f(x, y) = (3x^3 + 2x)y^3 + (x^2 - 6x + 1)y^2 + (x^4 - 2x)y + (x^4 - 3x^2 + 2)$ as an element of $(\mathbb{Q}[y])[x]$.

Fraleigh 27.21 For the evaluation homomorphism $\varphi_5 : \mathbb{Q}[x] \to \mathbb{R}$, find six elements in its kernel.

Fraleigh 27.22 Find a polynomial of degree > 0 in $\mathbb{Z}_4[x]$ that is a unit.

Fraleigh 27.23 Decide true or false for ten statements about $R[x]$: degree behavior of products, when $R[x]$ is commutative or an integral domain, zero divisors and units in $R[x]$, and zeros of f versus fg.

Fraleigh 27.25 Let D be an integral domain: (a) describe the units of $D[x]$; (b) find the units of $\mathbb{Z}[x]$; (c) find the units of $\mathbb{Z}_7[x]$.

Fraleigh 28.1 Find $q(x), r(x)$ with $f = gq + r$ for $f = x^6 + 3x^5 + 4x^2 - 3x + 2$, $g = x^2 + 2x - 3$ in $\mathbb{Z}_7[x]$.

Fraleigh 28.2 Find $q(x), r(x)$ for $f = x^6 + 3x^5 + 4x^2 - 3x + 2$, $g = 3x^2 + 2x - 3$ in $\mathbb{Z}_7[x]$.

Fraleigh 28.3 Find $q(x), r(x)$ for $f = x^5 - 2x^4 + 3x - 5$, $g = 2x + 1$ in $\mathbb{Z}_{11}[x]$.

Fraleigh 28.4 Find $q(x), r(x)$ for $f = x^4 + 5x^3 - 3x^2$, $g = 5x^2 - x + 2$ in $\mathbb{Z}_{11}[x]$.

Fraleigh 28.5 Find all generators of the cyclic multiplicative group of units of $\mathbb{Z}_5$.

Fraleigh 28.6 Find all generators of the cyclic multiplicative group of units of $\mathbb{Z}_7$.

Fraleigh 28.7 Find all generators of the cyclic multiplicative group of units of $\mathbb{Z}_{17}$.

Fraleigh 28.8 Find all generators of the cyclic multiplicative group of units of $\mathbb{Z}_{23}$.

Fraleigh 28.9 Factor $x^4 + 4$ into linear factors in $\mathbb{Z}_5[x]$.

Fraleigh 28.10 Factor $x^3 + 2x^2 + 2x + 1$ into linear factors in $\mathbb{Z}_7[x]$.

Fraleigh 28.11 Factor $2x^3 + 3x^2 - 7x - 5$ into linear factors in $\mathbb{Z}_{11}[x]$.

Fraleigh 28.12 Is $x^3 + 2x + 3$ irreducible in $\mathbb{Z}_5[x]$? Justify and express it as a product of irreducibles in $\mathbb{Z}_5[x]$.

Fraleigh 28.13 Is $2x^3 + x^2 + 2x + 2$ irreducible in $\mathbb{Z}_5[x]$? Justify and factor into irreducibles in $\mathbb{Z}_5[x]$.

Fraleigh 28.14 Show $f(x) = x^2 + 8x - 2$ is irreducible over $\mathbb{Q}$; decide whether it is irreducible over $\mathbb{R}$ and over $\mathbb{C}$.

Fraleigh 28.15 Show $g(x) = x^2 + 6x + 12$ is irreducible over $\mathbb{Q}$; decide irreducibility over $\mathbb{R}$ and $\mathbb{C}$.

Fraleigh 28.16 Show $x^3 + 3x^2 - 8$ is irreducible over $\mathbb{Q}$.

Fraleigh 28.17 Show $x^4 - 22x^2 + 1$ is irreducible over $\mathbb{Q}$.

Fraleigh 28.18 Determine whether $x^2 - 12$ satisfies an Eisenstein criterion for irreducibility over $\mathbb{Q}$.

Fraleigh 28.19 Determine whether $8x^3 + 6x^2 - 9x + 24$ satisfies an Eisenstein criterion over $\mathbb{Q}$.

Fraleigh 28.20 Determine whether $4x^{10} - 9x^3 + 24x - 18$ satisfies an Eisenstein criterion over $\mathbb{Q}$.

Fraleigh 28.21 Determine whether $2x^{10} - 25x^3 + 10x^2 - 30$ satisfies an Eisenstein criterion over $\mathbb{Q}$.

Fraleigh 28.22 Find all zeros of $6x^4 + 17x^3 + 7x^2 + x - 10$ in $\mathbb{Q}$.

Fraleigh 28.23 Correct, if needed, the definition: $f(x) \in F[x]$ is irreducible over F iff $f \neq gh$ for any $g, h \in F[x]$.

Fraleigh 28.24 Correct, if needed, the definition: a nonconstant $f(x) \in F[x]$ is irreducible over F iff in any factorization in $F[x]$ one factor lies in F.

Fraleigh 28.25 Decide true or false for ten statements: irreducibility of various linear and quadratic polynomials, units of $F[x]$ and $F(x)$, and bounds on the number of zeros of a degree-n polynomial.

Fraleigh 28.26 Find all primes p such that $x + 2$ is a factor of $x^4 + x^3 + x^2 - x + 1$ in $\mathbb{Z}_p[x]$.

Fraleigh 28.27 Find all irreducible polynomials of degree 2 in $\mathbb{Z}_2[x]$.

Fraleigh 28.28 Find all irreducible polynomials of degree 3 in $\mathbb{Z}_2[x]$.

Fraleigh 28.29 Find all irreducible polynomials of degree 2 in $\mathbb{Z}_3[x]$.

Fraleigh 28.30 Find all irreducible polynomials of degree 3 in $\mathbb{Z}_3[x]$.

Fraleigh 28.32 Give a synopsis of the proof that a degree-n polynomial over a field has at most n zeros.

Fraleigh 28.33 Give a synopsis of the proof that a finite subgroup of $F^\times$ is cyclic.

Fraleigh 28.36 (Remainder Theorem) For $f(x) \in F[x]$ and $\alpha \in F$, show the remainder on dividing $f(x)$ by $x - \alpha$ is $f(\alpha)$.

Fraleigh 29.1 A code has word length 10 and rate 1/2; how many code words does it contain?

Fraleigh 29.2 A linear code has exactly 16 code words and rate 2/3; find the code-word length.

Fraleigh 29.6 Decide true or false for ten statements about codes: subsets of $\mathbb{Z}_2^n$, word length, linearity, error detection/correction thresholds, information rate, and the zero code word.

Fraleigh 38.1 Write $2xy^3z^5 - 5x^2yz^3 + 7x^2y^2z - 3x^3$ in decreasing term order under lex with $z < y < x$.

Fraleigh 38.2 Write $3y^2z^5 - 4x + 5y^3z^3 - 8z^7$ in decreasing term order under lex with $z < y < x$.

Fraleigh 38.3 Write $3y - 7x + 10z^3 - 2xy^2z^2 + 2x^2yz^2$ in decreasing term order under lex with $z < y < x$.

Fraleigh 38.4 Write $38 - 4xz + 2yz - 8xy + 3yz^3$ in decreasing term order under lex with $z < y < x$.

Fraleigh 38.5 Reorder the polynomial of Exercise 38.1 in decreasing term order under lex with $x < y < z$.

Fraleigh 38.6 Reorder the polynomial of Exercise 38.2 in decreasing term order under lex with $x < y < z$.

Fraleigh 38.7 Reorder the polynomial of Exercise 38.3 in decreasing term order under lex with $x < y < z$.

Fraleigh 38.8 Reorder the polynomial of Exercise 38.4 in decreasing term order under lex with $x < y < z$.

Fraleigh 38.9 List, in increasing order, the smallest 20 power products in $\mathbb{R}[x, y, z]$ for deglex with $z < y < x$.

Fraleigh 38.10 Write the polynomial of Exercise 38.1 in decreasing term order under deglex with $z < y < x$.

Fraleigh 38.11 Write the polynomial of Exercise 38.2 in decreasing term order under deglex with $z < y < x$.

Fraleigh 38.12 Write the polynomial of Exercise 38.3 in decreasing term order under deglex with $z < y < x$.

Fraleigh 38.13 Write the polynomial of Exercise 38.4 in decreasing term order under deglex with $z < y < x$.

Fraleigh 38.27 Decide true or false for ten statements about Grobner bases: independence, the bases $\{1\}$ and $\{0\}$, order dependence, power-product comparisons, and graph coloring.

Fraleigh 38.28 In $\mathbb{R}[x, y]$ ordered by lex, give an example showing $P_i < P_j$ need not imply P_i divides P_j.

Medium

DF 9.1.3 If R is commutative and $x_1, \ldots, x_n$ are independent variables, prove $R[x_{\pi(1)}, \ldots, x_{\pi(n)}] \cong R[x_1, \ldots, x_n]$ for any permutation π.

DF 9.1.4 Prove that (x) and (x, y) are prime ideals in $\mathbb{Q}[x, y]$ but only (x, y) is maximal.

DF 9.1.5 Prove that (x, y) and $(2, x, y)$ are prime ideals in $\mathbb{Z}[x, y]$ but only $(2, x, y)$ is maximal.

DF 9.1.6 Prove that (x, y) is not a principal ideal in $\mathbb{Q}[x, y]$.

DF 9.1.7 Let R be a commutative ring with 1. Prove that a polynomial ring in more than one variable over R is never a PID.

DF 9.1.11 Show the radical of $I = (x, y^2)$ in $\mathbb{Q}[x, y]$ is (x, y); deduce I is primary but not a power of a prime ideal.

DF 9.1.13 Prove that $F[x, y]/(y^2 - x)$ and $F[x, y]/(y^2 - x^2)$ are not isomorphic for any field F.

DF 9.1.17 Prove that the product of two homogeneous polynomials is again homogeneous.

DF 9.2.1 For $f(x) \in F[x]$ of degree $n \geq 1$, prove each coset of $F[x]/(f(x))$ has a unique representative of degree $\leq n-1$; equivalently $\overline{1}, \overline{x}, \ldots, \overline{x^{n-1}}$ form an F-basis.

DF 9.2.2 If F is finite of order q and $\deg f = n \geq 1$, prove $F[x]/(f(x))$ has q^n elements.

DF 9.2.3 Prove $F[x]/(f(x))$ is a field iff $f(x)$ is irreducible.

DF 9.2.5 Exhibit all ideals of $F[x]/(p(x))$ in terms of the factorization of $p(x)$.

DF 9.2.6 Describe the ring structure and characteristic of $\mathbb{Z}[x]/(2)$, $\mathbb{Z}[x]/(x)$, $\mathbb{Z}[x]/(x^2)$, $\mathbb{Z}[x]/(2,x)$, $\mathbb{Z}[x]/(2,x^2)$.

DF 9.2.7 Determine all ideals of $\mathbb{Z}[x]/(2, x^3+1)$.

DF 9.3.2 Prove: if $f(x), g(x) \in \mathbb{Q}[x]$ have product with integer coefficients, then any coefficient of g times any coefficient of f is an integer.

DF 9.3.3 For a field F, show $R = \{f \in F[x] : \text{coeff of } x \text{ is } 0\}$ is a subring of $F[x]$ that is not a UFD, using $x^6 = (x^2)^3 = (x^3)^2$.

DF 9.4.2 Prove the following are irreducible in $\mathbb{Z}[x]$: (a) $x^4 - 4x^3 + 6$; (b) $x^6 + 30x^5 - 15x^3 + 6x - 120$; (c) $x^4 + 4x^3 + 6x^2 + 2x + 1$; (d) $((x+2)^p - 2^p)/x$ for p an odd prime.

DF 9.4.6 Construct fields of orders 9, 49, 8, and 81, exhibiting each as $F[x]/(f(x))$.

DF 9.4.8 Prove $K_1 = \mathbb{F}_{11}[x]/(x^2+1)$ and $K_2 = \mathbb{F}_{11}[y]/(y^2+2y+2)$ are fields of 121 elements, and that $p(\overline{x}) \mapsto p(\overline{y}+1)$ is a well-defined ring isomorphism $K_1 \to K_2$.

DF 9.4.9 Prove $p(x) = x^2 - \sqrt{2}$ is irreducible over $\mathbb{Z}[\sqrt{2}]$.

DF 9.4.11 Prove $x^2 + y^2 - 1$ is irreducible in $\mathbb{Q}[x, y]$.

DF 9.4.12 Prove $x^{n-1} + x^{n-2} + \cdots + x + 1$ is irreducible over $\mathbb{Z}$ iff n is prime.

DF 9.4.13 Prove $x^3 + nx + 2$ is irreducible over $\mathbb{Z}$ for all integers $n \neq 1, -3, -5$.

DF 9.4.16 For $f(x)$ of degree n in $F[x]$ with reverse $g(x) = x^n f(1/x)$: describe the coefficients of g, and, if $f(0) \neq 0$, prove f is irreducible iff g is.

DF 9.4.18 Show $6x^5 + 14x^3 - 21x + 35$ and $18x^5 - 30x^2 + 120x + 360$ are irreducible in $\mathbb{Q}[x]$.

DF 9.4.19 Using the derivative criterion, determine whether each has a multiple root: (a) $x^3 - 3x - 2$; (b) $x^3 + 3x + 2$; (c) $x^6 - 4x^4 + 6x^3 + 4x^2 - 12x + 9$ in $\mathbb{Q}[x]$; (d) show $x^p - a$ has a multiple root over $\mathbb{F}_p$.

DF 9.5.1 For a field F and nonconstant $f(x)$, describe the nilradical of $F[x]/(f(x))$ via the factorization of f.

DF 9.5.2 For each field constructed in 9.4.6, exhibit a generator of the cyclic multiplicative group of nonzero elements.

DF 9.5.7 Prove that the additive and multiplicative groups of a field are never isomorphic.

DF 9.6.6 Show $x^3y > x^3z^2 > x^3z > x^2y^2z > x^2y > xz^2 > y^2z^2 > y^2z$ under lex $x > y > z$, and give the corresponding grlex and grevlex orderings of these monomials.

DF 9.6.7 Order the monomials $x^2z, x^2y^2z, xy^2z, x^3y, x^3z^2, x^7, x^2yz^2, x^7z^2$ for lex $(x > y > z)$, grlex, and grevlex.

DF 9.6.8 Show there are $n!$ distinct lexicographic monomial orderings on $F[x_1, \ldots, x_n]$, and likewise $n!$ grlex and $n!$ grevlex orderings.

DF 9.6.10 Prove $f \in (m_1, \ldots, m_k)$ (monomials) iff each term of f is a multiple of some m_j; show $x^2yz + 3xy^2 \in (xyz, y^2)$ but not in (xz^2, y^2).

DF 9.6.17 Fix lex $x > y$ on $F[x, y]$. Use Buchberger's Criterion to show $\{x^2y - y^2,\ x^3 - xy\}$ is a Grobner basis for $I = (x^2y - y^2, x^3 - xy)$.

DF 9.6.18 Show $\{x - y^3,\ y^6 - y^5\}$ is the reduced Grobner basis for $I = (x - y^3, -x^2 + xy^2)$ under lex $x > y$.

DF 9.6.20 Show $\{x^2 + xy + z,\ xyz + z^2,\ xz^2,\ z^3\}$ is the reduced Grobner basis for $I = (x^2 + xy + z, xyz + z^2)$ under lex $x > y > z$, and conclude $LT(I)$ needs four generators.

DF 9.6.24 Show $\{x^3 - y^3,\ x^2 + xy^2 + y^4,\ x^2y + xy^3 + y^2\}$ is a reduced Grobner basis with respect to grlex.

DF 9.6.26 Solve $x^2 - yz = 3$, $y^2 - xz = 4$, $z^2 - xy = 5$ over $\mathbb{C}$.

DF 9.6.31 Sum/product of monomial ideals: prove $M + N = (m_i, n_j)$ and $MN = (m_i n_j)$, so each is a monomial ideal.

DF 9.6.33 Prove the intersection of two monomial ideals is a monomial ideal via $M \cap N = (\text{lcm}(m_i, n_j))$.

DF 9.6.39 Use Dickson's Lemma to prove $LT(I)$ is finitely generated, so I has a Grobner basis, and deduce Hilbert's Basis Theorem.

Fraleigh 27.24 Prove that if D is an integral domain, then $D[x]$ is an integral domain.

Fraleigh 27.26 Prove the left distributive law in $R[x]$, for R a ring and x an indeterminate.

Fraleigh 27.27 For F of characteristic zero and D formal differentiation: show D is an additive group homomorphism (is it a ring homomorphism?), and find its kernel and image.

Fraleigh 27.28 (a) State and define the evaluation homomorphism $\varphi_{\alpha_1,\ldots,\alpha_n} : F[x_1, \ldots, x_n] \to E$; (b) compute $\varphi_{-3,2}(x_1^2 x_2^3 + 3x_1^4 x_2)$; (c) define a zero of $f(x_1, \ldots, x_n)$.

Fraleigh 27.30 Let P_F be the polynomial functions on a field F: (a) show P_F is a subring of F^F; (b) show P_F need not be isomorphic to $F[x]$.

Fraleigh 27.32 For a ring homomorphism $\varphi : R_1 \to R_2$, show there is a unique ring homomorphism $\psi : R_1[x] \to R_2[x]$ with $\psi|_{R_1} = \varphi$ and $\psi(x) = x$.

Fraleigh 28.31 Find the number of irreducible quadratic polynomials in $\mathbb{Z}_p[x]$ for p prime.

Fraleigh 28.34 Show that for p prime, $x^p + a$ in $\mathbb{Z}_p[x]$ is reducible for every $a \in \mathbb{Z}_p$.

Fraleigh 28.35 If $a \neq 0$ is a zero of $f(x) = a_0 + a_1 x + \cdots + a_n x^n$ in $F[x]$, show $1/a$ is a zero of $a_n + a_{n-1}x + \cdots + a_0 x^n$.

Fraleigh 28.37 For the reduction map $\sigma_m : \mathbb{Z}[x] \to \mathbb{Z}_m[x]$: (a) show it is a homomorphism onto; (b) show if f and $\sigma_m(f)$ have degree n and $\sigma_m(f)$ does not factor into lower-degree polynomials in $\mathbb{Z}_m[x]$, then f is irreducible in $\mathbb{Q}[x]$; (c) deduce $x^3 + 17x + 36$ is irreducible in $\mathbb{Q}[x]$.

Fraleigh 28.38 Prove that the product of two primitive polynomials in $\mathbb{Z}[x]$ is primitive.

Fraleigh 29.3 Find the smallest cyclic linear code C containing $(1, 0, 0, 0, 0)$.

Fraleigh 29.4 Find all cyclic linear codes C in $\mathbb{Z}_2^5$ with transmission rate $2/5$.

Fraleigh 29.5 Find all cyclic linear codes of length n for (a) $n = 2$, (b) $n = 3$, (c) $n = 4$.

Fraleigh 38.14 Under lex $z < y < x$, perform a single-step reduction lowering the maximum term order of $\langle xy^2 - 2x,\ x^2y + 4xy,\ xy - y^2\rangle$.

Fraleigh 38.15 Under lex $z < y < x$, perform a single-step reduction on $\langle xy + y^3,\ y^3 + z,\ x - y^4\rangle$.

Fraleigh 38.16 Under lex $z < y < x$, perform a single-step reduction on $\langle xyz - 3z^2,\ x^3 + y^2z^3,\ x^2yz^3 + 4\rangle$.

Fraleigh 38.17 Under lex $z < y < x$, perform a single-step reduction on $\langle y^2z^3 + 3,\ y^3z^2 - 2z,\ y^2z^2 + 3\rangle$.

Fraleigh 38.18 Under lex $z < y < x < w$ on $\mathbb{R}[w, x, y, z]$, find a Grobner basis for $\langle w + x - y + 4z - 3,\ 2w + x + y - 2z + 4,\ w + 3x - 3y + z - 5\rangle$.

Fraleigh 38.19 Under lex $z < y < x < w$, find a Grobner basis for $\langle w - 4x + 3y - z + 2,\ 2w - 2x + y - 2z + 5,\ w - 10x + 8y - z - 1\rangle$.

Fraleigh 38.20 Find a Grobner basis in $\mathbb{R}[x]$ for $\langle x^4 + x^3 - 3x^2 - 4x - 4,\ x^3 + x^2 - 4x - 4\rangle$.

Fraleigh 38.21 Find a Grobner basis in $\mathbb{R}[x]$ for $\langle x^4 - 4x^3 + 5x^2 - 2x,\ x^3 - x^2 - 4x + 4,\ x^3 - 3x + 2\rangle$.

Fraleigh 38.22 Find a Grobner basis in $\mathbb{R}[x]$ for $\langle x^5 + x^2 + 2x - 5,\ x^3 - x^2 + x - 1\rangle$.

Fraleigh 38.23 Under lex $y < x$ on $\mathbb{R}[x, y]$, find a Grobner basis for $\langle x^2y - x - 2,\ xy + 2y - 9\rangle$ and describe the variety.

Fraleigh 38.24 Under lex $y < x$, find a Grobner basis for $\langle x^2y + x,\ xy^2 - y\rangle$ and describe the variety.

Fraleigh 38.25 Under lex $y < x$, find a Grobner basis for $\langle x^2y + x + 1,\ xy^2 + y - 1\rangle$ and describe the variety.

Fraleigh 38.26 Under lex $y < x$, find a Grobner basis for $\langle x^2y + xy^2,\ xy - x\rangle$ and describe the variety.

Fraleigh 38.29 Determine which other orderings of the indeterminates a, c, x, y, d_1, d_2 would be expected to yield the equation of an ellipse from a Grobner basis computation.

Fraleigh 38.32 Show $\{xy,\ y^2 - y\}$ is a Grobner basis for $\langle xy, y^2 - y\rangle$.

Fraleigh 38.33 Show $\{-4yp + x^2,\ d - y - p\}$ is a Grobner basis for $\langle -4yp + x^2,\ d - y - p\rangle$.

Hard

DF 9.1.8 For $R = F[x, x^2y, x^3y^2, \dots, x^ny^{n-1}, \dots] \subset F[x, y]$: (a) prove $\mathrm{Frac}(R) = \mathrm{Frac}(F[x, y])$; (b) prove R contains an ideal that is not finitely generated.

DF 9.1.9 Prove a polynomial ring in infinitely many variables over any commutative ring contains ideals that are not finitely generated.

DF 9.1.10 Prove $\mathbb{Z}[x_1, x_2, x_3, \dots]/(x_1x_2, x_3x_4, x_5x_6, \dots)$ contains infinitely many minimal prime ideals.

DF 9.1.12 In $R = \mathbb{Q}[x, y, z]$ with bars denoting passage to $\mathbb{Q}[x, y, z]/(xy - z^2)$: prove $\overline{P} = (\overline{x}, \overline{z})$ is prime, show $\overline{xy} \in \overline{P}^2$ but no power of $\overline{y}$ lies in $\overline{P}^2$.

DF 9.1.14 For an integral domain R and coprime integers i, j, prove $(x^i - y^j)$ is a prime ideal in $R[x, y]$.

DF 9.1.18 Prove an ideal of $R[x_1, \dots, x_n]$ is homogeneous iff it is generated by homogeneous polynomials.

DF 9.1.19 For $\mathrm{Func}(R)$ the ring of functions $R \to R$ and $f_p(r) = p(r)$: (a) show evaluation at a is a ring homomorphism; (b) show $p \mapsto f_p$ is not a homomorphism in general (use $\mathbb{H}$); (c) show the composite evaluation at a is a homomorphism iff a is central.

DF 9.2.11 For nonzero $f, g \in \mathbb{Q}[x]$ with $\gcd = d$: (a) show $af + bg = h$ is solvable iff $d \mid h$; (b) describe the full solution set (a, b) in terms of a particular solution.

DF 9.2.12 For $R = F[x_0, x_1, x_2, \dots]/I$ with $I = (x_i - x_{i+1}^2 : i \geq 0)$ and R_n the subring generated by F and $\overline{x_n}$: (a) prove $R_0 \subseteq R_1 \subseteq \cdots$ with union R; (b) prove each $R_n \cong F[x_n]$, so R is a Bezout domain; (c) prove the ideal $(x_0, x_1, x_2, \dots)$ is not finitely generated.

DF 9.2.13 For the noncommutative ring R with $xa = a^px$ over a field F of characteristic p with t not a pth power: (a) verify $x^ia = a^{p^i}x^i$ and that R is a ring; (b) prove a right division algorithm and that R has no zero divisors; (c) prove R is right Euclidean and left PID but not left Euclidean.

DF 9.3.1 For an integral domain R with fraction field F and monic $p \in R[x]$ factoring as $a(x)b(x)$ with a, b monic in $F[x]$ of smaller degree: prove $a \notin R[x]$ implies R is not a UFD; deduce $\mathbb{Z}[2\sqrt{2}]$ is not a UFD.

DF 9.3.4 For $R = \mathbb{Z} + x\mathbb{Q}[x]$: (a) show R is a domain with units ± 1; (b) describe its irreducibles and show they are prime; (c) show x is not a product of irreducibles, so R is not a UFD; (d) show x is not prime and describe $R/(x)$.

DF 9.3.5 For $R = \mathbb{Z} + x\mathbb{Q}[x]$: prove the gcd construction and that R is a Bezout domain, and show $I = x\mathbb{Q}[x]$ is an ideal of R that is not finitely generated.

DF 9.4.3 Show $(x - 1)(x - 2)\cdots(x - n) - 1$ is irreducible over $\mathbb{Z}$ for all $n \geq 1$.

DF 9.4.4 Show $(x - 1)(x - 2)\cdots(x - n) + 1$ is irreducible over $\mathbb{Z}$ for all $n \geq 1$, $n \neq 4$.

DF 9.4.10 Prove $p(x) = x^4 - 4x^2 + 8x + 2$ is irreducible over $F = \mathbb{Q}(\sqrt{-2})$.

DF 9.4.15 Prove that if F is a field then for $n \geq 1$ the polynomial $X^n - x$ in the variable X, with coefficients in $F[[x]]$, is irreducible over $F[[x]]$.

DF 9.4.17 Prove the prime-ideal variant of Eisenstein's Criterion: for a prime ideal P of a UFD R with $a_n \notin P$, all lower $a_i \in P$, and $a_0 \notin P^2$, then f is irreducible over $\mathrm{Frac}(R)$.

DF 9.4.20 Show $f(x) = x$ in $\mathbb{Z}/6\mathbb{Z}[x]$ factors as $(3x+4)(4x+3)$; (a) show reductions mod (2) and (3) are irreducible; (b) determine all factorizations via CRT; (c) show $(3, x)$ is principal; (d) give the factorization over $\mathbb{Z}/30\mathbb{Z}[x]$.

DF 9.5.3 For an odd prime p and positive integer n, prove $x^n - p$ is irreducible over $\mathbb{Z}[i]$.

DF 9.5.4 Prove $x^3 + 12x^2 + 18x + 6$ is irreducible over $\mathbb{Z}[i]$.

DF 9.5.5 Prove the identity $\sum_{d|n} \varphi(d) = n$.

DF 9.5.6 For a finite subgroup G of order n of $F^\times$ with $\psi(d)$ the number of elements of order d, prove $\psi(d) \le \varphi(d)$ for each $d \mid n$; conclude G is cyclic.

DF 9.6.1 If $I \subseteq F[x_1, \ldots, x_n]$ is generated by a possibly infinite set $\mathcal{S}$, prove a finite subset of $\mathcal{S}$ generates I.

DF 9.6.2 For any monomial ordering, prove: (a) $LT(fg) = LT(f)LT(g)$ and $\partial(fg) = \partial(f) + \partial(g)$; (b) $\partial(f+g) \le \max(\partial f, \partial g)$ with equality when degrees differ; (c) $m \ge 1$ for every monomial; (d) $m_1 \mid m_2 \Rightarrow m_2 \ge m_1$.

DF 9.6.3 Prove a (partial) ordering has the minimal-element property (every nonempty subset has a minimal element) iff it satisfies the descending chain condition; deduce general polynomial division terminates.

DF 9.6.4 For the grading $\ge_g$ of a monomial ordering: (a) prove $\ge_g$ is a monomial ordering; (b) give the grlex comparisons for the stated monomials versus lex.

DF 9.6.5 Define and verify the grevlex ordering: (a) prove it is a monomial ordering with $x_1 > \cdots > x_n$; (b) compare grevlex and graded lex on $F[x_1, x_2]$ and $F[x_1, x_2, x_3]$; (c) verify the stated chain of grevlex inequalities.

DF 9.6.9 For a monomial ordering built from pairwise-orthogonal vectors $v_1, \ldots, v_k$: (a) recover lex from coordinate vectors; (b) recover grevlex from the stated vectors.

DF 9.6.11 For a Grobner basis $\{g_1, \ldots, g_m\}$ of I, prove $h \in LT(I)$ iff h is a sum of monomial terms each divisible by some $LT(g_i)$.

DF 9.6.12 For a monomial ideal with monomial generators $g_1, \ldots, g_m$, prove $\{g_1, \ldots, g_m\}$ is a Grobner basis (via the divisibility characterization).

DF 9.6.13 Use Buchberger's Criterion to prove the monomial generators of a monomial ideal form a Grobner basis.

DF 9.6.14 For a monomial ideal I with minimal monomial generating set $\{m_1, \ldots, m_k\}$, prove the m_i are unique.

DF 9.6.15 (a) Prove a subset $\{g_1, \ldots, g_m\}$ of I is a minimal Grobner basis of I iff $(LT(g_1), \ldots, LT(g_m))$ is a minimal generating set of $LT(I)$; (b) prove the leading terms and the size of a minimal Grobner basis are determined by I.

DF 9.6.16 Show that if the remainder r of $S(g_i, g_j)$ on division by G is nonzero then $(LT(G), LT(r))$ strictly contains $(LT(G))$; conclude the Grobner basis algorithm terminates.

DF 9.6.19 (a) Show $\{x^3 - y,\ x^2y - y^2,\ xy^2 - y^2,\ y^3 - y^2\}$ is the reduced Grobner basis for $I = (-x^3 + y, x^2y - y^2)$ under lex $x > y$; (b) decide whether $f = x^6 - x^5y \in I$.

DF 9.6.21 For $I = (x^2 - y, x^2y - z) \subseteq F[x, y, z]$, find the reduced Grobner basis under each of the lex orderings $x > y > z$, $z > x > y$, and $z > y > x$.

DF 9.6.22 Show the ideals $I = (x^2y + xy^2 - 2y,\ x^2 + xy - x + y^2 - 2y,\ xy^2 - x - y + y^3)$ and $J = (x - y^2, xy - y, x^2 - y)$ in $F[x, y]$ are equal.

DF 9.6.23 Use reduced Grobner bases to show $I = (x^3 - yz, yz + y)$ and $J = (x^3z + x^3, x^3 + y)$ in $F[x, y, z]$ are equal.

DF 9.6.25 Show the reduced Grobner basis under lex $x > y$ for $I = (x^2 + xy^2, x^2 - y^3, y^3 - y^2)$ is $\{x^2 - y^2, y^3 - y^2, xy^2 + y^2\}$.

DF 9.6.27 Show the reduced Grobner basis for $I = (xy + y^2, x^2y + xy^2 + x^2)$ is $\{x^2, xy + y^2, y^3\}$ under lex $x > y$ and $\{y^2 + yx, x^2\}$ under lex $y > x$.

DF 9.6.28 For $I = (x^4 - y^4 + z^3 - 1, x^3 + y^2 + z^2 - 1)$, show the reduced Grobner basis has five elements under lex $x > y > z$, two under lex $y > z > x$, and the stated two under grevlex.

DF 9.6.29 Find a Grobner basis for $I = (x^2 + xy + y^2 - 1, x^2 + 4y^2 - 4)$ under lex $x > y$ and use it to find the four intersection points of the two ellipses in $\mathbb{R}^2$.

DF 9.6.30 Use Grobner bases to find all six solutions of $2x^3 + 2x^2y^2 + 3y^3 = 0$ and $3x^5 + 2x^3y^3 + 2y^5 = 0$ over $\mathbb{C}$.

DF 9.6.32 Use Grobner bases to show $(x, z) \cap (y^2, x - yz) = (xy, x - yz)$ in $F[x, y, z]$.

DF 9.6.34 Use Grobner bases to compute the intersection of $(x^3y - xy^2 + 1, x^2y^2 - y^3 - 1)$ and $(x^2 - y^2, x^3 + y^3)$ in $F[x, y]$.

DF 9.6.35 (a) For a domain R, nonzero f, and ideal I, show generators of $I \cap (f)$ divided by f generate $(I : (f))$; (b) show $(I : (f_1, \ldots, f_s)) = \bigcap_i (I : (f_i))$.

DF 9.6.36 For $I = (x^2y + z^3, x + y^3 - z, 2y^4z - yz^2 - z^3)$ and $J = (x^2y^5, x^3z^4, y^3z^7)$ in $\mathbb{Q}[x, y, z]$, show $(I : J) = (z^2, y + z, x - z)$.

DF 9.6.37 For ideals $K \subseteq I$ and any J, with bars denoting images in R/K, show $\overline{(I : J)} = (\overline{I} : \overline{J})$.

DF 9.6.38 For $K = (y^5 - z^4)$ in $\mathbb{Q}[y, z]$, verify the three stated ideal quotients $(\overline{I} : \overline{J})$ in R/K.

DF 9.6.40 Prove that any nonempty totally ordered (by inclusion) collection of monomial ideals has monomial union.

DF 9.6.41 For a monomial n, prove $(M : (n)) = (m_i/d_i)$ with $d_i = \gcd(m_i, n)$; show $(M : N)$ of monomial ideals is monomial when N is finitely generated.

DF 9.6.42 (a) Show M is a monomial prime iff $M = (S)$ for some $S \subseteq \{x_1, \ldots, x_n\}$; (b) show $(x_1, \ldots, x_n)$ is the only monomial maximal ideal.

DF 9.6.43 (Dickson's Lemma) Prove every monomial ideal in $F[x_1, \ldots, x_n]$ is finitely generated, via a maximal counterexample and Exercises 9.6.39, 9.6.41 and 9.6.42.

DF 9.6.44 (n-colorings of graphs) Set up the polynomial system whose solutions are n-colorings and: (a) find the reduced Grobner basis and colorings for the 8-vertex, 14-edge graph over $\mathbb{F}_3$; (b) show the 5-vertex graph is 4-colorable but not 3-colorable over $\mathbb{F}_5$; (c) count the 4-colorings of the 9-vertex, 22-edge graph and show adding edge $(1, 5)$ makes it non-4-colorable.

Fraleigh 27.29 For R^R the set of functions $R \to R$ with pointwise sum and product, show $\langle R^R, +, \cdot \rangle$ is a ring.

Fraleigh 27.31 For $\mathbb{Z}_2^{\mathbb{Z}_2}$ and $\mathbb{Z}_3^{\mathbb{Z}_3}$: (a) count the elements; (b) classify the additive groups by the fundamental theorem; (c) show $F^F = P_F$ for any finite field F.

Fraleigh 28.39 Prove $\text{cont}(f(x)g(x)) = \text{cont}(f(x)) \cdot \text{cont}(g(x))$ for $f, g \in \mathbb{Z}[x]$.

Fraleigh 28.40 Prove Theorem 28.12: $f \in \mathbb{Z}[x]$ factors into lower-degree polynomials over $\mathbb{Q}$ iff it so factors over $\mathbb{Z}$.

Fraleigh 29.7 For $g(x) = x^3 + x + 1 \in \mathbb{Z}_2[x]$: (a) verify $g \mid x^7 + 1$; (b) find all code words of the polynomial code C of length 7 generated by g; (c) decide whether C detects/corrects single-bit errors; (d) decide whether C detects/corrects two-bit errors.

Fraleigh 38.30 Use a Grobner basis to derive the standard-form equation of a hyperbola.

Fraleigh 38.31 Use a Grobner basis to show that the graph with vertices $x_1, \ldots, x_5$ and edges $\{x_1, x_2\}$, $\{x_2, x_3\}$, $\{x_3, x_4\}$, $\{x_1, x_3\}$, $\{x_1, x_5\}$, $\{x_5, x_4\}$ can be colored with three colors but not with two.

Fraleigh 38.34 Prove Theorem 38.8: the n-coloring criterion via the nonemptiness of $V(I)$.

Chapter 10

Introduction to Module Theory

10.1 Basic Definitions and Examples

Modules and submodules: the basic definitions

Throughout, R is a ring with identity $1 \neq 0$ (not necessarily commutative). The single most important new idea in this chapter: a module is "a vector space over a ring." Where a field F gave us F-vector spaces, an arbitrary ring R gives us R-modules. Almost everything is the same — until you remember that R need not be a field, need not be commutative, and need not have inverses. Those three failures are exactly where module theory becomes interesting.

Definition 10.1.1 (Left R-module)**.** Let R be a ring with 1. A *left R-module* (or *left module over R*) is an abelian group $(M, +)$ together with an action

$$R \times M \longrightarrow M, \qquad (r, m) \longmapsto rm,$$

called *(left) scalar multiplication*, such that for all $r, s \in R$ and all $m, n \in M$:

(M1) $(r+s)m = rm + sm$ (distributivity over ring addition);

(M2) $(rs)m = r(sm)$ (associativity of the action);

(M3) $r(m+n) = rm + rn$ (distributivity over module addition);

(M4) $1m = m$ (the identity acts as identity).

A module satisfying (M4) is called *unital*; we assume (M4) always. A *right R-module* is defined symmetrically with the action written $m \mapsto mr$ and (M2) reading $m(rs) = (mr)s$.

Remark 10.1.1. Three consequences are immediate and worth recording once and for all, by exactly the arguments used for vector spaces. For all $r \in R$, $m \in M$:

$$0_R\, m = 0_M, \qquad r\, 0_M = 0_M, \qquad (-r)m = -(rm) = r(-m).$$

Indeed $0_R m = (0_R + 0_R)m = 0_R m + 0_R m$, so subtract $0_R m$; and $r0_M = r(0_M + 0_M) = r0_M + r0_M$; and $0_M = 0_R m = (r + (-r))m = rm + (-r)m$ gives $(-r)m = -(rm)$. Note we did *not* use (M4) for these — but (M4) is essential to rule out the trivial action $rm = 0$ for all r, m, which satisfies (M1)–(M3) on any abelian group.

Remark 10.1.2 (Why "left," and the role of commutativity). When R is commutative, (M2) reads $(rs)m = r(sm)$ and we may also write $mr := rm$; then there is no distinction between left and right modules and we simply say "R-module." When R is noncommutative the left/right distinction is real: with $mr := rm$, the right-module axiom $m(rs) = (mr)s$ would force $(rs)m = r(sm) = s(rm)$ in general, which fails. We work with *left* modules by default.

Method (Checking "M is a left R-module")**.** Recognition trigger: you are handed an abelian group M, a ring R, and a proposed rule $(r, m) \mapsto rm$.

1. Confirm $(M, +)$ is an abelian group (identity, inverses, commutativity, associativity).
2. Confirm the action lands in M and is well defined (especially if m is an equivalence class).
3. Verify (M1), (M2), (M3), (M4) by direct computation. Do not skip (M4): it is the one most often false.
4. If R is noncommutative, decide left vs. right and keep the order of scalars straight.

Worked Example 10.1.2 (Vector spaces are exactly modules over a field)**.** Let F be a field. Show that an F-module is precisely an F-vector space.

Recognition. Compare the module axioms (M1)–(M4) with the vector-space axioms. The *rule & why*: the four module axioms over a ring R are word-for-word the vector-space axioms; "F a field" adds nothing to the list of axioms, it only restricts the scalar ring.

Solution. The axioms for an F-vector space V are: V is an abelian group, and for $a, b \in F$, $v, w \in V$: $(a+b)v = av + bv$, $(ab)v = a(bv)$, $a(v+w) = av + aw$, $1v = v$. These are literally (M1)–(M4) with $R = F$. Conversely an F-module satisfies exactly these. So the notion of F-module *is* the notion of F-vector space. *Check.* $\mathbb{R}^n$ over $\mathbb{R}$, $\mathbb{C}$ over $\mathbb{Q}$, $F[x]$ over F are all both vector spaces and F-modules, with the same scalar action — consistent.

Worked Example 10.1.3 (An abelian group is exactly a $\mathbb{Z}$-module — and the action is forced)**.** Let A be an abelian group. Show that there is exactly one way to make A a $\mathbb{Z}$-module, and that conversely every $\mathbb{Z}$-module is an abelian group. Hence "$\mathbb{Z}$-module" and "abelian group" are the same thing.

Recognition. There is no choice of scalar action to make: (M1) and (M4) *force* $n \cdot a$ to be the n-fold sum. The *rule & why*: 1 generates $\mathbb{Z}$ additively, so by (M1)+(M4) the action on 1 determines the action on every integer.

Solution. Given an abelian group A, define for $n \in \mathbb{Z}$, $a \in A$:

$$n \cdot a = \underbrace{a + \cdots + a}_{n} \ (n > 0), \qquad 0 \cdot a = 0, \qquad n \cdot a = \underbrace{(-a) + \cdots + (-a)}_{-n} \ (n < 0).$$

Axioms: (M1) $(m+n)a = ma + na$ and (M3) $n(a+b) = na + nb$ are the laws of integer multiples in an abelian group; (M2) $(mn)a = m(na)$ is iteration; (M4) $1 \cdot a = a$ holds by definition. So A is a $\mathbb{Z}$-module. *Uniqueness/forcing:* suppose A carries *any* $\mathbb{Z}$-module structure $*$. By (M4), $1 * a = a$. By induction with (M1), $n * a = (\,(n-1)+1) * a = (n-1) * a + 1 * a = (n-1) * a + a$, so $n * a$ is the n-fold sum for $n \geq 1$; (M1) with $n = 0$ gives $0 * a = 0$; and $(-1) * a = -(1 * a) = -a$ from the Remark. Thus $*$ coincides with the action above — it is forced. Conversely any $\mathbb{Z}$-module is in particular an abelian group $(A, +)$. *Check.* In $\mathbb{Z}/6\mathbb{Z}$, $4 \cdot \bar{5} = \bar{20} = \bar{2}$, and indeed $\bar{5} + \bar{5} + \bar{5} + \bar{5} = \bar{20} = \bar{2}$. Consistent.

Worked Example 10.1.4 (R as a module over itself, and R^n)**.** Let R be any ring with 1. Verify that R is a left R-module via $r \cdot a := ra$ (ring multiplication), and that $R^n = \{(a_1, \ldots, a_n) : a_i \in R\}$ is a left R-module via $r(a_1, \ldots, a_n) = (ra_1, \ldots, ra_n)$.

Recognition. The action "is" the ring's own multiplication. The *rule & why*: the module axioms (M1)–(M4) for this action are exactly the ring axioms (both distributive laws, associativity of multiplication, and $1a = a$).

Solution. For R on itself: (M1) $(r+s)a = ra + sa$ is right distributivity in R; (M2) $(rs)a = r(sa)$ is associativity of multiplication; (M3) $r(a+b) = ra + rb$ is left distributivity; (M4) $1a = a$ is the identity axiom. So R is a left R-module, called the *left regular module* ${}_RR$. For R^n, all axioms hold coordinatewise from the case $n = 1$. *Check.* Take $R = M_2(\mathbb{R})$ (noncommutative). With $r = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, $a = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ we get $ra = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ but $ar = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 0 \end{smallmatrix}\right)$; the *left* action $r \cdot a = ra$ is the right one to use, and $1 \cdot a = I_2 a = a$ confirms (M4).

Worked Example 10.1.5 (Quotient R/I and R/I-modules)**.** Let I be a (two-sided) ideal of R. Show R/I is a left R-module via $r \cdot (a + I) := ra + I$, and that any R/I-module is automatically an R-module.

Recognition. There is a quotient and a coset action — the danger is well-definedness. The *rule & why*: scalar multiplication on a quotient must be checked independent of coset representative, and that is exactly where the ideal condition $rI \subseteq I$ is used.

Solution. Well defined: if $a + I = a' + I$ then $a - a' \in I$, so $r(a - a') = ra - ra' \in I$ (since I is a left ideal), giving $ra + I = ra' + I$. *Axioms* are inherited from R: e.g. $(rs)(a+I) = (rs)a + I = r(sa) + I = r \cdot (s \cdot (a + I))$, and $1 \cdot (a + I) = a + I$. So R/I is a left R-module. *R/I-module $\Rightarrow$ R-module:* if M is a module over the ring R/I, define $r \cdot m := (r + I)m$; the projection $R \to R/I$ is a ring homomorphism, so (M1)–(M4) transfer. *Check.* $R = \mathbb{Z}$, $I = 6\mathbb{Z}$; then $\mathbb{Z}/6\mathbb{Z} = \mathbb{Z}/6\mathbb{Z}$ as a $\mathbb{Z}$-module via $n \cdot \bar{a} = \overline{na}$, e.g. $4 \cdot \bar{5} = \bar{2}$, matching the $\mathbb{Z}$-module structure of the abelian group $\mathbb{Z}/6\mathbb{Z}$. Consistent.

Caution. **Scalars genuinely act; $1m = m$ is not optional.** On any abelian group M over any ring R the "zero action" $r \cdot m := 0$ for all r, m satisfies (M1),(M2),(M3) but *fails* (M4) unless $M = 0$. Likewise, dropping (M4) lets pathological actions sneak in. Always verify $1m = m$. A second pitfall in the noncommutative case: $(rs)m = r(sm)$ requires the scalars to act *in the same order* they multiply — writing the action on the right (mr) and still demanding $(rs)m$-style laws is inconsistent.

$F[x]$-modules: a vector space with a chosen linear operator

This is the example that powers the rest of the chapter and all of D&F Chapter 12. It deserves its own treatment.

Theorem 10.1.6 ($F[x]$-modules $\leftrightarrow$ linear operators)**.** *Let F be a field. To give an $F[x]$-module is the same as to give an F-vector space V together with a single F-linear operator $T : V \to V$. Explicitly: given (V, T), define for $p(x) = \sum_i a_i x^i \in F[x]$,*

$$p(x) \cdot v := p(T)v = \sum_i a_i \, T^i(v), \qquad T^0 = \mathrm{id}_V \, .$$

This makes V an $F[x]$-module in which x acts as T. Conversely, every $F[x]$-module V is an F-vector space (restrict scalars to the subring $F \subseteq F[x]$) and the map $T(v) := x \cdot v$ is F-linear; the two constructions are mutually inverse.

Proof. $(V, T) \Rightarrow$ module. V is already an abelian group. Check (M1)–(M4) for $p(x) \cdot v := p(T)v$. Since $p \mapsto p(T)$ is the evaluation ring homomorphism $F[x] \to \mathrm{End}_F(V)$ (it exists and is a homomorphism because $\mathrm{End}_F(V)$ is an F-algebra and $x \mapsto T$ extends uniquely by the universal property of the polynomial ring), we have $(p+q)(T) = p(T)+q(T)$ giving (M1); $(pq)(T) = p(T)q(T)$ giving (M2) since $(pq)\cdot v = p(T)q(T)v = p\cdot(q\cdot v)$; $p(T)(v + w) = p(T)v + p(T)w$ since $p(T)$ is linear, giving (M3); and $1(x) = 1$ acts as id_V, giving (M4).

Module $\Rightarrow$ (V, T). If V is an $F[x]$-module, restrict the action to constants $a \in F \subseteq F[x]$: axioms (M1)–(M4) for these scalars make V an F-vector space. Define $T : V \to V$ by $Tv := x \cdot v$. Then T is additive by (M3) and F-linear because for $a \in F$, $T(av) = x \cdot (a \cdot v) = (xa) \cdot v = (ax) \cdot v = a \cdot (x \cdot v) = aTv$ (using commutativity of $F[x]$).

Inverse. Starting from (V, T), the recovered operator is $v \mapsto x \cdot v = p(T)v$ with $p = x$, i.e. T itself. Starting from a module, defining $p \cdot v := p(T)v$ recovers the original action because both are determined by the action of x (the algebra is generated by x over F) and they agree on x and on F. Hence the correspondence is a bijection. □

$$\big(V,\ T : V \to V\big) \underset{T(v)\ :=\ x\cdot v}{\overset{p(x)\cdot v\ :=\ p(T)v}{\rightleftarrows}} \big(V \text{ as } F[x]\text{-module}\big)$$

Diagram explanation. Objects: The left node is a pair (V, T) where V is an F-vector space and $T : V \to V$ is an F-linear operator; as a set it is still V, but the *data* includes the choice of T. The right node is V viewed as a left $F[x]$-module: the same underlying abelian group, now equipped with a scalar action by all of $F[x]$, not merely by the field F.

Arrows: The top arrow (left to right) sends the pair (V, T) to the $F[x]$-module whose scalar action is $p(x) \cdot v := p(T)v$, where $p(T) = \sum_i a_i T^i \in \mathrm{End}_F(V)$. This uses the evaluation homomorphism $\mathrm{ev}_T : F[x] \to \mathrm{End}_F(V)$, which is a ring map because $F[x]$ is the free commutative F-algebra on one generator. The bottom arrow (right to left) extracts the operator: given an $F[x]$-module structure on V, define $T(v) := x \cdot v$; this T is F-linear by axioms (M1)–(M3) together with the commutativity $xa = ax$ in $F[x]$.

What commutes: The two arrows are *mutually inverse*, not paths around a square. Composing top-then-bottom: start with (V, T), form the module $p(x) \cdot v = p(T)v$, then extract the operator as $v \mapsto x \cdot v = T(v)$ — we recover T exactly. Composing bottom-then-top: start with an $F[x]$-module, extract $T(v) = x \cdot v$, then re-form the action as $p(x) \cdot v = p(T)v$ — this equals the original action because every $p(x)$ is an F-linear combination of powers of x, and both actions agree on each x^k.

Why it commutes: Element chase for bottom-then-top: let V be an $F[x]$-module and write $T(v) = x \cdot v$. For $p(x) = \sum a_i x^i$, compute via the new action: $p(x) \cdot v = p(T)v = \sum a_i T^i v = \sum a_i (x^i \cdot v)$. That last sum equals $(\sum a_i x^i) \cdot v$ by axioms (M1) and (M2) applied to the original module. So both actions send (p, v) to the same element. The key step is (M2): $(x^i) \cdot v = x \cdot (x \cdot (\cdots (x \cdot v) \cdots))$, i.e. repeated application of the x-action, which is precisely $T^i v$.

Why this matters here: This diagram is the visual summary of the Theorem immediately above it. The theorem converts a potentially abstract $F[x]$-module structure into something concrete (a single matrix/operator) and vice versa. Every subsequent result about $F[x]$-modules (submodules = T-invariant subspaces, annihilator = minimal polynomial, rational canonical form in Chapter 12) is secretly a statement about operators; this bijection is the translation dictionary. The author places it here to show that the two-way passage loses no information.

Concrete example: Take $F = \mathbb{R}$, $V = \mathbb{R}^2$, $T = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ (90° rotation). Top arrow: $p(x) \cdot v = p(T)v$; in particular $x \cdot v = Tv$ (rotate v) and $x^2 \cdot v = T^2 v = -v$ (since $T^2 = -I$), so $x^2 + 1$ annihilates V. Bottom arrow applied to this module: $T(v) = x \cdot v$ recovers the rotation. Both compositions return to the starting data — the bijection works.

Common pitfall: Students often read the two arrows as saying there is a *canonical isomorphism* $\mathbb{R}^2 \cong$ something, or that the two nodes are the same object. They are not: the left node packages the data as an F-vector space together with one operator T, the right node as a module over the larger ring $F[x]$; neither carries more information than the other. The bijection is between *categories of data*, not between two copies of V. A second pitfall: assuming T can be read off from V alone. It cannot; many different operators on the same V give non-isomorphic $F[x]$-modules (they are isomorphic only if the matrices are similar, a fact proved in Chapter 12).

Takeaway: The point of this diagram is that specifying an $F[x]$-module structure on an F-vector space V is *exactly the same data* as choosing a single F-linear operator $T : V \to V$, with no information lost in either direction.

Method (Building or reading an $F[x]$-module)**.** Recognition trigger: the ring is $F[x]$ (or $\mathbb{R}[x]$, $\mathbb{C}[x]$, $\mathbb{Z}/p\mathbb{Z}[x]$), or you see a vector space with a distinguished operator/matrix.

1. **To build one:** choose an F-vector space V and an operator T (often a matrix). Decree $x \cdot v = Tv$, hence $x^k \cdot v = T^k v$, and extend F-linearly: $\left(\sum a_i x^i\right) \cdot v = \sum a_i T^i v$.
2. **To read one:** the operator is $T(v) = x \cdot v$; the F-vector space structure is the action of the constants.
3. **Submodules** = T-invariant subspaces (see below). **Distinct T's can give isomorphic modules** iff the matrices are similar (Ch. 12).

Worked Example 10.1.7 ($F[x]$-module structures on F^2 correspond to 2×2 matrices)**.** Fix a field F. Describe all $F[x]$-module structures on the underlying space $V = F^2$.

Recognition. An $F[x]$-module on a fixed V is the data of one operator T. The *rule & why*: by the Theorem, an $F[x]$-module with underlying space F^2 is exactly a choice of F-linear $T : F^2 \to F^2$, and such T are exactly 2×2 matrices over F.

Solution. By the correspondence, $F[x]$-module structures on F^2 (with its given F-space structure) biject with F-linear maps $T : F^2 \to F^2$, i.e. with matrices $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in M_2(F)$ via $x \cdot v = Av$. Then $p(x) \cdot v = p(A)v$. *Two concrete instances on $\mathbb{R}^2$:*

$$A_1 = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 0 \end{smallmatrix}\right) \text{ (x acts as 0)}, \qquad A_2 = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) \text{ (x acts as 90° rotation)}.$$

For A_1: $x \cdot v = 0$, so $(3 + 2x + 5x^2) \cdot v = 3v$ — every polynomial acts through its constant term. For A_2: $A_2^2 = -I$, so $x^2 \cdot v = -v$; here $(1 + x^2) \cdot v = v + (-v) = 0$ for all v, i.e. $1 + x^2$ annihilates the whole module,

reflecting $A_2^2 + I = 0$. *Check.* Take $v = \binom{1}{0}$ under A_2: $x \cdot v = \binom{0}{1}$, $x^2 \cdot v = A_2\binom{0}{1} = \binom{-1}{0} = -v$. Indeed $A_2^2 = \left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right) = -I$. Consistent.

Worked Example 10.1.8 (Reading off the operator from a polynomial action)**.** Suppose $V = \mathbb{R}^3$ is given an $\mathbb{R}[x]$-module structure in which $x \cdot (a, b, c) = (b, c, 0)$. Identify the operator T, compute $x^2 \cdot v$ and $x^3 \cdot v$, and find a nonzero polynomial annihilating all of V.

Recognition. The action of x *is* the operator. The *rule & why*: $T(v) = x \cdot v$, and $x^k \cdot v = T^k v$; a polynomial p annihilates V iff $p(T) = 0$.

Solution. $T(a, b, c) = (b, c, 0)$ is the "shift" nilpotent, matrix $N = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{smallmatrix}\right)$. Then $x^2 \cdot (a, b, c) = T^2(a, b, c) = T(b, c, 0) = (c, 0, 0)$ and $x^3 \cdot (a, b, c) = T(c, 0, 0) = (0, 0, 0)$. So $T^3 = 0$, i.e. $x^3 \cdot v = 0$ for all v: the polynomial $p(x) = x^3$ annihilates V. *Check.* N^3 is the zero matrix (shift three times in dimension 3), matching $x^3 \cdot v = 0$. Note x^2 does *not* annihilate V: $x^2 \cdot (0, 0, 1) = (1, 0, 0) \neq 0$. Consistent.

Worked Example 10.1.9 (Different ground fields: $\mathbb{C}$ as an $\mathbb{R}[x]$-module)**.** Make $V = \mathbb{C}$ (a 2-dimensional $\mathbb{R}$-vector space) into an $\mathbb{R}[x]$-module by letting x act as multiplication by i. Compute $(x^2 + 1) \cdot z$ for $z \in \mathbb{C}$.

Recognition. Pick the operator $T =$ "multiply by i." The *rule & why*: any $\mathbb{R}$-linear $T : \mathbb{C} \to \mathbb{C}$ defines an $\mathbb{R}[x]$-module; here $T(z) = iz$.

Solution. $T(z) = iz$ is $\mathbb{R}$-linear (it is $\mathbb{C}$-linear, hence $\mathbb{R}$-linear). Then $x^2 \cdot z = T^2(z) = i(iz) = -z$, so $(x^2 + 1) \cdot z = x^2 \cdot z + 1 \cdot z = -z + z = 0$ for all z. Thus $x^2 + 1$ annihilates the module — the minimal polynomial of T over $\mathbb{R}$ is $x^2 + 1$. *Check.* In the basis $\{1, i\}$, T has matrix $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, whose square is $-I$; so $x^2 \cdot v = -v$. Consistent. (Compare wex on A_2 above: same operator, same annihilator.)

Submodules and the submodule criterion

Definition 10.1.10 (Submodule)**.** Let M be a left R-module. A subset $N \subseteq M$ is a *submodule*, written $N \leq M$, if N is a subgroup of $(M, +)$ that is closed under the action: $rn \in N$ for all $r \in R$, $n \in N$. Equivalently, N is itself a left R-module under the restricted operations. The submodules 0 and M are the *trivial* submodules.

Proposition 10.1.11 (Submodule Criterion)**.** *Let M be a left R-module and $N \subseteq M$. Then $N \leq M$ if and only if*

(i) $N \neq \varnothing$ (equivalently $0 \in N$), and

(ii) $x + ry \in N$ for all $x, y \in N$ and all $r \in R$.

Proof. ($\Rightarrow$) If N is a submodule it contains 0, and for $x, y \in N$, $r \in R$ we have $ry \in N$ (closure under the action) and then $x + ry \in N$ (closure under $+$). ($\Leftarrow$) Assume (i),(ii). First, $0 \in N$: pick $y_0 \in N$ by (i) and take $x = y = y_0$, $r = -1$ in (ii) to get $y_0 + (-1)y_0 = 0 \in N$. Taking $r = -1$ and $x = 0$ in (ii): $0 + (-1)y = -y \in N$, so N is closed under negatives. Taking $r = 1$: $x + y \in N$, so N is closed under addition. With $0 \in N$, N is a subgroup. Finally, taking $x = 0$: $0 + ry = ry \in N$ for all $r \in R$, $y \in N$, so N is closed under the action. Hence $N \leq M$. □

Method (Applying the Submodule Criterion)**.** Recognition trigger: "is N a submodule of M?" or "show the following set is a submodule."

1. Check $N \neq \varnothing$ — usually by exhibiting $0 \in N$.
2. Take arbitrary $x, y \in N$ and arbitrary $r \in R$ and show $x + ry \in N$ in one combined step.
3. One line replaces three (subgroup closure under $+$, under $-$, and under the action). For $F[x]$-modules this collapses to: *N is an F-subspace that is T-invariant* ($TN \subseteq N$).

Worked Example 10.1.12 (Submodules of ${}_RR$ are exactly the left ideals)**.** Let R be a ring with 1 and view R as a left module over itself. Show: the submodules of ${}_RR$ are precisely the left ideals of R.

Recognition. The module action is ring multiplication, so closure under the action = absorption of left multiplication. The *rule & why*: "$rn \in N$ for all $r \in R$" for the regular module is exactly the defining absorption property of a *left* ideal.

Solution. Let $N \subseteq R$. As a left R-module, $N \leq {}_RR$ means: N is an additive subgroup and $rn \in N$ for all $r \in R$, $n \in N$ (where rn is ring multiplication). That is exactly the definition of a left ideal of R. Conversely every left ideal is an additive subgroup closed under left multiplication, hence a submodule. So $\{\text{submodules of } {}_RR\} = \{\text{left ideals of } R\}$. *Check.* $R = \mathbb{Z}$: submodules of ${}_{\mathbb{Z}}\mathbb{Z}$ are the subgroups $n\mathbb{Z}$, which are exactly the ideals of $\mathbb{Z}$. $R = \mathbb{R}$ (a field): the only left ideals are 0 and $\mathbb{R}$, matching "a 1-dim space has only trivial subspaces." Consistent. (For commutative R this says: submodules of R = ideals.)

Worked Example 10.1.13 (Using the criterion: a torsion-style set and a non-example)**.** Let $R = \mathbb{Z}$, $M = \mathbb{Z}/12\mathbb{Z}$. Decide whether $N = \{\, \bar{a} \in \mathbb{Z}/12\mathbb{Z} : 3\bar{a} = \bar{0} \,\}$ is a submodule, and whether $S = \{\bar{0}, \bar{1}\}$ is.

Recognition. Apply (i)+(ii) of the criterion directly. The *rule & why*: a single check $x + ry \in N$ settles it; for S we look for one failure.

Solution. For N: $3\bar{a} = \bar{0}$ in $\mathbb{Z}/12\mathbb{Z}$ means $12 \mid 3a$, i.e. $4 \mid a$, so $N = \{\bar{0}, \bar{4}, \bar{8}\}$. (i) $\bar{0} \in N$. (ii) For $x, y \in N$ and $r \in \mathbb{Z}$: $3(x + ry) = 3x + r(3y) = \bar{0} + r\bar{0} = \bar{0}$, so $x + ry \in N$. Hence $N \leq M$ (it is the 3-torsion subgroup). *For $S = \{\bar{0}, \bar{1}\}$:* take $x = \bar{1} \in S$, $r = 2$, $y = \bar{1}$: $x + ry = \bar{1} + 2\bar{1} = \bar{3} \notin S$. Criterion (ii) fails, so S is *not* a submodule. *Check.* $N = \{\bar{0}, \bar{4}, \bar{8}\}$ is the unique subgroup of order 3 in $\mathbb{Z}/12\mathbb{Z}$; closed under the $\mathbb{Z}$-action automatically, since every subgroup of an abelian group is a $\mathbb{Z}$-submodule. Consistent. S fails despite having order 2: it is not even a subgroup, because $\bar{1}$ has additive order 12, so $\bar{1} + \bar{1} = \bar{2} \notin S$ — the criterion catches it.

Worked Example 10.1.14 (Submodules of $F[x]$-modules are T-invariant subspaces)**.** Let V be an $F[x]$-module with x acting as T. Show $W \subseteq V$ is a submodule iff W is an F-subspace with $TW \subseteq W$. Then for $V = \mathbb{R}^2$ with $T = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 3 \end{smallmatrix}\right)$, find all submodules.

Recognition. Specialize the criterion to $R = F[x]$. The *rule & why*: the criterion's "$x + ry \in N$ for all $r \in F[x]$" reduces, since $F[x]$ is generated over F by x, to: closed under F-scalars (subspace) and closed under T (invariance).

Solution. ($\Rightarrow$) A submodule W is closed under multiplication by constants $a \in F$ (so it is a subspace) and by x (so $TW \subseteq W$). ($\Leftarrow$) If W is a T-invariant subspace, then W is closed under each T^k, hence under $p(T) = \sum a_i T^i$ for every $p \in F[x]$; with W a subgroup this gives $w + p(x)w' \in W$, the criterion. *For $T = \operatorname{diag}(2, 3)$ on $\mathbb{R}^2$:* T-invariant subspaces are 0, $\mathbb{R}^2$, and the eigenlines $\langle e_1 \rangle$ (eigenvalue 2), $\langle e_2 \rangle$ (eigenvalue 3). No other line is invariant: a line $\langle (a, b) \rangle$ with $a, b \neq 0$ maps to $\langle (2a, 3b) \rangle$, not a scalar multiple of (a, b). So the submodules are $\{0,\ \langle e_1 \rangle,\ \langle e_2 \rangle,\ \mathbb{R}^2\}$. *Check.* Four submodules match the four T-invariant subspaces of a diagonalizable operator with distinct eigenvalues on a 2-dim space. Consistent.

Worked Example 10.1.15 (The torsion submodule over an integral domain)**.** Let R be an integral domain (in particular commutative) and M a left R-module. Define the *torsion submodule*

$$\operatorname{Tor}(M) = \{\, m \in M :\ rm = 0 \text{ for some } r \in R,\ r \neq 0 \,\}.$$

Show $\operatorname{Tor}(M) \leq M$, and exhibit why the domain hypothesis is needed.

Recognition. Verify closure with the criterion, watching where "no zero divisors" enters. The *rule & why*: to add two torsion elements you multiply by the *product* of their annihilators, and that product is nonzero precisely because R has no zero divisors.

Solution. (i) $0 \in \operatorname{Tor}(M)$ since $r \cdot 0 = 0$ for any $r \neq 0$ (take $r = 1$). (ii) Let $x, y \in \operatorname{Tor}(M)$ and $s \in R$. Choose $a, b \in R \setminus \{0\}$ with $ax = 0$, $by = 0$, and put $r := ab$. Then, using commutativity of R,

$$(ab)(x + sy) = ab\,x + ab\,s\,y.$$

Now $ab\,x = b(ax) = b \cdot 0 = 0$, and $ab\,sy = as\,(by) = as \cdot 0 = 0$, so $(ab)(x + sy) = 0$. Since $a \neq 0$ and $b \neq 0$ and R is a domain, $ab \neq 0$. Hence $x + sy \in \operatorname{Tor}(M)$ and $\operatorname{Tor}(M) \leq M$. *Domain needed:* over $R = \mathbb{Z}/6\mathbb{Z}$ (not a domain) in $M = {}_RR$, $\bar{2}$ is torsion ($\bar{3} \cdot \bar{2} = \bar{0}$) and $\bar{3}$ is torsion ($\bar{2} \cdot \bar{3} = \bar{0}$), but $\bar{2} + \bar{3} = \bar{5}$ is a unit, so $r\bar{5} = \bar{0}$ forces $r = \bar{0}$ — $\bar{5} \notin \operatorname{Tor}(M)$. The sum of two torsion elements stayed torsion above only because the annihilator product ab remained nonzero. *Check ($R = \mathbb{Z}$, $M = \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}$).* $\operatorname{Tor}(M) = \mathbb{Z}/4\mathbb{Z} \oplus 0$ (every element of $\mathbb{Z}/4\mathbb{Z}$ is killed by 4; nonzero integers are killed by no nonzero r), a genuine submodule. Consistent.

Worked Example 10.1.16 (Annihilators are submodules / ideals)**.** Let M be a left R-module and $m \in M$. Show $\mathrm{Ann}(m) = \{r \in R : rm = 0\}$ is a left ideal of R, and $\mathrm{Ann}(M) = \{r \in R : rM = 0\}$ is a two-sided ideal.

Recognition. View $\mathrm{Ann}(m)$ as the kernel of $R \to M$, $r \mapsto rm$. The *rule & why*: this map is a left-R-module homomorphism from ${}_RR$, so its kernel is a submodule of ${}_RR$, i.e. a left ideal.

Solution. The map $\varphi : {}_RR \to M$, $\varphi(r) = rm$, satisfies $\varphi(r+s) = \varphi(r) + \varphi(s)$ and $\varphi(sr) = (sr)m = s(rm) = s\varphi(r)$, so it is a left-module homomorphism. Then $\mathrm{Ann}(m) = \ker\varphi$ is a submodule of ${}_RR$, hence a left ideal (by the regular-module example). For $\mathrm{Ann}(M) = \bigcap_{m\in M} \mathrm{Ann}(m)$: it is a left ideal (intersection of left ideals); and it is closed under right multiplication, for if $rM = 0$ and $s \in R$ then $(rs)M = r(sM) \subseteq rM = 0$, so $rs \in \mathrm{Ann}(M)$. Thus $\mathrm{Ann}(M)$ is two-sided. *Check.* $M = \mathbb{Z}/12\mathbb{Z}$ over $\mathbb{Z}$: $\mathrm{Ann}(\bar{4}) = \{n : 12 \mid 4n\} = \{n : 3 \mid n\} = 3\mathbb{Z}$, an ideal; $\mathrm{Ann}(M) = 12\mathbb{Z}$. Indeed $3 \cdot \bar{4} = \bar{0}$ and $12 \cdot \bar{a} = \bar{0}$ for all $\bar{a}$. Consistent.

R-algebras

Definition 10.1.17 (R-algebra)**.** Let R be a commutative ring with 1. An *R-algebra* is a ring A with 1_A together with a ring homomorphism $f : R \to A$ with $f(1_R) = 1_A$ whose image lies in the center of A (i.e. $f(r)$ commutes with every element of A). Equivalently, A is an R-module via $r \cdot a := f(r)a$ such that the module action is compatible with the ring multiplication of A:

$$r \cdot (ab) = (r \cdot a)b = a(r \cdot b) \qquad \text{for all } r \in R,\ a, b \in A.$$

A homomorphism of R-algebras $A \to B$ is a ring homomorphism that sends 1_A to 1_B and is also R-linear.

Worked Example 10.1.18 (Three quick R-algebras)**.** Verify each is an R-algebra: (a) $F[x]$ over F; (b) $M_n(R)$ over commutative R; (c) R/I over R (with R commutative).

Recognition. Exhibit the structure map $f : R \to A$ into the center. The *rule & why*: an R-algebra is exactly a ring with a central copy of R inside it; produce that homomorphism.

Solution. (a) $f : F \hookrightarrow F[x]$ as constant polynomials; the image (scalars) is central since $F[x]$ is commutative, and $a \cdot p(x) = ap(x)$ is the module action. So $F[x]$ is an F-algebra. (b) $f : R \to M_n(R)$, $r \mapsto rI_n$; scalar matrices are central in $M_n(R)$, and $r \cdot (AB) = (rI)(AB) = ((rI)A)B = (r \cdot A)B$. So $M_n(R)$ is an R-algebra (noncommutative for $n \geq 2$). (c) $f : R \to R/I$ the quotient map; the image is all of R/I, central since R/I is commutative, and $r \cdot (\bar{a}\bar{b}) = \overline{rab} = (r \cdot \bar{a})\bar{b}$. So R/I is an R-algebra. *Check.* In each, $f(1_R) = 1_A$: $1 \in F[x]$, $I_n \in M_n(R)$, $\bar{1} \in R/I$. Consistent.

Caution. **An R-algebra is more than an R-module.** It is a ring *and* a module with the two structures linked by $r(ab) = (ra)b = a(rb)$. Forgetting the centrality/compatibility condition lets in "modules with a multiplication" that are not algebras. Also: the structure map $f : R \to A$ need not be injective (e.g. $\mathbb{Z}/n\mathbb{Z}$ is a $\mathbb{Z}$-algebra with non-injective $f : \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$), so an R-algebra need not literally *contain* R.

Exercises (from the text).

1. Prove that $0m = 0$ and $(-1)m = -m$ for all $m \in M$.
2. Prove that $R^\times$ and M satisfy the two axioms in Section 1.7 for a group action of the multiplicative group $R^\times$ on the set M.
3. Assume that $rm = 0$ for some $r \in R$ and some $m \in M$ with $m \neq 0$. Prove that r does not have a left inverse (i.e., there is no $s \in R$ such that $sr = 1$).
4. Let M be the module R^n described in Example 3 and let $I_1, I_2, \ldots, I_n$ be left ideals of R. Prove that the following are submodules of M: (a) $\{(x_1, x_2, \ldots, x_n) \mid x_i \in I_i\}$ (b) $\{(x_1, x_2, \ldots, x_n) \mid x_i \in R \text{ and } x_1 + x_2 + \cdots + x_n = 0\}$.
5. For any left ideal I of R define

$$IM = \left\{ \sum_{\text{finite}} a_i m_i \mid a_i \in I,\ m_i \in M \right\}$$

to be the collection of all finite sums of elements of the form am where $a \in I$ and $m \in M$. Prove that IM is a submodule of M.

6. Show that the intersection of any nonempty collection of submodules of an R-module is a submodule.

7. Let $N_1 \subseteq N_2 \subseteq \cdots$ be an ascending chain of submodules of M. Prove that $\bigcup_{i=1}^{\infty} N_i$ is a submodule of M.

8. An element m of the R-module M is called a *torsion element* if $rm = 0$ for some nonzero element $r \in R$. The set of torsion elements is denoted

$$\text{Tor}(M) = \{m \in M \mid rm = 0 \text{ for some nonzero } r \in R\}.$$

(a) Prove that if R is an integral domain then $\text{Tor}(M)$ is a submodule of M (called the *torsion submodule* of M). (b) Give an example of a ring R and an R-module M such that $\text{Tor}(M)$ is not a submodule. [Consider the torsion elements in the R-module R.] (c) If R has zero divisors show that every nonzero R-module has nonzero torsion elements.

9. If N is a submodule of M, the *annihilator of N in R* is defined to be $\{r \in R \mid rn = 0 \text{ for all } n \in N\}$. Prove that the annihilator of N in R is a 2-sided ideal of R.

10. If I is a right ideal of R, the *annihilator of I in M* is defined to be $\{m \in M \mid am = 0 \text{ for all } a \in I\}$. Prove that the annihilator of I in M is a submodule of M.

11. Let M be the abelian group (i.e., $\mathbb{Z}$-module) $\mathbb{Z}/24\mathbb{Z} \times \mathbb{Z}/15\mathbb{Z} \times \mathbb{Z}/50\mathbb{Z}$. (a) Find the annihilator of M in $\mathbb{Z}$ (i.e., a generator for this principal ideal). (b) Let $I = 2\mathbb{Z}$. Describe the annihilator of I in M as a direct product of cyclic groups.

12. In the notation of the preceding exercise prove the following facts about annihilators. (a) Let N be a submodule of M and let $\text{Ann}(N)$ be the annihilator of N in R. Prove that the annihilator of $\text{Ann}(N)$ in M contains N. Give an example where the annihilator of $\text{Ann}(N)$ in M does not equal N. (b) Let I be a right ideal of R and let $\text{Ann}(I)$ be the annihilator of I in M. Prove that the annihilator of $\text{Ann}(I)$ in R contains I. Give an example where the annihilator of $\text{Ann}(I)$ in R does not equal I.

13. Let I be an ideal of R. Let M' be the subset of elements a of M that are annihilated by some power, I^k, of the ideal I, where the power may depend on a. Prove that M' is a submodule of M. [Use Exercise 7.]

14. Let z be an element of the center of R, i.e., $zr = rz$ for all $r \in R$. Prove that zM is a submodule of M, where $zM = \{zm \mid m \in M\}$. Show that if R is the ring of 2×2 matrices over a field and e is the matrix with a 1 in position $1, 1$ and zeros elsewhere then eR is not a left R-submodule (where $M = R$ is considered as a left R-module as in Example 1) — in this case the matrix e is not in the center of R.

15. If M is a finite abelian group then M is naturally a $\mathbb{Z}$-module. Can this action be extended to make M into a $\mathbb{Q}$-module?

16. Prove that the submodules U_k described in the example of $F[x]$-modules are all of the $F[x]$-submodules for the shift operator.

17. Let T be the shift operator on the vector space V and let $e_1, \ldots, e_n$ be the usual basis vectors described in the example of $F[x]$-modules. If $m \geq n$ find $(a_m x^m + a_{m-1}x^{m-1} + \cdots + a_0)e_n$.

18. Let $F = \mathbb{R}$, let $V = \mathbb{R}^2$ and let T be the linear transformation from V to V which is rotation clockwise about the origin by $\pi/2$ radians. Show that V and 0 are the only $F[x]$-submodules for this T.

19. Let $F = \mathbb{R}$, let $V = \mathbb{R}^2$ and let T be the linear transformation from V to V which is projection onto the y-axis. Show that V, 0, the x-axis and the y-axis are the only $F[x]$-submodules for this T.

20. Let $F = \mathbb{R}$, let $V = \mathbb{R}^2$ and let T be the linear transformation from V to V which is rotation clockwise about the origin by π radians. Show that *every* subspace of V is an $F[x]$-submodule for this T.

21. Let $n \in \mathbb{Z}^+$, $n > 1$ and let R be the ring of $n \times n$ matrices with entries from a field F. Let M be the set of $n \times n$ matrices with arbitrary elements of F in the first column and zeros elsewhere. Show that M is a submodule of R when R is considered as a left module over itself, but M is not a submodule of R when R is considered as a right R-module.

22. Suppose that A is a ring with identity 1_A that is a (unital) left R-module satisfying $r\cdot(ab) = (r\cdot a)b = a(r\cdot b)$ for all $r \in R$ and $a, b \in A$. Prove that the map $f : R \to A$ defined by $f(r) = r \cdot 1_A$ is a ring homomorphism mapping 1_R to 1_A and that $f(R)$ is contained in the center of A. Conclude that A is an R-algebra and that the R-module structure on A induced by its algebra structure is precisely the original R-module structure.

23. Let A be the direct product ring $\mathbb{C} \times \mathbb{C}$ (cf. Section 7.6). Let τ_1 denote the identity map on $\mathbb{C}$ and let τ_2 denote complex conjugation. For any pair $p, q \in \{1, 2\}$ (not necessarily distinct) define

$$f_{p,q} : \mathbb{C} \to \mathbb{C} \times \mathbb{C} \qquad \text{by} \qquad f_{p,q}(z) = (\tau_p(z), \tau_q(z)).$$

So, for example, $f_{2,1} : z \mapsto (\bar{z}, z)$, where $\bar{z}$ is the complex conjugate of z, i.e., $\tau_2(z)$. (a) Prove that each $f_{p,q}$ is an injective ring homomorphism, and that they all agree on the subfield $\mathbb{R}$ of $\mathbb{C}$. Deduce that A has four distinct $\mathbb{C}$-algebra structures. Explicitly give the action $z \cdot (u, v)$ of a complex number z on an ordered pair in A in each case. (b) Prove that if $f_{p,q} \neq f_{p',q'}$ then the identity map on A is *not* a $\mathbb{C}$-algebra homomorphism from A considered as a $\mathbb{C}$-algebra via $f_{p,q}$ to A considered as a $\mathbb{C}$-algebra via $f_{p',q'}$ (although the identity is an $\mathbb{R}$-algebra isomorphism). (c) Prove that for any pair p, q there is some ring isomorphism from A to itself such that A is isomorphic as a $\mathbb{C}$-algebra via $f_{p,q}$ to A considered as a $\mathbb{C}$-algebra via $f_{1,1}$ (the "natural" $\mathbb{C}$-algebra structure on A).

Practice problems.

1. Let R be a ring with 1 and let M be the set of R-valued sequences $(a_1, a_2, \dots)$ with all but finitely many a_i equal to 0. With componentwise addition and the action $r \cdot (a_i) = (ra_i)$, verify the four module axioms hold, and exhibit a generating set.

2. Let M be a left R-module. Prove that $0_R \cdot m = 0_M$ and $(-1) \cdot m = -m$ for all $m \in M$, using only the module axioms.

3. Let V be an F-vector space and T a linear operator on V, making V an $F[x]$-module via $x \cdot v = T(v)$. Describe explicitly how the polynomial $p(x) = x^2 - 3x + 2$ acts on a vector v.

4. Take $V = \mathbb{F}^2$ over $\mathbb{F} = \mathbb{Q}$ and $T = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. View V as a $\mathbb{Q}[x]$-module via T. Compute $(x^2 + 1) \cdot v$ for an arbitrary $v = (a, b)$, and conclude that $x^2 + 1$ annihilates V.

5. Show that an abelian group A is the same thing as a $\mathbb{Z}$-module by describing how $n \cdot a$ is forced by the axioms for $n \in \mathbb{Z}$, $a \in A$.

6. For the abelian group $A = \mathbb{Z}/12\mathbb{Z}$ viewed as a $\mathbb{Z}$-module, compute the annihilator $\mathrm{Ann}_{\mathbb{Z}}(A)$, and compute $\mathrm{Ann}_{\mathbb{Z}}(\bar{3})$ where $\bar{3} \in \mathbb{Z}/12\mathbb{Z}$.

7. Let R be commutative and M an R-module. Prove that $\mathrm{Ann}_R(M) = \{\, r \in R \mid rm = 0 \text{ for all } m \in M \,\}$ is a two-sided ideal of R.

8. Which of the following subsets of the $\mathbb{Z}$-module $\mathbb{Z}^2$ are submodules? (a) $\{\, (a, b) \mid a + b = 0 \,\}$; (b) $\{\, (a, b) \mid a + b = 1 \,\}$; (c) $\{\, (a, b) \mid ab = 0 \,\}$; (d) $\{\, (a, b) \mid 2a = 3b \,\}$. Justify each answer.

9. Let $R = \mathbb{Z}$ and $M = \mathbb{Q}$ as a $\mathbb{Z}$-module. Show that M is not finitely generated.

10. Let M and N be R-modules. Show that $M \times N$ with componentwise operations and action $r(m, n) = (rm, rn)$ is an R-module, and that $M \times \{\, 0 \,\}$ and $\{\, 0 \,\} \times N$ are submodules whose internal direct sum is all of $M \times N$.

11. Let $\varphi\colon M \to N$ be an R-module homomorphism. Prove that $\ker \varphi \leq M$ and $\operatorname{im} \varphi \leq N$ are submodules.

12. Let R be a ring with 1. Show that $\mathrm{Hom}_R(R, M) \cong M$ as abelian groups via $\varphi \mapsto \varphi(1)$, and identify which R-module structure on $\mathrm{Hom}_R(R, M)$ (when R is commutative) makes this an isomorphism of R-modules.

13. Let I be a left ideal of R. Show I is a submodule of R (viewed as a left R-module over itself), and that R/I is an R-module. Compute the $\mathbb{Z}$-module $\mathbb{Z}/6\mathbb{Z}$ and list its submodules.

14. Decide whether the map $\varphi\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$, $\bar{a} \mapsto \overline{2a}$, is a $\mathbb{Z}$-module homomorphism; if so, compute $\ker\varphi$ and $\operatorname{im}\varphi$.

15. Let $M = \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ as a $\mathbb{Z}$-module. Show $M \cong \mathbb{Z}/6\mathbb{Z}$, and explain why this fails if 2 and 3 are replaced by 2 and 2.

Additional exercises.

1. Let R be a ring with 1 that need not be commutative, and let M be a left R-module. Give an example showing that the set $\{\, m \in M \mid rm = 0 \,\}$ for a fixed $r \in R$ need not be a submodule of M. (Hint: noncommutativity of R.)

2. Let V be a finite-dimensional F-vector space and T a linear operator. Prove that the $F[x]$-module V (action via T) is finitely generated, and is in fact generated by a finite set of size at most $\dim_F V$. Can a single element ever generate V as an $F[x]$-module when $\dim_F V > 1$?

3. Let R be an integral domain and M an R-module. The torsion submodule is $\operatorname{Tor}(M) = \{\, m \in M \mid rm = 0 \text{ for some } r \neq 0 \,\}$. Prove $\operatorname{Tor}(M)$ is a submodule, and show by example that this can fail when R has zero divisors.

4. Let M be a left R-module and let $\operatorname{End}_R(M) = \operatorname{Hom}_R(M, M)$. Show that $\operatorname{End}_R(M)$ is a ring under addition and composition, and that M is a left $\operatorname{End}_R(M)$-module.

5. Let R be commutative with 1. Show that giving an R-module M a structure of $R[x]$-module extending the R-action is the same as choosing an R-linear operator $T \in \operatorname{End}_R(M)$. Make the correspondence precise in both directions.

6. Let A be an abelian group, regarded as a $\mathbb{Z}$-module. Prove that the $\mathbb{Z}$-action on A descends to a $\mathbb{Z}/n\mathbb{Z}$-module structure on A if and only if $nA = 0$, i.e. A is annihilated by n.

Commutative-diagram exercises.

1. (Universal property of the free module.) Let A be a set and $R^{(A)}$ the free R-module on A with inclusion $\iota\colon A \to R^{(A)}$. State and prove that for every R-module M and every set map $f\colon A \to M$ there is a unique R-homomorphism Φ making the diagram commute:

$$\begin{array}{ccc} A & \xhookrightarrow{\ \iota\ } & R^{(A)} \\ & {\scriptstyle f}\searrow & \downarrow{\scriptstyle \exists!\,\Phi} \\ & & M \end{array}$$

   Then show any two R-modules with this universal property for A are uniquely isomorphic.

2. Let $\varphi\colon M \to N$ be a surjective R-homomorphism and $\pi\colon M \to M/\ker\varphi$ the quotient map. Show there is a unique isomorphism $\bar{\varphi}$ making the triangle commute, and label every arrow:

$$\begin{array}{ccc} M & \xrightarrow{\ \varphi\ } & N \\ & {\scriptstyle \pi}\searrow & \uparrow{\scriptstyle \bar{\varphi}} \\ & & M/\ker\varphi \end{array}$$

3. Consider the sequence of $\mathbb{Z}$-modules

$$0 \longrightarrow \mathbb{Z} \xrightarrow{\ \psi\ } \mathbb{Z} \xrightarrow{\ \varphi\ } \mathbb{Z}/n\mathbb{Z} \longrightarrow 0$$

   with $\psi(a) = na$ (for a fixed integer $n > 1$) and φ the reduction map. Verify this is a short exact sequence, and determine for which n it splits.

4. (Splitting.) Let

$$0 \longrightarrow A \xhookrightarrow{\ \psi\ } B \xrightarrow{\ \varphi\ } C \longrightarrow 0$$

   be a short exact sequence of R-modules. Prove that the existence of a section $s\colon C \to B$ with $\varphi \circ s = \mathrm{id}_C$ implies $B \cong A \oplus C$, and draw the diagram exhibiting the isomorphism.

5. Suppose both rows are short exact (with zeros prepended and appended) and the squares commute in

$$\begin{array}{ccccc} A & \xhookrightarrow{f} & B & \xrightarrow{g} & C \\ \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \beta} & & \downarrow{\scriptstyle \gamma} \\ A' & \xhookrightarrow{f'} & B' & \xrightarrow{g'} & C' \end{array}$$

Prove that if α and γ are isomorphisms then β is an isomorphism (the short five lemma).

10.2 Quotient Modules and Module Homomorphisms

Module homomorphisms, quotient modules, and the isomorphism theorems

Throughout, R is a ring with 1, and "module" means left R-module unless stated otherwise. We develop the structure-preserving maps between modules, the quotient construction, the four isomorphism theorems, and the algebra of $\mathrm{Hom}_R(M,N)$.

Definition 10.2.1 (R-module homomorphism)**.** Let M and N be R-modules. A map $\varphi\colon M \to N$ is an *R-module homomorphism* (or *R-linear map*) if for all $m, m' \in M$ and all $r \in R$:

$$\varphi(m+m') = \varphi(m) + \varphi(m'), \qquad \varphi(rm) = r\,\varphi(m).$$

An R-module homomorphism that is a bijection is an *isomorphism*, written $M \cong N$. The set of all R-module homomorphisms $M \to N$ is denoted $\mathrm{Hom}_R(M,N)$. We write $\mathrm{End}_R(M) = \mathrm{Hom}_R(M,M)$.

Remark 10.2.1. The two conditions combine into a single one: φ is R-linear iff $\varphi(rm+sm') = r\,\varphi(m)+s\,\varphi(m')$ for all $r,s \in R$ and $m,m' \in M$. Taking $r=1$, $s=1$ gives additivity; taking $m'=0$ gives $\varphi(rm) = r\varphi(m)$. In particular every $\varphi \in \mathrm{Hom}_R(M,N)$ satisfies $\varphi(0)=0$ and $\varphi(-m) = -\varphi(m)$, since φ is in particular a homomorphism of abelian groups.

Remark 10.2.2 (Special cases). The definition is a single template that specializes to familiar notions:

- $R = \mathbb{Z}$: a $\mathbb{Z}$-module is an abelian group, and $\mathbb{Z}$-linearity $\varphi(nm) = n\varphi(m)$ is automatic from additivity. So $\mathrm{Hom}_{\mathbb{Z}}(M,N)$ is exactly the set of *abelian group homomorphisms*.
- $R = \mathbb{F}$ a field: an $\mathbb{F}$-module is an $\mathbb{F}$-vector space, and $\mathrm{Hom}_{\mathbb{F}}(M,N)$ is the set of $\mathbb{F}$-*linear transformations*.
- $R = \mathbb{F}[x]$: an $\mathbb{F}[x]$-module is a pair (V,T) where V is an $\mathbb{F}$-vector space and T is the $\mathbb{F}$-linear operator "multiplication by x." An $\mathbb{F}[x]$-module homomorphism is an $\mathbb{F}$-linear map *commuting with the operators* (see Worked Example below).

Method (Checking R-linearity)**.** *Trigger.* You are handed a map $\varphi\colon M \to N$ between R-modules and asked whether it is a homomorphism, or to find all homomorphisms. *Recipe.*

1. Verify additivity: $\varphi(m+m') = \varphi(m)+\varphi(m')$.
2. Verify the scalar rule: $\varphi(rm) = r\varphi(m)$ for all $r \in R$. When R is generated as a ring by a small set (e.g. $R=\mathbb{Z}$ generated by 1, or $R=\mathbb{F}[x]$ generated by $\mathbb{F}$ and x), it suffices to check the rule on generators.
3. To *find all* homs, note φ is determined by its values on a generating set of M, subject to the relations among those generators.

Proposition 10.2.2 (Kernel and image are submodules)**.** *Let $\varphi\colon M \to N$ be an R-module homomorphism. Then*

$$\ker\varphi = \{m \in M : \varphi(m) = 0\} \le M, \qquad \mathrm{im}\,\varphi = \{\varphi(m) : m \in M\} \le N.$$

Moreover φ is injective iff $\ker\varphi = 0$.

Proof. We use the Submodule Criterion: a nonempty subset S with $rx+y \in S$ for all $r \in R$ and $x,y \in S$ is a submodule. Both sets contain 0. For the kernel: if $m,m' \in \ker\varphi$ and $r \in R$, then $\varphi(rm+m') = r\varphi(m)+\varphi(m') = r\cdot 0 + 0 = 0$, so $rm+m' \in \ker\varphi$. For the image: if $\varphi(m),\varphi(m') \in \mathrm{im}\,\varphi$ and $r \in R$, then $r\varphi(m)+\varphi(m') = \varphi(rm+m') \in \mathrm{im}\,\varphi$. Finally, if $\ker\varphi = 0$ and $\varphi(m) = \varphi(m')$, then $\varphi(m-m') = 0$ so $m = m'$; conversely injectivity forces $\ker\varphi = 0$ since $\varphi(0)=0$. □

The quotient module

Theorem 10.2.3 (Quotient module)**.** *Let $N \leq M$ be a submodule. The quotient abelian group M/N becomes an R-module under the action*

$$r\,(m+N) = rm + N \qquad (r \in R,\ m \in M),$$

and the natural projection $\pi\colon M \to M/N$, $\pi(m) = m + N$, is a surjective R-module homomorphism with $\ker \pi = N$.

Proof. M/N is already an abelian group (cosets of the subgroup N). We must check the action is *well defined*: if $m + N = m' + N$ then $m - m' \in N$, and since N is a submodule $r(m - m') \in N$, i.e. $rm + N = rm' + N$. The module axioms for M/N follow coset-wise from those of M: e.g. $(r + s)(m + N) = (r + s)m + N = (rm + sm) + N = r(m + N) + s(m + N)$, and $1 \cdot (m + N) = m + N$. The projection π is additive and $\pi(rm) = rm + N = r(m + N) = r\pi(m)$, hence R-linear; it is surjective by construction, and $\pi(m) = 0 + N$ iff $m \in N$, so $\ker \pi = N$. □

Theorem 10.2.4 (Universal property of the quotient)**.** *Let $N \leq M$ and let $\varphi\colon M \to L$ be an R-module homomorphism with $N \subseteq \ker \varphi$. Then there is a* unique *R-module homomorphism $\overline{\varphi}\colon M/N \to L$ with $\overline{\varphi} \circ \pi = \varphi$, namely $\overline{\varphi}(m + N) = \varphi(m)$. The diagram commutes:*

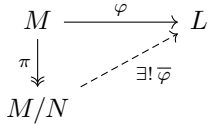

Diagram explanation. Objects: Three R-modules: M (the domain module), M/N (the quotient module by the submodule $N \leq M$), and L (the target module). The hypothesis is $N \subseteq \ker \varphi$.

Arrows: $\varphi\colon M \to L$ is the given R-module homomorphism (solid, top). $\pi\colon M \to M/N$ is the canonical surjective projection $\pi(m) = m + N$ (solid, left side going down). $\overline{\varphi}\colon M/N \to L$ is the unique induced map (dashed, diagonal), given by $\overline{\varphi}(m + N) = \varphi(m)$; it exists precisely because $N \subseteq \ker \varphi$.

What commutes: The triangle commutes: $\overline{\varphi} \circ \pi = \varphi$. That is, going down to M/N and then diagonally to L equals going directly right to L.

Why it commutes: Chase $m \in M$: along the direct path, $m \overset{\varphi}{\mapsto} \varphi(m)$. Along the factored path, $m \overset{\pi}{\mapsto} m + N \overset{\overline{\varphi}}{\mapsto} \varphi(m)$. These agree by the very definition of $\overline{\varphi}$. Well-definedness: if $m + N = m' + N$ then $m - m' \in N \subseteq \ker \varphi$, so $\varphi(m) = \varphi(m')$; the formula $\overline{\varphi}(m + N) = \varphi(m)$ is unambiguous regardless of coset representative.

Why this matters here: This is the module version of the universal property of the quotient. It encodes exactly when a map defined on M descends to a well-defined map on M/N: precisely when N is killed. Every subsequent isomorphism theorem is a direct application of this triangle.

Concrete example: Take $M = \mathbb{Z}$, $N = 3\mathbb{Z}$, $L = \mathbb{Z}/3\mathbb{Z}$, and $\varphi = \pi_3$ the reduction mod 3. Then $N = 3\mathbb{Z} = \ker \varphi$, and the induced $\overline{\varphi}\colon \mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$ is the identity; the triangle says the projection factors through itself, the trivial but prototypical case.

Common pitfall: Students often try to define $\overline{\varphi}$ without checking that $N \subseteq \ker \varphi$; if that condition fails, different coset representatives produce different outputs and $\overline{\varphi}$ is not well defined. The dashed arrow represents existence and uniqueness together – do not write it as solid until the condition is verified.

Takeaway: The point of this diagram is that a homomorphism φ on M factors through the quotient M/N if and only if N is entirely killed by φ, and when it does the factored map is uniquely determined.

Proof. Well defined: if $m + N = m' + N$ then $m - m' \in N \subseteq \ker \varphi$, so $\varphi(m) = \varphi(m')$; thus $\overline{\varphi}(m + N) := \varphi(m)$ is unambiguous. *R-linear:* $\overline{\varphi}(r(m + N) + (m' + N)) = \overline{\varphi}(rm + m' + N) = \varphi(rm + m') = r\varphi(m) + \varphi(m') = r\overline{\varphi}(m + N) + \overline{\varphi}(m' + N)$. *Commutes:* $\overline{\varphi}(\pi(m)) = \overline{\varphi}(m + N) = \varphi(m)$. *Unique:* any ψ with $\psi \circ \pi = \varphi$ satisfies $\psi(m + N) = \psi(\pi(m)) = \varphi(m)$, forcing $\psi = \overline{\varphi}$. □

Method (Using the universal property to define maps out of M/N)**.** *Trigger.* You want to define a map $\overline{\varphi}\colon M/N \to L$ on cosets, or prove two such maps agree. *Recipe.*

1. Define $\varphi\colon M \to L$ on representatives.
2. Check $N \subseteq \ker\varphi$ (this is exactly the "well-defined" check).
3. Conclude $\overline{\varphi}$ exists, is unique, and $\overline{\varphi}(m+N) = \varphi(m)$.

The isomorphism theorems

Theorem 10.2.5 (First Isomorphism Theorem)**.** *Let $\varphi\colon M \to N$ be an R-module homomorphism. Then $\ker\varphi \leq M$, and φ induces an isomorphism*

$$\overline{\varphi}\colon M/\ker\varphi \xrightarrow{\cong} \operatorname{im}\varphi, \qquad \overline{\varphi}(m+\ker\varphi) = \varphi(m).$$

Equivalently, φ factors as the composite of the projection, an isomorphism, and the inclusion:

$$\begin{array}{ccc} M & \xrightarrow{\quad\varphi\quad} & N \\ {\scriptstyle\pi}\downarrow & & \uparrow{\scriptstyle\iota} \\ M/\ker\varphi & \xrightarrow[\cong]{\overline{\varphi}} & \operatorname{im}\varphi \end{array}$$

Diagram explanation. Objects: Four R-modules at the four corners: M (upper-left, domain), N (upper-right, codomain), $M/\ker\varphi$ (lower-left, the quotient by the kernel), and $\operatorname{im}\varphi$ (lower-right, the image submodule of N). The lower-right is a submodule of N.

Arrows: $\varphi\colon M \to N$ (top, the given homomorphism). $\pi\colon M \twoheadrightarrow M/\ker\varphi$ (left, the surjective quotient projection, two-headed arrow). $\overline{\varphi}\colon M/\ker\varphi \xrightarrow{\cong} \operatorname{im}\varphi$ (bottom, the induced isomorphism, $\overline{\varphi}(m+\ker\varphi) = \varphi(m)$). $\iota\colon \operatorname{im}\varphi \hookrightarrow N$ (right, the inclusion of the image into N, hooked arrow).

What commutes: The square commutes: $\iota \circ \overline{\varphi} \circ \pi = \varphi$. That is, going down-then-right-then-up equals going directly right. In particular, $\overline{\varphi}\circ\pi = \iota^{-1}\circ\varphi$ on the image, but the full equality as maps $M \to N$ is $\varphi = \iota\circ\overline{\varphi}\circ\pi$.

Why it commutes: For any $m \in M$: the direct path gives $\varphi(m) \in N$. The factored path sends $m \overset{\pi}{\mapsto} m+\ker\varphi \overset{\overline{\varphi}}{\mapsto} \varphi(m) \in \operatorname{im}\varphi \overset{\iota}{\mapsto} \varphi(m) \in N$. Well-definedness of $\overline{\varphi}$: if $m+\ker\varphi = m'+\ker\varphi$ then $m-m' \in \ker\varphi$ so $\varphi(m) = \varphi(m')$; the induced map is unambiguous on cosets.

Why this matters here: This diagram is the canonical decomposition of any module homomorphism into three pieces of pure type: a surjection, then an isomorphism, then an injection. It makes visible why $M/\ker\varphi \cong \operatorname{im}\varphi$: the only obstruction to φ being injective is its kernel, and killing it produces an honest isomorphism onto the image.

Concrete example: Let $\varphi\colon \mathbb{Z}^2 \to \mathbb{Z}$ be $\varphi(a,b) = a - 2b$. Then $\ker\varphi = \{(2b,b) : b \in \mathbb{Z}\} = \mathbb{Z}(2,1)$, $\operatorname{im}\varphi = \mathbb{Z}$, and the diagram says $\mathbb{Z}^2/\mathbb{Z}(2,1) \cong \mathbb{Z}$, confirmed by the basis change identifying $(2,1)$ and $(1,0)$ as a $\mathbb{Z}$-basis of $\mathbb{Z}^2$.

Common pitfall: The isomorphism $\overline{\varphi}$ maps $M/\ker\varphi$ to $\operatorname{im}\varphi$, not to all of N. Identifying $M/\ker\varphi$ with N directly is wrong unless φ is surjective; the inclusion ι is a reminder that $\operatorname{im}\varphi$ may be a proper submodule of N.

Takeaway: The point of this diagram is that every R-module homomorphism factors uniquely as a surjection onto the quotient by its kernel, followed by a canonical isomorphism, followed by an inclusion – making the First Isomorphism Theorem a structural decomposition rather than just an existence statement.

Proof. Let $K = \ker\varphi$, a submodule by Proposition 10.2.2. Apply Theorem 10.2.4 with $L = N$ (using $K \subseteq \ker\varphi$ trivially): we get $\overline{\varphi}\colon M/K \to N$, $\overline{\varphi}(m+K) = \varphi(m)$, an R-homomorphism. Its image is $\operatorname{im}\varphi$, so restricting the codomain gives a surjection $M/K \to \operatorname{im}\varphi$. It is injective: $\overline{\varphi}(m+K) = 0$ means $\varphi(m) = 0$, i.e. $m \in K$, i.e. $m + K = 0$ in M/K. A bijective R-homomorphism is an isomorphism (its set-theoretic inverse is automatically R-linear). The factorization $\varphi = \iota \circ \overline{\varphi} \circ \pi$ is read off the diagram. □

Theorem 10.2.6 (Second (Diamond) Isomorphism Theorem)**.** *Let A and B be submodules of M. Then $A+B$ and $A\cap B$ are submodules, and*

$$(A+B)/B \cong A/(A\cap B).$$

Proof. $A+B=\{a+b : a\in A, b\in B\}$ and $A\cap B$ are submodules by the submodule criterion. Define $\varphi\colon A\to (A+B)/B$ by $\varphi(a)=a+B$; this is the composite of the inclusion $A\hookrightarrow A+B$ with the projection $A+B\to (A+B)/B$, hence R-linear. It is surjective: any coset $(a+b)+B=a+B=\varphi(a)$. Its kernel is $\{a\in A : a\in B\}=A\cap B$. By the First Isomorphism Theorem, $A/(A\cap B)\cong (A+B)/B$. □

Theorem 10.2.7 (Third Isomorphism Theorem)**.** *Let $A\le B\le M$ be submodules. Then $B/A\le M/A$, and*

$$(M/A)/(B/A)\cong M/B.$$

Proof. Define $\varphi\colon M/A\to M/B$ by $\varphi(m+A)=m+B$. This is well defined and R-linear since $A\subseteq B$: it is the map induced by $\pi_B\colon M\to M/B$ through Theorem 10.2.4 (as $A\subseteq B=\ker\pi_B$). It is surjective, with kernel $\{m+A : m\in B\}=B/A$. The First Isomorphism Theorem gives $(M/A)/(B/A)\cong M/B$. □

Theorem 10.2.8 (Fourth (Lattice/Correspondence) Theorem)**.** *Let $N\le M$. There is an inclusion-preserving bijection*

$$\{\text{ submodules } A \text{ with } N\le A\le M\} \longleftrightarrow \{\text{ submodules of } M/N\},\qquad A\longmapsto A/N,$$

with inverse $\overline{A}\mapsto \pi^{-1}(\overline{A})$. This bijection preserves sums and intersections.

Proof (sketch). The projection $\pi\colon M\to M/N$ carries submodules to submodules and pulls submodules back to submodules containing $N=\ker\pi$. The maps $A\mapsto \pi(A)=A/N$ and $\overline{A}\mapsto\pi^{-1}(\overline{A})$ are mutually inverse on the indicated sets (because every A in the left family contains N, so $\pi^{-1}(A/N)=A$). Both maps clearly respect inclusion; surjectivity of π and the modular law give preservation of $+$ and $\cap$. □

Caution. The Second Isomorphism Theorem requires B to be a submodule so that $A+B$ makes sense as a submodule. The quotient in the Third Theorem, $(M/A)/(B/A)$, is a "quotient of a quotient": do not confuse B/A (a submodule of M/A) with B itself. And in the Fourth Theorem, only the submodules *containing* N correspond to submodules of M/N — submodules of M not containing N have no counterpart.

Worked examples: homomorphisms and the first theorem

Worked Example 10.2.9 (Group homs $\mathbb{Z}/m\mathbb{Z}\to\mathbb{Z}/n\mathbb{Z}$ and their count)**.** Determine all $\mathbb{Z}$-module homomorphisms $\varphi\colon\mathbb{Z}/m\mathbb{Z}\to\mathbb{Z}/n\mathbb{Z}$ and count them.

Recognition. A $\mathbb{Z}$-module hom is an abelian-group hom; $\mathbb{Z}/m\mathbb{Z}=\langle\bar1\rangle$ is cyclic, so φ is determined by $\varphi(\bar1)$, subject to the relation $m\bar1=0$. *Recognition:* "maps out of a cyclic module" = choose the image of the generator, respecting its order.

Solution. Write $\varphi(\bar1)=\bar a\in\mathbb{Z}/n\mathbb{Z}$. Then $\varphi(\bar k)=k\bar a$, so φ is determined by $\bar a$. The single relation $m\bar1=\bar0$ in $\mathbb{Z}/m\mathbb{Z}$ forces $\varphi(m\bar1)=m\bar a=\bar0$ in $\mathbb{Z}/n\mathbb{Z}$, i.e. $n\mid ma$. Conversely, any $\bar a$ with $n\mid ma$ yields a well-defined hom (the assignment respects the only relation). The condition $n\mid ma$ says a is a multiple of $n/\gcd(m,n)$ modulo n. With $d=\gcd(m,n)$, the elements $\bar a\in\mathbb{Z}/n\mathbb{Z}$ with $\frac{n}{d}\mid a$ are exactly $0,\ \frac{n}{d},\ 2\frac{n}{d},\dots,(d-1)\frac{n}{d}$, and there are d of them. *Check.* Count $=\gcd(m,n)$. For $m=4,n=6$: $d=2$, valid $\bar a\in\{\bar0,\bar3\}$, indeed $6\mid 4\cdot0$ and $6\mid 4\cdot3=12$; exactly 2 homs. Matches $|\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/4\mathbb{Z},\mathbb{Z}/6\mathbb{Z})|=2$.

Worked Example 10.2.10 ($M/\ker\cong\mathrm{im}$ for a concrete map)**.** Let $\varphi\colon\mathbb{Z}^2\to\mathbb{Z}$ be the $\mathbb{Z}$-linear map $\varphi(a,b)=2a-4b$. Identify $\ker\varphi$, $\mathrm{im}\,\varphi$, and verify the First Isomorphism Theorem.

Recognition. φ is $\mathbb{Z}$-linear (additive, and $\mathbb{Z}$-scalars come from additivity). *Recognition:* "compute a quotient by realizing it as the kernel of an explicit map" = apply $M/\ker\cong\mathrm{im}$.

Solution. Image: $\mathrm{im}\,\varphi=\{2a-4b : a,b\in\mathbb{Z}\}=2\mathbb{Z}$ since $\gcd(2,4)=2$ and $2a-4b$ ranges over all multiples of 2 (take $a=1,b=0$ to get 2). *Kernel:* $2a-4b=0\iff a=2b$, so $\ker\varphi=\{(2b,b) : b\in\mathbb{Z}\}=\mathbb{Z}\cdot(2,1)$, a rank-1 free submodule. *First Theorem:* $\mathbb{Z}^2/\mathbb{Z}(2,1)\cong2\mathbb{Z}\cong\mathbb{Z}$. *Check via a basis:* $\{(2,1),(1,0)\}$ is a $\mathbb{Z}$-basis of $\mathbb{Z}^2$ (the matrix with these as columns has determinant $2\cdot0-1\cdot1=-1$, a unit), so modding by $\mathbb{Z}(2,1)$ leaves the free rank-1 quotient generated by the image of $(1,0)$, i.e. $\mathbb{Z}$. Consistent with $2\mathbb{Z}\cong\mathbb{Z}$.

Worked Example 10.2.11 ($\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/m\mathbb{Z}) \cong \mathbb{Z}/\gcd(m,n)\mathbb{Z}$)**.** Prove $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/m\mathbb{Z}) \cong \mathbb{Z}/d\mathbb{Z}$ where $d = \gcd(m,n)$, as abelian groups.

Recognition. Maps out of the cyclic module $\mathbb{Z}/n\mathbb{Z}$ are determined by the image of $\bar{1}$; the set of valid images is itself a subgroup of $\mathbb{Z}/m\mathbb{Z}$. *Recognition:* "Hom out of a cyclic group" = annihilator subgroup of the codomain.

Solution. By the previous analysis, $\varphi \mapsto \varphi(\bar{1})$ is a map $\Theta\colon \mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/m\mathbb{Z}) \to \mathbb{Z}/m\mathbb{Z}$, and it is an injective group homomorphism: $\Theta(\varphi+\psi) = (\varphi+\psi)(\bar{1}) = \varphi(\bar{1}) + \psi(\bar{1})$, and φ is recovered from $\varphi(\bar{1})$. Its image is $\{\bar{a} \in \mathbb{Z}/m\mathbb{Z} : m \mid na\} = \{\bar{a} : \frac{m}{d} \mid a\} = \frac{m}{d}\mathbb{Z}/m\mathbb{Z} = \langle \overline{m/d} \rangle$. This is the unique subgroup of $\mathbb{Z}/m\mathbb{Z}$ of order d, which is cyclic, hence $\cong \mathbb{Z}/d\mathbb{Z}$. Therefore $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/m\mathbb{Z}) \cong \mathbb{Z}/d\mathbb{Z}$. *Check.* $n = 4, m = 6$ gives $d = 2$ and Hom $\cong \mathbb{Z}/2\mathbb{Z}$ (the two homs of the first example, $\bar{0}$ and $\bar{3}$, with $\bar{3} = \overline{6/2}$ generating the order-2 subgroup inside $\mathbb{Z}/6\mathbb{Z}$). $n = m$ gives $d = n$ and $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$, matching $\mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$.

Worked Example 10.2.12 ($\mathrm{Hom}_R(R, M) \cong M$)**.** For any R-module M, show evaluation at 1 gives an isomorphism $\mathrm{Hom}_R(R, M) \cong M$ (of R-modules when R is commutative).

Recognition. R is the free module on one generator 1; a hom out of it is determined by $\varphi(1)$, with no relations. *Recognition:* "Hom out of the free rank-1 module" = evaluation at the basis element.

Solution. Define $\Phi\colon \mathrm{Hom}_R(R, M) \to M$ by $\Phi(\varphi) = \varphi(1)$. *Homomorphism of abelian groups:* $\Phi(\varphi+\psi) = (\varphi+\psi)(1) = \varphi(1) + \psi(1)$. *Injective:* if $\varphi(1) = 0$ then $\varphi(r) = \varphi(r \cdot 1) = r\varphi(1) = 0$ for all r, so $\varphi = 0$. *Surjective:* given $m \in M$, define $\varphi_m(r) = rm$; this is R-linear since $\varphi_m(rr' + r'') = (rr' + r'')m = r(r'm) + r''m = r\varphi_m(r') + \varphi_m(r'')$, and $\Phi(\varphi_m) = \varphi_m(1) = m$. Hence Φ is a bijective homomorphism. When R is commutative, $\mathrm{Hom}_R(R, M)$ is an R-module (see below) and $\Phi(s\varphi) = (s\varphi)(1) = s\,\varphi(1) = s\Phi(\varphi)$, so Φ is R-linear. *Check.* For $R = M = \mathbb{Z}$, $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z}) \cong \mathbb{Z}$ (each hom is "multiply by $\varphi(1)$"), as expected.

Worked Example 10.2.13 ($F[x]$-module homs are operator-commuting linear maps)**.** Let V, W be $F[x]$-modules, i.e. F-vector spaces with linear operators $T\colon V \to V$ (action of x on V) and $S\colon W \to W$ (action of x on W). Show $\mathrm{Hom}_{F[x]}(V, W)$ is exactly the set of F-linear maps $\varphi\colon V \to W$ with $\varphi \circ T = S \circ \varphi$.

Recognition. $F[x]$ is generated as an F-algebra by F and x; an $F[x]$-hom must be F-linear and respect multiplication by x. *Recognition:* "module hom over $F[x]$" = intertwiner of the two operators.

Solution. An $F[x]$-linear φ is in particular F-linear (restrict scalars to $F \subseteq F[x]$). The scalar rule on the generator x reads $\varphi(x \cdot v) = x \cdot \varphi(v)$, i.e. $\varphi(Tv) = S\varphi(v)$, the intertwining relation $\varphi T = S\varphi$. Conversely, if φ is F-linear and $\varphi T = S\varphi$, then for any $p(x) = \sum c_i x^i \in F[x]$ we have $p(x) \cdot v = p(T)v$ and

$$\varphi(p(x) \cdot v) = \varphi\Big(\textstyle\sum_i c_i T^i v\Big) = \sum_i c_i\, \varphi(T^i v) = \sum_i c_i\, S^i \varphi(v) = p(S)\varphi(v) = p(x) \cdot \varphi(v),$$

where $\varphi(T^i v) = S^i \varphi(v)$ follows by iterating $\varphi T = S\varphi$. So φ is $F[x]$-linear. The intertwining condition is exactly commutativity of

$$\begin{array}{ccc} V & \xrightarrow{\ \varphi\ } & W \\ {\scriptstyle T}\downarrow & & \downarrow{\scriptstyle S} \\ V & \xrightarrow[\ \varphi\ ]{} & W \end{array}$$

Diagram explanation. Objects: Four copies of two F-vector spaces: V appears at upper-left and lower-left, W appears at upper-right and lower-right. Each space carries the structure of an $F[x]$-module: V is equipped with the linear operator T (multiplication by x on V), and W is equipped with S (multiplication by x on W).

Arrows: $\varphi\colon V \to W$ (top and bottom, the F-linear map being tested); it appears twice because the square depicts the two ways of composing with the operators. $T\colon V \to V$ (left side, the operator on V, i.e. the action of x on V). $S\colon W \to W$ (right side, the operator on W, the action of x on W).

What commutes: The square commutes iff $S \circ \varphi = \varphi \circ T$: applying φ then S (top-then-right) equals applying T then φ (left-then-bottom). This is exactly the intertwining relation.

Why it commutes: Take $v \in V$. Right-then-down: $v \overset{\varphi}{\mapsto} \varphi(v) \overset{S}{\mapsto} S(\varphi(v))$. Down-then-right: $v \overset{T}{\mapsto} Tv \overset{\varphi}{\mapsto} \varphi(Tv)$. These agree iff $\varphi(Tv) = S\varphi(v)$ for all v, which is exactly the condition that φ is $F[x]$-linear (respects multiplication by x). No well-definedness issue arises since φ is an ordinary F-linear map; the content is purely the commutativity condition.

Why this matters here: The worked example has just shown that $F[x]$-linearity of φ is equivalent to commutativity of this square. This repackages the algebraic condition $\varphi(x \cdot v) = x \cdot \varphi(v)$ into a visual that makes the intertwining requirement impossible to misstate.

Concrete example: Let $V = W = F^2$, $T = S = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ (the nilpotent Jordan block). The $F[x]$-module homs φ are exactly the F-linear maps whose matrix A satisfies $AS = SA$, i.e. matrices commuting with T. These are scalar multiples of I and T plus their span: $A = aI + bT$ for $a, b \in F$, giving a 2-dimensional commutant.

Common pitfall: Students sometimes read the diagram as saying $\varphi = T$ or $\varphi = S$; in fact φ goes between different spaces (or between two copies of the same space with possibly different operators) and the arrows T, S represent the module structure, not the map being studied. Also, commutativity of the square is a condition on φ, not a conclusion that follows for free.

Takeaway: The point of this diagram is that an $F[x]$-module homomorphism is precisely an F-linear map φ that intertwines the two operators, $\varphi \circ T = S \circ \varphi$ (φ need not be invertible, so it need not conjugate T into S), making the representation-theory notion of "intertwiner" identical to the module-homomorphism notion.

Check. If $V = W = F^2$ with $T = S = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, then the φ commuting with T are exactly the matrices $\left(\begin{smallmatrix} a & b \\ 0 & a \end{smallmatrix}\right)$ $(a, b \in F)$, a 2-dimensional space, consistent with $\operatorname{End}_{F[x]}(V)$ being the commutant of T.

Worked Example 10.2.14 (Quotient by a relation: $F[x]/(x^2)$ as a module map)**.** Let $R = F[x]$ and $M = F[x]$. Consider $\pi\colon F[x] \to F[x]/(x^2)$, the projection. Use the First Theorem to identify the quotient, and find im and ker of multiplication-by-x on $F[x]/(x^2)$.

Recognition. Projection onto a quotient ring viewed as a module: ker $= (x^2)$. Multiplication by x is an $F[x]$-endomorphism. *Recognition:* "identify a quotient module" = exhibit it as im of a surjection.

Solution. The projection $\pi\colon F[x] \to F[x]/(x^2)$ is surjective $F[x]$-linear with $\ker \pi = (x^2)$, so by Theorem 10.2.5, $F[x]/(x^2) \cong \operatorname{im} \pi = F[x]/(x^2)$ (tautologically), and as an F-vector space it has basis $\{\bar{1}, \bar{x}\}$. Now let $\mu_x\colon F[x]/(x^2) \to F[x]/(x^2)$, $\mu_x(\bar{f}) = x\bar{f}$. Then $\mu_x(\bar{1}) = \bar{x}$ and $\mu_x(\bar{x}) = \overline{x^2} = \bar{0}$. So $\operatorname{im} \mu_x = F\bar{x} = (x)/(x^2)$ and $\ker \mu_x = F\bar{x} = (x)/(x^2)$ as well. By the First Theorem applied to μ_x: $\big(F[x]/(x^2)\big)/\ker \mu_x \cong \operatorname{im} \mu_x$, i.e. $\big(F[x]/(x^2)\big)/\big((x)/(x^2)\big) \cong (x)/(x^2)$; both sides are 1-dimensional over F, consistent. *Check.* $\dim_F \ker \mu_x + \dim_F \operatorname{im} \mu_x = 1 + 1 = 2 = \dim_F F[x]/(x^2)$ (rank–nullity).

Worked Example 10.2.15 (Second and Third Theorems in $\mathbb{Z}$)**.** Inside $M = \mathbb{Z}$, take $A = 4\mathbb{Z}$ and $B = 6\mathbb{Z}$. Verify the Second Isomorphism Theorem; then with $A = 12\mathbb{Z} \leq B = 4\mathbb{Z} \leq \mathbb{Z}$, verify the Third.

Recognition. Submodules of $\mathbb{Z}$ are the ideals $n\mathbb{Z}$; sums and intersections are computed by gcd and lcm. *Recognition:* "check an isomorphism theorem on a concrete lattice."

Solution. Second: $A + B = 4\mathbb{Z} + 6\mathbb{Z} = \gcd(4,6)\mathbb{Z} = 2\mathbb{Z}$ and $A \cap B = 4\mathbb{Z} \cap 6\mathbb{Z} = \operatorname{lcm}(4,6)\mathbb{Z} = 12\mathbb{Z}$. The theorem predicts $(A + B)/B \cong A/(A \cap B)$, i.e. $2\mathbb{Z}/6\mathbb{Z} \cong 4\mathbb{Z}/12\mathbb{Z}$. Both are cyclic of order 3: $2\mathbb{Z}/6\mathbb{Z} = \{\bar{0}, \bar{2}, \bar{4}\} \cong \mathbb{Z}/3\mathbb{Z}$ and $4\mathbb{Z}/12\mathbb{Z} = \{\bar{0}, \bar{4}, \bar{8}\} \cong \mathbb{Z}/3\mathbb{Z}$. Confirmed. *Third:* with $12\mathbb{Z} \leq 4\mathbb{Z} \leq \mathbb{Z}$, the theorem gives $(\mathbb{Z}/12\mathbb{Z})/(4\mathbb{Z}/12\mathbb{Z}) \cong \mathbb{Z}/4\mathbb{Z}$. Now $\mathbb{Z}/12\mathbb{Z}$ has order 12, $4\mathbb{Z}/12\mathbb{Z}$ has order 3, so the quotient has order $12/3 = 4$, matching $|\mathbb{Z}/4\mathbb{Z}| = 4$. Confirmed.

The Hom group, the Hom module, and the endomorphism ring

Proposition 10.2.16 ($\operatorname{Hom}_R(M,N)$ is an abelian group)**.** *Let M, N be R-modules. Define $(\varphi + \psi)(m) = \varphi(m) + \psi(m)$. Then $\operatorname{Hom}_R(M,N)$ is an abelian group with this addition, identity the zero map, and inverse $(-\varphi)(m) = -\varphi(m)$.*

Proof. First, $\varphi+\psi$ is R-linear: $(\varphi+\psi)(rm+m') = \varphi(rm+m')+\psi(rm+m') = r\varphi(m)+\varphi(m')+r\psi(m)+\psi(m') = r(\varphi+\psi)(m) + (\varphi+\psi)(m')$, where commutativity of N was used to regroup. The group axioms (associativity, commutativity, identity, inverses) are inherited pointwise from the abelian group N. □

Proposition 10.2.17 ($\operatorname{Hom}_R(M,N)$ is an R-module when R is commutative)**.** *Suppose R is commutative. For $r \in R$ and $\varphi \in \operatorname{Hom}_R(M,N)$ define $(r\varphi)(m) = r\big(\varphi(m)\big)$. Then $r\varphi \in \operatorname{Hom}_R(M,N)$ and this makes $\operatorname{Hom}_R(M,N)$ an R-module.*

Proof. We must check $r\varphi$ is again R-linear — this is where commutativity is needed. For $s \in R$, $m \in M$:

$$(r\varphi)(sm) = r\big(\varphi(sm)\big) = r\big(s\,\varphi(m)\big) = (rs)\varphi(m) = (sr)\varphi(m) = s\big(r\varphi(m)\big) = s\,(r\varphi)(m),$$

using $rs = sr$ in the middle. Additivity of $r\varphi$ is immediate. The module axioms for $\mathrm{Hom}_R(M,N)$ follow pointwise from those of N. □

Caution. If R is *not* commutative, $(r\varphi)(m) = r\varphi(m)$ generally fails to be R-linear: the computation above breaks at $rs = sr$. So in general $\mathrm{Hom}_R(M,N)$ is only an abelian group, not an R-module. (It does carry actions by the center of R and by End_R, but not by R itself in general.)

Theorem 10.2.18 ($\mathrm{End}_R(M)$ is a ring)**.** *$\mathrm{End}_R(M) = \mathrm{Hom}_R(M,M)$ is a ring with 1 under pointwise addition and composition as multiplication; the identity is id_M. When R is commutative, $\mathrm{End}_R(M)$ is an R-algebra, and M is naturally a left $\mathrm{End}_R(M)$-module via $\varphi \cdot m = \varphi(m)$.*

Proof. By Proposition 10.2.16, $(\mathrm{End}_R(M), +)$ is an abelian group. Composition of R-linear maps is R-linear and associative, with two-sided identity id_M. Distributivity: $(\varphi \circ (\psi + \chi))(m) = \varphi(\psi(m) + \chi(m)) = \varphi\psi(m) + \varphi\chi(m)$ (using additivity of φ), and $((\psi + \chi) \circ \varphi)(m) = \psi\varphi(m) + \chi\varphi(m)$. Hence $\mathrm{End}_R(M)$ is a ring with $1 = \mathrm{id}_M$. When R is commutative, $r \mapsto r \cdot \mathrm{id}_M$ maps R into the center of $\mathrm{End}_R(M)$ (since $r\,\mathrm{id}_M$ commutes with every R-linear φ: $\varphi(rm) = r\varphi(m)$), making $\mathrm{End}_R(M)$ an R-algebra. The action $\varphi \cdot m = \varphi(m)$ satisfies $(\varphi\psi)\cdot m = \varphi(\psi(m)) = \varphi \cdot (\psi \cdot m)$ and $\mathrm{id}_M \cdot m = m$, so M is a left $\mathrm{End}_R(M)$-module. □

Method (Recognizing $\mathrm{End}_R(M)$)**.** *Trigger.* Asked to compute or describe $\mathrm{End}_R(M)$ for a specific module. *Recipe.*

1. If R is commutative and $M = R^n$ is free, $\mathrm{End}_R(R^n) \cong M_n(R)$ (matrices acting on column vectors). For noncommutative R, left multiplication by a matrix is not R-linear: the R-linear maps of the left module R^n (row vectors) are $v \mapsto vB$, and $\mathrm{End}_R(R^n) \cong M_n(R^{\mathrm{op}})$, where the opposite ring R^{op} is R with the product $a * b = ba$ (so $\mathrm{End}_R(R) \cong R^{\mathrm{op}}$).
2. If M is an $F[x]$-module (V, T), $\mathrm{End}_{F[x]}(V)$ is the *commutant* of T: all F-linear maps commuting with T.
3. If $M = \mathbb{Z}/n\mathbb{Z}$ over $\mathbb{Z}$, $\mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$ (each endomorphism is multiplication by a residue).

Worked Example 10.2.19 ($\mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$ as a ring)**.** Show $\mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$ as rings.

Recognition. Endomorphisms of the cyclic group $\mathbb{Z}/n\mathbb{Z}$ are determined by the image of $\bar{1}$, which can be any element. *Recognition:* "endomorphism ring of a cyclic module."

Solution. By the analysis of homs out of cyclic modules with $m = n$ (so $d = \gcd(n,n) = n$), *every* $\bar{a} \in \mathbb{Z}/n\mathbb{Z}$ arises as $\varphi(\bar{1})$, giving $\varphi_a(\bar{k}) = k\bar{a} = \overline{ka}$. The map $\bar{a} \mapsto \varphi_a$ is a bijection $\mathbb{Z}/n\mathbb{Z} \to \mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z})$. It respects addition: $\varphi_a + \varphi_b = \varphi_{a+b}$. It respects multiplication via composition: $(\varphi_a \circ \varphi_b)(\bar{1}) = \varphi_a(\bar{b}) = \overline{ab} = \varphi_{ab}(\bar{1})$, so $\varphi_a \circ \varphi_b = \varphi_{ab}$. And $\varphi_1 = \mathrm{id}$. Hence $\bar{a} \mapsto \varphi_a$ is a ring isomorphism $\mathbb{Z}/n\mathbb{Z} \cong \mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z})$. *Check.* Units of $\mathrm{End}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z})$ = automorphisms $\mathrm{Aut}(\mathbb{Z}/n\mathbb{Z}) \cong (\mathbb{Z}/n\mathbb{Z})^\times$, matching the units on the ring side. For $n = 6$: $|(\mathbb{Z}/6\mathbb{Z})^\times| = \phi(6) = 2$, and indeed $\mathrm{Aut}(\mathbb{Z}/6\mathbb{Z})$ has order 2.

Worked Example 10.2.20 (Hom is additive: $\mathrm{Hom}_R(M, N_1 \oplus N_2) \cong \mathrm{Hom}_R(M,N_1) \oplus \mathrm{Hom}_R(M,N_2)$)**.** Establish the natural isomorphism of abelian groups (of R-modules if R commutative).

Recognition. A map into a direct sum is the same as a pair of maps into the factors, via the projections. *Recognition:* "Hom into a direct sum splits."

Solution. Let $p_i \colon N_1 \oplus N_2 \to N_i$ be the projections. Define $\Theta(\varphi) = (p_1\varphi, p_2\varphi)$. This is an additive map $\mathrm{Hom}_R(M, N_1 \oplus N_2) \to \mathrm{Hom}_R(M,N_1) \oplus \mathrm{Hom}_R(M,N_2)$. *Inverse:* given (α, β), set $\Psi(\alpha,\beta)(m) = (\alpha(m), \beta(m))$, which is R-linear into $N_1 \oplus N_2$. Then $\Theta\Psi(\alpha,\beta) = (\alpha,\beta)$ and $\Psi\Theta(\varphi) = \varphi$ since $\varphi(m) = (p_1\varphi(m), p_2\varphi(m))$. Hence Θ is an isomorphism. *Check.* $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$, matching $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}, \mathbb{Z}/6\mathbb{Z}) \cong \mathbb{Z}/6\mathbb{Z}$ and the CRT $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}$.

Worked Example 10.2.21 (A non-example, then repaired to a linear map)**.** Decide whether $\varphi\colon \mathbb{R}^2 \to \mathbb{R}$, $\varphi(x,y) = x^2 + y$, is an $\mathbb{R}$-module homomorphism; then repair it.

Recognition. Test the two axioms; squaring destroys additivity/scaling. *Recognition:* "is this a module map?" = check linearity, do not assume.

Solution. Scalar test: $\varphi(r(x,y)) = \varphi(rx,ry) = (rx)^2 + ry = r^2x^2 + ry$, whereas $r\varphi(x,y) = r(x^2+y) = rx^2 + ry$. These differ (e.g. $r = 2, (x,y) = (1,0)$: $\varphi(2,0) = 4$ but $2\varphi(1,0) = 2$). So φ is *not* $\mathbb{R}$-linear. *Repair:* drop the square: $\psi(x,y) = ax + by$ for fixed $a, b \in \mathbb{R}$ is $\mathbb{R}$-linear, and these are *all* of $\mathrm{Hom}_{\mathbb{R}}(\mathbb{R}^2, \mathbb{R})$ (the dual space), since ψ is determined by $\psi(e_1) = a$, $\psi(e_2) = b$. *Check.* $\mathrm{Hom}_{\mathbb{R}}(\mathbb{R}^2, \mathbb{R}) \cong \mathbb{R}^2$ as $\mathbb{R}$-modules, consistent with $\mathrm{Hom}_R(R^2, M) \cong M^2$ at $M = \mathbb{R}$.

Exercises (from the text).

1. Use the submodule criterion to show that kernels and images of R-module homomorphisms are submodules.
2. Show that the relation "is R-module isomorphic to" is an equivalence relation on any set of R-modules.
3. Give an explicit example of a map from one R-module to another which is not an R-module homomorphism but which is a homomorphism of the groups involved (i.e., is a $\mathbb{Z}$-module homomorphism).
4. Let A be any $\mathbb{Z}$-module, let a be any element of A and let n be a positive integer. Prove that the map $\varphi_a : \mathbb{Z}/n\mathbb{Z} \to A$ given by $\varphi_a(\bar{k}) = ka$ is a well defined $\mathbb{Z}$-module homomorphism if and only if $na = 0$. Prove that $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, A) \cong A_n$, where $A_n = \{a \in A \mid na = 0\}$ (so A_n is the annihilator in A of the ideal (n) of $\mathbb{Z}$, cf. Exercise 10, Section 1).
5. Exhibit all $\mathbb{Z}$-module homomorphisms from $\mathbb{Z}/3\mathbb{Z}$ to $\mathbb{Z}/9\mathbb{Z}$.
6. Prove that $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/m\mathbb{Z}) \cong \mathbb{Z}/(n,m)\mathbb{Z}$.
7. Let z be a fixed element of the center of R. Prove that the map $m \mapsto zm$ is an R-module homomorphism from M to itself. Show that for a commutative ring R the map from R to $\mathrm{End}_R(M)$ given by $r \mapsto r\,\mathrm{id}_M$ is a ring homomorphism (where id_M is the identity endomorphism).
8. Let $\varphi : M \to N$ be an R-module homomorphism. Prove that $\varphi(\mathrm{Tor}(M)) \subseteq \mathrm{Tor}(N)$ (cf. Exercise 8 in Section 1).
9. Let R be a commutative ring. Prove that $\mathrm{Hom}_R(R, M)$ and M are isomorphic as left R-modules. [Show that each element of $\mathrm{Hom}_R(R, M)$ is determined by its value on the identity of R.]
10. Let R be a commutative ring. Prove that $\mathrm{Hom}_R(R, R)$ and R are isomorphic as rings.
11. Let $A_1, A_2, \ldots, A_n$ be R-modules and let B_i be a submodule of A_i for each $i = 1, 2, \ldots, n$. Prove that
$$(A_1 \times \cdots \times A_n)/(B_1 \times \cdots \times B_n) \cong (A_1/B_1) \times \cdots \times (A_n/B_n).$$
[Recall Exercise 14 in Section 5.1.]
12. Let I be a left ideal of R and let n be a positive integer. Prove
$$R^n/IR^n \cong \underbrace{R/IR \times \cdots \times R/IR}_{n}$$
where IR^n is defined as in Exercise 5 of Section 1. [Use the preceding exercise.]
13. Let I be a nilpotent ideal in a commutative ring R (cf. Exercise 37, Section 7.3), let M and N be R-modules and let $\varphi : M \to N$ be an R-module homomorphism. Show that if the induced map $\bar{\varphi} : M/IM \to N/IN$ is surjective, then φ is surjective.
14. Let $R = \mathbb{Z}[x]$ be the ring of polynomials in x and let $A = \mathbb{Z}[\theta_1, \theta_2, \ldots]$ be the ring of polynomials in independent indeterminates $\theta_1, \theta_2, \ldots$. Define an action of R on A as follows: (1) let $1 \in R$ act on A as the identity, (2) for $n \geq 1$ let $x^n \circ 1 = \theta_n$, let $x^n \circ \theta_i = \theta_{n+i}$ for all $i \geq 1$, and let x^n act as 0 on every monomial of total degree at least 2, and (3) extend $\mathbb{Z}$-linearly in both variables, i.e., $(f+g) \circ a = f \circ a + g \circ a$ and $f \circ (a+b) = f \circ a + f \circ b$ for all $f, g \in R$ and $a, b \in A$.

(a) Show that $x^{p+q}\circ a = x^p\circ(x^q\circ a)$ for all $p, q \geq 0$ and every monomial a (the key case is $x^{p+q}\circ\theta_i = \theta_{p+q+i}$), and deduce that A is a (unital) R-module under this action.
(b) Show that the map $\varphi\colon R \to A$, $\varphi(r) = r \circ 1$, is an R-module homomorphism with $\varphi(1) = 1$, but is not a ring homomorphism.

15. Let M be an R-module. Prove that if R is a commutative ring then $\mathrm{Hom}_R(M, M)$ is an R-module. [Show how an element r acting on the map φ gives a map $r\varphi$, and that this map is again an R-module homomorphism.]

16. For any left ideal I of R define

$$IM = \left\{ \sum_{\text{finite}} a_i m_i \mid a_i \in I,\ m_i \in M \right\}$$

to be the collection of all finite sums of elements of the form am where $a \in I$ and $m \in M$. Prove that IM is a submodule of M.

Practice problems.

1. Let R be a ring with 1 and let M be a left R-module. Show that the map $\varphi\colon M \to M$ defined by $\varphi(m) = rm$ for a fixed central element r (i.e. $rs = sr$ for all $s \in R$) is an R-module homomorphism. Give an example with R noncommutative and r not central where φ fails to be a homomorphism.

2. Let $N \leq M$ be a submodule. Verify directly from the axioms that the quotient M/N is a left R-module under $r(m + N) = rm + N$, including a check that this action is well defined.

3. Let $\varphi\colon M \to N$ be an R-module homomorphism. Prove that $\ker\varphi \leq M$ and $\mathrm{im}\,\varphi \leq N$, and that φ is injective if and only if $\ker\varphi = 0$.

4. Regard $\mathbb{Z}/12\mathbb{Z}$ as a $\mathbb{Z}$-module. List all of its submodules, and for each submodule N identify the quotient $(\mathbb{Z}/12\mathbb{Z})/N$ up to isomorphism.

5. Let $R = \mathbb{Z}$ and let $\varphi\colon \mathbb{Z}^2 \to \mathbb{Z}$ be given by $\varphi(a, b) = 2a - 3b$. Compute $\ker\varphi$ and $\mathrm{im}\,\varphi$, and describe $\mathbb{Z}^2/\ker\varphi$.

6. Let $V = \mathbb{R}^2$ be viewed as an $\mathbb{R}[x]$-module via the linear operator $T(x_1, x_2) = (x_2, -x_1)$ (so x acts as T). Determine all $\mathbb{R}[x]$-submodules of V. (Hint: these are the T-invariant subspaces.)

7. Let M be a left R-module and let $A \subseteq M$ be any subset. Show that

$$RA = \left\{ \textstyle\sum_{i=1}^{k} r_i a_i : k \in \mathbb{Z}_{\geq 0},\ r_i \in R,\ a_i \in A \right\}$$

is the smallest submodule of M containing A.

8. Let $\varphi\colon M \to N$ be an R-module homomorphism and let $L \leq N$. Prove that $\varphi^{-1}(L) = \{m \in M : \varphi(m) \in L\}$ is a submodule of M containing $\ker\varphi$.

9. Show that the map $\mathrm{Hom}_R(R, M) \to M$ sending $\varphi \mapsto \varphi(1)$ is an isomorphism of abelian groups, where R is viewed as a left R-module over itself.

10. Let M and N be R-modules. Prove that $\mathrm{Hom}_R(M, N)$ is an abelian group under pointwise addition. If R is commutative, show that $\mathrm{Hom}_R(M, N)$ is itself an R-module via $(r\varphi)(m) = r\,\varphi(m)$, and explain where commutativity is used.

11. Let R be commutative and let $M = R^n$ be the free module of rank n. Prove that $\mathrm{End}_R(M) = \mathrm{Hom}_R(M, M)$ is isomorphic to the ring $M_n(R)$ of $n \times n$ matrices over R.

12. Let $\varphi\colon M \to N$ be a surjective R-module homomorphism. Establish a bijection between the submodules of N and the submodules of M that contain $\ker\varphi$, and show this bijection preserves inclusions.

13. Let $A, B \leq M$. Prove the Second Isomorphism Theorem for modules:

$$(A + B)/B \ \cong\ A/(A \cap B).$$

14. Let $N \le L \le M$. Prove the Third Isomorphism Theorem for modules:

$$(M/N)/(L/N) \;\cong\; M/L.$$

15. Let $\varphi\colon \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ be a $\mathbb{Z}$-module homomorphism with $\varphi(\bar{1}) = \bar{4}$. Compute $\ker\varphi$ and $\operatorname{im}\varphi$ explicitly, and decide whether φ is an isomorphism.

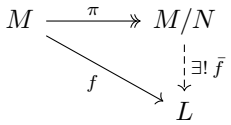
16. Let R be a ring with 1. Show that a left R-module M is the same data as an abelian group M together with a ring homomorphism $R \to \operatorname{End}_{\mathbb{Z}}(M)$ that sends 1_R to id_M (this is where (M4) enters).

Additional exercises.

1. Let R be commutative and M an R-module. Recall $\operatorname{Ann}_R(M) = \{r \in R : rm = 0 \text{ for all } m \in M\}$. Show $\operatorname{Ann}_R(M)$ is a two-sided ideal of R, and that M is naturally a module over $R/\operatorname{Ann}_R(M)$. If $M = \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$ as a $\mathbb{Z}$-module, compute $\operatorname{Ann}_{\mathbb{Z}}(M)$.

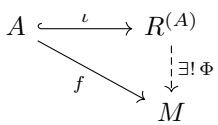
2. Let M be a left R-module. An element $m \in M$ is a *torsion element* if $rm = 0$ for some nonzero $r \in R$. Suppose R is an integral domain. Prove that the set $\operatorname{Tor}(M)$ of torsion elements is a submodule of M, and that $M/\operatorname{Tor}(M)$ is torsion-free. Show by example that $\operatorname{Tor}(M)$ need not be a submodule when R has zero divisors.

3. Let $\varphi\colon M \to N$ be an R-module homomorphism and suppose there exists an R-module homomorphism $\psi\colon N \to M$ with $\varphi\circ\psi = \mathrm{id}_N$. Prove that $M \cong \ker\varphi \oplus \operatorname{im}\psi$, and that ψ is injective with $\operatorname{im}\psi$ a complement to $\ker\varphi$.



4. Let R be commutative with $1 \neq 0$. Prove that any two bases of the free module R^n have the same cardinality (so rank is well defined), by reducing modulo a maximal ideal $\mathfrak{m}$ of R and using dimension over the field $R/\mathfrak{m}$.

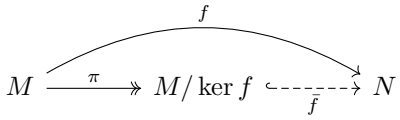
5. Let M be an R-module generated by a single element, say $M = Rm$. Prove that $M \cong R/\operatorname{Ann}_R(m)$ as R-modules, where $\operatorname{Ann}_R(m) = \{r \in R : rm = 0\}$. Conclude that every cyclic abelian group is $\cong \mathbb{Z}/n\mathbb{Z}$ for some $n \ge 0$.



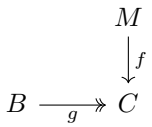
6. Let R be a ring and let $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ be a short exact sequence of R-modules. Prove that the following are equivalent: (i) there is $s\colon C \to B$ with $\varphi \circ s = \mathrm{id}_C$; (ii) there is $r\colon B \to A$ with $r \circ \psi = \mathrm{id}_A$; (iii) $B \cong A \oplus C$ compatibly with ψ, φ.

Commutative-diagram exercises.

1. (Universal property of the quotient.) Let $N \le M$ and let $\pi\colon M \to M/N$ be the canonical projection. Prove that for every R-module homomorphism $f\colon M \to L$ with $N \subseteq \ker f$ there is a *unique* R-module homomorphism $\bar{f}\colon M/N \to L$ making the diagram commute:

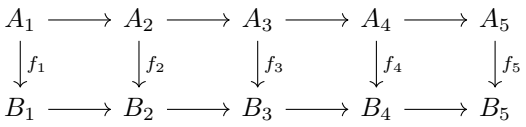


2. (Free module / universal property.) Let A be a set, $R^{(A)}$ the free R-module on A, and $\iota\colon A \to R^{(A)}$ the inclusion of basis. Given an R-module M and any set map $f\colon A \to M$, show there is a unique R-module homomorphism $\Phi\colon R^{(A)} \to M$ with $\Phi \circ \iota = f$:



Deduce that every R-module is a quotient of a free R-module.

3. (Factoring a homomorphism.) Let $f\colon M \to N$ be an R-module homomorphism. Using the universal property of the quotient, construct the canonical factorization through $\bar{f}$ and prove $\bar{f}$ is injective:



Conclude the First Isomorphism Theorem $M/\ker f \cong \operatorname{im} f$.

4. (Lifting against a surjection.) Suppose

is given with g surjective and M free on a basis $\{e_i\}$. Construct a homomorphism $\tilde{f}\colon M \to B$ with $g \circ \tilde{f} = f$ by choosing preimages of $f(e_i)$, and explain which property of free modules makes the lift exist. Is $\tilde{f}$ unique?

5. (The five lemma.) Consider a commutative diagram of R-modules with exact rows

Prove the Five Lemma: if f_1 is surjective, f_5 is injective, and f_2, f_4 are isomorphisms, then f_3 is an isomorphism. (Do an honest diagram chase, surjectivity of f_3 first, then injectivity.)

10.3 Generation of Modules, Direct Sums, and Free Modules

Generating submodules, direct sums, and free modules

Throughout, R is a ring with $1 \neq 0$ and modules are unital left R-modules unless stated otherwise. We study three constructions: the submodule *generated* by a subset, the *direct sum* (external and internal), and the *free* module on a set together with its universal property.

1. The submodule generated by a subset.

Definition 10.3.1 (Submodule generated by a subset)**.** Let M be an R-module and $A \subseteq M$ a subset.

- $RA = \{ r_1a_1 + \cdots + r_na_n \,:\, n \in \mathbb{Z}_{\geq 0},\ r_i \in R,\ a_i \in A \}$ is the set of all (finite) R-linear combinations of elements of A (with the empty sum equal to 0). This is the *submodule generated by* A; it is the smallest submodule of M containing A, and equals the intersection of all submodules containing A.
- If $RA = M$ we say A *generates* M, or A is a *set of generators*.
- M is *finitely generated* if $M = RA$ for some finite set A.
- M is *cyclic* if $M = Rm = \{rm : r \in R\}$ for a single $m \in M$.

Proposition 10.3.2 (Cyclic modules are quotients of R: $Rm \cong R/\operatorname{Ann}(m)$)**.** *Let M be an R-module and $m \in M$. Define $\pi : R \to M$ by $\pi(r) = rm$. Then π is an R-module homomorphism with image Rm, and*

$$\ker \pi = \operatorname{Ann}(m) := \{r \in R : rm = 0\},$$

which is a left ideal of R. Hence

$$Rm \;\cong\; R/\operatorname{Ann}(m)$$

as left R-modules. In particular M is cyclic iff $M \cong R/I$ for some left ideal I of R.

Proof. For $r, s \in R$ and the module axioms, $\pi(r+s) = (r+s)m = rm + sm = \pi(r) + \pi(s)$ and $\pi(sr) = (sr)m = s(rm) = s\,\pi(r)$, so π is an R-module map (here R is viewed as a left module over itself). Its image is $\{rm : r \in R\} = Rm$. Its kernel is $\{r : rm = 0\} = \operatorname{Ann}(m)$, a submodule of the left R-module R, i.e. a left ideal. The First Isomorphism Theorem for modules gives $R/\ker\pi \cong \operatorname{im}\pi$, that is $R/\operatorname{Ann}(m) \cong Rm$. If $M = Rm$ then $M \cong R/\operatorname{Ann}(m)$; conversely if $M \cong R/I$ then the image of 1 generates, so M is cyclic. □

Method (Identifying and analyzing RA, finitely generated, cyclic)**.** *Trigger.* You are asked what a subset *generates*, whether a module is finitely generated/cyclic, or to identify a cyclic module up to isomorphism.

1. To compute RA: take *all* finite R-linear combinations $\sum r_i a_i$. Verify it is closed under $+$ and under R-scaling (it is, by construction).
2. "Cyclic" means *one* generator m: then $M = Rm \cong R/\operatorname{Ann}(m)$. Compute $\operatorname{Ann}(m) = \{r : rm = 0\}$ as a left ideal; read off the quotient.
3. "Finitely generated" means *some finite* A works; to disprove, show no finite set generates (e.g. a divisibility/denominator obstruction).
4. Over a field $R = F$: modules are vector spaces; "finitely generated" = "finite-dimensional", "cyclic" = "dimension ≤ 1".

Worked Example 10.3.3 (Cyclic $\mathbb{Z}$-modules: $\mathbb{Z}m \cong \mathbb{Z}/\operatorname{Ann}(m)$)**.** Let $M = \mathbb{Z}/12\mathbb{Z}$ as a $\mathbb{Z}$-module and $m = \overline{8}$. Identify the cyclic submodule $\mathbb{Z}m$ and write it as $\mathbb{Z}/\operatorname{Ann}(m)$.

Recognition. The rule $Rm \cong R/\operatorname{Ann}(m)$ with $R = \mathbb{Z}$, $M = \mathbb{Z}/12\mathbb{Z}$: compute $\operatorname{Ann}(\overline{8})$ as an ideal of $\mathbb{Z}$.

Solution. $\operatorname{Ann}(\overline{8}) = \{k \in \mathbb{Z} : 8k \equiv 0 \pmod{12}\}$. Now $8k \equiv 0 \pmod{12}$ iff $12 \mid 8k$ iff $3 \mid 2k$ iff $3 \mid k$. So $\operatorname{Ann}(\overline{8}) = 3\mathbb{Z}$, and

$$\mathbb{Z}\,\overline{8} \;\cong\; \mathbb{Z}/3\mathbb{Z} = \mathbb{Z}/3\mathbb{Z}.$$

Concretely $\mathbb{Z}\overline{8} = \{\overline{0}, \overline{8}, \overline{4}\}$ (since $2 \cdot \overline{8} = \overline{16} = \overline{4}$, $3 \cdot \overline{8} = \overline{24} = \overline{0}$), a 3-element submodule. *Check.* $|\mathbb{Z}\overline{8}| = 12/\gcd(8,12) = 12/4 = 3$, matching $|\mathbb{Z}/3\mathbb{Z}| = 3$. Consistent.

Worked Example 10.3.4 (A cyclic module over a polynomial ring)**.** Let $R = \mathbb{F}[x]$ where $\mathbb{F}$ is a field, and let $M = R$, $m = x^2 - 1 \in R$. Describe Rm and its annihilator. Then redo with $M = R/(x^2-1)$ and $m = \overline{x}$.

Recognition. $Rm \cong R/\operatorname{Ann}(m)$. In an integral domain Ann of a nonzero element is 0; in a quotient ring use the quotient law.

Solution. (a) $R = \mathbb{F}[x]$ is a domain, so $\operatorname{Ann}_R(x^2-1) = \{f : f \cdot (x^2-1) = 0\} = 0$. Hence $R(x^2-1) \cong R/0 \cong R$, the principal ideal (x^2-1), a free rank-1 submodule. (b) In $M = R/(x^2-1)$, $\operatorname{Ann}_M(\overline{x}) = \{f : f\,\overline{x} = \overline{0}\} = \{f : (x^2-1) \mid xf\}$. Since $\gcd(x, x^2-1) = 1$, $(x^2-1) \mid xf$ iff $(x^2-1) \mid f$, so $\operatorname{Ann}(\overline{x}) = (x^2-1)$ and $R\overline{x} \cong R/(x^2-1) = M$; thus $\overline{x}$ generates M and M is cyclic. *Check.* $\dim_{\mathbb{F}} M = 2$ with basis $\overline{1}, \overline{x}$; and $\overline{x} \cdot \overline{x} = \overline{x^2} = \overline{1}$, so $R\overline{x} \supseteq \{\overline{1}, \overline{x}\}$ spans, confirming $M = R\overline{x}$.

Worked Example 10.3.5 (Cyclic over a noncommutative ring: Ann is only a left ideal)**.** Let $R = M_2(\mathbb{F})$ (a noncommutative ring) acting on the column space $M = \mathbb{F}^2$. Take $m = \binom{1}{0}$. Show $M = Rm$ and compute $\operatorname{Ann}(m)$.

Recognition. $Rm \cong R/\operatorname{Ann}(m)$ where $\operatorname{Ann}(m)$ is a *left* ideal (not two-sided when R is noncommutative).

Solution. For $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, $Am = \binom{a}{c}$ ranges over all of $\mathbb{F}^2$ as a, c vary, so $Rm = \mathbb{F}^2 = M$ (cyclic). And $\operatorname{Ann}(m) = \{A : Am = 0\} = \{A : a = c = 0\} = \left\{\left(\begin{smallmatrix} 0 & b \\ 0 & d \end{smallmatrix}\right)\right\}$, the matrices with zero first column. *Check.* This set is closed under left multiplication: $B\left(\begin{smallmatrix} 0 & b \\ 0 & d \end{smallmatrix}\right)$ again has zero first column, confirming it is a left ideal. It is *not* a right ideal (multiplying on the right by a permutation can move the nonzero column), as expected.

Worked Example 10.3.6 (Generators need not be unique or minimal)**.** In $M = \mathbb{Z}/6\mathbb{Z}$ (a $\mathbb{Z}$-module), show $A = \{\overline{2}, \overline{3}\}$ generates M but M is also cyclic.

Recognition. RA is all $\mathbb{Z}$-combinations; cyclic means a single generator suffices.

Solution. $\mathbb{Z}\{\overline{2}, \overline{3}\} \ni \overline{3} - \overline{2} = \overline{1}$, and $\overline{1}$ generates $\mathbb{Z}/6\mathbb{Z}$, so A generates M. But also $M = \mathbb{Z}\overline{1}$ is cyclic with the single generator $\overline{1}$. Thus $\{\overline{2}, \overline{3}\}$ is a (non-minimal) generating set. *Check.* $\operatorname{Ann}(\overline{1}) = 6\mathbb{Z}$ so $\mathbb{Z}\overline{1} \cong \mathbb{Z}/6\mathbb{Z} = M$; the two-element set is genuinely redundant.

2. Direct sums: external and internal.

Definition 10.3.7 (External direct sum)**.** Given R-modules $M_1, \dots, M_n$, their *(external) direct sum* is the Cartesian product

$$M_1 \oplus \cdots \oplus M_n = \{(m_1, \dots, m_n) : m_i \in M_i\}$$

with componentwise operations $(m_i) + (m_i') = (m_i + m_i')$ and $r(m_i) = (rm_i)$. For an arbitrary index set, the direct sum $\bigoplus_{i \in I} M_i$ consists of tuples with *finitely many* nonzero entries (inside the direct product $\prod_{i \in I} M_i$).

Proposition 10.3.8 (Internal direct sum criterion)**.** *Let $N_1, \dots, N_k$ be submodules of an R-module M. The following are equivalent.*

(1) The map $\pi : N_1 \oplus \cdots \oplus N_k \to M$, $\pi(a_1, \dots, a_k) = a_1 + \cdots + a_k$, is an isomorphism (onto M).

(2) $M = N_1 + \cdots + N_k$ and for each i,

$$N_i \cap \Big(\sum_{j \neq i} N_j \Big) = 0.$$

(3) Every $m \in M$ is written uniquely *as $m = a_1 + \cdots + a_k$ with $a_i \in N_i$.*

When these hold we write $M = N_1 \oplus \cdots \oplus N_k$ and call it the internal direct sum*.*

Proof. π is always an R-module homomorphism, and $\operatorname{im} \pi = N_1 + \cdots + N_k$; so π is surjective iff $M = \sum N_i$. It remains to relate injectivity of π to (2) and to (3). Injectivity is equivalent to: the only way to write $0 = a_1 + \cdots + a_k$ with $a_i \in N_i$ is $a_i = 0$ for all i. If some $a_i \neq 0$ with $\sum a_j = 0$, then $a_i = -\sum_{j \neq i} a_j \in N_i \cap \sum_{j \neq i} N_j$, a nonzero element; conversely a nonzero element of $N_i \cap \sum_{j \neq i} N_j$ produces a nontrivial relation. Hence injectivity $\iff$ (2). Finally, two representations $m = \sum a_i = \sum a_i'$ differ by a representation of 0, so uniqueness in (3) is exactly injectivity of π together with surjectivity. Thus (1) $\iff$ (2) $\iff$ (3). □

Caution. For three or more submodules, *pairwise* trivial intersection $N_i \cap N_j = 0$ $(i \neq j)$ is **not** enough for a direct sum. The correct condition is $N_i \cap \big(\sum_{j \neq i} N_j \big) = 0$ for each i. Example in $M = \mathbb{R}^2$: lines $N_1 = \mathbb{R}(1,0)$, $N_2 = \mathbb{R}(0,1)$, $N_3 = \mathbb{R}(1,1)$ meet pairwise in 0, yet $N_3 \subseteq N_1 + N_2$, so $N_3 \cap (N_1 + N_2) = N_3 \neq 0$ and the sum is not direct.

Method (Recognizing a direct sum)**.** *Trigger.* You must decide whether M splits as $N_1 \oplus \cdots \oplus N_k$, or build a module out of pieces.

1. **External:** just form tuples with componentwise structure; this always exists.
2. **Internal (two summands):** check $M = N_1 + N_2$ *and* $N_1 \cap N_2 = 0$.
3. **Internal ($k \geq 3$):** check $M = \sum N_i$ *and* $N_i \cap \sum_{j \neq i} N_j = 0$ for every i (NOT just pairwise).
4. Equivalent shortcut: show *unique* representation $m = \sum a_i$. Existence ⇒ spanning; uniqueness ⇒ the intersection condition.

Worked Example 10.3.9 ($\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ as $\mathbb{Z}$-modules (CRT))**.** Show $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ as $\mathbb{Z}$-modules, both externally (via a map) and internally (via submodules).

Recognition. Internal direct sum criterion plus the cyclic isomorphism $Rm \cong R/\operatorname{Ann}(m)$; $\mathbb{Z}$-module = abelian group.

Solution. **External map.** Define $\varphi : \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ by $\varphi(k) = (k \bmod 2,\ k \bmod 3)$, a $\mathbb{Z}$-module homomorphism. $\ker \varphi = \{k : 2 \mid k \text{ and } 3 \mid k\} = 6\mathbb{Z}$ (since $\gcd(2,3) = 1$). It is surjective: $|\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}| = 6 = [\mathbb{Z} : 6\mathbb{Z}]$ and injectivity on the quotient forces a bijection. So $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$, i.e. $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$.

Internal. In $M = \mathbb{Z}/6\mathbb{Z}$ set $N_1 = \mathbb{Z}\overline{3} = \{\overline{0}, \overline{3}\}$ and $N_2 = \mathbb{Z}\overline{2} = \{\overline{0}, \overline{2}, \overline{4}\}$. Then $\operatorname{Ann}(\overline{3}) = 2\mathbb{Z}$ so $N_1 \cong \mathbb{Z}/2\mathbb{Z}$; $\operatorname{Ann}(\overline{2}) = 3\mathbb{Z}$ so $N_2 \cong \mathbb{Z}/3\mathbb{Z}$. Also $N_1 \cap N_2 = \{\overline{0}\}$ (orders 2 and 3 are coprime) and $N_1 + N_2 \ni \overline{3} + \overline{2} = \overline{5}$ and $\overline{3} + \overline{4} = \overline{1}$, so $N_1 + N_2 = M$. By the two-summand criterion $M = N_1 \oplus N_2 \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$. *Check.* $\overline{1} = \overline{3} + \overline{4} = \overline{3} + 2 \cdot \overline{2}$ uniquely splits as $(\overline{3},\ \overline{4}) \in N_1 \times N_2$; orders multiply $2 \cdot 3 = 6$. Consistent.

Worked Example 10.3.10 (When CRT fails: $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$)**.** Decide whether $\mathbb{Z}/4\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$ as $\mathbb{Z}$-modules.

Recognition. Direct sum / structure: compare element orders (a $\mathbb{Z}$-module invariant).

Solution. $\mathbb{Z}/4\mathbb{Z}$ has an element of additive order 4 (namely $\overline{1}$). In $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$ every nonzero element (a, b) satisfies $2(a, b) = (0, 0)$, so the maximal order is 2. An isomorphism preserves orders, so no isomorphism exists: $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$. *Check.* CRT needs coprime moduli; $4 = 2 \cdot 2$ is not a product of coprimes, so the splitting must fail, consistent with the order obstruction.

Worked Example 10.3.11 (Internal sum of three lines failing directness)**.** In $M = \mathbb{F}^2$ ($\mathbb{F}$ a field), let $N_1 = \mathbb{F}e_1$, $N_2 = \mathbb{F}e_2$, $N_3 = \mathbb{F}(e_1 + e_2)$. Is $M = N_1 \oplus N_2 \oplus N_3$?

Recognition. Internal criterion for $k = 3$: need $N_i \cap \sum_{j \neq i} N_j = 0$, not just pairwise.

Solution. Spanning holds: already $N_1 + N_2 = M$. Pairwise intersections are 0 (distinct lines). But $N_3 \subseteq N_1 + N_2$, so $N_3 \cap (N_1 + N_2) = N_3 \neq 0$, violating the $i = 3$ condition. Hence the sum is *not* direct. *Check.* The relation $1 \cdot e_1 + 1 \cdot e_2 + (-1)(e_1 + e_2) = 0$ is a nontrivial way to write 0, exactly the obstruction the criterion detects.

Worked Example 10.3.12 (Splitting a $\mathbb{Z}$-module: $\mathbb{Z}/30\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/5\mathbb{Z}$)**.** Decompose $\mathbb{Z}/30\mathbb{Z}$ as an internal direct sum of cyclic $\mathbb{Z}$-modules.

Recognition. Iterated CRT via the internal criterion for three submodules.

Solution. Let $N_1 = \mathbb{Z}\overline{15} \cong \mathbb{Z}/2\mathbb{Z}$, $N_2 = \mathbb{Z}\overline{10} \cong \mathbb{Z}/3\mathbb{Z}$, $N_3 = \mathbb{Z}\overline{6} \cong \mathbb{Z}/5\mathbb{Z}$ (annihilators $2\mathbb{Z}, 3\mathbb{Z}, 5\mathbb{Z}$ respectively). Their orders $2, 3, 5$ are pairwise coprime, so $N_i \cap \sum_{j \neq i} N_j$ has order dividing both $|N_i|$ and $|\sum_{j \neq i} N_j|$ (orders dividing $15, 10, 6$ respectively, since $N_j + N_k$ is the image of $N_j \oplus N_k$), and gcd forces 0 in each case. Sum: $\overline{15} + \overline{10} + \overline{6} = \overline{31} = \overline{1}$ generates, so $\sum N_i = M$. Hence $\mathbb{Z}/30\mathbb{Z} = N_1 \oplus N_2 \oplus N_3 \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/5\mathbb{Z}$. *Check.* $2 \cdot 3 \cdot 5 = 30 = |M|$. Consistent.

3. Free modules and the universal property.

Definition 10.3.13 (Free module on a set)**.** Let A be a set. The *free R-module on A* is

$$R^{(A)} = \bigoplus_{a \in A} R,$$

the set of finitely-supported functions $A \to R$, written as formal finite sums $\sum_{a \in A} r_a\, a$ with $r_a \in R$ (almost all 0). There is a canonical injection $\iota : A \to R^{(A)}$, $\iota(a) = 1 \cdot a$, identifying A with the standard basis $\{e_a\}_{a \in A}$. When $A = \{1, \ldots, n\}$ we write R^n. A module M is *free* (with basis $\iota(A)$) if $M \cong R^{(A)}$ for some A.

Theorem 10.3.14 (Universal property of the free module)**.** *Let A be a set and $\iota : A \to R^{(A)}$ the canonical inclusion. For every R-module M and every set map $f : A \to M$, there is a* unique *R-module homomorphism $\Phi : R^{(A)} \to M$ with $\Phi \circ \iota = f$, namely $\Phi\big(\sum_a r_a\, a\big) = \sum_a r_a\, f(a)$.*

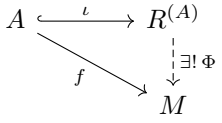


Diagram explanation. Objects: A is a plain set (no module structure); $R^{(A)}$ is the free left R-module on A, consisting of formal finite R-linear combinations of elements of A; M is an arbitrary left R-module.

Arrows: $\iota : A \to R^{(A)}$ is the canonical set-map sending $a \mapsto 1 \cdot a$, i.e. the inclusion of A as the standard basis of $R^{(A)}$. $f : A \to M$ is any set-map (no linearity required). $\Phi : R^{(A)} \to M$ is the unique R-module homomorphism extending f; its existence and uniqueness are what the theorem asserts, hence the dashed arrow labelled $\exists!\, \Phi$.

What commutes: The triangle commutes: $\Phi \circ \iota = f$. That is, for every $a \in A$, $\Phi(\iota(a)) = f(a)$.

Why it commutes: Take any $a \in A$. Along the top-then-down path: $a \overset{\iota}{\mapsto} 1 \cdot a \overset{\Phi}{\mapsto} \Phi(1 \cdot a) = 1 \cdot f(a) = f(a)$. Along the diagonal: $a \overset{f}{\mapsto} f(a)$. Both give $f(a)$ because Φ is defined by R-linear extension of f on basis elements, and $\iota(a)$ is exactly the basis element corresponding to a.

Why this matters here: This diagram is the precise statement of the universal property of the free module. It says that $R^{(A)}$ is the "most efficient" module receiving A: every set-map out of A into any R-module lifts to a unique R-module map out of $R^{(A)}$. The uniqueness (expressed by the dashed arrow) distinguishes this from mere existence of some extension.

Concrete example: Take $R = \mathbb{Z}$, $A = \{e_1, e_2\}$, $R^{(A)} = \mathbb{Z}^2$, $M = \mathbb{Z}/6\mathbb{Z}$, $f(e_1) = \overline{2}$, $f(e_2) = \overline{3}$. The unique extension is $\Phi(a, b) = \overline{2a + 3b}$, and $\Phi \circ \iota(e_1) = \overline{2} = f(e_1)$, confirming commutativity.

Common pitfall: Students sometimes think Φ is the same as f; in fact f is a set-map on A while Φ is an R-module map on all of $R^{(A)}$, a much larger domain. The diagram emphasizes this by drawing f and ι separately.

Takeaway: The point of this diagram is that specifying an R-module map out of $R^{(A)}$ is exactly the same data as specifying a set-map out of A, so there are no relations to check when building maps from free modules.

Equivalently, restriction $\mathrm{Hom}_R(R^{(A)}, M) \to \mathrm{Map}(A, M)$, $g \mapsto g \circ \iota$, *is a bijection.*

Proof. Existence. Define $\Phi(\sum_a r_a a) = \sum_a r_a f(a)$ (a finite sum). This is well defined because each element of $R^{(A)}$ has a unique finitely-supported expression $\sum r_a a$. It is additive and R-linear because the operations on $R^{(A)}$ are componentwise, and $\Phi(\iota(a)) = \Phi(1 \cdot a) = f(a)$. *Uniqueness.* Any R-map Ψ with $\Psi\iota = f$ must satisfy $\Psi(\sum_a r_a a) = \sum_a r_a \Psi(a) = \sum_a r_a f(a) = \Phi(\sum r_a a)$, since $\{a\}$ generates $R^{(A)}$ and Ψ respects R-linear combinations. So $\Psi = \Phi$. □

Corollary 10.3.15 (Every module is a quotient of a free module)**.** *Every R-module M is a quotient of a free module. If $A \subseteq M$ generates M (e.g. $A = M$), the universal map $\Phi : R^{(A)} \to M$ determined by $a \mapsto a$ is surjective, giving a short exact sequence*

$$0 \longrightarrow \ker \Phi \hookrightarrow R^{(A)} \xrightarrow{\Phi} M \longrightarrow 0 \qquad \textit{and} \qquad M \cong R^{(A)} / \ker \Phi.$$

Diagram explanation. Objects: 0 denotes the trivial module; $\ker \Phi$ is the kernel of Φ, a submodule of $R^{(A)}$ (explicitly, the set of formal combinations $\sum r_a a$ that map to 0 under Φ); $R^{(A)}$ is the free module on the generating set A; M is the given R-module being presented.

Arrows: The left $0 \to \ker \Phi$ is the zero map (inclusion of the trivial module). The map $\ker \Phi \to R^{(A)}$ is the inclusion of the kernel as a submodule. The map $\Phi : R^{(A)} \twoheadrightarrow M$ (double-headed arrow) is the surjection induced by $a \mapsto a$, the universal map extending the inclusion $A \hookrightarrow M$. The right $M \to 0$ is the zero map.

What commutes: The sequence is exact: (i) $\mathrm{im}(0 \to \ker \Phi) = 0 = \ker(\ker \Phi \to R^{(A)})$; (ii) $\mathrm{im}(\ker \Phi \to R^{(A)}) = \ker \Phi = \ker \Phi$, the kernel of Φ; (iii) $\mathrm{im}(\Phi) = M = \ker(M \to 0)$.

Why it commutes: Condition (ii) is the definition of $\ker \Phi$: the inclusion picks out exactly those elements sent to 0 by Φ. Condition (iii) is surjectivity of Φ: since A generates M, every element of M is an R-linear combination of elements of A, hence in the image of Φ.

Why this matters here: This short exact sequence encodes the *presentation* of M as a quotient of a free module. The kernel $\ker \Phi$ records exactly the relations among the generators in A. The isomorphism $M \cong R^{(A)} / \ker \Phi$ displayed alongside is the First Isomorphism Theorem applied to Φ. This is the foundation for the theory of module presentations and resolutions.

Concrete example: Take $M = \mathbb{Z}/6\mathbb{Z}$, $A = M$ (all elements), $R^{(A)}$ free of rank 6. Alternatively, take $A = \{1\}$, $R^{(A)} = \mathbb{Z}$, $\Phi(n) = \overline{n}$; then $\ker \Phi = 6\mathbb{Z}$ and the sequence is $0 \to 6\mathbb{Z} \to \mathbb{Z} \to \mathbb{Z}/6\mathbb{Z} \to 0$, the standard presentation of $\mathbb{Z}/6\mathbb{Z}$.

Common pitfall: The sequence tells you $M \cong R^{(A)} / \ker \Phi$, but this does *not* mean $R^{(A)} \cong \ker \Phi \oplus M$ in general. A short exact sequence splits only when M is projective (e.g., free), which is not guaranteed here.

Takeaway: The point of this diagram is that every module, however complicated, can be described by generators and relations—the free module supplies the generators and its kernel under Φ records all the relations.

Moreover M is finitely generated iff M is a quotient of some R^n.

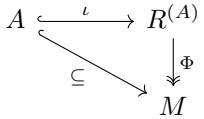

Diagram explanation. Objects: A is a generating subset of M (a set, not a module); $R^{(A)}$ is the free module on A; M is the R-module being presented as a quotient.

Arrows: $\iota : A \to R^{(A)}$ is the standard basis inclusion $a \mapsto 1 \cdot a$. The hooked diagonal arrow $A \hookrightarrow M$ is the set-theoretic inclusion of A as a subset of M (the map $f = \text{incl}$ in the universal property). $\Phi : R^{(A)} \twoheadrightarrow M$ (double-headed arrow) is the unique R-module surjection extending the inclusion; it is surjective precisely because A generates M.

What commutes: The triangle commutes: $\Phi \circ \iota = \text{incl}$, i.e. for every $a \in A$, $\Phi(1 \cdot a) = a$. This is the defining property of Φ as the universal extension of the inclusion $f = \text{incl}$.

Why it commutes: Well-definedness: different choices of representative within the basis element $1 \cdot a$ do not arise since the free module has a canonical basis. Commutativity follows directly: $\Phi(\iota(a)) = \Phi(1 \cdot a) = 1 \cdot \text{incl}(a) = a$, matching the diagonal arrow. No coset ambiguity arises because the domain is free.

Why this matters here: This diagram instantiates the universal property in the specific case $f = \text{incl}$ (when $A \subseteq M$), yielding a canonical surjection. It visually separates the *generating* role of A (diagonal arrow into M) from the *free* extension role of $R^{(A)}$ (vertical arrow), making clear that the surjection is induced, not assumed.

Concrete example: $M = \mathbb{Z}/n\mathbb{Z}$, $A = \{\overline{1}\}$, $R^{(A)} = \mathbb{Z}$, $\iota(1) = 1 \in \mathbb{Z}$, $\Phi(k) = \overline{k}$. The diagram says $\Phi(\iota(1)) = \overline{1}$, which is the inclusion of the generator; Φ surjects because $\overline{1}$ generates $\mathbb{Z}/n\mathbb{Z}$.

Common pitfall: Students confuse this triangle with the one in the theorem statement. There, $f : A \to M$ was an arbitrary set-map and Φ was merely asserted to exist. Here, f is specifically the inclusion $A \subseteq M$ and surjectivity of Φ follows from the generating hypothesis—this is the application, not the definition, of the universal property.

Takeaway: The point of this diagram is that when A generates M, the universal property of $R^{(A)}$ immediately produces a surjection $R^{(A)} \twoheadrightarrow M$, so every module is a quotient of a free module with no additional construction needed.

Proof. Take A a generating set and $f : A \hookrightarrow M$ the inclusion. The induced Φ has image $\Phi(R^{(A)}) = R \cdot A = M$, so Φ is onto. By the First Isomorphism Theorem $M \cong R^{(A)} / \ker \Phi$. If M is finitely generated, choose A finite of size n; then $R^{(A)} = R^n$ surjects onto M. Conversely a quotient of R^n is generated by the n images of the standard basis. □

Theorem 10.3.16 (Rank of a free module is well defined over a commutative ring)**.** *Let R be a nonzero* commutative *ring. If $R^m \cong R^n$ as R-modules, then $m = n$. Thus the* rank *of a free module R^n is a well-defined invariant.*

Proof. Let $\mathfrak{m}$ be a maximal ideal of R (exists since $R \neq 0$), and let $k = R/\mathfrak{m}$, a field. Tensoring with k, $k \otimes_R R^n \cong k^n$ as k-vector spaces (tensor commutes with finite direct sums and $k \otimes_R R \cong k$). An isomorphism $R^m \cong R^n$ of R-modules induces an isomorphism $k^m \cong k^n$ of k-vector spaces, so $m = \dim_k k^m = \dim_k k^n = n$ by uniqueness of dimension over a field. □

Method (Using the universal property to define a map out of $R^{(A)}$)**.** *Trigger.* You must *construct* an R-homomorphism whose domain is free (or R^n), or prove two maps out of a free module agree.

1. Specify the map *only on the basis*: choose any $f(a) \in M$ for each basis element a. No relations to check — a free module has none.

2. Extend R-linearly: $\Phi(\sum r_a a) = \sum r_a f(a)$. The theorem guarantees this is a well-defined homomorphism and is the *unique* extension.

3. To prove $\Phi = \Psi$ on $R^{(A)}$, check only $\Phi(a) = \Psi(a)$ on basis elements.

4. To present a module: pick generators A, get $\Phi : R^{(A)} \twoheadrightarrow M$, then $M \cong R^{(A)} / \ker \Phi$ and $\ker \Phi$ records the relations.

Worked Example 10.3.17 (Build a map out of a free module via the universal property)**.** Construct the $\mathbb{Z}$-module homomorphism $\Phi : \mathbb{Z}^2 \to \mathbb{Z}/6\mathbb{Z}$ with $\Phi(e_1) = \overline{2}$, $\Phi(e_2) = \overline{3}$, and identify $\operatorname{im}\Phi$ and $\ker\Phi$.

Recognition. Universal property of $R^{(A)} = \mathbb{Z}^2$: a map is determined by its values on the basis $\{e_1, e_2\}$.

Solution. By the universal property $\Phi(a,b) = a\,\overline{2} + b\,\overline{3} = \overline{2a+3b}$. Image: $2a+3b$ realizes $\overline{1} = \overline{3} - \overline{2}$ (take $a=-1, b=1$), so $\operatorname{im}\Phi = \mathbb{Z}/6\mathbb{Z}$ (surjective). Kernel: $(a,b) \in \ker\Phi$ iff $2a+3b \equiv 0 \pmod 6$. Reduce: mod 2, $3b \equiv b \equiv 0$, so b is even; mod 3, $2a \equiv -a \equiv 0$, so a is divisible by 3. These two congruences are independent and together necessary and sufficient, so $\ker\Phi = 3\mathbb{Z} \oplus 2\mathbb{Z} = \mathbb{Z}(3,0) + \mathbb{Z}(0,2)$. *Check.* $\Phi(3,0) = \overline{6} = \overline{0}$, $\Phi(0,2) = \overline{6} = \overline{0}$. Index: $[\mathbb{Z}^2 : \ker\Phi] = \det\left(\begin{smallmatrix} 3 & 0 \\ 0 & 2 \end{smallmatrix}\right) = 6 = |\operatorname{im}\Phi|$, confirming $\mathbb{Z}^2/\ker\Phi \cong \mathbb{Z}/6\mathbb{Z}$.

Worked Example 10.3.18 (Free of rank 2: a basis and coordinates)**.** In $M = \mathbb{Z}^2$, let $v_1 = (2,1)$ and $v_2 = (1,1)$. Decide whether $\{v_1, v_2\}$ is a basis of $\mathbb{Z}^2$, and if so give the coordinates of $(3,2)$.

Recognition. A free module of rank 2: $\{v_1, v_2\}$ is a basis iff the change-of-basis matrix is invertible over $R = \mathbb{Z}$ (determinant a unit).

Solution. Form $B = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ with columns v_1, v_2. $\det B = 2\cdot 1 - 1\cdot 1 = 1 \in \mathbb{Z}^\times = \{\pm 1\}$, so B is invertible over $\mathbb{Z}$ with $B^{-1} = \left(\begin{smallmatrix} 1 & -1 \\ -1 & 2 \end{smallmatrix}\right)$. Hence $\{v_1, v_2\}$ is a $\mathbb{Z}$-basis. Coordinates of $w = (3,2)$: solve $Bc = w$, $c = B^{-1}w = \left(\begin{smallmatrix} 1 & -1 \\ -1 & 2 \end{smallmatrix}\right)\left(\begin{smallmatrix} 3 \\ 2 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 \\ 1 \end{smallmatrix}\right)$, so $(3,2) = 1\cdot v_1 + 1\cdot v_2$. *Check.* $1\cdot(2,1) + 1\cdot(1,1) = (3,2)$. Correct, and integer coordinates confirm $w \in \mathbb{Z}^2$ exactly.

Worked Example 10.3.19 (A determinant that is not a unit: NOT a basis)**.** In $M = \mathbb{Z}^2$, is $\{(2,0),(0,3)\}$ a basis?

Recognition. Same criterion: over $\mathbb{Z}$ a generating square matrix must have determinant ± 1.

Solution. $\det\left(\begin{smallmatrix} 2 & 0 \\ 0 & 3 \end{smallmatrix}\right) = 6 \notin \mathbb{Z}^\times$. The set is $\mathbb{Z}$-linearly independent (no nontrivial integer relation $a(2,0)+b(0,3) = 0$ except $a = b = 0$), but it does *not* span: $(1,0) \notin \mathbb{Z}(2,0) + \mathbb{Z}(0,3)$. So it is independent but not a basis. *Check.* $\mathbb{Z}(2,0) + \mathbb{Z}(0,3) = 2\mathbb{Z} \oplus 3\mathbb{Z}$ has index 6 in $\mathbb{Z}^2$, so it is a proper submodule; over a field this could not happen, but over $\mathbb{Z}$ independence does not give spanning.

Worked Example 10.3.20 ($\mathbb{Q}$ is not a free $\mathbb{Z}$-module)**.** Show the $\mathbb{Z}$-module $\mathbb{Q}$ is not free; in particular it has no basis and is not finitely generated.

Recognition. Free $= R^{(A)}$ with a basis; over $\mathbb{Z}$, freeness forces a $\mathbb{Z}$-independent generating set. Find an obstruction (any two elements are $\mathbb{Z}$-dependent).

Solution. Any two nonzero elements $\frac{a}{b}, \frac{c}{d} \in \mathbb{Q}$ $(a,b,c,d \neq 0)$ satisfy the nontrivial $\mathbb{Z}$-relation $(cb)\frac{a}{b} - (ad)\frac{c}{d} = ca - ca = 0$ with integer coefficients cb, ad not both zero. So any $\mathbb{Z}$-linearly independent subset of $\mathbb{Q}$ has at most one element. Thus a basis would be a single element $\{q\}$, giving $\mathbb{Q} = \mathbb{Z}q \cong \mathbb{Z}$ — false, since $\mathbb{Z}$ is not a divisible group ($\frac{q}{2} \in \mathbb{Q}$ but $\frac{q}{2} \notin \mathbb{Z}q$ for $q \neq 0$). Hence $\mathbb{Q}$ has no basis and is not free. It is also not finitely generated: a finite set $\{\frac{a_1}{b_1}, \ldots, \frac{a_n}{b_n}\}$ generates a subgroup inside $\frac{1}{b_1 \cdots b_n}\mathbb{Z} \neq \mathbb{Q}$. *Check.* Divisibility is the obstruction: $\mathbb{Q}$ is divisible, $\mathbb{Z}^{(A)}$ is not (for $A \neq \varnothing$), so $\mathbb{Q} \ncong \mathbb{Z}^{(A)}$.

Worked Example 10.3.21 (Uniqueness in the universal property forces a relation)**.** Suppose $R = \mathbb{F}[x]$ and M is the R-module $\mathbb{F}^2$ where x acts as the matrix $T = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. Use the universal property of $R^1 = R$ to find $\operatorname{Ann}_R(v)$ for $v = e_1$ and identify Rv.

Recognition. Free module $R = \mathbb{F}[x]$ on one generator; map $1 \mapsto v$ extends uniquely to $\Phi : R \to M$, $\Phi(f) = f(T)v$, and $\ker\Phi = \operatorname{Ann}(v)$.

Solution. $\Phi : R \to M$, $f \mapsto f(T)e_1$. Compute the orbit: $1\cdot e_1 = e_1$, $x\cdot e_1 = Te_1 = e_2$, $x^2\cdot e_1 = T^2e_1 = -e_1$. So $\{e_1, xe_1\} = \{e_1, e_2\}$ spans M, hence Φ is onto and $Rv = M$. The relation $x^2e_1 = -e_1$ means $(x^2+1)e_1 = 0$, so $x^2+1 \in \operatorname{Ann}(v)$. Since $\mathbb{F}[x]$ is a PID and $\dim_{\mathbb{F}} M = 2$ forces deg of the generator $= 2$, $\operatorname{Ann}(v) = (x^2+1)$. Thus $Rv \cong \mathbb{F}[x]/(x^2+1)$. *Check.* $\dim_{\mathbb{F}} \mathbb{F}[x]/(x^2+1) = 2 = \dim_{\mathbb{F}} M$, and $T^2 + I = 0$ confirms x^2+1 annihilates. Consistent.

Remark 10.3.1. The universal property characterizes $R^{(A)}$ *up to unique isomorphism*: any module F with a map $\iota : A \to F$ having the same universal extension property is canonically isomorphic to $R^{(A)}$. This is the module-theoretic instance of "free objects are unique," and is the template for the analogous characterizations of the tensor product and of projective/injective modules later in the chapter.

Exercises (from the text).

1. Prove that if A and B are sets of the same cardinality, then the free modules $F(A)$ and $F(B)$ are isomorphic.

2. Assume R is commutative. Prove that $R^n \cong R^m$ if and only if $n = m$, i.e., two free R-modules of finite rank are isomorphic if and only if they have the same rank. [Apply Exercise 12 of Section 2 with I a maximal ideal of R. You may assume that if F is a field, then $F^n \cong F^m$ if and only if $n = m$; i.e., two finite dimensional vector spaces over F are isomorphic if and only if they have the same dimension — this will be proved later in Section 11.1.]

3. Show that the $F[x]$-modules in Exercises 18 and 19 of Section 1 are both cyclic.

4. An R-module M is called a torsion module if for each $m \in M$ there is a nonzero element $r \in R$ such that $rm = 0$, where r may depend on m (i.e., $M = \mathrm{Tor}(M)$ in the notation of Exercise 8 of Section 1). Prove that every finite abelian group is a torsion $\mathbb{Z}$-module. Give an example of an infinite abelian group that is a torsion $\mathbb{Z}$-module.

5. Let R be an integral domain. Prove that every finitely generated torsion R-module has a nonzero annihilator i.e., there is a nonzero element $r \in R$ such that $rm = 0$ for all $m \in M$ — here r does not depend on m (the annihilator of a module was defined in Exercise 9 of Section 1). Give an example of a torsion R-module whose annihilator is the zero ideal.

6. Prove that if M is a finitely generated R-module that is generated by n elements then every quotient of M may be generated by n (or fewer) elements. Deduce that quotients of cyclic modules are cyclic.

7. Let N be a submodule of M. Prove that if both M/N and N are finitely generated then so is M.

8. Let S be the collection of sequences $(a_1, a_2, a_3, \ldots)$ of integers $a_1, a_2, a_3, \ldots$ where all but finitely many of the a_i are 0 (called the direct sum of infinitely many copies of $\mathbb{Z}$). Recall that S is a ring under componentwise addition and multiplication but S does not have a multiplicative identity — cf. Exercise 20, Section 7.1. Prove that S is not finitely generated as a module over itself.

9. An R-module M is called irreducible if $M \neq 0$ and if 0 and M are the only submodules of M. Show that M is irreducible if and only if $M \neq 0$ and M is a cyclic module with any nonzero element as generator. Determine all the irreducible $\mathbb{Z}$-modules.

10. Assume R is commutative. Show that an R-module M is irreducible if and only if M is isomorphic (as an R-module) to R/I where I is a maximal ideal of R. [By the previous exercise, if M is irreducible there is a natural map $R \to M$ defined by $r \mapsto rm$, where m is any fixed nonzero element of M.]

11. Show that if M_1 and M_2 are irreducible R-modules, then any nonzero R-module homomorphism from M_1 to M_2 is an isomorphism. Deduce that if M is irreducible then $\mathrm{End}_R(M)$ is a division ring (this result is called Schur's Lemma). [Consider the kernel and the image.]

12. Let R be a commutative ring and let A, B and M be R-modules. Prove the following isomorphisms of R-modules:

    (a) $\mathrm{Hom}_R(A \oplus B, M) \cong \mathrm{Hom}_R(A, M) \times \mathrm{Hom}_R(B, M)$

    (b) $\mathrm{Hom}_R(M, A \oplus B) \cong \mathrm{Hom}_R(M, A) \times \mathrm{Hom}_R(M, B)$.

13. Let R be a commutative ring and let F be a free R-module of finite rank. Prove the following isomorphism of R-modules: $\mathrm{Hom}_R(F, R) \cong F$.

14. Let R be a commutative ring and let F be the free R-module of rank n. Prove that $\mathrm{Hom}_R(F, M) \cong M \times \cdots \times M$ (n times). [Use Exercise 9 in Section 2 and Exercise 12.]

15. An element $e \in R$ is called a central idempotent if $e^2 = e$ and $er = re$ for all $r \in R$. If e is a central idempotent in R, prove that $M = eM \oplus (1 - e)M$. [Recall Exercise 14 in Section 1.]

16. For any ideal I of R let IM be the submodule defined in Exercise 5 of Section 1. Let $A_1, \ldots, A_k$ be any ideals in the ring R. Prove that the map

$$M \to M/A_1M \times \cdots \times M/A_kM \qquad \text{defined by} \qquad m \mapsto (m + A_1M, \ldots, m + A_kM)$$

    is an R-module homomorphism with kernel $A_1M \cap A_2M \cap \cdots \cap A_kM$.

17. In the notation of the preceding exercise, assume further that R is commutative and the ideals $A_1, \ldots, A_k$ are pairwise comaximal (i.e., $A_i + A_j = R$ for all $i \neq j$). Prove that

$$M/(A_1 \cdots A_k)M \cong M/A_1M \times \cdots \times M/A_kM.$$

[See the proof of the Chinese Remainder Theorem for rings in Section 7.6.]

18. Let R be a Principal Ideal Domain and let M be an R-module that is annihilated by the nonzero, proper ideal (a). Let $a = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_k^{\alpha_k}$ be the unique factorization of a into distinct prime powers in R. Let M_i be the annihilator of $p_i^{\alpha_i}$ in M, i.e., M_i is the set $\{m \in M \mid p_i^{\alpha_i} m = 0\}$ — called the p_i-primary component of M. Prove that

$$M = M_1 \oplus M_2 \oplus \cdots \oplus M_k.$$

19. Show that if M is a finite abelian group of order $a = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_n^{\alpha_n}$ then, considered as a $\mathbb{Z}$-module, M is annihilated by (a), the p_i-primary component of M is the unique Sylow p_i-subgroup of M and M is isomorphic to the direct product of its Sylow subgroups.

20. Let I be a nonempty index set and for each $i \in I$ let M_i be an R-module. The direct product of the modules M_i is defined to be their direct product as abelian groups (cf. Exercise 15 in Section 5.1) with the action of R componentwise multiplication. The direct sum of the modules M_i is defined to be the restricted direct product of the abelian groups M_i (cf. Exercise 17 in Section 5.1) with the action of R componentwise multiplication. In other words, the direct sum of the M_i's is the subset of the direct product, $\prod_{i \in I} M_i$, which consists of all elements $\prod_{i \in I} m_i$ such that only finitely many of the components m_i are nonzero; the action of R on the direct product or direct sum is given by $r \prod_{i \in I} m_i = \prod_{i \in I} rm_i$ (cf. Appendix I for the definition of Cartesian products of infinitely many sets). The direct sum will be denoted by $\bigoplus_{i \in I} M_i$.

    (a) Prove that the direct product of the M_i's is an R-module and the direct sum of the M_i's is a submodule of their direct product.

    (b) Show that if $R = \mathbb{Z}$, $I = \mathbb{Z}^+$ and M_i is the cyclic group of order i for each i, then the direct sum of the M_i's is not isomorphic to their direct product. [Look at torsion.]

21. Let I be a nonempty index set and for each $i \in I$ let N_i be a submodule of M. Prove that the following are equivalent:

    (i) the map from the (external) direct sum $\bigoplus_{i \in I} N_i$ to the submodule of M generated by all the N_i's sending a tuple to the sum of its components is an isomorphism (cf. Exercise 20)

    (ii) if $\{i_1, i_2, \ldots, i_k\}$ is any finite subset of I then $N_{i_1} \cap (N_{i_2} + \cdots + N_{i_k}) = 0$

    (iii) if $\{i_1, i_2, \ldots, i_k\}$ is any finite subset of I then $N_{i_1} + \cdots + N_{i_k} = N_{i_1} \oplus \cdots \oplus N_{i_k}$

    (iv) for every element x of the submodule of M generated by the N_i's there are unique elements $a_i \in N_i$ for all $i \in I$ such that all but a finite number of the a_i are zero and x is the (finite) sum of the a_i.

22. Let R be a Principal Ideal Domain, let M be a torsion R-module (cf. Exercise 4) and let p be a prime in R (do not assume M is finitely generated, hence it need not have a nonzero annihilator — cf. Exercise 5). The p-primary component of M is the set of all elements of M that are annihilated by some positive power of p.

    (a) Prove that the p-primary component is a submodule. [See Exercise 13 in Section 1.]

    (b) Prove that this definition of p-primary component agrees with the one given in Exercise 18 when M has a nonzero annihilator.

    (c) Prove that M is the (possibly infinite) direct sum of its p-primary components, as p runs over all primes of R.

23. Show that any direct sum of free R-modules is free.

24. (An arbitrary direct product of free modules need not be free) For each positive integer i let M_i be the free $\mathbb{Z}$-module $\mathbb{Z}$, and let M be the direct product $\prod_{i\in\mathbb{Z}^+} M_i$ (cf. Exercise 20). Each element of M can be written uniquely in the form $(a_1, a_2, a_3, \ldots)$ with $a_i \in \mathbb{Z}$ for all i. Let N be the submodule of M consisting of all such tuples with only finitely many nonzero a_i. Assume M is a free $\mathbb{Z}$-module with basis $\mathcal{B}$.

    (a) Show that N is countable.

    (b) Show that there is some countable subset $\mathcal{B}_1$ of $\mathcal{B}$ such that N is contained in the submodule, N_1, generated by $\mathcal{B}_1$. Show also that N_1 is countable.

    (c) Let $\overline{M} = M/N_1$. Show that $\overline{M}$ is a free $\mathbb{Z}$-module. Deduce that if $\overline{x}$ is any nonzero element of $\overline{M}$ then there are only finitely many distinct positive integers k such that $\overline{x} = k\overline{m}$ for some $m \in \overline{M}$ (depending on k).

    (d) Let $\mathcal{S} = \{(b_1, b_2, b_3, \ldots) \mid b_i = \pm i! \text{ for all } i\}$. Prove that $\mathcal{S}$ is uncountable. Deduce that there is some $s \in \mathcal{S}$ with $s \notin N_1$.

    (e) Show that the assumption M is free leads to a contradiction: By (d) we may choose $s \in \mathcal{S}$ with $s \notin N_1$. Show that for each positive integer k there is some $m \in \overline{M}$ and $\overline{s} = k\overline{m}$, contrary to (c). [Use the fact that $N \subseteq N_1$.]

25. In the construction of direct limits, Exercise 8 of Section 7.6, show that if all A_i are R-modules and the maps ρ_{ij} are R-module homomorphisms, then the direct limit $A = \varinjlim A_i$ may be given the structure of an R-module in a natural way such that the maps $\rho_i : A_i \to A$ are all R-module homomorphisms. Verify the corresponding universal property (part (e)) for R-module homomorphisms $\varphi_i : A_i \to C$ commuting with the ρ_{ij}.

26. Carry out the analysis of the preceding exercise corresponding to inverse limits to show that an inverse limit of R-modules is an R-module satisfying the appropriate universal property (cf. Exercise 10 of Section 7.6).

27. (Free modules over noncommutative rings need not have a unique rank) Let M be the $\mathbb{Z}$-module $\mathbb{Z}\times\mathbb{Z}\times\cdots$ of Exercise 24 and let R be its endomorphism ring, $R = \mathrm{End}_{\mathbb{Z}}(M)$ (cf. Exercises 29 and 30 in Section 7.1). Define $\varphi_1, \varphi_2 \in R$ by

$$\varphi_1(a_1, a_2, a_3, \ldots) = (a_1, a_3, a_5, \ldots) \qquad \varphi_2(a_1, a_2, a_3, \ldots) = (a_2, a_4, a_6, \ldots).$$

    (a) Prove that $\{\varphi_1, \varphi_2\}$ is a free basis of the left R-module R. [Define the maps ψ_1 and ψ_2 by $\psi_1(a_1, a_2, \ldots) = (a_1, 0, a_2, 0, \ldots)$ and $\psi_2(a_1, a_2, \ldots) = (0, a_1, 0, a_2, \ldots)$. Verify that $\varphi_i\psi_i = 1$, $\varphi_1\psi_2 = 0 = \varphi_2\psi_1$ and $\psi_1\varphi_1 + \psi_2\varphi_2 = 1$. Use these relations to prove that φ_1, φ_2 are independent and generate R as a left R-module.]

    (b) Use (a) to prove that $R \cong R^2$ and deduce that $R \cong R^n$ for all $n \in \mathbb{Z}^+$.

Practice problems.

1. Let R be a ring with 1 and let M be a left R-module. Show that the subset N of M consisting of all R-linear combinations of a fixed set $A \subseteq M$ equals the intersection of all submodules of M containing A. Conclude that $RA = \langle A \rangle$.

2. In the $\mathbb{Z}$-module $\mathbb{Z}$, find a generating set of size 1. Show that the single element 2 does *not* generate $\mathbb{Z}$ as a $\mathbb{Z}$-module (since $\mathbb{Z} \cdot 2 = 2\mathbb{Z} \neq \mathbb{Z}$), but that $\{2, 3\}$ *does* generate $\mathbb{Z}$ as a $\mathbb{Z}$-module because $\gcd(2, 3) = 1$. Identify a minimal generating set of the $\mathbb{Z}$-module $\mathbb{Z}$.

3. Let $M = \mathbb{Z}/6\mathbb{Z}$ as a $\mathbb{Z}$-module. List all submodules, and for each give a single generator. Which elements of M generate M?

4. Show that $\mathbb{Q}$ is not a finitely generated $\mathbb{Z}$-module. (Hint: a finite generating set has a common denominator.)

5. Let R be a ring and let $M_1, \ldots, M_k$ be submodules of a module M. Prove that the sum $M_1 + \cdots + M_k = \{m_1 + \cdots + m_k \mid m_i \in M_i\}$ is a submodule, and that it is the smallest submodule containing every M_i.

6. Give an explicit isomorphism $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ of $\mathbb{Z}$-modules, and verify it is a bijective R-homomorphism. Explain why $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$.

7. Let M and N be R-modules. Show that the external direct sum $M \oplus N$ together with the maps $\iota_M \colon m \mapsto (m, 0)$ and $\pi_M \colon (m, n) \mapsto m$ satisfies $\pi_M \iota_M = \mathrm{id}_M$, $\pi_N \iota_N = \mathrm{id}_N$, and $\iota_M \pi_M + \iota_N \pi_N = \mathrm{id}_{M \oplus N}$.

8. Prove that for R-modules A, B, C there is a natural isomorphism $\mathrm{Hom}_R(A \oplus B,\, C) \cong \mathrm{Hom}_R(A, C) \oplus \mathrm{Hom}_R(B, C)$.

9. Let F be the free $\mathbb{Z}$-module on the set $A = \{x, y, z\}$. Write down the element $3x - 2y + 5z$ as a function $A \to \mathbb{Z}$ with finite support, and compute the image of this element under the unique homomorphism $F \to \mathbb{Z}/4\mathbb{Z}$ sending $x \mapsto 1,\ y \mapsto 1,\ z \mapsto 2$.

10. Suppose R is a nonzero commutative ring and $R^m \cong R^n$ as R-modules. Use the fact that R has a maximal ideal $\mathfrak{m}$ and reduce modulo $\mathfrak{m}$ to prove $m = n$ (so free rank is well defined over a nonzero commutative ring).

11. Let V be the $\mathbb{F}[x]$-module given by $V = \mathbb{F}^2$ with x acting as the matrix $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ over $\mathbb{F} = \mathbb{R}$. Determine whether V is generated by a single element as an $\mathbb{F}[x]$-module, and if so exhibit a generator.

12. Let $N \leq M$ be R-modules. Prove that if M/N and N are both finitely generated, then M is finitely generated. Give generators of M explicitly in terms of generators of N and lifts of generators of M/N.

13. Show that a finitely generated module over a field $\mathbb{F}$ (i.e. a finite dimensional vector space) is free, and that its rank equals its dimension.

14. Let $R = \mathbb{Z}$ and consider the submodule $N = \langle (2, 0), (0, 3) \rangle \leq \mathbb{Z}^2$. Compute the quotient $\mathbb{Z}^2/N$ as an explicit direct sum of cyclic groups.

15. Prove that an R-module M is generated by a single element if and only if $M \cong R/I$ for some left ideal I of R. Identify I as an annihilator.

Additional exercises.

1. Let R be a ring with 1 and suppose the left R-module R has a proper submodule that is also a direct summand, say $R = I \oplus J$ with I, J nonzero left ideals. Prove that $1 = e + f$ with $e \in I$, $f \in J$, that e, f are orthogonal idempotents, and that $I = Re$, $J = Rf$.

2. Show that $\mathbb{Q}$ is not a projective $\mathbb{Z}$-module. (Hint: $\mathbb{Q}$ is not free since it is not finitely generated and any free $\mathbb{Z}$-module of rank ≥ 2 has linearly independent elements, while any two elements of $\mathbb{Q}$ are $\mathbb{Z}$-linearly dependent; then argue that a projective module is a direct summand of a free module, and a nonzero divisible submodule of a free $\mathbb{Z}$-module must be 0.)

3. Let A be an infinite set and R a nonzero ring. Prove that the free module $R^{(A)}$ (finite support) is *not* isomorphic to the direct product R^A when R is a field and A is countably infinite, by a cardinality / dimension argument.

4. Let M be an R-module with submodules N_1, N_2 such that $M = N_1 + N_2$ and $N_1 \cap N_2 = 0$. Prove $M \cong N_1 \oplus N_2$ via $n_1 + n_2 \mapsto (n_1, n_2)$, and show by example over $R = \mathbb{Z}$ that $M = N_1 + N_2$ alone is insufficient.

5. Prove that a finitely generated module M over a commutative ring R cannot be generated by fewer than n elements if $M/\mathfrak{m}M$ has dimension n over $R/\mathfrak{m}$ for some maximal ideal $\mathfrak{m}$ (Nakayama-style lower bound). State precisely the version of Nakayama's lemma you use.

6. Let $0 \to A \to B \to C \to 0$ be a short exact sequence of R-modules with C free. Prove the sequence splits, so $B \cong A \oplus C$.

Commutative-diagram exercises.

1. (Universal property of free modules.) Let A be a set, $R^{(A)}$ the free module with basis map $\iota\colon A \to R^{(A)}$, M any R-module, and $f\colon A \to M$ any set map. State and prove the universal property by constructing the unique R-homomorphism Φ making the triangle commute:

$$\begin{array}{ccc} A & \xhookrightarrow{\ \iota\ } & R^{(A)} \\ & \searrow^{f} & \downarrow{\scriptstyle \exists!\,\Phi} \\ & & M \end{array}$$

   Then prove that this universal property characterizes $R^{(A)}$ up to unique isomorphism.

2. (Projectivity via lifting.) Call P projective if for every surjection $g\colon B \twoheadrightarrow C$ and every $f\colon P \to C$ there is $\tilde{f}\colon P \to B$ with $g\tilde{f} = f$:

$$\begin{array}{ccc} & & P \\ & {\scriptstyle \exists\,\tilde{f}}\swarrow & \downarrow{\scriptstyle f} \\ B & \xrightarrow[g]{} & C \end{array}$$

   Using the universal property of free modules from the previous exercise, prove that every free module is projective.

3. (Splitting a short exact sequence.) Given

$$0 \longrightarrow A \xhookrightarrow{\ \psi\ } B \xrightarrow{\ \varphi\ } C \longrightarrow 0$$

   prove the equivalence of: (a) there is $s\colon C \to B$ with $\varphi s = \mathrm{id}_C$; (b) there is $r\colon B \to A$ with $r\psi = \mathrm{id}_A$; (c) $B \cong A \oplus C$ compatibly with ψ, φ. Draw the maps s and r on the diagram and verify each implication.

4. (Pullback of generators.) Let $\pi\colon R^{(A)} \twoheadrightarrow M$ be the surjection induced by a generating set $\{m_a\}_{a\in A}$ of M, with kernel K. Display the short exact sequence $0 \to K \to R^{(A)} \xrightarrow{\pi} M \to 0$ and prove that M is finitely generated iff A may be chosen finite. Show K is the module of relations among the m_a.

5. (Hom is left exact.) Given an exact sequence $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C$ of R-modules and an R-module D, prove the induced sequence

$$0 \longrightarrow \mathrm{Hom}_R(D, A) \xrightarrow{\ \psi_*\ } \mathrm{Hom}_R(D, B) \xrightarrow{\ \varphi_*\ } \mathrm{Hom}_R(D, C)$$

   is exact, and give an example with $D = \mathbb{Z}/2\mathbb{Z}$ over $R = \mathbb{Z}$ showing φ_* need not be surjective even when φ is.

10.4 Tensor Products of Modules

Tensor products of modules

Throughout, R is a ring with 1. The tensor product mixes a *right* R-module with a *left* R-module to produce an *abelian group*. Let M be a right R-module and N a left R-module.

Definition 10.4.1 (R-balanced map)**.** A map $\varphi\colon M \times N \to L$ into an abelian group L is **R-balanced** (or *middle linear*) if for all $m, m' \in M$, $n, n' \in N$, $r \in R$:

$$\varphi(m + m',\, n) = \varphi(m, n) + \varphi(m', n), \quad \varphi(m,\, n + n') = \varphi(m, n) + \varphi(m, n'), \quad \varphi(mr,\, n) = \varphi(m,\, rn).$$

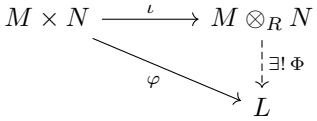
The first two say φ is biadditive; the third lets scalars "slide across" the $\times$.

Definition 10.4.2 (Tensor product $M \otimes_R N$)**.** The **tensor product** of M and N over R is the abelian group

$$M \otimes_R N \;=\; F \big/ H,$$

where F is the free abelian group $\mathbb{Z}^{(M\times N)}$ on the set $M \times N$, and H is the subgroup generated by all elements

$$(m+m',n)-(m,n)-(m',n), \quad (m,n+n')-(m,n)-(m,n'), \quad (mr,n)-(m,rn),$$



for $m, m' \in M$, $n, n' \in N$, $r \in R$. The image of (m,n) in $M \otimes_R N$ is the **simple tensor** $m \otimes n$. Every element of $M \otimes_R N$ is a *finite sum* $\sum_i m_i \otimes n_i$.

By construction the relations defining H become, in $M \otimes_R N$, exactly the bilinearity identities:

$$(m+m')\otimes n = m\otimes n + m'\otimes n, \qquad m\otimes(n+n') = m\otimes n + m\otimes n', \qquad mr\otimes n = m\otimes rn.$$

Useful consequences: $0\otimes n = m\otimes 0 = 0$ and $(-m)\otimes n = -(m\otimes n) = m\otimes(-n)$, since $0\otimes n = (0+0)\otimes n = 0\otimes n + 0\otimes n$.

Theorem 10.4.3 (Universal property of $\otimes$)**.** *The canonical map $\iota\colon M\times N \to M\otimes_R N$, $\iota(m,n) = m\otimes n$, is R-balanced, and it is universal: for every R-balanced map $\varphi\colon M\times N\to L$ there is a* unique *group homomorphism $\Phi\colon M\otimes_R N \to L$ with $\Phi(m\otimes n) = \varphi(m,n)$, i.e. $\varphi = \Phi\circ\iota$.*

Thus $\{R$-balanced maps $M\times N\to L\} \longleftrightarrow \{$group homs $M\otimes_R N\to L\}$, naturally in L.

Diagram explanation. Objects: Three objects. Top-left: the *Cartesian product* $M\times N$, a set (not a module), where M is a right R-module and N is a left R-module. Top-right: the *tensor product* $M\otimes_R N$, an abelian group, constructed as the free abelian group on $M\times N$ modulo the balanced relations. Bottom: an arbitrary abelian group L, the target of any R-balanced map.

Arrows: (1) $\iota\colon M\times N\to M\otimes_R N$, $\iota(m,n) = m\otimes n$, is the canonical R-balanced map whose existence is the whole point of the construction. (2) $\varphi\colon M\times N\to L$ is an arbitrary R-balanced map. (3) The dashed $\Phi\colon M\otimes_R N\to L$ is the *unique* group homomorphism induced by φ via the universal property; it satisfies $\Phi(m\otimes n) = \varphi(m,n)$.

What commutes: The triangle commutes: $\Phi\circ\iota = \varphi$, i.e., for every $(m,n)\in M\times N$, $\Phi(\iota(m,n)) = \Phi(m\otimes n) = \varphi(m,n)$.

Why it commutes: Start with $(m,n)\in M\times N$. Along the top-then-down path: ι sends (m,n) to $m\otimes n$, then Φ sends $m\otimes n$ to $\varphi(m,n)$—that is exactly how Φ is defined on simple tensors. Along the diagonal: φ sends (m,n) directly to $\varphi(m,n)$. Both paths produce $\varphi(m,n)$. Well-definedness: Φ is defined first on the free group F by $\tilde{\varphi}(m,n) = \varphi(m,n)$, then one checks $\tilde{\varphi}$ kills the subgroup H of balanced relations (possible exactly because φ is balanced), so Φ descends to $F/H = M\otimes_R N$.

Why this matters here: This is the *raison d'etre* of the tensor product: it converts the non-additive data of a balanced map into a clean group homomorphism. The theorem is placed here immediately after defining $M\otimes_R N$ to show that the messy quotient construction is the *right* object: one never has to return to the quotient; one just works with balanced maps.

Concrete example: Take $M = \mathbb{Z}/m\mathbb{Z}$, $N = \mathbb{Z}/n\mathbb{Z}$, $L = \mathbb{Z}/d\mathbb{Z}$ ($d = \gcd(m,n)$), and $\varphi(\bar{a},\bar{b}) = \overline{ab}$. This is $\mathbb{Z}$-balanced and well defined on cosets; the induced $\Phi\colon \mathbb{Z}/m\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/n\mathbb{Z}\to\mathbb{Z}/d\mathbb{Z}$ is an isomorphism, recovering $\mathbb{Z}/m\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/n\mathbb{Z}\cong\mathbb{Z}/d\mathbb{Z}$.

Common pitfall: Students try to define Φ directly by "$\Phi(m\otimes n) = \varphi(m,n)$" without first verifying φ is balanced. This is circular: the universal property only hands you Φ *after* the balanced-axiom check. Skipping that check means Φ may not be well defined on the tensor product (different representatives of a simple tensor could give different outputs).

Takeaway: The point of this diagram is that the tensor product $M\otimes_R N$ is precisely the abelian group that linearizes balanced maps—every balanced map out of $M\times N$ corresponds uniquely to a group homomorphism out of $M\otimes_R N$.

Sketch (existence/uniqueness). ι is balanced because the three defining families of relations in H are killed in the quotient. Given a balanced φ, define a group hom $\tilde{\varphi}\colon F \to L$ on the free generators by $\tilde{\varphi}(m,n) = \varphi(m,n)$. Balancedness says $\tilde{\varphi}$ vanishes on every generator of H, hence on H, so $\tilde{\varphi}$ factors through $F/H = M \otimes_R N$ to give Φ with $\Phi(m \otimes n) = \varphi(m,n)$. Uniqueness: the simple tensors $m \otimes n$ generate $M \otimes_R N$, so a homomorphism is determined by its values on them, and $\Phi(m \otimes n) = \varphi(m,n)$ is forced. (This is the precise sense in which $M \otimes_R N$ is the "most general" target receiving a balanced map.) □

Remark 10.4.1. The universal property characterizes $M \otimes_R N$ up to a *unique* isomorphism: any abelian group T with a balanced $\iota'\colon M \times N \to T$ through which all balanced maps factor uniquely is canonically isomorphic to $M \otimes_R N$. This is why, to compute a tensor product, one almost never returns to the quotient construction — one identifies a group with the right universal property.

Method (Computing $M \otimes_R N$ via the universal property)**.** *Trigger.* You must identify a tensor product, or define / evaluate a homomorphism *out of* one.

1. **To define a map out of $M \otimes_R N$:** never define it on simple tensors directly. Define a balanced map $\varphi\colon M \times N \to L$, *check all three balanced axioms*, then the UP hands you Φ with $\Phi(m \otimes n) = \varphi(m,n)$.
2. **To identify the group:** guess the answer T, build maps both ways. Forward: a balanced $M \times N \to T$ gives $M \otimes_R N \to T$. Back: a map $T \to M \otimes_R N$ on generators. Check they are mutually inverse on simple tensors / generators.
3. **To kill an element:** exhibit it as 0 using $0 \otimes n = 0$, $mr \otimes n = m \otimes rn$, and biadditivity — relations only flow *in* this way.

Worked Example 10.4.4 ($\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/\gcd(m,n)\mathbb{Z}$)**.** Compute $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z}$ as an abelian group; deduce $\mathbb{Z}/2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/3\mathbb{Z}$.

Recognition. Here $R = \mathbb{Z}$, so balanced = $\mathbb{Z}$-bilinear; both sides are cyclic, generated by $\bar{1} \otimes \bar{1}$. Use the slide relation with integer scalars to force the order.

Solution. Let $d = \gcd(m,n)$. The group $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z}$ is generated by $\bar{1} \otimes \bar{1}$ since $\bar{a} \otimes \bar{b} = ab(\bar{1} \otimes \bar{1})$. So it is cyclic. Now

$$m(\bar{1} \otimes \bar{1}) = \overline{m} \otimes \bar{1} = \bar{0} \otimes \bar{1} = 0, \qquad n(\bar{1} \otimes \bar{1}) = \bar{1} \otimes \overline{n} = \bar{1} \otimes \bar{0} = 0,$$

so the order of $\bar{1} \otimes \bar{1}$ divides both m and n, hence divides $d = \gcd(m,n)$. Thus there is a surjection $\mathbb{Z}/d\mathbb{Z} \twoheadrightarrow \mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z}$. For the reverse, the map $\varphi\colon \mathbb{Z}/m\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} \to \mathbb{Z}/d\mathbb{Z}$, $\varphi(\bar{a},\bar{b}) = \overline{ab}$, is well defined ($\mathbb{Z}/d\mathbb{Z}$ is a quotient of both $\mathbb{Z}/m\mathbb{Z}$ and $\mathbb{Z}/n\mathbb{Z}$) and $\mathbb{Z}$-bilinear, so by the UP it induces $\Phi\colon \mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \to \mathbb{Z}/d\mathbb{Z}$ with $\bar{1} \otimes \bar{1} \mapsto \bar{1}$, a generator. A surjection $\mathbb{Z}/d\mathbb{Z} \to G \to \mathbb{Z}/d\mathbb{Z}$ sending generator to generator forces $|G| = d$, so $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/d\mathbb{Z}$. *Check.* $\mathbb{Z}/2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/\gcd(2,3)\mathbb{Z} = \mathbb{Z}/1\mathbb{Z} = 0$. Sanity: $\bar{1} \otimes \bar{1} = 3(\bar{1} \otimes \bar{1}) - 2(\bar{1} \otimes \bar{1}) = \bar{1} \otimes \bar{3} - \bar{2} \otimes \bar{1} = 0 - 0 = 0$. Every simple tensor is 0, so the group is 0. Correct.

Worked Example 10.4.5 ($\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} = 0$)**.** Show $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} = 0$ for every $n \geq 1$.

Recognition. A torsion module tensored with a divisible group: clear the torsion by absorbing n into a denominator using the slide $qr \otimes x = q \otimes rx$.

Solution. Take a simple tensor $q \otimes \bar{a}$ with $q \in \mathbb{Q}$, $\bar{a} \in \mathbb{Z}/n\mathbb{Z}$. Write $q = \frac{q}{n} \cdot n$. Then

$$q \otimes \bar{a} = \left(\tfrac{q}{n} \cdot n\right) \otimes \bar{a} = \tfrac{q}{n} \otimes (n \cdot \bar{a}) = \tfrac{q}{n} \otimes \bar{0} = 0.$$

(Here $\frac{q}{n} \in \mathbb{Q}$ is a legitimate scalar; the slide moves the integer n from the $\mathbb{Q}$-side to the $\mathbb{Z}/n\mathbb{Z}$-side, where it annihilates.) Every simple tensor is 0 and simple tensors generate, so $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} = 0$. *Check.* Consistency with the previous example via $\mathbb{Z}/n\mathbb{Z}$ being torsion — a divisible group tensored with finite torsion vanishes. E.g. $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/5\mathbb{Z}$: $q \otimes \bar{a} = \frac{q}{5} \otimes \overline{5a} = \frac{q}{5} \otimes \bar{0} = 0$. Correct.

Worked Example 10.4.6 ($R \otimes_R N \cong N$ (unit object))**.** For a left R-module N (with R a right module over itself), prove $R \otimes_R N \cong N$ as abelian groups, naturally.

Recognition. R is the multiplicative "unit" for $\otimes$; expect $r \otimes n \mapsto rn$, with inverse $n \mapsto 1 \otimes n$.

Solution. Forward. Define $\varphi\colon R\times N\to N$ by $\varphi(r,n)=rn$. Biadditive in each slot, and balanced: $\varphi(rs,n)=(rs)n=r(sn)=\varphi(r,sn)$. By the UP, get $\Phi\colon R\otimes_R N\to N$, $\Phi(r\otimes n)=rn$. *Backward.* Define $\Psi\colon N\to R\otimes_R N$ by $\Psi(n)=1\otimes n$; it is a group hom. *Inverse check.* $\Phi\Psi(n)=\Phi(1\otimes n)=1\cdot n=n$. And on a simple tensor, $\Psi\Phi(r\otimes n)=\Psi(rn)=1\otimes rn=1\cdot r\otimes n=r\otimes n$ (slide $1r\otimes n=1\otimes rn$ read backwards). Since simple tensors generate, $\Psi\Phi=\mathrm{id}$. Hence $R\otimes_R N\cong N$. *Check.* With $R=\mathbb{Z}$, $\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/n\mathbb{Z}\cong\mathbb{Z}/n\mathbb{Z}$, consistent with the gcd formula at $m=0$ read as $\gcd(0,n)=n$. Correct.

Worked Example 10.4.7 (A bilinear map factoring through $\otimes$)**.** Let $V=W=\mathbb{R}^2$ over $R=\mathbb{R}$. The determinant-style map $\beta\colon\mathbb{R}^2\times\mathbb{R}^2\to\mathbb{R}$, $\beta\big((a,b),(c,d)\big)=ad-bc$, is $\mathbb{R}$-bilinear. Realize it as a homomorphism out of $\mathbb{R}^2\otimes_{\mathbb{R}}\mathbb{R}^2$.

Recognition. "$\mathbb{R}$-bilinear map into a group" is exactly the UP trigger: it must factor uniquely through $\otimes$.

Solution. Check β is balanced over $\mathbb{R}$: additive in each argument (determinant expansion is linear in each row), and for $\lambda\in\mathbb{R}$, $\beta(\lambda u,v)=\lambda\beta(u,v)=\beta(u,\lambda v)$. (Over the commutative ring $\mathbb{R}$, an $\mathbb{R}$-bilinear map is in particular balanced, and λ slides freely.) By the UP there is a unique $\mathbb{R}$-linear $B\colon\mathbb{R}^2\otimes_{\mathbb{R}}\mathbb{R}^2\to\mathbb{R}$ with $B(u\otimes v)=ad-bc$. On the basis $\{e_1\otimes e_1,e_1\otimes e_2,e_2\otimes e_1,e_2\otimes e_2\}$ of $\mathbb{R}^2\otimes_{\mathbb{R}}\mathbb{R}^2\cong\mathbb{R}^4$, B takes values $0,1,-1,0$. *Check.* $B(e_1\otimes e_2-e_2\otimes e_1)=1-(-1)=2$; directly $\beta(e_1,e_2)-\beta(e_2,e_1)=1-(-1)=2$. Note $e_1\otimes e_2-e_2\otimes e_1\neq 0$ is *not* a simple tensor (it is the alternating combination det detects). Correct.

Worked Example 10.4.8 (Symmetry and a vanishing simple tensor)**.** In $\mathbb{Z}/6\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/10\mathbb{Z}$, evaluate $\bar3\otimes\bar5$ and $\bar2\otimes\bar5$, and identify the whole group.

Recognition. Cyclic generator argument plus slide relations to test individual simple tensors.

Solution. $\gcd(6,10)=2$, so $\mathbb{Z}/6\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/10\mathbb{Z}\cong\mathbb{Z}/2\mathbb{Z}$, generated by $\bar1\otimes\bar1$ of order 2. Now

$$\bar3\otimes\bar5=15(\bar1\otimes\bar1)=\overline{15}\cdot(\bar1\otimes\bar1)=\bar1\cdot(\bar1\otimes\bar1)=\bar1\otimes\bar1\neq0,$$

since $15\equiv1\pmod 2$. And

$$\bar2\otimes\bar5=10(\bar1\otimes\bar1)=\bar0,$$

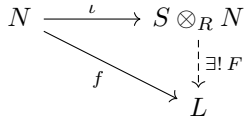
since $10\equiv0\pmod 2$ (equivalently $\bar2\otimes\bar5=\bar1\otimes\overline{10}=\bar1\otimes\bar0=0$). *Check.* Both $\bar2$ and $\bar5$ are nonzero, yet $\bar2\otimes\bar5=0$ — a concrete instance of "$m\otimes n=0$ with $m,n\neq0$". The image of $\bar a\otimes\bar b$ is $\overline{ab}\in\mathbb{Z}/2\mathbb{Z}$, matching $\bar3\otimes\bar5\mapsto\overline{15}=\bar1$ and $\bar2\otimes\bar5\mapsto\overline{10}=\bar0$. Correct.

Caution. **Simple tensors can vanish and do not exhaust the group.** Two traps:

- $m\otimes n=0$ does *not* imply $m=0$ or $n=0$. E.g. $\bar2\otimes\bar5=0$ in $\mathbb{Z}/6\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/10\mathbb{Z}$, and *every* simple tensor is 0 in $\mathbb{Q}\otimes_{\mathbb{Z}}\mathbb{Z}/n\mathbb{Z}$ or in $\mathbb{Z}/2\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/3\mathbb{Z}$.
- Not every element is a simple tensor; a general element is a *finite sum* $\sum_i m_i\otimes n_i$. In $\mathbb{R}^2\otimes_{\mathbb{R}}\mathbb{R}^2$ the element $e_1\otimes e_1+e_2\otimes e_2$ is not equal to any single $u\otimes v$. *Never* define a map on $\otimes$ by a formula on simple tensors without checking balancedness — consistency across the relations is exactly what the UP guarantees and a naive formula may not.

Quick checks.

1. Compute $\mathbb{Z}/12\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/18\mathbb{Z}$ as an abelian group, and find the order of the simple tensor $\bar4\otimes\bar3$ in it.
2. Show that the simple tensor $\bar2\otimes\bar3$ is 0 in $\mathbb{Z}/4\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/9\mathbb{Z}$, yet $\bar2\neq\bar0$ and $\bar3\neq\bar0$.
3. Let A be an abelian group with $nA=A$ for some fixed $n\geq2$ (i.e. multiplication by n is surjective). Prove $A\otimes_{\mathbb{Z}}\mathbb{Z}/n\mathbb{Z}=0$.
4. Using only the universal property, prove that the canonical map $M\times N\to M\otimes_R N$ has image generating the whole group, and deduce that if M and N are each generated by one element over a commutative R then $M\otimes_R N$ is cyclic as an R-module.



Extension of scalars

If $R \subseteq S$ are rings (sharing 1), an R-module does not automatically become an S-module. Tensoring with S *extends the scalars* from R up to S.

Theorem 10.4.9 (Extension of scalars / induced module)**.** *Let $R \subseteq S$ be a subring (with $1_R = 1_S$) and N a left R-module. Regard S as an (S, R)-bimodule (left S-action by multiplication, right R-action by multiplication). Then*

$$S \otimes_R N$$

is a left S-module *via $s' \cdot (s \otimes n) = (s's) \otimes n$, extended additively. Moreover $\iota \colon N \to S \otimes_R N$, $\iota(n) = 1 \otimes n$, is an R-module homomorphism, and the pair $(S \otimes_R N, \iota)$ is universal for R-maps into S-modules:*

i.e. for every S-module L and R-module hom $f \colon N \to L$ there is a unique S-module hom $F \colon S \otimes_R N \to L$ with $F \circ \iota = f$ (so $F(s \otimes n) = s\, f(n)$).

Diagram explanation. Objects: Top-left: N, a left R-module (living at the smaller scalar level). Top-right: $S \otimes_R N$, the *extended* module, a left S-module formed by tensoring over R with the (S, R)-bimodule S; simple tensors $s \otimes n$ span it, with S-action $s'(s \otimes n) = (s's) \otimes n$. Bottom: L, an arbitrary left S-module serving as target.

Arrows: (1) $\iota \colon N \to S \otimes_R N$, $\iota(n) = 1 \otimes n$, is the canonical R-module map from N into the extended module, given by tensoring with the identity $1 \in S$; it need not be injective (e.g. for $\mathbb{Z} \subseteq \mathbb{Q}$, $\iota \colon \mathbb{Z}/2\mathbb{Z} \to \mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} = 0$). (2) $f \colon N \to L$, any R-module homomorphism (the map to be "extended" to S-linearity). (3) The dashed $F \colon S \otimes_R N \to L$, the unique S-module homomorphism with $F(s \otimes n) = s\, f(n)$, is induced by the UP.

What commutes: $F \circ \iota = f$: for every $n \in N$, $F(\iota(n)) = F(1 \otimes n) = 1 \cdot f(n) = f(n)$.

Why it commutes: Start with $n \in N$. Top-then-down: ι sends n to $1 \otimes n$; then F sends $1 \otimes n$ to $1 \cdot f(n) = f(n)$. Diagonal: f sends n directly to $f(n)$. They agree. Well-definedness of F: the assignment $(s, n) \mapsto s\, f(n)$ must be checked R-balanced into L; the key relation is $(sr) \otimes n \mapsto (sr)f(n) = s(r f(n)) = s\, f(rn)$, which holds because f is R-linear. So the balanced map induces F as a group hom; F is S-linear because $F(s'(s \otimes n)) = F((s's) \otimes n) = (s's)f(n) = s'(sF(1 \otimes n))$.

Why this matters here: The theorem justifies why $S \otimes_R N$ is the *correct* way to promote an R-module to an S-module: the diagram encodes that any R-linear information about N can be uniquely lifted to S-linear information about $S \otimes_R N$. This is the adjunction between restriction and induction (extension of scalars $\dashv$ restriction of scalars).

Concrete example: $R = \mathbb{R}$, $S = \mathbb{C}$, $N = \mathbb{R}^n$, $L = \mathbb{C}^n$, $f(v) = v$ (view real vectors in $\mathbb{C}^n$). The induced $F \colon \mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n \to \mathbb{C}^n$ sends $z \otimes v \mapsto zv$; this is the complexification isomorphism $\mathbb{C}^n \cong \mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n$.

Common pitfall: Confusing $\iota \colon N \to S \otimes_R N$ with an S-module map. It is only R-linear: $\iota(rn) = 1 \otimes rn = r \otimes n = r \cdot (1 \otimes n)$ for $r \in R$, but N carries no S-action, so S-linearity of ι is not even meaningful. The induced F is the S-linear one, not ι.

Takeaway: The point of this diagram is that $S \otimes_R N$ is the universal S-module receiving N, meaning every R-linear map from N into any S-module extends uniquely to an S-linear map out of $S \otimes_R N$.

Sketch. For fixed $s' \in S$ the map $(s, n) \mapsto (s's) \otimes n$ is R-balanced, so it induces an additive endomorphism of $S \otimes_R N$; one checks these define a unital, associative left S-action. For the universal property: given f, the map $(s, n) \mapsto s\, f(n)$ is R-balanced into L ($sr \otimes n \mapsto (sr)f(n) = s\, f(rn)$ using that f is R-linear), so it induces an additive F; F is S-linear by the displayed action, and $F(1 \otimes n) = f(n)$. Uniqueness holds because the $s \otimes n$ generate $S \otimes_R N$ as a group and $F(s \otimes n) = sF(1 \otimes n) = s\, f(n)$ is forced. □

Method (Recognizing / using extension of scalars)**.** *Trigger.* You have an R-module N but need an S-module ($R \subseteq S$), e.g. complexify a real space ($R = \mathbb{R} \subseteq S = \mathbb{C}$), pass from $\mathbb{Z}$ to $\mathbb{Q}$, or induce from a subring/subgroup.

1. Form $S \otimes_R N$; its S-action is $s'(s \otimes n) = (s's) \otimes n$.
2. If N is free/has a basis $\{n_i\}$ over R, then $\{1 \otimes n_i\}$ is an S-basis: $S \otimes_R R^k \cong S^k$.
3. To extend an R-map $f\colon N \to L$ (L an S-module) to an S-map, use $F(s \otimes n) = s\, f(n)$.

Worked Example 10.4.10 (Complexification $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n \cong \mathbb{C}^n$)**.** With $R = \mathbb{R} \subseteq S = \mathbb{C}$, compute $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n$ as a $\mathbb{C}$-vector space.

Recognition. Free module of rank n; extension of scalars sends $\mathbb{R}^n \mapsto$ rank-n free $\mathbb{C}$-module.

Solution. $\mathbb{R}^n$ has $\mathbb{R}$-basis $e_1, \dots, e_n$. By the method, $\{1 \otimes e_i\}_{i=1}^n$ is a $\mathbb{C}$-basis of $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n$, so $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n \cong \mathbb{C}^n$ as $\mathbb{C}$-modules, with $z \otimes (a_1, \dots, a_n) \mapsto (za_1, \dots, za_n)$. *Check.* $\dim_{\mathbb{C}}(\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n) = n$ while $\dim_{\mathbb{R}}(\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^n) = 2n$, matching $\dim_{\mathbb{R}} \mathbb{C}^n = 2n$. For $n = 1$: $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R} \cong \mathbb{C}$ (a special case of $R \otimes_R N \cong N$, with $R = \mathbb{R}$, $N = \mathbb{C}$ and the two factors interchanged). Correct.

Worked Example 10.4.11 ($\mathbb{Q} \otimes_{\mathbb{Z}} M$ kills torsion)**.** Let M be an abelian group ($\mathbb{Z}$-module) and $T(M)$ its torsion subgroup. Show extension of scalars to $\mathbb{Q}$ annihilates torsion: $\mathbb{Q} \otimes_{\mathbb{Z}} M \cong \mathbb{Q} \otimes_{\mathbb{Z}} (M/T(M))$, and $\mathbb{Q} \otimes_{\mathbb{Z}} M = 0$ iff M is torsion.

Recognition. Same denominator trick as $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z}$, applied element-by-element to torsion.

Solution. If $x \in M$ is torsion, say $kx = 0$ with $k \geq 1$, then for any $q \in \mathbb{Q}$,

$$q \otimes x = \left(\tfrac{q}{k} \cdot k\right) \otimes x = \tfrac{q}{k} \otimes (kx) = \tfrac{q}{k} \otimes 0 = 0.$$

So every simple tensor with torsion right entry vanishes; hence the quotient map $M \to M/T(M)$ induces an isomorphism $\mathbb{Q} \otimes_{\mathbb{Z}} M \xrightarrow{\sim} \mathbb{Q} \otimes_{\mathbb{Z}} (M/T(M))$ (its kernel is generated by tensors $q \otimes t$, $t \in T(M)$, all 0). In particular, if $M = T(M)$ is all torsion then $\mathbb{Q} \otimes_{\mathbb{Z}} M = 0$. Conversely if M has an element x of infinite order, $\mathbb{Z}x \cong \mathbb{Z}$ embeds and (since $\mathbb{Q}$ is flat / $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z} = \mathbb{Q}$) contributes a nonzero $\mathbb{Q}$ inside $\mathbb{Q} \otimes_{\mathbb{Z}} M$. *Check.* $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z} \cong \mathbb{Q}$ (rank 1), $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} = 0$ (torsion), and $\mathbb{Q} \otimes_{\mathbb{Z}} (\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Q} \oplus 0 = \mathbb{Q}$. The dimension equals the free rank of M. Correct.

Worked Example 10.4.12 (Extending scalars on a free module: $S \otimes_R R^k \cong S^k$)**.** For $R \subseteq S$, show $S \otimes_R R^k \cong S^k$ as S-modules, and apply to $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}^3$.

Recognition. Free-module case of extension of scalars; basis $\mapsto$ basis.

Solution. R^k is free with R-basis $e_1, \dots, e_k$. By the universal property of extension of scalars (or: tensor distributes over $\oplus$ and $S \otimes_R R \cong S$),

$$S \otimes_R R^k \cong S \otimes_R \Big(\bigoplus_{i=1}^{k} R\Big) \cong \bigoplus_{i=1}^{k} (S \otimes_R R) \cong \bigoplus_{i=1}^{k} S = S^k,$$

with $1 \otimes e_i \mapsto$ the ith standard basis vector. *Check.* $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}^3 \cong \mathbb{Q}^3$, a 3-dimensional $\mathbb{Q}$-vector space; its $\mathbb{Z}$-rank as the free part of $\mathbb{Z}^3$ is 3, matching $\dim_{\mathbb{Q}} \mathbb{Q}^3 = 3$. Correct.

Worked Example 10.4.13 (Reduction mod p: $\mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} M \cong M/pM$)**.** For $R = \mathbb{Z}$, $S = \mathbb{Z}/p\mathbb{Z}$ is a *quotient* ring; show $\mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} M \cong M/pM$ for any abelian group M.

Recognition. Tensoring with a cyclic quotient ring $\mathbb{Z}/p\mathbb{Z} = \mathbb{Z}/(p)$; expect to mod out by p.

Solution. Define $\varphi\colon \mathbb{Z}/p\mathbb{Z} \times M \to M/pM$ by $\varphi(\bar{a}, m) = \overline{am}$. Well defined: if $a \equiv a' \pmod{p}$ then $am - a'm = (a - a')m \in pM$. It is $\mathbb{Z}$-balanced (biadditive; $\varphi(\bar{a}r, m) = \overline{arm} = \varphi(\bar{a}, rm)$ for $r \in \mathbb{Z}$). The UP gives $\Phi\colon \mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} M \to M/pM$, $\bar{a} \otimes m \mapsto \overline{am}$. Inverse: $\Psi\colon M/pM \to \mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} M$, $\Psi(\bar{m}) = \bar{1} \otimes m$, well defined since $\bar{1} \otimes pm = \bar{p} \otimes m = \bar{0} \otimes m = 0$. They invert each other on generators. *Check.* $\mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z} \cong \mathbb{Z}/p\mathbb{Z}$ ($M = \mathbb{Z}$), and $\mathbb{Z}/p\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/n\mathbb{Z}/p\mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/\gcd(p, n)\mathbb{Z}$, agreeing with the gcd formula. Correct.

Quick checks.

1. Compute $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$ as a $\mathbb{C}$-vector space and as an $\mathbb{R}$-algebra; in particular find its $\mathbb{C}$-dimension and exhibit a $\mathbb{C}$-basis. (Note: the left and right $\mathbb{C}$-actions differ.)

2. For an abelian group M, prove $\mathbb{Q} \otimes_{\mathbb{Z}} M = 0$ if and only if every element of M is torsion, by writing a general element of $\mathbb{Q} \otimes_{\mathbb{Z}} M$ as a single simple tensor $q \otimes x$ over a common denominator.

3. Let $R = \mathbb{Z}$ and $S = \mathbb{Z}[i]$. Compute $S \otimes_{\mathbb{Z}} \mathbb{Z}/3\mathbb{Z}$ and $S \otimes_{\mathbb{Z}} \mathbb{Z}^2$ as S-modules, identifying each with a standard form.

4. Show that $\mathbb{Z}/6\mathbb{Z} \otimes_{\mathbb{Z}} M \cong M/6M$ directly from the reduction-mod-p idea applied to a composite modulus, and verify it agrees with $\mathbb{Z}/6\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/4\mathbb{Z}$.

When R is commutative: $M \otimes_R N$ is an R-module

Proposition 10.4.14 ($\otimes$ over a commutative ring)**.** *Let R be commutative and M, N be R-modules (a right module* is *a left module via $mr := rm$). Then $M \otimes_R N$ is an R-module via*

$$r \cdot (m \otimes n) = (rm) \otimes n = m \otimes (rn),$$

extended additively, and this action is well defined. The canonical map $\iota\colon M \times N \to M \otimes_R N$ is R-bilinear, and $M \otimes_R N$ is universal among R-modules receiving an R-bilinear map: every R-bilinear $\varphi\colon M \times N \to L$ into an R-module L factors uniquely through an R-module hom $\Phi\colon M \otimes_R N \to L$.

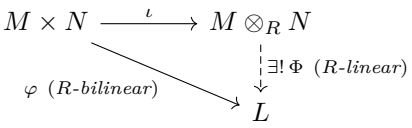


Diagram explanation. Objects: Top-left: the Cartesian product $M \times N$ of two R-modules (here R is commutative, so left and right actions coincide). Top-right: $M \otimes_R N$, now an *R-module* (not just an abelian group), via $r(m \otimes n) = (rm) \otimes n = m \otimes (rn)$. Bottom: L, an arbitrary R-module serving as target.

Arrows: (1) $\iota\colon M \times N \to M \otimes_R N$, $\iota(m, n) = m \otimes n$, the canonical map, now R-bilinear (not merely balanced) because $r(m \otimes n) = (rm) \otimes n = m \otimes (rn)$ in the R-module $M \otimes_R N$. (2) $\varphi\colon M \times N \to L$, any R-bilinear map. (3) The dashed $\Phi\colon M \otimes_R N \to L$, the unique *$R$-module* homomorphism with $\Phi(m \otimes n) = \varphi(m, n)$; this upgrades the abelian-group UP to the R-module level.

What commutes: $\Phi \circ \iota = \varphi$: for every (m, n), $\Phi(m \otimes n) = \varphi(m, n)$.

Why it commutes: The abelian-group universal property already gives a unique group hom Φ with $\Phi(m \otimes n) = \varphi(m, n)$. One then checks Φ is R-linear: $\Phi(r(m \otimes n)) = \Phi((rm) \otimes n) = \varphi(rm, n) = r\varphi(m, n) = r\Phi(m \otimes n)$, using R-linearity of φ in the first argument. Commutativity of R is used to make $(rm) \otimes n = m \otimes (rn)$ a single well-posed relation rather than two separate axioms.

Why this matters here: This proposition is placed here to show that, over a commutative ring, the tensor product is the universal *R-module* for bilinear maps—it lives in the category of R-modules, not just abelian groups. This is the natural setting for all subsequent applications (direct-sum decompositions, rank computation, symmetry $M \otimes_R N \cong N \otimes_R M$).

Concrete example: $R = \mathbb{R}$, $M = N = \mathbb{R}^2$, $L = \mathbb{R}$, $\varphi = \det$ (the determinant, which is $\mathbb{R}$-bilinear). The unique $\Phi\colon \mathbb{R}^2 \otimes_{\mathbb{R}} \mathbb{R}^2 \to \mathbb{R}$ sends $e_i \otimes e_j \mapsto \det(e_i, e_j)$. Here Φ is an $\mathbb{R}$-linear map between $\mathbb{R}$-modules (not just an abelian-group hom).

Common pitfall: Over a non-commutative ring R, $M \otimes_R N$ is only an abelian group, not an R-module (there is no canonical way to make the scalar action well defined without commutativity). Students sometimes write $r(m \otimes n)$ for general R without checking; this is only valid when R is commutative (or M/N are bimodules).

Takeaway: The point of this diagram is that over a commutative ring the universal property of the tensor product holds in the richer category of R-modules, so R-bilinear maps correspond bijectively to R-linear maps out of $M \otimes_R N$—not just group homomorphisms.

Sketch. For fixed r, $(m, n) \mapsto (rm) \otimes n$ is R-balanced (using commutativity: $(mr') \mapsto r(mr') \otimes n = (mr') \otimes rn$ etc.), so $r \cdot (-)$ is a well-defined endomorphism; commutativity gives $(rm) \otimes n = m \otimes (rn)$. Unitality and associativity of the action are routine. The middle-linear relation $mr \otimes n = m \otimes rn$ now coincides with R-bilinearity, so the abelian-group UP upgrades to an R-module UP. □

Remark 10.4.2. Over commutative R, every R-bilinear map is R-balanced (not conversely: $(u,v)\mapsto \overline{uv}$, the complex conjugate of uv, is a $\mathbb{C}$-balanced map $\mathbb{C}\times\mathbb{C}\to\mathbb{C}$ that is not $\mathbb{C}$-bilinear), and one writes $r(m\otimes n)$ unambiguously. The earlier examples $\mathbb{Z}/m\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/n\mathbb{Z}\cong\mathbb{Z}/\gcd(m,n)\mathbb{Z}$, $\mathbb{R}^2\otimes_{\mathbb{R}}\mathbb{R}^2\cong\mathbb{R}^4$, $\mathbb{C}\otimes_{\mathbb{R}}\mathbb{R}^n\cong\mathbb{C}^n$ are all instances. Tensor distributes over direct sums: $M\otimes_R\left(\bigoplus_i N_i\right)\cong\bigoplus_i(M\otimes_R N_i)$, which together with $R\otimes_R N\cong N$ and $R/(a)\otimes_R R/(b)\cong R/(a,b)$ computes all tensor products of finitely generated modules over a PID.

Method (Tensor products over a PID / commutative ring)**.** *Trigger.* R commutative (often a PID like $\mathbb{Z}$ or $F[x]$) and M,N finitely generated.

1. Decompose each module into cyclic pieces $R/(a)$ (structure theorem); R itself is $R/(0)$.
2. Use bilinearity of $\otimes$ over $\oplus$: $\left(\bigoplus_i R/(a_i)\right)\otimes_R\left(\bigoplus_j R/(b_j)\right)\cong\bigoplus_{i,j}R/(a_i)\otimes_R R/(b_j)$.
3. Evaluate each block: $R/(a)\otimes_R R/(b)\cong R/(a,b)=R/(\gcd(a,b))$ (for $\mathbb{Z}$: $\mathbb{Z}/a\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/b\mathbb{Z}\cong\mathbb{Z}/\gcd(a,b)\mathbb{Z}$).

Worked Example 10.4.15 (A PID tensor over $F[x]$)**.** Let $R=F[x]$ (F a field). Compute $\big(R/(x)\big)\otimes_R\big(R/(x^2)\big)$ and $\big(R/(x)\big)\otimes_R\big(R/(x-1)\big)$.

Recognition. Cyclic-over-cyclic blocks over the PID $F[x]$: answer is $R/(\gcd)$.

Solution. By the block formula $R/(a)\otimes_R R/(b)\cong R/(\gcd(a,b))$. First, $\gcd(x,x^2)=x$, so

$$\big(F[x]/(x)\big)\otimes_{F[x]}\big(F[x]/(x^2)\big)\cong F[x]/(x)\cong F.$$

Second, $\gcd(x,\,x-1)=1$ (they are coprime: $1\cdot x-1\cdot(x-1)=1$), so

$$\big(F[x]/(x)\big)\otimes_{F[x]}\big(F[x]/(x-1)\big)\cong F[x]/(1)=0.$$

Check. The second is the $F[x]$-analogue of $\mathbb{Z}/2\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/3\mathbb{Z}=0$ (coprime annihilators $\Rightarrow$ tensor 0). For the first, $1\otimes 1$ generates and $x(1\otimes 1)=\bar{x}\otimes 1=0\otimes 1=0$, so the module is killed by x and is 1-dimensional over F. Correct.

Worked Example 10.4.16 (Direct sums: a 2×2 block computation)**.** Over $R=\mathbb{Z}$, compute $(\mathbb{Z}/4\mathbb{Z}\oplus\mathbb{Z}/6\mathbb{Z})\otimes_{\mathbb{Z}}\mathbb{Z}/9\mathbb{Z}$.

Recognition. Distribute $\otimes$ over $\oplus$, then apply the gcd rule to each block.

Solution.

$$\begin{aligned}(\mathbb{Z}/4\mathbb{Z}\oplus\mathbb{Z}/6\mathbb{Z})\otimes_{\mathbb{Z}}\mathbb{Z}/9\mathbb{Z}&\cong(\mathbb{Z}/4\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/9\mathbb{Z})\oplus(\mathbb{Z}/6\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/9\mathbb{Z})\\&\cong\mathbb{Z}/\gcd(4,9)\mathbb{Z}\oplus\mathbb{Z}/\gcd(6,9)\mathbb{Z}=\mathbb{Z}/1\mathbb{Z}\oplus\mathbb{Z}/3\mathbb{Z}\cong\mathbb{Z}/3\mathbb{Z}.\end{aligned}$$

Check. $\gcd(4,9)=1\Rightarrow$ first block 0; $\gcd(6,9)=3\Rightarrow$ second block $\mathbb{Z}/3\mathbb{Z}$. The generator $(\bar{0},\bar{1})\otimes\bar{1}$ has order 3 (it corresponds to the generator $\bar{1}\otimes\bar{1}\neq 0$ of the block $\mathbb{Z}/6\mathbb{Z}\otimes_{\mathbb{Z}}\mathbb{Z}/9\mathbb{Z}\cong\mathbb{Z}/3\mathbb{Z}$, and $3\cdot\big((\bar{0},\bar{1})\otimes\bar{1}\big)=(\bar{0},\bar{3})\otimes\bar{1}$ corresponds to $\bar{3}\otimes\bar{1}=3(\bar{1}\otimes\bar{1})=0$). Correct.

Worked Example 10.4.17 (Free $\otimes$ free: $R^m\otimes_R R^n\cong R^{mn}$)**.** For commutative R, show $R^m\otimes_R R^n\cong R^{mn}$ and exhibit a basis.

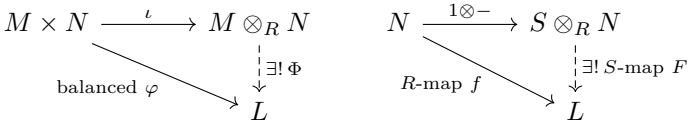
Recognition. Both factors free; distribute over $\oplus$ and use $R\otimes_R R\cong R$.

Solution.

$$R^m\otimes_R R^n\cong\Big(\bigoplus_{i=1}^{m}R\Big)\otimes_R\Big(\bigoplus_{j=1}^{n}R\Big)\cong\bigoplus_{i=1}^{m}\bigoplus_{j=1}^{n}(R\otimes_R R)\cong\bigoplus_{i,j}R=R^{mn},$$

with R-basis $\{e_i\otimes f_j : 1\le i\le m,\ 1\le j\le n\}$. *Check.* Ranks multiply: rank $=mn$. For $R=\mathbb{R}$, $m=n=2$ recovers $\mathbb{R}^2\otimes_{\mathbb{R}}\mathbb{R}^2\cong\mathbb{R}^4$ with basis $e_1\otimes e_1, e_1\otimes e_2, e_2\otimes e_1, e_2\otimes e_2$, consistent with the determinant example. Correct.

Worked Example 10.4.18 (Scalars commute past $\otimes$)**.** Over commutative $R = \mathbb{Z}$, verify directly in $\mathbb{Z}/6\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/10\mathbb{Z}$ that $3 \cdot (\bar{1} \otimes \bar{1})$ can be computed on either factor.



Recognition. Proposition: $r(m \otimes n) = (rm) \otimes n = m \otimes (rn)$ over commutative R.

Solution. Compute three ways: $3 \cdot (\bar{1} \otimes \bar{1}) = \bar{3} \otimes \bar{1}$ (act on the left factor) $= \bar{1} \otimes \bar{3}$ (act on the right factor) $= 3(\bar{1} \otimes \bar{1})$ again. In $\mathbb{Z}/6\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/10\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z}$ (from $\gcd(6, 10) = 2$), the generator $\bar{1} \otimes \bar{1}$ has order 2, so $3(\bar{1} \otimes \bar{1}) = 1 \cdot (\bar{1} \otimes \bar{1}) = \bar{1} \otimes \bar{1}$. *Check.* $\bar{3} \otimes \bar{1} \mapsto \overline{3} = \bar{1} \in \mathbb{Z}/2\mathbb{Z}$ and $\bar{1} \otimes \bar{3} \mapsto \overline{3} = \bar{1} \in \mathbb{Z}/2\mathbb{Z}$ under the iso $\bar{a} \otimes \bar{b} \mapsto \overline{ab}$; both equal $\bar{1} \otimes \bar{1}$. The action is consistent on both factors, as the Proposition guarantees. Correct.

Quick checks.

1. Over $R = \mathbb{Z}$, compute $(\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}) \otimes_{\mathbb{Z}} (\mathbb{Z}/8\mathbb{Z} \oplus \mathbb{Z}/18\mathbb{Z})$ by expanding into a 2×2 block table and applying the gcd rule to each block.
2. Let $R = F[x]$. Compute $\big(F[x]/(x^2)\big) \otimes_{F[x]} \big(F[x]/(x^3)\big)$ and give its dimension as an F-vector space.
3. Over a commutative ring R, prove the symmetry isomorphism $M \otimes_R N \cong N \otimes_R M$ via the universal property (construct maps both ways and check they are mutually inverse on simple tensors).
4. Over commutative R, suppose M is generated by m elements and N by n elements. Prove $M \otimes_R N$ is generated by at most mn elements, and show by example over $R = \mathbb{Z}$ that the bound need not be attained.

Remark 10.4.3 (Summary of the universal pictures). The three universal properties in this section are the same diagram with different decorations:

Left: ordinary tensor product (balanced maps $\leftrightarrow$ group homs). Right: extension of scalars (induction $\dashv$ restriction). In each case the dashed arrow exists and is unique — that uniqueness is what makes "define a map on simple tensors" legitimate *after* verifying balancedness.

Diagram explanation. Objects: Left diagram — same three objects as the original tensor UP: $M \times N$ (Cartesian product, not a module), $M \otimes_R N$ (abelian group, or R-module when R is commutative), and L (an abelian group). This is the balanced-map / tensor-product universal property.

Arrows: $\iota\colon M \times N \to M \otimes_R N$, $\iota(m, n) = m \otimes n$, canonical balanced map (top). $\varphi\colon M \times N \to L$, any balanced map (diagonal). Dashed $\Phi\colon M \otimes_R N \to L$, unique group hom with $\Phi \circ \iota = \varphi$ (vertical, induced).

What commutes: $\Phi \circ \iota = \varphi$: both paths $(m, n) \to L$ agree.

Why it commutes: Φ is defined on generators $m \otimes n$ by $\Phi(m \otimes n) = \varphi(m, n)$; well-defined because φ is balanced and therefore kills all relations in H. The summary presents this schematically to contrast it with the right-hand diagram.

Why this matters here: The remark is placed after all three UP results to make visible that the *same categorical pattern* governs ordinary tensor products, extension of scalars, and the commutative-ring case. The left diagram encodes: to get a map out of $M \otimes_R N$, supply a balanced map and the UP does the rest.

Concrete example: $M = \mathbb{Z}/m\mathbb{Z}$, $N = \mathbb{Z}/n\mathbb{Z}$, $L = \mathbb{Z}/\gcd(m, n)\mathbb{Z}$, $\varphi(\bar{a}, \bar{b}) = \overline{ab}$; the induced Φ is the isomorphism $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/\gcd(m, n)\mathbb{Z}$.

Common pitfall: Students reading the summary in isolation may think the two diagrams describe different objects. They describe the same *shape* (a universal triangle) applied to two different situations; the objects and arrow-types differ in each.

Takeaway: The point of this diagram is that the tensor-product UP and the extension-of-scalars UP share the same universal-triangle shape, so mastering the pattern in one context immediately transfers to the other.

Diagram explanation. Objects: Right diagram — N (a left R-module, the module before extension), $S \otimes_R N$ (the extended left S-module), and L (an arbitrary left S-module).

Arrows: $1\otimes -\colon N \to S\otimes_R N$, $n \mapsto 1\otimes n$, the canonical R-module map (top; not injective in general). $f\colon N \to L$, any R-module homomorphism (diagonal). Dashed $F\colon S \otimes_R N \to L$, unique S-module homomorphism extending f via $F(s \otimes n) = s\, f(n)$ (vertical).

What commutes: $F \circ (1 \otimes -) = f$: $F(1 \otimes n) = 1 \cdot f(n) = f(n)$ for every $n \in N$.

Why it commutes: Well-definedness of F relies on the R-balanced check $(s, n) \mapsto s\, f(n)$: the relation $(sr) \otimes n \mapsto (sr)f(n) = s\, f(rn)$ holds because f is R-linear. Thus the balanced map induces F as a group hom; it is S-linear by the S-action on $S \otimes_R N$. The uniqueness in the "induction $\dashv$ restriction" adjunction means any R-map $N \to L$ extends to a unique S-map $S \otimes_R N \to L$.

Why this matters here: The right diagram records that extension of scalars is the *left adjoint* to restriction of scalars: $\mathrm{Hom}_S(S \otimes_R N, L) \cong \mathrm{Hom}_R(N, L)$, a bijection natural in L. Placing it beside the tensor UP makes clear that both are instances of a single "represent a functor by a universal object" construction.

Concrete example: $R = \mathbb{R}$, $S = \mathbb{C}$, $N = \mathbb{R}^2$, $L = \mathbb{C}^3$, $f\colon \mathbb{R}^2 \to \mathbb{C}^3$ an $\mathbb{R}$-linear embedding. The unique $\mathbb{C}$-linear extension is $F\colon \mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}^2 \cong \mathbb{C}^2 \to \mathbb{C}^3$, $F(z \otimes v) = z f(v)$.

Common pitfall: Thinking F is the same map as f. They differ: f is only R-linear into L, while F is S-linear out of the larger module $S \otimes_R N$. The canonical map $\iota = 1 \otimes -$ is the bridge between them.

Takeaway: The point of this diagram is that the extension-of-scalars construction $S \otimes_R N$ is the universal way to convert an R-linear map into an S-linear one, exhibiting the adjunction between induction and restriction of scalars.

Exercises (from the text).

1. Let $f : R \to S$ be a ring homomorphism from the ring R to the ring S with $f(1_R) = 1_S$. Verify the details that $sr = sf(r)$ defines a right R-action on S under which S is an (S, R)-bimodule.
2. Show that the element "$2 \otimes 1$" is 0 in $\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$ but is nonzero in $2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$.
3. Show that $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$ and $\mathbb{C} \otimes_{\mathbb{C}} \mathbb{C}$ are both left $\mathbb{R}$-modules but are not isomorphic as $\mathbb{R}$-modules.
4. Show that $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Q}$ and $\mathbb{Q} \otimes_{\mathbb{Q}} \mathbb{Q}$ are isomorphic left $\mathbb{Q}$-modules. [Show they are both 1-dimensional vector spaces over $\mathbb{Q}$.]
5. Let A be a finite abelian group of order n and let p^k be the largest power of the prime p dividing n. Prove that $\mathbb{Z}/p^k\mathbb{Z} \otimes_{\mathbb{Z}} A$ is isomorphic to the Sylow p-subgroup of A.
6. If R is any integral domain with quotient field Q, prove that $(Q/R) \otimes_R (Q/R) = 0$.
7. If R is any integral domain with quotient field Q and N is a left R-module, prove that every element of the tensor product $Q \otimes_R N$ can be written as a simple tensor of the form $(1/d) \otimes n$ for some nonzero $d \in R$ and some $n \in N$.
8. Suppose R is an integral domain with quotient field Q and let N be any R-module. Let $U = R \setminus \{0\}$ be the set of nonzero elements in R and define $U^{-1}N$ to be the set of equivalence classes of ordered pairs of elements (u, n) with $u \in U$ and $n \in N$ under the equivalence relation $(u, n) \sim (u', n')$ if and only if $xu'n = xun'$ in N for some $x \in U$.
   (a) Prove that $U^{-1}N$ is an abelian group under the addition defined by $\overline{(u_1, n_1)} + \overline{(u_2, n_2)} = \overline{(u_1u_2, u_2n_1 + u_1n_2)}$. Prove that $r\overline{(u, n)} = \overline{(u, rn)}$ defines an action of R on $U^{-1}N$ making it into an R-module. [This is an example of *localization* considered in general in Section 4 of Chapter 15, cf. also Section 5 in Chapter 7.]
   (b) Show that the map from $Q \times N$ to $U^{-1}N$ defined by sending $(a/b, n)$ to $\overline{(b, an)}$ for $a \in R$, $b \in U$, $n \in N$, is an R-balanced map, so induces a homomorphism f from $Q \otimes_R N$ to $U^{-1}N$. Show that the map g from $U^{-1}N$ to $Q \otimes_R N$ defined by $g(\overline{(u, n)}) = (1/u) \otimes n$ is well defined and is an inverse homomorphism to f. Conclude that $Q \otimes_R N \cong U^{-1}N$ as R-modules.
   (c) Conclude from (b) that $(1/d) \otimes n$ is 0 in $Q \otimes_R N$ if and only if $rn = 0$ for some nonzero $r \in R$.
   (d) If A is an abelian group, show that $\mathbb{Q} \otimes_{\mathbb{Z}} A = 0$ if and only if A is a torsion abelian group (i.e., every element of A has finite order).
9. Suppose R is an integral domain with quotient field Q and let N be any R-module. Let $Q \otimes_R N$ be the module obtained from N by extension of scalars from R to Q. Prove that the kernel of the R-module

homomorphism $\iota : N \to Q \otimes_R N$ is the torsion submodule of N (cf. Exercise 8 in Section 1). [Use the previous exercise.]

10. Suppose R is commutative and $N \cong R^n$ is a free R-module of rank n with R-module basis $e_1, \ldots, e_n$.
(a) For any nonzero R-module M show that every element of $M \otimes N$ can be written uniquely in the form $\sum_{i=1}^n m_i \otimes e_i$ where $m_i \in M$. Deduce that if $\sum_{i=1}^n m_i \otimes e_i = 0$ in $M \otimes N$ then $m_i = 0$ for $i = 1, \ldots, n$.
(b) Show that if $\sum_i m_i \otimes n_i = 0$ in $M \otimes N$ where the n_i are merely assumed to be R-linearly independent then it is not necessarily true that all the m_i are 0. [Consider $R = \mathbb{Z}$, $n = 1$, and $M = \mathbb{Z}/2\mathbb{Z}$, and the element $1 \otimes 2$.]

11. Let $\{e_1, e_2\}$ be a basis of $V = \mathbb{R}^2$. Show that the element $e_1 \otimes e_2 + e_2 \otimes e_1$ in $V \otimes_{\mathbb{R}} V$ cannot be written as a simple tensor $v \otimes w$ for any $v, w \in \mathbb{R}^2$.

12. Let V be a vector space over the field F and let v, v' be nonzero elements of V. Prove that $v \otimes v' = v' \otimes v$ in $V \otimes_F V$ if and only if $v = av'$ for some $a \in F$.

13. Prove that the usual dot product of vectors defined by letting $(a_1, \ldots, a_n) \cdot (b_1, \ldots, b_n) = a_1 b_1 + \cdots + a_n b_n$ is a bilinear map from $\mathbb{R}^n \times \mathbb{R}^n$ to $\mathbb{R}$.

14. Let I be an arbitrary nonempty index set and for each $i \in I$ let N_i be a left R-module. Let M be a right R-module. Prove the group isomorphism: $M \otimes (\oplus_{i \in I} N_i) \cong \oplus_{i \in I}(M \otimes N_i)$, where the direct sum of an arbitrary collection of modules is defined in Exercise 20, Section 3. [Use the same argument as for the direct sum of two modules, taking care to note where the direct *sum* hypothesis is needed — cf. the next exercise.]

15. Show that tensor products do not commute with direct products in general. [Consider the extension of scalars from $\mathbb{Z}$ to $\mathbb{Q}$ of the direct product of the modules $M_i = \mathbb{Z}/2^i\mathbb{Z}$, $i = 1, 2, \ldots$]

16. Suppose R is commutative and let I and J be ideals of R, so R/I and R/J are naturally R-modules.
(a) Prove that every element of $R/I \otimes_R R/J$ can be written as a simple tensor of the form $(1 \bmod I) \otimes (r \bmod J)$.
(b) Prove that there is an R-module isomorphism $R/I \otimes_R R/J \cong R/(I+J)$ mapping $(r \bmod I) \otimes (r' \bmod J)$ to $rr' \bmod (I + J)$.

17. Let $I = (2, x)$ be the ideal generated by 2 and x in the ring $R = \mathbb{Z}[x]$. The ring $\mathbb{Z}/2\mathbb{Z} = R/I$ is naturally an R-module annihilated by both 2 and x.
(a) Show that the map $\varphi : I \times I \to \mathbb{Z}/2\mathbb{Z}$ defined by $\varphi(a_0 + a_1 x + \cdots + a_n x^n, b_0 + b_1 x + \cdots + b_m x^m) = \frac{a_0}{2} b_1 \bmod 2$ is R-bilinear.
(b) Show that there is an R-module homomorphism from $I \otimes_R I \to \mathbb{Z}/2\mathbb{Z}$ mapping $p(x) \otimes q(x)$ to $\frac{p(0)}{2} q'(0)$ where q' denotes the usual polynomial derivative of q.
(c) Show that $2 \otimes x \neq x \otimes 2$ in $I \otimes_R I$.

18. Suppose I is a principal ideal in the integral domain R. Prove that the R-module $I \otimes_R I$ has no nonzero torsion elements (i.e., $rm = 0$ with $0 \neq r \in R$ and $m \in I \otimes_R I$ implies that $m = 0$).

19. Let $I = (2, x)$ be the ideal generated by 2 and x in the ring $R = \mathbb{Z}[x]$ as in Exercise 17. Show that the nonzero element $2 \otimes x - x \otimes 2$ in $I \otimes_R I$ is a torsion element. Show in fact that $2 \otimes x - x \otimes 2$ is annihilated by both 2 and x and that the submodule of $I \otimes_R I$ generated by $2 \otimes x - x \otimes 2$ is isomorphic to R/I.

20. Let $I = (2, x)$ be the ideal generated by 2 and x in the ring $R = \mathbb{Z}[x]$. Show that the element $2 \otimes 2 + x \otimes x$ in $I \otimes_R I$ is not a simple tensor, i.e., cannot be written as $a \otimes b$ for some $a, b \in I$.

21. Suppose R is commutative and let I and J be ideals of R.
(a) Show there is a surjective R-module homomorphism from $I \otimes_R J$ to the product ideal IJ mapping $i \otimes j$ to the element ij.
(b) Give an example to show that the map in (a) need not be injective (cf. Exercise 17).

22. Suppose that M is a left and a right R-module such that $rm = mr$ for all $r \in R$ and $m \in M$. Show that the elements $r_1 r_2$ and $r_2 r_1$ act the same on M for every $r_1, r_2 \in R$. (This explains why the assumption that R is commutative in the definition of an R-algebra is a fairly natural one.)

23. Verify the details that the multiplication in Proposition 21 makes $A \otimes_R B$ into an R-algebra.

24. Prove that the extension of scalars from $\mathbb{Z}$ to the Gaussian integers $\mathbb{Z}[i]$ of the ring $\mathbb{R}$ is isomorphic to $\mathbb{C}$ as a ring: $\mathbb{Z}[i] \otimes_{\mathbb{Z}} \mathbb{R} \cong \mathbb{C}$ as rings.

25. Let S be a commutative ring containing R (with $1_S = 1_R$) and let x be an indeterminate over S. Prove that $S[x]$ and $S \otimes_R R[x]$ are isomorphic as S-algebras.

26. Let S be a commutative ring containing R (with $1_S = 1_R$) and let $x_1, \ldots, x_n$ be independent indeterminates over the ring S. Show that for every ideal I in the polynomial ring $R[x_1, \ldots, x_n]$ that $S \otimes_R (R[x_1, \ldots, x_n]/I) \cong S[x_1, \ldots, x_n]/IS[x_1, \ldots, x_n]$ as S-algebras.

27. (a) Write down a formula for the multiplication of two elements $a \cdot 1 + b \cdot e_2 + c \cdot e_3 + d \cdot e_4$ and $a' \cdot 1 + b' \cdot e_2 + c' \cdot e_3 + d' \cdot e_4$ in the example $A = \mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$ following Proposition 21 (where $1 = 1 \otimes 1$ is the identity of A).
(b) Let $\epsilon_1 = \frac{1}{2}(1 \otimes 1 + i \otimes i)$ and $\epsilon_2 = \frac{1}{2}(1 \otimes 1 - i \otimes i)$. Show that $\epsilon_1 \epsilon_2 = 0$, $\epsilon_1 + \epsilon_2 = 1$, and $\epsilon_j^2 = \epsilon_j$ for $j = 1, 2$ (ϵ_1 and ϵ_2 are called *orthogonal idempotents* in A). Deduce that A is isomorphic as a ring to the direct product of two principal ideals: $A \cong A\epsilon_1 \times A\epsilon_2$ (cf. Exercise 1, Section 7.6).
(c) Prove that the map $\varphi : \mathbb{C} \times \mathbb{C} \to \mathbb{C} \times \mathbb{C}$ by $\varphi(z_1, z_2) = (z_1 z_2, z_1 \overline{z_2})$, where $\overline{z_2}$ denotes the complex conjugate of z_2, is an $\mathbb{R}$-bilinear map.
(d) Let Φ be the $\mathbb{R}$-module homomorphism from A to $\mathbb{C} \times \mathbb{C}$ obtained from φ in (c). Show that $\Phi(\epsilon_1) = (0, 1)$ and $\Phi(\epsilon_2) = (1, 0)$. Show also that Φ is $\mathbb{C}$-linear, where the action of $\mathbb{C}$ is on the left tensor factor in A and on both factors in $\mathbb{C} \times \mathbb{C}$. Deduce that Φ is surjective. Show that Φ is a $\mathbb{C}$-algebra isomorphism.

Practice problems.

1. Let $R = \mathbb{Z}$. Compute $\mathbb{Z}/4\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/6\mathbb{Z}$ explicitly, identifying it with $\mathbb{Z}/d\mathbb{Z}$ for the appropriate d, and write down the image of $\bar{1} \otimes \bar{1}$.

2. Show that $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} = 0$ for every $n \geq 1$. (Hint: write $\frac{a}{b} \otimes \bar{x} = \frac{a}{bn} \otimes n\bar{x}$.)

3. Let R be a commutative ring and M an R-module. Construct a natural isomorphism $R \otimes_R M \cong M$ of R-modules, and verify it sends $r \otimes m \mapsto rm$.

4. Prove that $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/\gcd(m, n)\mathbb{Z}$ for all positive integers m, n.

5. Let V, W be finite-dimensional vector spaces over a field $\mathbb{F}$ with $\dim_{\mathbb{F}} V = p$ and $\dim_{\mathbb{F}} W = q$. Prove $\dim_{\mathbb{F}}(V \otimes_{\mathbb{F}} W) = pq$ by exhibiting a basis of the tensor product in terms of bases of V and W.

6. Let R be commutative and let M, N be R-modules. Prove the commutativity isomorphism $M \otimes_R N \cong N \otimes_R M$ as R-modules, sending $m \otimes n \mapsto n \otimes m$. Explain where you use the balanced (middle-linear) property.

7. Let A be a nonzero finite abelian group. Show $A \otimes_{\mathbb{Z}} \mathbb{Q} = 0$ but $A \otimes_{\mathbb{Z}} A$ need not vanish; illustrate with $A = \mathbb{Z}/2\mathbb{Z}$.

8. Let $f\colon M \to M'$ and $g\colon N \to N'$ be R-module homomorphisms (R commutative). Define $f \otimes g\colon M \otimes_R N \to M' \otimes_R N'$ on simple tensors and verify it is a well-defined R-module homomorphism.

9. Compute $\mathbb{Z}/n\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Q}/\mathbb{Z}$ and determine whether it is zero. Justify.

10. Let I, J be ideals of a commutative ring R. Prove $R/I \otimes_R R/J \cong R/(I + J)$ as R-modules.

11. Let $R = \mathbb{Z}$ and consider the free module $\mathbb{Z}^2$. Compute $\mathbb{Z}^2 \otimes_{\mathbb{Z}} \mathbb{Z}/3\mathbb{Z}$ and identify it as an abelian group; state its order.

12. For R commutative, prove the associativity isomorphism $(M \otimes_R N) \otimes_R L \cong M \otimes_R (N \otimes_R L)$, sending $(m \otimes n) \otimes \ell \mapsto m \otimes (n \otimes \ell)$.

13. Let S be a commutative ring containing the commutative ring R as a subring (so S is an R-algebra). For the R-module R^n, compute the S-module $S \otimes_R R^n$ obtained by extension of scalars and identify it as a free S-module of a stated rank.

14. Let $M = \mathbb{Z}/12\mathbb{Z}$ as a $\mathbb{Z}$-module. Compute $M \otimes_{\mathbb{Z}} \mathbb{Z}/8\mathbb{Z}$ and $M \otimes_{\mathbb{Z}} \mathbb{Z}/9\mathbb{Z}$, giving each as a cyclic group $\mathbb{Z}/d\mathbb{Z}$.

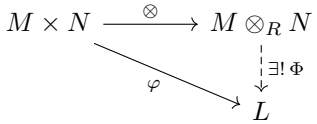
15. Let R be commutative and M a free R-module with basis $\{e_1, \dots, e_n\}$. Show that every element of $M \otimes_R N$ can be written uniquely as $\sum_{i=1}^{n} e_i \otimes n_i$ with $n_i \in N$.

Additional exercises.

1. Let R be a commutative ring and let $\{M_i\}_{i \in I}$ be a family of R-modules. Prove the distributivity isomorphism
$$\Big(\bigoplus_{i \in I} M_i\Big) \otimes_R N \;\cong\; \bigoplus_{i \in I} (M_i \otimes_R N).$$
Deduce that $R^{(A)} \otimes_R N \cong N^{(A)}$.

2. Let R be commutative and $S \subseteq R$ a multiplicatively closed set containing 1. Show that $S^{-1}R \otimes_R M \cong S^{-1}M$ as $S^{-1}R$-modules, where $S^{-1}M$ is the localization. (Localization is extension of scalars along $R \to S^{-1}R$.)

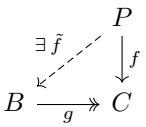
3. Prove that the $\mathbb{Z}$-module $\mathbb{Q}$ is flat but not projective: show $\mathbb{Q} \otimes_{\mathbb{Z}} (-)$ preserves injections, yet $\mathbb{Q}$ is not a direct summand of any free $\mathbb{Z}$-module.



4. Let A be a finitely generated abelian group with $A \cong \mathbb{Z}^r \oplus T$, T finite. Compute $A \otimes_{\mathbb{Z}} \mathbb{Q}$ and $\mathbb{Q}/\mathbb{Z} \otimes_{\mathbb{Z}} A$ in terms of r and T, and use the first to recover the rank r.

5. Let R be commutative and M, N finitely generated R-modules. Prove $M \otimes_R N$ is finitely generated, and give an example over $R = \mathbb{Z}$ of infinite $\mathbb{Z}$-modules M, N (necessarily not finitely generated) with $M \otimes_R N = 0$.

6. Let $\mathbb{F}$ be a field and $K/\mathbb{F}$ a field extension. For an $\mathbb{F}$-algebra A, show $K \otimes_{\mathbb{F}} A$ is naturally a K-algebra, and compute $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$ as an $\mathbb{R}$-algebra, identifying it with $\mathbb{C} \oplus \mathbb{C}$.



Commutative-diagram exercises.

1. State and prove the universal property of the tensor product: for every R-balanced (middle-linear) map $\varphi\colon M \times N \to L$ there is a unique group homomorphism Φ making the diagram commute.

Verify that this universal property characterizes $M \otimes_R N$ up up to unique isomorphism.

2. Recall the lifting property of projective modules. Use it together with the right-exactness of $- \otimes_R N$ to prove that if P is projective then $P \otimes_R N$ is a direct summand of a free-module tensor, and that $- \otimes_R P$ takes the surjection g to a surjection in the diagram below.

3. Let R be commutative and let
$$0 \longrightarrow A \xrightarrow{\;\psi\;} B \xrightarrow{\;\varphi\;} C \longrightarrow 0$$
be a short exact sequence of R-modules. Prove that for any R-module N the induced sequence
$$A \otimes_R N \xrightarrow{\psi \otimes 1} B \otimes_R N \xrightarrow{\varphi \otimes 1} C \otimes_R N \longrightarrow 0$$
is exact (right-exactness), and give an explicit example with $R = \mathbb{Z}$, $N = \mathbb{Z}/n\mathbb{Z}$ showing $\psi \otimes 1$ need not be injective.

4. Define an R-module N to be flat if $- \otimes_R N$ is exact. Show that in the diagram of exercise 3, N is flat iff $\psi \otimes 1$ is injective for every injection ψ, and use this criterion to verify that every free R-module is flat.

5. Consider a commutative diagram of R-modules with exact rows

$$\begin{array}{ccccccccc} & & A & \xrightarrow{\psi} & B & \xrightarrow{\varphi} & C & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \\ 0 & \longrightarrow & A' & \xrightarrow{\psi'} & B' & \xrightarrow{\varphi'} & C' & & \end{array}$$

   Using the snake lemma, derive the exact sequence relating $\ker a, \ker b, \ker c$ and $\operatorname{coker} a, \operatorname{coker} b, \operatorname{coker} c$, then specialize to the rows obtained by applying $- \otimes_R N$ to a short exact sequence to interpret the connecting map.

10.5 Exact Sequences — Projective, Injective, and Flat Modules

Exact sequences, projective, injective, and flat modules

Throughout, R is a ring with 1 and modules are left R-modules unless noted. The organizing idea of this section is to track when applying a functor (taking Hom, or tensoring) to a sequence of modules preserves the property "image = kernel at every spot." Three classes of modules are exactly the ones that make a given functor preserve exactness: projective for $\operatorname{Hom}_R(P, -)$, injective for $\operatorname{Hom}_R(-, Q)$, and flat for $M \otimes_R -$.

Definition 10.5.1 (Exact sequence)**.** A pair of R-module homomorphisms $X \xrightarrow{\alpha} Y \xrightarrow{\beta} Z$ is *exact at* Y if $\operatorname{im} \alpha = \ker \beta$. A (finite or infinite) sequence

$$\cdots \longrightarrow X_{n+1} \xrightarrow{\alpha_{n+1}} X_n \xrightarrow{\alpha_n} X_{n-1} \longrightarrow \cdots$$

Diagram explanation. Objects: Each X_n is an R-module (a term in the sequence). The dots indicate the sequence may extend infinitely in either direction. The subscript tracks position: X_{n+1} feeds into X_n, which feeds into X_{n-1}.

Arrows: $\alpha_{n+1} \colon X_{n+1} \to X_n$ and $\alpha_n \colon X_n \to X_{n-1}$ are R-module homomorphisms. The entire collection $\{\alpha_n\}$ is the chain of maps whose image-kernel relations the definition controls.

What commutes: This is an exact sequence, not a commutative square, so the relevant condition is not a path equality but the exactness conditions: $\operatorname{im} \alpha_{n+1} = \ker \alpha_n$ at every interior term X_n.

Why it commutes: Exactness at X_n has two parts. First, $\alpha_n \circ \alpha_{n+1} = 0$ (the composite vanishes), giving $\operatorname{im} \alpha_{n+1} \subseteq \ker \alpha_n$. Second, the reverse inclusion: every element of $\ker \alpha_n$ is in the image of α_{n+1}. Together these force im = ker at X_n.

Why this matters here: This diagram introduces the definition of an exact sequence in full generality. The image-kernel condition is the single organizing equation that makes the whole theory of projective, injective, and flat modules meaningful.

Concrete example: Take $\cdots \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \to 0 \to \cdots$; exactness at the middle $\mathbb{Z}$ says $\operatorname{im}(\times 2) = 2\mathbb{Z} = \ker \pi$.

Common pitfall: Students confuse $\alpha_n \circ \alpha_{n+1} = 0$ (the composite kills everything) with full exactness; the first condition gives only $\subseteq$, not equality. A chain complex satisfies only the first; an exact sequence needs equality at every term.

Takeaway: The point of this diagram is that exactness at each node is the precise local condition image-equals-kernel, and the full sequence is exact when this holds simultaneously at every interior term.

is *exact* if it is exact at every interior X_n, i.e. $\operatorname{im} \alpha_{n+1} = \ker \alpha_n$ for all n.

Two boundary cases pin down the language. With 0 the zero module:

- $0 \to A \xrightarrow{\psi} B$ is exact at $A \iff \ker \psi = 0 \iff \psi$ is *injective*.

- $B \xrightarrow{\varphi} C \to 0$ is exact at $C \iff \operatorname{im}\varphi = C \iff \varphi$ is *surjective*.

Definition 10.5.2 (Short exact sequence)**.** A *short exact sequence (SES)* is an exact sequence of the form

$$0 \longrightarrow A \xhookrightarrow{\psi} B \xrightarrow{\varphi} C \longrightarrow 0.$$

Diagram explanation. Objects: 0 is the zero module (placed at both ends). A, B, C are R-modules. The zero modules bookend the sequence to enforce injectivity at the left and surjectivity at the right.

Arrows: The map $0 \to A$ is forced to be the zero map. $\psi\colon A \to B$ is an R-module homomorphism required to be injective (exactness at A). $\varphi\colon B \to C$ is an R-module homomorphism required to be surjective (exactness at C). The map $C \to 0$ is also forced.

What commutes: Three exactness conditions hold simultaneously: (i) $\ker\psi = 0$ so ψ is injective; (ii) $\operatorname{im}\varphi = C$ so φ is surjective; (iii) $\operatorname{im}\psi = \ker\varphi$ in the middle.

Why it commutes: Condition (i) follows from exactness at A: $\operatorname{im}(0 \to A) = 0 = \ker\psi$. Condition (ii) follows from exactness at C: $\ker(C \to 0) = C = \operatorname{im}\varphi$. Condition (iii) is exactness at B. Together they say ψ identifies A as a submodule of B and φ exhibits C as the quotient $B/\operatorname{im}\psi$.

Why this matters here: The SES is the standard package for encoding a submodule–quotient relationship. It unifies injectivity, surjectivity, and the image-kernel equation into a single compact object that is the building block for all splitting, projectivity, and injectivity arguments that follow.

Concrete example: $0 \to n\mathbb{Z} \hookrightarrow \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/n\mathbb{Z} \to 0$, with ψ the inclusion and $\varphi = \pi$ the quotient map. Then $\operatorname{im}\psi = n\mathbb{Z} = \ker\pi$.

Common pitfall: Students sometimes read a SES as saying $B \cong A \oplus C$; this is the split case only. The sequence records the relationship $C \cong B/A$ but says nothing about a complementary copy of C inside B.

Takeaway: The point of this diagram is that a short exact sequence packages the three conditions – ψ injective, φ surjective, $\operatorname{im}\psi = \ker\varphi$ – into one object that describes B as an extension of C by A.

Exactness at all three interior spots means precisely: ψ is injective, φ is surjective, and $\operatorname{im}\psi = \ker\varphi$. Thus ψ embeds A as a submodule of B and φ induces an isomorphism $B/\operatorname{im}\psi \cong C$, i.e. $C \cong B/A$.

Method (Testing exactness of a (short) sequence)**.** *Trigger.* You are handed a chain of maps and asked whether it is exact, or whether the two end zeros are legitimate. *Recipe.*

1. At each interior node Y with incoming α and outgoing β, first check $\beta \circ \alpha = 0$ (this gives $\operatorname{im}\alpha \subseteq \ker\beta$ for free).
2. Then check the reverse $\ker\beta \subseteq \operatorname{im}\alpha$: take $y \in \ker\beta$ and exhibit a preimage under α.
3. Leftmost zero $\Rightarrow$ check the first nonzero map is injective; rightmost zero $\Rightarrow$ check the last nonzero map is surjective.
4. For a SES, equivalently verify: ψ injective, φ surjective, $\operatorname{im}\psi = \ker\varphi$; often it is fastest to use the dimension/order count $|B| = |A| \cdot |C|$ (finite case) or rank count as a sanity check.

Worked Example 10.5.3 (An exact sequence of abelian groups)**.** Problem. Show $0 \to \mathbb{Z} \xrightarrow{\times 3} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/3\mathbb{Z} \to 0$ is exact, where π is reduction mod 3.

Recognition. A length-5 sequence with end zeros is a SES; check injective, surjective, and im = ker in the middle.

Solution. Left: $\times 3\colon n \mapsto 3n$ has kernel $\{n : 3n = 0\} = 0$, so it is injective; exact at the left $\mathbb{Z}$. *Right:* π is surjective onto $\mathbb{Z}/3\mathbb{Z}$; exact at $\mathbb{Z}/3\mathbb{Z}$. *Middle:* $\operatorname{im}(\times 3) = 3\mathbb{Z}$ and $\ker\pi = \{n : 3 \mid n\} = 3\mathbb{Z}$, so $\operatorname{im}(\times 3) = \ker\pi$; exact at the middle $\mathbb{Z}$. Hence exact everywhere. *Check.* $\mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/3\mathbb{Z}$, consistent with $C \cong B/A$, and the first isomorphism theorem gives $\mathbb{Z}/\ker\pi = \mathbb{Z}/3\mathbb{Z} \cong \operatorname{im}\pi = \mathbb{Z}/3\mathbb{Z}$. Correct.

Worked Example 10.5.4 (A four-term sequence that fails exactness)**.** Problem. Is $0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \to 0$ exact?

Recognition. Same SES test; watch the middle composite and the surjectivity.

Solution. Compose the two middle maps: $n \mapsto 2n \mapsto 4n$, which is *not* zero, so $\operatorname{im}(\times 2) = 2\mathbb{Z} \subsetneq \ker(\times 2) = 0$. Already exactness at the middle fails. Also the right map $\times 2 \colon \mathbb{Z} \to \mathbb{Z}$ has image $2\mathbb{Z} \neq \mathbb{Z}$, so it is not surjective and the rightmost zero is illegitimate. *Check.* A SES with $A = C = \mathbb{Z}$ would force B to be an extension of $\mathbb{Z}$ by $\mathbb{Z}$ with $B/A \cong C = \mathbb{Z}$; that is possible (e.g. $B = \mathbb{Z}^2$ with the maps being inclusion of the first factor and projection to the second), but here the chosen maps simply fail the equalities. Not exact.

Worked Example 10.5.5 (Exactness with a direct sum in the middle)**.** Problem. For R-modules A, C, show $0 \to A \xrightarrow{\iota} A \oplus C \xrightarrow{p} C \to 0$ is exact, where $\iota(a) = (a, 0)$ and $p(a, c) = c$.

Recognition. "Inclusion then projection" is the prototype SES; check the three conditions.

Solution. ι is injective since $\iota(a) = (0, 0) \Rightarrow a = 0$. p is surjective since $p(0, c) = c$. Middle: $\operatorname{im} \iota = \{(a, 0)\} = A \oplus 0$ and $\ker p = \{(a, c) : c = 0\} = A \oplus 0$, equal. Exact. *Check.* $(A \oplus C)/(A \oplus 0) \cong C$, matching $C \cong B/A$. Correct.

Worked Example 10.5.6 (Kernel–cokernel exact sequence)**.** Problem. Given any R-homomorphism $f \colon M \to N$, build a four-term exact sequence recording $\ker f$ and $\operatorname{coker} f = N/\operatorname{im} f$.

Recognition. Any single map spawns a canonical exact sequence through its kernel and cokernel.

Solution. Take $0 \to \ker f \xrightarrow{\subseteq} M \xrightarrow{f} N \xrightarrow{q} \operatorname{coker} f \to 0$, with q the quotient map. Exact at $\ker f$: inclusion is injective. At M: image of inclusion is $\ker f$. At N: $\operatorname{im} f = \ker q$ by definition of the quotient $N/\operatorname{im} f$. At $\operatorname{coker} f$: q is surjective. *Check.* f injective $\iff \ker f = 0$ (left three terms collapse to a SES) and f surjective $\iff \operatorname{coker} f = 0$. Correct.

Worked Example 10.5.7 (A vector-space exact sequence and dimension count)**.** Problem. Over $\mathbb{F} = \mathbb{Q}$, is $0 \to \mathbb{Q}^2 \xrightarrow{A} \mathbb{Q}^3 \xrightarrow{B} \mathbb{Q} \to 0$ exact for $A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 0 & 0 & 1 \end{pmatrix}$?

Recognition. For vector spaces, exactness of a SES is equivalent to the rank–nullity count $\dim B = \dim A + \dim C$ together with $\operatorname{im} = \ker$.

Solution. A has rank 2, so injective; exact at $\mathbb{Q}^2$. B has rank 1, so surjective onto $\mathbb{Q}$; exact at $\mathbb{Q}$. Middle: $\operatorname{im} A = \{(x, y, 0)\}$ and $\ker B = \{(x, y, z) : z = 0\} = \{(x, y, 0)\}$, equal. Exact. *Check.* $\dim \mathbb{Q}^3 = 3 = 2 + 1 = \dim \mathbb{Q}^2 + \dim \mathbb{Q}$, consistent. Correct.

Remark 10.5.1. For abelian groups (i.e. $\mathbb{Z}$-modules) and more generally for modules over any commutative domain, exactness of a SES forces the order count $|B| = |A| \cdot |C|$ when all are finite. This single equality is a fast necessary check, though not sufficient on its own.

Split short exact sequences

Definition 10.5.8 (Split SES; splitting and retraction)**.** A SES $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ is *split* if there is an R-homomorphism $s \colon C \to B$ (a *splitting / section*) with $\varphi \circ s = \mathrm{id}_C$; equivalently, if there is an R-homomorphism $t \colon B \to A$ (a *retraction*) with $t \circ \psi = \mathrm{id}_A$.

Proposition 10.5.9 (Splitting criterion)**.** *For a SES $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ the following are equivalent:*

1. *there is a splitting $s \colon C \to B$ with $\varphi s = \mathrm{id}_C$;*
2. *there is a retraction $t \colon B \to A$ with $t\psi = \mathrm{id}_A$;*
3. *$B = \operatorname{im} \psi \oplus K$ for some submodule K with $\varphi|_K \colon K \xrightarrow{\cong} C$; and in all cases $B \cong A \oplus C$ via an isomorphism compatible with ψ, φ.*

Proof. (1) $\Rightarrow$ (3): Given s, set $K = \operatorname{im} s$. For $b \in B$, write $b = (b - s\varphi(b)) + s\varphi(b)$. Now $\varphi(b - s\varphi(b)) = \varphi(b) - \varphi s \varphi(b) = \varphi(b) - \varphi(b) = 0$, so $b - s\varphi(b) \in \ker \varphi = \operatorname{im} \psi$. Thus $B = \operatorname{im} \psi + K$. If $x \in \operatorname{im} \psi \cap K$, then $x = s(c)$ and $\varphi(x) = 0$, but $\varphi(x) = \varphi s(c) = c$, so $c = 0$ and $x = 0$; the sum is direct. The map $\varphi|_K \colon K \to C$ has inverse s, so it is an isomorphism. (3) $\Rightarrow$ (2): With $B = \operatorname{im} \psi \oplus K$, define $t \colon B \to A$ by $t(\psi(a) + k) = a$ (well defined since ψ is injective). Then $t\psi = \mathrm{id}_A$. (2) $\Rightarrow$ (1): Given t, restrict φ to $\ker t$; one checks $\varphi|_{\ker t}$ is an isomorphism whose inverse is a splitting s. Concretely, for $c \in C$ pick b with $\varphi(b) = c$ and set $s(c) = b - \psi t(b)$; this is independent of the choice of b and satisfies $\varphi s = \mathrm{id}_C$. Finally, in every case the assignment $a + c \mapsto \psi(a) + s(c)$ gives an isomorphism $A \oplus C \xrightarrow{\cong} B$. $\square$

Method (Deciding whether a SES splits)**.** *Trigger.* You have a SES and want to know if $B \cong A \oplus C$, or you must build a splitting. *Recipe.*

1. Try to define a section $s\colon C \to B$ by sending generators of C to chosen preimages *that respect all relations*; if the relations can be honored, s exists and the sequence splits.
2. Equivalently hunt for a retraction $t\colon B \to A$ fixing the copy of A.
3. To prove *non*-splitting, show $B \ncong A \oplus C$ as R-modules (compare torsion, order of elements, number of elements of a given order, etc.).
4. Special automatic case: if C is *projective* (e.g. free), the sequence always splits.

Worked Example 10.5.10 (The classic non-split SES $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$)**.** Problem. Show $0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \to 0$ is exact but does *not* split.

Recognition. A SES of abelian groups; non-splitting is detected by comparing B with $A \oplus C$.

Solution. Exact: $\times 2$ injective, π surjective, $\operatorname{im}(\times 2) = 2\mathbb{Z} = \ker \pi$. Suppose a splitting $s\colon \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}$ existed. Then $s(\bar{1}) \in \mathbb{Z}$ must satisfy $2 \cdot s(\bar{1}) = s(2 \cdot \bar{1}) = s(\bar{0}) = 0$, forcing $s(\bar{1}) = 0$, so $s = 0$ and $\pi s = 0 \neq \mathrm{id}$. No splitting exists. Equivalently $B = \mathbb{Z}$ is torsion-free while $A \oplus C = \mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$ has a nonzero element of order 2, so $\mathbb{Z} \ncong \mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$. *Check.* $|A| \cdot |C|$ as orders matches the index $[\mathbb{Z} : 2\mathbb{Z}] = 2 = |\mathbb{Z}/2\mathbb{Z}|$; the order count passes yet the sequence still fails to split, confirming the order count is not sufficient.

Worked Example 10.5.11 (A split SES of abelian groups)**.** Problem. Show $0 \to \mathbb{Z}/2\mathbb{Z} \xrightarrow{\iota} \mathbb{Z}/6\mathbb{Z} \xrightarrow{\varphi} \mathbb{Z}/3\mathbb{Z} \to 0$ splits, where $\iota(\bar{1}) = \bar{3}$ and φ is reduction mod 3.

Recognition. Build a section sending the generator of $\mathbb{Z}/3\mathbb{Z}$ to a compatible preimage in $\mathbb{Z}/6\mathbb{Z}$.

Solution. Exact: $\iota(\bar{1}) = \bar{3}$ has order 2 in $\mathbb{Z}/6\mathbb{Z}$, injective; $\ker \varphi = \{\bar{0}, \bar{3}\} = \operatorname{im} \iota$; φ surjective. Define $s\colon \mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z}$ by $s(\bar{1}) = \bar{4}$. Check well defined: $3 \cdot \bar{4} = \bar{12} = \bar{0}$ in $\mathbb{Z}/6\mathbb{Z}$, so the relation $3\bar{1} = 0$ is honored. Then $\varphi(s(\bar{1})) = \varphi(\bar{4}) = \bar{1}$, so $\varphi s = \mathrm{id}$. Splits, and indeed $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ by CRT. *Check.* $|\mathbb{Z}/6\mathbb{Z}| = 6 = 2 \cdot 3 = |\mathbb{Z}/2\mathbb{Z}| \cdot |\mathbb{Z}/3\mathbb{Z}|$ and the direct sum decomposition exists. Correct.

Worked Example 10.5.12 (Surjection onto a free module always splits)**.** Problem. Show every SES $0 \to A \to B \xrightarrow{\varphi} R^n \to 0$ of R-modules splits.

Recognition. The right-hand term is free; lift a basis to define a section.

Solution. Let $e_1, \ldots, e_n$ be the standard basis of R^n. Since φ is surjective, pick $b_i \in B$ with $\varphi(b_i) = e_i$. Define $s\colon R^n \to B$ by $s(\sum r_i e_i) = \sum r_i b_i$; this is well defined precisely because R^n is free on the e_i (no relations to honor). Then $\varphi s(e_i) = \varphi(b_i) = e_i$, so $\varphi s = \mathrm{id}_{R^n}$. Splits. *Check.* Consequently $B \cong A \oplus R^n$. Correct.

Worked Example 10.5.13 (A non-split SES of $\mathbb{F}[x]$-modules)**.** Problem. Let $R = \mathbb{F}[x]$ and let $V = R/(x^2)$ with $A = (x)/(x^2) \cong R/(x) = \mathbb{F}$, $C = R/(x) = \mathbb{F}$. Show $0 \to A \to V \to C \to 0$ is non-split.

Recognition. An $\mathbb{F}[x]$-module is a vector space with operator x; non-splitting shows up as a single Jordan block rather than two.

Solution. Here x acts on $V = R/(x^2)$ as the nilpotent operator with $x \cdot \bar{1} = \bar{x} \neq 0$ but $x \cdot \bar{x} = 0$ – a single 2×2 Jordan block for eigenvalue 0. A splitting would give $V \cong A \oplus C$ with x acting as 0 on each summand, i.e. $x \cdot v = 0$ for all v. But $x \cdot \bar{1} = \bar{x} \neq 0$, contradiction. Non-split. *Check.* As $\mathbb{F}$-spaces $\dim V = 2 = \dim A + \dim C$, so the order/dimension count passes while the operator structure forbids splitting. Correct.

Caution. "$|B| = |A| \cdot |C|$, so $B \cong A \oplus C$" is false. The order/dimension count is a *necessary* consequence of a SES but says nothing about splitting: $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ passes the count yet does not split, and $0 \to \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ has $|B| = 4 = 2 \cdot 2$ but $\mathbb{Z}/4\mathbb{Z} \ncong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$.

Projective modules

Definition 10.5.14 (Projective module)**.** An R-module P is *projective* if for every surjection $g\colon B \twoheadrightarrow C$ and every homomorphism $f\colon P \to C$ there is a (not necessarily unique) lift $\tilde{f}\colon P \to B$ with $g \circ \tilde{f} = f$:

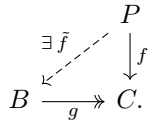


Diagram explanation. Objects: P is the module being tested for projectivity. B and C are R-modules. The diagram encodes a universal lifting problem: can every map out of P be routed through B instead of going directly to C?

Arrows: $g\colon B \twoheadrightarrow C$ is a surjective R-module homomorphism (the twoheads notation). $f\colon P \to C$ is an arbitrary R-homomorphism. The dashed arrow $\tilde{f}\colon P \to B$ is the asserted lift, with $\exists$ indicating it need not be unique.

What commutes: The triangle commutes: $g \circ \tilde{f} = f$. That is, the two paths from P to C agree: going directly via f equals going via $\tilde{f}$ and then g.

Why it commutes: By definition, P is projective precisely when such a $\tilde{f}$ always exists. The surjectivity of g guarantees enough elements in B to hit any $f(p)$; projectivity says a coherent (homomorphism) choice of preimages can always be made.

Why this matters here: This diagram is the definition of projectivity. It asserts that P is "free enough" to lift maps through any surjection, and it is the precise condition that later characterizes free modules and direct summands of free modules, and makes $\mathrm{Hom}_R(P, -)$ exact.

Concrete example: Take $P = \mathbb{Z}$, $g\colon \mathbb{Z} \twoheadrightarrow \mathbb{Z}/5\mathbb{Z}$ (reduction mod 5), $f\colon \mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$ with $f(1) = \bar{3}$. Lift: $\tilde{f}(1) = 3 \in \mathbb{Z}$; then $g(\tilde{f}(1)) = \bar{3} = f(1)$.

Common pitfall: The dashed arrow is not unique in general; the definition asks only for existence. Also the diagram requires g to be surjective: if g is merely an arbitrary homomorphism, the lift need not exist even for free P.

Takeaway: The point of this diagram is that P is projective when every map from P into a quotient can be lifted to a map into the module above it, making P "resolution-proof" against surjections.

Theorem 10.5.15 (Characterizations of projectives)**.** *For an R-module P the following are equivalent:*

1. *P is projective (the lifting property above);*
2. *every SES $0 \to A \to B \to P \to 0$ splits;*
3. *P is a direct summand of a free module: $F \cong P \oplus Q$ for some free F;*
4. *the functor $\mathrm{Hom}_R(P, -)$ is exact (equivalently, it takes surjections to surjections; it is always left exact).*

In particular every free module is projective.

Proof. (1) $\Rightarrow$ (2): In $0 \to A \to B \xrightarrow{g} P \to 0$ apply lifting to $f = \mathrm{id}_P$ and the surjection g; the lift $\tilde{f}\colon P \to B$ satisfies $g\tilde{f} = \mathrm{id}_P$, a splitting. (2) $\Rightarrow$ (3): Every module is a quotient of a free module, so there is a SES $0 \to Q \to F \xrightarrow{p} P \to 0$ with F free. By (2) it splits, so $F \cong P \oplus Q$. (3) $\Rightarrow$ (1): Free modules lift (Worked Ex. "free $\Rightarrow$ projective" below), and a direct summand of a lifter lifts: given $f\colon P \to C$ and $g\colon B \twoheadrightarrow C$, extend f by 0 on Q to get $F = P \oplus Q \to C$, lift that to B since F is free, then restrict to P. (1) $\iff$ (4): $\mathrm{Hom}_R(P, -)$ is always left exact (Thm. 10.5.31); it is exact iff it preserves surjections, which is exactly the lifting property. □

Method (Recognizing / using projectivity)**.** *Trigger.* You must lift a map through a surjection, split a SES whose quotient is P, or certify a module is projective. *Recipe.*

1. If P is free, it is projective – lift by sending a basis to chosen preimages.

2. To show P projective, exhibit a free F with $F \cong P \oplus Q$ (find a complementary summand).

3. Over $\mathbb{Z}/n\mathbb{Z}$ with $n = ab$, $\gcd(a, b) = 1$: $\mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/a\mathbb{Z} \oplus \mathbb{Z}/b\mathbb{Z}$, so each factor is a projective $\mathbb{Z}/n\mathbb{Z}$-module.

4. To *use* projectivity, invoke the lift $\tilde{f}$ or the automatic splitting of $0 \to A \to B \to P \to 0$.

Worked Example 10.5.16 (Free ⇒ projective)**.** Problem. Show every free R-module $F = R^{(A)}$ is projective.

Recognition. Lifting on a free module is determined freely by where the basis goes.

Solution. Let $\{e_a\}_{a \in A}$ be a basis, $g\colon B \twoheadrightarrow C$ surjective, $f\colon F \to C$. For each a pick $b_a \in B$ with $g(b_a) = f(e_a)$ (possible by surjectivity). Define $\tilde{f}\colon F \to B$ on the basis by $\tilde{f}(e_a) = b_a$ and extend R-linearly; this is well defined since F is free. Then $g\tilde{f}(e_a) = g(b_a) = f(e_a)$ for all a, so $g\tilde{f} = f$. *Check.* The diagram commutes on a generating set, hence everywhere. Correct.

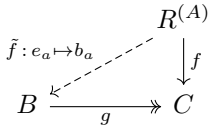

Diagram explanation. Objects: $R^{(A)}$ is the free R-module on index set A with basis $\{e_a\}_{a \in A}$. B and C are arbitrary R-modules. This is the same lifting triangle as in the definition of projective, now specialized to a free module.

Arrows: $f\colon R^{(A)} \to C$ is the map to be lifted. $g\colon B \twoheadrightarrow C$ is a surjection. The dashed $\tilde{f}\colon R^{(A)} \to B$ is the explicit lift constructed by sending $e_a \mapsto b_a$ where $g(b_a) = f(e_a)$.

What commutes: The triangle commutes: $g \circ \tilde{f} = f$. Concretely $g(\tilde{f}(e_a)) = g(b_a) = f(e_a)$ for all $a \in A$, and since $\{e_a\}$ is a basis this forces $g\tilde{f} = f$ everywhere.

Why it commutes: The key is that $R^{(A)}$ is *free*: defining a homomorphism on a free module requires only a choice of images for each basis element with no relations to satisfy. Surjectivity of g supplies the needed b_a, and freeness lets the formula $\tilde{f}(\sum r_a e_a) = \sum r_a b_a$ extend consistently.

Why this matters here: This diagram provides the base case (free ⇒ projective) for the whole theory. All other projectivity proofs either cite this directly or use summand arguments that reduce to it.

Concrete example: $R^{(A)} = \mathbb{Z}$, $g\colon \mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$, $f\colon \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z}$ with $f(1) = \bar{k}$. Pick any $b_1 \in \mathbb{Z}$ with $g(b_1) = \bar{k}$, e.g. $b_1 = k$; then $\tilde{f}(n) = kn$ lifts f.

Common pitfall: The lift $\tilde{f}$ depends on the choice of preimages b_a and is not unique. Students sometimes think the diagram forces a canonical lift; it does not. What freeness guarantees is only that some consistent choice always works.

Takeaway: The point of this diagram is that a free module lifts every map through every surjection because its basis elements can be sent independently to any chosen preimages, with no relations obstructing the construction.

Worked Example 10.5.17 ($\mathbb{Z}/2\mathbb{Z}$ is a projective $\mathbb{Z}/6\mathbb{Z}$-module)**.** Problem. Show $\mathbb{Z}/2\mathbb{Z}$ is projective as a $\mathbb{Z}/6\mathbb{Z}$-module.

Recognition. Direct summand of a free module ⇒ projective; use CRT to split the free module $\mathbb{Z}/6\mathbb{Z}$.

Solution. By the Chinese Remainder Theorem $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ as rings and as $\mathbb{Z}/6\mathbb{Z}$-modules. The free rank-1 module $F = \mathbb{Z}/6\mathbb{Z}$ thus decomposes as $F \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$, exhibiting $\mathbb{Z}/2\mathbb{Z}$ as a direct summand of the free module $\mathbb{Z}/6\mathbb{Z}$. By Thm. 10.5.15(3), $\mathbb{Z}/2\mathbb{Z}$ is projective. *Check.* The complementary summand is $Q = \mathbb{Z}/3\mathbb{Z}$, and $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ has order $6 = |\mathbb{Z}/6\mathbb{Z}|$. Note $\mathbb{Z}/2\mathbb{Z}$ is *not* free over $\mathbb{Z}/6\mathbb{Z}$ (it has 2 elements, not a multiple of 6), so projective $\not\Rightarrow$ free in general. Correct.

Worked Example 10.5.18 ($\mathbb{Z}/2\mathbb{Z}$ is NOT projective over $\mathbb{Z}/4\mathbb{Z}$)**.** Problem. Show $\mathbb{Z}/2\mathbb{Z}$ is not a projective $\mathbb{Z}/4\mathbb{Z}$-module.

Recognition. If projective, the surjection $\mathbb{Z}/4\mathbb{Z} \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$ would split.

Solution. Consider $0 \to \mathbb{Z}/2\mathbb{Z} \xrightarrow{\times 2} \mathbb{Z}/4\mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \to 0$ (with $\times 2\colon \bar{1} \mapsto \bar{2}$). If $\mathbb{Z}/2\mathbb{Z}$ were projective, this SES would split, giving $\mathbb{Z}/4\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$. But $\mathbb{Z}/4\mathbb{Z}$ has an element of order 4 while $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$ has exponent 2. Contradiction. *Check.* Equivalently no section $s\colon \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$ with $\pi s = \mathrm{id}$ exists: $s(\bar{1})$ would need odd value, but $2s(\bar{1}) = s(\bar{2}) = s(\bar{0}) = 0$ forces $s(\bar{1}) \in \{\bar{0}, \bar{2}\}$, both even, contradiction. Correct.

Worked Example 10.5.19 (Lifting a map using projectivity of $\mathbb{Z}$)**.** Problem. Let $g\colon \mathbb{Z} \twoheadrightarrow \mathbb{Z}/5\mathbb{Z}$ be reduction and $f\colon \mathbb{Z} \to \mathbb{Z}/5\mathbb{Z}$ be $f(1) = \bar{3}$. Lift f through g.

Recognition. $\mathbb{Z}$ is free, hence projective; lift by choosing one preimage of f of a generator.

Solution. Choose $b \in \mathbb{Z}$ with $g(b) = \bar{3}$, e.g. $b = 3$. Define $\tilde{f}\colon \mathbb{Z} \to \mathbb{Z}$ by $\tilde{f}(1) = 3$, i.e. $\tilde{f}(n) = 3n$. Then $g\tilde{f}(1) = g(3) = \bar{3} = f(1)$, so $g\tilde{f} = f$. *Check.* Any $b \in 3 + 5\mathbb{Z}$ also works (lifts are non-unique), confirming the lift need not be unique. Correct.

Worked Example 10.5.20 (Direct sum of projectives is projective)**.** Problem. Show $P_1 \oplus P_2$ is projective whenever P_1, P_2 are.

Recognition. Lift on each summand separately and combine; or use that a summand-of-free plus summand-of-free is a summand of free.

Solution. Given $g\colon B \twoheadrightarrow C$ and $f\colon P_1 \oplus P_2 \to C$, restrict to $f_i = f|_{P_i}$. Lift each to $\tilde{f}_i\colon P_i \to B$ with $g\tilde{f}_i = f_i$. Define $\tilde{f}(p_1, p_2) = \tilde{f}_1(p_1) + \tilde{f}_2(p_2)$. Then $g\tilde{f}(p_1, p_2) = g\tilde{f}_1(p_1) + g\tilde{f}_2(p_2) = f_1(p_1) + f_2(p_2) = f(p_1, p_2)$. *Check.* If $F_i \cong P_i \oplus Q_i$ are free then $F_1 \oplus F_2$ is free and $\cong (P_1 \oplus P_2) \oplus (Q_1 \oplus Q_2)$, re-deriving projectivity via Thm. 10.5.15(3). Correct.

Injective modules

Definition 10.5.21 (Injective module)**.** An R-module Q is *injective* if for every injection $\iota\colon A \hookrightarrow B$ and every homomorphism $f\colon A \to Q$ there is an extension $\tilde{f}\colon B \to Q$ with $\tilde{f} \circ \iota = f$:

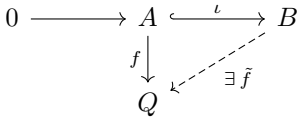

Diagram explanation. Objects: A and B are R-modules with A a submodule of B (witnessed by ι). Q is the module being tested for injectivity. The 0 at the left signals that ι is injective (the sequence $0 \to A \to B$ is exact at A).

Arrows: $\iota\colon A \hookrightarrow B$ is an injection. $f\colon A \to Q$ is an arbitrary R-homomorphism from the submodule. The dashed $\tilde{f}\colon B \to Q$ is the asserted extension of f past the inclusion, with $\exists$ indicating it need not be unique.

What commutes: The triangle commutes: $\tilde{f} \circ \iota = f$. That is, the two paths from A to Q agree: the direct map f equals the composition $\tilde{f}$ followed back along ι, i.e. $\tilde{f}$ restricted to A is f.

Why it commutes: Q is injective precisely when such a $\tilde{f}$ always exists. This is the dual of projectivity: instead of lifting through a surjection on the output side, we extend along an injection on the input side. Divisibility over $\mathbb{Z}$ supplies the solutions needed to make the extension a homomorphism.

Why this matters here: This diagram is the definition of injectivity. It is the categorical dual of the projective lifting diagram, and it encodes the precise condition that makes $\mathrm{Hom}_R(-, Q)$ exact: every map into Q from a submodule extends to the whole ambient module.

Concrete example: $A = 2\mathbb{Z} \subset B = \mathbb{Z}$, $f\colon 2\mathbb{Z} \to \mathbb{Q}$ with $f(2) = 3$. Since $\mathbb{Q}$ is divisible, extend: $\tilde{f}(1) = 3/2$ and $\tilde{f}(n) = 3n/2$; then $\tilde{f}(2) = 3 = f(2)$.

Common pitfall: Students confuse the direction of duality: in the projective diagram P maps *into* a surjection; in the injective diagram Q is the *target* and the extension goes *from B to Q*. The arrows run opposite to each other.

Takeaway: The point of this diagram is that Q is injective when any map into Q defined on a submodule can always be extended to the entire ambient module, making Q "absorption-proof" against injections.

This is the arrow-reversal (dual) of projectivity: projectives lift through surjections on the source side; injectives extend along injections into the target side.

Theorem 10.5.22 (Characterizations of injectives)**.** *For an R-module Q the following are equivalent:*

1. *Q is injective (the extension property above);*
2. *every SES $0 \to Q \to B \to C \to 0$ splits;*
3. *the functor $\mathrm{Hom}_R(-, Q)$ is exact (it is always left exact; injectivity is the extra statement that it sends injections to surjections of* Hom*).*

Proof sketch. (1) $\Rightarrow$ (2): extend id_Q along $Q \hookrightarrow B$ to get a retraction $B \to Q$, which splits the sequence (Prop. 10.5.9). (2) $\Rightarrow$ (1) and the link to exactness of $\mathrm{Hom}_R(-, Q)$ follow from the long-exactness machinery; $\mathrm{Hom}_R(-, Q)$ is always left exact (Thm. 10.5.31), and injectivity is exactly the statement that it carries injections $A \hookrightarrow B$ to surjections $\mathrm{Hom}_R(B, Q) \twoheadrightarrow \mathrm{Hom}_R(A, Q)$, i.e. every $f\colon A \to Q$ extends to B. □

Theorem 10.5.23 (Baer's Criterion)**.** *An R-module Q is injective if and only if for every left ideal $I \subseteq R$, every R-homomorphism $g\colon I \to Q$ extends to an R-homomorphism $\tilde{g}\colon R \to Q$.*

Proof sketch. ($\Rightarrow$) is the extension property applied to $I \hookrightarrow R$. ($\Leftarrow$) Given $f\colon A \to Q$ with $A \subseteq B$, use Zorn's Lemma on the poset of partial extensions (A', f') with $A \subseteq A' \subseteq B$ and $f'|_A = f$. A maximal element (A^*, f^*) must have $A^* = B$: if some $b \in B \smallsetminus A^*$, the set $I = \{r \in R : rb \in A^*\}$ is a left ideal, $r \mapsto f^*(rb)$ defines $g\colon I \to Q$, and the hypothesis extends g to R, which lets us extend f^* to $A^* + Rb$, contradicting maximality. Hence $f^*\colon B \to Q$ extends f. □

Definition 10.5.24 (Divisible module)**.** An abelian group (i.e. $\mathbb{Z}$-module) D is *divisible* if for every $d \in D$ and every nonzero $n \in \mathbb{Z}$ there exists $d' \in D$ with $nd' = d$.

Corollary 10.5.25. *A $\mathbb{Z}$-module is injective if and only if it is divisible. In particular $\mathbb{Q}$, $\mathbb{Q}/\mathbb{Z}$, and $\mathbb{R}/\mathbb{Z}$ are injective $\mathbb{Z}$-modules, while $\mathbb{Z}$ and $\mathbb{Z}/n\mathbb{Z}$ ($n \geq 2$) are not.*

Proof. By Baer's Criterion over $R = \mathbb{Z}$ it suffices to extend maps from ideals $I = n\mathbb{Z}$ to $\mathbb{Z}$. A map $g\colon n\mathbb{Z} \to D$ is determined by $g(n) = d \in D$; an extension $\tilde{g}\colon \mathbb{Z} \to D$ exists iff there is $d' = \tilde{g}(1)$ with $nd' = g(n) = d$, i.e. iff D is divisible. □

Method (Showing a module is (not) injective)**.** *Trigger.* Certify injectivity, or extend a map past an inclusion. *Recipe.*

1. Over $\mathbb{Z}$: injective $\iff$ divisible – check $nd' = d$ solvable for all $n \neq 0$, d.
2. General ring: use **Baer** – only need to extend maps $I \to Q$ from ideals I to R.
3. To extend a concrete $f\colon A \to Q$, push along $A \hookrightarrow B$ by choosing images of new generators consistently (divisibility supplies the needed solutions).
4. To prove *not* injective, exhibit an inclusion $A \hookrightarrow B$ and $f\colon A \to Q$ admitting no extension (often a torsion/divisibility obstruction).

Worked Example 10.5.26 ($\mathbb{Q}/\mathbb{Z}$ is injective (divisible))**.** Problem. Show $\mathbb{Q}/\mathbb{Z}$ is an injective $\mathbb{Z}$-module.

Recognition. Over $\mathbb{Z}$, injective = divisible; verify n-divisibility of every coset.

Solution. Take $\bar{a} = a + \mathbb{Z} \in \mathbb{Q}/\mathbb{Z}$ with $a \in \mathbb{Q}$, and $n \geq 1$. Set $\bar{a}' = (a/n) + \mathbb{Z}$. Then $n\bar{a}' = (n \cdot a/n) + \mathbb{Z} = a + \mathbb{Z} = \bar{a}$. So every element is n-divisible; $\mathbb{Q}/\mathbb{Z}$ is divisible, hence injective by Cor. 10.5.25. *Check.* Concretely $2 \cdot (\frac{1}{4} + \mathbb{Z}) = \frac{1}{2} + \mathbb{Z}$ and $3 \cdot (\frac{1}{12} + \mathbb{Z}) = \frac{1}{4} + \mathbb{Z}$, illustrating solvability. Correct.

Worked Example 10.5.27 ($\mathbb{Q}$ is injective; extend a map)**.** Problem. Let $f\colon 2\mathbb{Z} \to \mathbb{Q}$ be $f(2) = 3$. Extend f to $\mathbb{Z} \to \mathbb{Q}$ (witnessing injectivity of $\mathbb{Q}$).

Recognition. $\mathbb{Q}$ is divisible, so by Baer extend from the ideal $2\mathbb{Z}$ to $\mathbb{Z}$.

Solution. f is determined by $f(2) = 3$. An extension $\tilde{f}\colon \mathbb{Z} \to \mathbb{Q}$ needs $\tilde{f}(1) = q$ with $2q = f(2) = 3$, so $q = \frac{3}{2}$. Define $\tilde{f}(n) = \frac{3}{2}n$. Then $\tilde{f}(2) = 3 = f(2)$ and $\tilde{f}|_{2\mathbb{Z}} = f$. *Check.* $\tilde{f}(4) = 6 = 2f(2) = 2 \cdot 3$, agrees with $f(4) = 6$. Correct.

Worked Example 10.5.28 ($\mathbb{Z}$ is NOT injective)**.** Problem. Show $\mathbb{Z}$ is not an injective $\mathbb{Z}$-module.

Recognition. Injective over $\mathbb{Z}$ means divisible; $\mathbb{Z}$ is not divisible.

Solution. $\mathbb{Z}$ is not divisible: $1 \in \mathbb{Z}$ is not divisible by 2 (no integer m with $2m = 1$). Concretely take $\mathrm{id}\colon \mathbb{Z} \to \mathbb{Z}$ and the inclusion $\mathbb{Z} \xrightarrow{\times 2} \mathbb{Z}$; an extension $\tilde{f}\colon \mathbb{Z} \to \mathbb{Z}$ of id along $\times 2$ would need $\tilde{f}(\times 2 \cdot 1) = \tilde{f}(2)$ to equal $\mathrm{id}(1) = 1$, i.e. $2\tilde{f}(1) = 1$, impossible in $\mathbb{Z}$. So no extension; $\mathbb{Z}$ is not injective. *Check.* Consistent with Cor. 10.5.25, since $\mathbb{Z}$ is non-divisible. Correct.

Worked Example 10.5.29 ($\mathbb{Z}/n\mathbb{Z}$ is not injective over $\mathbb{Z}$)**.** Problem. Show $\mathbb{Z}/4\mathbb{Z}$ is not an injective $\mathbb{Z}$-module.

Recognition. Finite nonzero groups are never divisible.

Solution. If $\mathbb{Z}/4\mathbb{Z}$ were divisible, then for $\bar{1}$ and $n = 4$ there would be $\bar{x}$ with $4\bar{x} = \bar{1}$. But $4\bar{x} = \bar{0}$ for every $\bar{x} \in \mathbb{Z}/4\mathbb{Z}$, so $\bar{0} = \bar{1}$ is forced, false. Not divisible, hence not injective. *Check.* Any finite group G with $|G| = m > 1$ fails m-divisibility, so no nonzero finite abelian group is injective over $\mathbb{Z}$. Correct.

Worked Example 10.5.30 (A direct product of injectives is injective)**.** Problem. Show $\prod_i Q_i$ is injective if each Q_i is.

Recognition. Extension into a product is extension coordinatewise.

Solution. Given $\iota\colon A \hookrightarrow B$ and $f\colon A \to \prod_i Q_i$, write $f = (f_i)$ with $f_i = \pi_i \circ f\colon A \to Q_i$. Each f_i extends to $\tilde{f}_i\colon B \to Q_i$ by injectivity of Q_i. Set $\tilde{f} = (\tilde{f}_i)\colon B \to \prod_i Q_i$. Then $\pi_i \tilde{f} \iota = \tilde{f}_i \iota = f_i = \pi_i f$ for all i, so $\tilde{f}\iota = f$. *Check.* The universal property of the product makes the coordinatewise map a genuine homomorphism. Correct.

Caution. Injectivity is *not* the same as "f is injective." An injective module is a target Q with the extension property; it has nothing to do with any one map being one-to-one. Likewise "divisible $\Rightarrow$ injective" is a theorem *only over special rings* ($\mathbb{Z}$, PIDs, and more generally Dedekind domains); over a general ring use Baer's Criterion.

Hom is left exact; tensor is right exact

Theorem 10.5.31 (Left exactness of Hom)**.** *Let $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ be a SES of R-modules and D any R-module. Then the induced sequences*

$$0 \longrightarrow \mathrm{Hom}_R(D, A) \xrightarrow{\psi_*} \mathrm{Hom}_R(D, B) \xrightarrow{\varphi_*} \mathrm{Hom}_R(D, C)$$

Diagram explanation. Objects: Each node is a Hom-set: $\mathrm{Hom}_R(D, A)$ is the abelian group of all R-module homomorphisms from D to A, and similarly for B and C. The fixed module D is the source; applying $\mathrm{Hom}_R(D, -)$ to the SES $0 \to A \to B \to C \to 0$ produces this three-term sequence.

Arrows: $\psi_*\colon \mathrm{Hom}_R(D, A) \to \mathrm{Hom}_R(D, B)$ is post-composition with ψ: $\psi_*(h) = \psi \circ h$. $\varphi_*\colon \mathrm{Hom}_R(D, B) \to \mathrm{Hom}_R(D, C)$ is post-composition with φ: $\varphi_*(h) = \varphi \circ h$. The leading 0 forces ψ_* to be injective.

What commutes: Exactness holds at $\mathrm{Hom}_R(D, A)$: ψ_* is injective (if $\psi h = 0$ then $h = 0$ since ψ is mono). Exactness at $\mathrm{Hom}_R(D, B)$: $\mathrm{im}\,\psi_* = \ker \varphi_*$, i.e. a map $h\colon D \to B$ satisfies $\varphi(h(d)) = 0$ for all d iff h factors through ψ.

Why it commutes: For $\ker \varphi_* \subseteq \mathrm{im}\,\psi_*$: if $\varphi \circ h = 0$ then $\mathrm{im}\, h \subseteq \ker \varphi = \mathrm{im}\,\psi$, so h factors as $h = \psi \circ h'$ for a unique $h'\colon D \to A$ (injectivity of ψ makes h' unique). The right end need not be exact: a map $D \to C$ need not lift to $D \to B$ unless D is projective.

Why this matters here: This is the covariant left-exactness theorem, the foundational algebraic fact that $\mathrm{Hom}_R(D, -)$ does not destroy exactness at the left, but the right end may fail. The extent of that failure is measured by Ext^1.

Concrete example: Take $0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ and $D = \mathbb{Z}/2\mathbb{Z}$. Then $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}) = 0$ (no nonzero map), $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}) = 0$, $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/2\mathbb{Z}) = \mathbb{Z}/2\mathbb{Z}$. The right arrow cannot be surjective since there is no lift $\mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}$.

Common pitfall: Students forget the sequence is only three terms long and not right-exact. Writing $0 \to \mathrm{Hom}(D,A) \to \mathrm{Hom}(D,B) \to \mathrm{Hom}(D,C) \to 0$ is wrong in general; the terminal 0 requires D projective.

Takeaway: The point of this diagram is that applying $\mathrm{Hom}_R(D,-)$ to a SES preserves the left two exactness conditions but can fail to be surjective at the right, with projectivity of D being exactly the condition that restores full exactness.

$$0 \longrightarrow \mathrm{Hom}_R(C,D) \xhookrightarrow{\varphi^*} \mathrm{Hom}_R(B,D) \xrightarrow{\psi^*} \mathrm{Hom}_R(A,D)$$

Diagram explanation. Objects: Each node is again a Hom-set, but now the fixed module D is the *target* and the source varies. $\mathrm{Hom}_R(C,D)$, $\mathrm{Hom}_R(B,D)$, $\mathrm{Hom}_R(A,D)$ are abelian groups. Applying the contravariant $\mathrm{Hom}_R(-,D)$ reverses the order of the original $A \to B \to C$.

Arrows: $\varphi^*\colon \mathrm{Hom}_R(C,D) \to \mathrm{Hom}_R(B,D)$ is pre-composition with φ: $\varphi^*(h) = h \circ \varphi$. $\psi^*\colon \mathrm{Hom}_R(B,D) \to \mathrm{Hom}_R(A,D)$ is pre-composition with ψ: $\psi^*(h) = h \circ \psi$. Note the arrows in the Hom sequence run *opposite* to the original SES.

What commutes: Exactness at $\mathrm{Hom}_R(C,D)$: φ^* is injective (if $h \circ \varphi = 0$ and φ is surjective then $h = 0$). Exactness at $\mathrm{Hom}_R(B,D)$: $\operatorname{im}\varphi^* = \ker\psi^*$, since $h \circ \psi = 0$ iff h kills $\operatorname{im}\psi = \ker\varphi$, iff h factors through $C = B/\ker\varphi$.

Why it commutes: For $\ker\psi^* \subseteq \operatorname{im}\varphi^*$: if $h \circ \psi = 0$ then $\ker\varphi = \operatorname{im}\psi \subseteq \ker h$, so h factors through $B/\operatorname{im}\psi \cong C$ via the map induced by φ, i.e. $h = h' \circ \varphi = \varphi^*(h')$. The right end need not be surjective unless D is injective.

Why this matters here: This is the contravariant left-exactness result, the dual partner of the covariant sequence above. Together they establish that both Hom functors are left exact but generally not right exact, with the two possible failures governed by injectivity (contravariant) and projectivity (covariant).

Concrete example: Take $0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ and $D = \mathbb{Z}$. Then $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z},\mathbb{Z}) = 0$, $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z},\mathbb{Z}) = \mathbb{Z}$, and $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z},\mathbb{Z}) = \mathbb{Z}$. The map ψ^* is $\times 2\colon \mathbb{Z} \to \mathbb{Z}$, which is not surjective (the identity $\mathrm{id}\colon \mathbb{Z} \to \mathbb{Z}$ has no preimage), showing the right end can fail.

Common pitfall: Contravariance flips the arrows: the sequence runs $C \to B \to A$ in the Hom-sequence even though the original ran $A \to B \to C$. Students sometimes write the Hom sequence in the same order as the original, which is wrong.

Takeaway: The point of this diagram is that the contravariant functor $\mathrm{Hom}_R(-,D)$ reverses the direction of maps and is left-exact, with the failure at the right end measuring the obstruction to extending maps into D – cured precisely when D is injective.

are exact, where $\psi_*(h) = \psi h$, $\varphi^*(h) = h\varphi$, etc. The covariant $\mathrm{Hom}_R(D,-)$ becomes exact (the final arrow surjective) iff D is projective; the contravariant $\mathrm{Hom}_R(-,D)$ becomes exact iff D is injective.

Proof sketch. For the covariant case: ψ_* injective since $\psi h = 0 \Rightarrow h = 0$ as ψ is mono; $\ker\varphi_* = \operatorname{im}\psi_*$ because $\varphi h = 0 \iff \operatorname{im} h \subseteq \ker\varphi = \operatorname{im}\psi \iff h$ factors through ψ. The last map φ_* need not be surjective: a map $D \to C$ need not lift to $D \to B$ unless D is projective. The contravariant case is dual, with non-surjectivity of ψ^* measuring failure of extending $A \to D$ to $B \to D$, repaired exactly when D is injective. □

Theorem 10.5.32 (Right exactness of $\otimes$)**.** *Let $A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ be exact (right exact) and M a right R-module. Then*

$$M \otimes_R A \xrightarrow{1\otimes\psi} M \otimes_R B \xrightarrow{1\otimes\varphi} M \otimes_R C \longrightarrow 0$$

Diagram explanation. Objects: $M \otimes_R A$, $M \otimes_R B$, $M \otimes_R C$ are tensor products of the right R-module M with left R-modules A, B, C respectively. The terminal 0 signals right-exactness: the last map is surjective.

Arrows: $1\otimes\psi\colon M\otimes_R A \to M\otimes_R B$ is the map induced on simple tensors by $m\otimes a \mapsto m\otimes\psi(a)$. $1\otimes\varphi\colon M\otimes_R B \to M \otimes_R C$ is $m \otimes b \mapsto m \otimes \varphi(b)$. The trailing 0 says $1 \otimes \varphi$ is surjective.

What commutes: Three exactness conditions: (i) $1 \otimes \varphi$ is surjective (exactness at $M \otimes_R C$); (ii) $\mathrm{im}(1 \otimes \psi) \subseteq \ker(1 \otimes \varphi)$ since $\varphi \circ \psi = 0$; (iii) $\ker(1 \otimes \varphi) = \mathrm{im}(1 \otimes \psi)$ (exactness at $M \otimes_R B$). The left map $1 \otimes \psi$ need *not* be injective.

Why it commutes: Surjectivity of $1 \otimes \varphi$: every simple tensor $m \otimes c$ with $c = \varphi(b)$ equals $(1 \otimes \varphi)(m \otimes b)$. For exactness at $M \otimes_R B$: the identification $M \otimes_R C \cong (M \otimes_R B)/\operatorname{im}(1 \otimes \psi)$ follows from the universal property of the tensor product applied to the composite $M \times C \to M \otimes_R B/\operatorname{im}(1 \otimes \psi)$.

Why this matters here: This theorem draws the dividing line between flat and non-flat modules. Right-exactness is free; left-exactness (injectivity of $1 \otimes \psi$) is the flatness condition on M. The diagram organizes what tensor always preserves versus what it can destroy.

Concrete example: Take $M = \mathbb{Z}/2\mathbb{Z}$, $A \xrightarrow{\times 2} B = \mathbb{Z}$ (injective). Then $1 \otimes (\times 2)\colon \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ sends $\bar{a} \mapsto \overline{2a} = \bar{0}$, the zero map; left-exactness fails. But the surjection $\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ is preserved: $\mathbb{Z}/2\mathbb{Z} \otimes \mathbb{Z}/2\mathbb{Z} \to 0$ remains exact.

Common pitfall: Students assume tensor preserves injectivity as well as surjectivity, writing $0 \to M \otimes A \to M \otimes B \to \cdots$ without checking flatness. The left 0 is wrong unless M is flat.

Takeaway: The point of this diagram is that tensoring with M always preserves the right end of an exact sequence (surjections become surjections) but can destroy the left end (injections may become non-injective), with flatness of M being the exact condition that restores full exactness.

is exact. The functor $M \otimes_R -$ is in general not *left exact: $1 \otimes \psi$ need not be injective even when ψ is. M is called* flat *when $M \otimes_R -$ also preserves injections (equivalently, is exact).*

Proof sketch. Surjectivity of $1 \otimes \varphi$: simple tensors $m \otimes c$ with $c = \varphi(b)$ generate the target and equal $(1 \otimes \varphi)(m \otimes b)$. The inclusion $\operatorname{im}(1 \otimes \psi) \subseteq \ker(1 \otimes \varphi)$ holds since $\varphi\psi = 0$. For the reverse, one checks $M \otimes_R C \cong (M \otimes_R B)/\operatorname{im}(1 \otimes \psi)$ by building the inverse map out of the universal property of the tensor product; this identifies $\ker(1 \otimes \varphi)$ with $\operatorname{im}(1 \otimes \psi)$. The left end can fail: see the worked example over $\mathbb{Z}$ with $M = \mathbb{Z}/2\mathbb{Z}$. □

Flat modules

Definition 10.5.33 (Flat module)**.** A right R-module M is *flat* if the functor $M \otimes_R -$ preserves injections: for every injection $\iota\colon A \hookrightarrow B$ of left R-modules, $1 \otimes \iota\colon M \otimes_R A \to M \otimes_R B$ is injective. Equivalently (with right exactness), $M \otimes_R -$ is exact.

Proposition 10.5.34. *Free modules are flat; more generally projective modules are flat; and a direct sum $\bigoplus_i M_i$ is flat iff each M_i is flat. Over $\mathbb{Z}$, a module is flat iff it is torsion-free.*

Proof sketch. R itself is flat since $R \otimes_R - \cong \mathrm{id}$. Tensor commutes with direct sums, so free and (by summand) projective modules are flat, and flatness passes to/from direct summands and sums. Over a PID, torsion-free $\iff$ flat by a direct limit / finitely generated submodule argument. □

Method (Detecting flatness / failure of left-exactness)**.** *Trigger.* You tensor an injection and ask if it stays injective, or must certify a module flat. *Recipe.*

1. Free or projective ⇒ flat (safe default).
2. Over $\mathbb{Z}$ (or a PID): flat $\iff$ torsion-free. So $\mathbb{Q}, \mathbb{Z}, \mathbb{Z}^n$ are flat; $\mathbb{Z}/n\mathbb{Z}$ ($n \geq 2$) is not.
3. To show non-flatness, tensor the injection $\mathbb{Z} \xrightarrow{\times n} \mathbb{Z}$ with the module and find a nonzero kernel.
4. Right-exactness always holds: only the left end ($1 \otimes \psi$ injective) is at stake.

Worked Example 10.5.35 ($\mathbb{Z}/2\mathbb{Z}$ is not flat: $\times 2$ becomes zero)**.** Problem. Tensor the injection $\mathbb{Z} \xrightarrow{\times 2} \mathbb{Z}$ with $\mathbb{Z}/2\mathbb{Z}$ and show injectivity is lost.

Recognition. Tensoring with a torsion module can kill an injection – compute the induced map on simple tensors.

Solution. The map $1 \otimes (\times 2)\colon \mathbb{Z}/2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}$ sends $\bar{a} \otimes n \mapsto \bar{a} \otimes 2n$. Using $\mathbb{Z}/2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z}$ (via $\bar{a} \otimes n \mapsto \overline{an}$), the map becomes $\bar{a} \mapsto \overline{2a} = \bar{0}$ in $\mathbb{Z}/2\mathbb{Z}$. So $1 \otimes (\times 2) = 0$ is the zero map, hence *not* injective although $\times 2$ is. Therefore $\mathbb{Z}/2\mathbb{Z}$ is not flat. *Check.* Consistent with Prop. 10.5.34: $\mathbb{Z}/2\mathbb{Z}$ has torsion (every element killed by 2). Correct.

Worked Example 10.5.36 ($\mathbb{Q}$ is flat over $\mathbb{Z}$ (torsion-free) and restores exactness)**.** Problem. Tensor $0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ with $\mathbb{Q}$ and identify the result.

Recognition. $\mathbb{Q}$ is torsion-free over $\mathbb{Z}$, hence flat; tensoring should keep the left injection injective.

Solution. Using $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z} \cong \mathbb{Q}$ and $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} \cong 0$ (since $q \otimes \bar{a} = \frac{q}{2} \cdot 2 \otimes \bar{a} = \frac{q}{2} \otimes 2\bar{a} = \frac{q}{2} \otimes \bar{0} = 0$), the sequence becomes

$$0 \longrightarrow \mathbb{Q} \xrightarrow[\cong]{\times 2} \mathbb{Q} \longrightarrow 0 \longrightarrow 0.$$

Diagram explanation. Objects: The four nodes after the initial 0 arise from tensoring $0 \to \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ with $\mathbb{Q}$. The left two nodes are $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z} \cong \mathbb{Q}$; the third is $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} = 0$; the final 0 is $\mathbb{Q} \otimes_{\mathbb{Z}} 0 = 0$.

Arrows: The map $\times 2 \colon \mathbb{Q} \to \mathbb{Q}$ is $1 \otimes (\times 2)$, i.e. $q \mapsto 2q$. The subsequent arrow $\mathbb{Q} \to 0$ is the zero map. The initial $0 \to \mathbb{Q}$ says the left map is injective.

What commutes: The sequence is exact at all spots: $0 \to \mathbb{Q} \xrightarrow{\times 2} \mathbb{Q} \to 0 \to 0$. Exactness at the left $\mathbb{Q}$: $\times 2$ is injective (kernel is $\{q \in \mathbb{Q} : 2q = 0\} = 0$). Exactness at the right $\mathbb{Q}$: $\times 2$ is surjective (bijection on $\mathbb{Q}$). The middle term 0 causes no issue.

Why it commutes: Flatness of $\mathbb{Q}$ over $\mathbb{Z}$ (it is torsion-free, hence flat by the PID criterion) means $1 \otimes (\times 2)$ inherits the injectivity of $\times 2 \colon \mathbb{Z} \to \mathbb{Z}$. The collapse $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} = 0$ occurs because $q \otimes \bar{a} = \frac{q}{2} \otimes 2\bar{a} = \frac{q}{2} \otimes \bar{0} = 0$ for all $q, \bar{a}$.

Why this matters here: This diagram is the worked demonstration of flatness at work: tensoring the non-split SES with a flat module produces a fully exact (even split) sequence where the torsion term has been annihilated. It contrasts sharply with the $\mathbb{Z}/2\mathbb{Z}$ computation that precedes it.

Concrete example: This diagram *is* the concrete example, but note the phenomenon more sharply: $\times 2 \colon \mathbb{Q} \to \mathbb{Q}$ has the inverse $\times \frac{1}{2}$, so the tensored sequence is not merely exact but actually has $\times 2$ as an isomorphism, making the sequence split.

Common pitfall: Students may think that when the right-hand term becomes 0 after tensoring, something went wrong. In fact $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} = 0$ is correct and expected: $\mathbb{Q}$ is divisible, and any torsion module tensored with $\mathbb{Q}$ collapses to zero.

Takeaway: The point of this diagram is that tensoring a SES with a flat module such as $\mathbb{Q}$ preserves full exactness, here visibly converting the original non-split sequence into a fully exact sequence with the torsion term annihilated.

Here $\times 2 \colon \mathbb{Q} \to \mathbb{Q}$ is a bijection (invert by $\times \frac{1}{2}$), so the sequence is exact at every spot. Flatness of $\mathbb{Q}$ kept the left map injective, and indeed exact. *Check.* $\mathbb{Q} \otimes \mathbb{Z}/2\mathbb{Z} = 0$ matches $\mathbb{Q}$ being divisible (multiplication by 2 surjective), so the cokernel collapses; consistent. Correct.

Worked Example 10.5.37 ($\mathbb{Z}^n$ is flat)**.** Problem. Show $\mathbb{Z}^3$ is a flat $\mathbb{Z}$-module.

Recognition. Free $\Rightarrow$ flat; tensoring with a free module is taking direct sums of copies.

Solution. For any injection $\iota \colon A \hookrightarrow B$, $\mathbb{Z}^3 \otimes_{\mathbb{Z}} A \cong A^3$ and $\mathbb{Z}^3 \otimes_{\mathbb{Z}} B \cong B^3$, with $1 \otimes \iota$ becoming $\iota^3 = (\iota, \iota, \iota)$, which is injective since each coordinate ι is. So $\mathbb{Z}^3$ is flat. *Check.* $\mathbb{Z}^3$ is torsion-free, matching the PID criterion. Correct.

Worked Example 10.5.38 (Tensoring computes $\mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/\gcd(m,n)\mathbb{Z}$)**.** Problem. Compute $\mathbb{Z}/6\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/4\mathbb{Z}$ and use it to see non-flatness in action.

Recognition. Right-exactness of tensor: present $\mathbb{Z}/4\mathbb{Z}$ as $\mathbb{Z} \xrightarrow{\times 4} \mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \to 0$ and tensor.

Solution. Tensoring the presentation with $\mathbb{Z}/6\mathbb{Z}$ gives, by right exactness, $\mathbb{Z}/6\mathbb{Z} \xrightarrow{\times 4} \mathbb{Z}/6\mathbb{Z} \to \mathbb{Z}/6\mathbb{Z} \otimes \mathbb{Z}/4\mathbb{Z} \to 0$, so $\mathbb{Z}/6\mathbb{Z} \otimes \mathbb{Z}/4\mathbb{Z} \cong \mathbb{Z}/6\mathbb{Z}/4\mathbb{Z}/6\mathbb{Z}$. In $\mathbb{Z}/6\mathbb{Z}$, $4\mathbb{Z}/6\mathbb{Z} = \{\bar{0}, \bar{4}, \bar{2}\} = 2\mathbb{Z}/6\mathbb{Z}$ has order 3, so $\mathbb{Z}/6\mathbb{Z}/4\mathbb{Z}/6\mathbb{Z}$ has order 2, i.e. $\cong \mathbb{Z}/2\mathbb{Z}$. Since $\gcd(6,4) = 2$, this matches $\mathbb{Z}/\gcd(6,4)\mathbb{Z} = \mathbb{Z}/2\mathbb{Z}$. *Check.* The formula $\mathbb{Z}/m\mathbb{Z} \otimes \mathbb{Z}/n\mathbb{Z} \cong \mathbb{Z}/\gcd(m,n)\mathbb{Z}$ gives $\mathbb{Z}/2\mathbb{Z}$, agreeing. The very fact that tensoring with $\mathbb{Z}/6\mathbb{Z}$ turned the injection $\times 4$ into a non-injection on a torsion quotient again shows $\mathbb{Z}/6\mathbb{Z}$ is not flat ($\mathbb{Z}/4\mathbb{Z}$ is not flat either, by the torsion criterion of Prop. 10.5.34). Correct.

Worked Example 10.5.39 (Failure then repair of left-exactness)**.** Problem. Contrast tensoring $0 \to \mathbb{Z} \xrightarrow{\times 3} \mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \to 0$ with $M = \mathbb{Z}/3\mathbb{Z}$ versus $M = \mathbb{Q}$.

Recognition. Same SES, two coefficient modules: torsion $\mathbb{Z}/3\mathbb{Z}$ breaks injectivity, flat $\mathbb{Q}$ preserves it.

Solution. With $M = \mathbb{Z}/3\mathbb{Z}$: $1 \otimes (\times 3)\colon \mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z}$ is $\bar{a} \mapsto \overline{3a} = \bar{0}$, the zero map – not injective, so left-exactness fails; the full tensored sequence $\mathbb{Z}/3\mathbb{Z} \xrightarrow{0} \mathbb{Z}/3\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \otimes \mathbb{Z}/3\mathbb{Z} \to 0$ has $\mathbb{Z}/3\mathbb{Z} \otimes \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/3\mathbb{Z}$. With $M = \mathbb{Q}$: $1 \otimes (\times 3)\colon \mathbb{Q} \to \mathbb{Q}$ is multiplication by 3, a bijection, so the left map stays injective; and $\mathbb{Q} \otimes \mathbb{Z}/3\mathbb{Z} = 0$, yielding the exact $0 \to \mathbb{Q} \xrightarrow{\times 3} \mathbb{Q} \to 0$. *Check.* $\mathbb{Z}/3\mathbb{Z}$ has torsion (non-flat), $\mathbb{Q}$ is torsion-free (flat), exactly predicting the two behaviors. Correct.

Caution. Tensoring is only *right* exact: $1 \otimes \psi$ may fail to be injective even when ψ is. Do not assume $M \otimes_R (-)$ preserves submodules – e.g. $\mathbb{Z} \subset \mathbb{Z}$ via $\times 2$ tensored with $\mathbb{Z}/2\mathbb{Z}$ collapses to the zero map. The fix is exactly flatness of M. Dually, Hom is only *left* exact, with the right-hand surjectivity governed by projectivity (covariant slot) or injectivity (contravariant slot).

Remark 10.5.2 (The three dictionaries)*.* Projective, injective, flat are the modules that "correct" the one-sided exactness of the three basic functors:

$$P \text{ projective} \longleftrightarrow \mathrm{Hom}_R(P, -) \text{ exact}$$

$$Q \text{ injective} \longleftrightarrow \mathrm{Hom}_R(-, Q) \text{ exact}$$

$$M \text{ flat} \longleftrightarrow M \otimes_R - \text{ exact}$$

Diagram explanation. Objects: The left column lists module-theoretic properties: P projective, Q injective, M flat. The right column lists the corresponding functor-exactness properties for $\mathrm{Hom}_R(P, -)$, $\mathrm{Hom}_R(-, Q)$, and $M \otimes_R -$, each of which is only partially exact in general.

Arrows: Each horizontal double-headed arrow $\leftrightarrow$ denotes a biconditional (if and only if). The three rows are three separate equivalences, not a commutative diagram in the traditional sense: no path-composition is being equated. Rather, this is a correspondences table displayed diagrammatically.

What commutes: The three equivalences hold simultaneously and independently: (i) P projective $\iff$ $\mathrm{Hom}_R(P, -)$ carries every surjection to a surjection (i.e. is exact); (ii) Q injective $\iff$ $\mathrm{Hom}_R(-, Q)$ carries every injection to a surjection (i.e. is exact); (iii) M flat $\iff$ $M \otimes_R -$ carries every injection to an injection (i.e. is exact).

Why it commutes: Each iff was established in the section: (i) the lifting property of P is equivalent to exactness of $\mathrm{Hom}_R(P, -)$ because lifting is exactly preserving surjections. (ii) The extension property of Q is equivalent to $\mathrm{Hom}_R(-, Q)$ preserving injections-to-surjections. (iii) The definition of flat is directly that $M \otimes_R -$ preserves injections.

Why this matters here: This diagram is the organizational capstone of the entire section. It collects the three module classes and their functor-exactness characterizations into one unified picture, clarifying that projective, injective, and flat are each the "right" hypothesis to add to the base functor to make it fully exact.

Concrete example: Over $\mathbb{Z}$: $\mathbb{Z}$ is projective (free) and flat (torsion-free); $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}, -) = \mathrm{id}$ is trivially exact. $\mathbb{Q}/\mathbb{Z}$ is injective (divisible). $\mathbb{Z}/2\mathbb{Z}$ is neither projective, injective, nor flat, and all three functors applied to it can fail exactness.

Common pitfall: The implications run only one way downward: free $\Rightarrow$ projective $\Rightarrow$ flat, but not conversely in general. Students sometimes read the triple list as saying projective, injective, and flat are equivalent to each other; they are not – they correspond to three different functors.

Takeaway: The point of this diagram is that projective, injective, and flat modules are precisely the three module classes that upgrade their associated functor from one-sided exact to fully exact, organizing the entire theory around a single unifying principle.

Implications: free $\Rightarrow$ projective $\Rightarrow$ flat (none reversible in general), and over $\mathbb{Z}$: projective = free for finitely generated, injective = divisible, flat = torsion-free.

Exercises

Exact sequences and splitting.

1. Determine whether $0 \to \mathbb{Z} \xrightarrow{\times 6} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/6\mathbb{Z} \to 0$ is exact, where π is reduction mod 6; if so, decide whether it splits.
2. Show $0 \to \mathbb{Z}/3\mathbb{Z} \xrightarrow{\iota} \mathbb{Z}/12\mathbb{Z} \xrightarrow{\varphi} \mathbb{Z}/4\mathbb{Z} \to 0$ is a split SES, where $\iota(\bar{1}) = \bar{4}$ and φ is reduction mod 4; exhibit a section.
3. For an R-homomorphism $f\colon M \to N$, prove the sequence $0 \to \ker f \to M \xrightarrow{f} \operatorname{im} f \to 0$ is exact, and give an example over $R = \mathbb{Z}$ where it does not split.
4. Prove that $0 \to \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z} \to 0$ does not split, and conclude $\mathbb{Z}/4\mathbb{Z} \not\cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$.

Projective, injective, flat.

1. Show $\mathbb{Z}/3\mathbb{Z}$ is a projective $\mathbb{Z}/12\mathbb{Z}$-module but is not free over $\mathbb{Z}/12\mathbb{Z}$.
2. Using Baer's Criterion, decide whether $\mathbb{Z}$ is an injective module over itself, and whether $\mathbb{Q}$ is.
3. Prove that $\mathbb{Q}/\mathbb{Z}$ is divisible, and deduce that it is an injective $\mathbb{Z}$-module.
4. Show that a finite direct sum of flat modules is flat, and that $\mathbb{Z}/n\mathbb{Z}$ ($n \geq 2$) is never flat over $\mathbb{Z}$.

Hom and tensor computations.

1. Compute $\operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/4\mathbb{Z}, \mathbb{Z}/6\mathbb{Z})$ and $\operatorname{Hom}_{\mathbb{Z}}(\mathbb{Z}/6\mathbb{Z}, \mathbb{Z}/4\mathbb{Z})$, and verify each has order $\gcd(4,6) = 2$.
2. Compute $\mathbb{Z}/4\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/6\mathbb{Z}$ and $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/5\mathbb{Z}$ from presentations, identifying each result.
3. For a left R-module M, prove $R \otimes_R M \cong M$ and use it to show R is a flat module over itself.
4. Tensor the SES $0 \to \mathbb{Z} \xrightarrow{\times 5} \mathbb{Z} \to \mathbb{Z}/5\mathbb{Z} \to 0$ with $M = \mathbb{Z}/10\mathbb{Z}$ and exhibit explicitly the failure of injectivity at the left end.

Exercises (from the text).

1. Suppose that

$$\begin{array}{ccccc} A & \xrightarrow{\psi} & B & \xrightarrow{\varphi} & C \\ \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} \\ A' & \xrightarrow{\psi'} & B' & \xrightarrow{\varphi'} & C' \end{array}$$

   is a commutative diagram of groups and the rows are exact. Prove that

   (a) if φ and α are surjective, and β is injective then γ is injective. [If $c \in \ker\gamma$, show there is a $b \in B$ with $\varphi(b) = c$. Show that $\varphi'(\beta(b)) = 0$ and deduce that $\beta(b) = \psi'(a')$ for some $a' \in A'$. Show there is an $a \in A$ with $\alpha(a) = a'$ and that $\beta(\psi(a)) = \beta(b)$. Conclude that $b = \psi(a)$ and hence $c = \varphi(b) = 0$.]

   (b) if ψ', α, and γ are injective, then β is injective,

   (c) if φ, α, and γ are surjective, then β is surjective,

   (d) if β is injective, α and φ are surjective, then γ is injective,

   (e) if β is surjective, γ and ψ' are injective, then α is surjective.

2. Suppose

$$\begin{array}{ccccccccc} A & \longrightarrow & B & \longrightarrow & C & \longrightarrow & D & \longrightarrow & E \\ \downarrow{\scriptstyle\alpha} & & \downarrow{\scriptstyle\beta} & & \downarrow{\scriptstyle\gamma} & & \downarrow{\scriptstyle\delta} & & \downarrow{\scriptstyle\varepsilon} \\ A' & \longrightarrow & B' & \longrightarrow & C' & \longrightarrow & D' & \longrightarrow & E' \end{array}$$

   is a commutative diagram of groups, and the rows are exact. Prove that

(a) if α is surjective, and β, δ are injective, then γ is injective,

(b) if ε is injective, and β, δ are surjective, then γ is surjective.

3. Let P_1 and P_2 be R-modules. Prove that $P_1 \oplus P_2$ is a projective R-module if and only if both P_1 and P_2 are projective.

4. Let Q_1 and Q_2 be R-modules. Prove that $Q_1 \oplus Q_2$ is an injective R-module if and only if both Q_1 and Q_2 are injective.

5. Let A_1 and A_2 be R-modules. Prove that $A_1 \oplus A_2$ is a flat R-module if and only if both A_1 and A_2 are flat. More generally, prove that an arbitrary direct sum $\sum_i A_i$ of R-modules is flat if and only if each A_i is flat. (Use the fact that tensor product commutes with arbitrary direct sums.)

6. Prove that the following are equivalent for a ring R:

(i) Every R-module is projective.

(ii) Every R-module is injective.

7. Let A be a nonzero finite abelian group.

(a) Prove that A is not a projective $\mathbb{Z}$-module.

(b) Prove that A is not an injective $\mathbb{Z}$-module.

8. Let Q be a nonzero divisible $\mathbb{Z}$-module. Prove that Q is not a projective $\mathbb{Z}$-module. Deduce that the rational numbers $\mathbb{Q}$ is not a projective $\mathbb{Z}$-module. [Show first that if F is any free module then $\bigcap_{n=1}^{\infty} nF = 0$ (use a basis of F to prove this). Now suppose to the contrary that Q is projective and derive a contradiction from Proposition 30(4).]

9. Assume R is commutative with 1.

(a) Prove that the tensor product of two free R-modules is free. (Use the fact that tensor products commute with direct sums.)

(b) Use (a) to prove that the tensor product of two projective R-modules is a projective R-module.

10. Let R and S be rings with 1 and let M and N be left R-modules. Assume also that M is an (R, S)-bimodule.

(a) For $s \in S$ and for $\varphi \in \mathrm{Hom}_R(M, N)$ define $s\varphi : M \to N$ by $(s\varphi)(m) = \varphi(ms)$. Prove that $s\varphi$ is a homomorphism of left R-modules, and that this action of S on $\mathrm{Hom}_R(M, N)$ makes it into a left S-module.

(b) Let $S = R$ and let $M = R$ (as an (R, R)-bimodule by left and right ring multiplication on itself). For each $n \in N$ define $\varphi_n \in \mathrm{Hom}_R(R, N)$ by $\varphi_n(r) = rn$, i.e., φ_n is the unique R-module homomorphism mapping 1_R to n. Show that $s\varphi_n$ as defined in (a) is the homomorphism φ_{sn}. Deduce that the map $n \mapsto \varphi_n$ is an isomorphism of left R-modules: $N \cong \mathrm{Hom}_R(R, N)$.

11. Let R and S be rings with 1 and let M and N be left R-modules. Assume also that N is an (R, S)-bimodule.

(a) For $s \in S$ and for $\varphi \in \mathrm{Hom}_R(M, N)$ define $\varphi s : M \to N$ by $(\varphi s)(m) = \varphi(m)s$. Prove that φs is a homomorphism of left R-modules, and that this action of S on $\mathrm{Hom}_R(M, N)$ makes it into a right S-module.

(b) Let $N = R$ as an (R, R)-bimodule as above. Deduce that $\mathrm{Hom}_R(M, R)$ is a right R-module — called the dual module to M.

12. Let R be a ring with 1. Let M and N be left R-modules and suppose A is an (R, R)-bimodule. Prove that $\mathrm{Hom}_R(A, M)$ is a left R-module under the action $(r\varphi)(a) = \varphi(ar)$ for $r \in R$ and $\varphi \in \mathrm{Hom}_R(A, M)$ (cf. Exercise 10).

13. Let A be a finitely generated abelian group.

(a) Prove that A is projective if and only if A is a free $\mathbb{Z}$-module.

(b) Prove that A is injective if and only if $A = 0$.

14. Let $0 \to L \xrightarrow{\psi} M \xrightarrow{\varphi} N \to 0$ be a sequence of R-modules.

(a) Prove that the associated sequence

$$0 \to \mathrm{Hom}_R(D, L) \xrightarrow{\psi'} \mathrm{Hom}_R(D, M) \xrightarrow{\varphi'} \mathrm{Hom}_R(D, N) \to 0$$

is a short exact sequence of abelian groups for all R-modules D if and only if the original sequence is a split short exact sequence. [To show the sequence splits, take $D = N$ and show the lift of the identity map in $\mathrm{Hom}_R(N, N)$ to $\mathrm{Hom}_R(N, M)$ is a splitting homomorphism for φ.]

(b) Prove that the associated sequence

$$0 \to \mathrm{Hom}_R(N, D) \xrightarrow{\varphi'} \mathrm{Hom}_R(M, D) \xrightarrow{\psi'} \mathrm{Hom}_R(L, D) \to 0$$

is a short exact sequence of abelian groups for all R-modules D if and only if the original sequence is a split short exact sequence.

15. Let M be a left $\mathbb{Z}$-module and let R be a ring with 1.

(a) Show that $\mathrm{Hom}_{\mathbb{Z}}(R, M)$ is a left R-module under the action $(r\varphi)(r') = \varphi(r'r)$ (see Exercise 10).

(b) Suppose that $0 \to A \xrightarrow{\psi} B$ is an exact sequence of R-modules. Prove that if every $\mathbb{Z}$-module homomorphism f from A to M lifts to a $\mathbb{Z}$-module homomorphism F from B to M with $f = F \circ \psi$, then every R-module homomorphism f' from A to $\mathrm{Hom}_{\mathbb{Z}}(R, M)$ lifts to an R-module homomorphism F' from B to $\mathrm{Hom}_{\mathbb{Z}}(R, M)$ with $f' = F' \circ \psi$. [Given f', show that $f(a) = f'(a)(1)$ defines a $\mathbb{Z}$-module homomorphism of A to M. If F is a lift of f to B, show that $F'(b)(r) = F(rb)$ defines an R-module homomorphism from B to $\mathrm{Hom}_{\mathbb{Z}}(R, M)$ that lifts f'.]

(c) Prove that if Q is an injective $\mathbb{Z}$-module then $\mathrm{Hom}_{\mathbb{Z}}(R, Q)$ is an injective R-module. (cf. Exercise 19.)

16. Let J be an (R, R)-bimodule, let A be a left R-module and let $M = \mathrm{Hom}_R(J, A)$.

(a) For $r \in R$ and for $\varphi \in \mathrm{Hom}_R(J, A)$ define $r\varphi$ by $(r\varphi)(j) = \varphi(jr)$. Prove that $r\varphi$ is a homomorphism of left R-modules, and that this action of R on $\mathrm{Hom}_R(J, A)$ makes it into a left R-module. (cf. Exercise 10.)

(b) If A is an injective R-module and J is flat as a right R-module, prove that $M = \mathrm{Hom}_R(J, A)$ is an injective R-module. [Use the natural isomorphism $\mathrm{Hom}_R(X, M) \cong \mathrm{Hom}_R(J \otimes_R X, A)$ for left R-modules X. Flatness cannot be dropped: $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/2\mathbb{Z}, \mathbb{Q}/\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$ is not an injective $\mathbb{Z}$-module.]

17. Show that if R is a Noetherian ring (cf. Exercise 14 in Section 10.3) and Q is an injective R-module then any direct sum of copies of Q is also an injective R-module. [Use Baer's Criterion, Proposition 36.]

18. This exercise proves that $\mathbb{Q}/\mathbb{Z}$ is an injective $\mathbb{Z}$-module (cf. Corollary 35).

(a) Prove that a quotient of a divisible group is again divisible.

(b) Prove that $\mathbb{Q}/\mathbb{Z}$ is a divisible group, hence is an injective $\mathbb{Z}$-module.

19. Let M be any left R-module. This exercise proves that M may be embedded in an injective R-module.

(a) Show that M is contained in an injective $\mathbb{Z}$-module Q (cf. Exercise 18 and Corollary 10.5.25).

(b) Show that $\mathrm{Hom}_R(R, M) \subseteq \mathrm{Hom}_{\mathbb{Z}}(R, M) \subseteq \mathrm{Hom}_{\mathbb{Z}}(R, Q)$ as R-modules, and that $\mathrm{Hom}_{\mathbb{Z}}(R, Q)$ is an injective R-module by Exercise 15.

(c) Deduce that M is contained in an injective R-module. [Use the R-module isomorphism $M \cong \mathrm{Hom}_R(R, M)$ of Exercise 10.]

20. This exercise completes the proof of Proposition 34. Suppose that Q is an R-module with the property that every short exact sequence $0 \to Q \to M_1 \to M_2 \to 0$ splits and suppose that the sequence $0 \to A \xrightarrow{\psi} B$ is exact. Prove that every R-module homomorphism f from A to Q lifts to an R-module homomorphism F from B to Q with $f = F \circ \psi$ (i.e., Q has the injective property with respect to all injections). [Imitate the proof of Proposition 34 (and use the previous exercise) to embed Q into an injective module I. Then the splitting property together with Exercise 4 using Exercise 1(b) gives an isomorphism from Q to a direct summand of I. Use the fact that the property in Proposition 36 holds for injective modules.]

21. Prove that the injective hull of the $\mathbb{Z}$-module $\mathbb{Z}$ is $\mathbb{Q}$ and that $\mathbb{Q}$ contains an isomorphic copy of $\mathbb{Z}$ as an essential submodule.

22. Prove that the injective hull of the $\mathbb{Z}$-module $\mathbb{Z}/p^n\mathbb{Z}$ is the injective hull of $\mathbb{Z}/p\mathbb{Z}$ and deduce that $\mathbb{Z}/p^n\mathbb{Z}$ has the Prüfer group $\mathbb{Z}[1/p]/\mathbb{Z}$ (the p-primary part of $\mathbb{Q}/\mathbb{Z}$), not $\mathbb{Q}/\mathbb{Z}$ itself, as its injective hull.

23. If F is a field, prove that the injective hull of $F[x]$ is the rational function field $F(x)$.

24. Prove that the polynomial ring $R[x]$ in the indeterminate x over the commutative ring R is a flat R-module.

25. Let R and S be rings with 1 and suppose M is a right R-module, and N is an (R, S)-bimodule. If M is flat over R and N is flat as an S-module then prove that $M \otimes_R N$ is flat as a right S-module.

26. Suppose that R is a commutative ring and that M and N are flat R-modules. Prove that $M \otimes_R N$ is a flat R-module. (See the previous exercise.)

27. Prove that the (right) module $M \otimes_R S$ obtained by changing the base from the ring R to the ring S by some homomorphism $f : R \to S$ with $f(1_R) = 1_S$ (cf. Example 6 following Corollary 12 in Section 4) of the flat (right) R-module M is the flat (right) S-module $M \otimes_R S$.

28. Prove that A is a flat R-module if and only if for every finitely generated ideal I of R the map from $A \otimes_R I$ to $A \otimes_R R \cong A$ induced by the inclusion $I \subseteq R$ is injective. [The image of $A \otimes_R I$ in $A \otimes_R R = A$ is AI, so this is equivalent to showing that the natural map $A \otimes_R I \to AI$ is injective.]

29. *(A Flatness Criterion)* Parts (a)–(c) of this exercise prove that A is a flat R-module if and only if (I) for every finitely generated ideal I of R, the map from $A \otimes_R I \to A$ given by $a \otimes i \mapsto ai$ is injective (cf. the preceding exercise). By the previous two exercises it suffices to prove that (I) implies A is flat, i.e., that $A \otimes_R B \to A \otimes_R C$ is injective for every injection of (left) R-modules $\iota : B \to C$.

    (a) Suppose that $L_2 \subseteq L_1$ are two left ideals of R. Show that if (I) is satisfied for both L_1 and L_2 then (I) is satisfied for L_1/L_2.

    (b) Suppose $D_1 \subseteq D_2 \subseteq \cdots$ is an ascending chain of left ideals of R and let $D = \bigcup_i D_i$. Show that if (I) is satisfied for each D_i then (I) is satisfied for D.

    (c) Use Zorn's Lemma to prove that (I) is satisfied for every left ideal of R. Prove that this implies A is flat as follows. Let B be a submodule of the R-module C. By the previous exercises it suffices to consider the case where $C = R^n$ is a finitely generated free module; use induction on n, the case $n = 1$ being the assumption that (I) holds, together with parts (a) and (b), to complete the proof. [Use the commutative diagram with exact rows obtained from $0 \to K \to R^n \to R \to 0$, where $K = R^{n-1}$, and apply the snake lemma.]

30. *(A Flatness Criterion for quotients)* Suppose $A = F/K$ where F is flat (e.g., if F is free) and K is an R-submodule of F. Show that $A = F/K$ is flat if and only if $K \cap FI = KI$ for every finitely generated ideal I of R. (Use the flatness criterion in the preceding exercise.) [Use the previous exercise. Since F is flat, $F \otimes I \cong FI$, and the image of $K \otimes I$ in FI is KI; tensoring $0 \to K \to F \to A \to 0$ with I gives $A \otimes I \cong FI/KI$. Under this identification the map $A \otimes I \to A = F/K$ is $FI/KI \to F/K$, whose kernel is $(K \cap FI)/KI$.]

31. Let M and N be submodules of the R-module L.

    (a) Suppose $\alpha : A \to M$ and $\beta : A \to N$ are R-module homomorphisms. Prove that $X = \{(\alpha(a), -\beta(a)) \mid a \in A\}$ is an R-submodule of the direct sum $M \oplus N$ and prove that α and β factor through the

quotient $(M \oplus N)/X$ (called the *pushout* or *fiber sum* of α and β) and that there is a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{\beta} & N \\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\pi_2} \\ M & \xrightarrow[\pi_1]{} & P \end{array}$$

where π_1 and π_2 are the natural maps to the quotient induced by the maps into the first and second components.

(b) Suppose $f : M \to D$ and $g : N \to D$ are R-module homomorphisms with $f \circ \alpha = g \circ \beta$. Prove that there is a unique R-module homomorphism from the pushout P to D making the natural diagram commute.

(c) If M and N are submodules of an R-module L, show that the pushout of the inclusion maps $M \cap N \hookrightarrow M$ and $M \cap N \hookrightarrow N$ is isomorphic to the submodule $M + N$ of L.

32. *(Schanuel's Lemma)* If $0 \to K \to P \xrightarrow{\varphi} M \to 0$ and $0 \to K' \to P' \xrightarrow{\varphi'} M \to 0$ are exact sequences of R-modules where P and P' are projective, prove that $K \oplus P' \cong K' \oplus P$ as R-modules. [Show that there is an exact sequence $0 \to \ker \pi \to X \xrightarrow{\pi} P \to 0$ where $X = \{(x, y) \in P \oplus P' \mid \varphi(x) = \varphi'(y)\}$ is the submodule that is the pullback (or fiber product) of φ and φ', and the map π is the natural projection onto the first component. Show that $\ker \pi \cong K'$ and that this sequence splits since P is projective. Deduce that $X \cong K' \oplus P$. Show similarly that $X \cong K \oplus P'$.] The R-modules M and N are said to be *projectively equivalent* if $M \oplus P \cong N \oplus Q$ for some projective R-modules P and Q. Similarly, M and N are *injectively equivalent* if $M \oplus Q \cong N \oplus Q'$ for some injective modules Q, Q'. This exercise shows K and K' are projectively equivalent.

Practice problems.

1. Show that a sequence $0 \to A \xrightarrow{\psi} B$ of R-modules is exact (at A) if and only if ψ is injective. Dually, show that $B \xrightarrow{\varphi} C \to 0$ is exact (at C) if and only if φ is surjective.

2. Let $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ be a short exact sequence of R-modules. Prove that $C \cong B/\psi(A)$ as R-modules.

3. Determine whether the sequence

$$0 \longrightarrow \mathbb{Z} \xrightarrow{2} \mathbb{Z} \longrightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 0$$

of $\mathbb{Z}$-modules is exact, where the first map is multiplication by 2 and the second is reduction mod 2. Justify exactness at each of the three middle positions.

4. Consider the $\mathbb{Z}$-module homomorphisms in

$$\mathbb{Z} \xrightarrow{f} \mathbb{Z} \oplus \mathbb{Z} \xrightarrow{g} \mathbb{Z}$$

where $f(n) = (n, -n)$ and $g(a, b) = a + b$. Verify that $\operatorname{im} f = \ker g$, i.e. the sequence is exact at $\mathbb{Z} \oplus \mathbb{Z}$.

5. Let R be a ring with 1. Prove that the free R-module R^n is projective. More generally, prove that every free R-module is projective.

6. Prove that a finite direct sum $P_1 \oplus \cdots \oplus P_n$ of R-modules is projective if and only if each P_i is projective.

7. Show that $\mathbb{Z}/2\mathbb{Z}$ is a projective $\mathbb{Z}/6\mathbb{Z}$-module by exhibiting a $\mathbb{Z}/6\mathbb{Z}$-module Q with $\mathbb{Z}/2\mathbb{Z} \oplus Q$ free. Conclude $\mathbb{Z}/2\mathbb{Z}$ is projective but not free over $\mathbb{Z}/6\mathbb{Z}$.

8. Show that $\mathbb{Z}/2\mathbb{Z}$ is *not* a projective $\mathbb{Z}/4\mathbb{Z}$-module. (Show the surjection $\mathbb{Z}/4\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ does not split, i.e. the identity map $\mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/2\mathbb{Z}$ does not lift through it.)

9. Prove that the short exact sequence

$$0 \longrightarrow \mathbb{Z} \xhookrightarrow{2} \mathbb{Z} \longrightarrow\!\!\!\!\!\rightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 0$$

of $\mathbb{Z}$-modules does not split. Compare with problem 8.

10. Let $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ be a short exact sequence of R-modules. Prove the following are equivalent: (a) the sequence splits; (b) there is an R-module homomorphism $\lambda : B \to A$ with $\lambda \circ \psi = \mathrm{id}_A$; (c) there is an R-module homomorphism $\mu : C \to B$ with $\varphi \circ \mu = \mathrm{id}_C$. In each splitting case prove $B \cong A \oplus C$.

11. Prove that an R-module P is projective if and only if every short exact sequence $0 \to A \to B \to P \to 0$ of R-modules splits.

12. Show that $\mathbb{Q}$ is an injective $\mathbb{Z}$-module. (Use the criterion that a $\mathbb{Z}$-module Q is injective if and only if it is divisible, i.e. $nQ = Q$ for every nonzero integer n.)

13. Show that $\mathbb{Z}$ is *not* an injective $\mathbb{Z}$-module by exhibiting an injection $\mathbb{Z} \to \mathbb{Q}$ and a homomorphism $\mathbb{Z} \to \mathbb{Z}$ that does not extend to $\mathbb{Q}$.

14. Compute the following tensor products of $\mathbb{Z}$-modules, identifying each as a familiar abelian group:

$$\mathbb{Z}/4\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/6\mathbb{Z}, \qquad \mathbb{Z}/m\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z}, \qquad \mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Z}/n\mathbb{Z} \ (n > 0), \qquad \mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Q}.$$

15. Let R be commutative with 1 and let $I, J \le R$ be ideals. Prove that there is an R-module isomorphism $R/I \otimes_R R/J \cong R/(I + J)$.

16. Prove that every free R-module $R^{(A)}$ is flat. Deduce that every projective R-module is flat. (You may use that a direct summand of a flat module is flat.)

Additional exercises.

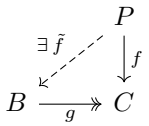
1. (Five Lemma) Suppose the diagram of R-modules

$$\begin{array}{ccccccccc} A_1 & \longrightarrow & A_2 & \longrightarrow & A_3 & \longrightarrow & A_4 & \longrightarrow & A_5 \\ \downarrow{\scriptstyle \alpha_1} & & \downarrow{\scriptstyle \alpha_2} & & \downarrow{\scriptstyle \alpha_3} & & \downarrow{\scriptstyle \alpha_4} & & \downarrow{\scriptstyle \alpha_5} \\ B_1 & \longrightarrow & B_2 & \longrightarrow & B_3 & \longrightarrow & B_4 & \longrightarrow & B_5 \end{array}$$

has exact rows and is commutative. Prove that if $\alpha_1, \alpha_2, \alpha_4, \alpha_5$ are isomorphisms then α_3 is an isomorphism. (Prove the stronger statement: α_3 injective when α_2, α_4 injective and α_1 surjective; α_3 surjective when α_2, α_4 surjective and α_5 injective.)

2. Prove that an R-module P is projective if and only if P is a direct summand of a free module. (Show every module is a quotient of a free module, then use the lifting property to split the resulting surjection onto P.)

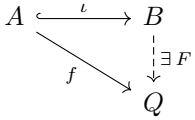
3. Let R be a PID and let P be a finitely generated projective R-module. Prove that P is free. (Use the structure theorem: a finitely generated module over a PID that is a submodule of a free module is free.)



4. (Flatness via Tor) Show that the $\mathbb{Z}$-module $\mathbb{Z}/n\mathbb{Z}$ is not flat for $n > 1$ by tensoring the exact sequence $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n\mathbb{Z} \to 0$ with $\mathbb{Z}/n\mathbb{Z}$ and exhibiting where left-exactness fails. Identify $\mathrm{Tor}_1^{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/n\mathbb{Z})$.

5. Let R be commutative with 1 and S a multiplicatively closed subset. Prove that the localization $S^{-1}R$ is a flat R-module, i.e. $S^{-1}R \otimes_R (-)$ is exact. (You may take as known that localization is an exact functor.)

6. (Schanuel's Lemma) Suppose $0 \to K_1 \to P_1 \to M \to 0$ and $0 \to K_2 \to P_2 \to M \to 0$ are short exact sequences of R-modules with P_1, P_2 projective. Prove $K_1 \oplus P_2 \cong K_2 \oplus P_1$.



Commutative-diagram exercises.

1. (Lifting property of projectives) Let P be a projective R-module, let $g : B \to C$ be a surjection of R-modules, and let $f : P \to C$ be any homomorphism. State and prove the existence of the dashed lift in

   Then show by example (over $R = \mathbb{Z}$) that the lift $\tilde{f}$ need not be unique.

2. (Extension property of injectives) Let Q be an injective R-module, let $\iota : A \to B$ be an injection of R-modules, and let $f : A \to Q$ be any homomorphism. Prove the existence of the dashed extension F making

   commute. Using this with $A = \mathbb{Z} \hookrightarrow B = \mathbb{Q} = Q$, find all extensions of $f = \mathrm{id}_{\mathbb{Z}}$.

3. (Universal property of tensor product) Let M, N, L be R-modules over a commutative ring R and let $\varphi : M \times N \to L$ be R-bilinear. State the universal property realized by

   and use it to prove the canonical isomorphism $R \otimes_R N \cong N$ as R-modules.

4. (Snake Lemma) Given a commutative diagram of R-modules with exact rows

   state the snake lemma (the existence of the connecting map $\delta : \ker c \to \operatorname{coker} a$ and the resulting six-term exact sequence $\ker a \to \ker b \to \ker c \xrightarrow{\delta} \operatorname{coker} a \to \operatorname{coker} b \to \operatorname{coker} c$), and prove that δ is well defined.

5. (Splitting via a section) Let $0 \to A \xrightarrow{\psi} B \xrightarrow{\varphi} C \to 0$ be a short exact sequence of R-modules. Suppose a homomorphism $\mu : C \to B$ exists with $\varphi \circ \mu = \mathrm{id}_C$, as in

   Prove that $B = \psi(A) \oplus \mu(C)$ and hence $B \cong A \oplus C$.

10.6 Graded Problem Bank

Easy

DF 10.1.1 Prove that $0m = 0$ and $(-1)m = -m$ for all m in an R-module M.

DF 10.1.2 Prove that $R^\times$ and M satisfy the two group-action axioms for the action of the multiplicative group $R^\times$ on the set M.

DF 10.1.3 If $rm = 0$ for some $r \in R$ and some $m \neq 0$, prove that r has no left inverse in R.

DF 10.1.6 Show that the intersection of any nonempty collection of submodules of an R-module is a submodule.

DF 10.1.7 If $N_1 \subseteq N_2 \subseteq \cdots$ is an ascending chain of submodules of M, prove that $\bigcup_i N_i$ is a submodule.

DF 10.1.9 If $N \leq M$, prove that the annihilator $\mathrm{Ann}_R(N) = \{r \in R \mid rn = 0 \ \forall n \in N\}$ is a two-sided ideal of R.

DF 10.1.10 If I is a right ideal of R, prove that the annihilator of I in M, namely $\{m \in M \mid am = 0 \ \forall a \in I\}$, is a submodule of M.

DF 10.1.11 For $M = \mathbb{Z}/24\mathbb{Z} \times \mathbb{Z}/15\mathbb{Z} \times \mathbb{Z}/50\mathbb{Z}$ as a $\mathbb{Z}$-module, find a generator of the annihilator of M in $\mathbb{Z}$, and describe the annihilator of $I = 2\mathbb{Z}$ in M as a direct product of cyclic groups.

DF 10.1.15 If M is a finite abelian group, hence a $\mathbb{Z}$-module, can this action be extended to make M into a $\mathbb{Q}$-module?

DF 10.2.1 Use the submodule criterion to show that kernels and images of R-module homomorphisms are submodules.

DF 10.2.2 Show that "is R-module isomorphic to" is an equivalence relation on any set of R-modules.

DF 10.2.3 Give an explicit map between R-modules that is a $\mathbb{Z}$-module homomorphism but not an R-module homomorphism.

DF 10.2.5 Exhibit all $\mathbb{Z}$-module homomorphisms from $\mathbb{Z}/3\mathbb{Z}$ to $\mathbb{Z}/9\mathbb{Z}$.

DF 10.3.4 Prove that every finite abelian group is a torsion $\mathbb{Z}$-module, and give an example of an infinite abelian group that is a torsion $\mathbb{Z}$-module.

DF 10.3.6 Prove that a quotient of an R-module generated by n elements is generated by n or fewer elements; deduce that quotients of cyclic modules are cyclic.

DF 10.4.2 Show that $2 \otimes 1$ is 0 in $\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$ but nonzero in $2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z}$.

DF 10.4.4 Show that $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Q}$ and $\mathbb{Q} \otimes_{\mathbb{Q}} \mathbb{Q}$ are isomorphic left $\mathbb{Q}$-modules, each being a 1-dimensional $\mathbb{Q}$-vector space.

DF 10.4.11 For a basis $\{e_1, e_2\}$ of $\mathbb{R}^2$, show that $e_1 \otimes e_2 + e_2 \otimes e_1$ in $\mathbb{R}^2 \otimes_{\mathbb{R}} \mathbb{R}^2$ is not a simple tensor $v \otimes w$.

DF 10.4.13 Prove that the usual dot product $(a_1, \ldots, a_n) \cdot (b_1, \ldots, b_n) = a_1b_1 + \cdots + a_nb_n$ is a bilinear map $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$.

DF 10.4.23 Prove the ring isomorphism $\mathbb{Z}[i] \otimes_{\mathbb{Z}} \mathbb{R} \cong \mathbb{C}$.

DF 10.5.3 Prove that $P_1 \oplus P_2$ is a projective R-module if and only if both P_1 and P_2 are projective.

DF 10.5.4 Prove that $Q_1 \oplus Q_2$ is an injective R-module if and only if both Q_1 and Q_2 are injective.

Artin 1.1 Let R be a ring and $V = R$ the R-module R. Determine all R-module homomorphisms $\varphi : V \to V$.

Artin 1.2 Let V be an abelian group. Prove that if V admits a $\mathbb{Q}$-module structure compatible with its given addition, then that structure is uniquely determined.

Artin 1.3 Let $R = \mathbb{Z}[\alpha]$ where α is an algebraic integer. Prove that for any nonzero integer m the quotient R/mR is finite, and determine its order.

Artin 2.1 For $R = \mathbb{C}[x, y]$, let M be the ideal generated by x and y. Is M a free R-module?

Artin 5.2 Identify the abelian group presented by the integer matrix $\left(\begin{smallmatrix} 3 & 1 & 2 \\ 1 & 1 & 1 \\ 2 & 3 & 6 \end{smallmatrix}\right)$.

Artin 7.1 Find a direct sum of cyclic groups isomorphic to the abelian group with presentation matrix $\left(\begin{smallmatrix} 2 & 2 & 2 \\ 2 & 2 & 0 \\ 2 & 0 & 2 \end{smallmatrix}\right)$.

Artin 7.2 Write the abelian group generated by x, y with the single relation $3x + 4y = 0$ as a direct sum of cyclic groups.

Artin 7.5 Determine the number of isomorphism classes of abelian groups of order 400.

Artin 8.1 For the operator T on $\mathbb{C}^2$ with matrix $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, decide whether the corresponding $\mathbb{C}[t]$-module is cyclic.

Artin M.1 In how many ways can the additive group $\mathbb{Z}/5\mathbb{Z}$ be given the structure of a module over the Gaussian integers $\mathbb{Z}[i]$?

Artin M.2 Classify the finitely generated modules over the ring $\mathbb{Z}/6\mathbb{Z}$.

Medium

DF 10.1.4 For $M = R^n$ and left ideals $I_1, \ldots, I_n$ of R, prove that $\{(x_1, \ldots, x_n) \mid x_i \in I_i\}$ and $\{(x_1, \ldots, x_n) \mid x_i \in R,\ \sum x_i = 0\}$ are submodules of M.

DF 10.1.5 For a left ideal I of R, prove that $IM = \{\sum_{\text{finite}} a_i m_i \mid a_i \in I,\ m_i \in M\}$ is a submodule of M.

DF 10.1.8 Prove that if R is an integral domain then $\mathrm{Tor}(M)$ is a submodule; give a ring R and module M with $\mathrm{Tor}(M)$ not a submodule; and show that if R has zero divisors then every nonzero R-module has nonzero torsion.

DF 10.1.12 Prove that the annihilator in M of $\mathrm{Ann}_R(N)$ contains N (with an example of strict containment), and that the annihilator in R of $\mathrm{Ann}_M(I)$ contains I (with an example of strict containment).

DF 10.1.13 For an ideal I of R, let M' be the elements of M annihilated by some power I^k. Prove that M' is a submodule of M.

DF 10.1.14 For z in the center of R, prove that zM is a submodule, and show that for $R = \mathrm{M}_2(F)$ and e the matrix unit E_{11}, the set eR is not a left R-submodule of R.

DF 10.1.16 Prove that the submodules U_k in the $F[x]$-module example of the shift operator are all of its $F[x]$-submodules.

DF 10.1.18 For $V = \mathbb{R}^2$ and T rotation clockwise by $\pi/2$, show that V and 0 are the only $F[x]$-submodules.

DF 10.1.19 For $V = \mathbb{R}^2$ and T projection onto the y-axis, show that V, 0, the x-axis, and the y-axis are the only $F[x]$-submodules.

DF 10.1.20 For $V = \mathbb{R}^2$ and T rotation clockwise by π, show that every subspace of V is an $F[x]$-submodule.

DF 10.1.21 For $R = \mathrm{M}_n(F)$ $(n > 1)$ and M the matrices with arbitrary first column and zeros elsewhere, show M is a left R-submodule of R but not a right R-submodule.

DF 10.2.4 For a $\mathbb{Z}$-module A, $a \in A$, and $n > 0$, prove $\varphi_a : \mathbb{Z}/n\mathbb{Z} \to A$, $\varphi_a(\bar{k}) = ka$, is a well-defined $\mathbb{Z}$-module homomorphism iff $na = 0$, and prove $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, A) \cong A_n$ where $A_n = \{a \mid na = 0\}$.

DF 10.2.6 Prove that $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}, \mathbb{Z}/m\mathbb{Z}) \cong \mathbb{Z}/(n, m)\mathbb{Z}$.

DF 10.2.7 For z in the center of R, prove $m \mapsto zm$ is an R-module endomorphism of M, and for commutative R that $r \mapsto r\ \mathrm{id}_M$ (multiplication by r) gives a ring homomorphism $R \to \mathrm{End}_R(M)$.

DF 10.2.8 For an R-module homomorphism $\varphi : M \to N$, prove $\varphi(\mathrm{Tor}(M)) \subseteq \mathrm{Tor}(N)$.

DF 10.2.9 For commutative R, prove $\mathrm{Hom}_R(R, M) \cong M$ as left R-modules.

DF 10.2.10 For commutative R, prove $\mathrm{Hom}_R(R, R) \cong R$ as rings.

DF 10.2.11 For R-modules A_i with submodules $B_i \leq A_i$, prove $(A_1 \times \cdots \times A_n)/(B_1 \times \cdots \times B_n) \cong (A_1/B_1) \times \cdots \times (A_n/B_n)$.

DF 10.2.12 For a left ideal I of R and $n > 0$, prove $R^n/IR^n \cong (R/IR)^n$.

DF 10.2.15 For commutative R, prove $\mathrm{Hom}_R(M, M)$ is an R-module via $(r\varphi)(m) = r\varphi(m)$.

DF 10.2.16 For a left ideal I of R, prove $IM = \{\sum_{\text{finite}} a_i m_i \mid a_i \in I,\ m_i \in M\}$ is a submodule of M.

DF 10.3.1 Prove that if A and B have the same cardinality then the free modules $F(A)$ and $F(B)$ are isomorphic.

DF 10.3.3 Show that the $F[x]$-modules of Exercises 18 and 19 of Section 1 are both cyclic.

DF 10.3.5 For an integral domain R, prove that every finitely generated torsion R-module has a nonzero annihilator; give a torsion R-module whose annihilator is 0.

DF 10.3.7 Let $N \leq M$ with both M/N and N finitely generated. Prove that M is finitely generated.

DF 10.3.9 Prove M is irreducible iff $M \neq 0$ and M is cyclic with every nonzero element a generator; determine all irreducible $\mathbb{Z}$-modules.

DF 10.3.12 For commutative R, prove $\mathrm{Hom}_R(A \oplus B, M) \cong \mathrm{Hom}_R(A, M) \times \mathrm{Hom}_R(B, M)$ and $\mathrm{Hom}_R(M, A \oplus B) \cong \mathrm{Hom}_R(M, A) \times \mathrm{Hom}_R(M, B)$.

DF 10.3.13 For commutative R and a free R-module F of finite rank, prove $\mathrm{Hom}_R(F, R) \cong F$.

DF 10.3.14 For commutative R and F free of rank n, prove $\mathrm{Hom}_R(F, M) \cong M^n$.

DF 10.3.15 For a central idempotent $e \in R$, prove $M = eM \oplus (1-e)M$.

DF 10.3.16 For ideals $A_1, \ldots, A_k$ of R, prove the map $m \mapsto (m + A_1M, \ldots, m + A_kM)$ is an R-module homomorphism $M \to \prod_i M/A_iM$ with kernel $\bigcap_i A_iM$.

DF 10.3.21 Define the direct product and direct sum of an arbitrary family $\{M_i\}$ of R-modules; prove the product is an R-module and the sum is a submodule of it; show for $R = \mathbb{Z}$, $M_i = \mathbb{Z}/i\mathbb{Z}$ that the sum and product are not isomorphic.

DF 10.3.24 Show that any direct sum of free R-modules is free.

DF 10.4.1 For a ring homomorphism $f : R \to S$ with $f(1_R) = 1_S$, verify that $s \cdot r = sf(r)$ makes S an (S, R)-bimodule.

DF 10.4.5 For a finite abelian group A of order n and p^k the largest power of p dividing n, prove $\mathbb{Z}/p^k\mathbb{Z} \otimes_{\mathbb{Z}} A$ is isomorphic to the Sylow p-subgroup of A.

DF 10.4.7 For an integral domain R with fraction field Q and a left R-module N, prove every element of $Q \otimes_R N$ is a simple tensor $(1/d) \otimes n$ with $0 \neq d \in R$.

DF 10.4.12 For a field F and nonzero $v, v' \in V$, prove $v \otimes v' = v' \otimes v$ in $V \otimes_F V$ iff $v = av'$ for some $a \in F$.

DF 10.4.14 For left R-modules N_i $(i \in I)$ and a right R-module M, prove the group isomorphism $M \otimes (\bigoplus_i N_i) \cong \bigoplus_i (M \otimes N_i)$.

DF 10.4.16 For commutative R and ideals I, J, prove every element of $R/I \otimes_R R/J$ is a simple tensor $(1 \bmod I) \otimes (r \bmod J)$, and prove $R/I \otimes_R R/J \cong R/(I + J)$.

DF 10.4.18 For a principal ideal I of an integral domain R, prove that $I \otimes_R I$ has no nonzero torsion elements.

DF 10.4.20 For commutative R and ideals I, J, exhibit a surjective R-module homomorphism $I \otimes_R J \to IJ$, $i \otimes j \mapsto ij$, and give an example where it is not injective.

DF 10.4.21 If M is both a left and right R-module with $rm = mr$ for all r, m, show r_1r_2 and r_2r_1 act identically on M.

DF 10.4.24 For a commutative ring S containing R (with $1_S = 1_R$) and an indeterminate x, prove $S[x] \cong S \otimes_R R[x]$ as S-algebras.

DF 10.5.7 For a nonzero finite abelian group A, prove A is neither a projective nor an injective $\mathbb{Z}$-module.

DF 10.5.9 For commutative R, prove the tensor product of two free R-modules is free, and deduce the tensor product of two projective R-modules is projective.

DF 10.5.10 For an (R, S)-bimodule M and left R-modules M, N, prove $(s\varphi)(m) = \varphi(ms)$ makes $\mathrm{Hom}_R(M, N)$ a left S-module; deduce $N \cong \mathrm{Hom}_R(R, N)$ as left R-modules.

DF 10.5.11 For an (R, S)-bimodule N, prove $(\varphi s)(m) = \varphi(m)s$ makes $\mathrm{Hom}_R(M, N)$ a right S-module; deduce $\mathrm{Hom}_R(M, R)$ is a right R-module (the dual module).

DF 10.5.12 For an (R, R)-bimodule A, prove $(r\varphi)(a) = \varphi(ar)$ makes $\mathrm{Hom}_R(A, M)$ a left R-module.

DF 10.5.13 For a finitely generated abelian group A, prove A is projective iff A is free, and injective iff $A = 0$.

DF 10.5.16 For a left R-module M, show $\mathrm{Hom}_{\mathbb{Z}}(R, M)$ is a left R-module via $(r\varphi)(r') = \varphi(r'r)$, and if Q is an injective $\mathbb{Z}$-module then $\mathrm{Hom}_{\mathbb{Z}}(R, Q)$ is an injective R-module.

DF 10.5.18 For a Noetherian ring R and an injective R-module Q, show that any direct sum of copies of Q is injective.

DF 10.5.19 Prove that a quotient of a divisible group is divisible, and deduce $\mathbb{Q}/\mathbb{Z}$ is a divisible group, hence an injective $\mathbb{Z}$-module.

DF 10.5.21 For commutative R and flat R-modules M, N, prove $M \otimes_R N$ is flat.

DF 10.5.22 Prove that changing base by a homomorphism $f : R \to S$ sends a flat right R-module M to the flat right S-module $M \otimes_R S$.

Artin 1.4 A module is simple if it is nonzero and has no proper nonzero submodule. (a) Prove every simple R-module is isomorphic to R/M for a maximal ideal M. (b) Prove Schur's Lemma: a homomorphism of simple modules is either zero or an isomorphism.

Artin 2.4 For an ideal I of a ring R, determine under what conditions I is a free R-module, and under what conditions the quotient ring R/I is a free R-module.

Artin 4.4 Find a basis for the $\mathbb{Z}$-module of integer solutions of $x + 2y + 3z = 0$, $x + 4y + 9z = 0$.

Artin 4.5 For complex numbers α, β, γ, determine under what conditions the set of integer linear combinations $\{\ell\alpha + m\beta + n\gamma \mid \ell, m, n \in \mathbb{Z}\}$ is a lattice in the complex plane.

Artin 4.6 For φ given by multiplication by an integer matrix A, show the image of φ has finite index iff A is nonsingular, and that the index is then $|\det A|$.

Artin 4.7 For an integer column vector $A = (a_1, \ldots, a_n)^t$ with $\gcd(a_1, \ldots, a_n) = d$, prove there is $P \in \mathrm{GL}_n(\mathbb{Z})$ with $PA = (d, 0, \ldots, 0)^t$.

Artin 5.1 For $R = \mathbb{Z}[\delta]$ with $\delta = \sqrt{-5}$, determine a presentation matrix as R-module for the ideal $(2, 1 + \delta)$.

Artin 7.3 Write as a direct sum of cyclic groups the abelian group on generators x, y, z with relations (a) $3x+2y+8z = 0$, $2x + 4z = 0$; (b) $x + y = 0$, $2x = 0$, $4x + 2z = 0$, $4x + 2y + 2z = 0$; (c) $2x + y = 0$, $x - y + 3z = 0$; (d) $7x + 5y + 2z = 0$, $3x + 3y = 0$, $13x + 11y + 2z = 0$.

Artin 7.6 For relatively prime positive integers a, b, prove by manipulating the diagonal matrix with entries a, b that $C_{ab} \cong C_a \oplus C_b$; discuss what happens when the coprimality hypothesis is dropped.

Artin 7.7 For $R = \mathbb{Z}[i]$, write as a direct sum of cyclic modules the R-module on generators v_1, v_2 with relations $(1 + i)v_1 + (2 - i)v_2 = 0$, $3v_1 + 5iv_2 = 0$.

Artin 7.8 For $F = \mathbb{F}_p$, determine for which primes p the additive group F^1 admits a $\mathbb{Z}[i]$-module structure, and likewise for F^2.

Artin 7.9 Show that a $\mathbb{Z}[i]$-module is equivalent to an abelian group V together with a homomorphism $\varphi : V \to V$ satisfying $\varphi \circ \varphi = -\mathrm{id}$.

Artin 8.2 For a $\mathbb{C}[t]$-module of the form $\mathbb{C}[t]/(t-a)^n$, show there is a $\mathbb{C}$-basis in which the matrix of the corresponding linear operator is a Jordan block.

Artin 8.3 For $R = F[x]$ and V the R-module on a generator v with relation $(x^3 + 3x + 2)v = 0$, choose an F-basis and find the matrix of multiplication by x.

Artin 8.4 For an $F[t]$-module V with F-basis $(v_1, \ldots, v_n)$ and B the matrix of T, prove $A = tI - B$ is a presentation matrix for the module.

Artin 8.6 Classify finitely generated modules over the ring $\mathbb{C}[\epsilon]$ where $\epsilon^2 = 0$.

Artin 9.2 Prove that the $\mathbb{C}[x, y]$-module with generators v_1, v_2, v_3, v_4 and relations $v_1 + yv_2 + xv_3 + x^2v_4 = 0$, $xv_1 + (x + 3)v_2 + yv_3 + y^2v_4 = 0$ is free by exhibiting a basis.

Artin M.3 For a finite abelian group A and a nontrivial homomorphism $\varphi : A \to \mathbb{C}^\times$, prove that $\sum_{a \in A} \varphi(a) = 0$.

Artin M.4 When an integer 2×2 matrix A is diagonalized as $Q^{-1}AP$, determine how unique the matrices P and Q are.

Artin M.7 Let S be a subring of $R = \mathbb{C}[t]$ containing $\mathbb{C}$ and not equal to $\mathbb{C}$. Prove that R is a finitely generated S-module.

Hard

DF 10.1.17 For the shift operator T on V with usual basis $e_1, \ldots, e_n$ and $m \geq n$, compute $(a_m x^m + a_{m-1}x^{m-1} + \cdots + a_0)e_n$.

DF 10.1.22 For an R-module A that is a ring with identity 1_A satisfying $r(ab) = (ra)b = a(rb)$, prove $f(r) = r \cdot 1_A$ is a ring homomorphism into the center of A, making A an R-algebra whose induced module structure is the original one.

DF 10.1.23 For $A = \mathbb{C} \times \mathbb{C}$, $\tau_1 = \mathrm{id}$, $\tau_2 =$ conjugation, and $f_{p,q}(z) = (\tau_p(z), \tau_q(z))$: prove each $f_{p,q}$ is an injective ring homomorphism agreeing on $\mathbb{R}$, giving four distinct $\mathbb{C}$-algebra structures; show distinct $f_{p,q}$ make the identity not a $\mathbb{C}$-algebra homomorphism; and show each structure is $\mathbb{C}$-algebra isomorphic to the natural one.

DF 10.2.13 For a nilpotent ideal I of commutative R and an R-module homomorphism $\varphi : M \to N$, show that if $\bar{\varphi} : M/IM \to N/IN$ is surjective then φ is surjective.

DF 10.2.14 For $R = \mathbb{Z}[x]$ and $A = \mathbb{Z}[\theta_1, \theta_2, \ldots]$, let $1 \in R$ act as the identity, for $n \geq 1$ let $x^n \circ 1 = \theta_n$ and $x^n \circ \theta_i = \theta_{n+i}$, let x^n act as 0 on monomials of total degree at least 2, and extend $\mathbb{Z}$-linearly in both variables: show that $x^{p+q} \circ \theta_i = x^p \circ (x^q \circ \theta_i)$ and that A is a (unital) R-module, and that $\varphi(r) = r \circ 1$ is an R-module homomorphism $R \to A$ with $\varphi(1) = 1$ that is not a ring homomorphism.

DF 10.3.2 For commutative R, prove $R^n \cong R^m$ iff $n = m$ (apply Exercise 10.2.12 with I a maximal ideal).

DF 10.3.8 For the ring S of eventually-zero integer sequences (direct sum of copies of $\mathbb{Z}$, no identity), prove S is not finitely generated as a module over itself.

DF 10.3.10 For commutative R, prove an R-module M is irreducible iff $M \cong R/I$ for a maximal ideal I.

DF 10.3.11 For irreducible R-modules M_1, M_2, prove any nonzero homomorphism $M_1 \to M_2$ is an isomorphism; deduce $\mathrm{End}_R(M)$ is a division ring (Schur's Lemma).

DF 10.3.17 For commutative R and pairwise comaximal ideals $A_1, \ldots, A_k$ of R, prove $M/(A_1 \cdots A_k)M \cong \prod_i M/A_i M$.

DF 10.3.18 For a PID R and a module M annihilated by (a) with $a = \prod_i p_i^{\alpha_i}$, prove $M = M_1 \oplus \cdots \oplus M_k$ where M_i is the p_i-primary component.

DF 10.3.19 For a finite abelian group M of order $\prod_i p_i^{\alpha_i}$, show as a $\mathbb{Z}$-module it is annihilated by (a), each primary component is the Sylow p_i-subgroup, and M is the direct product of its Sylow subgroups.

DF 10.3.20 For a PID R, a torsion R-module M, and a prime p, prove the p-primary component is a submodule, agrees with the earlier definition when M has nonzero annihilator, and that M is the (possibly infinite) direct sum of its p-primary components.

DF 10.3.22 For submodules N_i $(i \in I)$ of M, prove the equivalence of: the submodule generated by the N_i is their direct sum; finite intersections $N_{i_1} \cap (N_{i_2} + \cdots + N_{i_k}) = 0$; finite sums are direct; and unique finite representation of each element.

DF 10.3.23 Prove that an arbitrary direct product of free modules need not be free, using $M = \prod_{i \in \mathbb{Z}^+} \mathbb{Z}$ and the countable submodule of finitely-supported tuples.

DF 10.3.25 Show that the direct limit of R-modules A_i over R-module maps ρ_{ij} carries a natural R-module structure making the ρ_i homomorphisms, and verify its universal property.

DF 10.3.26 Carry out the analogue for inverse limits: an inverse limit of R-modules is an R-module satisfying the appropriate universal property.

DF 10.3.27 For $M = \mathbb{Z} \times \mathbb{Z} \times \cdots$, $R = \mathrm{End}_{\mathbb{Z}}(M)$, and $\varphi_1, \varphi_2 \in R$ given by $\varphi_1(a_1, a_2, \ldots) = (a_1, a_3, a_5, \ldots)$ and $\varphi_2(a_1, a_2, \ldots) = (a_2, a_4, a_6, \ldots)$, prove $\{\varphi_1, \varphi_2\}$ is a free basis of the left R-module R; deduce $R \cong R^2$ and hence $R \cong R^n$ for all n (free modules over noncommutative rings need not have unique rank).

DF 10.4.3 Show that $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$ and $\mathbb{C} \otimes_{\mathbb{C}} \mathbb{C}$ are both left $\mathbb{R}$-modules but are not isomorphic as $\mathbb{R}$-modules.

DF 10.4.6 For an integral domain R with fraction field Q, prove $(Q/R) \otimes_R (Q/R) = 0$.

DF 10.4.8 For an integral domain R with fraction field Q and an R-module N, construct $U^{-1}N$ (localization at $U = R \setminus \{0\}$), prove it is an R-module, prove $Q \otimes_R N \cong U^{-1}N$, deduce $(1/d) \otimes n = 0$ iff $rn = 0$ for some nonzero r, and conclude $\mathbb{Q} \otimes_{\mathbb{Z}} A = 0$ iff A is torsion.

DF 10.4.9 For an integral domain R with fraction field Q and an R-module N, prove the kernel of $\iota : N \to Q \otimes_R N$ is the torsion submodule of N.

DF 10.4.10 For commutative R and free $N \cong R^n$ with basis $e_1, \dots, e_n$: prove every element of $M \otimes N$ is uniquely $\sum_i m_i \otimes e_i$, and show this uniqueness fails for merely linearly independent n_i (use $R = \mathbb{Z}$, $M = \mathbb{Z}/2\mathbb{Z}$, $1 \otimes 2$).

DF 10.4.15 Show that tensor products do not commute with direct products in general, using extension of scalars from $\mathbb{Z}$ to $\mathbb{Q}$ of $\prod_i \mathbb{Z}/2^i\mathbb{Z}$.

DF 10.4.17 For $I = (2, x) \subseteq \mathbb{Z}[x]$ and $R/I = \mathbb{Z}/2\mathbb{Z}$: show $\varphi(p, q) = \frac{a_0}{2} b_1 \bmod 2$ is R-bilinear, induce a homomorphism $I \otimes_R I \to \mathbb{Z}/2\mathbb{Z}$ sending $p \otimes q \mapsto \frac{p(0)}{2} q'(0)$, and conclude $2 \otimes x \neq x \otimes 2$ in $I \otimes_R I$.

DF 10.4.19 For $I = (2, x) \subseteq \mathbb{Z}[x]$, show $2 \otimes x - x \otimes 2$ is a nonzero torsion element of $I \otimes_R I$ annihilated by both 2 and x, generating a submodule isomorphic to R/I.

DF 10.4.22 Verify that the multiplication of Proposition 21 makes $A \otimes_R B$ into an R-algebra.

DF 10.4.25 For a commutative ring $S \supseteq R$ with $1_S = 1_R$ and independent indeterminates $x_1, \dots, x_n$, prove $S \otimes_R (R[x_1, \dots, x_n]/I) \cong S[x_1, \dots, x_n]/IS[x_1, \dots, x_n]$ as S-algebras for every ideal I.

DF 10.4.26 For $A = \mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$: write the multiplication formula in the basis $1, e_2, e_3, e_4$; show $\epsilon_1 = \frac{1}{2}(1 \otimes 1 + i \otimes i)$, $\epsilon_2 = \frac{1}{2}(1 \otimes 1 - i \otimes i)$ are orthogonal idempotents with $A \cong A\epsilon_1 \times A\epsilon_2$; and build an explicit $\mathbb{C}$-algebra isomorphism $A \cong \mathbb{C} \times \mathbb{C}$.

DF 10.5.1 For a commutative diagram with exact rows $A \xrightarrow{\psi} B \xrightarrow{\varphi} C$ and $A' \xrightarrow{\psi'} B' \xrightarrow{\varphi'} C'$ and vertical maps α, β, γ, prove: if φ, α are surjective and β is injective then γ is injective; if ψ', α, γ are injective then β is injective; if φ, α, γ are surjective then β is surjective; if β is surjective and γ, ψ' are injective then α is surjective.

DF 10.5.2 For the two-row commutative ladder with five vertical maps and exact rows, prove: if α is surjective and β, δ injective then γ is injective; and if ε is injective and β, δ surjective then γ is surjective (the Five Lemma).

DF 10.5.5 Prove $A_1 \oplus A_2$ is flat iff both are flat, and more generally an arbitrary direct sum $\bigoplus_i A_i$ is flat iff each A_i is flat.

DF 10.5.6 Prove that for a ring R, every R-module is projective iff every R-module is injective.

DF 10.5.8 For a nonzero divisible $\mathbb{Z}$-module Q, prove Q is not projective; deduce $\mathbb{Q}$ is not a projective $\mathbb{Z}$-module.

DF 10.5.14 For $0 \to L \to M \to N \to 0$, prove the induced sequence $0 \to \mathrm{Hom}_R(D, L) \to \mathrm{Hom}_R(D, M) \to \mathrm{Hom}_R(D, N) \to 0$ is exact for all D iff the original sequence splits, and the dual statement for $\mathrm{Hom}_R(-, D)$.

DF 10.5.15 For a left R-module M, show $\mathrm{Hom}_{\mathbb{Z}}(R, M)$ is a left R-module, prove a lifting-of-homomorphisms transfer property, and deduce that if Q is an injective $\mathbb{Z}$-module then $\mathrm{Hom}_{\mathbb{Z}}(R, Q)$ is an injective R-module.

DF 10.5.17 For an (R, R)-bimodule J, a left R-module A and $M = \mathrm{Hom}_R(J, A)$, prove $(r\varphi)(j) = \varphi(jr)$ makes M a left R-module, and that if A is injective and J is flat as a right R-module then M is injective.

DF 10.5.20 Prove $\mathbb{Q}$ is the injective hull of the $\mathbb{Z}$-module $\mathbb{Z}$, with $\mathbb{Z}$ embedded as an essential submodule.

DF 10.5.23 Prove the injective hull of $\mathbb{Z}/p^n\mathbb{Z}$ equals that of $\mathbb{Z}/p\mathbb{Z}$, and deduce that the injective hull of $\mathbb{Z}/p^n\mathbb{Z}$ is the Prüfer group $\mathbb{Z}[1/p]/\mathbb{Z}$, not $\mathbb{Q}/\mathbb{Z}$.

DF 10.5.24 If F is a field, prove the injective hull of $F[x]$ is the rational function field $F(x)$.

DF 10.5.25 Prove that the polynomial ring $R[x]$ over a commutative ring R is a flat R-module.

DF 10.5.26 For rings R, S, a right R-module M flat over R, and an (R, S)-bimodule N flat as an S-module, prove $M \otimes_R N$ is flat as a right S-module.

DF 10.5.27 Prove A is flat iff for every finitely generated ideal I the map $A \otimes_R I \to A \otimes_R R \cong A$ induced by $I \subseteq R$ is injective.

DF 10.5.28 Prove the Flatness Criterion: A is flat iff for every finitely generated ideal I the map $A \otimes_R I \to A$, $a \otimes i \mapsto ai$, is injective; reduce via quotients, ascending unions, and Zorn's Lemma to free modules and conclude using the snake lemma.

DF 10.5.29 For $A = F/K$ with F flat, prove A is flat iff $K \cap FI = KI$ for every finitely generated ideal I.

DF 10.5.30 For submodules M, N of L, construct the pushout (fiber sum) $(M \oplus N)/X$ of α, β, verify its universal property, and show the pushout of the inclusions $M \cap N \hookrightarrow M$, $M \cap N \hookrightarrow N$ is isomorphic to $M + N$.

DF 10.5.31 Prove Schanuel's Lemma: for exact $0 \to K \to P \to M \to 0$ and $0 \to K' \to P' \to M \to 0$ with P, P' projective, $K \oplus P' \cong K' \oplus P$; conclude K and K' are projectively equivalent.

Artin 2.2 Prove that a ring R over which every finitely generated module is free is either a field or the zero ring.

Artin 2.3 For the matrix A of a homomorphism $\varphi : \mathbb{Z}^n \to \mathbb{Z}^m$ of free $\mathbb{Z}$-modules, prove φ is injective iff $\operatorname{rank}(A) = n$ over $\mathbb{R}$, and surjective iff the gcd of the $m \times m$ minors of A is 1.

Artin 9.5 For $R = \mathbb{Z}[\sqrt{-5}]$ and the module V presented by the matrix $A = \begin{pmatrix} 2 & 1-\sqrt{-5} \\ 1+\sqrt{-5} & 3 \end{pmatrix}$, prove the residue of A in R/P has rank 1 for every prime ideal P, yet V is not a free module.

Artin M.5 Determine which matrices $A \in \mathrm{GL}_2(\mathbb{R})$ stabilize some lattice L in $\mathbb{R}^2$.

Artin M.6 (a) Describe the orbits of right multiplication by $G = \mathrm{GL}_2(\mathbb{Z})$ on the space of 2×2 integer matrices. (b) Show that for any integer matrix A there is an invertible integer matrix P with AP in Hermite normal form.

Artin M.8 For a complex number α, prove α is an algebraic integer iff $\mathbb{Z}[\alpha]$ is a finitely generated abelian group; deduce $\mathbb{Z}[\alpha, \beta]$ is finitely generated for algebraic integers α, β, and hence the algebraic integers form a subring of $\mathbb{C}$.

Artin M.9 For a lattice L in Euclidean space with dual $L^* = \{w \mid (v \cdot w) \in \mathbb{Z}\ \forall v \in L\}$: show L has a lattice basis, L^* is a lattice, describe a basis of L^* in terms of one for L, determine when $L \subseteq L^*$, and find $[L^* : L]$ when $L \subseteq L^*$.

Artin M.10 Prove that the multiplicative group $\mathbb{Q}^\times$ is the direct sum of a cyclic group of order 2 and a free abelian group of countable rank; prove the additive group $\mathbb{Q}$ is not a direct sum of two proper subgroups; and prove $\mathbb{Q}/\mathbb{Z}$ is not a direct sum of cyclic groups.

Chapter 11

Vector Spaces

11.1 Definitions and Basic Theory

Vector spaces and subspaces

Throughout, F denotes a field; its elements are called *scalars*. A vector space over F is, axiomatically, just a unital module over F (D&F Chapter 10), but because F is a field every such module behaves far better than a general module: it always has a basis, its "size" is a single well-defined number, and a linear map is pinned down by its action on a basis. The whole of linear algebra is the unwinding of these facts.

Definition 11.1.1 (Vector space over F)**.** A *vector space over F* (or *F-vector space*) is an abelian group $(V,+)$ together with a scalar action $F\times V\to V$, $(\alpha,v)\mapsto \alpha v$, such that for all $\alpha,\beta\in F$ and all $v,w\in V$:

(V1) $(\alpha+\beta)v=\alpha v+\beta v$;

(V2) $(\alpha\beta)v=\alpha(\beta v)$;

(V3) $\alpha(v+w)=\alpha v+\alpha w$;

(V4) $1\,v=v$.

Elements of V are called *vectors*. A map $T\colon V\to W$ of F-vector spaces is *F-linear* (a *linear transformation*) if $T(\alpha v+\beta w)=\alpha T(v)+\beta T(w)$ for all $\alpha,\beta\in F$, $v,w\in V$. We write $\mathrm{Hom}_F(V,W)$ for the set of all such maps, $\mathrm{End}_F(V)=\mathrm{Hom}_F(V,V)$, and $V^*=\mathrm{Hom}_F(V,F)$ for the *dual space*.

Remark 11.1.1. The familiar cancellations $0v=0$, $\alpha 0=0$, and $(-1)v=-v$ hold by the module arguments: $0v=(0+0)v=0v+0v$; $\alpha 0=\alpha(0+0)=\alpha 0+\alpha 0$; and $0=0v=(1+(-1))v=v+(-1)v$. Over a field there is one more, decisive consequence: if $\alpha v=0$ then either $\alpha=0$ or $v=0$. Indeed if $\alpha\neq 0$ then $v=1v=(\alpha^{-1}\alpha)v=\alpha^{-1}(\alpha v)=\alpha^{-1}0=0$. This "no zero divisors for scalar action" is exactly what fails for modules over a ring with zero divisors, and it is the engine behind every uniqueness statement below.

Definition 11.1.2 (Subspace)**.** A subset $W\subseteq V$ is a *subspace* (written $W\leq V$) if W is nonempty and closed under addition and scalar multiplication: for all $\alpha\in F$ and $w_1,w_2\in W$, both $w_1+w_2\in W$ and $\alpha w_1\in W$. Equivalently, $W\neq\varnothing$ and $\alpha w_1+w_2\in W$ for all $\alpha\in F$, $w_1,w_2\in W$. A subspace is itself a vector space under the restricted operations.

Worked Example 11.1.3 (The one-step subspace test on $\mathbb{R}^3$)**.** Decide whether $W=\{\,(x,y,z)\in\mathbb{R}^3 : x-2y+z=0\,\}$ is a subspace of $\mathbb{R}^3$, and whether $U=\{\,(x,y,z) : x-2y+z=1\,\}$ is.

Recognition. Use the one-step test: a nonempty subset is a subspace iff it is closed under αw_1+w_2. A defining equation that is *homogeneous* (right side 0) survives this closure; an inhomogeneous one (right side 1) does not, because it fails to contain 0.

Solution. W contains $0=(0,0,0)$ since $0-0+0=0$, so $W\neq\varnothing$. If $w_1=(x_1,y_1,z_1)$, $w_2=(x_2,y_2,z_2)$ lie in W and $\alpha\in\mathbb{R}$, then the coordinate satisfying the test is

$$(x_1-2y_1+z_1)\alpha+(x_2-2y_2+z_2)=\alpha\cdot 0+0=0,$$

so $\alpha w_1 + w_2 \in W$. Hence $W \leq \mathbb{R}^3$. For U: $0 \notin U$ because $0 - 0 + 0 = 1$ is false, so U is not even nonempty-with-zero; concretely $(1,0,0) \in U$ but $2 \cdot (1,0,0) = (2,0,0)$ has $2 - 0 + 0 = 2 \neq 1$, so U is not closed. *Check.* W is the kernel of the linear functional $(x,y,z) \mapsto x - 2y + z$, a plane through the origin — exactly the shape a subspace of $\mathbb{R}^3$ should have.

Worked Example 11.1.4 (Subspaces of Hom and a non-subspace)**.** Inside $\mathrm{End}_{\mathbb{R}}(\mathbb{R}^2) \cong \mathrm{M}_2(\mathbb{R})$, show the symmetric matrices $S = \{\, A : A^{\mathsf{T}} = A \,\}$ form a subspace, and the invertible matrices do not.

Recognition. One-step test again, now in a function/matrix space; transpose is $\mathbb{R}$-linear, so the symmetry condition is homogeneous. "Invertible" is multiplicative, not additive, so expect failure.

Solution. $S \neq \varnothing$ (it contains 0). If $A^{\mathsf{T}} = A$, $B^{\mathsf{T}} = B$, $\alpha \in \mathbb{R}$, then $(\alpha A + B)^{\mathsf{T}} = \alpha A^{\mathsf{T}} + B^{\mathsf{T}} = \alpha A + B$, so S is a subspace; in fact $S = \mathrm{Span}(E_{11}, E_{22}, E_{12} + E_{21})$ has dimension 3. The invertible matrices fail closure under addition: I and $-I$ are invertible but $I + (-I) = 0$ is not. *Check.* A subspace must contain 0; the zero matrix is never invertible, so the invertible set can never be a subspace — consistent with the failure we found.

Proposition 11.1.5 (Intersections and sums)**.** *Let $\{\, W_i \,\}_{i \in I}$ be a family of subspaces of V. Then $\bigcap_{i \in I} W_i$ is a subspace. The* sum $W_1 + \cdots + W_k = \{\, w_1 + \cdots + w_k : w_j \in W_j \,\}$ *is a subspace, and is the smallest subspace containing every W_j. (The union of subspaces is in general* not *a subspace.)*

Proof. Each contains 0, hence is nonempty. For the intersection, if $v, w \in \bigcap W_i$ and $\alpha \in F$, then $\alpha v + w \in W_i$ for every i since each W_i is a subspace; thus $\alpha v + w \in \bigcap W_i$. For the sum, given two elements $\sum_j w_j$ and $\sum_j w'_j$ and $\alpha \in F$, the combination $\alpha \sum_j w_j + \sum_j w'_j = \sum_j (\alpha w_j + w'_j)$ has j-th term in W_j, so lies in the sum. Any subspace containing all W_j must contain all such finite sums, so the sum is the smallest such subspace. □

Span and linear (in)dependence

Definition 11.1.6 (Linear combination and span)**.** Let $A \subseteq V$. A *linear combination* of A is a vector $\alpha_1 v_1 + \cdots + \alpha_n v_n$ with $n \geq 0$, $v_i \in A$, $\alpha_i \in F$. The *span* of A,

$$\mathrm{Span}(A) = \{\, \textstyle\sum_{i=1}^{n} \alpha_i v_i : n \geq 0,\ v_i \in A,\ \alpha_i \in F \,\},$$

is the set of all linear combinations of finitely many elements of A; it is the smallest subspace of V containing A (the empty combination gives 0, so $\mathrm{Span}(\varnothing) = \{\, 0 \,\}$). We say A *spans* (or *generates*) V if $\mathrm{Span}(A) = V$.

Definition 11.1.7 (Linear dependence and independence)**.** A set $A \subseteq V$ is *linearly dependent* if there exist distinct $v_1, \ldots, v_n \in A$ and scalars $\alpha_1, \ldots, \alpha_n \in F$ *not all zero* with $\alpha_1 v_1 + \cdots + \alpha_n v_n = 0$. Otherwise A is *linearly independent*: the only way to write 0 as a finite combination of distinct elements of A is with all coefficients 0.

Remark 11.1.2. Independence is exactly a *uniqueness of representation* statement: A is independent iff every vector in $\mathrm{Span}(A)$ is a linear combination of elements of A in at most one way. Indeed if $\sum \alpha_i v_i = \sum \beta_i v_i$ then $\sum (\alpha_i - \beta_i) v_i = 0$, so independence forces $\alpha_i = \beta_i$; conversely a nontrivial relation gives two representations of 0.

Worked Example 11.1.8 (Independence over $\mathbb{R}$ via a determinant)**.** Are $v_1 = (1,2,1)$, $v_2 = (2,1,0)$, $v_3 = (1,-1,1)$ linearly independent in $\mathbb{R}^3$?

Recognition. In F^n with n vectors, independence is equivalent to the matrix with these columns being invertible, i.e. having nonzero determinant: $\det \neq 0 \iff$ independent.

Solution. Form $A = \left(\begin{smallmatrix} 1 & 2 & 1 \\ 2 & 1 & -1 \\ 1 & 0 & 1 \end{smallmatrix}\right)$ (columns v_1, v_2, v_3). Expanding along the bottom row,

$$\det A = 1 \cdot \det\left(\begin{smallmatrix} 2 & 1 \\ 1 & -1 \end{smallmatrix}\right) - 0 + 1 \cdot \det\left(\begin{smallmatrix} 1 & 2 \\ 2 & 1 \end{smallmatrix}\right) = 1(-2-1) + 1(1-4) = -3 - 3 = -6 \neq 0.$$

So the only solution of $\alpha_1 v_1 + \alpha_2 v_2 + \alpha_3 v_3 = 0$ is $\alpha = 0$, and the set is independent. *Check.* Since $\det A = -6 \neq 0$, A is invertible, so the three columns also *span* $\mathbb{R}^3$; three independent vectors in a 3-dimensional space ought to be a basis, as the next subsection confirms.

Worked Example 11.1.9 (Dependence over $\mathbb{F}_2$ that would be independence over $\mathbb{Q}$)**.** In $\mathbb{F}_2^3$ ($\mathbb{F}_2 = \mathbb{Z}/2\mathbb{Z}$) consider $v_1 = (1,1,0)$, $v_2 = (0,1,1)$, $v_3 = (1,0,1)$. Are they independent?

Recognition. The field matters: solve $\alpha_1 v_1 + \alpha_2 v_2 + \alpha_3 v_3 = 0$ with $\alpha_i \in \mathbb{F}_2$. A relation valid mod 2 need not be valid over $\mathbb{Q}$, and vice versa.

Solution. Try $\alpha_1 = \alpha_2 = \alpha_3 = 1$:

$$v_1 + v_2 + v_3 = (1{+}0{+}1,\ 1{+}1{+}0,\ 0{+}1{+}1) = (0,0,0) \text{ in } \mathbb{F}_2.$$

This is a nontrivial relation (coefficients all $1 \neq 0$), so the set is *dependent* over $\mathbb{F}_2$. *Check.* Over $\mathbb{Q}$ the same three vectors give $v_1 + v_2 + v_3 = (2,2,2) \neq 0$, and one checks $\det\left(\begin{smallmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{smallmatrix}\right) = 2 \neq 0$, so they are *independent* over $\mathbb{Q}$. The dependence appeared precisely because $2 \equiv 0$ in $\mathbb{F}_2$ — a vivid reminder that (in)dependence is relative to F.

Worked Example 11.1.10 (Functions: $\{1, \cos^2 x, \cos 2x\}$ in the space of real functions)**.** Show $\{1, \cos^2 x, \cos 2x\}$ is linearly dependent in the $\mathbb{R}$-vector space $C(\mathbb{R})$ of continuous functions, while $\{1, \cos x, \cos 2x\}$ is independent.

Recognition. A relation among functions must hold *for every* input x. Use a known identity to exhibit dependence; to prove independence, evaluate at enough points to force the coefficients to 0.

Solution. The identity $\cos 2x = 2\cos^2 x - 1$ rearranges to $1 \cdot 1 - 2 \cdot \cos^2 x + 1 \cdot \cos 2x = 0$ for all x — a nontrivial relation, so $\{1, \cos^2 x, \cos 2x\}$ is dependent. For $\{1, \cos x, \cos 2x\}$, suppose $a + b\cos x + c\cos 2x = 0$ for all x. Evaluate at $x = 0$: $a + b + c = 0$; at $x = \pi$: $a - b + c = 0$; at $x = \pi/2$: $a - c = 0$. From the first two, $b = 0$; then $a = -c$ and $a = c$, forcing $a = c = 0$. So all coefficients vanish and the set is independent. *Check.* The dependence used a genuine identity (true for *all* x), whereas the independence argument only needed three sample points to pin down three unknowns — exactly the count one expects.

Bases, the replacement lemma, and dimension

Definition 11.1.11 (Basis)**.** A subset $\mathcal{B} \subseteq V$ is a *basis* of V if $\mathcal{B}$ is linearly independent and $\operatorname{Span}(\mathcal{B}) = V$. Equivalently, every $v \in V$ is a linear combination of elements of $\mathcal{B}$ in exactly one way.

The single most useful property of a basis is the following universal property, which says a linear map "is whatever you want it to be on a basis," and nothing more.

Proposition 11.1.12 (Universal property of a basis)**.** *Let $\mathcal{B} = \{e_i\}_{i \in I}$ be a basis of V and let W be any F-vector space. For every function $f : \mathcal{B} \to W$ there is a unique F-linear map $T : V \to W$ with $T(e_i) = f(e_i)$ for all i. Pictorially, writing $\iota : \mathcal{B} \hookrightarrow V$ for the inclusion:*

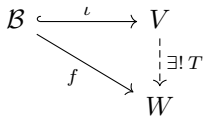


Diagram explanation. Objects: $\mathcal{B}$ is the basis (a set, not yet a vector space); V is the F-vector space spanned by $\mathcal{B}$; W is an arbitrary F-vector space. These are the two categories in play: on top sits the set-theoretic datum f, and below sits the linear-algebraic world where T must live.

Arrows: $\iota : \mathcal{B} \hookrightarrow V$ is the set-inclusion, not a linear map (its domain is a set, not a vector space). $f : \mathcal{B} \to W$ is any set-function, the freely chosen target values. $T : V \to W$ (dashed) is the unique F-linear map whose existence the proposition asserts; it is not given but constructed.

What commutes: The triangle commutes: $T \circ \iota = f$, i.e. $T(e_i) = f(e_i)$ for every $e_i \in \mathcal{B}$. This single equation, stated for set-elements of $\mathcal{B}$, determines T on all of V by linearity.

Why it commutes: Take any $v \in V$; write $v = \sum_i \alpha_i e_i$ (unique, since $\mathcal{B}$ is a basis). Then $T(v) = \sum_i \alpha_i T(e_i) = \sum_i \alpha_i f(e_i)$. Along the top-then-down path, $e_i \xrightarrow{\iota} e_i \xrightarrow{T} T(e_i) = f(e_i)$ by this formula, which is the value of the diagonal arrow f. Well-definedness (the reason T is a genuine function): the coefficients α_i are *unique* by linear independence, so the formula $T(v) = \sum \alpha_i f(e_i)$ depends only on v, not on any choice of representative.

Why this matters here: This diagram is the engine of all linear algebra: it says the set-function f on the basis is the *only* data needed to pin down the linear map T on all of V. Every matrix calculation, every change-of-basis argument, and every representation-theoretic construction reduces to specifying a map on a basis and invoking this universal property.

Concrete example: $\mathcal{B} = \{e_1, e_2\}$ standard basis of $\mathbb{R}^2$, $W = \mathbb{R}^3$, $f(e_1) = (1, 0, -1)$, $f(e_2) = (2, 1, 0)$. The unique linear T sends $(a, b) \mapsto a(1, 0, -1) + b(2, 1, 0)$, i.e. the matrix with columns $f(e_i)$; this is the worked example immediately following.

Common pitfall: Students sometimes think ι is a linear map and that the diagram is a composition of linear maps on the top edge. It is not: ι is a set inclusion and f is a set-function; only the dashed T is linear. The diagram lives in two categories simultaneously, and that is its whole point.

Takeaway: The point of this diagram is that specifying a linear map out of V is *equivalent* to specifying a set-function out of any basis of V, with uniqueness guaranteed by independence and existence guaranteed by spanning.

Proof. Existence. Each $v \in V$ has a unique expression $v = \sum_i \alpha_i e_i$ (finite sum) by the basis property; set $T(v) = \sum_i \alpha_i f(e_i)$. This is well defined precisely because the α_i are unique, and linearity is immediate from the coordinatewise definition. *Uniqueness.* Any linear T' agreeing with f on $\mathcal{B}$ satisfies $T'(v) = T'(\sum \alpha_i e_i) = \sum \alpha_i T'(e_i) = \sum \alpha_i f(e_i) = T(v)$. □

Worked Example 11.1.13 (Building a linear map from its values on a basis)**.** Let $\mathcal{B} = \{ e_1, e_2 \}$ be the standard basis of $\mathbb{R}^2$ and define $T\colon \mathbb{R}^2 \to \mathbb{R}^3$ by $T(e_1) = (1, 0, -1)$, $T(e_2) = (2, 1, 0)$. Compute $T(3, -2)$ and the matrix of T.

Recognition. By the universal property, naming T on a basis determines T everywhere; just expand the input in the basis and push the coefficients through.

Solution. Write $(3, -2) = 3e_1 - 2e_2$. Then

$$T(3, -2) = 3T(e_1) - 2T(e_2) = 3(1, 0, -1) - 2(2, 1, 0) = (3 - 4,\ 0 - 2,\ -3 - 0) = (-1, -2, -3).$$

The matrix (columns $= T(e_j)$) is $[\,T\,] = \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, and indeed $\left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)\left(\begin{smallmatrix} 3 \\ -2 \end{smallmatrix}\right) = \left(\begin{smallmatrix} -1 \\ -2 \\ -3 \end{smallmatrix}\right)$. *Check.* The two outputs agree, confirming the map computed abstractly equals the matrix computed concretely.

Lemma 11.1.14 (Replacement / Exchange Lemma)**.** *Suppose $A = \{ a_1, \dots, a_m \} \subseteq V$ is linearly independent and $S = \{ s_1, \dots, s_n \}$ spans V. Then $m \le n$, and one may reorder S so that $\{ a_1, \dots, a_m, s_{m+1}, \dots, s_n \}$ still spans V. In words: an independent set is never larger than a spanning set, and its members can be swapped in for spanning vectors one at a time.*

Proof. We exchange $a_1, \dots, a_m$ into S inductively, maintaining a spanning set of size n. Suppose for some $0 \le k < m$ we have a spanning set $\{ a_1, \dots, a_k, s_{k+1}, \dots, s_n \}$ (the case $k = 0$ is S). Since this set spans, write $a_{k+1} = \sum_{i \le k} \beta_i a_i + \sum_{j > k} \gamma_j s_j$. Not all γ_j are 0: otherwise $a_{k+1} \in \operatorname{Span}(a_1, \dots, a_k)$, contradicting independence of A. Reorder so $\gamma_{k+1} \neq 0$; then $s_{k+1} = \gamma_{k+1}^{-1}\big(a_{k+1} - \sum_{i \le k} \beta_i a_i - \sum_{j > k+1} \gamma_j s_j\big)$, so $s_{k+1} \in \operatorname{Span}(a_1, \dots, a_{k+1}, s_{k+2}, \dots, s_n)$, and replacing s_{k+1} by a_{k+1} keeps the set spanning. This requires a fresh s_j at each step, so we can never run out before exhausting A; hence $m \le n$. □

Theorem 11.1.15 (Invariance of dimension)**.** *If V has a finite basis, then any two bases of V have the same number of elements. This common number is the* dimension $\dim_F V$*. More generally (using the lemma in the infinite case via Zorn) any two bases of V have the same cardinality.*

Proof. Let $\mathcal{B} = \{ e_1, \dots, e_n \}$ be a finite basis and $\mathcal{B}'$ any basis. Every finite subset of $\mathcal{B}'$ is independent and $\mathcal{B}$ spans, so by the Replacement Lemma every finite subset of $\mathcal{B}'$ has at most n elements; hence $\mathcal{B}'$ is finite, say $\mathcal{B}' = \{ f_1, \dots, f_m \}$, and $m \le n$. Symmetrically ($\mathcal{B}$ independent, $\mathcal{B}'$ spanning) $n \le m$. Hence $n = m$. □

Theorem 11.1.16 (Existence of a basis, via Zorn's Lemma)**.** *Every vector space V has a basis. More precisely, every linearly independent subset $A \subseteq V$ is contained in a basis, and every spanning set contains a basis.*

Proof. Let $\mathcal{P}$ be the set of linearly independent subsets of V containing A, partially ordered by inclusion; $\mathcal{P} \neq \varnothing$ since $A \in \mathcal{P}$. Given a chain $\mathcal{C} \subseteq \mathcal{P}$, its union $U = \bigcup \mathcal{C}$ is independent: any finite relation involves finitely many vectors, all lying in a single member of the chain (chains are totally ordered), which is independent; so $U \in \mathcal{P}$ is an upper bound. By Zorn's Lemma $\mathcal{P}$ has a maximal element $\mathcal{B} \supseteq A$. If $\mathcal{B}$ failed to span, some $v \notin \operatorname{Span}(\mathcal{B})$ would make $\mathcal{B} \cup \{ v \}$ independent (a relation $\alpha v + \sum \alpha_i e_i = 0$ forces $\alpha = 0$ by $v \notin \operatorname{Span} \mathcal{B}$, then the rest $= 0$ by independence of $\mathcal{B}$), contradicting maximality. So $\mathcal{B}$ is a basis containing A. For the last assertion, let S span V and run the same argument with $\mathcal{P}$ the set of independent subsets of S (and $A = \varnothing$): a maximal one $\mathcal{B} \subseteq S$ contains every $s \in S$ in its span (otherwise $\mathcal{B} \cup \{ s \}$ would be a larger independent subset of S), so $\operatorname{Span}(\mathcal{B}) \supseteq \operatorname{Span}(S) = V$ and $\mathcal{B} \subseteq S$ is a basis. □

Worked Example 11.1.17 (Extending an independent set to a basis)**.** Extend $\{ (1,1,0), (0,1,1) \}$ to a basis of $\mathbb{R}^3$.

Recognition. By the existence theorem an independent set extends to a basis; concretely, adjoin standard vectors and test independence by a determinant until it is nonzero.

Solution. The two vectors are independent (neither is a scalar multiple of the other). Try adjoining $e_1 = (1,0,0)$ and form

$$\det\begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix} = 1 \cdot \det\begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix} - 0 + 1 \cdot \det\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = 0 + 1 \cdot 1 = 1 \neq 0.$$

So $\{ (1,1,0), (0,1,1), (1,0,0) \}$ is independent, and being three independent vectors in $\mathbb{R}^3$ it is a basis. *Check.* $\dim_{\mathbb{R}} \mathbb{R}^3 = 3$, and we produced exactly 3 independent vectors — the count matches, confirming we have a genuine basis.

Worked Example 11.1.18 (Dimension counts over different fields)**.** Compute dim in each case: $\mathrm{M}_2(\mathbb{F}_2)$ over $\mathbb{F}_2$; $\mathbb{C}$ over $\mathbb{R}$; $\mathbb{R}$ over $\mathbb{Q}$; and the space P_3 of real polynomials of degree ≤ 3, over $\mathbb{R}$.

Recognition. Find an explicit basis and count it; invariance of dimension guarantees the count is independent of the basis chosen.

Solution. $\mathrm{M}_2(\mathbb{F}_2)$ has basis $\{ E_{11}, E_{12}, E_{21}, E_{22} \}$, so $\dim_{\mathbb{F}_2} \mathrm{M}_2(\mathbb{F}_2) = 4$ (and the space has $2^4 = 16$ elements). $\mathbb{C} = \mathbb{R} \cdot 1 \oplus \mathbb{R} \cdot i$ has basis $\{ 1, i \}$, so $\dim_{\mathbb{R}} \mathbb{C} = 2$. P_3 has basis $\{ 1, x, x^2, x^3 \}$, so $\dim_{\mathbb{R}} P_3 = 4$. Finally $\dim_{\mathbb{Q}} \mathbb{R} = \infty$: a finite basis would make $\mathbb{R}$ countable (finitely many rational coordinates), but $\mathbb{R}$ is uncountable. *Check.* For $\mathrm{M}_2(\mathbb{F}_2)$, $|\mathrm{M}_2(\mathbb{F}_2)| = |\mathbb{F}_2|^{\dim} = 2^4 = 16$, matching the direct count of 2×2 binary matrices.

Corollary 11.1.19. *Let $\dim_F V = n < \infty$. Then: (i) any independent set has $\leq n$ elements, with equality iff it is a basis; (ii) any spanning set has $\geq n$ elements, with equality iff it is a basis; (iii) any n vectors that are independent, or that span, form a basis.*

Proof. Both bounds are the Replacement Lemma applied against a fixed basis of size n. If an independent set has exactly n elements but failed to span, it would extend (by the existence theorem) to a strictly larger independent set, exceeding n — impossible; so it is a basis. Dually, a spanning set of exactly n elements that were dependent would contain a basis of size $< n$, contradicting invariance. Part (iii) is the equality cases of (i),(ii). □

Isomorphism and dimension

Theorem 11.1.20 (Classification by dimension)**.** *Two F-vector spaces V, W are isomorphic ($V \cong W$) if and only if $\dim_F V = \dim_F W$. In particular every n-dimensional space is isomorphic to F^n via a choice of basis.*

Proof. ($\Rightarrow$) An isomorphism $T \colon V \to W$ carries a basis of V to a basis of W (it preserves both independence and spanning, being bijective and linear), so the dimensions agree. ($\Leftarrow$) Pick bases $\mathcal{B} = \{ e_i \}$ of V and $\mathcal{C} = \{ f_i \}$ of W indexed by the same set. By the universal property the assignment $e_i \mapsto f_i$ extends to a linear map $T \colon V \to W$, and $f_i \mapsto e_i$ to a linear $S \colon W \to V$; both composites fix basis elements, hence equal the identity, so T is an isomorphism. □

Worked Example 11.1.21 ($P_3 \cong \mathbb{R}^4$ explicitly)**.** Exhibit an isomorphism $P_3 \to \mathbb{R}^4$ and use it to test whether $\{ 1 + x,\ x + x^2,\ x^2 + x^3,\ 1 + x^3 \}$ is a basis of P_3.

Recognition. Both spaces are 4-dimensional, so they are isomorphic; the coordinate map sending a polynomial to its coefficient vector is the canonical such isomorphism, and it turns a basis question into a determinant.

Solution. Define $\Phi(a+bx+cx^2+dx^3)=(a,b,c,d)$; it is linear with inverse $(a,b,c,d)\mapsto a+bx+cx^2+dx^3$, so Φ is an isomorphism. Under Φ the four polynomials become the columns of

$$M=\begin{pmatrix}1&0&0&1\\1&1&0&0\\0&1&1&0\\0&0&1&1\end{pmatrix}.$$

Compute by cofactor along the first row:

$$\det M = 1\cdot\det\begin{pmatrix}1&0&0\\1&1&0\\0&1&1\end{pmatrix}+1\cdot(-1)^{1+4}\det\begin{pmatrix}1&1&0\\0&1&1\\0&0&1\end{pmatrix}=1\cdot 1-1\cdot 1=0.$$

Since $\det M=0$, the images are dependent, so the original set is *not* a basis. *Check.* Indeed $(1+x)-(x+x^2)+(x^2+x^3)-(1+x^3)=0$, an explicit dependence relation, confirming $\det M=0$.

The dimension formula, direct sums, and quotients

Theorem 11.1.22 (Dimension formula for sums)**.** *If U,W are finite-dimensional subspaces of V, then*

$$\dim(U+W)=\dim U+\dim W-\dim(U\cap W).$$

Proof. Choose a basis $\{x_1,\dots,x_k\}$ of $U\cap W$ ($k=\dim(U\cap W)$). Extend it (existence theorem) to a basis $\{x_1,\dots,x_k,u_1,\dots,u_p\}$ of U and to a basis $\{x_1,\dots,x_k,w_1,\dots,w_q\}$ of W, so $\dim U=k+p$, $\dim W=k+q$. We claim $\mathcal{B}=\{x_1,\dots,x_k,u_1,\dots,u_p,w_1,\dots,w_q\}$ is a basis of $U+W$. It spans, since every element of $U+W$ is a sum of an element of U and one of W. For independence, suppose $\sum\alpha_i x_i+\sum\beta_j u_j+\sum\gamma_l w_l=0$. Then $\sum\gamma_l w_l=-\sum\alpha_i x_i-\sum\beta_j u_j\in U\cap W$, so $\sum\gamma_l w_l\in\operatorname{Span}(x_1,\dots,x_k)$; but $\{x_i,w_l\}$ is independent in W, forcing all $\gamma_l=0$. The remaining relation $\sum\alpha_i x_i+\sum\beta_j u_j=0$ is in the basis of U, so all $\alpha_i,\beta_j=0$. Thus $|\mathcal{B}|=k+p+q$ and

$$\dim(U+W)=k+p+q=(k+p)+(k+q)-k=\dim U+\dim W-\dim(U\cap W).\qquad\square$$

Definition 11.1.23 (Direct sum)**.** V is the *(internal) direct sum* $V=U\oplus W$ if $V=U+W$ and $U\cap W=\{0\}$; equivalently every $v\in V$ is uniquely $v=u+w$ with $u\in U$, $w\in W$. When V is finite-dimensional, $V=U\oplus W$ implies $\dim V=\dim U+\dim W$ by the formula above (the $\dim(U\cap W)=0$ case).

Worked Example 11.1.24 (The dimension formula on two planes in $\mathbb{R}^3$)**.** Let $U=\{(x,y,z):z=0\}$ and $W=\{(x,y,z):x=0\}$ in $\mathbb{R}^3$. Compute $\dim(U+W)$ and $\dim(U\cap W)$ and verify the formula.

Recognition. Both summands are 2-dimensional planes; find $U\cap W$ directly, then read off $U+W$ from the formula and confirm against an explicit basis.

Solution. $U=\operatorname{Span}((1,0,0),(0,1,0))$ and $W=\operatorname{Span}((0,1,0),(0,0,1))$, so $\dim U=\dim W=2$. Their intersection is $\{(x,y,z):z=0,\,x=0\}=\operatorname{Span}((0,1,0))$, so $\dim(U\cap W)=1$. The formula predicts $\dim(U+W)=2+2-1=3$, i.e. $U+W=\mathbb{R}^3$. *Check.* $U+W$ contains $(1,0,0),(0,1,0),(0,0,1)$, hence is all of $\mathbb{R}^3$ — dimension 3, matching. Note the sum is *not* direct since $U\cap W\neq\{0\}$, consistent with $3<2+2$.

Worked Example 11.1.25 (A genuine direct-sum decomposition of M_n)**.** Show $\mathrm{M}_n(\mathbb{R})=S\oplus K$ where S is the symmetric and K the skew-symmetric matrices, and check the dimension count for $n=3$.

Recognition. "Unique decomposition $v=u+w$" is the definition of a direct sum; produce the decomposition explicitly and verify $S\cap K=\{0\}$, then count.

Solution. For any A write $A=\frac{1}{2}(A+A^{\mathsf{T}})+\frac{1}{2}(A-A^{\mathsf{T}})$; the first summand is symmetric, the second skew, so $\mathrm{M}_n=S+K$. If $A\in S\cap K$ then $A^{\mathsf{T}}=A$ and $A^{\mathsf{T}}=-A$, so $A=-A$, i.e. $2A=0$, hence $A=0$ (char $\mathbb{R}\neq 2$). Thus $S\cap K=\{0\}$ and $\mathrm{M}_n(\mathbb{R})=S\oplus K$. Dimensions: $\dim S=\binom{n+1}{2}$, $\dim K=\binom{n}{2}$. *Check ($n=3$).* $\dim S=6$, $\dim K=3$, and $6+3=9=\dim\mathrm{M}_3(\mathbb{R})$, exactly n^2 — the direct-sum count holds.

Definition 11.1.26 (Quotient space)**.** Let $W\le V$. The *quotient space* V/W is the abelian group of cosets $v+W$ with scalar action $\alpha(v+W)=\alpha v+W$. This is well defined (if $v+W=v'+W$ then $v-v'\in W$, so $\alpha v-\alpha v'=\alpha(v-v')\in W$) and makes V/W an F-vector space. The map $\pi\colon V\to V/W$, $\pi(v)=v+W$, is linear and surjective with $\ker\pi=W$.

The quotient is characterized by a universal property dual to that of a basis: it is the universal target that kills W.

Proposition 11.1.27 (Universal property of the quotient)**.** *Let $W \leq V$ and $\pi\colon V \to V/W$ the projection. For any linear $T\colon V \to U$ with $W \subseteq \ker T$, there is a unique linear $\bar{T}\colon V/W \to U$ with $\bar{T} \circ \pi = T$:*

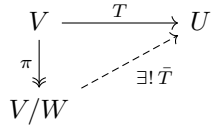

Diagram explanation. Objects: V is an F-vector space; W is a subspace; V/W is the quotient space (cosets $v + W$ with F-action $\alpha(v + W) = \alpha v + W$); U is an arbitrary F-vector space serving as the target.

Arrows: $\pi\colon V \to V/W$ is the canonical projection, $\pi(v) = v + W$, linear and surjective with $\ker \pi = W$. $T\colon V \to U$ is any linear map satisfying $W \subseteq \ker T$ (the hypothesis). $\bar{T}\colon V/W \to U$ (dashed) is the unique induced linear map defined by $\bar{T}(v + W) = T(v)$.

What commutes: The triangle commutes: $\bar{T} \circ \pi = T$, that is, for every $v \in V$, $\bar{T}(v + W) = T(v)$. Equivalently, the composition down-then-diagonally-up equals the horizontal map T.

Why it commutes: Well-definedness is the essential check: if $v + W = v' + W$, then $v - v' \in W \subseteq \ker T$, so $T(v) = T(v')$. Hence the formula $\bar{T}(v + W) := T(v)$ does not depend on the choice of coset representative. Once well-definedness holds, commutativity is the definition: $(\bar{T} \circ \pi)(v) = \bar{T}(v + W) = T(v)$. Uniqueness follows because π is surjective: any S with $S \circ \pi = T$ must satisfy $S(v + W) = S(\pi(v)) = T(v) = \bar{T}(v + W)$ for all v.

Why this matters here: This diagram encodes the condition $W \subseteq \ker T$ as a *factorization*: T passes through V/W if and only if W is killed. It justifies the first isomorphism theorem (take $W = \ker T$, then $\bar{T}$ is injective) and rank–nullity ($\dim V/\ker T = \dim \operatorname{im} T$). It is the key step in the proof that $\dim(V/W) = \dim V - \dim W$.

Concrete example: $V = \mathbb{R}^3$, $W = \operatorname{Span}((1, 1, 1))$, $T(x, y, z) = (x - y, y - z)$: then $\ker T = W$, so T factors as $\bar{T}\colon \mathbb{R}^3/W \xrightarrow{\sim} \mathbb{R}^2$. The coset $(e_1 + W)$ maps to $(1, 0)$; this is the worked example that follows the theorem.

Common pitfall: The condition $W \subseteq \ker T$ is necessary for well-definedness, not a consequence of the diagram. If $W \not\subseteq \ker T$, the formula $\bar{T}(v + W) = T(v)$ gives different values for different representatives, and $\bar{T}$ is not a function at all. Students sometimes draw the diagram without checking this condition first.

Takeaway: The point of this diagram is that V/W is the *universal* way to kill the subspace W: every linear map out of V that vanishes on W factors uniquely through the quotient projection.

Proof. Define $\bar{T}(v + W) = T(v)$. Well defined: if $v + W = v' + W$ then $v - v' \in W \subseteq \ker T$, so $T(v) = T(v')$. Linearity is inherited from T, and $\bar{T}\pi(v) = T(v)$. Uniqueness: any S with $S\pi = T$ satisfies $S(v + W) = S\pi(v) = T(v) = \bar{T}(v + W)$. □

Theorem 11.1.28 (Dimension of a quotient and rank–nullity)**.** *If $\dim V < \infty$ and $W \leq V$, then $\dim(V/W) = \dim V - \dim W$. Consequently, for any linear $T\colon V \to U$ the first isomorphism theorem gives $V/\ker T \cong \operatorname{im} T$ and hence*

$$\dim V = \dim \ker T + \dim \operatorname{im} T \qquad (\textit{rank–nullity}),$$

encoded by the short exact sequence

$$0 \longrightarrow \ker T \xhookrightarrow{\iota} V \xrightarrow{T} \operatorname{im} T \longrightarrow 0.$$

Diagram explanation. Objects: Five nodes on a horizontal line: 0 (the trivial vector space, appearing at both ends), $\ker T$ (the kernel of T, a subspace of V), V (the domain), and $\operatorname{im} T$ (the image of T, a subspace of U). This is a short exact sequence of F-vector spaces and linear maps.

Arrows: $0 \to \ker T$ is the unique map from the zero space (sends 0 to 0, trivially injective). $\iota\colon \ker T \hookrightarrow V$ is the subspace inclusion, injective by definition. $T\colon V \to \operatorname{im} T$ is the linear map T corestricted to its image, surjective by construction. $\operatorname{im} T \to 0$ is the unique map to the zero space, trivially surjective.

What commutes: Exactness conditions at each node: (1) at $\ker T$: $\operatorname{im}(0 \to \ker T) = \{0\} = \ker(\iota)$, i.e. ι is injective; (2) at V: $\operatorname{im}(\iota) = \ker T = \ker(T)$, the key condition; (3) at $\operatorname{im} T$: $\operatorname{im}(T) = \operatorname{im} T = \ker(\operatorname{im} T \to 0)$, i.e. T is surjective onto $\operatorname{im} T$. A sequence is called *exact* because im = ker at every internal node.

Why it commutes: At the critical middle node: the image of ι is exactly $\ker T$ (by definition of kernel and the inclusion), and $\ker(T\colon V \to \operatorname{im} T) = \ker T$ (since any v mapping to $0 \in \operatorname{im} T$ satisfies $T(v) = 0$). The two sets agree, giving $\operatorname{im} \iota = \ker T$. No element-chasing is needed beyond the definitions.

Why this matters here: The short exact sequence is the diagrammatic encoding of rank–nullity: a short exact sequence $0 \to A \to B \to C \to 0$ of finite-dimensional vector spaces satisfies $\dim B = \dim A + \dim C$ (since it splits). Applying this here gives $\dim V = \dim \ker T + \dim \operatorname{im} T$, i.e. $\text{nullity}(T) + \text{rank}(T) = \dim V$. The diagram says in one picture what the formula says in words.

Concrete example: $T\colon \mathbb{Q}^4 \to \mathbb{Q}^3$ with $\operatorname{rank} T = 2$: the sequence is $0 \to \mathbb{Q}^2 \to \mathbb{Q}^4 \to \mathbb{Q}^2 \to 0$ (abstractly), with $\dim \ker T = 2$ and $\dim \operatorname{im} T = 2$, summing to $4 = \dim \mathbb{Q}^4$, as worked in the example following this theorem.

Common pitfall: Students sometimes conflate $\operatorname{im} T \subseteq U$ with U itself, writing the sequence as $0 \to \ker T \to V \to U \to 0$. That sequence is exact only when T is surjective. The correct sequence uses $\operatorname{im} T$, not U, at the right end, so that the last map is surjective by construction.

Takeaway: The point of this diagram is that rank–nullity is not just a formula but a structural statement: V fits exactly between its kernel and its image, with no overlap and no gap, as captured by the exactness conditions im = ker at all three internal nodes.

Proof. Take a basis $\{ w_1, \dots, w_k \}$ of W and extend to a basis $\{ w_1, \dots, w_k, v_1, \dots, v_m \}$ of V, so $\dim V = k+m$. The cosets $\{ v_1 + W, \dots, v_m + W \}$ span V/W (the $w_i + W = 0$) and are independent: $\sum \beta_j (v_j + W) = 0$ means $\sum \beta_j v_j \in W = \operatorname{Span}(w_i)$, and independence of the full basis forces all $\beta_j = 0$. So $\dim(V/W) = m = \dim V - \dim W$. Applying this with $W = \ker T$ and the isomorphism $V/\ker T \cong \operatorname{im} T$ (which follows from the universal property: T factors through π as an injection onto $\operatorname{im} T$) gives $\dim \operatorname{im} T = \dim V - \dim \ker T$. □

Worked Example 11.1.29 (Rank–nullity for an explicit matrix over $\mathbb{Q}$)**.** Let $T\colon \mathbb{Q}^4 \to \mathbb{Q}^3$ have matrix $A = \left(\begin{smallmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 3 & 1 & 2 \end{smallmatrix}\right)$. Find $\dim \ker T$ and $\dim \operatorname{im} T$ and verify rank–nullity.

Recognition. Row-reduce to read off $\operatorname{rank} T = \dim \operatorname{im} T$; then $\dim \ker T = \dim V - \operatorname{rank} T$ by the theorem. The domain has dimension 4.

Solution. Row-reduce: $R_3 \to R_3 - R_1$ gives $\left(\begin{smallmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 \end{smallmatrix}\right)$, then $R_3 \to R_3 - R_2$ gives $\left(\begin{smallmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{smallmatrix}\right)$. There are 2 nonzero rows, so $\operatorname{rank} T = \dim \operatorname{im} T = 2$. By rank–nullity, $\dim \ker T = 4 - 2 = 2$. *Check.* The free columns (3rd and 4th) give two independent kernel vectors, e.g. back-substitution yields $(2, -1, 1, 0)$ and $(1, -1, 0, 1)$ in $\ker T$; one verifies $A(2, -1, 1, 0)^{\mathsf{T}} = 0$ and $A(1, -1, 0, 1)^{\mathsf{T}} = 0$. Two independent kernel vectors confirm $\dim \ker T = 2$, and $2 + 2 = 4 = \dim \mathbb{Q}^4$.

Worked Example 11.1.30 (A quotient computed by coordinates)**.** In $V = \mathbb{R}^3$ let $W = \operatorname{Span}((1, 1, 1))$. Show $V/W \cong \mathbb{R}^2$ and find images of e_1, e_2, e_3 under a concrete coordinate isomorphism.

Recognition. $\dim(V/W) = 3 - 1 = 2$, so $V/W \cong \mathbb{R}^2$; a clean isomorphism comes from a linear functional pair whose common kernel is W, factored through π.

Solution. Define $T\colon \mathbb{R}^3 \to \mathbb{R}^2$ by $T(x, y, z) = (x - y,\ y - z)$. Then T is linear, surjective ($T(s, 0, -t) = (s, t)$), and $\ker T = \{ (x, y, z) : x = y = z \} = W$. By the universal property T factors as $\bar{T}\colon V/W \xrightarrow{\sim} \mathbb{R}^2$. The induced images of the standard basis cosets are

$$\bar{T}(e_1 + W) = (1, 0), \quad \bar{T}(e_2 + W) = (-1, 1), \quad \bar{T}(e_3 + W) = (0, -1).$$

Check. These three images sum to $(0, 0)$, mirroring $e_1 + e_2 + e_3 = (1, 1, 1) \in W$, i.e. $(e_1 + e_2 + e_3) + W = 0$ in V/W. The relation downstairs matches the relation upstairs, confirming $\bar{T}$ is well defined and an isomorphism.

Worked Example 11.1.31 ($\mathbb{Q}[x]/(x^2 - 2)$ as a 2-dimensional $\mathbb{Q}$-vector space)**.** Regard $V = \mathbb{Q}[x]$ as a $\mathbb{Q}$-vector space and $W = (x^2 - 2)$ as the subspace of multiples of $x^2 - 2$. Show V/W has $\mathbb{Q}$-dimension 2 with basis $\{ 1 + W,\ x + W \}$, and compute $(x + W)^2$.

Recognition. Division with remainder gives unique coset representatives of degree < 2; counting them gives the dimension, and the relation $x^2 \equiv 2$ does the arithmetic.

Solution. Every $p(x) \in \mathbb{Q}[x]$ divides as $p = (x^2-2)q + r$ with $\deg r < 2$, so $p + W = r + W$ with $r = a + bx$; thus $\{\, 1 + W, x + W \,\}$ spans. Independence: $a + bx \in W$ forces $a + bx = (x^2-2)q$, impossible unless $a = b = 0$ by degrees. So $\dim_{\mathbb{Q}}(V/W) = 2$. In the quotient $x^2 + W = (x^2-2) + W + 2 + W = 2 + W$, i.e. $(x+W)^2 = 2 + W$. *Check.* This V/W is exactly the field $\mathbb{Q}(\sqrt{2}) = \{\, a + b\sqrt{2} \,\}$ with $\sqrt{2} \leftrightarrow x + W$ and $(\sqrt{2})^2 = 2$ — a 2-dimensional $\mathbb{Q}$-vector space, matching the count.

Remark 11.1.3 (Looking ahead). The two universal-property diagrams above are the prototypes for the rest of the chapter. Fixing bases turns the basis diagram into the matrix functor $\mathrm{Hom}_F(V,W) \to \mathrm{M}(F)$ of §11.2, whose change-of-basis square and rank–nullity sequence are the diagrams just drawn; the quotient diagram reappears as the first isomorphism theorem. The dual space V^* introduced here is the subject of §11.3 (the natural map $V \to (V^*)^*$ and the transpose), and the multilinear refinements — the determinant as $\wedge^n$ and the algebras $T(V), S(V), \wedge(V)$ — occupy §11.4–11.5.

Exercises (from the text).

1. Let $V = \mathbb{R}^n$ and let $(a_1, a_2, \ldots, a_n)$ be a fixed vector in V. Prove that the collection of elements $(x_1, x_2, \ldots, x_n)$ of V with $a_1x_1 + a_2x_2 + \cdots + a_nx_n = 0$ is a subspace of V. Determine the dimension of this subspace and find a basis.

2. Let V be the collection of polynomials with coefficients in $\mathbb{Q}$ in the variable x of degree at most 5. Prove that V is a vector space over $\mathbb{Q}$ of dimension 6, with $1, x, x^2, \ldots, x^5$ as basis. Prove that $1, 1+x, 1+x+x^2, \ldots, 1+x+x^2+x^3+x^4+x^5$ is also a basis for V.

3. Let φ be the linear transformation $\varphi : \mathbb{R}^4 \to \mathbb{R}$ such that

$$\varphi((1,0,0,0)) = 1 \qquad \varphi((1,-1,0,0)) = 0$$

$$\varphi((1,-1,1,0)) = 1 \qquad \varphi((1,-1,1,-1)) = 0.$$

   Determine $\varphi((a,b,c,d))$.

4. Prove that the space of real-valued functions on the closed interval $[a,b]$ is an infinite dimensional vector space over $\mathbb{R}$, where $a < b$.

5. Prove that the space of continuous real-valued functions on the closed interval $[a,b]$ is an infinite dimensional vector space over $\mathbb{R}$, where $a < b$.

6. Let V be a vector space of finite dimension. If φ is any linear transformation from V to V prove there is an integer m such that the intersection of the image of φ^m and the kernel of φ^m is $\{0\}$.

7. Let φ be a linear transformation from a vector space V of dimension n to itself that satisfies $\varphi^2 = 0$. Prove that the image of φ is contained in the kernel of φ and hence that the rank of φ is at most $n/2$.

8. Let V be a vector space over F and let φ be a linear transformation of the vector space V to itself. A nonzero element $v \in V$ satisfying $\varphi(v) = \lambda v$ for some $\lambda \in F$ is called an *eigenvector* of φ with *eigenvalue* λ. Prove that for any fixed $\lambda \in F$ the collection of eigenvectors of φ with eigenvalue λ together with 0 forms a subspace of V.

9. Let V be a vector space over F and let φ be a linear transformation of the vector space V to itself. Suppose for $i = 1, 2, \ldots, k$ that $v_i \in V$ is an eigenvector for φ with eigenvalue $\lambda_i \in F$ (cf. the preceding exercise) and that all the eigenvalues λ_i are distinct. Prove that $v_1, v_2, \ldots, v_k$ are linearly independent. [Use induction on k: write a linear dependence relation among the v_i and apply φ to get another linear dependence relation among the v_i involving the eigenvalues—now subtract a suitable multiple of the first linear relation to get a linear dependence relation on fewer elements.] Conclude that any linear transformation on an n-dimensional vector space has at most n distinct eigenvalues.

   In the following exercises let V be a vector space of arbitrary dimension over a field F.

10. Prove that any vector space V has a basis (by convention the null set is the basis for the zero space). [Let $\mathcal{S}$ be the set of subsets of V consisting of linearly independent vectors, partially ordered under inclusion; apply Zorn's Lemma to $\mathcal{S}$ and show a maximal element of $\mathcal{S}$ is a basis.]

11. Refine your argument in the preceding exercise to prove that any set of linearly independent vectors of V is contained in a basis of V.

12. If F is a field with a finite or countable number of elements and V is an infinite dimensional vector space over F with basis $\mathcal{B}$, prove that the cardinality of V equals the cardinality of $\mathcal{B}$. Deduce in this case that any two bases of V have the same cardinality.

13. Prove that as vector spaces over $\mathbb{Q}$, $\mathbb{R}^n \cong \mathbb{R}$, for all $n \in \mathbb{Z}^+$ (note that, in particular, this means $\mathbb{R}^n$ and $\mathbb{R}$ are isomorphic as additive abelian groups).

14. Let $\mathcal{A}$ be a basis for the infinite dimensional space V. Prove that V is isomorphic to the *direct sum* of copies of the field F indexed by the set $\mathcal{A}$. Prove that the *direct product* of copies of F indexed by $\mathcal{A}$ is a vector space over F and it has strictly larger dimension than the dimension of V (see the exercises in Section 10.3 for the definitions of direct sum and direct product of infinitely many modules).

Practice problems.

1. Let $V = \mathbb{R}^4$ and let $W = \{ (x_1, x_2, x_3, x_4) \in \mathbb{R}^4 : x_1 + x_2 + x_3 + x_4 = 0 \text{ and } x_1 - x_4 = 0 \}$. Show that W is a subspace of V, exhibit an explicit basis for W, and compute $\dim W$.

2. In $V = \mathbb{Q}^3$ consider the vectors $v_1 = (1, 2, -1)$, $v_2 = (0, 1, 3)$, $v_3 = (2, 5, 1)$. Determine whether $\{ v_1, v_2, v_3 \}$ is linearly independent over $\mathbb{Q}$. If it is dependent, exhibit an explicit nontrivial dependence relation and compute $\dim \operatorname{Span}(v_1, v_2, v_3)$.

3. Let F be a field and let $V = F[x]_{\leq 3}$ be the space of polynomials of degree at most 3. Show that $\{ 1, x-1, (x-1)^2, (x-1)^3 \}$ is a basis of V, and find the coordinates of x^3 in this basis.

4. Let $U = \operatorname{Span}\big((1,1,0,0), (0,0,1,1)\big)$ and $W = \operatorname{Span}\big((1,0,1,0), (0,1,0,1)\big)$ in $\mathbb{R}^4$. Compute $\dim(U + W)$ and $\dim(U \cap W)$, and verify directly that $\dim(U + W) = \dim U + \dim W - \dim(U \cap W)$.

5. Let V be a vector space over F with $\dim V = n < \infty$, and let $S = \{ v_1, \ldots, v_n \}$ be a set of exactly n vectors. Prove that S spans V if and only if S is linearly independent. (You may use the replacement/exchange lemma.)

6. Let W be the subspace $\{ (x, y, z) \in \mathbb{R}^3 : x + 2y - z = 0 \}$ of $V = \mathbb{R}^3$. Describe the quotient space V/W: compute $\dim(V/W)$, and exhibit a coset that generates it together with a representative.

7. Let V be a finite-dimensional F-vector space and let $W \leq V$ be a subspace. Prove $\dim(V/W) = \dim V - \dim W$ by lifting a basis of W to a basis of V.

8. Let $T : \mathbb{R}^3 \to \mathbb{R}^3$ be the linear map $T(x, y, z) = (x - y,\ y - z,\ z - x)$. Compute bases for $\ker T$ and $\operatorname{im} T$, and verify the rank–nullity relation $\dim \ker T + \operatorname{rank} T = \dim \mathbb{R}^3$.

Additional exercises.

1. (Replacement lemma in action.) Let V be an F-vector space spanned by $\{ w_1, \ldots, w_m \}$ and suppose $\{ u_1, \ldots, u_k \} \subseteq V$ is linearly independent. Prove $k \leq m$, and show that k of the w_i may be deleted so that the remaining $m - k$ of them together with the u_j still span V.

2. (Existence of a basis via Zorn.) Let V be an arbitrary F-vector space. Using Zorn's lemma, prove that any linearly independent subset $S \subseteq V$ is contained in a basis of V. (Partially order the linearly independent sets containing S by inclusion and verify chains have upper bounds.)

3. (Invariance of dimension.) Let V be a finite-dimensional F-vector space. Using the exchange lemma, prove that any two bases of V have the same number of elements.

4. (Classification by dimension.) Let V, W be finite-dimensional F-vector spaces. Prove that $V \cong W$ as F-vector spaces if and only if $\dim V = \dim W$. Conclude that every n-dimensional F-vector space is isomorphic to F^n.

5. (Complements need not be unique.) Let V be finite-dimensional and $W \leq V$ a subspace. Prove there exists a subspace $W' \leq V$ with $V = W \oplus W'$, and give an explicit example with $\dim V = 2$, $\dim W = 1$ showing W' is not uniquely determined by W.

Commutative-diagram exercises.

1. (Universal property of the quotient.) Let $W \le V$ be a subspace with projection $\pi : V \to V/W$, and let $T : V \to U$ be a linear map of F-vector spaces with $W \subseteq \ker T$. Prove there is a unique linear map $\overline{T} : V/W \to U$ making the diagram

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & U \\ {\scriptstyle\pi}\big\downarrow & \nearrow_{\overline{T}} & \\ V/W & & \end{array}$$

commute, i.e. $\overline{T} \circ \pi = T$. Compute $\dim \operatorname{im} \overline{T}$ in terms of $\dim V$, $\dim W$, and $\dim \ker T$.

2. (First isomorphism theorem for vector spaces.) Let $T : V \to U$ be a linear map of finite-dimensional F-vector spaces. Using the previous universal property, construct the isomorphism $\overline{T} : V/\ker T \xrightarrow{\cong} \operatorname{im} T$ fitting into

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & U \\ {\scriptstyle\pi}\big\downarrow & & \big\uparrow \\ V/\ker T & \xrightarrow[\cong]{\overline{T}} & \operatorname{im} T \end{array}$$

and deduce $\dim V = \dim \ker T + \dim \operatorname{im} T$ directly from this diagram.

3. (Short exact sequence splits.) Let $W \le V$ be a subspace of a finite-dimensional F-vector space, giving the short exact sequence

$$0 \longrightarrow W \xhookrightarrow{\;\iota\;} V \xrightarrow{\;\pi\;} V/W \longrightarrow 0,$$

where ι is inclusion and π the projection. Prove this sequence splits, i.e. there is a linear map $s : V/W \to V$ with $\pi \circ s = \mathrm{id}_{V/W}$, and deduce $V \cong W \oplus (V/W)$ and hence $\dim V = \dim W + \dim(V/W)$.

4. (Functoriality of $V \mapsto V/W$.) Let $T : V \to V'$ be a linear map and let $W \le V$, $W' \le V'$ be subspaces with $T(W) \subseteq W'$. Prove there is a unique linear map $\overline{T} : V/W \to V'/W'$ making

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & V' \\ {\scriptstyle\pi}\big\downarrow & & \big\downarrow{\scriptstyle\pi'} \\ V/W & \xrightarrow{\;\overline{T}\;} & V'/W' \end{array}$$

commute, and show that if $S : V' \to V''$ satisfies $S(W') \subseteq W''$ then $\overline{S \circ T} = \overline{S} \circ \overline{T}$ and $\overline{\mathrm{id}_V} = \mathrm{id}_{V/W}$.

5. (Universal property of the direct sum.) Let U_1, U_2 be F-vector spaces with $V = U_1 \oplus U_2$ and inclusions $\iota_1 : U_1 \to V$, $\iota_2 : U_2 \to V$. Given linear maps $f_1 : U_1 \to Z$ and $f_2 : U_2 \to Z$ into an F-vector space Z, prove there is a unique linear map $f : V \to Z$ with $f \circ \iota_1 = f_1$ and $f \circ \iota_2 = f_2$, as in

$$\begin{array}{ccccc} U_1 & \xrightarrow{\;\iota_1\;} & V & \xleftarrow{\;\iota_2\;} & U_2 \\ & {\scriptstyle f_1}\searrow & \big\downarrow{\scriptstyle f} & \swarrow{\scriptstyle f_2} & \\ & & Z & & \end{array}$$

and verify that $\dim V = \dim U_1 + \dim U_2$ is forced by this property when all spaces are finite-dimensional.

11.2 The Matrix of a Linear Transformation

The matrix attached to a linear transformation

Throughout, F is a field and all vector spaces are finite-dimensional over F unless stated otherwise. Fix vector spaces V and W. Recall $\mathrm{Hom}_F(V, W)$ is the set of all F-linear maps $\varphi\colon V \to W$, and $\mathrm{End}(V) = \mathrm{Hom}_F(V, V)$.

Proposition 11.2.1 ($\mathrm{Hom}_F(V,W)$ is a vector space)**.** *Under pointwise operations*

$$(\varphi+\psi)(v)=\varphi(v)+\psi(v),\qquad (c\varphi)(v)=c\,\varphi(v)\qquad (c\in F,\ v\in V),$$

the set $\mathrm{Hom}_F(V,W)$ *is an* F*-vector space. The zero map is the additive identity, and* $-\varphi$ *is the additive inverse of* φ*.*

Proof. If φ,ψ are F-linear and $c\in F$, then for $v,v'\in V$ and $a\in F$, $(\varphi+\psi)(av+v')=\varphi(av+v')+\psi(av+v')=a(\varphi+\psi)(v)+(\varphi+\psi)(v')$, so $\varphi+\psi\in\mathrm{Hom}_F(V,W)$; likewise $c\varphi\in\mathrm{Hom}_F(V,W)$. The vector-space axioms are inherited entry-by-entry from those of W. □

Definition 11.2.2 (Matrix of a linear transformation)**.** Let $\varphi\colon V\to W$ be linear, let $\mathcal{B}=\{v_1,\dots,v_n\}$ be an ordered basis of V and $\mathcal{E}=\{w_1,\dots,w_m\}$ an ordered basis of W. For each j write the image $\varphi(v_j)$ in the basis $\mathcal{E}$:

$$\varphi(v_j)=\sum_{i=1}^{m}\alpha_{ij}\,w_i\qquad(\alpha_{ij}\in F).$$

The *matrix of* φ *with respect to* $\mathcal{B}$ *and* $\mathcal{E}$ is the $m\times n$ matrix

$$\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)=(\alpha_{ij})\in\mathrm{M}_{m\times n}(F).$$

Its j-th column is the coordinate vector of $\varphi(v_j)$ relative to $\mathcal{E}$. When $V=W$ and $\mathcal{B}=\mathcal{E}$ we abbreviate $\mathrm{M}_{\mathcal{B}}(\varphi)$.

For an ordered basis $\mathcal{B}=\{v_1,\dots,v_n\}$ of V, the *coordinate isomorphism* $[\,\cdot\,]_{\mathcal{B}}\colon V\to F^n$ sends $v=\sum_j c_jv_j$ to the column $(c_1,\dots,c_n)^{\mathsf{T}}$. The whole point of the matrix is that it makes the following square commute: applying φ and then taking coordinates equals taking coordinates and then multiplying by the matrix.

$$\begin{array}{ccc} V & \xrightarrow{\ \varphi\ } & W \\ {\scriptstyle [\,\cdot\,]_{\mathcal{B}}}\downarrow & & \downarrow{\scriptstyle [\,\cdot\,]_{\mathcal{E}}} \\ F^n & \xrightarrow[\ \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)\ ]{} & F^m \end{array}$$

Diagram explanation. Objects: Four vector spaces: V (the domain, dimension n), W (the codomain, dimension m), and two coordinate spaces F^n and F^m. The bottom row lives entirely in column-vector space; the top row lives in the abstract vector-space world.

Arrows: The top horizontal arrow is $\varphi\colon V\to W$, the given linear map. The left vertical arrow $[\,\cdot\,]_{\mathcal{B}}\colon V\to F^n$ is the coordinate isomorphism sending $v=\sum_j c_jv_j$ to the column $(c_1,\dots,c_n)^{\mathsf{T}}$; it is the canonical bijection determined by the ordered basis $\mathcal{B}$. The right vertical arrow $[\,\cdot\,]_{\mathcal{E}}\colon W\to F^m$ is the analogous coordinate isomorphism for W and $\mathcal{E}$. The bottom horizontal arrow is left-multiplication by the matrix $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)\in\mathrm{M}_{m\times n}(F)$.

What commutes: The square commutes: $[\,\cdot\,]_{\mathcal{E}}\circ\varphi=\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)\circ[\,\cdot\,]_{\mathcal{B}}$. In words: apply φ then coordinatize in $\mathcal{E}$, or coordinatize in $\mathcal{B}$ then multiply by the matrix – same result.

Why it commutes: Take $v=\sum_j c_jv_j\in V$. Going right-then-down: $\varphi(v)=\sum_j c_j\varphi(v_j)=\sum_j c_j\sum_i\alpha_{ij}w_i$, so $[\varphi(v)]_{\mathcal{E}}=(\sum_j\alpha_{ij}c_j)_i=\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)\,(c_1,\dots,c_n)^{\mathsf{T}}$. Going down-then-right: $[v]_{\mathcal{B}}=(c_1,\dots,c_n)^{\mathsf{T}}$, then multiply by the matrix, giving exactly the same column. They agree because the matrix was defined precisely via the expansion coefficients α_{ij}.

Why this matters here: This square is the definition's payoff: it says that after choosing bases, φ is completely encoded by a matrix, and computation with φ reduces to matrix-vector multiplication. It justifies calling $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$ "the matrix of φ".

Concrete example: For $D\colon\mathbb{Q}[x]_{\le 3}\to\mathbb{Q}[x]_{\le 3}$, $D(p)=p'$, and the monomial basis $\{1,x,x^2,x^3\}$: the coordinate map sends $p=a_0+a_1x+a_2x^2+a_3x^3$ to $(a_0,a_1,a_2,a_3)^{\mathsf{T}}$, and $\mathrm{M}(D)$ is the strictly upper-triangular matrix; left-multiplying by it shifts the coefficient vector, matching differentiation.

Common pitfall: Students write the columns of $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$ as $\varphi(v_j)$ in standard coordinates rather than in the $\mathcal{E}$-basis. The right vertical arrow requires expanding $\varphi(v_j)$ in $\mathcal{E}$; forgetting to change to $\mathcal{E}$ coordinates gives the wrong matrix whenever $\mathcal{E}$ is not the standard basis of W.

Takeaway: The point of this diagram is that the matrix of a linear map is precisely the data needed to make the coordinate isomorphisms intertwine φ with matrix-vector multiplication.

Method (Writing down $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$)**.** *Trigger.* You are given a linear map φ and ordered bases $\mathcal{B}$ (domain), $\mathcal{E}$ (codomain). *Recipe.*

1. Apply φ to each domain basis vector v_j in turn.
2. Expand $\varphi(v_j)$ in the codomain basis $\mathcal{E}$; the coefficients are the entries $\alpha_{1j}, \dots, \alpha_{mj}$.
3. Stack these as the j-th *column*. The result is $m \times n$ (rows $= \dim W$, columns $= \dim V$).
4. Sanity check: column j is $[\varphi(v_j)]_{\mathcal{E}}$; recompute $\varphi(v_j)$ from the column and compare.

Worked Example 11.2.3 (Matrix of a map $\mathbb{Q}^3 \to \mathbb{Q}^2$ in standard bases)**.** Let $\varphi\colon \mathbb{Q}^3 \to \mathbb{Q}^2$, $\varphi(x, y, z) = (x + 2y + 3z,\ 2x + 4y + 6z)$. Find $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$ for the standard ordered bases $\mathcal{B} = \{ e_1, e_2, e_3 \}$, $\mathcal{E} = \{ f_1, f_2 \}$.

Recognition. Apply φ to each e_j and read off the coordinates; columns are $[\varphi(e_j)]_{\mathcal{E}}$.

Solution. $\varphi(e_1) = (1, 2) = 1 \cdot f_1 + 2 \cdot f_2$, $\varphi(e_2) = (2, 4)$, $\varphi(e_3) = (3, 6)$. Hence

$$\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi) = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}.$$

Sanity check: column 3 is $(3, 6)^{\mathsf{T}}$, and indeed $\varphi(0, 0, 1) = (3, 6)$. The matrix is $2 \times 3 = (\dim W) \times (\dim V)$, as required.

Worked Example 11.2.4 (Differentiation on polynomials)**.** Let $V = \{ p \in \mathbb{Q}[x] : \deg p \le 3 \}$ with ordered basis $\mathcal{B} = \{ 1, x, x^2, x^3 \}$, and let $D\colon V \to V$ be $D(p) = p'$. Find $\mathrm{M}_{\mathcal{B}}(D)$.

Recognition. D is linear; compute D on each basis monomial and expand in $\mathcal{B}$.

Solution. $D(1) = 0$, $D(x) = 1$, $D(x^2) = 2x$, $D(x^3) = 3x^2$. Coordinate columns:

$$\mathrm{M}_{\mathcal{B}}(D) = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Sanity check: this is strictly upper triangular, consistent with D being nilpotent ($D^4 = 0$ on cubics). Squaring gives the matrix of $D^2 = \frac{d^2}{dx^2}$, with entries 2 in position $(1, 3)$ and 6 in position $(2, 4)$, matching $D^2(x^2) = 2$, $D^2(x^3) = 6x$.

Worked Example 11.2.5 (A map written in a nonstandard codomain basis)**.** Let $\varphi\colon \mathbb{Q}^2 \to \mathbb{Q}^2$, $\varphi(x, y) = (x + y,\ x - y)$, with domain basis $\mathcal{B} = \{ e_1, e_2 \}$ but codomain basis $\mathcal{E} = \{ (1, 1), (1, -1) \}$. Find $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$.

Recognition. The columns are the coordinates of $\varphi(e_1), \varphi(e_2)$ in the *new* basis $\mathcal{E}$, not the standard one.

Solution. $\varphi(e_1) = (1, 1) = 1 \cdot (1, 1) + 0 \cdot (1, -1)$ and $\varphi(e_2) = (1, -1) = 0 \cdot (1, 1) + 1 \cdot (1, -1)$. Therefore

$$\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = I_2.$$

Sanity check: $\mathcal{E}$ is exactly the image of the standard basis, so in these coordinates φ looks like the identity. Choosing bases adapted to a map can simplify its matrix dramatically.

Worked Example 11.2.6 (A linear map over $\mathbb{F}_2$)**.** Over $F = \mathbb{F}_2 = \mathbb{Z}/2\mathbb{Z}$, let $\varphi\colon \mathbb{F}_2^3 \to \mathbb{F}_2^3$ be $\varphi(x, y, z) = (x + y,\ y + z,\ x + z)$. Find $\mathrm{M}_{\mathcal{B}}(\varphi)$ in the standard basis and decide whether φ is invertible.

Recognition. Columns are $\varphi(e_1), \varphi(e_2), \varphi(e_3)$ over $\mathbb{F}_2$; invertibility is detected by the rank.

Solution. $\varphi(e_1) = (1,0,1)$, $\varphi(e_2) = (1,1,0)$, $\varphi(e_3) = (0,1,1)$, so

$$\mathrm{M}_{\mathcal{B}}(\varphi) = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix} \in \mathrm{M}_3(\mathbb{F}_2).$$

Row-reduce over $\mathbb{F}_2$: $R_3 \mapsto R_3 + R_1$ gives row $(0,1,1)$, which equals R_2; subtracting leaves a zero row. So the rank is $2 < 3$ and φ is *not* invertible. Sanity check: $\varphi(1,1,1) = (1+1, 1+1, 1+1) = (0,0,0)$, so $(1,1,1) \in \ker\varphi$ confirms φ is singular.

Worked Example 11.2.7 (Matrix of an evaluation-type map)**.** Let $\varphi\colon \mathbb{R}^3 \to \mathbb{R}^2$, $\varphi(a,b,c) = (a+b+c,\ a-c)$, with $\mathcal{B} = \{\,(1,1,0),(0,1,1),(1,0,1)\,\}$ and $\mathcal{E}$ standard. Find $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$.

Recognition. Apply φ to the (nonstandard) domain basis vectors; the codomain basis is standard, so coordinates are just the output entries.

Solution. $\varphi(1,1,0) = (2,1)$, $\varphi(0,1,1) = (2,-1)$, $\varphi(1,0,1) = (2,0)$. Hence

$$\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi) = \begin{pmatrix} 2 & 2 & 2 \\ 1 & -1 & 0 \end{pmatrix}.$$

Sanity check: $(1,1,0)+(0,1,1)+(1,0,1) = (2,2,2)$, and $\varphi(2,2,2) = (6,0)$; summing the three columns gives $(6,0)^{\mathsf{T}}$ as well. Linearity is respected.

Composition is matrix multiplication

Theorem 11.2.8 (The matrix of a composite is the product)**.** *Let $\psi\colon V \to U$ and $\varphi\colon U \to W$ be linear, and fix ordered bases $\mathcal{B}$ of V, $\mathcal{D}$ of U, $\mathcal{E}$ of W. Then*

$$\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi \circ \psi) = \mathrm{M}_{\mathcal{D}}^{\mathcal{E}}(\varphi)\ \mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi).$$

Proof. Write $\mathcal{B} = \{\,v_1,\dots,v_n\,\}$, $\mathcal{D} = \{\,u_1,\dots,u_p\,\}$, $\mathcal{E} = \{\,w_1,\dots,w_m\,\}$, and put $\mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi) = (\beta_{kj})$, $\mathrm{M}_{\mathcal{D}}^{\mathcal{E}}(\varphi) = (\alpha_{ik})$, so $\psi(v_j) = \sum_k \beta_{kj} u_k$ and $\varphi(u_k) = \sum_i \alpha_{ik} w_i$. Then

$$(\varphi\circ\psi)(v_j) = \varphi\Big(\sum_k \beta_{kj} u_k\Big) = \sum_k \beta_{kj} \sum_i \alpha_{ik} w_i = \sum_i \Big(\sum_k \alpha_{ik}\beta_{kj}\Big) w_i.$$

The coefficient of w_i is $\sum_k \alpha_{ik}\beta_{kj}$, which is exactly the (i,j) entry of the product $\mathrm{M}_{\mathcal{D}}^{\mathcal{E}}(\varphi)\,\mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi)$. □

Remark 11.2.1. This identity is the conceptual reason matrix multiplication is defined the way it is: it is forced by the requirement that "matrix of a map" turn composition into a product. The commuting triangle of coordinate squares is

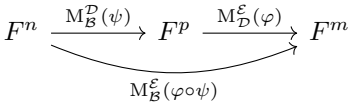

Diagram explanation. Objects: Three coordinate spaces: F^n (coordinate columns for V via $\mathcal{B}$), F^p (coordinate columns for U via $\mathcal{D}$), and F^m (coordinate columns for W via $\mathcal{E}$).

Arrows: The top-straight arrow $F^n \to F^p$ is left-multiplication by $\mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi)$, representing ψ. The straight arrow $F^p \to F^m$ is left-multiplication by $\mathrm{M}_{\mathcal{D}}^{\mathcal{E}}(\varphi)$, representing φ. The curved arrow $F^n \to F^m$ at the bottom is left-multiplication by $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi\circ\psi)$, representing the composite $\varphi\circ\psi$ directly.

What commutes: The two paths from F^n to F^m agree: $\mathrm{M}_{\mathcal{D}}^{\mathcal{E}}(\varphi)\,\mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi) = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi\circ\psi)$. This is the composition theorem in coordinate form.

Why it commutes: Take column $c \in F^n$. Straight through F^p: ψ in coordinates sends c to $\mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi)\,c$, then φ sends that to $\mathrm{M}_{\mathcal{D}}^{\mathcal{E}}(\varphi)\,\mathrm{M}_{\mathcal{B}}^{\mathcal{D}}(\psi)\,c$. Curved path: $(\varphi\circ\psi)$ in coordinates sends c directly to $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi\circ\psi)\,c$. The proof of the composition theorem shows the (i,j) entry of $\mathrm{M}(\varphi\circ\psi)$ is $\sum_k \alpha_{ik}\beta_{kj}$, which is the (i,j) entry of the matrix product; so both paths give the same column.

Why this matters here: This diagram is the conceptual explanation of why matrix multiplication is defined the way it is: it is the only definition that makes composition of linear maps correspond to multiplication of their matrices. The remark places it immediately after the proof to drive home that the multiplication rule is not arbitrary.

Concrete example: With $\psi\colon \mathbb{Q}^2 \to \mathbb{Q}^3$ and $\varphi\colon \mathbb{Q}^3 \to \mathbb{Q}^2$ from the worked example: $\mathrm{M}(\varphi)\,\mathrm{M}(\psi) = \begin{pmatrix} 3 & 1 \\ 1 & 2 \end{pmatrix}$, and computing $\varphi \circ \psi$ directly gives the same 2×2 matrix, confirming the bent arrow.

Common pitfall: The order matters: the arrow ψ comes first but its matrix is the right factor in the product $\mathrm{M}(\varphi)\,\mathrm{M}(\psi)$. Writing $\mathrm{M}(\psi)\,\mathrm{M}(\varphi)$ reverses composition and is generally wrong. Read the diagram left-to-right, matching the matrix product right-to-left.

Takeaway: The point of this diagram is that matrix multiplication is precisely the coordinate expression of composition of linear maps, so the product rule is forced by the requirement that the "matrix of" construction respects composition.

Corollary 11.2.9 ($\mathrm{End}(V)$ and $\mathrm{GL}(V)$ as matrices)**.** *Fix a basis $\mathcal{B}$ of an n-dimensional space V. The map $\varphi \mapsto \mathrm{M}_{\mathcal{B}}(\varphi)$ is a ring isomorphism $\mathrm{End}(V) \cong \mathrm{M}_n(F)$ carrying id_V to I_n, and it restricts to a group isomorphism $\mathrm{GL}(V) \cong \mathrm{GL}_n(F)$ of units. In particular φ is invertible iff $\mathrm{M}_{\mathcal{B}}(\varphi)$ is, and $\mathrm{M}_{\mathcal{B}}(\varphi^{-1}) = \mathrm{M}_{\mathcal{B}}(\varphi)^{-1}$.*

Proof. Additivity is clear and multiplicativity is the theorem with $V = U = W$, $\mathcal{B} = \mathcal{D} = \mathcal{E}$; id_V fixes each v_j, giving I_n. A ring homomorphism between rings with 1 that is bijective sends units to units, and the inverse of $\mathrm{M}_{\mathcal{B}}(\varphi)$ is $\mathrm{M}_{\mathcal{B}}(\varphi^{-1})$ since their product is $\mathrm{M}_{\mathcal{B}}(\mathrm{id}_V) = I_n$. □

Worked Example 11.2.10 (Verifying $\mathrm{M}(\varphi\psi) = \mathrm{M}(\varphi)\,\mathrm{M}(\psi)$ concretely)**.** Let $\psi\colon \mathbb{Q}^2 \to \mathbb{Q}^3$, $\psi(x, y) = (x + y,\ 2y,\ x)$, and $\varphi\colon \mathbb{Q}^3 \to \mathbb{Q}^2$, $\varphi(a, b, c) = (a + 2c,\ b + c)$, all bases standard. Compute the two matrices, their product, and $\mathrm{M}(\varphi \circ \psi)$ directly.

Recognition. Build each matrix column-by-column, multiply, then compute the composite map and compare.

Solution. $\mathrm{M}(\psi) = \begin{pmatrix} 1 & 1 \\ 0 & 2 \\ 1 & 0 \end{pmatrix}$, $\mathrm{M}(\varphi) = \begin{pmatrix} 1 & 0 & 2 \\ 0 & 1 & 1 \end{pmatrix}$, so

$$\mathrm{M}(\varphi)\,\mathrm{M}(\psi) = \begin{pmatrix} 1 & 0 & 2 \\ 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 2 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 3 & 1 \\ 1 & 2 \end{pmatrix}.$$

Directly, $(\varphi \circ \psi)(x, y) = \varphi(x + y, 2y, x) = \big((x + y) + 2x,\ 2y + x\big) = (3x + y,\ x + 2y)$, with matrix $\begin{pmatrix} 3 & 1 \\ 1 & 2 \end{pmatrix}$. They agree.

Worked Example 11.2.11 (Powers of an operator)**.** With D the differentiation operator on $\{\, p : \deg p \le 3 \,\}$ (basis $\{\, 1, x, x^2, x^3 \,\}$), use the theorem to find $\mathrm{M}(D^2)$ and confirm $\mathrm{M}(D^4) = 0$.

Recognition. $D^2 = D \circ D$, so $\mathrm{M}(D^2) = \mathrm{M}(D)^2$ by the composition theorem.

Solution. With $\mathrm{M}(D)$ the strictly upper-triangular matrix found earlier,

$$\mathrm{M}(D)^2 = \begin{pmatrix} 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 6 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

This matches $D^2(x^2) = 2$, $D^2(x^3) = 6x$. Since $\mathrm{M}(D)$ is 4×4 strictly upper triangular, $\mathrm{M}(D)^4 = 0$; hence $D^4 = 0$ on cubics. Sanity check: a degree-3 polynomial vanishes after four derivatives.

Worked Example 11.2.12 (Inverse via matrix inverse)**.** Let $\varphi\colon \mathbb{Q}^2 \to \mathbb{Q}^2$, $\varphi(x, y) = (2x+y,\ x+y)$, standard basis. Show φ is invertible and find φ^{-1} using $\mathrm{M}_{\mathcal{B}}(\varphi^{-1}) = \mathrm{M}_{\mathcal{B}}(\varphi)^{-1}$.

Recognition. By the corollary, φ is invertible iff its matrix is, and the inverse map has the inverse matrix.

Solution. $A = \mathrm{M}(\varphi) = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}$, $\det A = 1 \neq 0$, so $A^{-1} = \begin{pmatrix} 1 & -1 \\ -1 & 2 \end{pmatrix}$. Reading off columns, $\varphi^{-1}(x, y) = (x - y,\ -x+2y)$. Sanity check: $\varphi^{-1}(\varphi(x, y)) = \varphi^{-1}(2x+y, x+y) = \big((2x+y)-(x+y),\ -(2x+y)+2(x+y)\big) = (x, y)$.

Worked Example 11.2.13 (Composition over $\mathbb{F}_2$)**.** Over $\mathbb{F}_2$, let $\psi\colon \mathbb{F}_2^2 \to \mathbb{F}_2^2$ have matrix $\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix}$ and φ have matrix $\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}$. Find $\mathrm{M}(\varphi\circ\psi)$ and check $(\varphi\circ\psi)$ on $(1,1)$.

Recognition. Multiply the matrices over $\mathbb{F}_2$ (arithmetic mod 2), then verify on a vector.

Solution.

$$\begin{pmatrix}1 & 0\\ 1 & 1\end{pmatrix}\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix} = \begin{pmatrix}1 & 1\\ 1 & 1+1\end{pmatrix} = \begin{pmatrix}1 & 1\\ 1 & 0\end{pmatrix} \quad (\text{over } \mathbb{F}_2).$$

Check: $\psi(1,1) = (1+1,\,1) = (0,1)$, then $\varphi(0,1) = (0,\,0+1) = (0,1)$. The product matrix sends $(1,1)^{\mathsf{T}}$ to $(1+1,\,1+0)^{\mathsf{T}} = (0,1)^{\mathsf{T}}$. Agreement confirms the computation mod 2.

Change of basis and similar matrices

Definition 11.2.14 (Change-of-basis matrix; similarity)**.** Let $\mathcal{B}$ and $\mathcal{E}$ be two ordered bases of V. The *change-of-basis matrix* from $\mathcal{B}$ to $\mathcal{E}$ is $P = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\mathrm{id}_V)$; its j-th column gives the coordinates of the $\mathcal{B}$-vector v_j in the basis $\mathcal{E}$. Two matrices $A, B \in \mathrm{M}_n(F)$ are *similar* if $B = PAP^{-1}$ for some invertible $P \in \mathrm{GL}_n(F)$.

Theorem 11.2.15 (Change of basis for an operator)**.** *Let $\varphi \in \mathrm{End}(V)$ and let $\mathcal{B}, \mathcal{E}$ be ordered bases of V. With $P = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\mathrm{id}_V)$,*

$$\mathrm{M}_{\mathcal{E}}(\varphi) = P\,\mathrm{M}_{\mathcal{B}}(\varphi)\,P^{-1}.$$

Hence the matrices of φ relative to different bases are exactly the matrices in a single similarity class; conversely $A \sim B$ iff A, B represent one operator in two bases.

Proof. Factor $\varphi = \mathrm{id}_V \circ \varphi \circ \mathrm{id}_V$ and read the source/target bases off each factor:

$$\mathrm{M}_{\mathcal{E}}(\varphi) = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\mathrm{id}_V)\;\mathrm{M}_{\mathcal{B}}(\varphi)\;\mathrm{M}_{\mathcal{E}}^{\mathcal{B}}(\mathrm{id}_V) = P\,\mathrm{M}_{\mathcal{B}}(\varphi)\,P^{-1},$$

using the composition theorem and $\mathrm{M}_{\mathcal{E}}^{\mathcal{B}}(\mathrm{id}_V) = \big(\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\mathrm{id}_V)\big)^{-1} = P^{-1}$. □

The content is captured by a commuting square in which the vertical maps are the change-of-coordinates isomorphism P:

$$\begin{array}{ccc} F^n & \xrightarrow{\mathrm{M}_{\mathcal{B}}(\varphi)} & F^n \\ {\scriptstyle P}\downarrow & & \downarrow{\scriptstyle P} \\ F^n & \xrightarrow[\mathrm{M}_{\mathcal{E}}(\varphi)]{} & F^n \end{array}$$

Diagram explanation. Objects: All four nodes are the same space F^n, but they carry different interpretations: the top row uses $\mathcal{B}$-coordinates and the bottom row uses $\mathcal{E}$-coordinates. The operator φ acts on both rows.

Arrows: The top horizontal arrow is left-multiplication by $\mathrm{M}_{\mathcal{B}}(\varphi)$, the matrix of φ in the $\mathcal{B}$-basis. The bottom horizontal arrow is left-multiplication by $\mathrm{M}_{\mathcal{E}}(\varphi)$, the matrix in the $\mathcal{E}$-basis. Both vertical arrows are left-multiplication by the change-of-basis matrix $P = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\mathrm{id}_V)$, an isomorphism; the left P converts $\mathcal{B}$-input coordinates to $\mathcal{E}$-input coordinates, and the right P does the same for output coordinates.

What commutes: Down-then-right equals right-then-down: $\mathrm{M}_{\mathcal{E}}(\varphi)\,P = P\,\mathrm{M}_{\mathcal{B}}(\varphi)$, equivalently $\mathrm{M}_{\mathcal{E}}(\varphi) = P\,\mathrm{M}_{\mathcal{B}}(\varphi)\,P^{-1}$. This is the similarity relation.

Why it commutes: Factor $\varphi = \mathrm{id}_V \circ \varphi \circ \mathrm{id}_V$ and apply the composition theorem:

$$\mathrm{M}_{\mathcal{E}}(\varphi) = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\mathrm{id}_V)\;\mathrm{M}_{\mathcal{B}}(\varphi)\;\mathrm{M}_{\mathcal{E}}^{\mathcal{B}}(\mathrm{id}_V) = P\,\mathrm{M}_{\mathcal{B}}(\varphi)\,P^{-1},$$

since $\mathrm{M}_{\mathcal{E}}^{\mathcal{B}}(\mathrm{id}_V) = P^{-1}$.

Why this matters here: This square makes the theorem on change of basis visual: two matrices in the same similarity class describe the same operator in different coordinate systems. It also motivates the definition of similarity: $A \sim B$ iff there exists an invertible P such that $B = PAP^{-1}$, i.e. iff A, B are the matrices of one operator in two bases.

Concrete example: In the worked example below with $V = \mathbb{Q}^3$ and φ given by A, the new basis gives $\mathrm{M}_{\mathcal{E}}(\varphi) = PAP^{-1} = J = \left(\begin{smallmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{smallmatrix}\right)$, a Jordan form; it is not diagonal, and A is not diagonalizable. The square says: apply A, then left-multiply by P, equals left-multiply by P, then apply J. Both paths track how φ acts, just in different coordinates.

Common pitfall: Students often write $\mathrm{M}_{\mathcal{E}}(\varphi) = P^{-1}\,\mathrm{M}_{\mathcal{B}}(\varphi)P$ instead of $P\,\mathrm{M}_{\mathcal{B}}(\varphi)P^{-1}$. The correct formula depends on whether $P = \mathrm{M}^{\mathcal{E}}_{\mathcal{B}}(\mathrm{id}_V)$ or $P = \mathrm{M}^{\mathcal{B}}_{\mathcal{E}}(\mathrm{id}_V)$; here P converts from $\mathcal{B}$ to $\mathcal{E}$, so it appears on the left.

Takeaway: The point of this diagram is that passing from one basis to another conjugates the matrix of an operator by the change-of-basis matrix P, so similarity of matrices is exactly the coordinate-change equivalence relation on operators.

Worked Example 11.2.16 (The Dummit–Foote change-of-basis example)**.** Let $V = \mathbb{Q}^3$ and $\varphi(x, y, z) = (9x + 4y + 5z,\ -4x - 3z,\ -6x - 4y - 2z)$. In the standard basis $\mathcal{B}$,

$$A = \mathrm{M}_{\mathcal{B}}(\varphi) = \begin{pmatrix} 9 & 4 & 5 \\ -4 & 0 & -3 \\ -6 & -4 & -2 \end{pmatrix}.$$

Take the new ordered basis $\mathcal{E} = \{\,(2,-1,-2),\ (1,0,-1),\ (3,-2,-2)\,\}$. Find $\mathrm{M}_{\mathcal{E}}(\varphi)$.

Recognition. Use $\mathrm{M}_{\mathcal{E}}(\varphi) = PAP^{-1}$ with $P^{-1} = \mathrm{M}^{\mathcal{B}}_{\mathcal{E}}(\mathrm{id})$ having the new basis vectors as its columns (in standard coordinates).

Solution. Let

$$P^{-1} = \begin{pmatrix} 2 & 1 & 3 \\ -1 & 0 & -2 \\ -2 & -1 & -2 \end{pmatrix}, \qquad P = \begin{pmatrix} -2 & -1 & -2 \\ 2 & 2 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

Then a direct computation gives

$$\mathrm{M}_{\mathcal{E}}(\varphi) = P\,A\,P^{-1} = \begin{pmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{pmatrix},$$

the simplest matrix representing φ (a Jordan form). Sanity check: $\operatorname{tr} A = 9 + 0 - 2 = 7$ equals $2 + 2 + 3 = 7$, and both matrices are similar so share trace and determinant; $\det A = 12 = 2 \cdot 2 \cdot 3$.

Worked Example 11.2.17 (Similar matrices share invariants)**.** Decide whether $A = \begin{pmatrix} 2 & 0 \\ 0 & 3 \end{pmatrix}$ and $B = \begin{pmatrix} 2 & 2 \\ 0 & 3 \end{pmatrix}$ are similar over $\mathbb{Q}$.

Recognition. Similar matrices have equal trace, determinant, and characteristic polynomial; check these first.

Solution. $\operatorname{tr} A = 5 = \operatorname{tr} B$ and $\det A = 6 = \det B$, so both have characteristic polynomial $t^2 - 5t + 6 = (t-2)(t-3)$. Each has distinct eigenvalues $2, 3$, hence each is diagonalizable to $\mathrm{diag}(2,3)$. Therefore $A \sim B$. Sanity check: an eigenvector of B for 2 is $(1,0)$ and for 3 solve $(B - 3I)v = 0$: $v = (2,1)$; with $Q = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}$ one verifies $Q^{-1}BQ = \mathrm{diag}(2,3) = A$.

Worked Example 11.2.18 (Change of basis for a rotation)**.** Let $\varphi\colon \mathbb{R}^2 \to \mathbb{R}^2$ be rotation by $90°$, $\varphi(x, y) = (-y, x)$. Compute its matrix in $\mathcal{B} = \{\,e_1, e_2\,\}$ and in $\mathcal{E} = \{\,(1,1), (1,-1)\,\}$, and exhibit the conjugating P.

Recognition. The two matrices must be similar (same operator); find $P = \mathrm{M}^{\mathcal{E}}_{\mathcal{B}}(\mathrm{id})$.

Solution. $\mathrm{M}_{\mathcal{B}}(\varphi) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. For $\mathcal{E}$: $\varphi(1,1) = (-1,1) = 0 \cdot (1,1) - 1 \cdot (1,-1)$ and $\varphi(1,-1) = (1,1) = 1 \cdot (1,1) + 0 \cdot (1,-1)$, so $\mathrm{M}_{\mathcal{E}}(\varphi) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. Sanity check: both have trace 0, determinant 1, characteristic polynomial $t^2 + 1$ (no real eigenvalues, as expected for a rotation). Here $P^{-1} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$ conjugates one to the other.

Worked Example 11.2.19 (Idempotent operator in an adapted basis)**.** Let $\varphi\colon \mathbb{R}^2 \to \mathbb{R}^2$ be the projection onto the line $y = x$ along the line $y = -x$. Find a basis making $\mathrm{M}(\varphi)$ diagonal, and the standard-basis matrix via $P^{-1} \operatorname{diag} P$.

Recognition. Eigenvectors of a projection are the directions it fixes ($\lambda = 1$) and kills ($\lambda = 0$); these form an adapted basis.

Solution. Take $\mathcal{E} = \{(1,1), (1,-1)\}$: $\varphi(1,1) = (1,1)$ (eigenvalue 1) and $\varphi(1,-1) = (0,0)$ (eigenvalue 0), so $\mathrm{M}_{\mathcal{E}}(\varphi) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$. With $P^{-1} = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$, conjugating back gives $\mathrm{M}_{\mathcal{B}}(\varphi) = P^{-1} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} P = \frac{1}{2} \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$. Sanity check: this matrix is idempotent ($\mathrm{M}(\varphi)^2 = \mathrm{M}(\varphi)$), as every projection must be, and it sends $(2,0)$ to $(1,1)$, the foot of the projection.

Rank and the rank–nullity theorem

Definition 11.2.20 (Rank of a map and of a matrix)**.** The *rank* of $\varphi \in \operatorname{Hom}_F(V,W)$ is $\operatorname{rank} \varphi = \dim(\operatorname{im} \varphi)$. The rank of a matrix A is the dimension of its column space (equivalently, of its row space); if $A = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$ then $\operatorname{rank} A = \operatorname{rank} \varphi$. A map is called *nonsingular* if its rank equals $\dim V$, i.e. if it is injective.

Theorem 11.2.21 (Rank–Nullity)**.** *Let $\varphi\colon V \to W$ be linear with V finite-dimensional. Then*

$$\dim V = \dim(\ker \varphi) + \dim(\operatorname{im} \varphi).$$

Proof. Let $\{u_1, \dots, u_k\}$ be a basis of $\ker \varphi$ and extend to a basis $\{u_1, \dots, u_k, v_1, \dots, v_r\}$ of V (so $\dim V = k+r$). It suffices to show $\{\varphi(v_1), \dots, \varphi(v_r)\}$ is a basis of $\operatorname{im} \varphi$. They span: any $\varphi(v)$ with $v = \sum a_i u_i + \sum b_j v_j$ equals $\sum b_j \varphi(v_j)$ since $\varphi(u_i) = 0$. They are independent: if $\sum b_j \varphi(v_j) = 0$ then $\varphi(\sum b_j v_j) = 0$, so $\sum b_j v_j \in \ker \varphi = \operatorname{Span}(u_i)$; but the u_i, v_j are independent, forcing all $b_j = 0$. Hence $\dim(\operatorname{im} \varphi) = r$ and $\dim V = k + r$. □

The argument is the splitting of the short exact sequence $0 \to \ker \varphi \hookrightarrow V \twoheadrightarrow \operatorname{im} \varphi \to 0$; dimension is additive along it.

$$0 \longrightarrow \ker \varphi \xhookrightarrow{\ \iota\ } V \xrightarrow{\ \varphi\ } \operatorname{im} \varphi \longrightarrow 0$$

Diagram explanation. Objects: Five objects in a row: the trivial vector space 0 at each end, the kernel $\ker \varphi$ (a subspace of V), the full domain V, and the image $\operatorname{im} \varphi$ (a subspace of W).

Arrows: The leftmost arrow $0 \to \ker \varphi$ is the zero map (unique). The hook arrow $\iota\colon \ker \varphi \hookrightarrow V$ is the inclusion, an injective linear map. The two-headed arrow $\varphi\colon V \twoheadrightarrow \operatorname{im} \varphi$ is φ viewed as a surjection onto its own image (by definition φ hits every element of $\operatorname{im} \varphi$). The rightmost arrow $\operatorname{im} \varphi \to 0$ is the zero map.

What commutes: Exactness conditions (no actual commutativity to check in a sequence): $\operatorname{im}(0 \to \ker \varphi) = 0 = \ker(\iota)$; $\operatorname{im}(\iota) = \ker \varphi = \ker(\varphi\colon V \to \operatorname{im} \varphi)$; $\operatorname{im}(\varphi) = \operatorname{im} \varphi = \ker(\operatorname{im} \varphi \to 0)$. So exactness at every position holds by construction.

Why it commutes: ι is injective, so $\ker \iota = 0 = \operatorname{im}(0 \to \ker \varphi)$. Every element of $\ker \varphi \subseteq V$ is sent to 0 by φ, so $\operatorname{im} \iota = \ker \varphi \subseteq \ker \varphi_{\mathrm{restr}}$; and conversely any $v \in V$ with $\varphi(v) = 0$ lies in $\ker \varphi = \operatorname{im} \iota$. The restricted φ is surjective onto $\operatorname{im} \varphi$ by definition, matching $\ker(\operatorname{im} \varphi \to 0) = \operatorname{im} \varphi$.

Why this matters here: Exactness of this short sequence is a compact way to encode the rank–nullity theorem: in a short exact sequence of finite-dimensional spaces $0 \to A \to B \to C \to 0$, dimensions satisfy $\dim B = \dim A + \dim C$. Here $\dim V = \dim \ker \varphi + \dim \operatorname{im} \varphi$, which is rank–nullity.

Concrete example: For $\varphi\colon \mathbb{Q}^3 \to \mathbb{Q}^2$, $\varphi(x,y,z) = (x+2y+3z,\ 2x+4y+6z)$: $\ker \varphi$ is the plane $x+2y+3z = 0$ (dimension 2), $\operatorname{im} \varphi = \mathbb{Q}^1$ (rank 1), and $0 \to \mathbb{Q}^2 \hookrightarrow \mathbb{Q}^3 \twoheadrightarrow \mathbb{Q}^1 \to 0$ has $2 + 1 = 3 = \dim \mathbb{Q}^3$.

Common pitfall: Students read the hook arrow as meaning $\ker \varphi$ is all of V; it only means the inclusion is injective (which is trivially true for any subset inclusion). The key exactness information is at V: the image of the inclusion equals the kernel of φ.

Takeaway: The point of this diagram is that the rank–nullity theorem is dimension-additivity in a short exact sequence, so the proof becomes: exhibit the splitting $V = \ker \varphi \oplus C$ and read off $\dim V = \dim \ker \varphi + \dim C = \operatorname{null} \varphi + \operatorname{rank} \varphi$.

Corollary 11.2.22. *For $\varphi\colon V \to W$ with $\dim V = \dim W = n$, the following are equivalent: φ injective; φ surjective; φ bijective;* $\operatorname{rank}\varphi = n$.

Proof. By rank–nullity, $\ker\varphi = 0$ iff $\operatorname{rank}\varphi = n$ iff $\dim(\operatorname{im}\varphi) = n = \dim W$ iff $\operatorname{im}\varphi = W$. So injective, surjective, and full rank coincide, hence all give bijective. □

Worked Example 11.2.23 (Rank–nullity for a rank-one map)**.** For $\varphi\colon \mathbb{Q}^3 \to \mathbb{Q}^2$, $\varphi(x,y,z) = (x+2y+3z,\ 2x+4y+6z)$, verify rank–nullity and describe $\ker\varphi$.

Recognition. Compute rank from the matrix, then $\dim\ker = \dim V - \operatorname{rank}$, and confirm by solving $\varphi = 0$.

Solution. The matrix $\begin{pmatrix}1&2&3\\2&4&6\end{pmatrix}$ has second row twice the first, so $\operatorname{rank}\varphi = 1$. Rank–nullity predicts $\dim\ker\varphi = 3-1 = 2$. Indeed $\ker\varphi = \{\,(x,y,z) : x+2y+3z = 0\,\}$, a plane, with basis $\{\,(-2,1,0),(-3,0,1)\,\}$, of dimension 2. Sanity check: $1 + \dim\ker = 1+2 = 3 = \dim\mathbb{Q}^3$.

Worked Example 11.2.24 (An injective non-surjective map)**.** Let $\psi\colon \mathbb{Q}^2 \to \mathbb{Q}^3$, $\psi(x,y) = (x,\ y,\ x+y)$. Compute $\operatorname{rank}\psi$, $\dim\ker\psi$, and decide injectivity/surjectivity.

Recognition. Form the 3×2 matrix, find its rank, and apply rank–nullity with $\dim V = 2$.

Solution. $\mathrm{M}(\psi) = \begin{pmatrix}1&0\\0&1\\1&1\end{pmatrix}$ has two independent columns, so $\operatorname{rank}\psi = 2$. Then $\dim\ker\psi = 2-2 = 0$, so ψ is injective. But $\dim(\operatorname{im}\psi) = 2 < 3 = \dim\mathbb{Q}^3$, so ψ is not surjective; its image is the plane $\{\,(a,b,c) : c = a+b\,\}$. Sanity check: $\psi(x,y) = 0$ forces $x = y = 0$, confirming the trivial kernel.

Worked Example 11.2.25 (Rank over $\mathbb{F}_2$)**.** Let $\varphi\colon \mathbb{F}_2^3 \to \mathbb{F}_2^3$ have matrix $A = \begin{pmatrix}1&1&0\\0&1&1\\1&0&1\end{pmatrix}$ over $\mathbb{F}_2$. Find $\operatorname{rank}\varphi$ and $\dim\ker\varphi$, and exhibit a kernel vector.

Recognition. Row-reduce A over $\mathbb{F}_2$; nullity $= 3 -$ rank.

Solution. Replace R_3 by $R_3 + R_1 = (0,1,1)$, which equals R_2; then $R_3 + R_2 = 0$. So the echelon form has two nonzero rows: $\operatorname{rank}\varphi = 2$, hence $\dim\ker\varphi = 3-2 = 1$. A kernel vector: solving $x+y = 0,\ y+z = 0$ over $\mathbb{F}_2$ gives $x = y = z$, so $(1,1,1) \in \ker\varphi$. Sanity check: $A(1,1,1)^{\mathsf{T}} = (1+1,\ 1+1,\ 1+1)^{\mathsf{T}} = (0,0,0)^{\mathsf{T}}$, and $1+2 = 3 = \dim\mathbb{F}_2^3$.

Worked Example 11.2.26 (Full-rank map $\mathbb{Q}^4 \to \mathbb{Q}^3$)**.** Let $B = \begin{pmatrix}1&1&0&2\\0&1&1&1\\1&0&2&1\end{pmatrix}$ be the matrix of $\varphi\colon \mathbb{Q}^4 \to \mathbb{Q}^3$. Compute the rank, the nullity, and conclude whether φ is surjective.

Recognition. Row-reduce over $\mathbb{Q}$; surjectivity onto $\mathbb{Q}^3$ means rank $= 3$.

Solution. Row reduction yields three pivots (the three rows are independent: $R_3 - R_1 = (0,-1,2,-1)$, and $R_3 - R_1 + R_2 = (0,0,3,0)$ is nonzero, so all three are independent). Thus $\operatorname{rank}\varphi = 3$, and φ is surjective. By rank–nullity $\dim\ker\varphi = 4-3 = 1$. Sanity check: $\dim\operatorname{im} = 3 = \dim\mathbb{Q}^3$ confirms surjectivity; a 3×4 matrix can have rank at most 3, achieved here.

Worked Example 11.2.27 (Using the dimension-count corollary)**.** Let $\varphi\colon V \to V$ with $\dim V = 5$ satisfy $\operatorname{rank}\varphi = 5$. Show φ is an isomorphism, and that the equation $\varphi(v) = w$ has a unique solution for every w.

Recognition. Apply the equal-dimension corollary: full rank forces bijectivity.

Solution. Since $\dim V = \dim W = 5$ and $\operatorname{rank}\varphi = 5$, the corollary gives φ bijective, so it is an isomorphism. Bijectivity means $\varphi(v) = w$ has exactly one solution $v = \varphi^{-1}(w)$ for each w. Sanity check: rank–nullity gives $\dim\ker = 5-5 = 0$, so the homogeneous equation $\varphi(v) = 0$ has only $v = 0$, which is precisely uniqueness.

The isomorphism $\mathrm{Hom}_F(V,W) \cong \mathrm{M}_{m\times n}(F)$

Theorem 11.2.28 (Hom as a matrix space)**.** *Fix ordered bases $\mathcal{B}$ of V ($\dim V = n$) and $\mathcal{E}$ of W ($\dim W = m$). The map*

$$\Phi\colon \mathrm{Hom}_F(V,W) \longrightarrow \mathrm{M}_{m\times n}(F), \qquad \Phi(\varphi) = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi),$$

is an isomorphism of F-vector spaces. Consequently

$$\dim_F \mathrm{Hom}_F(V,W) = mn = (\dim V)(\dim W).$$

Proof. Φ is linear: $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi+\psi) = \mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)+\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\psi)$ and $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(c\varphi) = c\,\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)$ entrywise, directly from the definition of the entries via $\varphi(v_j) = \sum_i \alpha_{ij} w_i$. It is injective: if $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi) = 0$ then $\varphi(v_j) = 0$ for all j, and a linear map vanishing on a basis is 0. It is surjective: given any $A = (\alpha_{ij})$, the assignment $v_j \mapsto \sum_i \alpha_{ij} w_i$ extends uniquely (by the universal property of a basis) to a linear φ with $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi) = A$. Finally $\dim \mathrm{M}_{m\times n}(F) = mn$. □

This is the "matrix functor" on objects: choosing bases turns the space of maps $V \to W$ into a concrete matrix space, compatibly with composition (the multiplication square below, where μ denotes "compose" and the bottom map is matrix multiplication).

$$\begin{array}{ccc} \mathrm{Hom}_F(U,W)\times\mathrm{Hom}_F(V,U) & \xrightarrow{\ \mu\ } & \mathrm{Hom}_F(V,W) \\ \Big\downarrow{\scriptstyle \Phi\times\Phi} & & \Big\downarrow{\scriptstyle \Phi} \\ \mathrm{M}_{m\times p}(F)\times\mathrm{M}_{p\times n}(F) & \xrightarrow[(A,B)\mapsto AB]{} & \mathrm{M}_{m\times n}(F) \end{array}$$

Diagram explanation. Objects: The top-left node is the set of composable pairs of linear maps: $\mathrm{Hom}_F(U,W)\times \mathrm{Hom}_F(V,U)$ with $\dim V = n$, $\dim U = p$, $\dim W = m$. The top-right node is $\mathrm{Hom}_F(V,W)$. The bottom-left node is the set of composable matrix pairs $\mathrm{M}_{m\times p}(F)\times \mathrm{M}_{p\times n}(F)$, and the bottom-right is $\mathrm{M}_{m\times n}(F)$.

Arrows: The top horizontal arrow μ is composition of linear maps: $(\varphi,\psi)\mapsto \varphi\circ\psi$. The bottom horizontal arrow $(A,B)\mapsto AB$ is matrix multiplication. The left vertical arrow $\Phi\times\Phi$ applies the basis-determined isomorphism $\Phi(\chi) = \mathrm{M}^{\text{appropriate bases}}(\chi)$ component-wise; the right vertical arrow Φ does the same for maps in $\mathrm{Hom}_F(V,W)$.

What commutes: Right-then-down equals down-then-right: $\Phi(\varphi\circ\psi) = \Phi(\varphi)\cdot\Phi(\psi)$, i.e. $\mathrm{M}(\varphi\circ\psi) = \mathrm{M}(\varphi)\,\mathrm{M}(\psi)$. This is the composition theorem restated as commutativity of this square.

Why it commutes: Take (φ,ψ) in the top-left. Right-then-down: compose first to get $\varphi\circ\psi$, then take its matrix – the composition theorem gives $\mathrm{M}(\varphi\circ\psi)$. Down-then-right: take each matrix separately to get $(\mathrm{M}(\varphi),\mathrm{M}(\psi))$, then multiply – the composition theorem says this product equals $\mathrm{M}(\varphi\circ\psi)$. The two outcomes are equal by the composition theorem.

Why this matters here: This square expresses that Φ is a functor (or, concretely, a ring isomorphism $\mathrm{End}(V)\cong \mathrm{M}_n(F)$): it not only sends objects to objects but also respects the multiplicative structure. It subsumes both the isomorphism theorem for Hom and the composition theorem in one picture, and explains why $\mathrm{M}_{m\times n}(F)$ is the right model for $\mathrm{Hom}_F(V,W)$.

Concrete example: For $V=\mathbb{Q}^2$, $U=\mathbb{Q}^3$, $W=\mathbb{Q}^2$ with ψ and φ from the worked example: $\Phi(\varphi) = \begin{pmatrix}1&0&2\\0&1&1\end{pmatrix}$, $\Phi(\psi) = \begin{pmatrix}1&1\\0&2\\1&0\end{pmatrix}$, and their product $\begin{pmatrix}3&1\\1&2\end{pmatrix} = \Phi(\varphi\circ\psi)$.

Common pitfall: The two Φ arrows use different bases (matching dimensions of U, V, W); students sometimes apply the wrong-size matrix. The left $\Phi\times\Phi$ converts a pair of maps using basis $\mathcal{D}$ for U; if $\mathcal{D}$ changes, both factors change simultaneously.

Takeaway: The point of this diagram is that the assignment $\varphi\mapsto \mathrm{M}(\varphi)$ is not just a bijection but a functor that converts composition of maps into multiplication of matrices, making $\mathrm{Hom}_F(V,W)\cong \mathrm{M}_{m\times n}(F)$ an isomorphism of F-vector spaces that also respects the ring (multiplicative) structure.

Worked Example 11.2.29 (A basis of $\mathrm{Hom}_F(V,W)$)**.** Take $V=\mathbb{Q}^2$, $W=\mathbb{Q}^3$ with standard bases. Exhibit a basis of $\mathrm{Hom}_{\mathbb{Q}}(\mathbb{Q}^2,\mathbb{Q}^3)$ and confirm dim = 6.

Recognition. Pull back the standard matrix-unit basis $\{E_{ij}\}$ of $\mathrm{M}_{3\times 2}(\mathbb{Q})$ through Φ^{-1}.

Solution. The matrix units E_{ij} $(1\le i\le 3,\ 1\le j\le 2)$ form a basis of $\mathrm{M}_{3\times 2}(\mathbb{Q})$, of size 6. Their preimages $\varphi_{ij}=\Phi^{-1}(E_{ij})$ are the maps $\varphi_{ij}(e_j)=f_i$, $\varphi_{ij}(e_{j'})=0$ for $j'\neq j$. These six maps form a basis of $\mathrm{Hom}_{\mathbb{Q}}(\mathbb{Q}^2,\mathbb{Q}^3)$, so dim $=6=2\cdot 3$. Sanity check: a general φ has matrix $\sum_{i,j}\alpha_{ij}E_{ij}$, hence $\varphi=\sum\alpha_{ij}\varphi_{ij}$ uniquely.

Worked Example 11.2.30 ($\dim\mathrm{End}(V)$ and the regular representation)**.** For $V=\mathbb{Q}^3$, what is $\dim\mathrm{End}(V)$, and how many basis operators are needed?

Recognition. $\mathrm{End}(V)=\mathrm{Hom}(V,V)$, so dim $=n^2$ by the theorem with $m=n=3$.

Solution. $\dim\mathrm{End}(\mathbb{Q}^3)=3^2=9$, with basis the nine operators φ_{ij} corresponding to the matrix units $E_{ij}\in\mathrm{M}_3(\mathbb{Q})$. Sanity check: $\mathrm{End}(V)$ is also a ring isomorphic to $\mathrm{M}_3(\mathbb{Q})$, whose dimension as a $\mathbb{Q}$-vector space is indeed 9.

Worked Example 11.2.31 (Counting maps over a finite field)**.** How many linear maps are there in $\mathrm{Hom}_{\mathbb{F}_2}(\mathbb{F}_2^2,\mathbb{F}_2^3)$?

Recognition. $\mathrm{Hom}_{\mathbb{F}_2}(\mathbb{F}_2^2,\mathbb{F}_2^3)\cong\mathrm{M}_{3\times 2}(\mathbb{F}_2)$, and a finite-dimensional space over $\mathbb{F}_q$ of dimension d has q^d elements.

Solution. The dimension is $mn=3\cdot 2=6$, so the space has $|\mathbb{F}_2|^6=2^6=64$ elements; there are 64 linear maps. Sanity check: each map is a 3×2 matrix over $\mathbb{F}_2$ with 6 free entries, each 0 or 1, giving $2^6=64$.

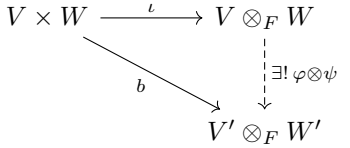
Worked Example 11.2.32 (Recovering a map from its matrix)**.** Suppose $\varphi\in\mathrm{Hom}_{\mathbb{Q}}(\mathbb{Q}^2,\mathbb{Q}^2)$ has $\mathrm{M}_{\mathcal{B}}^{\mathcal{E}}(\varphi)=\begin{pmatrix}0&1\\1&0\end{pmatrix}$ with $\mathcal{B}=\{e_1,e_2\}$ and $\mathcal{E}=\{(1,1),(1,-1)\}$. Recover φ explicitly.

Recognition. Φ is a bijection, so the matrix determines φ; read columns as coordinates in $\mathcal{E}$.

Solution. Column 1 is $(0,1)^{\mathsf{T}}$, meaning $\varphi(e_1)=0\cdot(1,1)+1\cdot(1,-1)=(1,-1)$. Column 2 is $(1,0)^{\mathsf{T}}$, so $\varphi(e_2)=(1,1)$. Hence $\varphi(x,y)=x(1,-1)+y(1,1)=(x+y,\ -x+y)$. Sanity check: $\varphi(e_1)=(1,-1)$ and $\varphi(e_2)=(1,1)$ as required, and these are the codomain basis vectors swapped, matching the off-diagonal matrix.

Linear transformations on tensor products of vector spaces

If V has basis $\{v_1,\dots,v_n\}$ and W has basis $\{w_1,\dots,w_m\}$ over F, then $V\otimes_F W$ has the nm basis $\{v_i\otimes w_j\}$, so $\dim(V\otimes_F W)=(\dim V)(\dim W)$. Tensoring is functorial on maps:



Proposition 11.2.33 (Tensor product of linear maps)**.** *Let $\varphi\colon V\to V'$ and $\psi\colon W\to W'$ be linear. There is a unique linear map*

$$\varphi\otimes\psi\colon V\otimes_F W\longrightarrow V'\otimes_F W',\qquad(\varphi\otimes\psi)(v\otimes w)=\varphi(v)\otimes\psi(w).$$

It satisfies $(\varphi'\otimes\psi')\circ(\varphi\otimes\psi)=(\varphi'\circ\varphi)\otimes(\psi'\circ\psi)$ and $\mathrm{id}_V\otimes\mathrm{id}_W=\mathrm{id}_{V\otimes W}$, and $\mathrm{rank}(\varphi\otimes\psi)=(\mathrm{rank}\,\varphi)(\mathrm{rank}\,\psi)$.

Proof. The map $(v,w)\mapsto\varphi(v)\otimes\psi(w)$ is F-bilinear, so by the universal property of the tensor product it factors uniquely through $V\otimes_F W$, giving $\varphi\otimes\psi$. Functoriality is checked on simple tensors $v\otimes w$ (which span), and the rank formula follows because $\mathrm{im}(\varphi\otimes\psi)=\mathrm{im}\,\varphi\otimes\mathrm{im}\,\psi$ has dimension $(\mathrm{rank}\,\varphi)(\mathrm{rank}\,\psi)$. □

The defining universal property is the commuting triangle through the canonical bilinear map $\iota\colon(v,w)\mapsto v\otimes w$:

where $b(v,w)=\varphi(v)\otimes\psi(w)$.

Diagram explanation. Objects: Three objects: the cartesian product $V \times W$ (a set with a bilinear structure, not itself a tensor product), the tensor product $V \otimes_F W$ (the universal recipient of F-bilinear maps out of $V \times W$), and the target tensor product $V' \otimes_F W'$ (where $\varphi\colon V \to V'$ and $\psi\colon W \to W'$ map to).

Arrows: The top arrow $\iota\colon V \times W \to V \otimes_F W$ is the canonical bilinear map $(v, w) \mapsto v \otimes w$, the universal bilinear map. The diagonal arrow $b\colon V \times W \to V' \otimes_F W'$ is the bilinear map $b(v, w) = \varphi(v) \otimes \psi(w)$; it is F-bilinear because φ, ψ are linear. The dashed vertical arrow $\varphi \otimes \psi\colon V \otimes_F W \to V' \otimes_F W'$ is the unique linear map guaranteed by the universal property of the tensor product.

What commutes: The triangle commutes: $(\varphi \otimes \psi) \circ \iota = b$, i.e. $(\varphi \otimes \psi)(v \otimes w) = \varphi(v) \otimes \psi(w)$ for all $v \in V$, $w \in W$. This is both the definition of $\varphi \otimes \psi$ and the commutativity condition.

Why it commutes: Well-definedness (the crucial check): the map b is F-bilinear in (v, w), so by the universal property of the tensor product there exists a *unique* linear map $V \otimes_F W \to V' \otimes_F W'$ making the triangle commute. That unique map is $\varphi \otimes \psi$. No ambiguity arises because simple tensors $v \otimes w$ generate $V \otimes_F W$ and the value on generators is fixed by $b(v, w) = \varphi(v) \otimes \psi(w)$.

Why this matters here: This triangle justifies that $\varphi \otimes \psi$ is well-defined as a linear map: a general element of $V \otimes_F W$ is a *sum* of simple tensors, so specifying $(\varphi \otimes \psi)(v \otimes w)$ alone does not automatically give a well-defined linear map; the universal property is the guarantee. Without this triangle, one could not legitimately write "$(\varphi \otimes \psi)(v \otimes w) = \varphi(v) \otimes \psi(w)$" as a definition.

Concrete example: Take $\varphi = \mathrm{id}_{\mathbb{Q}^2}$ and $\psi = \mathrm{id}_{\mathbb{Q}^2}$. The bilinear map $b(v, w) = v \otimes w$ is already the canonical one, so the universal property gives $\mathrm{id}_{\mathbb{Q}^2} \otimes \mathrm{id}_{\mathbb{Q}^2} = \mathrm{id}_{\mathbb{Q}^2 \otimes \mathbb{Q}^2}$. For $\varphi(x, y) = (x + y, 0)$ and $\psi = \mathrm{id}$, $b(e_1, f_1) = e_1 \otimes f_1 + 0 \otimes f_1$ would need to be checked as bilinear before applying the universal property to define $\varphi \otimes \psi$.

Common pitfall: Students treat $\varphi \otimes \psi$ as if it were defined on all of $V \otimes_F W$ by "applying to each summand" without checking that the result is independent of the choice of simple-tensor decomposition. The dashed arrow's existence and uniqueness via the universal property is exactly the well-definedness check that prevents this error.

Takeaway: The point of this diagram is that $\varphi \otimes \psi$ is well-defined because the bilinear map $b(v, w) = \varphi(v) \otimes \psi(w)$ factors uniquely through the tensor product via the universal property, so "applying φ and ψ factor-wise" has an unambiguous meaning as a linear map on $V \otimes_F W$.

Theorem 11.2.34 (Matrix of $\varphi \otimes \psi$ is the Kronecker product)**.** *With respect to the basis $\{ v_i \otimes w_k \}$ (ordered lexicographically), if $A = \mathrm{M}(\varphi)$ and $B = \mathrm{M}(\psi)$ then $\mathrm{M}(\varphi \otimes \psi) = A \otimes B$, the Kronecker product, whose blocks are $\alpha_{ij} B$.*

Proof. Compute $(\varphi \otimes \psi)(v_j \otimes w_l) = \varphi(v_j) \otimes \psi(w_l) = \big(\sum_i \alpha_{ij} v_i'\big) \otimes \big(\sum_k \beta_{kl} w_k'\big) = \sum_{i,k} \alpha_{ij} \beta_{kl} \, (v_i' \otimes w_k')$. The coefficient of $v_i' \otimes w_k'$ is $\alpha_{ij} \beta_{kl}$, which is precisely the entry of $A \otimes B$ in the row indexed (i, k) and column indexed (j, l). □

Worked Example 11.2.35 (Dimension of a tensor product)**.** Compute $\dim_{\mathbb{Q}}(\mathbb{Q}^3 \otimes_{\mathbb{Q}} \mathbb{Q}^4)$ and write down a basis.

Recognition. $\dim(V \otimes W) = (\dim V)(\dim W)$, with basis the simple tensors of basis vectors.

Solution. $\dim_{\mathbb{Q}}(\mathbb{Q}^3 \otimes_{\mathbb{Q}} \mathbb{Q}^4) = 3 \cdot 4 = 12$, with basis $\{ e_i \otimes f_j : 1 \le i \le 3,\ 1 \le j \le 4 \}$. Sanity check: this matches $\dim \mathrm{Hom}_{\mathbb{Q}}(\mathbb{Q}^3, \mathbb{Q}^4) = 12$, reflecting $V^* \otimes W \cong \mathrm{Hom}(V, W)$.

Worked Example 11.2.36 (Kronecker product of two small matrices)**.** Let $A = \begin{pmatrix} 1 & 2 \\ 0 & 3 \end{pmatrix} = \mathrm{M}(\varphi)$ and $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \mathrm{M}(\psi)$ over $\mathbb{Q}$. Compute $\mathrm{M}(\varphi \otimes \psi) = A \otimes B$.

Recognition. Replace each entry α_{ij} of A by the block $\alpha_{ij} B$.

Solution.

$$A \otimes B = \begin{pmatrix} 1 \cdot B & 2 \cdot B \\ 0 \cdot B & 3 \cdot B \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 2 \\ 1 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 3 & 0 \end{pmatrix}.$$

Sanity check: $\det(A \otimes B) = (\det A)^{\dim W} (\det B)^{\dim V} = 3^2 \cdot (-1)^2 = 9$, and $\mathrm{rank}(A \otimes B) = \mathrm{rank}\, A \cdot \mathrm{rank}\, B = 2 \cdot 2 = 4$ (full rank), consistent with the displayed 4×4 matrix having nonzero determinant.

Worked Example 11.2.37 (Functoriality on simple tensors)**.** With $\varphi\colon \mathbb{Q}^2 \to \mathbb{Q}^2$ given by $\mathrm{M}(\varphi) = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $\psi = \mathrm{id}_{\mathbb{Q}^2}$, evaluate $(\varphi \otimes \psi)(e_1 \otimes f_2 + e_2 \otimes f_1)$.

Recognition. Apply $\varphi \otimes \psi$ to each simple tensor separately, using $(\varphi \otimes \psi)(v \otimes w) = \varphi(v) \otimes \psi(w)$.

Solution. $\varphi(e_1) = e_1$, $\varphi(e_2) = e_1 + e_2$, $\psi = \mathrm{id}$. So

$$(\varphi \otimes \psi)(e_1 \otimes f_2) = e_1 \otimes f_2, \qquad (\varphi \otimes \psi)(e_2 \otimes f_1) = (e_1 + e_2) \otimes f_1 = e_1 \otimes f_1 + e_2 \otimes f_1.$$

The sum is $e_1 \otimes f_1 + e_1 \otimes f_2 + e_2 \otimes f_1$. Sanity check: $\operatorname{rank}(\varphi \otimes \psi) = \operatorname{rank}\varphi \cdot \operatorname{rank}\psi = 2 \cdot 2 = 4$, so $\varphi \otimes \psi$ is invertible on the 4-dimensional space $\mathbb{Q}^2 \otimes \mathbb{Q}^2$; in particular it is injective, and the output above is nonzero as expected.

Worked Example 11.2.38 (Trace is multiplicative under tensor)**.** For operators φ, ψ on finite-dimensional spaces, show $\operatorname{tr}(\varphi \otimes \psi) = \operatorname{tr}(\varphi)\ \operatorname{tr}(\psi)$, and verify on the matrices of the previous Kronecker example.

Recognition. The matrix of $\varphi \otimes \psi$ is $A \otimes B$; use the block structure to read its trace.

Solution. The diagonal blocks of $A \otimes B$ are $\alpha_{ii}B$, so $\operatorname{tr}(A \otimes B) = \sum_i \alpha_{ii} \operatorname{tr} B = (\operatorname{tr} A)(\operatorname{tr} B)$. For $A = \begin{pmatrix} 1 & 2 \\ 0 & 3 \end{pmatrix}$, $B = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$: $\operatorname{tr} A = 4$, $\operatorname{tr} B = 0$, so $\operatorname{tr}(A \otimes B) = 0$. Sanity check: the explicit 4×4 matrix above has diagonal $(0, 0, 0, 0)$, trace 0, matching $4 \cdot 0 = 0$.

Exercises (from the text).

1. Let V be the collection of polynomials with coefficients in $\mathbb{Q}$ in the variable x of degree at most 5. Determine the transition matrix from the basis $1, x, x^2, \ldots, x^5$ for V to the basis $1, 1+x, 1+x+x^2, \ldots, 1+x+x^2+x^3+x^4+x^5$ for V.
2. Let V be the vector space of the preceding exercise. Let $\varphi = d/dx$ be the linear transformation of V to itself given by usual differentiation of a polynomial with respect to x. Determine the matrix of φ with respect to the two bases for V in the previous exercise.
3. Let V be the collection of polynomials with coefficients in F in the variable x of degree at most n. Determine the transition matrix from the basis $1, x, x^2, \ldots, x^n$ for V to the elements

   $$1,\ x - \lambda, \ldots,\ (x-\lambda)^{n-1},\ (x-\lambda)^n$$

   where λ is a fixed element of F. Conclude that these elements are a basis for V.
4. Let φ be the linear transformation of $\mathbb{R}^2$ to itself given by rotation counterclockwise around the origin through an angle θ. Show that the matrix of φ with respect to the standard basis for $\mathbb{R}^2$ is $\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$.
5. Show that the $m \times n$ matrix A is nonsingular if and only if the linear transformation φ is a nonsingular linear transformation from the n-dimensional vector space V to the m-dimensional vector space W, where $A = M_{\mathcal{B}}^{\mathcal{E}}(\varphi)$, regardless of the choice of bases $\mathcal{B}$ and $\mathcal{E}$.
6. Prove if $\varphi \in \operatorname{Hom}_F(F^n, F^m)$, and $\mathcal{B}, \mathcal{E}$ are the natural bases of F^n, F^m respectively, then the range of φ equals the span of the set of columns of $M_{\mathcal{B}}^{\mathcal{E}}(\varphi)$. Deduce that the rank of φ (as a linear transformation) equals the column rank of $M_{\mathcal{B}}^{\mathcal{E}}(\varphi)$.
7. Prove that any two similar matrices have the same column rank.
8. Let V be an n-dimensional vector space over F and let φ be a linear transformation of the vector space V to itself.
   (a) Prove that if V has a basis consisting of eigenvectors for φ (cf. Exercise 8 of Section 1) then with respect to this basis the matrix of φ is diagonal (for both domain and range) with the eigenvalues as diagonal entries.

(b) If A is the $n \times n$ matrix representing φ with respect to a given basis for V for both domain and range) prove that A is similar to a diagonal matrix if and only if V has a basis of eigenvectors for φ.

9. If W is a subspace of the vector space V stable under the linear transformation φ (i.e., $\varphi(W) \subseteq W$), show that φ induces linear transformations $\varphi|_W$ on W and $\overline{\varphi}$ on the quotient vector space V/W. If $\varphi|_W$ and $\overline{\varphi}$ are nonsingular prove φ is nonsingular. Prove the converse holds if V has finite dimension and give a counterexample with V infinite dimensional.

10. Let V be an n-dimensional vector space and let φ be a linear transformation of V to itself. Suppose W is a subspace of V of dimension m that is stable under φ.

    (a) Prove that there is a basis for V with respect to which the matrix for φ is of the form

    $$\begin{pmatrix} A & B \\ 0 & C \end{pmatrix}$$

    where A is an $m \times m$ matrix, B is an $m \times (n-m)$ matrix and C is an $(n-m) \times (n-m)$ matrix (such a matrix is called *block upper triangular*).

    (b) Prove that if there is a subspace W' invariant under φ so that $V = W \oplus W'$ decomposes as a direct sum then the bases for W and W' give a basis for V with respect to which the matrix for φ is *block diagonal*:

    $$\begin{pmatrix} A & 0 \\ 0 & C \end{pmatrix}$$

    where A is an $m \times m$ matrix and C is an $(n-m) \times (n-m)$ matrix.

    (c) Prove conversely that if there is a basis for V with respect to which the matrix for φ is block diagonal as in (b) then the subspace W spanned by the basis vectors giving the first block and the subspace W' spanned by the basis vectors giving the second block are φ-invariant subspaces W and W' of dimensions m and $n-m$, respectively, with $V = W \oplus W'$.

11. Let φ be a linear transformation from the finite dimensional vector space V to itself such that $\varphi^2 = \varphi$.

    (a) Prove that image $\varphi \cap \ker \varphi = 0$.

    (b) Prove that $V = \text{image } \varphi \oplus \ker \varphi$.

    (c) Prove there is a basis of V such that the matrix of φ with respect to this basis is a diagonal matrix whose entries are all 0 or 1.

    A linear transformation φ satisfying $\varphi^2 = \varphi$ is called an *idempotent* linear transformation. This exercise proves that idempotent linear transformations are simply projections onto some subspace.

12. Let $V = \mathbb{R}^2$, $v_1 = (1,0)$, $v_2 = (0,1)$, so that v_1, v_2 are a basis for V. Let φ be the linear transformation of V to itself whose matrix with respect to this basis is $\begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$. Prove that if W is the subspace generated by v_1 then W is stable under the action of φ. Prove that there is no subspace W' invariant under φ so that $V = W \oplus W'$.

13. Let V be a vector space of dimension n and let W be a vector space of dimension m over a field F. Suppose A is the $m \times n$ matrix representing a linear transformation φ from V to W with respect to the bases $\mathcal{B}_1$ for V and $\mathcal{E}_1$ for W. Suppose similarly that B is the $m \times n$ matrix representing φ with respect to the bases $\mathcal{B}_2$ for V and $\mathcal{E}_2$ for W. Let $P = M_{\mathcal{B}_2}^{\mathcal{B}_1}(I)$ where I denotes the identity map from V to V, and let $Q = M_{\mathcal{E}_2}^{\mathcal{E}_1}(I)$ where I denotes the identity map from W to W. Prove that $Q^{-1} = M_{\mathcal{E}_1}^{\mathcal{E}_2}(I)$ and that $Q^{-1}AP = B$, giving the general relation between matrices representing the same linear transformation but with respect to different choices of bases.

14. Prove that if A can be row reduced to C then C can be row reduced to A. Prove that the relation "$A \sim C$ if and only if A can be row reduced to C" is an equivalence relation. [Observe that the elementary row operations are reversible.]

15. Prove that the row rank of two row equivalent matrices is the same. [It suffices to prove this for two matrices differing by an elementary row operation.]

16. Prove by induction that any augmented matrix can be put in reduced row echelon form by a series of elementary row operations.

17. Let A and C be two matrices in reduced row echelon form. Prove that if A and C are row equivalent then $A = C$.

18. Prove that the row rank of a matrix in reduced row echelon form is the number of nonzero rows.

19. Prove that the reduced row echelon form of the matrices

$$\left(\begin{array}{cccccc|c} 1 & 1 & 4 & 8 & 0 & -1 & -1 \\ 1 & 2 & 3 & 9 & 0 & -5 & -2 \\ 0 & -2 & 2 & -2 & 1 & 14 & 3 \\ 1 & 4 & 1 & 11 & 0 & -13 & -4 \end{array}\right) \qquad \left(\begin{array}{cccc|c} 0 & -3 & 3 & 1 & 5 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 2 & -2 & 0 & -3 \end{array}\right)$$

are the two matrices preceding Exercise 16.

20. (*Solving Systems of Linear Equations*) Let $(A' \mid C')$ be the reduced row echelon form of the augmented matrix $(A \mid C)$. The number of zero rows of A' is clearly at least as great as the number of zero rows of $(A' \mid C')$.

    (a) Prove that if the number of zero rows of A' is strictly larger than the number of zero rows of $(A' \mid C')$ then there are no solutions to $AX = C$.

    (b) By (a) we may assume that A' and $(A' \mid C')$ have the same number, r, of nonzero rows (so $r \leq n$, where n is the number of unknowns, i.e. of columns of A). Prove that if $r = n$ then there is precisely one solution to the system of equations $AX = C$.

    (c) Prove that if $r < n$ then there are $|F|^{n-r}$ solutions to the system of equations $AX = C$ (infinitely many when F is infinite). Prove in fact that the values of the $n - r$ variables corresponding to the nonpivotal columns of $(A' \mid C')$ can be chosen arbitrarily and that the remaining r variables corresponding to the pivotal columns of $(A' \mid C')$ are then determined uniquely.

21. Determine the solutions of the following systems of equations:

    (a)
    $$\begin{aligned} -3x + 3y + z &= 5 \\ x - y &= 0 \\ 2x - 2y &= -3 \end{aligned}$$

    (b)
    $$\begin{aligned} x - 2y + z &= 5 \\ x - 4y + 6z &= 10 \\ 4x - 11y + 11z &= 12 \end{aligned}$$

    (c)
    $$\begin{aligned} x - 2y + z &= 5 \\ y - 2z &= 17 \\ 2x - 3y &= 27 \end{aligned}$$

    (d)
    $$\begin{aligned} x + y - 3z + 2u &= 2 \\ 3x - 2y + 5z + u &= 1 \\ 6x + y - 4z + 3u &= 7 \\ 2x + 2y - 6z &= 4 \end{aligned}$$

    (e)
    $$\begin{aligned} x + y + 4z + 8u - w &= -1 \\ x + 2y + 3z + 9u - 5w &= -2 \\ -2y + 2z - 2u + v + 14w &= 3 \\ x + 4y + z + 11u - 13w &= -4 \end{aligned}$$

22. Suppose A and B are two row equivalent $m \times n$ matrices.

    (a) Prove that the set

    $$X = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}$$

    of solutions to the homogeneous linear equations $AX = 0$ in equation (4) above are the same as the set of solutions to the homogeneous linear equations $BX = 0$. [It suffices to prove this for two matrices differing by an elementary row operation.]

    (b) Prove that any linear dependence relation satisfied by the columns of A viewed as vectors in F^m is also satisfied by the columns of B.

    (c) Conclude from (b) that the number of linearly independent columns of A is the same as the number of linearly independent columns of B.

23. Let A' be a matrix in reduced row echelon form.

    (a) Prove that the nonzero rows of A' are linearly independent. Prove that the pivotal columns of A' are linearly independent and that the nonpivotal columns of A' are linearly dependent on the pivotal columns. (Note the role the pivotal elements play.)

    (b) Prove that the number of linearly independent columns of a matrix in reduced row echelon form is the same as the number of linearly independent rows, i.e., the row rank and the column rank of such a matrix are the same.

24. Use the previous two exercises and Exercise 15 above to prove in general that the row rank and the column rank of a matrix are the same.

25. (*Computing Inverses of Matrices*) Let A be an $n \times n$ matrix.

    (a) Show that A has an inverse matrix B with columns $B_1, \ldots, B_n$ if and only if the systems of equations:

    $$AB_1 = \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \\ 0 \end{pmatrix}, \quad AB_2 = \begin{pmatrix} 0 \\ 1 \\ \vdots \\ 0 \\ 0 \end{pmatrix}, \quad \ldots, \quad AB_n = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}$$

    have solutions.

    (b) Prove that A has an inverse if and only if A is row equivalent to the $n \times n$ identity matrix.

    (c) Prove that A has an inverse B if and only if the augmented matrix $(A \mid I)$ can be row reduced to the augmented matrix $(I \mid B)$ where I is the $n \times n$ identity matrix.

26. Determine the inverses of the following matrices using row reduction:

    $$A = \begin{pmatrix} -7 & -1 & -4 \\ 7 & 1 & 3 \\ 1 & 0 & 1 \end{pmatrix}, \qquad B = \begin{pmatrix} 1 & 1 & 0 & 2 \\ 0 & 2 & 1 & -1 \\ 0 & 2 & 0 & 0 \\ -1 & 1 & 1 & 0 \end{pmatrix}.$$

27. (*Computing Spans, Linear Independence and Linear Dependencies in Vector Spaces*) Let V be an m-dimensional vector space with basis $e_1, e_2, \ldots, e_m$ and let $v_1, v_2, \ldots, v_n$ be vectors in V. Let A be the $m \times n$ matrix whose columns are the coordinates of the vectors v_i (with respect to the basis $e_1, e_2, \ldots, e_m$) and let A' be its reduced row echelon form of A.

(a) Let B be any matrix row equivalent to A. Let $w_1, w_2, \ldots, w_n$ be the vectors whose coordinates (with respect to the basis $e_1, e_2, \ldots, e_m$) are the columns of B. Prove that any linear relation

$$x_1v_1 + x_2v_2 + \cdots + x_nv_n = 0 \tag{11.5}$$

satisfied by $v_1, v_2, \ldots, v_n$ is also satisfied by v_i when v_i is replaced by w_i, $i = 1, 2, \ldots, n$.

(b) Prove that the vectors whose coordinates are given by the pivotal columns of A' are linearly independent and that the vectors whose coordinates are given by the nonpivotal columns of A' are linearly dependent on these.

(c) (*Determining Linear Independence of Vectors*) Prove that the vectors $v_1, v_2, \ldots, v_n$ are linearly independent if and only if A' has n nonzero rows (i.e., has rank n).

(d) (*Determining Linear Dependencies of Vectors*) By (c), the vectors $v_1, v_2, \ldots, v_n$ are linearly dependent if and only if A' has nonpivotal columns. The solutions to (11.5), which define the linear dependence relations among $v_1, v_2, \ldots, v_n$, are given by the linear equations defined by A'. Show that each of the variables $x_1, x_2, \ldots, x_n$ in (11.5) corresponding to the nonpivotal columns of A' can be prescribed arbitrarily and the values of the remaining variables are then uniquely determined to give a linear dependence relation among $v_1, v_2, \ldots, v_n$ as in (11.5).

(e) (*Determining the Span of a Set of Vectors*) Prove that the subspace W spanned by $v_1, v_2, \ldots, v_n$ has dimension r where r is the number of nonzero rows of A' and that a basis for W is given by the original vectors v_{j_i} $(i = 1, 2, \ldots, r)$ corresponding to the pivotal columns of A'.

28. Let $V = \mathbb{R}^5$ with the standard basis and consider the vectors

$$v_1 = (1, 1, 3, -2, 3), \quad v_2 = (0, 1, 0, -1, 0), \quad v_3 = (2, 3, 6, -5, 6)$$

$$v_4 = (0, 3, 1, -3, 1), \quad v_5 = (2, -1, -1, -1, -1).$$

(a) Show that the reduced row echelon form of the matrix

$$A = \begin{pmatrix} 1 & 0 & 2 & 0 & 2 \\ 1 & 1 & 3 & 3 & -1 \\ 3 & 0 & 6 & 1 & -1 \\ -2 & -1 & -5 & -3 & -1 \\ 3 & 0 & 6 & 1 & -1 \end{pmatrix}$$

whose columns are the coordinates of v_1, v_2, v_3, v_4, v_5 in the matrix

$$A' = \begin{pmatrix} 1 & 0 & 2 & 0 & 2 \\ 0 & 1 & 1 & 0 & 18 \\ 0 & 0 & 0 & 1 & -7 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

where the 1st, 2nd and 4th columns are pivotal and the remaining two are nonpivotal.

(b) Conclude from (a) that these vectors are linearly dependent, that the subspace W spanned by v_1, v_2, v_3, v_4, v_5 is 3-dimensional and that the vectors

$$v_1 = (1, 1, 3, -2, 3), \quad v_2 = (0, 1, 0, -1, 0) \quad \text{and} \quad v_4 = (0, 3, 1, -3, 1)$$

are a basis for W.

(c) Conclude from (a) that the coefficients x_1, x_2, x_3, x_4, x_5 of any linear relation

$$x_1v_1 + x_2v_2 + x_3v_3 + x_4v_4 + x_5v_5 = 0$$

satisfied by v_1, v_2, v_3, v_4, v_5 are given by the equations

$$\begin{aligned} x_1 \quad + 2x_3 \quad + 2x_5 &= 0 \\ x_2 + x_3 \quad + 18x_5 &= 0 \\ x_4 - 7x_5 &= 0 \end{aligned}$$

Deduce that the 3rd and 5th variables, namely x_3 and x_5, corresponding to the nonpivotal columns of A', can be prescribed arbitrarily and the remaining variables are then uniquely determined as:

$$\begin{aligned} x_1 &= -2x_3 - 2x_5 \\ x_2 &= -x_3 - 18x_5 \\ x_4 &= 7x_5 \end{aligned}$$

to give all the linear dependence relations satisfied by v_1, v_2, v_3, v_4, v_5. In particular show that

$$-2v_1 - v_2 + v_3 = 0$$

and

$$-2v_1 - 18v_2 + 7v_4 + v_5 = 0$$

corresponding to ($x_3 = 1$, $x_5 = 0$) and ($x_3 = 0$, $x_5 = 1$), respectively.

29. For each exercise below, determine whether the given vectors in $\mathbb{R}^4$ are linearly independent. If they are linearly dependent, determine an explicit linear dependence among them.

    (a) $(1, -4, 3, 0)$, $(0, -1, 4, -3)$, $(1, -1, 1, -1)$, $(2, 2, -1, -3)$.

    (b) $(1, -4, 2, 5)$, $(2, -3, 9, -1)$, $(1, 0, 6, -5)$, $(2, -5, 7, 5)$.

    (c) $(1, -2, 0, 1)$, $(2, -3, 0, -1)$, $(-1, 3, 0, -2)$, $(1, 0, 0, 1)$.

    (d) $(0, 1, 1, 0)$, $(1, 0, 1, 1)$, $(2, 2, 2, 0)$, $(0, -1, 1, 1)$.

30. For each exercise below, determine the subspace spanned in $\mathbb{R}^4$ by the given vectors and give a basis for this subspace.

    (a) $(1, -2, 5, 3)$, $(2, 3, 1, -4)$, $(3, 8, -3, -5)$.

    (b) $(2, -5, 3, 0)$, $(0, -2, 5, -3)$, $(1, -1, 1, -1)$, $(-3, 2, -1, 3)$.

    (c) $(1, -2, 0, 1)$, $(2, -2, 0, 0)$, $(-1, 3, 0, -2)$, $(-2, 1, 0, 1)$.

    (d) $(1, 1, 0, -1)$, $(1, 2, 3, 0)$, $(2, 3, 3, -1)$, $(1, 2, 2, -2)$, $(2, 3, 2, -3)$, $(1, 3, 4, -3)$.

31. (*Computing the Image and Kernel of a Linear Transformation*) Let V be an n-dimensional vector space with basis $e_1, e_2, \ldots, e_n$ and let W be an m-dimensional vector space with basis $f_1, f_2, \ldots, f_m$. Let φ be a linear transformation from V to W and let the corresponding $m \times n$ matrix with respect to these bases: $A = (a_{ij})$ be

$$\varphi(e_j) = \sum_{i=1}^{m} a_{ij} f_i, \qquad j = 1, 2, \ldots, n,$$

    i.e., the columns of A are the coordinates of the vectors $\varphi(e_1), \varphi(e_2), \ldots, \varphi(e_n)$ with respect to the basis $f_1, f_2, \ldots, f_m$ of W. Let A' be the reduced row echelon form of A.

    (a) (*Determining the Image of a Linear Transformation*) Prove that the image $\varphi(V)$ of V under φ has dimension r where r is the number of nonzero rows of A' and that a basis for $\varphi(V)$ is given by the vectors $\varphi(e_{j_i})$ $(i = 1, 2, \ldots, r)$, i.e., the columns of A corresponding to the pivotal columns of A' are the coordinates of a basis for the image of φ.

(b) (*Determining the Kernel of a Linear Transformation*) The elements in the kernel of φ are the vectors in V whose coordinates $(x_1, x_2, \ldots, x_n)$ with respect to the basis $e_1, e_2, \ldots, e_n$ satisfy the equation

$$A \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = 0,$$

and the solutions $x_1, x_2, \ldots, x_n$ to this system of linear equations are determined by the matrix A'.

(i) Prove that φ is injective if and only if A' has n nonzero rows (i.e., has rank n).

(ii) By (i), the kernel of φ is nontrivial if and only if A' has nonpivotal columns. Show that each of the variables $x_1, x_2, \ldots, x_n$ above corresponding to the nonpivotal columns of A' can be prescribed arbitrarily and the values of the remaining variables are then uniquely determined to give an element $x_1e_1 + x_2e_2 + \cdots + x_ne_n$ in the kernel of φ. In particular, show that the coordinates of a basis for the kernel are obtained by successively setting one nonpivotal variable equal to 1 and all other nonpivotal variables to 0 and solving for the remaining pivotal variables. Conclude that the kernel of φ has dimension $n - r$ where r is the rank of A.

32. Let $V = \mathbb{R}^5$ and $W = \mathbb{R}^4$ with the standard bases. Let φ be the linear transformation $\varphi : V \to W$ defined by

$$\varphi(x, y, z, u, v) = (x + 2y + 3z + 4u + 4v,\ -2x - 4y + 2v,\ x + 2y + u - 2v,\ x + 2y - v).$$

(a) Prove that the matrix A corresponding to φ and these basis is

$$A = \begin{pmatrix} 1 & 2 & 3 & 4 & 4 \\ -2 & -4 & 0 & 0 & 2 \\ 1 & 2 & 0 & 1 & -2 \\ 1 & 2 & 0 & 0 & -1 \end{pmatrix}$$

and that the reduced row echelon form A' row equivalent to A is

$$A' = \begin{pmatrix} 1 & 2 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 & 3 \\ 0 & 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

where the 1st, 3rd and 4th columns are pivotal and the remaining two are nonpivotal.

(b) Conclude that the image of φ is 3-dimensional and that the image of the 1st, 3rd and 4th basis elements of V, namely, $(1, -2, 1, 1)$, $(3, 0, 0, 0)$ and $(4, 0, 1, 0)$ give a basis for the image $\varphi(V)$ of V.

(c) Conclude from (a) that the elements in the kernel of φ are the vectors (x, y, z, u, v) satisfying the equations

$$\begin{aligned} x + 2y \quad - v &= 0 \\ z \quad + 3v &= 0 \\ u - v &= 0. \end{aligned}$$

Deduce that the 2nd and 5th variables, namely y and v, corresponding to the nonpivotal columns of A' can be prescribed arbitrarily and the remaining variables are then uniquely determined as

$$\begin{aligned} x &= -2y + v \\ z &= -3v \\ u &= v. \end{aligned}$$

Show that $(-2, 1, 0, 0, 0)$ and $(1, 0, -3, 1, 1)$ give a basis for the 2-dimensional kernel of φ, corresponding to ($y = 1$, $v = 0$) and ($y = 0$, $v = 1$), respectively.

33. Let φ be the linear transformation from $\mathbb{R}^4$ to itself defined by the matrix

$$A = \begin{pmatrix} 1 & -1 & 0 & 3 \\ -1 & 2 & 1 & -1 \\ -1 & 1 & 0 & -3 \\ 1 & -2 & -1 & 1 \end{pmatrix}$$

with respect to the standard basis for $\mathbb{R}^4$. Determine a basis for the image and for the kernel of φ.

34. Let φ be the linear transformation $\varphi : \mathbb{R}^4 \to \mathbb{R}^2$ such that

$$\varphi((1,0,0,0)) = (1,-1) \qquad \varphi((1,-1,0,0)) = (0,0)$$

$$\varphi((1,-1,1,0)) = (1,-1) \qquad \varphi((1,-1,1,-1)) = (0,0).$$

Determine a basis for the image and for the kernel of φ.

35. Let V be the vector space of all 2×2 matrices with real entries and let $\varphi : V \to \mathbb{R}$ be the map defined by sending a matrix $A \in V$ to the sum of the diagonal entries of A (the *trace* of A).

    (a) Show that
    $$\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$
    is a basis for V.

    (b) Prove that φ is a linear transformation and determine the matrix of φ with respect to the basis in (a) for V. Determine the dimension of and a basis for the kernel of φ.

36. Let V be the 6-dimensional vector space over $\mathbb{Q}$ consisting of the polynomials in the variable x of degree at most 5. Let φ be the map of V to itself defined by $\varphi(f) = x^2 f'' - 6xf' + 12f$ (where f'' denotes the usual second derivative with respect to x of the polynomial $f \in V$ and f' similarly denotes the usual first derivative).

    (a) Prove that φ is a linear transformation of V to itself.

    (b) Determine a basis for the image and for the kernel of φ.

37. Let V be the 7-dimensional vector space over the field F consisting of the polynomials in the variable x of degree at most 6. Let φ be the linear transformation of V to itself defined by $\varphi(f) = f'$, where f' denotes the usual derivative with respect to x of the polynomial $f \in V$. For each of the fields below, determine a basis for the image and for the kernel of φ:

    (a) $F = \mathbb{R}$.

    (b) $F = \mathbb{F}_2$, the finite field of 2 elements (note that, for example, $(x^2)' = 2x = 0$ over this field).

    (c) $F = \mathbb{F}_3$.

    (d) $F = \mathbb{F}_5$.

38. Let A and B be square matrices. Prove that the trace of their Kronecker product is $\mathrm{tr}(A \otimes B) = \mathrm{tr}(A) \cdot \mathrm{tr}(B)$. (Recall that the trace of a square matrix is the sum of its diagonal entries.)

39. Let F be a subfield of K and let $\psi : V \to W$ be a linear transformation of finite dimensional vector spaces over F.

    (a) Prove that $1 \otimes \psi$ is a K-linear transformation from the vector spaces $K \otimes_F V$ to $K \otimes_F W$ over K. (Here 1 denotes the identity map from K to itself.)

    (b) Let $\mathcal{B} = \{v_1, \ldots, v_n\}$ and $\mathcal{E} = \{w_1, \ldots, w_m\}$ be bases of V and W respectively. Prove that the matrix of $1 \otimes \psi$ with respect to the bases $\{1 \otimes v_1, \ldots, 1 \otimes v_n\}$ and $\{1 \otimes w_1, \ldots, 1 \otimes w_m\}$ is the same as the matrix of ψ with respect to $\mathcal{B}$ and $\mathcal{E}$.

Practice problems.

1. Let $T:\mathbb{R}^3\to\mathbb{R}^2$ be the linear map $T(x,y,z)=(2x-z,\ x+3y)$. Compute the matrix $\mathrm{M}(T)$ of T relative to the standard ordered bases of $\mathbb{R}^3$ and $\mathbb{R}^2$, and use it to evaluate $T(1,-1,4)$ by matrix multiplication.

2. Let $V=\mathbb{R}^2$ with ordered basis $\mathcal{B}=(e_1,e_2)$ and let $S:V\to V$ rotate vectors by 90° counterclockwise, so $S(e_1)=e_2$ and $S(e_2)=-e_1$. Write the matrix of S relative to $\mathcal{B}$, then write the matrix of S relative to the basis $\mathcal{B}'=(e_1+e_2,\ e_1-e_2)$. Are the two matrices similar? Justify.

3. Let P_2 denote the $\mathbb{R}$-vector space of real polynomials of degree at most 2, with ordered basis $(1,x,x^2)$. Let $D:P_2\to P_2$ be differentiation, $D(p)=p'$. Compute $\mathrm{M}(D)$, then compute $\dim(\ker D)$ and $\dim(\operatorname{im} D)$ directly and verify the rank–nullity theorem $\dim P_2=\dim(\ker D)+\dim(\operatorname{im} D)$.

4. Let $A=\begin{pmatrix}1&2&0&1\\0&1&1&1\\1&3&1&2\end{pmatrix}\in \mathrm{M}_{3\times 4}(\mathbb{R})$, viewed as a linear map $T_A:\mathbb{R}^4\to\mathbb{R}^3$. Determine $\operatorname{rank}(T_A)$, a basis of $\ker(T_A)$, and verify $\operatorname{rank}(T_A)+\dim(\ker T_A)=4$.

5. Let V be a 3-dimensional $\mathbb{F}$-vector space and W a 2-dimensional $\mathbb{F}$-vector space. Using the isomorphism $\mathrm{Hom}_{\mathbb{F}}(V,W)\cong \mathrm{M}_{2\times 3}(\mathbb{F})$, state $\dim_{\mathbb{F}}\mathrm{Hom}_{\mathbb{F}}(V,W)$. Then exhibit an explicit ordered basis of $\mathrm{Hom}_{\mathbb{F}}(V,W)$ as a set of maps E_{ij} described in terms of fixed bases of V and W.

6. Let $T:\mathbb{R}^2\to\mathbb{R}^2$ have matrix $\mathrm{M}(T)=\begin{pmatrix}4&1\\2&3\end{pmatrix}$ relative to the standard basis. Let $Q=\begin{pmatrix}1&1\\1&-1\end{pmatrix}$ be the matrix whose columns are the vectors of a new ordered basis $\mathcal{B}'$, i.e. the change-of-basis matrix $\mathrm{M}^{\mathcal{S}}_{\mathcal{B}'}(\mathrm{id})$ from $\mathcal{B}'$ to the standard basis $\mathcal{S}$. Compute the matrix of T relative to $\mathcal{B}'$ as $Q^{-1}\,\mathrm{M}(T)\,Q$.

7. Let $S:\mathbb{R}^3\to\mathbb{R}^2$ and $T:\mathbb{R}^2\to\mathbb{R}^4$ be linear maps with matrices (in standard bases) $\mathrm{M}(S)=\begin{pmatrix}1&0&2\\0&1&-1\end{pmatrix}$, $\mathrm{M}(T)=\begin{pmatrix}1&1\\0&2\\3&0\\1&1\end{pmatrix}$. Compute the matrix of the composite $T\circ S:\mathbb{R}^3\to\mathbb{R}^4$ and confirm $\mathrm{M}(T\circ S)=\mathrm{M}(T)\,\mathrm{M}(S)$ has the expected dimensions.

8. Let V be a finite-dimensional $\mathbb{F}$-vector space and let $T\in\mathrm{End}_{\mathbb{F}}(V)$ satisfy $T^2=T$ (a projection). Prove that $V=\ker(T)\oplus\operatorname{im}(T)$, and deduce $\dim V=\dim(\ker T)+\dim(\operatorname{im} T)$.

9. Let $\varphi:\mathbb{R}^2\to\mathbb{R}$ and $\psi:\mathbb{R}^2\to\mathbb{R}$ be given by $\varphi(x,y)=x-y$ and $\psi(x,y)=2x+y$. Show that φ,ψ form a basis of the dual space $(\mathbb{R}^2)^*$ and find the basis (v_1,v_2) of $\mathbb{R}^2$ dual to it, i.e. with $\varphi(v_j),\psi(v_j)$ giving the appropriate 0's and 1's.

Additional exercises.

1. Let V,W be finite-dimensional $\mathbb{F}$-vector spaces with $\dim V=n$, $\dim W=m$. Prove that the map $\Phi:\mathrm{Hom}_{\mathbb{F}}(V,W)\to\mathrm{M}_{m\times n}(\mathbb{F})$ sending a linear map to its matrix relative to fixed ordered bases is an isomorphism of $\mathbb{F}$-vector spaces. Be explicit about why Φ is linear and bijective.

2. Let $T:V\to W$ be a linear map of finite-dimensional $\mathbb{F}$-vector spaces. Define the transpose map $T^*:W^*\to V^*$ by $T^*(f)=f\circ T$. Show that if $A=\mathrm{M}(T)$ relative to chosen bases, then $\mathrm{M}(T^*)$ relative to the corresponding dual bases is A^{T}. Conclude that $\operatorname{rank}(T)=\operatorname{rank}(T^*)$.

3. Let $A\in\mathrm{M}_{m\times n}(\mathbb{F})$ and $B\in\mathrm{M}_{n\times p}(\mathbb{F})$. Prove the inequality $\operatorname{rank}(AB)\le\min\{\operatorname{rank}(A),\operatorname{rank}(B)\}$ by interpreting AB as the composite of linear maps and using $\operatorname{im}(AB)\subseteq\operatorname{im}(A)$ together with rank–nullity.

4. Let V be a finite-dimensional $\mathbb{F}$-vector space and U,W subspaces. Build a linear map whose kernel and image realize $U\cap W$ and $U+W$ respectively, and use rank–nullity to prove the dimension formula $\dim(U+W)=\dim U+\dim W-\dim(U\cap W)$.

5. Let V,V',W,W' be finite-dimensional $\mathbb{F}$-vector spaces. Given $T\in\mathrm{Hom}_{\mathbb{F}}(V,W)$, $f\in\mathrm{Hom}_{\mathbb{F}}(V',V)$, and $g\in\mathrm{Hom}_{\mathbb{F}}(W,W')$, show that the assignment $T\mapsto g\circ T\circ f$ is a linear map $\mathrm{Hom}_{\mathbb{F}}(V,W)\to\mathrm{Hom}_{\mathbb{F}}(V',W')$.

If $\dim V = n$, $\dim W = m$, $\dim V' = n'$, $\dim W' = m'$, describe this map in terms of matrix multiplication on the left and right by the matrices of g and f.

Commutative-diagram exercises.

1. (Coordinate functoriality.) Fix ordered bases of finite-dimensional $\mathbb{F}$-vector spaces V (dim n) and W (dim m), giving coordinate isomorphisms $\beta_V : V \to \mathbb{F}^n$ and $\beta_W : W \to \mathbb{F}^m$. Let $T : V \to W$ be linear with matrix $A = \mathrm{M}(T)$. Prove that the square

$$\begin{array}{ccc} V & \xrightarrow{T} & W \\ {\scriptstyle \beta_V}\downarrow & & \downarrow{\scriptstyle \beta_W} \\ \mathbb{F}^n & \xrightarrow[T_A]{} & \mathbb{F}^m \end{array}$$

commutes, where $T_A(x) = Ax$. State precisely the equation among T, A, β_V, β_W that commutativity asserts.

2. (Universal property of the direct sum.) Let U, W be $\mathbb{F}$-vector spaces with inclusions $\iota_U : U \to U \oplus W$ and $\iota_W : W \to U \oplus W$. Given any $\mathbb{F}$-vector space Z and linear maps $f : U \to Z$, $g : W \to Z$, show there is a unique linear map $h : U \oplus W \to Z$ making

$$\begin{array}{ccccc} U & \xrightarrow{\iota_U} & U \oplus W & \xleftarrow{\iota_W} & W \\ & {\scriptstyle f}\searrow & \downarrow{\scriptstyle h} & \swarrow{\scriptstyle g} & \\ & & Z & & \end{array}$$

commute. When U, W, Z are finite-dimensional, describe the matrix of h as a block matrix built from $\mathrm{M}(f)$ and $\mathrm{M}(g)$.

3. (Universal property of the tensor product.) Let V, W, Z be $\mathbb{F}$-vector spaces and let $\otimes : V \times W \to V \otimes W$ be the canonical bilinear map. Prove that for every bilinear map $b : V \times W \to Z$ there is a unique linear map $\tilde{b} : V \otimes W \to Z$ with

$$\begin{array}{ccc} V \times W & \xrightarrow{\otimes} & V \otimes W \\ & {\scriptstyle b}\searrow & \downarrow{\scriptstyle \tilde{b}} \\ & & Z \end{array}$$

commuting, i.e. $\tilde{b}(v \otimes w) = b(v, w)$. When $\dim V = n$ and $\dim W = m$, deduce $\dim(V \otimes W) = nm$ by exhibiting a basis of $V \otimes W$.

4. (Functoriality of the tensor product.) Given linear maps $S : V \to V'$ and $T : W \to W'$ of finite-dimensional $\mathbb{F}$-vector spaces, the tensor product map $S \otimes T : V \otimes W \to V' \otimes W'$ is defined on simple tensors by $(S \otimes T)(v \otimes w) = S(v) \otimes T(w)$. Show that for $S' : V' \to V''$ and $T' : W' \to W''$ the diagram

$$\begin{array}{ccc} V \otimes W & \xrightarrow{S \otimes T} & V' \otimes W' \\ & {\scriptstyle (S'S)\otimes(T'T)}\searrow & \downarrow{\scriptstyle S' \otimes T'} \\ & & V'' \otimes W'' \end{array}$$

commutes, i.e. $(S' \otimes T')(S \otimes T) = (S'S) \otimes (T'T)$. Relate $\mathrm{M}(S \otimes T)$ to the Kronecker product of $\mathrm{M}(S)$ and $\mathrm{M}(T)$.

5. (Snake-style rank–nullity via an exact sequence.) Let $T : V \to W$ be a linear map of finite-dimensional $\mathbb{F}$-vector spaces. Show that

$$0 \longrightarrow \ker T \xrightarrow{\ \iota\ } V \xrightarrow{\ T\ } \operatorname{im} T \longrightarrow 0$$

is a short exact sequence of $\mathbb{F}$-vector spaces, where ι is the inclusion. Using additivity of dimension over short exact sequences (which you should state), derive the rank–nullity theorem $\dim V = \dim(\ker T) + \dim(\operatorname{im} T)$, and identify $\operatorname{rank}(T)$ in the diagram.

11.3 Dual Vector Spaces

The dual space and linear functionals

Throughout this section V is a vector space over a field F. Recall that $\mathrm{Hom}_F(V,W)$ is itself an F-vector space under pointwise operations. Taking the codomain to be the ground field F itself (a 1-dimensional space over F) singles out a vector space attached canonically to V.

Definition 11.3.1 (Dual space, linear functional)**.** The **dual space** of V is

$$V^* \;=\; \mathrm{Hom}_F(V,F),$$

the space of all F-linear maps from V to F. An element $f \in V^*$ is called a **linear functional** on V. The vector space operations on V^* are pointwise:

$$(f+g)(v) = f(v)+g(v), \qquad (c\,f)(v) = c\,f(v) \qquad (f,g \in V^*,\ c \in F,\ v \in V).$$

Remark 11.3.1. A linear functional is just a "coordinate-like" measurement: it eats a vector and returns a scalar, linearly. Integration $f \mapsto \int_0^1 f$, evaluation $p \mapsto p(a)$, the trace $A \mapsto \mathrm{tr}(A)$, and "read off the ith coordinate" are all linear functionals on appropriate spaces.

Worked Example 11.3.2 (Functionals on F^n are dot products)**.** Identify every linear functional on $V = F^n$ (column vectors) explicitly.

Recognition. A functional is a linear map $F^n \to F$, i.e. a $1 \times n$ matrix acting by multiplication; this is the $W = F$ case of the matrix of a linear transformation from §11.2.

Solution. Let $e_1,\dots,e_n$ be the standard basis and $f \in V^*$. Set $a_i = f(e_i) \in F$. For $v = \sum_i x_i e_i$ linearity gives $f(v) = \sum_i x_i a_i = (a_1,\dots,a_n)\,v$, a dot product with the fixed row vector $a = (a_1,\dots,a_n)$. Conversely every such row vector defines a functional. *Check.* The map $f \mapsto (f(e_1),\dots,f(e_n))$ is a linear bijection $(F^n)^* \to F^n$, so $\dim (F^n)^* = n = \dim F^n$, previewing Theorem 11.3.5.

Worked Example 11.3.3 (Trace as a functional on $\mathrm{M}_n(F)$)**.** Show $\mathrm{tr}\colon \mathrm{M}_n(F) \to F$, $\mathrm{tr}(A) = \sum_i a_{ii}$, is a linear functional, and exhibit a matrix *not* in its kernel.

Recognition. Linearity in the entries makes tr a map to F, hence an element of $\mathrm{M}_n(F)^*$.

Solution. $\mathrm{tr}(A+B) = \sum_i (a_{ii}+b_{ii}) = \mathrm{tr}(A)+\mathrm{tr}(B)$ and $\mathrm{tr}(cA) = c\,\mathrm{tr}(A)$, so $\mathrm{tr} \in \mathrm{M}_n(F)^*$. The identity I_n has $\mathrm{tr}(I_n) = n \cdot 1$, which is nonzero in F provided $\mathrm{char}\,F \nmid n$. *Check.* Over $\mathbb{F}_2$ with $n=2$, $\mathrm{tr}(I_2) = 1+1 = 0$, so $I_2 \in \ker \mathrm{tr}$ there — whether I_n lies in the kernel depends on the characteristic. A matrix outside $\ker \mathrm{tr}$ over *every* field is the matrix unit E_{11} (entry 1 in position $(1,1)$, all other entries 0), since $\mathrm{tr}(E_{11}) = 1 \neq 0$.

Worked Example 11.3.4 (Evaluation and integration on a polynomial space)**.** On $V = \{\, p \in \mathbb{Q}[x] : \deg p \le 2 \,\}$, show $\mathrm{ev}_a(p) = p(a)$ and $I(p) = \int_0^1 p(x)\,dx$ are functionals, and write each in coordinates w.r.t. the basis $1, x, x^2$.

Recognition. Both are linear maps $V \to \mathbb{Q}$, hence live in V^*; coordinates come from evaluating on the basis as in the previous example.

Solution. For $p = c_0 + c_1 x + c_2 x^2$: $\mathrm{ev}_a(p) = c_0 + c_1 a + c_2 a^2$, the dot product with row $(1, a, a^2)$. And $I(p) = c_0 + \frac{1}{2}c_1 + \frac{1}{3}c_2$, the dot product with row $\left(1, \frac{1}{2}, \frac{1}{3}\right)$. Both are linear in (c_0,c_1,c_2), hence functionals. *Check.* $\mathrm{ev}_1(p) = c_0+c_1+c_2$ while $I(p) = c_0 + \frac{1}{2}c_1 + \frac{1}{3}c_2$; these differ on $p = x$ (1 vs. $\frac{1}{2}$), so $\mathrm{ev}_1 \neq I$ in V^*. Correct.

The dual basis

For finite-dimensional V, a choice of basis of V produces a canonical basis of V^*.

Theorem 11.3.5 (Dual basis)**.** *Let V be finite-dimensional with basis $v_1,\dots,v_n$. For each i define $v_i^* \in V^*$ by its action on the basis:*

$$v_i^*(v_j) = \delta_{ij} = \begin{cases} 1, & i = j, \\ 0, & i \neq j, \end{cases}$$

*extended linearly. Then $v_1^*, \dots, v_n^*$ is a basis of V^*, called the **dual basis** to $v_1, \dots, v_n$. In particular*

$$\dim_F V^* = \dim_F V.$$

Proof. By the universal property of a basis, defining v_i^* on the v_j determines a unique functional. *Spanning:* for $f \in V^*$ set $c_i = f(v_i)$. Then $g = \sum_i c_i v_i^*$ agrees with f on each v_j (both give c_j), so $f = g$; thus the v_i^* span. *Independence:* if $\sum_i c_i v_i^* = 0$, apply both sides to v_j to get $c_j = 0$ for every j. Hence the v_i^* form a basis of V^*, which therefore has dimension n. □

The recipe "coordinates of f in the dual basis are $f(v_1), \dots, f(v_n)$" is the key computational fact: $f = \sum_i f(v_i)\, v_i^*$, and dually $v = \sum_i v_i^*(v)\, v_i$, so the v_i^* are exactly the coordinate functions of the basis $\{ v_i \}$.

Remark 11.3.2. For infinite-dimensional V the functionals v_i^* are still independent but no longer span V^*: e.g. for V with countable basis $\{ v_i \}$, the functional $\sum_i v_i^*$ (well defined since any vector uses finitely many v_i) is not a finite combination of the v_i^*. In general $\dim V^* > \dim V$ when V is infinite-dimensional.

Method (Computing a dual basis)**.** *Trigger.* A basis $\{ v_i \}$ is given and you need the functionals v_i^* explicitly, or the coordinates of a given f.

1. Form the matrix $P = [\, v_1 \ \cdots \ v_n \,]$ whose columns are the v_i in standard coordinates.
2. The rows of P^{-1} are the dual basis functionals: $v_i^*(x) = (i\text{th row of } P^{-1})\, x$. (Reason: $v_i^*(v_j) = (P^{-1}P)_{ij} = \delta_{ij}$.)
3. To get the coordinates of a functional f in $\{ v_i^* \}$, just evaluate: $f = \sum_i f(v_i)\, v_i^*$.

Worked Example 11.3.6 (Dual basis on $\mathbb{Q}^2$ for a skew basis)**.** Find the dual basis to $v_1 = (1, 1)$, $v_2 = (1, 2)$ in $\mathbb{Q}^2$, and expand $f(x, y) = 3x - y$ in it.

Recognition. Theorem 11.3.5 plus the Method: invert the matrix of basis columns; read off rows.

Solution. Here $P = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix}$, $\det P = 1$, $P^{-1} = \begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix}$. So $v_1^*(x, y) = 2x - y$ and $v_2^*(x, y) = -x + y$. Check δ: $v_1^*(v_1) = 2 - 1 = 1$, $v_1^*(v_2) = 2 - 2 = 0$. Now $f(v_1) = 3 - 1 = 2$, $f(v_2) = 3 - 2 = 1$, so $f = 2\, v_1^* + 1\, v_2^*$. *Check.* $2(2x - y) + (-x + y) = 3x - y = f$. Correct.

Worked Example 11.3.7 (Dual basis over $\mathbb{F}_2$)**.** In $V = \mathbb{F}_2^2$ take the basis $v_1 = (1, 1)$, $v_2 = (0, 1)$. Compute the dual basis.

Recognition. Same inversion recipe; arithmetic is mod 2, where $-1 = 1$.

Solution. $P = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$, and over $\mathbb{F}_2$, $P^{-1} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$ (since $P^2 = I$). Thus $v_1^*(x, y) = x$, $v_2^*(x, y) = x + y$. *Check.* $v_1^*(v_1) = 1$, $v_1^*(v_2) = 0$; $v_2^*(v_2) = 0 + 1 = 1$, $v_2^*(v_1) = 1 + 1 = 0$. The δ-relations hold, so this is the dual basis.

Worked Example 11.3.8 (Monomial dual basis and Taylor coordinates)**.** On $V = \{ p \in \mathbb{Q}[x] : \deg p \le 2 \}$ with basis $1, x, x^2$, identify the dual basis and recognize it.

Recognition. The dual basis extracts coordinates; here coordinates are the Taylor coefficients at 0.

Solution. Write $p = c_0 + c_1 x + c_2 x^2$. The dual basis $\{ 1^*, x^*, (x^2)^* \}$ satisfies $1^*(p) = c_0 = p(0)$, $x^*(p) = c_1 = p'(0)$, $(x^2)^*(p) = c_2 = \frac{1}{2} p''(0)$. *Check.* $1^*(x) = 0$, $x^*(x) = 1$, $(x^2)^*(x) = 0$, matching δ_{ij} on the basis. So the dual basis is precisely "read off the Taylor coefficients," i.e. $p \mapsto \frac{1}{k!} p^{(k)}(0)$.

Worked Example 11.3.9 (Lagrange functionals as a dual basis)**.** On V (degree ≤ 2 over $\mathbb{Q}$) the evaluations $\mathrm{ev}_0, \mathrm{ev}_1, \mathrm{ev}_2$ form a basis of V^*. To which basis of V are they dual?

Recognition. A set of three functionals on a 3-dimensional space is a basis iff it is independent; finding the predual means solving $\ell_i(p_j) = \delta_{ij}$, which the Lagrange interpolation polynomials do.

Solution. Seek $p_0, p_1, p_2 \in V$ with $\mathrm{ev}_i(p_j) = p_j(i) = \delta_{ij}$. These are the Lagrange basis polynomials at nodes $0, 1, 2$:

$$p_0 = \tfrac{1}{2}(x - 1)(x - 2), \quad p_1 = -x(x - 2), \quad p_2 = \tfrac{1}{2} x(x - 1).$$

By construction $\{ \mathrm{ev}_0, \mathrm{ev}_1, \mathrm{ev}_2 \}$ is the dual basis to $\{ p_0, p_1, p_2 \}$, hence a basis of V^*. *Check.* $p_1(0) = 0$, $p_1(1) = -1 \cdot (-1) = 1$, $p_1(2) = -2 \cdot 0 = 0$, confirming $\mathrm{ev}_i(p_1) = \delta_{i1}$. Correct.

The double dual and the natural isomorphism

The dual of the dual carries V *back into itself* — and does so without choosing a basis.

Definition 11.3.10 (Double dual)**.** The **double dual** of V is $(V^*)^*$, written V^{**}. Its elements are linear functionals on V^*.

Theorem 11.3.11 (The natural map into the double dual)**.** *The map*

$$\Phi\colon V \longrightarrow V^{**}, \qquad \Phi(v) = \mathrm{ev}_v, \quad \textit{where } \mathrm{ev}_v(f) = f(v) \ \ (f \in V^*),$$

is an injective F-linear transformation defined without reference to a basis*. If V is finite-dimensional then Φ is an isomorphism; thus $V \cong V^{**}$ naturally for finite-dimensional V.*

Proof. ev_v *is linear in* f*:* $\mathrm{ev}_v(f+g) = (f+g)(v) = f(v) + g(v)$ and $\mathrm{ev}_v(cf) = cf(v)$, so $\mathrm{ev}_v \in V^{**}$. Φ *is linear in* v*:* $\mathrm{ev}_{v+w}(f) = f(v+w) = f(v) + f(w) = (\mathrm{ev}_v + \mathrm{ev}_w)(f)$, similarly for scalars. *Injective:* if $\Phi(v) = 0$ then $f(v) = 0$ for all $f \in V^*$; extending $v \neq 0$ to a basis and using its dual basis gives a functional with $f(v) = 1$, a contradiction, so $v = 0$. *Finite-dimensional case:* $\dim V^{**} = \dim V^* = \dim V$ by Theorem 11.3.5 applied twice, so an injective linear map between equal finite dimensions is an isomorphism. □

Remark 11.3.3. "Natural" has a precise meaning: Φ commutes with all linear maps, so no choices are involved. By contrast the isomorphism $V \cong V^*$ (matching $v_i \mapsto v_i^*$) *depends on the chosen basis* and is not natural. The double dual restores naturality. The square below records this naturality: for any linear $T\colon V \to W$, the double-transpose T^{**} makes the evaluation maps commute.

$$\begin{array}{ccc} V & \xrightarrow{\ T\ } & W \\ {\scriptstyle \Phi_V}\downarrow & & \downarrow{\scriptstyle \Phi_W} \\ V^{**} & \xrightarrow[\ T^{**}\ ]{} & W^{**} \end{array}$$

Diagram explanation. Objects: Four vector spaces over F: the domain V and codomain W of the original linear map (upper row), and their double duals $V^{**} = \mathrm{Hom}_F(V^*, F)$ and $W^{**} = \mathrm{Hom}_F(W^*, F)$ (lower row). All four are F-vector spaces; when V and W are finite-dimensional, the vertical arrows are isomorphisms.

Arrows: $T\colon V \to W$ is the given F-linear map. $\Phi_V\colon V \to V^{**}$ and $\Phi_W\colon W \to W^{**}$ are the canonical evaluation maps $\Phi_V(v) = \mathrm{ev}_v$ (where $\mathrm{ev}_v(f) = f(v)$ for $f \in V^*$), defined without any basis choice. $T^{**}\colon V^{**} \to W^{**}$ is the double transpose: $T^{**}(\xi)(g) = \xi(g \circ T)$ for $\xi \in V^{**}$, $g \in W^*$.

What commutes: The square commutes: $\Phi_W \circ T = T^{**} \circ \Phi_V$. That is, going right-then-down equals down-then-right.

Why it commutes: Take any $v \in V$ and any $g \in W^*$. Right-then-down: $\Phi_W(T(v))(g) = g(T(v))$. Down-then-right: $(T^{**}(\Phi_V(v)))(g) = \Phi_V(v)(g \circ T) = (g \circ T)(v) = g(T(v))$. Both paths give the same scalar $g(T(v))$, so the square commutes by the definition of T^{**} and the evaluation pairing.

Why this matters here: The remark preceding this diagram makes the key claim that Φ is *natural*, meaning it is compatible with every linear map T, not just some. This square is the precise encoding of that naturality: it says that the maps Φ_V form a *natural transformation* from the identity functor to the double-dual functor ($V \mapsto V^{**}$, $T \mapsto T^{**}$), so Φ is not an ad-hoc construction but is compatible with every linear map. By contrast, the basis-dependent identification $V \cong V^*$ does not satisfy an analogous commutative square.

Concrete example: Take $V = W = \mathbb{Q}^2$ and $T(x, y) = (x + 2y, 3x)$, the map from the worked example. For $v = (1, 0)$: $T(v) = (1, 3)$, so $\Phi_W(T(v)) = \mathrm{ev}_{(1,3)}$. Down-then-right: $T^{**}(\mathrm{ev}_{(1,0)})(g) = g(T(1,0)) = g(1,3) = \mathrm{ev}_{(1,3)}(g)$ for all g. Both routes produce $\mathrm{ev}_{(1,3)}$, confirming the square.

Common pitfall: Students often confuse T^{**} with T itself. While T^{**} does "act like T" via the natural iso $V \cong V^{**}$ in the finite-dimensional case, T^{**} is defined on the double duals $V^{**} \to W^{**}$, not on $V \to W$. The commutativity of this square is precisely what makes T and T^{**} interchangeable under Φ — and, as the check above shows, it follows directly from the definitions of Φ and T^{**}.

Takeaway: The point of this diagram is that the double-dual evaluation maps Φ_V and Φ_W interlock with every linear map T without any choice of basis, making the natural isomorphism $V \cong V^{**}$ genuinely functorial.

Worked Example 11.3.12 (An explicit double-dual element)**.** On $V = \mathbb{Q}^2$ with standard dual basis e_1^*, e_2^* of V^*, write the element $\Phi(v)$ of V^{**} for $v = (3, 5)$ in the basis $\{ e_1^{**}, e_2^{**} \}$ dual to $\{ e_1^*, e_2^* \}$.

Recognition. $\Phi(v)$ evaluates functionals at v; its coordinates in $\{ e_i^{**} \}$ are its values on e_1^*, e_2^*.

Solution. By Theorem 11.3.5, $\Phi(v) = \sum_i \Phi(v)(e_i^*)\, e_i^{**} = \sum_i e_i^*(v)\, e_i^{**}$. Here $e_1^*(v) = 3$, $e_2^*(v) = 5$, so $\Phi(v) = 3\, e_1^{**} + 5\, e_2^{**}$. *Check.* The coordinate vector of $\Phi(v)$ in the double-dual basis is $(3, 5)$, identical to v — the natural iso is the identity in matching bases, as it must be.

Worked Example 11.3.13 (Φ is independent of basis)**.** Verify on $V = \mathbb{Q}^2$ that $\Phi(v)(f) = f(v)$ gives the same element of V^{**} whether f is expressed in the standard or the skew dual basis of the earlier example.

Recognition. Naturality says Φ uses no basis; the test is that $\mathrm{ev}_v(f) = f(v)$ is computed intrinsically.

Solution. Take $v = (1, 1)$ and $f = 3x - y$. Directly, $\Phi(v)(f) = f(1, 1) = 3 - 1 = 2$. Using the skew basis $f = 2v_1^* + v_2^*$ (computed earlier) with $v = v_1$, and $v_1^*(v_1) = 1$, $v_2^*(v_1) = v_2^*(1, 1) = -1 + 1 = 0$: $\Phi(v_1)(f) = 2 \cdot 1 + 1 \cdot 0 = 2$. *Check.* Both routes give 2. The value $f(v)$ does not see the basis, confirming Φ is natural.

Worked Example 11.3.14 (Failure of surjectivity in infinite dimensions)**.** Let V have countable basis $v_1, v_2, \ldots$ over F. Exhibit an element of V^{**} not of the form $\Phi(v)$.

Recognition. Φ is always injective but only surjective when $\dim V < \infty$; the obstruction is a functional summing infinitely many dual-basis coordinates.

Solution. Consider $\Theta \in V^{**}$ defined on the (linearly independent) functionals v_i^* by $\Theta(v_i^*) = 1$ for all i, extended linearly to all of V^*. If $\Theta = \Phi(v)$ for some $v = \sum_i a_i v_i$ (finite sum), then $\Theta(v_i^*) = v_i^*(v) = a_i$, forcing $a_i = 1$ for *all* i — impossible for a finite combination. *Check.* So $\Theta \notin \mathrm{im}\, \Phi$, hence Φ is not surjective. This matches the Remark that $\dim V^* > \dim V$ for infinite-dimensional V.

Worked Example 11.3.15 (Double transpose recovers T)**.** For $T\colon \mathbb{Q}^2 \to \mathbb{Q}^2$, $T(x, y) = (x + 2y,\, 3x)$, verify the naturality square: $\Phi_W \circ T = T^{**} \circ \Phi_V$ on the vector $v = (1, 0)$.

Recognition. The square in the Remark must commute; check it on a vector by chasing both paths.

Solution. Top-right path: $T(1, 0) = (1, 3)$, then $\Phi_W(1, 3) = \mathrm{ev}_{(1,3)}$. Down-bottom path: $\Phi_V(1, 0) = \mathrm{ev}_{(1,0)}$, then T^{**} precomposes with T^*, giving $\mathrm{ev}_{(1,0)} \circ T^*$. For any $f \in W^*$, $(\mathrm{ev}_{(1,0)} \circ T^*)(f) = T^*(f)(1, 0) = f(T(1, 0)) = f(1, 3) = \mathrm{ev}_{(1,3)}(f)$. *Check.* Both paths equal $\mathrm{ev}_{(1,3)}$, so the square commutes at v. Correct.

Annihilators

Annihilators translate subspaces of V into subspaces of V^*, reversing inclusions and complementing dimensions.

Definition 11.3.16 (Annihilator)**.** For a subset $S \subseteq V$, the **annihilator** of S is

$$\mathrm{ann}(S) \;=\; \{\, f \in V^* \;:\; f(s) = 0 \text{ for all } s \in S \,\} \;\subseteq\; V^*.$$

$\mathrm{ann}(S)$ is always a subspace of V^* (an intersection of kernels of the evaluation functionals ev_s), and $\mathrm{ann}(S) = \mathrm{ann}(\mathrm{Span}\, S)$, so we may assume $S = W$ is a subspace. Annihilators are *inclusion-reversing*: $W_1 \subseteq W_2 \implies \mathrm{ann}(W_2) \subseteq \mathrm{ann}(W_1)$.

Proposition 11.3.17 (Dimension of the annihilator)**.** *Let V be finite-dimensional and $W \subseteq V$ a subspace. Then*

$$\dim_F \mathrm{ann}(W) \;=\; \dim_F V - \dim_F W.$$

Moreover, under the natural identification $V \cong V^{**}$ of Theorem 11.3.11, $\mathrm{ann}(\mathrm{ann}(W)) = W$.

Proof. Let $\dim W = k$, $\dim V = n$. Choose a basis $v_1, \ldots, v_k$ of W and extend to a basis $v_1, \ldots, v_n$ of V, with dual basis $v_1^*, \ldots, v_n^*$. A functional $f = \sum_i c_i v_i^*$ annihilates W iff $f(v_j) = c_j = 0$ for $j = 1, \ldots, k$. Thus $\mathrm{ann}(W) = \mathrm{Span}\{\, v_{k+1}^*, \ldots, v_n^* \,\}$, which has dimension $n - k$. The restriction map $V^* \to W^*$, $f \mapsto f|_W$, is surjective with kernel exactly $\mathrm{ann}(W)$, giving the short exact sequence below; rank–nullity reproduces the count. The equality $\mathrm{ann}(\mathrm{ann}(W)) = W$ follows by applying the dimension formula twice ($\dim \mathrm{ann}(\mathrm{ann}(W)) = n - (n - k) = k$) together with the evident inclusion $W \subseteq \mathrm{ann}(\mathrm{ann}(W))$. $\square$

The restriction-to-W map fits into a short exact sequence of dual spaces, the conceptual source of the dimension formula:

$$0 \longrightarrow \operatorname{ann}(W) \hookrightarrow V^* \xrightarrow{f \mapsto f|_W} W^* \longrightarrow 0.$$

Diagram explanation. Objects: Five nodes forming a short exact sequence. The zero groups at the ends are trivial. $\operatorname{ann}(W) \subseteq V^*$ is the subspace of functionals on V that vanish on the subspace $W \subseteq V$; $V^* = \operatorname{Hom}_F(V, F)$ is the full dual; $W^* = \operatorname{Hom}_F(W, F)$ is the dual of the subspace W. All are F-vector spaces.

Arrows: The left arrow $\operatorname{ann}(W) \hookrightarrow V^*$ is the inclusion (a hook arrow signals injection): elements of $\operatorname{ann}(W)$ are already functionals in V^*, just with the extra constraint of vanishing on W. The middle arrow $V^* \to W^*$, $f \mapsto f|_W$, is restriction to W: given $f\colon V \to F$, restrict its domain to $W \subseteq V$. The zeros record that the inclusion is injective and that restriction is surjective.

What commutes: This is an exact sequence, so exactness at each term must hold. Exactness at $\operatorname{ann}(W)$: the inclusion is injective (kernel = 0). Exactness at V^*: $\operatorname{im}(\text{inclusion}) = \operatorname{ann}(W) = \ker(\text{restriction})$, since f is in the kernel of restriction iff $f|_W = 0$ iff $f \in \operatorname{ann}(W)$. Exactness at W^*: restriction is surjective (every functional on W extends to one on V by extending a basis of W to one of V).

Why it commutes: Exactness at V^*: $f \in \ker(f \mapsto f|_W)$ iff $f(w) = 0$ for all $w \in W$, which is exactly the definition of $f \in \operatorname{ann}(W)$, so ker = im at V^*. Surjectivity at W^*: given any $g\colon W \to F$, extend a basis $v_1, \ldots, v_k$ of W to $v_1, \ldots, v_n$ of V, define $\tilde{g}(v_i) = g(v_i)$ for $i \le k$ and $\tilde{g}(v_i) = 0$ for $i > k$; then $\tilde{g} \in V^*$ and $\tilde{g}|_W = g$.

Why this matters here: The proof of Proposition 11.3.17 deduces $\dim \operatorname{ann}(W) = \dim V - \dim W$ from this exact sequence via rank-nullity: $\dim V^* = \dim \ker(\text{res}) + \dim \operatorname{im}(\text{res}) = \dim \operatorname{ann}(W) + \dim W^*$, and $\dim W^* = \dim W$ by the dual basis theorem applied to W.

Concrete example: Let $V = \mathbb{Q}^3$, $W = \operatorname{Span}\{e_1, e_2\}$. Then $\operatorname{ann}(W) = \{(a, b, c) : a = 0, b = 0\} = \operatorname{Span}\{e_3^*\}$, dimension $1 = 3 - 2$. The restriction map sends $f = (a, b, c)$ to $f|_W = (a, b)$, which is surjective: every row vector $(p, q) \in W^*$ lifts to $(p, q, 0) \in V^*$. Rank-nullity: $3 = 1 + 2$, matching dimensions of $\operatorname{ann}(W)$ and W^*.

Common pitfall: Students sometimes conflate $f|_W$ with the restriction of the matrix of f to columns indexed by W. In coordinate terms $f|_W$ simply evaluates f at vectors in W, not at a submatrix. Also, surjectivity of restriction uses the basis extension theorem; it is not obvious from the definition, but it holds over every field (algebraic closure plays no role). What can fail is the analogue for modules over a ring that is not a field: the $\mathbb{Z}$-linear map $2\mathbb{Z} \to \mathbb{Z}$, $2 \mapsto 1$, does not extend to a $\mathbb{Z}$-linear map $\mathbb{Z} \to \mathbb{Z}$.

Takeaway: The point of this diagram is that the annihilator of W in V^* is *exactly* the kernel of restriction, so a single short exact sequence encodes both the definition and the dimension count $\dim \operatorname{ann}(W) = \dim V - \dim W$ via rank-nullity.

Method (Working with annihilators)**.** *Trigger.* Compute $\operatorname{ann}(W)$, its dimension, or test membership.

1. Find a spanning set $w_1, \ldots, w_k$ of W. Then $f \in \operatorname{ann}(W)$ iff $f(w_1) = \cdots = f(w_k) = 0$ — a homogeneous linear system in the coordinates of f.
2. The solution space has dimension $\dim V^* - \operatorname{rank}(\text{system}) = n - \dim W$ (Proposition 11.3.17).
3. In coordinates: writing $W = \operatorname{Span}(\text{columns of } A)$, $\operatorname{ann}(W)$ is the left null space $\{\, f \in F^{1\times n} : fA = 0 \,\}$ of A.

Worked Example 11.3.18 (Annihilator of a line in $\mathbb{Q}^3$)**.** Compute $\operatorname{ann}(W)$ for $W = \operatorname{Span}\{\, (1, 2, 3) \,\} \subseteq \mathbb{Q}^3$.

Recognition. One generator gives one linear condition on f; Proposition 11.3.17 predicts $\dim \operatorname{ann}(W) = 3 - 1 = 2$.

Solution. Write $f = (a, b, c) \in (\mathbb{Q}^3)^*$ (row vector). Then $f \in \operatorname{ann}(W)$ iff $a + 2b + 3c = 0$. The solution space is $\{\, (a, b, c) : a = -2b - 3c \,\}$, spanned by $(-2, 1, 0)$ and $(-3, 0, 1)$, so $\dim \operatorname{ann}(W) = 2$. *Check.* $(-2, 1, 0) \cdot (1, 2, 3) = -2 + 2 + 0 = 0$ and $(-3, 0, 1) \cdot (1, 2, 3) = -3 + 0 + 3 = 0$. The dimension $2 = 3 - 1$ matches Proposition 11.3.17.

Worked Example 11.3.19 (Annihilator of a plane in $\mathbb{Q}^3$)**.** Compute $\operatorname{ann}(W)$ for $W = \operatorname{Span}\{\,(1,0,1), (0,1,1)\,\} \subseteq \mathbb{Q}^3$.

Recognition. Two generators give two conditions; expect $\dim \operatorname{ann}(W) = 3 - 2 = 1$.

Solution. $f = (a,b,c)$ annihilates W iff $a+c=0$ and $b+c=0$, i.e. $a = b = -c$. So $\operatorname{ann}(W) = \operatorname{Span}\{\,(1,1,-1)\,\}$, dimension 1. *Check.* $(1,1,-1)\cdot(1,0,1) = 1+0-1 = 0$ and $(1,1,-1)\cdot(0,1,1) = 0+1-1 = 0$. The single functional $a+b-c$ cuts out exactly the plane W, and $1 = 3-2$. Correct.

Worked Example 11.3.20 (Annihilator over $\mathbb{F}_2$)**.** In $V = \mathbb{F}_2^3$ let $W = \operatorname{Span}\{\,(1,1,0)\,\}$. Find $\operatorname{ann}(W)$ and its size.

Recognition. Same one-condition computation, arithmetic mod 2; $\dim \operatorname{ann}(W) = 3 - 1 = 2$ so $|\operatorname{ann}(W)| = 2^2 = 4$.

Solution. $f = (a,b,c)$ annihilates W iff $a + b = 0$, i.e. $b = a$. So $\operatorname{ann}(W) = \{\,(a,a,c) : a,c \in \mathbb{F}_2\,\} = \operatorname{Span}\{\,(1,1,0),(0,0,1)\,\}$, dimension 2, with 4 elements. *Check.* List them: $(0,0,0),(1,1,0),(0,0,1),(1,1,1)$; each dotted with $(1,1,0)$ gives $a+b=0$ in $\mathbb{F}_2$. Count $4 = 2^{3-1}$. Correct.

Worked Example 11.3.21 (Double annihilator recovers W)**.** For $W = \operatorname{Span}\{\,(1,2,3)\,\} \subseteq \mathbb{Q}^3$ from above, verify $\operatorname{ann}(\operatorname{ann}(W)) = W$ under $V \cong V^{**}$.

Recognition. Proposition 11.3.17 guarantees this; we confirm by direct computation that the double annihilator is 1-dimensional and contains W.

Solution. We found $\operatorname{ann}(W) = \operatorname{Span}\{\,(-2,1,0),(-3,0,1)\,\}$ in V^*. A vector $v = (x,y,z) \in V \cong V^{**}$ lies in $\operatorname{ann}(\operatorname{ann}(W))$ iff both generators vanish on it: $-2x + y = 0$ and $-3x + z = 0$, i.e. $y = 2x$, $z = 3x$. So $\operatorname{ann}(\operatorname{ann}(W)) = \operatorname{Span}\{\,(1,2,3)\,\} = W$. *Check.* Dimension $3 - 2 = 1 = \dim W$, and $(1,2,3)$ satisfies both equations. Correct.

Worked Example 11.3.22 (Annihilator reverses inclusions and sums)**.** In $\mathbb{Q}^4$ let $W_1 = \operatorname{Span}\{\,e_1\,\}$ and $W_2 = \operatorname{Span}\{\,e_1, e_2\,\}$. Confirm $W_1 \subseteq W_2 \implies \operatorname{ann}(W_2) \subseteq \operatorname{ann}(W_1)$ and check the dimension count for $\operatorname{ann}(W_1 + W_2)$.

Recognition. Inclusion-reversal is immediate from the definition; the dimension formula handles the sum.

Solution. $\operatorname{ann}(W_1) = \{\,f = (a,b,c,d) : a = 0\,\}$, dimension 3. $\operatorname{ann}(W_2) = \{\,f : a = 0,\ b = 0\,\}$, dimension 2. Indeed $\operatorname{ann}(W_2) \subseteq \operatorname{ann}(W_1)$, and dim drops from 3 to 2 as W grows from 1 to 2 dimensions. Since $W_1 + W_2 = W_2$, $\dim \operatorname{ann}(W_1 + W_2) = 4 - 2 = 2$. *Check.* $\operatorname{ann}(W_1 + W_2) = \operatorname{ann}(W_1) \cap \operatorname{ann}(W_2) = \operatorname{ann}(W_2)$, dimension 2. Consistent with Proposition 11.3.17.

The transpose (dual) of a linear map

Every linear map between vector spaces induces a map between their duals, going *backwards*, and its matrix is the transpose.

Definition 11.3.23 (Transpose / dual map)**.** Let $T\colon V \to W$ be F-linear. Its **transpose** (or **dual map**) is

$$T^*\colon W^* \longrightarrow V^*, \qquad T^*(f) = f \circ T \quad (f \in W^*).$$

Thus T^* *precomposes* with T; it reverses the direction of the arrow.

The assignment $T \mapsto T^*$ is linear and contravariant: $(S \circ T)^* = T^* \circ S^*$ and $\mathrm{id}_V^* = \mathrm{id}_{V^*}$. The defining relation $T^*(f) = f \circ T$ is exactly commutativity of the triangle

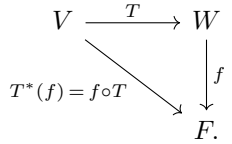


Diagram explanation. Objects: Three objects: the domain vector space V (upper left), the codomain vector space W (upper right), and the ground field F (lower right). The field F is itself a 1-dimensional F-vector space and serves as the target of linear functionals.

Arrows: $T\colon V \to W$ is the given F-linear map (top). $f\colon W \to F$ is a fixed linear functional in $W^* = \mathrm{Hom}_F(W, F)$ (right). The diagonal $T^*(f) = f \circ T\colon V \to F$ is the transpose applied to f: it precomposes f with T to produce a functional on V, i.e. an element of V^*.

What commutes: The triangle commutes: $T^*(f) = f \circ T$, i.e. the diagonal arrow equals the composition of the top and right arrows.

Why it commutes: This is not a constraint to check but a *definition*: the defining equation $T^*(f) := f \circ T$ is exactly the assertion that the triangle commutes. For any $v \in V$, traveling top-then-right gives $f(T(v))$; traveling the diagonal gives $T^*(f)(v) = (f \circ T)(v) = f(T(v))$. They are the same by definition.

Why this matters here: The sentence right before the diagram states that the defining relation for T^* is exactly the commutativity of this triangle. The diagram makes the definition of the dual map *visual*: T^* does not send vectors anywhere; it takes a functional f on W and produces the composite functional on V. The contravariance (arrows reverse: T goes $V \to W$ but T^* goes $W^* \to V^*$) is encoded here by the diagonal going from V to F rather than from W^* to V^*.

Concrete example: Take $V = \mathbb{Q}^2$, $W = \mathbb{Q}^3$, $T(x, y) = (x + y, 2x, x - y)$, and $f = w_1^*\colon (a, b, c) \mapsto a$ (first coordinate). Then $T^*(f) = f \circ T\colon (x, y) \mapsto x + y$, the functional $v_1^* + v_2^*$ on $\mathbb{Q}^2$. The triangle: $T(1, 0) = (1, 2, 1)$, then $f(1, 2, 1) = 1$; diagonal at $(1, 0)$: $(v_1^* + v_2^*)(1, 0) = 1 + 0 = 1$. Both give 1.

Common pitfall: Students often think T^* maps $V^* \to W^*$ (same direction as T). It goes the *opposite* direction: $T^*\colon W^* \to V^*$. The triangle makes this visible: the only route from a functional f on W to a functional on V is to precompose with T, which necessarily reverses the arrow direction.

Takeaway: The point of this diagram is that the dual map T^* is simply precomposition with T, which is why it reverses the direction of arrows and why its matrix is A^T.

Theorem 11.3.24 (Matrix of the transpose)**.** *Let $T\colon V \to W$ be linear, with $\dim V = n$, $\dim W = m$. Fix bases $\mathcal{B} = \{ v_1, \dots, v_n \}$ of V and $\mathcal{C} = \{ w_1, \dots, w_m \}$ of W, and let $A = \mathrm{M}_{\mathcal{B}}^{\mathcal{C}}(T) \in \mathrm{M}_{m \times n}(F)$ be the matrix of T. Then with respect to the dual bases $\mathcal{C}^* = \{ w_1^*, \dots, w_m^* \}$ of W^* and $\mathcal{B}^* = \{ v_1^*, \dots, v_n^* \}$ of V^*, the matrix of T^* is the transpose:*

$$\mathrm{M}_{\mathcal{C}^*}^{\mathcal{B}^*}\big(T^*\big) \;=\; A^{\mathsf{T}}.$$

Consequently $\mathrm{rank}(T^*) = \mathrm{rank}(T)$ *(row rank = column rank).*

Proof. Write $A = (a_{ij})$, so $T(v_j) = \sum_{i=1}^{m} a_{ij} w_i$. The (j, i) entry of the matrix of T^* is the v_j^*-coordinate of $T^*(w_i^*)$, namely $\big(T^*(w_i^*)\big)(v_j) = (w_i^* \circ T)(v_j) = w_i^*\Big(\sum_k a_{kj} w_k\Big) = a_{ij}$. Hence the matrix of T^* has (j, i) entry a_{ij}, i.e. it is A^{T}. For the rank equality: $f \in \ker T^*$ iff $f \circ T = 0$ iff f vanishes on $\mathrm{im}\, T$, so $\ker T^* = \mathrm{ann}(\mathrm{im}\, T)$, which has dimension $m - \mathrm{rank}\, T$ by Proposition 11.3.17; rank–nullity for $T^*\colon W^* \to V^*$ then gives $\mathrm{rank}\, T^* = m - (m - \mathrm{rank}\, T) = \mathrm{rank}\, T$. Since $\mathrm{rank}\, T^* = \mathrm{rank}\, A^{\mathsf{T}}$ is the row rank of A and $\mathrm{rank}\, T$ is its column rank, this also proves that row rank equals column rank. □

The functor $T \mapsto T^*$ turns the transpose square into the algebraic shadow of the diagram below: applying $\mathrm{Hom}_F(-, F)$ to $T\colon V \to W$ produces $T^*\colon W^* \to V^*$, and post-composing with a third map shows contravariance.

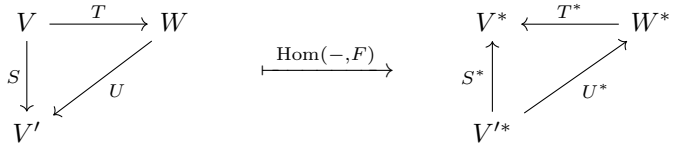

Diagram explanation. Objects: Left diagram: three vector spaces V (upper left), W (upper right), V' (lower left) with linear maps forming a commutative triangle ($U \circ T = S$, so the three paths compose correctly). Right diagram: their duals V^*, W^*, V'^*, all F-vector spaces, arranged with reversed arrows.

Arrows: Left: $T\colon V \to W$, $S\colon V \to V'$, and $U\colon W \to V'$ with $S = U \circ T$ (making the left triangle commute). Right: $T^*\colon W^* \to V^*$ (reversed), $S^*\colon V'^* \to V^*$ (reversed), $U^*\colon V'^* \to W^*$ (reversed). Each dual arrow is defined by precomposition: $T^*(f) = f \circ T$. The functor arrow $\xmapsto{\mathrm{Hom}(-,F)}$ between the two diagrams indicates that $\mathrm{Hom}_F(-, F)$ sends the left configuration to the right one.

What commutes: Left: $U \circ T = S$ (commutativity of the triangle). Right: $T^* \circ U^* = S^*$, i.e. going $V'^* \xrightarrow{U^*} W^* \xrightarrow{T^*} V^*$ equals $V'^* \xrightarrow{S^*} V^*$. The order of composition is *reversed* relative to the left diagram.

Why it commutes: Take any $g \in V'^*$. Along $T^* \circ U^*$: first $U^*(g) = g \circ U \in W^*$, then $T^*(g \circ U) = g \circ U \circ T$. Along S^*: $S^*(g) = g \circ S$. Since $U \circ T = S$ in the left diagram, $g \circ U \circ T = g \circ S$, so $T^* \circ U^* = S^*$. This is exactly the contravariance rule $(U \circ T)^* = T^* \circ U^*$.

Why this matters here: This display appears immediately after the statement that $T \mapsto T^*$ is contravariant ($(S \circ T)^* = T^* \circ S^*$). The diagram makes contravariance concrete: the functor $\mathrm{Hom}_F(-, F)$ sends an entire commutative triangle of maps to another commutative triangle with all arrows *flipped*. This is the foundational picture for understanding why dual maps are "backwards" and why transpose satisfies $(AB)^T = B^T A^T$.

Concrete example: Let $V = \mathbb{Q}^3$, $W = \mathbb{Q}^2$, $V' = \mathbb{Q}$, with $T(x, y, z) = (x + y, z)$, $U(a, b) = a - b$, and $S = U \circ T \colon (x, y, z) \mapsto x + y - z$. Then $T^* \colon (\mathbb{Q}^2)^* \to (\mathbb{Q}^3)^*$ sends $(p, q) \mapsto (p, p, q)$; $U^* \colon \mathbb{Q}^* \to (\mathbb{Q}^2)^*$ sends $\lambda \mapsto (\lambda, -\lambda)$; $T^*(U^*(\lambda)) = T^*(\lambda, -\lambda) = (\lambda, \lambda, -\lambda) = S^*(\lambda)$. Reversal verified.

Common pitfall: Students write $(U \circ T)^* = U^* \circ T^*$ (same order), copying the covariant rule. But precomposition *reverses* order: $(f \circ U) \circ T = f \circ (U \circ T)$ makes the outer composition come first on the dual side. The right diagram's arrow directions visually force you to write $T^* \circ U^*$, not $U^* \circ T^*$.

Takeaway: The point of this diagram is that $\mathrm{Hom}_F(-, F)$ is a *contravariant* functor, flipping every arrow and reversing the order of every composition, which is why $(AB)^T = B^T A^T$ and why dual maps go backwards.

Worked Example 11.3.25 (Transpose matrix, explicitly)**.** For $T \colon \mathbb{Q}^2 \to \mathbb{Q}^3$, $T(x, y) = (x + y,\, 2x,\, x - y)$, compute A and the matrix of T^* in standard dual bases.

Recognition. Theorem 11.3.24: build A by columns $T(e_j)$, then transpose.

Solution. $T(e_1) = (1, 2, 1)$, $T(e_2) = (1, 0, -1)$, so

$$A = \begin{pmatrix} 1 & 1 \\ 2 & 0 \\ 1 & -1 \end{pmatrix}, \qquad A^{\mathsf{T}} = \begin{pmatrix} 1 & 2 & 1 \\ 1 & 0 & -1 \end{pmatrix}.$$

Then $T^*(w_i^*)$ has coordinates given by the ith column of A^{T}. *Check.* $T^*(w_1^*) = w_1^* \circ T$, and $(w_1^* \circ T)(e_1) =$ first coordinate of $T(e_1) = 1$, $(w_1^* \circ T)(e_2) =$ first coordinate of $T(e_2) = 1$; so $T^*(w_1^*) = v_1^* + v_2^*$, whose coordinate vector $(1, 1)$ in $\{ v_1^*, v_2^* \}$ is exactly column 1 of A^{T}. Ranks agree: $\operatorname{rank} A = 2 = \operatorname{rank} A^{\mathsf{T}}$. Correct.

Worked Example 11.3.26 (Transpose of the trace's defining map)**.** Let $T \colon \mathbb{Q}^n \to \mathbb{Q}$ be the functional $T(x) = \sum_i x_i$ (so A is the $1 \times n$ row of ones). Describe T^*.

Recognition. $T^* \colon \mathbb{Q}^* \to (\mathbb{Q}^n)^*$; since $\mathbb{Q}^* \cong \mathbb{Q}$, T^* is determined by where it sends the generator $\mathrm{id}_{\mathbb{Q}}$.

Solution. $\mathbb{Q}^*$ is 1-dimensional, spanned by $\mathrm{id} \colon \mathbb{Q} \to \mathbb{Q}$. Then $T^*(\mathrm{id}) = \mathrm{id} \circ T = T$ itself, the functional $x \mapsto \sum_i x_i = (1, 1, \ldots, 1)\, x$. In matrices, $A = (1 \ \cdots \ 1)$ is $1 \times n$ and A^{T} is the $n \times 1$ column of ones. *Check.* $\operatorname{rank} A = 1 = \operatorname{rank} A^{\mathsf{T}}$, and A^{T} as a map $\mathbb{Q} \to \mathbb{Q}^n$ ($c \mapsto c(1, \ldots, 1)$) is exactly T^* in coordinates. Correct.

Worked Example 11.3.27 (Transpose over $\mathbb{F}_2$)**.** For $T \colon \mathbb{F}_2^2 \to \mathbb{F}_2^2$, $T(x, y) = (x + y,\, y)$, compute A^{T} and verify $T^*(w_1^*)$ directly.

Recognition. Theorem 11.3.24 with mod-2 arithmetic.

Solution. $T(e_1) = (1, 0)$, $T(e_2) = (1, 1)$, so $A = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $A^{\mathsf{T}} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}$. Direct: $T^*(w_1^*) = w_1^* \circ T$ reads the first output coordinate $x + y$, i.e. the functional $v_1^* + v_2^*$, with coordinate vector $(1, 1)$. *Check.* Column 1 of A^{T} is $(1, 1)^{\mathsf{T}}$, matching. And $T^*(w_2^*)$ reads $y = v_2^*$, coordinate $(0, 1)$ = column 2 of A^{T}. Correct.

Worked Example 11.3.28 (Annihilators and the transpose: $\ker T^* = \operatorname{ann}(\operatorname{im} T)$)**.** For a linear $T \colon V \to W$, prove $\ker T^* = \operatorname{ann}(\operatorname{im} T)$, and illustrate with $T \colon \mathbb{Q}^2 \to \mathbb{Q}^2$, $T(x, y) = (x, 0)$.

Recognition. Unwind the definition of T^*: $f \in \ker T^*$ means $f \circ T = 0$, i.e. f kills every output of T.

Solution. $f \in \ker T^* \iff T^*(f) = f \circ T = 0 \iff f(T(v)) = 0 \ \forall v \iff f(\operatorname{im} T) = 0 \iff f \in \operatorname{ann}(\operatorname{im} T)$. For the example, $\operatorname{im} T = \mathrm{Span}\{ e_1 \}$, so $\operatorname{ann}(\operatorname{im} T) = \{ f = (a, b) : a = 0 \} = \mathrm{Span}\{ e_2^* \}$. Directly, $A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} = A^{\mathsf{T}}$, and ker of the map $f \mapsto A^{\mathsf{T}} f$ (acting on coordinate columns of f) is $\{ (a, b) : a = 0 \}$. *Check.* $\dim \ker T^* = 1 = \dim \operatorname{ann}(\operatorname{im} T)$, and by Proposition 11.3.17 this equals $\dim W^* - \operatorname{rank} T = 2 - 1 = 1$. Consistent.

Worked Example 11.3.29 (Rank equality via the transpose)**.** Use Theorem 11.3.24 to explain why row rank equals column rank for $A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$ over $\mathbb{Q}$.

Recognition. The matrix of T^* is A^{T} and $\operatorname{rank} T^* = \operatorname{rank} T$, so $\operatorname{rank} A = \operatorname{rank} A^{\mathsf{T}}$; the latter is the row rank of A.

Solution. A has columns all proportional to $(1, 2)^{\mathsf{T}}$, so column rank = 1, i.e. $\operatorname{rank} T = 1$. By Theorem 11.3.24, $\operatorname{rank} T^* = \operatorname{rank} A^{\mathsf{T}} = 1$; but $\operatorname{rank} A^{\mathsf{T}}$ is the column rank of A^{T} = row rank of A. The two rows $(1, 2, 3), (2, 4, 6)$ are proportional, so row rank = 1 too. *Check.* Both ranks equal 1; rank–nullity for $T\colon \mathbb{Q}^3 \to \mathbb{Q}^2$ gives $\dim \ker T = 3 - 1 = 2$, and $\dim \ker T^* = \dim \operatorname{ann}(\operatorname{im} T) = 2 - 1 = 1$ (Proposition 11.3.17), consistent with $\operatorname{rank} T^* = 2 - 1 = 1$. Correct.

Summary of the duality dictionary

For finite-dimensional V over F the constructions of this section assemble into one coherent dictionary, all anchored by the natural isomorphism $V \cong V^{**}$:

- $\dim V^* = \dim V$, with dual basis $v_i^*(v_j) = \delta_{ij}$ (Theorem 11.3.5);
- $V \xrightarrow{\Phi} V^{**}$, $\Phi(v)(f) = f(v)$, a basis-free isomorphism (Theorem 11.3.11);
- $\dim \operatorname{ann}(W) = \dim V - \dim W$ and $\operatorname{ann}(\operatorname{ann}(W)) = W$ (Proposition 11.3.17);
- $T^*(f) = f \circ T$ has matrix A^{T}, with $\ker T^* = \operatorname{ann}(\operatorname{im} T)$ and $\operatorname{rank} T^* = \operatorname{rank} T$ (Theorem 11.3.24).

The contravariant functor $\operatorname{Hom}_F(-, F)$ ties these together: it sends $V \rightsquigarrow V^*$, $T \rightsquigarrow T^*$, subspaces to their annihilators, and — applied twice — returns V to itself.

Exercises (from the text).

1. Let V be a vector space over F of dimension $n < \infty$. Prove that the map $\varphi \mapsto \varphi^*$ of Theorem 11.3.24 is a vector space isomorphism of $\operatorname{End}(V)$ with $\operatorname{End}(V^*)$, but is not a ring homomorphism when $n > 1$. Exhibit an F-algebra isomorphism from $\operatorname{End}(V)$ to $\operatorname{End}(V^*)$.
2. Let V be the collection of polynomials with coefficients in $\mathbb{Q}$ in the variable x of degree at most 5 with $1, x, x^2, \ldots, x^5$ as basis. Prove that the following are elements of the dual space of V and express them as linear combinations of the dual basis:
   (a) $E : V \to \mathbb{Q}$ defined by $E(p(x)) = p(3)$ (i.e., evaluation at $x = 3$).
   (b) $\varphi : V \to \mathbb{Q}$ defined by $\varphi(p(x)) = \int_0^1 p(t)\, dt$.
   (c) $\varphi : V \to \mathbb{Q}$ defined by $\varphi(p(x)) = \int_0^1 t^2 p(t)\, dt$.
   (d) $\varphi : V \to \mathbb{Q}$ defined by $\varphi(p(x)) = p'(5)$ where $p'(x)$ denotes the usual derivative of the polynomial $p(x)$ with respect to x.
3. Let S be any subset of V for some finite dimensional space V. Define $\operatorname{Ann}(S) = \{f \in V^* \mid f(v) = 0 \text{ for all } v \in S\}$. ($\operatorname{Ann}(S)$ is called the *annihilator* of S in V^*.)
   (a) Prove that $\operatorname{Ann}(S)$ is a subspace of V^*.
   (b) Let W_1 and W_2 be subspaces of V. Prove that $\operatorname{Ann}(W_1 + W_2) = \operatorname{Ann}(W_1) \cap \operatorname{Ann}(W_2)$ and $\operatorname{Ann}(W_1 \cap W_2) = \operatorname{Ann}(W_1) + \operatorname{Ann}(W_2)$.
   (c) Let W_1 and W_2 be subspaces of V. Prove that $W_1 = W_2$ if and only if $\operatorname{Ann}(W_1) = \operatorname{Ann}(W_2)$.
   (d) Prove that the annihilator of S is the same as the annihilator of the subspace of V spanned by S.
   (e) Assume V is finite dimensional with basis $v_1, \ldots, v_n$. Prove that if $S = \{v_1, \ldots, v_k\}$ for some $k \leq n$, then $\operatorname{Ann}(S)$ is the subspace spanned by $\{v_{k+1}^*, \ldots, v_n^*\}$.
   (f) Assume V is finite dimensional. Prove that if W is any subspace of V then $\dim \operatorname{Ann}(W) = \dim V - \dim W$.

4. If V is infinite dimensional with basis $\mathcal{A}$, prove that $\mathcal{A}^* = \{v^* \mid v \in \mathcal{A}\}$ does not span V^*.
5. If V is infinite dimensional with basis $\mathcal{A}$, prove that V^* is isomorphic to the direct product of copies of $\mathbb{F}$ indexed by $\mathcal{A}$. Deduce that $\dim V^* > \dim V$. [Use Exercise 14, Section 1.]

Practice problems.

1. Let $V = \mathbb{F}^3$ and let $\{ e_1, e_2, e_3 \}$ be the standard basis. For the linear functional $\varphi \in V^*$ defined by $\varphi(a_1, a_2, a_3) = a_1 - 2a_2 + a_3$, write φ as a linear combination of the dual basis $\{ e_1^*, e_2^*, e_3^* \}$.
2. Let V be a vector space with basis $\{ v_1, v_2 \}$ over a field $\mathbb{F}$ with $\operatorname{char}\mathbb{F} \neq 2$, and let $\{ v_1^*, v_2^* \}$ be the dual basis of V^*. Consider the new basis $\{ w_1, w_2 \}$ with $w_1 = v_1 + v_2$ and $w_2 = v_1 - v_2$. Compute the dual basis $\{ w_1^*, w_2^* \}$ explicitly as linear combinations of v_1^* and v_2^*.
3. Let $\mathbb{F}$ be a field with $\operatorname{char}\mathbb{F} \neq 2$, and let $V = \mathbb{F}[x]_{\leq 2}$ be the space of polynomials of degree at most 2. Define functionals $\varphi_0, \varphi_1, \varphi_2 \in V^*$ by $\varphi_i(p) = p(i)$ for $i = 0, 1, 2$. Show that $\{ \varphi_0, \varphi_1, \varphi_2 \}$ is a basis of V^*, and find the basis $\{ p_0, p_1, p_2 \}$ of V for which it is the dual basis.
4. Let $\dim V = n$. Prove that for every nonzero $v \in V$ there exists $\varphi \in V^*$ with $\varphi(v) \neq 0$. Conclude that the only vector annihilated by every functional in V^* is 0.
5. Let $V = \mathbb{F}^4$ and let $W = \operatorname{Span}(\, (1,1,0,0),\ (0,1,1,0)\,)$. Find a basis for the annihilator $\operatorname{Ann}(W) \subseteq V^*$, and verify that $\dim \operatorname{Ann}(W) = \dim V - \dim W$.
6. Let $T\colon \mathbb{F}^2 \to \mathbb{F}^3$ be the linear map with matrix $\mathrm{M}(T) = \begin{pmatrix} 1 & 2 \\ 0 & 1 \\ 3 & 0 \end{pmatrix}$ relative to the standard bases. Compute the matrix of the transpose map $T^{\mathsf{T}}\colon (\mathbb{F}^3)^* \to (\mathbb{F}^2)^*$ relative to the dual bases, and verify directly that it equals $(\mathrm{M}(T))^{\mathsf{T}}$.
7. For finite-dimensional V, let $\mathrm{ev}\colon V \to (V^*)^*$ be the natural map sending v to the functional $\mathrm{ev}_v(\varphi) = \varphi(v)$. Show that ev is linear and injective, and explain why injectivity together with $\dim V = \dim (V^*)^*$ forces ev to be an isomorphism.
8. Let V be finite dimensional and let $\varphi_1, \varphi_2 \in V^*$ be nonzero. Prove that $\ker \varphi_1 = \ker \varphi_2$ if and only if $\varphi_2 = c\,\varphi_1$ for some nonzero scalar $c \in \mathbb{F}$.

Additional exercises.

1. Let V be finite dimensional and let $W_1, W_2 \subseteq V$ be subspaces. Prove that $\operatorname{Ann}(W_1 + W_2) = \operatorname{Ann}(W_1) \cap \operatorname{Ann}(W_2)$ and that $\operatorname{Ann}(W_1 \cap W_2) = \operatorname{Ann}(W_1) + \operatorname{Ann}(W_2)$.
2. Let $S\colon V \to W$ and $T\colon W \to U$ be linear maps of finite-dimensional spaces. Prove that $(T \circ S)^{\mathsf{T}} = S^{\mathsf{T}} \circ T^{\mathsf{T}}$ as maps $U^* \to V^*$, and that $\mathrm{id}_V^{\mathsf{T}} = \mathrm{id}_{V^*}$.
3. Let $T\colon V \to W$ be a linear map of finite-dimensional spaces, with transpose $T^{\mathsf{T}}\colon W^* \to V^*$. Prove that $\ker(T^{\mathsf{T}}) = \operatorname{Ann}(\operatorname{im} T)$ and that $\operatorname{im}(T^{\mathsf{T}}) = \operatorname{Ann}(\ker T)$. Deduce that $\operatorname{rank}(T^{\mathsf{T}}) = \operatorname{rank}(T)$.
4. Let V be finite dimensional and identify V with $(V^*)^*$ via the natural isomorphism. Prove that for any subspace $W \subseteq V$ the annihilator of $\operatorname{Ann}(W)$, computed inside $(V^*)^*$, corresponds under this identification exactly to W; that is, $\operatorname{Ann}(\operatorname{Ann}(W)) = W$.
5. Let V be a vector space (not assumed finite dimensional) with an infinite basis. Show that the natural map $\mathrm{ev}\colon V \to (V^*)^*$ is injective but not surjective, by exhibiting an element of $(V^*)^*$ not of the form ev_v.

Commutative-diagram exercises.

1. (Naturality of evaluation.) Let $T\colon V \to W$ be a linear map of finite-dimensional spaces, and let $\mathrm{ev}_V, \mathrm{ev}_W$ be the natural isomorphisms into the double duals. Prove that the diagram

$$\begin{array}{ccc} V & \xrightarrow{\ T\ } & W \\ {\scriptstyle \mathrm{ev}_V}\downarrow & & \downarrow{\scriptstyle \mathrm{ev}_W} \\ (V^*)^* & \xrightarrow[(T^{\mathsf{T}})^{\mathsf{T}}]{} & (W^*)^* \end{array}$$

commutes, i.e. $\mathrm{ev}_W \circ T = (T^{\mathsf{T}})^{\mathsf{T}} \circ \mathrm{ev}_V$. This says the double transpose $(T^{\mathsf{T}})^{\mathsf{T}}$ is identified with T itself under the natural isomorphisms.

2. (Functoriality of the dual on a short exact sequence.) Let

$$0 \longrightarrow U \xhookrightarrow{\ i\ } V \xrightarrow{\ p\ } W \longrightarrow 0$$

be a short exact sequence of finite-dimensional $\mathbb{F}$-vector spaces. Prove that applying $(\,\cdot\,)^*$ yields the short exact sequence

$$0 \longrightarrow W^* \xrightarrow{\ p^{\mathsf{T}}\ } V^* \xrightarrow{\ i^{\mathsf{T}}\ } U^* \longrightarrow 0,$$

identifying $\mathrm{im}(p^{\mathsf{T}}) = \ker(i^{\mathsf{T}})$ with $\mathrm{Ann}(\ker p) = \mathrm{Ann}(\mathrm{im}\, i)$.

3. (Universal property of the dual basis pairing.) Let V be finite dimensional with the natural pairing $\langle \cdot, \cdot \rangle \colon V^* \times V \to \mathbb{F}$ given by $\langle \varphi, v \rangle = \varphi(v)$. Show that for any linear map $T \colon V \to W$ between finite-dimensional spaces, T^{T} is the unique linear map making

$$\begin{array}{ccc} W^* \times V & \xrightarrow{\ \mathrm{id} \times T\ } & W^* \times W \\ {\scriptstyle T^{\mathsf{T}} \times \mathrm{id}}\downarrow & & \downarrow{\scriptstyle \langle \cdot, \cdot \rangle_W} \\ V^* \times V & \xrightarrow[\ \langle \cdot, \cdot \rangle_V\ ]{} & \mathbb{F} \end{array}$$

commute, i.e. the defining adjunction $\langle T^{\mathsf{T}}\psi,\, v \rangle_V = \langle \psi,\, Tv \rangle_W$ for all $\psi \in W^*$, $v \in V$.

4. (Annihilator and the quotient.) Let $W \subseteq V$ be a subspace of a finite-dimensional space, with inclusion $i \colon W \hookrightarrow V$ and quotient map $q \colon V \to V/W$. Prove that the natural isomorphism $\mathrm{Ann}(W) \cong (V/W)^*$ fits into the commutative diagram

$$\begin{array}{ccc} (V/W)^* & \xrightarrow{\ q^{\mathsf{T}}\ } & V^* \\ {\scriptstyle \cong}\downarrow & & \| \\ \mathrm{Ann}(W) & \hookrightarrow & V^* \end{array}$$

where the bottom arrow is inclusion; deduce $\dim \mathrm{Ann}(W) = \dim V - \dim W$ from $\dim (V/W)^* = \dim (V/W)$.

11.4 Determinants

The determinant is the unique scalar-valued function of the columns of a square matrix that is linear in each column, alternating, and normalized so that $\det I = 1$. Throughout, F is a field, V is a finite-dimensional F-vector space, and matrices are written over F. We view an $n \times n$ matrix A as the ordered n-tuple of its columns $A = (A_1, \dots, A_n)$, each $A_i \in F^n$.

The defining properties

Definition 11.4.1 (Alternating n-linear function)**.** A function $D : \underbrace{F^n \times \cdots \times F^n}_{n} \to F$ of the n columns is called *n-linear* (or *multilinear in the columns*) if for each fixed i and fixed columns $A_1, \dots, A_{i-1}, A_{i+1}, \dots, A_n$, the map $A_i \mapsto D(A_1, \dots, A_n)$ is F-linear:

$$D(\dots,\ \alpha A_i + \beta A_i',\ \dots) = \alpha\, D(\dots, A_i, \dots) + \beta\, D(\dots, A_i', \dots), \qquad \alpha, \beta \in F.$$

It is *alternating* if $D(A_1, \dots, A_n) = 0$ whenever two of the columns are equal: $A_i = A_j$ for some $i \neq j$.

Remark 11.4.1. Over any field, "alternating" (vanishing on repeated columns) implies *skew-symmetric*: swapping two columns negates D. Indeed expanding $D(\dots, A_i + A_j, \dots, A_i + A_j, \dots) = 0$ by multilinearity and killing the two repeated-column terms leaves $D(\dots, A_i, \dots, A_j, \dots) + D(\dots, A_j, \dots, A_i, \dots) = 0$. The converse holds when $\mathrm{char}\, F \neq 2$; over $\mathbb{F}_2$ one must take the vanishing-on-repeats version as the definition.

Theorem 11.4.2 (Existence and uniqueness of the determinant)**.** *For each $n \geq 1$ there is a unique alternating n-linear function $\det : \mathrm{M}_n(F) \to F$ of the columns with $\det I = 1$. It is given by the Leibniz formula*

$$\det A = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma)\, a_{\sigma(1)\,1}\, a_{\sigma(2)\,2} \cdots a_{\sigma(n)\,n}, \qquad A = (a_{ij}).$$

Moreover any alternating n-linear function D satisfies $D(A) = D(I) \det A$; the determinant is the one with $D(I) = 1$.

Sketch. Write each column $A_j = \sum_i a_{ij}\, e_i$ in the standard basis. By n-linearity,

$$D(A) = \sum_{i_1, \ldots, i_n} a_{i_1 1} \cdots a_{i_n n}\, D(e_{i_1}, \ldots, e_{i_n}).$$

Alternating kills all terms with a repeated index, leaving only those where $(i_1, \ldots, i_n)$ is a permutation σ, and skew-symmetry gives

$$D(e_{\sigma(1)}, \ldots, e_{\sigma(n)}) = \operatorname{sgn}(\sigma)\, D(e_1, \ldots, e_n) = \operatorname{sgn}(\sigma)\, D(I).$$

Hence $D(A) = D(I) \sum_\sigma \operatorname{sgn}(\sigma) \prod_j a_{\sigma(j)\,j}$. Setting $D(I) = 1$ forces the Leibniz formula, which proves uniqueness. For existence, one checks directly that the Leibniz formula is n-linear (each term contains exactly one entry from each column) and alternating: if $A_k = A_l$ with $k \neq l$, the terms for σ and $\sigma \circ (k\,l)$ have equal products and opposite signs, so they cancel in pairs. At $A = I$ only $\sigma = \mathrm{id}$ contributes, so $\det I = 1$. □

Worked Example 11.4.3 (2×2 from the axioms, over $\mathbb{Q}$)**.** Show the axioms force $\det \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) = ad - bc$, and evaluate at $\left(\begin{smallmatrix} 3 & 5 \\ 1 & 2 \end{smallmatrix}\right)$.

Recognition. Theorem 11.4.2: expand the columns in e_1, e_2 and use 2-linearity, vanishing on repeats, and $\det I = 1$.

Solution. Columns are $A_1 = ae_1 + ce_2$, $A_2 = be_1 + de_2$. By bilinearity,

$$\det(A_1, A_2) = ab\, \det(e_1, e_1) + ad\, \det(e_1, e_2) + cb\, \det(e_2, e_1) + cd\, \det(e_2, e_2).$$

The first and last terms vanish (repeated column); $\det(e_1, e_2) = \det I = 1$ and $\det(e_2, e_1) = -1$. Hence $\det = ad - bc$. At the given matrix: $3 \cdot 2 - 5 \cdot 1 = 1$. *Sanity check.* The Leibniz sum has $\sigma = \mathrm{id}$ giving $+a_{11}a_{22} = 6$ and $\sigma = (1\,2)$ giving $-a_{21}a_{12} = -5$, total 1.

Worked Example 11.4.4 (Repeated column forces zero, over $\mathbb{R}$)**.** Compute det of $A = \left(\begin{smallmatrix} 1 & 2 & 1 \\ 4 & 5 & 4 \\ 7 & 8 & 7 \end{smallmatrix}\right)$.

Recognition. The alternating property: columns 1 and 3 are equal.

Solution. Since $A_1 = A_3$, the alternating axiom gives $\det A = 0$ outright – no computation needed. *Sanity check.* The Leibniz expansion pairs each σ with $\sigma \cdot (1\,3)$, whose products are equal but signs opposite, so all terms cancel.

Worked Example 11.4.5 (Leibniz formula over $\mathbb{F}_2$)**.** In $\mathrm{M}_3(\mathbb{F}_2)$ compute $\det A$ for $A = \left(\begin{smallmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{smallmatrix}\right)$.

Recognition. Theorem 11.4.2; over $\mathbb{F}_2$ signs are irrelevant since $-1 = 1$, so $\det A = \sum_\sigma \prod_j a_{\sigma(j)\,j} \pmod 2$.

Solution. The nonzero products: $\sigma = \mathrm{id}$ gives $a_{11}a_{22}a_{33} = 1$; $\sigma = (1\,2\,3)$ gives $a_{21}a_{32}a_{13}$, which is $0 \cdot 0 \cdot 0 = 0$; $\sigma = (1\,3\,2)$ gives $a_{31}a_{12}a_{23} = 1 \cdot 1 \cdot 1 = 1$. The remaining three permutations all hit a zero entry. Sum $= 1 + 1 = 0$ in $\mathbb{F}_2$. So $\det A = 0$, i.e. A is singular over $\mathbb{F}_2$. *Sanity check.* $A_1 + A_2 + A_3 = (1{+}1{+}0,\ 0{+}1{+}1,\ 1{+}0{+}1)^{\mathsf{T}} = (0, 0, 0)^{\mathsf{T}}$, so the columns are dependent, confirming $\det A = 0$.

Worked Example 11.4.6 (Upper triangular: product of the diagonal, over $\mathbb{Q}$)**.** Compute $\det \left(\begin{smallmatrix} 2 & 9 & -1 \\ 0 & 3 & 7 \\ 0 & 0 & 5 \end{smallmatrix}\right)$.

Recognition. Leibniz: for an upper-triangular matrix the only permutation giving a nonzero product is the identity.

Solution. If $a_{ij} = 0$ for $i > j$, a term $\prod_j a_{\sigma(j)\,j} \neq 0$ needs $\sigma(j) \leq j$ for all j, forcing $\sigma = \mathrm{id}$. Thus $\det = a_{11}a_{22}a_{33} = 2 \cdot 3 \cdot 5 = 30$. *Sanity check.* The matrix is invertible (no zero on the diagonal), consistent with $\det \neq 0$ (Theorem 11.4.9).

Worked Example 11.4.7 (Effect of column operations, over $\mathbb{R}$)**.** Starting from $\det B = 4$ where $B = (B_1, B_2, B_3)$, find $\det(B_1,\ B_2 + 3B_1,\ 2B_3)$.

Recognition. Multilinearity (add a multiple of one column to another does not change det, since the extra term has a repeated column) plus scaling a column scales det.

Solution. Expand the middle column: $\det(B_1, B_2 + 3B_1, 2B_3) = \det(B_1, B_2, 2B_3) + 3\det(B_1, B_1, 2B_3)$. The second term vanishes (repeat). Pulling the scalar 2 out of the third column: $= 2\det(B_1, B_2, B_3) = 2 \cdot 4 = 8$. *Sanity check.* A single elementary "add multiple" operation has determinant 1, and scaling a column by 2 multiplies det by 2; product $1 \cdot 2 \cdot 4 = 8$.

Multiplicativity and invertibility

Theorem 11.4.8 (Multiplicativity)**.** *For all $A, B \in \mathrm{M}_n(F)$, $\det(AB) = \det(A)\det(B)$. Consequently $\det(A^k) = (\det A)^k$ and, if A is invertible, $\det(A^{-1}) = (\det A)^{-1}$.*

Sketch. Fix A and consider $D(B) := \det(AB)$ as a function of the columns of B: the jth column of AB is AB_j, and $B_j \mapsto AB_j$ is linear, so D is alternating n-linear in the columns of B. By the uniqueness clause of Theorem 11.4.2, $D(B) = D(I)\det B = \det(A)\det(B)$. □

Theorem 11.4.9 (Invertibility criterion)**.** *$A \in \mathrm{M}_n(F)$ is invertible if and only if $\det A \neq 0$. Equivalently, the columns of A are linearly independent iff $\det A \neq 0$. Moreover $\det(A^{\mathsf{T}}) = \det A$, so the same holds for rows.*

Sketch. If $AB = I$ then $\det(A)\det(B) = \det I = 1$ by Theorem 11.4.8, so $\det A \neq 0$. Conversely if the columns are dependent, some $A_i = \sum_{j \neq i} c_j A_j$; substituting and expanding gives a sum of determinants each with a repeated column, hence $\det A = 0$. So $\det A \neq 0 \Leftrightarrow$ columns independent $\Leftrightarrow A$ invertible. The identity $\det A^{\mathsf{T}} = \det A$ follows from the Leibniz formula by reindexing $\sigma \mapsto \sigma^{-1}$ (with $\operatorname{sgn}\sigma^{-1} = \operatorname{sgn}\sigma$). □

Worked Example 11.4.10 (Multiplicativity check over $\mathbb{Q}$)**.** Let $A = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. Verify $\det(AB) = \det A \det B$.

Recognition. Theorem 11.4.8.

Solution. $\det A = 4 - 6 = -2$, $\det B = 0 - 1 = -1$, so $\det A \det B = 2$. Now $AB = \left(\begin{smallmatrix} 2 & 3 \\ 4 & 7 \end{smallmatrix}\right)$, with $\det(AB) = 14 - 12 = 2$. They agree. *Sanity check.* Also $\det(BA)$ must equal 2; $BA = \left(\begin{smallmatrix} 3 & 4 \\ 4 & 6 \end{smallmatrix}\right)$, $\det = 18 - 16 = 2$. ■

Worked Example 11.4.11 (Determinant of an inverse over $\mathbb{Q}$)**.** Given $\det A = 7$ for $A \in \mathrm{M}_3(\mathbb{Q})$, find $\det(A^{-1})$ and $\det(A^2A^{-3})$.

Recognition. Theorem 11.4.8 and its corollary.

Solution. $\det(A^{-1}) = (\det A)^{-1} = 1/7$. And $A^2A^{-3} = A^{-1}$, so $\det(A^2A^{-3}) = 1/7$. *Sanity check.* $\det(A^2)\det(A^{-3}) = 7^2 \cdot 7^{-3} = 7^{-1}$. ■

Worked Example 11.4.12 (A suspected dependent column, over $\mathbb{R}$)**.** Decide whether $A = \left(\begin{smallmatrix} 1 & 0 & 2 \\ 2 & 1 & 5 \\ 0 & 3 & 6 \end{smallmatrix}\right)$ is invertible.

Recognition. Theorem 11.4.9: invertible iff columns independent iff $\det \neq 0$.

Solution. The first two rows suggest $A_3 = 2A_1 + A_2$, but $2(1,2,0)^{\mathsf{T}} + (0,1,3)^{\mathsf{T}} = (2,5,3)^{\mathsf{T}} \neq (2,5,6)^{\mathsf{T}} = A_3$, so there is no such relation, and a failed guess decides nothing. Compute directly by expanding along column 1: $\det A = 1 \cdot (1 \cdot 6 - 5 \cdot 3) - 2 \cdot (0 \cdot 6 - 2 \cdot 3) + 0 = (6 - 15) - 2(0 - 6) = -9 + 12 = 3 \neq 0$. Hence A is invertible. *Sanity check.* $\det \neq 0$ matches the columns being independent.

Worked Example 11.4.13 (Orthogonal-type matrix has det $= \pm 1$ over $\mathbb{R}$)**.** If $A^{\mathsf{T}}A = I$, show $\det A \in \{1, -1\}$; illustrate with a rotation.

Recognition. Theorems 11.4.8 and 11.4.9, plus $\det A^{\mathsf{T}} = \det A$.

Solution. $1 = \det I = \det(A^{\mathsf{T}}A) = \det(A^{\mathsf{T}})\det(A) = (\det A)^2$, so $\det A = \pm 1$. For $A = \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$, $\det A = \cos^2\theta + \sin^2\theta = 1$. *Sanity check.* The reflection $\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ also satisfies $A^{\mathsf{T}}A = I$ and has $\det = -1$, hitting the other value.

Worked Example 11.4.14 ($\det A^{\mathsf{T}} = \det A$ on a triangular example, over $\mathbb{Q}$)**.** Verify $\det A^{\mathsf{T}} = \det A$ for $A = \left(\begin{smallmatrix} 2 & 5 \\ 0 & 3 \end{smallmatrix}\right)$.

Recognition. Theorem 11.4.9 (transpose clause).

Solution. $\det A = 2 \cdot 3 - 5 \cdot 0 = 6$. $A^{\mathsf{T}} = \left(\begin{smallmatrix} 2 & 0 \\ 5 & 3 \end{smallmatrix}\right)$ has $\det = 2 \cdot 3 - 0 = 6$. Equal. *Sanity check.* Both are triangular with the same diagonal $(2, 3)$, so both equal $2 \cdot 3 = 6$.

Cofactor (Laplace) expansion

Definition 11.4.15 (Minor, cofactor, adjugate)**.** For $A = (a_{ij}) \in \mathrm{M}_n(F)$ let A_{ij} denote the $(n-1) \times (n-1)$ matrix obtained by deleting row i and column j. The (i, j) *minor* is $\det A_{ij}$ and the (i, j) *cofactor* is $c_{ij} = (-1)^{i+j} \det A_{ij}$. The *adjugate* is the transpose of the cofactor matrix: $(\operatorname{adj} A)_{ij} = c_{ji}$.

Theorem 11.4.16 (Laplace expansion and Cramer's rule)**.** *For each fixed column j (resp. row i),*

$$\det A = \sum_{i=1}^{n} (-1)^{i+j} a_{ij} \det A_{ij} = \sum_{i=1}^{n} a_{ij}\, c_{ij} \qquad \Big(\textit{resp. } \det A = \sum_{j=1}^{n} a_{ij}\, c_{ij}\Big).$$

*Furthermore $A \,(\operatorname{adj} A) = (\operatorname{adj} A)\, A = (\det A)\, I$, so when $\det A \neq 0$, $A^{-1} = (\det A)^{-1} \operatorname{adj} A$. If $Ax = b$ with $\det A \neq 0$, then $x_j = \det(A^{(j)}) / \det A$, where $A^{(j)}$ replaces column j of A by b (*Cramer's rule*).*

Worked Example 11.4.17 (Cofactor expansion of a 3×3 over $\mathbb{Q}$)**.** Compute $\det A$, $A = \left(\begin{smallmatrix} 2 & -1 & 0 \\ 1 & 3 & 4 \\ 0 & 2 & 1 \end{smallmatrix}\right)$, expanding along the first column.

Recognition. Theorem 11.4.16; column 1 has a zero, easing the work.

Solution. $\det A = 2\, c_{11} + 1\, c_{21} + 0$. Here $c_{11} = (+1) \det\left(\begin{smallmatrix} 3 & 4 \\ 2 & 1 \end{smallmatrix}\right) = 3 - 8 = -5$ and $c_{21} = (-1) \det\left(\begin{smallmatrix} -1 & 0 \\ 2 & 1 \end{smallmatrix}\right) = -(-1 - 0) = 1$. So $\det A = 2(-5) + 1(1) = -9$. *Sanity check.* Expanding along row 1: $2 \det\left(\begin{smallmatrix} 3 & 4 \\ 2 & 1 \end{smallmatrix}\right) - (-1) \det\left(\begin{smallmatrix} 1 & 4 \\ 0 & 1 \end{smallmatrix}\right) = 2(-5) + 1(1) = -9$. ■

Worked Example 11.4.18 (Inverse via the adjugate over $\mathbb{Q}$)**.** Find A^{-1} for $A = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$.

Recognition. Theorem 11.4.16: $A^{-1} = (\det A)^{-1} \operatorname{adj} A$.

Solution. $\det A = -2$. Cofactors: $c_{11} = 4$, $c_{12} = -3$, $c_{21} = -2$, $c_{22} = 1$, so $\operatorname{adj} A = \left(\begin{smallmatrix} c_{11} & c_{21} \\ c_{12} & c_{22} \end{smallmatrix}\right) = \left(\begin{smallmatrix} 4 & -2 \\ -3 & 1 \end{smallmatrix}\right)$. Hence $A^{-1} = -\frac{1}{2}\left(\begin{smallmatrix} 4 & -2 \\ -3 & 1 \end{smallmatrix}\right) = \begin{pmatrix} -2 & 1 \\ 3/2 & -1/2 \end{pmatrix}$. *Sanity check.* $AA^{-1} = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)\begin{pmatrix} -2 & 1 \\ 3/2 & -1/2 \end{pmatrix} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$. ■

Worked Example 11.4.19 (Cramer's rule over $\mathbb{Q}$)**.** Solve $\begin{cases} 2x + y = 5 \\ x + 3y = 6 \end{cases}$ by Cramer's rule.

Recognition. Theorem 11.4.16 (Cramer's rule).

Solution. $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 3 \end{smallmatrix}\right)$, $\det A = 5$; $b = (5, 6)^{\mathsf{T}}$. Then $x = \det\left(\begin{smallmatrix} 5 & 1 \\ 6 & 3 \end{smallmatrix}\right)/5 = (15 - 6)/5 = 9/5$ and $y = \det\left(\begin{smallmatrix} 2 & 5 \\ 1 & 6 \end{smallmatrix}\right)/5 = (12 - 5)/5 = 7/5$. *Sanity check.* $2(9/5) + 7/5 = 25/5 = 5$ and $9/5 + 3(7/5) = 30/5 = 6$. ■

Worked Example 11.4.20 (Adjugate identity over $\mathbb{F}_2$)**.** For $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ over $\mathbb{F}_2$, verify $A \operatorname{adj} A = (\det A) I$ and find A^{-1}.

Recognition. Theorem 11.4.16; recall $-1 = 1$ in $\mathbb{F}_2$.

Solution. $\det A = 1 \cdot 0 - 1 \cdot 1 = -1 = 1$. Cofactors: $c_{11} = 0$, $c_{12} = -1 = 1$, $c_{21} = -1 = 1$, $c_{22} = 1$, so $\operatorname{adj} A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. Then $A \operatorname{adj} A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) = (\det A) I$. Since $\det A = 1$, $A^{-1} = \operatorname{adj} A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)$. *Sanity check.* $A^{-1} = A^{-1}$ should satisfy $A^{-1} A = I$: $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$. ■

Worked Example 11.4.21 (Expansion along a sparse row, over $\mathbb{Q}$)**.** Compute $\det\left(\begin{smallmatrix} 0 & 0 & 3 \\ 1 & 2 & 5 \\ 0 & 4 & 6 \end{smallmatrix}\right)$ efficiently.

Recognition. Theorem 11.4.16: expand along row 1, which has a single nonzero entry.

Solution. Only $a_{13} = 3$ contributes: $\det A = 3\, c_{13} = 3(-1)^{1+3} \det\left(\begin{smallmatrix} 1 & 2 \\ 0 & 4 \end{smallmatrix}\right) = 3 \cdot (4 - 0) = 12$. *Sanity check.* Expand instead along column 1 (single entry $a_{21} = 1$): $1 \cdot (-1)^{2+1} \det\left(\begin{smallmatrix} 0 & 3 \\ 4 & 6 \end{smallmatrix}\right) = -(0 - 12) = 12$. ■

The determinant of a linear operator

Theorem 11.4.22 (Basis-independence; determinant of an operator)**.** *Let $T \in \mathrm{End}(V)$ with $\dim_F V = n$. If A and A' are the matrices of T in two ordered bases, related by $A' = P^{-1}AP$, where the columns of P are the new basis vectors written in the old basis (so P converts new coordinates to old; the change-of-basis matrix of §11.2 from the old basis to the new one is P^{-1}), then $\det A' = \det A$. Hence*

$$\det T := \det\left([T]_{\mathcal{B}}\right)$$

is well defined, independent of the basis $\mathcal{B}$. It satisfies $\det(\mathrm{id}_V) = 1$, $\det(ST) = \det(S)\det(T)$, and T is invertible iff $\det T \neq 0$.

Proof. By Theorem 11.4.8, $\det(P^{-1}AP) = \det(P^{-1})\det(A)\det(P) = \det(A)$ since $\det(P^{-1})\det(P) = 1$. The remaining properties transport from Theorems 11.4.8 and 11.4.9. □

The conjugation relation $A' = P^{-1}AP$ records the commuting square below: the two routes from $V_{\mathcal{B}}$ (coordinates in $\mathcal{B}$) to $V_{\mathcal{C}}$ (coordinates in $\mathcal{C}$) agree, and reading off det around the loop gives $\det A = \det A'$. The downward maps are the coordinate change $P^{-1} : V_{\mathcal{B}} \to V_{\mathcal{C}}$, so commutativity reads $A' \circ P^{-1} = P^{-1} \circ A$, i.e. $A' = P^{-1}AP$.

$$\begin{array}{ccc} V_{\mathcal{B}} & \xrightarrow{\;A\;} & V_{\mathcal{B}} \\ {\scriptstyle P^{-1}}\downarrow & & \downarrow{\scriptstyle P^{-1}} \\ V_{\mathcal{C}} & \xrightarrow[\;A'\;]{} & V_{\mathcal{C}} \end{array}$$

Diagram explanation. Objects: All four nodes represent F^n viewed as a coordinate space, but carrying different bases. $V_{\mathcal{B}}$ (top) is F^n with coordinates in basis $\mathcal{B}$; $V_{\mathcal{C}}$ (bottom) is F^n with coordinates in basis $\mathcal{C}$. There are two copies of each, one on the left and one on the right of the square.

Arrows: The horizontal top arrow labelled A is the matrix of T in basis $\mathcal{B}$, acting as left-multiplication $x \mapsto Ax$ on coordinate vectors in $\mathcal{B}$. The horizontal bottom arrow A' is the matrix of T in basis $\mathcal{C}$. Both vertical arrows are the same coordinate-change matrix P^{-1}, sending $\mathcal{B}$-coordinates to $\mathcal{C}$-coordinates via $x \mapsto P^{-1}x$.

What commutes: Down-then-right equals right-then-down: $A' \circ P^{-1} = P^{-1} \circ A$, which rearranges to $A' = P^{-1}AP$.

Why it commutes: Start with a vector $x \in V_{\mathcal{B}}$. Along the top-then-right path: apply T in basis $\mathcal{B}$ to get Ax, then change basis to get $P^{-1}(Ax)$. Along the left-then-bottom path: change basis first to get $P^{-1}x$, then apply T in basis $\mathcal{C}$ to get $A'(P^{-1}x)$. These agree because $P^{-1}A = A'P^{-1}$ is exactly the definition of how change-of-basis works: A' is defined to make P^{-1} an intertwining map.

Why this matters here: This square is the reason $\det T$ is well defined as an intrinsic scalar. Taking det around the loop: $\det(A') = \det(P^{-1})\det(A)\det(P) = \det(A)$ since $\det(P^{-1})\det(P) = 1$. The commutativity of the square is exactly the conjugacy relation, and the multiplicativity of det then gives basis-independence.

Concrete example: Take T on $\mathbb{Q}^2$ with $A = \left(\begin{smallmatrix} 2 & 1 \\ 0 & 3 \end{smallmatrix}\right)$ in $\mathcal{B} = \{e_1, e_2\}$. Let $P = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$. Then $A' = P^{-1}AP$ has $\det A' = \det A = 6$, verified in the worked example below.

Common pitfall: Students often confuse $A' = P^{-1}AP$ with $A' = PAP^{-1}$, getting the order backwards. The convention follows from P being the matrix whose columns are the new basis vectors expressed in the old basis, so P converts new-to-old and P^{-1} converts old-to-new.

Takeaway: The point of this diagram is that the two bases give matrices A and A' related by conjugation, and since det is multiplicative and $\det P \cdot \det P^{-1} = 1$, both matrices have the same determinant, making $\det T$ a basis-free invariant of the operator T.

Worked Example 11.4.23 (Operator determinant is basis-free, over $\mathbb{Q}$)**.** Let $T : \mathbb{Q}^2 \to \mathbb{Q}^2$, $T = \left(\begin{smallmatrix} 2 & 1 \\ 0 & 3 \end{smallmatrix}\right)$ in the standard basis. Recompute $\det T$ in the basis $\mathcal{C} = \{(1,1), (1,-1)\}$.

Recognition. Theorem 11.4.22: det is conjugation-invariant.

Solution. Standard-basis: $\det T = 6$. Change of basis $P = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, $\det P = -2$, $P^{-1} = -\frac{1}{2}\left(\begin{smallmatrix} -1 & -1 \\ -1 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1/2 & 1/2 \\ 1/2 & -1/2 \end{smallmatrix}\right)$. Then $A' = P^{-1}AP$. Compute $AP = \left(\begin{smallmatrix} 2 & 1 \\ 0 & 3 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 3 & 1 \\ 3 & -3 \end{smallmatrix}\right)$, so $A' = \left(\begin{smallmatrix} 1/2 & 1/2 \\ 1/2 & -1/2 \end{smallmatrix}\right)\left(\begin{smallmatrix} 3 & 1 \\ 3 & -3 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 3 & -1 \\ 0 & 2 \end{smallmatrix}\right)$. $\det A' = 3 \cdot 2 - (-1) \cdot 0 = 6$. *Sanity check.* Matches the standard-basis value 6, as Theorem 11.4.22 guarantees.

Worked Example 11.4.24 (Determinant of a composite operator over $\mathbb{R}$)**.** On $\mathbb{R}^2$ let R be rotation by 90° and S the shear $\left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right)$. Find $\det(SR)$.

Recognition. Theorem 11.4.22: $\det(ST) = \det S \det T$.

Solution. $R = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, $\det R = 1$; $\det S = 1$. So $\det(SR) = 1 \cdot 1 = 1$. *Sanity check.* Directly $SR = \left(\begin{smallmatrix} 1 & 2 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 2 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, $\det = 0 - (-1) = 1$. ■

Worked Example 11.4.25 (Scalar operator on $\mathbb{Q}^3$)**.** For the operator $T = \lambda\,\mathrm{id}$ on V with $\dim V = 3$, find $\det T$, and specialize to $\lambda = -2$.

Recognition. Theorem 11.4.22: in any basis $[T] = \lambda I_3$.

Solution. $\det(\lambda I_3) = \lambda^3$ (Leibniz: only $\sigma = \mathrm{id}$ survives, with product λ^3). At $\lambda = -2$: $\det T = (-2)^3 = -8$. *Sanity check.* basis-independence is automatic here since λ id has the same matrix λI in *every* basis.

Worked Example 11.4.26 (Projection has determinant 0, over $\mathbb{R}$)**.** Let $P : \mathbb{R}^3 \to \mathbb{R}^3$ be the projection onto the xy-plane. Compute $\det P$ and interpret.

Recognition. Theorem 11.4.22 with Theorem 11.4.9.

Solution. In the standard basis $P = \mathrm{diag}(1, 1, 0)$, so $\det P = 1 \cdot 1 \cdot 0 = 0$. *Sanity check.* P is not invertible (it kills the z-axis), consistent with $\det P = 0$.

Worked Example 11.4.27 (Determinant of a nilpotent operator over $\mathbb{Q}$)**.** If $N \in \mathrm{End}(\mathbb{Q}^3)$ satisfies $N^3 = 0$ but $N \neq 0$, show $\det N = 0$.

Recognition. Theorem 11.4.22/11.4.8.

Solution. $0 = \det(N^3) = (\det N)^3$, and $\mathbb{Q}$ is a field (no zero divisors), so $\det N = 0$. *Sanity check.* Concretely $N = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{smallmatrix}\right)$ is upper triangular with zero diagonal, giving $\det N = 0$. ■

The determinant via the top exterior power

The conceptual home of the determinant is the one-dimensional space $\wedge^n V$. Since $\dim_F V = n$, $\dim_F \wedge^n V = \binom{n}{n} = 1$; a basis is the single wedge $e_1 \wedge e_2 \wedge \cdots \wedge e_n$ for any basis $\{e_1, \ldots, e_n\}$ of V.

Theorem 11.4.28 (Determinant as the action on $\wedge^n V$)**.** *Let $T \in \mathrm{End}(V)$ with $\dim_F V = n$. The induced map $\wedge^n T : \wedge^n V \to \wedge^n V$,*

$$(\wedge^n T)(v_1 \wedge \cdots \wedge v_n) = Tv_1 \wedge \cdots \wedge Tv_n,$$

is multiplication by a scalar (because $\dim \wedge^n V = 1$), and that scalar is exactly $\det T$:

$$Tv_1 \wedge \cdots \wedge Tv_n = (\det T)\,(v_1 \wedge \cdots \wedge v_n).$$

In particular, taking $v_i = e_i$ the standard basis and $T = A$, the columns $Ae_i = A_i$ satisfy $A_1 \wedge \cdots \wedge A_n = (\det A)\, e_1 \wedge \cdots \wedge e_n$.

Sketch. The map $(v_1, \ldots, v_n) \mapsto Tv_1 \wedge \cdots \wedge Tv_n \in \wedge^n V$ is alternating and n-linear, hence by the universal property of $\wedge^n V$ descends to a linear endomorphism $\wedge^n T$ of the 1-dimensional space $\wedge^n V$, i.e. a scalar c. Evaluating on a basis and comparing with the column expansion of det (Theorem 11.4.2) identifies $c = \det T$. □

This is captured by the naturality square: T on V induces $\wedge^n T$ on the line $\wedge^n V$, and the wedge map $\wedge$ intertwines them.

$$\begin{array}{ccc} V^{\times n} & \xrightarrow{\;T^{\times n}\;} & V^{\times n} \\ {\scriptstyle\wedge}\downarrow & & \downarrow{\scriptstyle\wedge} \\ \wedge^n V & \xrightarrow[\det T]{} & \wedge^n V \end{array}$$

Diagram explanation. Objects: The top row nodes are $V^{\times n}$, the n-fold Cartesian product of the F-vector space V; these are vector spaces (products of copies of V), but the vertical wedge maps are only n-linear, not linear, so the square is a diagram of maps of sets. The bottom row nodes are $\wedge^n V$, the nth exterior power of V, which is a 1-dimensional F-vector space (since $\dim V = n$); its sole basis element is $e_1 \wedge \cdots \wedge e_n$.

Arrows: The top horizontal arrow $T^{\times n}$ applies T to each component: $(v_1, \ldots, v_n) \mapsto (Tv_1, \ldots, Tv_n)$. The two vertical arrows labelled $\wedge$ are the alternating n-linear wedge map $(v_1, \ldots, v_n) \mapsto v_1 \wedge \cdots \wedge v_n$, sending an n-tuple to its wedge product in $\wedge^n V$. The bottom arrow $\det T$ is multiplication by the scalar $\det T \in F$, the induced endomorphism $\wedge^n T$ on the 1-dimensional space $\wedge^n V$.

What commutes: Top-then-down equals down-then-right: $\wedge(T^{\times n}(v_1, \ldots, v_n)) = (\det T)(v_1 \wedge \cdots \wedge v_n)$. Concretely: $Tv_1 \wedge \cdots \wedge Tv_n = (\det T)\, v_1 \wedge \cdots \wedge v_n$.

Why it commutes: The map $(v_1, \ldots, v_n) \mapsto Tv_1 \wedge \cdots \wedge Tv_n$ is alternating n-linear in $(v_1, \ldots, v_n)$ (since T is linear and wedge is alternating multilinear). By uniqueness in the determinant theorem, every such function is a scalar multiple of the standard alternating n-linear function sending $(v_1, \ldots, v_n)$ to $v_1 \wedge \cdots \wedge v_n$, and evaluating at a basis shows that for this function the scalar is $\det T$. No element-chase is needed: it follows directly from the universal property of exterior powers.

Why this matters here: This square is the conceptual definition of $\det T$: instead of a formula, $\det T$ is the unique scalar by which T stretches the top exterior power. It replaces the Leibniz sum with an intrinsic geometric statement and makes the properties of det (multilinearity, alternating, multiplicativity) tautological consequences of how exterior powers behave.

Concrete example: Take $T = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$ on $V = \mathbb{Q}^2$. Then $Te_1 \wedge Te_2 = (e_1 + 3e_2) \wedge (2e_1 + 4e_2) = -2\, e_1 \wedge e_2$, confirming $\det T = -2$.

Common pitfall: The bottom arrow is NOT a new map – it is scalar multiplication by $\det T$ on the 1-dimensional space $\wedge^n V$. Students sometimes read it as a linear map between different spaces; it is simply the action of $\wedge^n T$ restricted to the line $\wedge^n V$, which a 1-dimensional space forces to be a scalar.

Takeaway: The point of this diagram is that T acting on V induces a scalar action $\det T$ on the one-dimensional top exterior power $\wedge^n V$, and commutativity of the square is exactly the statement that wedging before or after applying T differs only by that scalar.

The universal property of the top exterior power – factoring any alternating n-linear map through $\wedge^n V$ – is the diagram below; the determinant is the unique induced map $\widetilde{D}$ when the target is F and D is the determinant functional on columns.

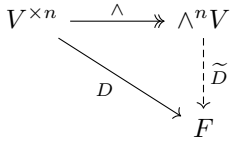

Diagram explanation. Objects: $V^{\times n}$ is the n-fold Cartesian product of the F-vector space V, the domain of all n-linear maps on V. $\wedge^n V$ is the top exterior power, a 1-dimensional F-vector space. F is the ground field, the codomain of the determinant-type functional D.

Arrows: The horizontal arrow $\wedge$ is the canonical alternating n-linear wedge map $(v_1, \ldots, v_n) \mapsto v_1 \wedge \cdots \wedge v_n$; it is the universal alternating n-linear map out of $V^{\times n}$. The diagonal arrow D is any alternating n-linear map $V^{\times n} \to F$ (in the main application, D is the determinant functional on columns). The vertical arrow $\widetilde{D}$ is the unique F-linear map $\wedge^n V \to F$ induced by the universal property; since $\wedge^n V$ is 1-dimensional, $\widetilde{D}$ is multiplication by the scalar $D(e_1, \ldots, e_n)$.

What commutes: The triangle commutes: $\widetilde{D} \circ \wedge = D$, meaning $\widetilde{D}(v_1 \wedge \cdots \wedge v_n) = D(v_1, \ldots, v_n)$ for all $(v_1, \ldots, v_n) \in V^{\times n}$.

Why it commutes: The universal property of $\wedge^n V$ says: any alternating n-linear map $D : V^{\times n} \to F$ factors uniquely through the wedge map via a linear map $\widetilde{D}$. Well-definedness of $\widetilde{D}$ holds because all alternating multilinear relations (vanishing on repeats, sign-flip on swaps) that D satisfies are exactly the defining relations of $\wedge^n V$, so $\widetilde{D}$ is consistent on equivalence classes.

Why this matters here: This triangle pins down the determinant uniquely. It says that every alternating n-linear functional D on columns is determined by its value on $e_1 \wedge \cdots \wedge e_n \in \wedge^n V$, which is a single scalar

$D(I)$. In particular, the determinant det is the unique such $\widetilde{D}$ satisfying $\widetilde{D}(e_1 \wedge \cdots \wedge e_n) = 1$, recovering the uniqueness clause of the existence-uniqueness theorem.

Concrete example: In $V = \mathbb{Q}^2$, let $D(A_1, A_2) = a_{11}a_{22} - a_{12}a_{21}$. The wedge $e_1 \wedge e_2$ is the basis of $\wedge^2\mathbb{Q}^2$, and $\widetilde{D}(e_1 \wedge e_2) = D(e_1, e_2) = 1$. Then $\widetilde{D}(v_1 \wedge v_2) = D(v_1, v_2) = \det[v_1\, v_2]$ for all v_1, v_2.

Common pitfall: The diagonal arrow D is not a matrix; it is an alternating n-linear function on n-tuples of vectors. Students sometimes confuse the universal property diagram with the earlier change-of-basis square; here there is NO second copy of $V^{\times n}$, and the diagram is about factoring D through $\wedge^n V$, not about conjugation.

Takeaway: The point of this diagram is that the top exterior power $\wedge^n V$ is the universal recipient of alternating n-linear maps, so every determinant-like function factors uniquely through $\widetilde{D}$, and the actual determinant is the unique such factorization normalized to send $e_1 \wedge \cdots \wedge e_n$ to 1.

Functoriality in the operator – $\wedge^n(ST) = \wedge^n(S) \circ \wedge^n(T)$ on the line $\wedge^n V$ – is precisely multiplicativity $\det(ST) = \det(S)\det(T)$, shown by the commuting triangle of scalars acting on $\wedge^n V$.

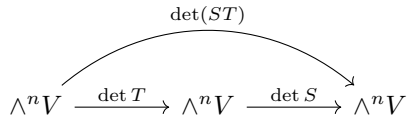

Diagram explanation. Objects: All three nodes are the same object: $\wedge^n V$, the top exterior power of V, which is a 1-dimensional F-vector space. The diagram uses three copies of it to track the sequential action of the operators T and S.

Arrows: The left horizontal arrow, labelled $\det T$, is the endomorphism $\wedge^n T$ of $\wedge^n V$, which is scalar multiplication by $\det T$. The right horizontal arrow, labelled $\det S$, is $\wedge^n S$, scalar multiplication by $\det S$. The bent arrow from the first node to the third, labelled $\det(ST)$, is $\wedge^n(ST)$, scalar multiplication by $\det(ST)$.

What commutes: The bent arrow equals the composition of the two straight arrows: $(\det S) \circ (\det T) = \det(ST)$ as endomorphisms of $\wedge^n V$. As scalars, this reads $\det(S) \cdot \det(T) = \det(ST)$.

Why it commutes: On the 1-dimensional space $\wedge^n V$, every endomorphism is a scalar. The functor $\wedge^n$ sends T to the scalar $\det T$ and sends ST to $\wedge^n(ST) = \wedge^n(S) \circ \wedge^n(T)$ (because $\wedge^n$ is a functor: it respects composition). Composing two scalars on a 1-dimensional space is just multiplying them, so $\det(ST) = \det(S) \cdot \det(T)$.

Why this matters here: This triangle is the exterior-power proof of multiplicativity $\det(ST) = \det(S)\det(T)$ for operators, reducing it to functoriality of $\wedge^n$ (a tautology once you know $\wedge^n$ is a functor). It also encodes $\det(T^k) = (\det T)^k$ and $\det(T^{-1}) = (\det T)^{-1}$ by iterating and inverting.

Concrete example: On $\mathbb{Q}^2$, $T = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$ $(\det T = -2)$, $S = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ $(\det S = -1)$. The bent arrow predicts $\det(ST) = (-1)(-2) = 2$, confirmed by $ST = \left(\begin{smallmatrix} 3 & 4 \\ 1 & 2 \end{smallmatrix}\right)$ with $\det = 6 - 4 = 2$.

Common pitfall: This is NOT the same as the earlier change-of-basis square; here all three nodes are $\wedge^n V$, not two bases of V. The roles of S and T matter: $\det(ST)$ corresponds to applying T first then S, so the left arrow is $\det T$ and the right is $\det S$ (matching operator-composition order).

Takeaway: The point of this diagram is that the exterior-power functor $\wedge^n$ converts composition of operators on V into multiplication of scalars on $\wedge^n V$, and this is exactly multiplicativity of the determinant.

Worked Example 11.4.29 (Determinant as a wedge ratio over $\mathbb{Q}$)**.** With $V = \mathbb{Q}^2$, e_1, e_2 standard, let $v_1 = 2e_1 + e_2$, $v_2 = e_1 + 3e_2$. Compute $v_1 \wedge v_2$ and read off the determinant.

Recognition. Theorem 11.4.28: $v_1 \wedge v_2 = (\det[v_1\, v_2])\, e_1 \wedge e_2$.

Solution. Expand by bilinearity and $e_i \wedge e_i = 0$, $e_2 \wedge e_1 = -e_1 \wedge e_2$:

$$v_1 \wedge v_2 = (2e_1 + e_2) \wedge (e_1 + 3e_2) = 6\, e_1 \wedge e_2 + 1\, e_2 \wedge e_1 = (6 - 1)\, e_1 \wedge e_2 = 5\, e_1 \wedge e_2.$$

So $\det\left(\begin{smallmatrix} 2 & 1 \\ 1 & 3 \end{smallmatrix}\right) = 5$. *Sanity check.* Directly $2 \cdot 3 - 1 \cdot 1 = 5$. ■

Worked Example 11.4.30 (3×3 wedge over $\mathbb{Q}$)**.** In $V = \mathbb{Q}^3$ compute $v_1 \wedge v_2 \wedge v_3$ for $v_1 = e_1 + e_2$, $v_2 = e_2 + e_3$, $v_3 = e_1 + e_3$, and identify $\det[v_1\, v_2\, v_3]$.

Recognition. Theorem 11.4.28.

Solution. Expand, dropping any term with a repeated e_i. The surviving terms are permutations of $e_1 \wedge e_2 \wedge e_3$:

$$(e_1 + e_2) \wedge (e_2 + e_3) \wedge (e_1 + e_3).$$

The nonzero products of one summand from each factor that use all three indices are: $e_1 \wedge e_2 \wedge e_3$ (coeff $+1$) and $e_2 \wedge e_3 \wedge e_1$ (coeff $+1$). Now $e_2 \wedge e_3 \wedge e_1 = e_1 \wedge e_2 \wedge e_3$ (cyclic shift, even permutation). Total: $2\, e_1 \wedge e_2 \wedge e_3$. Hence $\det[v_1\, v_2\, v_3] = 2$. *Sanity check.* $\det\left(\begin{smallmatrix} 1 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{smallmatrix}\right) = 1(1-0) - 0 + 1(1-0) = 2$. ■

Worked Example 11.4.31 (Dependent vectors wedge to zero, over $\mathbb{R}$)**.** In $\mathbb{R}^3$, $v_1 = (1, 2, 3)$, $v_2 = (2, 4, 6)$, $v_3 = (0, 1, 1)$. Compute $v_1 \wedge v_2 \wedge v_3$.

Recognition. Theorem 11.4.28: the wedge equals $(\det)\, e_1 \wedge e_2 \wedge e_3$, and a dependency forces 0.

Solution. $v_2 = 2v_1$, so $v_1 \wedge v_2 = v_1 \wedge (2v_1) = 2(v_1 \wedge v_1) = 0$, hence $v_1 \wedge v_2 \wedge v_3 = 0$. Thus $\det = 0$. *Sanity check.* The matrix with these columns has its second column twice the first, so $\det = 0$ by the alternating property. ■

Worked Example 11.4.32 (Wedge over $\mathbb{F}_2$ detecting singularity)**.** In $V = \mathbb{F}_2^2$, $v_1 = e_1 + e_2$, $v_2 = e_1 + e_2$. Compute $v_1 \wedge v_2$, and also for $v_2' = e_1$.

Recognition. Theorem 11.4.28.

Solution. $v_1 \wedge v_2 = (e_1 + e_2) \wedge (e_1 + e_2) = 0$ (a vector wedged with itself). So $\det[v_1\, v_2] = 0$ – singular. With $v_2' = e_1$: $v_1 \wedge v_2' = (e_1 + e_2) \wedge e_1 = e_2 \wedge e_1 = -e_1 \wedge e_2 = e_1 \wedge e_2$ (since $-1 = 1$ in $\mathbb{F}_2$), giving $\det = 1$ – invertible. *Sanity check.* $[v_1\, v_2'] = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has $\det = -1 = 1$ over $\mathbb{F}_2$. ■

Worked Example 11.4.33 (Action of an operator on the top wedge over $\mathbb{Q}$)**.** Let $T = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$ on $\mathbb{Q}^2$. Verify $Te_1 \wedge Te_2 = (\det T)\, e_1 \wedge e_2$.

Recognition. Theorem 11.4.28: $\wedge^2 T$ is multiplication by $\det T$.

Solution. $Te_1 = e_1 + 3e_2$, $Te_2 = 2e_1 + 4e_2$. Then

$$Te_1 \wedge Te_2 = (e_1 + 3e_2) \wedge (2e_1 + 4e_2) = 4\, e_1 \wedge e_2 + 6\, e_2 \wedge e_1 = (4 - 6)\, e_1 \wedge e_2 = -2\, e_1 \wedge e_2.$$

So the scalar is $-2 = \det T$. *Sanity check.* $\det T = 1 \cdot 4 - 2 \cdot 3 = -2$. ■

Remark 11.4.2. The exterior-power viewpoint makes the three pillars transparent at once: det is *alternating n-linear* because $\wedge^n$ is built from the alternating n-linear wedge; $\det(ST) = \det S \det T$ because $\wedge^n$ is a functor; and T is invertible iff $\det T \neq 0$ because a nonzero scalar on the line $\wedge^n V$ is invertible. The matrix formula and Laplace expansion are then just coordinate computations of this single intrinsic scalar.

Exercises (from the text).

1. Formulate and prove the cofactor expansion formula along the jth column of a square matrix A.
2. Let F be a field and let $A_1, A_2, \ldots, A_n$ be (column) vectors in F^n. Form the matrix A whose i^{th} column is A_i. Prove that these vectors form a basis of F^n if and only if $\det A \neq 0$.
3. Let R be any commutative ring with 1, let V be an R-module and let $x_1, x_2, \ldots, x_n \in V$. Assume that for some $A \in M_{n\times n}(R)$,
$$A \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = 0.$$
Prove that $(\det A)x_i = 0$ for all $i \in \{1, 2, \ldots, n\}$.
4. (*Computing Determinants of Matrices*) This exercise outlines the use of Gauss-Jordan elimination (cf. the exercises in Section 2) to compute determinants. This is the most efficient general procedure for computing large determinants. Let A be an $n \times n$ matrix.

(a) Prove that the elementary row operations have the following effect on determinants:

(i) interchanging two rows changes the sign of the determinant

(ii) adding a multiple of one row to another does not alter the determinant

(iii) multiplying any row by a nonzero element u multiplies the determinant by u.

(b) Prove that $\det A$ is nonzero if and only if A is row equivalent to an $n \times n$ identity matrix. Suppose A can be row reduced to the identity matrix using a total of s row interchanges as in (i) and by multiplying rows by the elements $u_1, u_2, \ldots, u_t$ as in (iii). Prove that $\det A = (-1)^s (u_1 u_2 \cdots u_t)^{-1}$.

5. Compute the determinants of the following matrices using row reduction:

$$A = \begin{pmatrix} 5 & 4 & 4 \\ -2 & 0 & 2 \\ 3 & 4 & -2 \end{pmatrix} \qquad B = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 4 & 8 \\ 1 & 3 & 9 & 27 \\ 1 & 4 & 16 & 64 \end{pmatrix}.$$

6. (*Minkowski's Criterion*) Suppose A is an $n \times n$ matrix with real entries such that the diagonal elements are all positive, the off-diagonal elements are all negative and the row sums are all positive. Prove that $\det A \neq 0$. [Consider the corresponding equations $Ax = 0$ and suppose there is a nontrivial solution $(x_1, \ldots, x_n)$. Let x_k have the largest absolute value among the x_i and consider the kth equation.]

Practice problems.

1. Let $A = \begin{pmatrix} 2 & 1 & 0 \\ 1 & 3 & 1 \\ 0 & 1 & 2 \end{pmatrix} \in \mathrm{M}_3(\mathbb{Q})$. Compute $\det A$ by Laplace (cofactor) expansion along the first column, and then again along the second row, and verify the two answers agree.

2. Using only the defining properties that det is alternating and n-linear in the columns with $\det(I) = 1$, prove that if two columns of $A \in \mathrm{M}_n(\mathbb{F})$ are equal then $\det A = 0$. Then deduce that adding a scalar multiple of one column to another column leaves $\det A$ unchanged.

3. Let $D\colon \mathrm{M}_2(\mathbb{F}) \to \mathbb{F}$ be the unique alternating 2-linear function of the columns with $D(I) = 1$. Write $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ as $A = (v_1 \mid v_2)$ with $v_1 = ae_1 + ce_2$, $v_2 = be_1 + de_2$, and expand $D(v_1, v_2)$ using bilinearity and the alternating property to recover the formula $D(A) = ad - bc$ directly from the axioms.

4. Let $A \in \mathrm{M}_n(\mathbb{F})$ be upper triangular with diagonal entries $a_{11}, \ldots, a_{nn}$. Prove $\det A = \prod_{i=1}^{n} a_{ii}$ using cofactor expansion (induct on n, expanding along the first column).

5. Let $\mathbb{F}$ be a field and $A, B \in \mathrm{M}_n(\mathbb{F})$. Using $\det(AB) = \det(A)\det(B)$ and $\det(I) = 1$, prove that A is invertible if and only if $\det A \neq 0$, and that in that case $\det(A^{-1}) = (\det A)^{-1}$.

6. Fix $B \in \mathrm{M}_n(\mathbb{F})$ with $\det B \neq 0$ and define $\varphi\colon \mathrm{M}_n(\mathbb{F}) \to \mathbb{F}$ by $\varphi(A) = \det(BA)$. Show that, viewed as a function of the columns of A, φ is alternating and n-linear, and that $\varphi(I) = \det B$. Conclude $\varphi(A) = \det(B)\det(A)$ by uniqueness, thereby reproving multiplicativity from the universal characterization.

7. Let $T\colon \mathbb{R}^3 \to \mathbb{R}^3$ be the linear operator sending $e_1 \mapsto e_2$, $e_2 \mapsto e_3$, $e_3 \mapsto e_1$. Compute $\det T$ in the standard basis, then recompute $[T]$ in the basis $\{\, e_1 + e_2 + e_3,\ e_1 - e_2,\ e_2 - e_3 \,\}$ and verify the determinant is unchanged, illustrating basis-independence.

8. Let $\mathbb{F} = \mathbb{Z}/2\mathbb{Z}$ and let $A = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{pmatrix} \in \mathrm{M}_3(\mathbb{F})$. Compute $\det A$ in $\mathbb{F}$ and decide whether A is invertible over $\mathbb{F}$.

9. For $A \in \mathrm{M}_n(\mathbb{F})$ let $\operatorname{adj}(A)$ denote the adjugate (transpose of the cofactor matrix). Prove $A \operatorname{adj}(A) = (\det A)\, I$ by relating the off-diagonal entries to cofactor expansions of a matrix with a repeated column. Use this to write A^{-1} explicitly when $\det A \neq 0$.

Additional exercises.

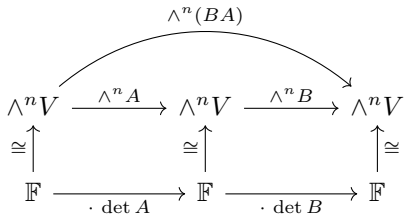
1. Let V be an n-dimensional vector space over $\mathbb{F}$ and $T \in \mathrm{End}(V)$. Using the natural identification of $\wedge^n V$ with a 1-dimensional space and the induced map $\wedge^n T\colon \wedge^n V \to \wedge^n V$, prove that $\wedge^n T$ is multiplication by a scalar, that this scalar equals $\det T$ for any basis representation, and hence that $\det T$ is independent of the chosen basis.

2. Let $A \in \mathrm{M}_n(\mathbb{Z})$. Prove that A is invertible over $\mathbb{Z}$ (i.e. $A^{-1} \in \mathrm{M}_n(\mathbb{Z})$) if and only if $\det A \in \{1, -1\}$. (Use multiplicativity and the adjugate formula.)

3. Let $A \in \mathrm{M}_n(\mathbb{F})$ and let $\lambda \in \mathbb{F}$. Show $\det(\lambda A) = \lambda^n \det A$ directly from n-linearity in the columns. Then show that the function $A \mapsto \det(A^{\mathsf{T}})$ is alternating and n-linear in the columns of A with value 1 at I, and conclude $\det(A^{\mathsf{T}}) = \det A$.

4. Let $A = (a_{ij}) \in \mathrm{M}_n(\mathbb{F})$ have a block-triangular form $A = \begin{pmatrix} P & Q \\ 0 & R \end{pmatrix}$ with $P \in \mathrm{M}_k(\mathbb{F})$, $R \in \mathrm{M}_{n-k}(\mathbb{F})$. Prove $\det A = \det(P)\det(R)$ using repeated cofactor expansion along the first k columns.

5. Let $T \in \mathrm{End}(V)$ with $\dim V = n$, and suppose $W \subseteq V$ is a T-invariant subspace. Let $\bar{T} \in \mathrm{End}(V/W)$ be the induced operator and $T|_W \in \mathrm{End}(W)$ the restriction. Using a basis of V extending one of W, prove $\det T = \det(T|_W) \cdot \det(\bar{T})$.



Commutative-diagram exercises.

1. The top exterior power has a universal property: for an n-dimensional space V over $\mathbb{F}$, the map $\omega\colon V^{\times n} \to \wedge^n V$, $(v_1, \dots, v_n) \mapsto v_1 \wedge \cdots \wedge v_n$, is alternating n-linear and is universal among such maps into $\mathbb{F}$. Given $T \in \mathrm{End}(V)$, fix an isomorphism $\wedge^n V \cong \mathbb{F}$ and show that the scalar $\det T$ is exactly the unique map making

$$\begin{array}{ccccc} V^{\times n} & \xrightarrow{\omega} & \wedge^n V & \xrightarrow{\cong} & \mathbb{F} \\ {\scriptstyle T^{\times n}}\downarrow & & \downarrow{\scriptstyle \wedge^n T} & & \downarrow{\scriptstyle \cdot \det T} \\ V^{\times n} & \xrightarrow[\omega]{} & \wedge^n V & \xrightarrow[\cong]{} & \mathbb{F} \end{array}$$

   commute. Explain precisely which property of ω forces $\wedge^n T$ to be a scalar.

2. Functoriality of $\wedge^n$ on the top power gives the diagram below for $A, B \in \mathrm{End}(V)$. Using $\wedge^n(BA) = (\wedge^n B) \circ (\wedge^n A)$ and that each $\wedge^n(\cdot)$ acts as a scalar on the 1-dimensional space $\wedge^n V$, prove $\det(BA) = \det(B)\det(A)$ by filling in and justifying the right-hand square:

3. Let $0 \to W \xrightarrow{i} V \xrightarrow{p} V/W \to 0$ be a short exact sequence of finite-dimensional $\mathbb{F}$-spaces with a $T \in \mathrm{End}(V)$ preserving W, inducing $T|_W$ and $\bar{T}$ so that the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & W & \xhookrightarrow{i} & V & \xrightarrow{p} & V/W & \longrightarrow & 0 \\ & & {\scriptstyle T|_W}\downarrow & & \downarrow{\scriptstyle T} & & \downarrow{\scriptstyle \bar{T}} & & \\ 0 & \longrightarrow & W & \xhookrightarrow[i]{} & V & \xrightarrow[p]{} & V/W & \longrightarrow & 0 \end{array}$$

   commutes with exact rows. Using the natural isomorphism $\wedge^{\dim V} V \cong \wedge^{\dim W} W \otimes \wedge^{\dim(V/W)}(V/W)$, prove $\det T = \det(T|_W)\det(\bar{T})$.

4. Let V, W be $\mathbb{F}$-spaces with $\dim V = m$, $\dim W = n$, and let $S \in \mathrm{End}(V)$, $T \in \mathrm{End}(W)$. Consider $S \oplus T \in \mathrm{End}(V \oplus W)$. Using the canonical isomorphism $\wedge^{m+n}(V \oplus W) \cong \wedge^m V \otimes \wedge^n W$ and naturality, draw and justify the square

$$\begin{array}{ccc} \wedge^{m+n}(V \oplus W) & \xrightarrow{\wedge^{m+n}(S \oplus T)} & \wedge^{m+n}(V \oplus W) \\ \cong\downarrow & & \downarrow\cong \\ \wedge^m V \otimes \wedge^n W & \xrightarrow[(\wedge^m S)\otimes(\wedge^n T)]{} & \wedge^m V \otimes \wedge^n W \end{array}$$

and conclude $\det(S \oplus T) = \det(S)\det(T)$.

5. Let $f\colon \mathrm{M}_n(\mathbb{F}) \to \mathbb{F}$ be any function that is alternating and n-linear in the columns. Show that f factors uniquely through the determinant: there is a unique $c \in \mathbb{F}$ with $f = c \cdot \det$. State this as the commuting triangle

$$\begin{array}{ccc} \mathrm{M}_n(\mathbb{F}) & \xrightarrow{\det} & \mathbb{F} \\ & \searrow^{f} & \downarrow{\scriptstyle \cdot c} \\ & & \mathbb{F} \end{array}$$

and identify c in terms of f, thereby expressing the uniqueness clause of the universal characterization of det as a universal-property statement.

11.5 Tensor Algebras, Symmetric and Exterior Algebras

Throughout, R is a commutative ring with 1 and M is an R-module; the running special case is $R = \mathbb{F}$ a field and $M = V$ a finite-dimensional vector space with basis $e_1, \dots, e_n$. We write $M^{\otimes k} = M \otimes_R \cdots \otimes_R M$ (k factors), the k-fold tensor power, with the conventions $M^{\otimes 0} = R$ and $M^{\otimes 1} = M$. The three algebras built in this section — the tensor algebra $T(M)$, the symmetric algebra $S(M)$, and the exterior algebra $\wedge(M)$ — are all *graded* and are each characterized by a universal mapping property: each is the universal target for a certain kind of map out of M. In categorical language T, S, $\wedge$ are left adjoints to forgetful functors; concretely each one "solves a mapping problem."

Graded algebras

Definition 11.5.1. A ring A (or R-algebra) is *graded* (more precisely $\mathbb{Z}^{\geq 0}$-graded) if $A = \bigoplus_{k \geq 0} A_k$ as R-modules and the multiplication satisfies $A_i\, A_j \subseteq A_{i+j}$ for all $i, j \geq 0$. The elements of A_k are the *homogeneous elements of degree k*. An ideal I is a *graded* (or *homogeneous*) ideal if $I = \bigoplus_k (I \cap A_k)$, equivalently I is generated by homogeneous elements; in that case A/I inherits a grading $A/I = \bigoplus_k A_k/(I \cap A_k)$.

The tensor algebra $T(M)$

Definition 11.5.2. The *tensor algebra* of M over R is the graded R-module

$$T(M) \;=\; \bigoplus_{k \geq 0} T^k(M), \qquad T^k(M) = M^{\otimes k},$$

with $T^0(M) = R$ and $T^1(M) = M$, made into an R-algebra by the multiplication that on homogeneous generators is concatenation of tensors:

$$(m_1 \otimes \cdots \otimes m_i) \cdot (m'_1 \otimes \cdots \otimes m'_j) \;=\; m_1 \otimes \cdots \otimes m_i \otimes m'_1 \otimes \cdots \otimes m'_j \;\in\; T^{i+j}(M),$$

extended R-bilinearly. The identity is $1 \in R = T^0(M)$. This product is associative but in general *not* commutative.

Remark 11.5.1. If V has basis $e_1, \dots, e_n$, then $T^k(V)$ has the n^k-element basis $\{\, e_{i_1} \otimes \cdots \otimes e_{i_k} \;:\; 1 \leq i_j \leq n \,\}$, so $\dim_{\mathbb{F}} T^k(V) = n^k$ and $T(V)$ is the free associative (noncommutative) $\mathbb{F}$-algebra on $e_1, \dots, e_n$ — the algebra of noncommutative polynomials in n variables. In particular $\dim T(V) = \infty$ whenever $n \geq 1$.

Theorem 11.5.3 (Universal property of $T(M)$)**.** *Let $\iota\colon M \to T(M)$ be the inclusion $M = T^1(M) \hookrightarrow T(M)$. Then for every R-algebra A and every R-module homomorphism $\varphi\colon M \to A$ there is a unique R-algebra homomorphism $\Phi\colon T(M) \to A$ with $\Phi \circ \iota = \varphi$, namely*

$$\Phi(m_1 \otimes \cdots \otimes m_k) = \varphi(m_1) \cdots \varphi(m_k), \qquad \Phi(r) = r \cdot 1_A \quad (r \in R = T^0(M)).$$

Thus $T(M)$ is the universal R-algebra containing the image of M: every R-module map out of M into an algebra extends uniquely to a multiplicative map out of $T(M)$.

The universal property is the commutative triangle:

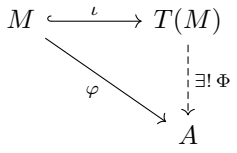


Diagram explanation. Objects: Three objects: M (an R-module), $T(M)$ (the tensor algebra, an R-algebra), and A (any R-algebra receiving the map).

Arrows: $\iota\colon M \to T(M)$ is the canonical inclusion $M = T^1(M) \hookrightarrow T(M)$, embedding M as the degree-1 piece. $\varphi\colon M \to A$ is any R-module homomorphism (not required to be multiplicative). $\Phi\colon T(M) \to A$ is the unique R-algebra homomorphism declared to exist by the universal property; the dashed arrow and the label $\exists!$ signal both existence and uniqueness.

What commutes: The triangle commutes: $\Phi \circ \iota = \varphi$. That is, the top path ($M \xrightarrow{\iota} T(M) \xrightarrow{\Phi} A$) equals the diagonal ($M \xrightarrow{\varphi} A$).

Why it commutes: Φ is defined on pure tensors by $\Phi(m_1 \otimes \cdots \otimes m_k) = \varphi(m_1) \cdots \varphi(m_k)$. For an element $m \in M = T^1(M)$, this gives $\Phi(\iota(m)) = \varphi(m)$. Well-definedness: the map $(m_1, \ldots, m_k) \mapsto \varphi(m_1) \cdots \varphi(m_k)$ is R-multilinear, so by the universal property of the tensor product it induces an R-linear map on each $T^k(M)$ (no freeness is needed, and $T^k(M)$ need not be free: $T^2(\mathbb{Z}/n\mathbb{Z}) \cong \mathbb{Z}/n\mathbb{Z}$ over $\mathbb{Z}$); these assemble to an R-linear Φ on the direct sum $T(M)$, which is multiplicative because it is so on pure tensors (concatenation goes to the product in A) and both sides of $\Phi(xy) = \Phi(x)\Phi(y)$ are bilinear in (x, y).

Why this matters here: This is the central organizing fact of the subsection: $T(M)$ is the *free R-algebra on M*. The diagram says that to give an algebra map out of $T(M)$, one need only specify a module map out of M; the algebra structure comes for free. The uniqueness clause is what makes $T(M)$ the *universal* solution rather than just a solution.

Concrete example: Take $R = \mathbb{F}$, $M = \mathbb{F}^2$, $A = \mathrm{M}_2(\mathbb{F})$, and $\varphi(e_1) = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $\varphi(e_2) = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$. Then $\Phi(e_1 \otimes e_2) = \varphi(e_1)\varphi(e_2) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$, and the triangle forces $\Phi(e_i) = \varphi(e_i)$ on the degree-1 part.

Common pitfall: Students often read Φ as extending φ by being "linear" in the algebra sense, and forget that Φ must also be multiplicative ($\Phi(xy) = \Phi(x)\Phi(y)$). The point of the universal property is precisely that the concatenation formula *makes* Φ multiplicative automatically; you do not check it separately.

Takeaway: The point of this diagram is that a module map $M \to A$ is exactly the same data as an algebra map $T(M) \to A$, making $T(M)$ the algebra that imposes no relations on M.

Proposition 11.5.4 (Functoriality)**.** *A module homomorphism $\psi\colon M \to N$ induces a unique graded R-algebra homomorphism $T(\psi)\colon T(M) \to T(N)$ with $T(\psi)(m_1 \otimes \cdots \otimes m_k) = \psi(m_1) \otimes \cdots \otimes \psi(m_k)$; moreover $T(\mathrm{id}_M) = \mathrm{id}_{T(M)}$ and $T(\psi' \circ \psi) = T(\psi') \circ T(\psi)$.*

The induced map is the unique fill-in making the square commute (apply the universal property to $\iota_N \circ \psi\colon M \to T(N)$):

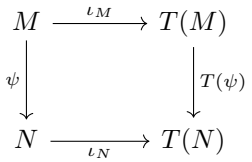

Diagram explanation. Objects: Four objects forming a square: M and N (two R-modules connected by ψ), $T(M)$ and $T(N)$ (their tensor algebras).

Arrows: $\psi\colon M \to N$ is any R-module homomorphism (the data input). $\iota_M\colon M \hookrightarrow T(M)$ and $\iota_N\colon N \hookrightarrow T(N)$ are the canonical degree-1 inclusions. $T(\psi)\colon T(M) \to T(N)$ is the induced graded R-algebra homomorphism, defined on decomposable tensors by $T(\psi)(m_1 \otimes \cdots \otimes m_k) = \psi(m_1) \otimes \cdots \otimes \psi(m_k)$.

What commutes: The square commutes: $T(\psi) \circ \iota_M = \iota_N \circ \psi$. That is, going right-then-down ($M \to T(M) \to T(N)$) equals going down-then-right ($M \to N \to T(N)$).

Why it commutes: On an element $m \in M$: the right-then-down path gives $T(\psi)(\iota_M(m)) = T(\psi)(m) = \psi(m) \in T^1(N) = \iota_N(N)$; the down-then-right path gives $\iota_N(\psi(m)) = \psi(m)$. These agree. The induced map $T(\psi)$ exists uniquely by the universal property applied to the composite $\iota_N \circ \psi\colon M \to T(N)$; well-definedness follows from that same universal property since $T(N)$ is an R-algebra and $\iota_N \circ \psi$ is a module map.

Why this matters here: This square encodes that T is a *functor* from R-modules to R-algebras: it acts on morphisms (not just objects) and preserves composition and identities. The proposition that follows from the diagram ($T(\mathrm{id}) = \mathrm{id}$, $T(\psi' \circ \psi) = T(\psi') \circ T(\psi)$) is the categorical content, and the square is the naturality condition for the inclusion ι.

Concrete example: Take $\psi\colon \mathbb{F}^1 \to \mathbb{F}^2$ sending $e \mapsto e_1$. Then $T(\psi)(e \otimes e) = e_1 \otimes e_1$, embedding the 1-dimensional $T^2(\mathbb{F}^1)$ into the 4-dimensional $T^2(\mathbb{F}^2)$ as the line $\mathbb{F}(e_1 \otimes e_1)$. The square checks out: $\iota_{\mathbb{F}^2}(\psi(e)) = \iota_{\mathbb{F}^2}(e_1) = e_1 = T(\psi)(e)$.

Common pitfall: Students sometimes think $T(\psi)$ is injective whenever ψ is. Surjectivity is preserved ($T^k(N)$ is spanned by the pure tensors $\psi(m_1) \otimes \cdots \otimes \psi(m_k)$ when ψ is onto), and so is bijectivity (by functoriality), but over a general ring injectivity is not: for $\psi\colon \mathbb{Z}/2\mathbb{Z} \to \mathbb{Z}/4\mathbb{Z}$, $1 \mapsto 2$, the map $T^2(\psi)$ sends the generator $1 \otimes 1$ of $\mathbb{Z}/2\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/2\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z}$ to $2 \otimes 2 = 4(1 \otimes 1) = 0$ in $\mathbb{Z}/4\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}/4\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z}$. Over a field, $T(\psi)$ is injective whenever ψ is.

Takeaway: The point of this diagram is that the tensor algebra construction is functorial, so every module map ψ lifts uniquely to an algebra map $T(\psi)$ that is compatible with the inclusions into the tensor algebras.

Worked Example 11.5.5 (Multiplication and noncommutativity in $T(V)$, $V = \mathbb{F}^2$)**.** Let $V = \mathbb{F}^2$ with basis e_1, e_2. Compute $(e_1 + e_2) \cdot e_1$ in $T(V)$ and compare $e_1 \otimes e_2$ with $e_2 \otimes e_1$.

Recognition. Use the definition of the product on $T(M)$ as concatenation of tensors, extended bilinearly; degrees add, and there is no relation forcing factors to commute.

Solution. Distribute over the sum in degree 1:

$$(e_1 + e_2) \cdot e_1 = e_1 \otimes e_1 + e_2 \otimes e_1 \in T^2(V).$$

The four monomials $e_1 \otimes e_1,\ e_1 \otimes e_2,\ e_2 \otimes e_1,\ e_2 \otimes e_2$ are a basis of the 4-dimensional space $T^2(V)$, so $e_1 \otimes e_2$ and $e_2 \otimes e_1$ are distinct basis vectors and hence unequal: $T(V)$ is noncommutative. *Sanity check.* $\dim T^2(V) = n^k = 2^2 = 4$, matching the four monomials listed.

Worked Example 11.5.6 (Extending a linear map to an algebra map)**.** Let $V = \mathbb{F}^2$ with basis e_1, e_2 and let $A = \mathrm{M}_2(\mathbb{F})$. Define a linear map $\varphi\colon V \to A$ by $\varphi(e_1) = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$, $\varphi(e_2) = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$. Find $\Phi(e_1 \otimes e_2)$ and $\Phi(e_2 \otimes e_1)$ for the induced $\Phi\colon T(V) \to A$.

Recognition. This is exactly the universal property of $T(V)$: any linear $\varphi\colon V \to A$ into an algebra extends uniquely to an algebra homomorphism Φ via $\Phi(m_1 \otimes \cdots \otimes m_k) = \varphi(m_1) \cdots \varphi(m_k)$.

Solution. Multiply the images in $A = \mathrm{M}_2(\mathbb{F})$:

$$\Phi(e_1 \otimes e_2) = \varphi(e_1)\varphi(e_2) = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)\left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right), \qquad \Phi(e_2 \otimes e_1) = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 1 \end{smallmatrix}\right).$$

Sanity check. The two outputs differ, consistent with $e_1 \otimes e_2 \neq e_2 \otimes e_1$ in $T(V)$; and Φ respects degree-0 data since $\Phi(1) = I$, the identity of A.

Worked Example 11.5.7 ($T(M)$ for a rank-one free module)**.** Take R any commutative ring and $M = R$ (free of rank 1). Identify $T(R)$.

Recognition. Use $T^k(R) = R^{\otimes k} \cong R$ for every k, together with the concatenation product.

Solution. Each $R^{\otimes k} \cong R$ via $1 \otimes \cdots \otimes 1 \mapsto 1$, and the product matches multiplication of these copies, so $T(R) \cong \bigoplus_{k \geq 0} R\, x^k = R[x]$, the polynomial ring in one variable. *Sanity check.* With one generator the "noncommutative" polynomial ring is just the ordinary polynomial ring $R[x]$, and indeed $T(V)$ is commutative when $\dim V \leq 1$.

Worked Example 11.5.8 (Functoriality on a coordinate inclusion)**.** Let $\psi\colon \mathbb{F}^1 \to \mathbb{F}^2$, $\psi(e) = e_1$. Describe $T(\psi)$ on T^2.

Recognition. Apply the functoriality proposition: $T(\psi)(u \otimes v) = \psi(u) \otimes \psi(v)$.

Solution. On the basis vector $e \otimes e$ of $T^2(\mathbb{F}^1)$ we get $T(\psi)(e \otimes e) = e_1 \otimes e_1 \in T^2(\mathbb{F}^2)$. So $T(\psi)$ embeds the 1-dimensional $T^2(\mathbb{F}^1)$ as the line $\mathbb{F}(e_1 \otimes e_1)$ inside the 4-dimensional $T^2(\mathbb{F}^2)$. *Sanity check.* $\dim T^2(\mathbb{F}^1) = 1^2 = 1$ and the image is one basis vector, as required for an injective induced map.

Worked Example 11.5.9 (Why $T(M)$ cannot be replaced by a commutative target)**.** Show there is no *commutative* R-algebra A with an injection $M = V \hookrightarrow A$ that is universal for *all* linear maps into algebras when $\dim V \geq 2$.

Recognition. The universal target must receive $e_1 \otimes e_2$ and $e_2 \otimes e_1$ as distinct elements (Worked Example with $A = \mathrm{M}_2$ separates them); a commutative target would force them equal.

Solution. If A were commutative and $\Phi\colon T(V) \to A$ were the universal map, then $\Phi(e_1 \otimes e_2) = \Phi(e_1)\Phi(e_2) = \Phi(e_2)\Phi(e_1) = \Phi(e_2 \otimes e_1)$ for *every* target, contradicting the matrix example where they differ. Hence the genuinely universal object $T(V)$ is forced to be noncommutative. *Sanity check.* This is precisely why imposing commutativity yields a *different* universal object, the symmetric algebra below.

The symmetric algebra $S(M)$

Definition 11.5.10. The *symmetric algebra* of M is the quotient

$$S(M) \;=\; T(M)/C(M),$$

where $C(M)$ is the two-sided ideal generated by all elements $m \otimes m' - m' \otimes m$ with $m, m' \in M$. Since these generators are homogeneous of degree 2, $C(M)$ is a graded ideal and $S(M) = \bigoplus_{k \geq 0} S^k(M)$ is graded, with $S^k(M) = T^k(M)/(C(M) \cap T^k(M))$. The image of $m_1 \otimes \cdots \otimes m_k$ in $S^k(M)$ is written $m_1 m_2 \cdots m_k$, and $S(M)$ is a *commutative* R-algebra.

Theorem 11.5.11 (Universal property of $S(M)$)**.** *Let $\iota\colon M \to S(M)$ be $M = S^1(M) \hookrightarrow S(M)$. For every* commutative *R-algebra A and every R-module homomorphism $\varphi\colon M \to A$, there is a unique R-algebra homomorphism $\Phi\colon S(M) \to A$ with $\Phi \circ \iota = \varphi$. Equivalently, $S(M)$ is the universal commutative R-algebra generated by M.*

Corollary 11.5.12. *If V is free with basis $e_1, \ldots, e_n$, then $S(V) \cong R[x_1, \ldots, x_n]$ (polynomial ring), with $e_i \mapsto x_i$; the degree grading matches, so*

$$\dim_{\mathbb{F}} S^k(V) = \binom{n+k-1}{k}.$$

The universal property of $S(M)$, and its relation to $T(M)$, is the diagram (the left triangle is the defining property; the right triangle shows $S(M)$ factoring the tensor algebra through commutativity):

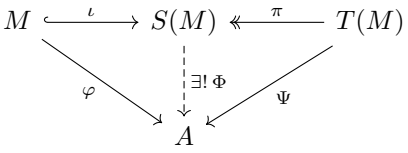

Diagram explanation. Objects: Four objects: M (the R-module), $S(M) = T(M)/C(M)$ (the symmetric algebra, a commutative R-algebra), $T(M)$ (the tensor algebra), and A (any commutative R-algebra).

Arrows: $\iota\colon M \hookrightarrow S(M)$ is the degree-1 inclusion $M = S^1(M)$. $\varphi\colon M \to A$ is any R-module map into a commutative target. $\Phi\colon S(M) \to A$ is the unique algebra map asserted by the universal property, with $\Phi \circ \iota = \varphi$ (left triangle). $\pi\colon T(M) \to S(M)$ is the canonical surjective quotient map killing the ideal $C(M)$ generated by all $m \otimes m' - m' \otimes m$. $\Psi\colon T(M) \to A$ is the algebra map into the commutative A induced by φ (universal property of $T(M)$, so $\Psi = \varphi$ on $M = T^1(M)$); it factors as $\Phi \circ \pi$ (right triangle).

What commutes: Left triangle: $\Phi \circ \iota = \varphi$. Right triangle: $\Psi = \Phi \circ \pi$. Combined: $\Phi \circ \pi \circ \iota_T = \varphi$, where $\iota_T\colon M \to T(M)$ is the degree-1 inclusion into $T(M)$ (since $\iota = \pi \circ \iota_T$).

Why it commutes: Left triangle (well-definedness): Φ is induced by φ via $\Phi(m_1 \cdots m_k) = \varphi(m_1) \cdots \varphi(m_k)$. This is well-defined on $S(M)$: a different representative of a coset in $T(M)/C(M)$ differs by an element of $C(M)$; since A is commutative, $\varphi(m)\varphi(m') = \varphi(m')\varphi(m)$, so the commutativity relations $m \otimes m' - m' \otimes m$ map to zero in A, confirming $C(M) \subseteq \ker(\text{map to } A)$. *Right triangle:* Ψ lands in a commutative A, so $\Psi(m \otimes m' - m' \otimes m) = \varphi(m)\varphi(m') - \varphi(m')\varphi(m) = 0$, i.e. $C(M) \subseteq \ker \Psi$, and the universal property of the quotient gives the factorization $\Psi = \Phi \circ \pi$.

Why this matters here: The diagram simultaneously states the universal property of $S(M)$ and clarifies the relation between $T(M)$ and $S(M)$: every map from $T(M)$ into a commutative algebra factors through $S(M)$. This is the precise sense in which $S(M)$ is the *best commutative approximation* to $T(M)$.

Concrete example: $M = \mathbb{F}^2$, $A = \mathbb{F}[t]$, $\varphi(e_1) = t$, $\varphi(e_2) = t^2$. Then $\Phi\colon S(\mathbb{F}^2) \cong \mathbb{F}[x_1, x_2] \to \mathbb{F}[t]$ sends $x_1 \mapsto t$, $x_2 \mapsto t^2$, and $\Phi(x_1x_2) = t^3 = \Phi(x_2x_1)$; commutativity in A absorbs the symmetry relation.

Common pitfall: The diagram requires A commutative: if $A = \mathrm{M}_2(\mathbb{F})$ (not commutative), there is no well-defined $\Phi\colon S(M) \to A$ induced by an arbitrary φ, because $\Phi(m_1m_2) - \Phi(m_2m_1) = \varphi(m_1)\varphi(m_2) - \varphi(m_2)\varphi(m_1)$ need not be zero.

Takeaway: The point of this diagram is that $S(M)$ is the universal commutative R-algebra on M, meaning any module map from M into a commutative algebra extends uniquely through $S(M)$, and any such extension from $T(M)$ factors through the quotient π.

Here $\pi\colon T(M) \to S(M)$ is the quotient map and any algebra map Ψ from $T(M)$ into a *commutative* A kills $C(M)$, hence factors uniquely through π.

Worked Example 11.5.13 (The dimension count $\binom{n+k-1}{k}$ for S^k)**.** Compute $\dim_{\mathbb{F}} S^k(V)$ for $n = \dim V = 3$ and $k = 2$, and list a basis.

Recognition. Use $S(V) \cong \mathbb{F}[x_1, x_2, x_3]$, so $S^2(V)$ is the space of homogeneous degree-2 polynomials; the dimension is $\binom{n+k-1}{k} = \binom{4}{2}$.

Solution. $\binom{3+2-1}{2} = \binom{4}{2} = 6$. A basis of $S^2(V)$ is the set of degree-2 monomials

$$\{\, x_1^2,\ x_2^2,\ x_3^2,\ x_1x_2,\ x_1x_3,\ x_2x_3 \,\}.$$

Sanity check. Count the monomials — 3 squares plus $\binom{3}{2} = 3$ mixed products $= 6$, agreeing with the formula. Contrast $\dim T^2(V) = 3^2 = 9$: the three extra dimensions are exactly the antisymmetric relations $x_ix_j - x_jx_i$ killed in passing to S.

Worked Example 11.5.14 (Symmetrizing a tensor)**.** In $S^2(V)$ with $V = \mathbb{F}^2$, $\operatorname{char} \mathbb{F} \neq 2$, express the image of $e_1 \otimes e_2$ and verify $e_1 \otimes e_2$ and $e_2 \otimes e_1$ have the same image.

Recognition. In $S(M)$ the defining relation forces $mm' = m'm$; the quotient identifies $e_1 \otimes e_2$ with $e_2 \otimes e_1$.

Solution. Both map to the product $e_1e_2 = e_2e_1 \in S^2(V)$. Their difference $e_1 \otimes e_2 - e_2 \otimes e_1$ is a generator of $C(V)$, hence zero in $S(V)$. The symmetric representative inside $T^2(V)$ is $\frac{1}{2}(e_1 \otimes e_2 + e_2 \otimes e_1)$, which maps isomorphically onto e_1e_2. *Sanity check.* $\dim S^2(\mathbb{F}^2) = \binom{3}{2} = 3$ with basis e_1^2, e_2^2, e_1e_2, while $\dim T^2(\mathbb{F}^2) = 4$; one dimension (the antisymmetric line) is collapsed.

Worked Example 11.5.15 ($S(M)$ realizes polynomial functions)**.** Identify $S(V^*)$ with polynomial functions on V, $V = \mathbb{R}^2$.

Recognition. By the corollary $S(V^*) \cong \mathbb{R}[e_1^*, e_2^*]$ where e_1^*, e_2^* is the dual basis of coordinate functionals.

Solution. A degree-2 element such as $e_1^*e_2^*$ acts on $v = ae_1 + be_2$ by $(e_1^*e_2^*)(v) = e_1^*(v)\, e_2^*(v) = ab$. Thus $S^k(V^*)$ is exactly the homogeneous degree-k polynomial functions on V. *Sanity check.* $\dim S^2(V^*) = \binom{3}{2} = 3$, matching the monomials a^2, b^2, ab in two coordinate variables.

Worked Example 11.5.16 (A universal-property factorization)**.** Let $V = \mathbb{F}^2$ and $A = \mathbb{F}[t]$ (commutative). Let $\varphi\colon V \to A$ send $e_1 \mapsto t$, $e_2 \mapsto t^2$. Compute $\Phi(e_1e_2)$ and $\Phi(e_1^2)$ for the induced $\Phi\colon S(V) \to A$.

Recognition. A is commutative, so the universal property of $S(V)$ gives a unique algebra map Φ with $\Phi(e_i) = \varphi(e_i)$.

Solution. $\Phi(e_1e_2) = \varphi(e_1)\varphi(e_2) = t \cdot t^2 = t^3$ and $\Phi(e_1^2) = t^2$. *Sanity check.* Order does not matter, $\Phi(e_2e_1) = t^2 \cdot t = t^3 = \Phi(e_1e_2)$, consistent with $S(V)$ commutative — the factorization through S would fail for the noncommutative target $\mathrm{M}_2(\mathbb{F})$.

Worked Example 11.5.17 (Hilbert dimensions $\dim S^k$ form a known sequence)**.** For $n = 2$, tabulate $\dim S^k(V)$ and recognize the pattern.

Recognition. Apply $\dim S^k = \binom{n+k-1}{k} = \binom{k+1}{k} = k+1$.

Solution. We have

$$\dim S^0 = 1, \quad \dim S^1 = 2, \quad \dim S^2 = 3, \quad \dim S^3 = 4, \ \ldots$$

the basis of $S^k(\mathbb{F}^2)$ being $\{\, e_1^k, e_1^{k-1}e_2, \ldots, e_2^k \,\}$, which has $k+1$ elements. *Sanity check.* For two variables the degree-k monomials are $x_1^{k-j}x_2^j$, $0 \le j \le k$, giving $k+1$, matching $\binom{k+1}{k} = k+1$.

The exterior algebra $\wedge(M)$

Definition 11.5.18. The *exterior algebra* of M is the quotient

$$\wedge(M) \;=\; T(M)/A(M),$$

where $A(M)$ is the two-sided ideal generated by all $m \otimes m$ with $m \in M$. The generators are homogeneous of degree 2, so $A(M)$ is graded and $\wedge(M) = \bigoplus_{k\ge 0} \wedge^k(M)$ with $\wedge^k(M) = T^k(M)/(A(M) \cap T^k(M))$. The image of $m_1 \otimes \cdots \otimes m_k$ is written $m_1 \wedge \cdots \wedge m_k$, and the product on $\wedge(M)$ is the *wedge* (exterior) product.

Remark 11.5.2. From $m \wedge m = 0$ for all m one gets, by expanding $(m+m') \wedge (m+m') = 0$, the *anticommutativity* on simple tensors:

$$m \wedge m' = -\, m' \wedge m \qquad (m, m' \in M),$$

and more generally $a \wedge b = (-1)^{ij}\, b \wedge a$ for homogeneous $a \in \wedge^i(M)$, $b \in \wedge^j(M)$. A wedge of vectors vanishes as soon as two factors are equal — hence, over a field, as soon as the factors are linearly dependent (over $\mathbb{Z}$ this fails: $(1,0) \wedge (0,1)$ generates $\wedge^2(\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}) \cong \mathbb{Z}/2\mathbb{Z}$, although $2 \cdot (0,1) = 0$).

Theorem 11.5.19 (Universal property of $\wedge(M)$ via alternating maps)**.** *A multilinear map $\Phi\colon M \times \cdots \times M \to N$ (k factors) is* alternating *if $\Phi(m_1, \ldots, m_k) = 0$ whenever $m_i = m_j$ for some $i \ne j$. The map $M \times \cdots \times M \to \wedge^k(M)$, $(m_1, \ldots, m_k) \mapsto m_1 \wedge \cdots \wedge m_k$, is alternating and universal: for every alternating R-multilinear Φ there is a unique R-module homomorphism $\varphi\colon \wedge^k(M) \to N$ with $\varphi(m_1 \wedge \cdots \wedge m_k) = \Phi(m_1, \ldots, m_k)$.*

Theorem 11.5.20 (Basis and dimension of $\wedge^k(V)$)**.** *If V is free with basis $e_1, \ldots, e_n$, then $\wedge^k(V)$ is free with basis*

$$\{\, e_{i_1} \wedge \cdots \wedge e_{i_k} \;:\; 1 \le i_1 < i_2 < \cdots < i_k \le n \,\},$$

so

$$\dim_{\mathbb{F}} \wedge^k(V) = \binom{n}{k} \qquad (0 \le k \le n), \qquad \wedge^k(V) = 0 \ \text{ for } k > n,$$

and $\dim_{\mathbb{F}} \wedge(V) = \sum_{k=0}^{n} \binom{n}{k} = 2^n$.

The universal property of $\wedge^k(M)$, together with the alternating k-linear map it represents, is captured by:

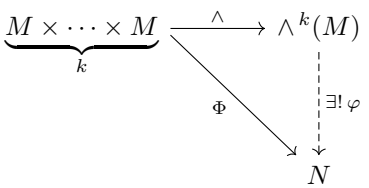

Diagram explanation. Objects: Three objects: the k-fold cartesian product $M^k = M \times \cdots \times M$ (k copies of the R-module M, not a tensor product), $\wedge^k(M)$ (the k-th graded piece of the exterior algebra, an R-module), and N (any R-module receiving an alternating map).

Arrows: The top map $M^k \xrightarrow{\wedge} \wedge^k(M)$ sends $(m_1, \ldots, m_k) \mapsto m_1 \wedge \cdots \wedge m_k$; it is R-multilinear and alternating (vanishes if any two entries are equal). $\Phi\colon M^k \to N$ is any R-multilinear alternating map. $\varphi\colon \wedge^k(M) \to N$ is the unique R-module homomorphism with $\varphi(m_1 \wedge \cdots \wedge m_k) = \Phi(m_1, \ldots, m_k)$.

What commutes: The triangle commutes: $\varphi \circ \wedge = \Phi$, meaning for every tuple $(m_1, \ldots, m_k) \in M^k$, $\varphi(m_1 \wedge \cdots \wedge m_k) = \Phi(m_1, \ldots, m_k)$.

Why it commutes: φ is defined by the formula on decomposable wedges and extended linearly (since $\wedge^k(M)$ is generated by decomposable elements). Well-definedness: a different representative of $m_1 \wedge \cdots \wedge m_k$ in $T^k(M)/A(M)$ differs by an element of $A(M)$; since Φ is alternating, every generator $m \otimes m$ of $A(M)$ maps to $\Phi(\ldots, m, m, \ldots) = 0$, so $A(M) \subseteq \ker \Phi$ and the quotient map is well-defined.

Why this matters here: This is the exterior-algebra analogue of the $T(M)$ and $S(M)$ universal properties. It provides the exact reason why the exterior algebra captures alternating multilinear algebra: every alternating k-form factors uniquely through $\wedge^k$. The determinant is the key application (the n-form det factors through $\wedge^n(V)$).

Concrete example: $M = \mathbb{F}^2$, $k = 2$, $N = \mathbb{F}$, $\Phi(u, v) = u_1 v_2 - u_2 v_1$ (the 2×2 determinant). Since $\wedge^2(\mathbb{F}^2)$ is 1-dimensional with basis $e_1 \wedge e_2$ and $\Phi(e_1, e_2) = 1$, the unique φ sends $e_1 \wedge e_2 \mapsto 1$, giving the isomorphism $\wedge^2(\mathbb{F}^2) \cong \mathbb{F}$.

Common pitfall: The map in the diagram goes from the *cartesian* product $M \times \cdots \times M$, not from $T^k(M)$ or $\wedge^k(M) \times \cdots$. Students sometimes write φ as a map out of the wrong domain. Also, φ is only guaranteed to be an R-module map (not an algebra map), since N is not assumed to be an algebra.

Takeaway: The point of this diagram is that $\wedge^k(M)$ is the universal target for alternating k-linear maps out of M, so giving such a map into any module is the same as giving an R-linear map out of $\wedge^k(M)$.

Worked Example 11.5.21 (Anticommutativity and a vanishing wedge in $\wedge(\mathbb{F}^3)$)**.** Let $V = \mathbb{F}^3$, basis e_1, e_2, e_3. Simplify $(e_1 + 2e_2) \wedge (e_1 + 2e_2)$ and reorder $e_2 \wedge e_1$.

Recognition. Use $m \wedge m = 0$ and the resulting anticommutativity $u \wedge v = -v \wedge u$.

Solution. $(e_1 + 2e_2) \wedge (e_1 + 2e_2) = 0$ directly, since it is $m \wedge m$ with $m = e_1 + 2e_2$. For the reorder, $e_2 \wedge e_1 = -e_1 \wedge e_2$. *Sanity check.* Expanding the first by bilinearity gives $e_1 \wedge e_1 + 2e_1 \wedge e_2 + 2e_2 \wedge e_1 + 4e_2 \wedge e_2 = 0 + 2e_1 \wedge e_2 - 2e_1 \wedge e_2 + 0 = 0$, confirming consistency.

Worked Example 11.5.22 (Basis and dimension of $\wedge^k(\mathbb{F}^4)$)**.** For $V = \mathbb{F}^4$ list the dimensions $\dim \wedge^k(V)$ for $k = 0, 1, 2, 3, 4$ and a basis of $\wedge^2(V)$.

Recognition. Apply $\dim \wedge^k(V) = \binom{n}{k}$ with $n = 4$, and the strictly-increasing-index basis.

Solution. $\binom{4}{0}, \binom{4}{1}, \binom{4}{2}, \binom{4}{3}, \binom{4}{4} = 1, 4, 6, 4, 1$ (sum $2^4 = 16$). A basis of $\wedge^2(V)$ is the 6 elements

$$e_1 \wedge e_2,\ e_1 \wedge e_3,\ e_1 \wedge e_4,\ e_2 \wedge e_3,\ e_2 \wedge e_4,\ e_3 \wedge e_4.$$

Sanity check. The dimensions are symmetric ($\binom{n}{k} = \binom{n}{n-k}$), as they must be since the wedge product $\wedge^k(V) \times \wedge^{n-k}(V) \to \wedge^n(V) = \mathbb{F}\, e_1 \wedge e_2 \wedge e_3 \wedge e_4$ is a perfect pairing of $\wedge^k$ with $\wedge^{n-k}$.

Worked Example 11.5.23 (Decomposable bivector and linear dependence)**.** In $\wedge^2(\mathbb{F}^3)$ compute $(e_1 + e_2) \wedge (e_1 + e_3)$ and decide whether $e_1 + e_2$ and $2e_1 + 2e_2$ wedge to zero.

Recognition. Wedge is bilinear and alternating; $u \wedge v = 0$ iff u, v are linearly dependent.

Solution. Expand:

$$(e_1 + e_2) \wedge (e_1 + e_3) = e_1 \wedge e_3 + e_2 \wedge e_1 + e_2 \wedge e_3 = -e_1 \wedge e_2 + e_1 \wedge e_3 + e_2 \wedge e_3,$$

a nonzero element (its coordinates in the basis are $(-1, 1, 1)$). For the second pair, $2e_1 + 2e_2 = 2(e_1 + e_2)$ is a scalar multiple of $e_1 + e_2$, so they are dependent and $(e_1 + e_2) \wedge (2e_1 + 2e_2) = 2\,(e_1 + e_2) \wedge (e_1 + e_2) = 0$. *Sanity check.* $\dim \wedge^2(\mathbb{F}^3) = \binom{3}{2} = 3$, and our answer is a genuine vector in that 3-dimensional space.

Worked Example 11.5.24 (The wedge as the universal alternating form: det of a 2×2 block)**.** Let $V = \mathbb{F}^2$ and define $\Phi\colon V \times V \to \mathbb{F}$ by $\Phi(u, v) = u_1 v_2 - u_2 v_1$ (the 2×2 determinant). Identify the induced $\varphi\colon \wedge^2(V) \to \mathbb{F}$.

Recognition. Φ is bilinear and alternating ($\Phi(u, u) = 0$), so the universal property of $\wedge^2$ produces a unique linear φ with $\varphi(u \wedge v) = \Phi(u, v)$.

Solution. Since $\wedge^2(\mathbb{F}^2)$ is 1-dimensional with basis $e_1 \wedge e_2$, and $\Phi(e_1, e_2) = 1$, we get $\varphi(e_1 \wedge e_2) = 1$, i.e. φ is the isomorphism $\wedge^2(\mathbb{F}^2) \cong \mathbb{F}$ reading off the coefficient of $e_1 \wedge e_2$. Then for $u = u_1 e_1 + u_2 e_2$, $v = v_1 e_1 + v_2 e_2$,

$$u \wedge v = (u_1 v_2 - u_2 v_1)\, e_1 \wedge e_2,$$

so $\varphi(u \wedge v) = u_1 v_2 - u_2 v_1 = \det \left(\begin{smallmatrix} u_1 & v_1 \\ u_2 & v_2 \end{smallmatrix}\right)$. *Sanity check.* Swapping u, v flips the sign, as the determinant must, and equal arguments give 0.

Worked Example 11.5.25 ($\wedge$ kills symmetric relations but not all of T)**.** Show $e_1 \otimes e_2$ and $e_2 \otimes e_1$ map to negatives in $\wedge^2$, in contrast to S^2.

Recognition. In $\wedge(M)$ the relation is $m \wedge m = 0$, giving $e_1 \wedge e_2 = -e_2 \wedge e_1$; in $S(M)$ the relation is symmetry, giving $e_1 e_2 = e_2 e_1$.

Solution. Under $T^2(V) \to \wedge^2(V)$, $e_1 \otimes e_2 \mapsto e_1 \wedge e_2$ and $e_2 \otimes e_1 \mapsto e_2 \wedge e_1 = -e_1 \wedge e_2$; they are negatives, not equal. *Sanity check.* $\dim \wedge^2(\mathbb{F}^2) = \binom{2}{2} = 1$ while $\dim S^2(\mathbb{F}^2) = \binom{3}{2} = 3$ and $\dim T^2(\mathbb{F}^2) = 4$; indeed $4 = 1 + 3$ splits a 2-tensor into its alternating and symmetric parts (when $\operatorname{char} \mathbb{F} \neq 2$).

Symmetric and alternating tensors; the splitting of T^k

Definition 11.5.26. The symmetric group S_k acts on $T^k(M)$ by permuting tensor factors: $\sigma \cdot (m_1 \otimes \cdots \otimes m_k) = m_{\sigma^{-1}(1)} \otimes \cdots \otimes m_{\sigma^{-1}(k)}$. A tensor $z \in T^k(M)$ is a *symmetric tensor* if $\sigma z = z$ for all σ, and an *alternating (skew-symmetric) tensor* if $\sigma z = \operatorname{sgn}(\sigma)\, z$ for all σ. For $z \in T^k(M)$ define the *symmetrization* and *skew-symmetrization*

$$\operatorname{Sym}(z) = \sum_{\sigma \in S_k} \sigma z, \qquad \operatorname{Alt}(z) = \sum_{\sigma \in S_k} \operatorname{sgn}(\sigma)\, \sigma z.$$

Proposition 11.5.27. $\operatorname{Sym}(z)$ *is symmetric and* $\operatorname{Alt}(z)$ *is alternating, and* $\tau \operatorname{Alt}(z) = \operatorname{sgn}(\tau) \operatorname{Alt}(z)$ *for* $\tau \in S_k$*. When* $k!$ *is invertible in* R *(e.g.* $\operatorname{char} \mathbb{F} = 0$ *or* $\operatorname{char} \mathbb{F} > k$*), the maps* $\frac{1}{k!}\operatorname{Sym}$ *and* $\frac{1}{k!}\operatorname{Alt}$ *are projections of* $T^k(M)$ *onto the submodules of symmetric and alternating tensors, and these submodules map isomorphically onto* $S^k(M)$ *and* $\wedge^k(M)$ *respectively.*

Worked Example 11.5.28 (Explicit Alt on a 2-tensor)**.** Compute $\operatorname{Alt}(e_1 \otimes e_2)$ in $T^2(\mathbb{F}^3)$ and confirm it is alternating.

Recognition. Use the definition with $S_2 = \{\, \mathrm{id}, (12) \,\}$, $\operatorname{sgn}(\mathrm{id}) = 1$, $\operatorname{sgn}((12)) = -1$.

Solution. $\operatorname{Alt}(e_1 \otimes e_2) = e_1 \otimes e_2 - e_2 \otimes e_1$. Applying the swap (12) sends it to $e_2 \otimes e_1 - e_1 \otimes e_2 = -(e_1 \otimes e_2 - e_2 \otimes e_1)$, so it is alternating. Its image in $\wedge^2$ is $e_1 \wedge e_2 - e_2 \wedge e_1 = 2\, e_1 \wedge e_2$. *Sanity check.* Over a field with $\operatorname{char} \mathbb{F} \neq 2$, $\frac{1}{2!}\operatorname{Alt}$ followed by the quotient sends $e_1 \otimes e_2 \mapsto e_1 \wedge e_2$, the expected projection.

Worked Example 11.5.29 (Explicit Sym on a 2-tensor)**.** Compute $\operatorname{Sym}(e_1 \otimes e_2)$ and its image in S^2.

Recognition. Same S_2 action but with all signs $+1$.

Solution. $\operatorname{Sym}(e_1 \otimes e_2) = e_1 \otimes e_2 + e_2 \otimes e_1$, which is fixed by the swap, hence symmetric. Its image in S^2 is $e_1 e_2 + e_2 e_1 = 2\, e_1 e_2$. *Sanity check.* $\frac{1}{2!}\operatorname{Sym}(e_1 \otimes e_2)$ maps to $e_1 e_2 \in S^2$, the projection onto symmetric tensors.

Worked Example 11.5.30 (The $\operatorname{char} 2$ pathology)**.** Over $\mathbb{F} = \mathbb{F}_2$, show Alt = Sym on T^2 and the $\frac{1}{k!}$ normalization fails.

Recognition. In characteristic 2, $-1 = +1$, so the two signed sums coincide; and $2 = 0$ is not invertible, so $\frac{1}{2!}$ is undefined.

Solution. $\operatorname{Alt}(e_1 \otimes e_2) = e_1 \otimes e_2 - e_2 \otimes e_1 = e_1 \otimes e_2 + e_2 \otimes e_1 = \operatorname{Sym}(e_1 \otimes e_2)$ over $\mathbb{F}_2$. One cannot divide by 2, so there is no projection splitting; the clean decomposition $T^2 = \operatorname{Sym} \oplus \operatorname{Alt}$ genuinely needs $2 = 2!$ invertible (and for $k \geq 3$ even $k!$ invertible is not enough: in the 8-dimensional $T^3(\mathbb{Q}^2)$ the symmetric and alternating tensors have dimensions 4 and 0). *Sanity check.* $\dim T^2(\mathbb{F}_2^2) = 4$ but the symmetric and alternating subspaces overlap here, so they cannot account for $4 = 3 + 1$ independently.

Worked Example 11.5.31 (Alternating tensor of degree 3)**.** Write $\mathrm{Alt}(e_1 \otimes e_2 \otimes e_3)$ in $T^3(\mathbb{F}^3)$ as a signed sum and relate it to $e_1 \wedge e_2 \wedge e_3$.

Recognition. Sum over S_3 with signs; there are $3! = 6$ permutations.

Solution. With the six permutations,

$$\mathrm{Alt}(e_1 \otimes e_2 \otimes e_3) = \sum_{\sigma \in S_3} \mathrm{sgn}(\sigma)\, e_{\sigma(1)} \otimes e_{\sigma(2)} \otimes e_{\sigma(3)},$$

the alternating sum of all 6 orderings. It projects to $3!\, e_1 \wedge e_2 \wedge e_3 = 6\, e_1 \wedge e_2 \wedge e_3$ in $\wedge^3$. *Sanity check.* $\dim \wedge^3(\mathbb{F}^3) = \binom{3}{3} = 1$, so every alternating 3-tensor is a scalar multiple of $e_1 \wedge e_2 \wedge e_3$, consistent with the output being $6\, e_1 \wedge e_2 \wedge e_3$.

The top exterior power and the determinant

Theorem 11.5.32. *Let* $\dim_{\mathbb{F}} V = n$*. Then* $\dim_{\mathbb{F}} \wedge^n(V) = \binom{n}{n} = 1$*, so the* top exterior power $\wedge^n(V)$ *is a line, with basis* $e_1 \wedge \cdots \wedge e_n$*. For a linear map* $\varphi \in \mathrm{End}(V)$*, the induced map* $\wedge^n(\varphi)\colon \wedge^n(V) \to \wedge^n(V)$ *is multiplication by a scalar, and that scalar is the determinant:*

$$\varphi(v_1) \wedge \cdots \wedge \varphi(v_n) = \det(\varphi)\,\big(v_1 \wedge \cdots \wedge v_n\big).$$

This is the coordinate-free definition of the determinant: $\det \varphi$ is the scalar by which φ acts on the one-dimensional top exterior power. The multiplicativity $\det(\varphi\psi) = \det(\varphi)\det(\psi)$ is then just functoriality $\wedge^n(\varphi\psi) = \wedge^n(\varphi) \wedge^n(\psi)$, expressed by the commuting triangle:

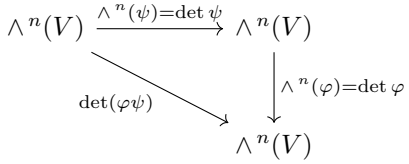

Diagram explanation. Objects: A single R-module $\wedge^n(V)$ appearing in three positions (upper-left, upper-right, lower-right): this is the one-dimensional top exterior power of the n-dimensional vector space V over $\mathbb{F}$, with basis $e_1 \wedge \cdots \wedge e_n$. All three nodes are the same object; the three occurrences mark different stages of the composition.

Arrows: $\wedge^n(\psi)\colon \wedge^n(V) \to \wedge^n(V)$ is scalar multiplication by $\det\psi$ (since the space is 1-dimensional, every endomorphism is a scalar). $\wedge^n(\varphi)\colon \wedge^n(V) \to \wedge^n(V)$ is multiplication by $\det\varphi$. The diagonal arrow is multiplication by $\det(\varphi\psi)$.

What commutes: The triangle commutes: $\wedge^n(\varphi) \circ \wedge^n(\psi) = \wedge^n(\varphi\psi)$, i.e. $(\det\varphi)(\det\psi) = \det(\varphi\psi)$ as scalar multiplications on the line $\wedge^n(V)$.

Why it commutes: On the generator $v_1 \wedge \cdots \wedge v_n$: the right-then-down path gives $\wedge^n(\varphi)(\psi(v_1) \wedge \cdots \wedge \psi(v_n)) = \varphi(\psi(v_1)) \wedge \cdots \wedge \varphi(\psi(v_n)) = (\varphi\psi)(v_1) \wedge \cdots \wedge (\varphi\psi)(v_n)$; the diagonal gives the same. The key step is that $\wedge^n$ is a functor, so composition of maps corresponds to composition of induced maps. No well-definedness issue arises because all maps go between copies of the same line.

Why this matters here: This is the coordinate-free proof that det is multiplicative. Rather than an algebraic manipulation of matrix entries, the argument is one line: $\wedge^n$ is a functor, functors preserve composition, and scalars on a 1-dimensional space multiply. This is why the exterior algebra definition of det is considered the *right* definition.

Concrete example: $\varphi = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, $\psi = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ on $\mathbb{F}^2$. $\wedge^2(\psi)$ scales $e_1 \wedge e_2$ by $\det\psi = 1$; $\wedge^2(\varphi)$ scales by $\det\varphi = 2$; the composition scales by 2. Direct check: $\varphi\psi = \left(\begin{smallmatrix} 2 & 2 \\ 0 & 1 \end{smallmatrix}\right)$, $\det = 2$, matching.

Common pitfall: The diagram has three copies of the *same* one-dimensional space, not three different spaces. Students sometimes draw it as three different modules. The content is entirely about scalars: $\det(\varphi\psi) = \det\varphi \det\psi$ is the statement that two scalar multiplications compose to their product, which is trivial once you know $\wedge^n$ is a functor.

Takeaway: The point of this diagram is that the multiplicativity of the determinant is not a matrix-entry computation but the trivial composition law in the endomorphism monoid of a one-dimensional space, forced by functoriality of $\wedge^n$.

Worked Example 11.5.33 (det as the action on the top wedge, 2×2)**.** Let $\varphi\colon \mathbb{F}^2 \to \mathbb{F}^2$ have matrix $A = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ in the basis e_1, e_2. Compute $\varphi(e_1) \wedge \varphi(e_2)$ and read off $\det \varphi$.

Recognition. Use the theorem: $\varphi(e_1) \wedge \varphi(e_2) = \det(\varphi)\, e_1 \wedge e_2$; compute the left side by bilinearity and $m \wedge m = 0$.

Solution. $\varphi(e_1) = ae_1 + ce_2$, $\varphi(e_2) = be_1 + de_2$, so

$$\varphi(e_1) \wedge \varphi(e_2) = (ae_1 + ce_2) \wedge (be_1 + de_2) = ad\, e_1 \wedge e_2 + cb\, e_2 \wedge e_1 = (ad - bc)\, e_1 \wedge e_2.$$

Hence $\det \varphi = ad - bc$. *Sanity check.* This is the familiar 2×2 determinant; the cross terms $e_1 \wedge e_1 = e_2 \wedge e_2 = 0$ dropped out and $e_2 \wedge e_1 = -e_1 \wedge e_2$ produced the minus sign.

Worked Example 11.5.34 (det as the action on the top wedge, 3×3)**.** With $A = \left(\begin{smallmatrix} 1 & 0 & 2 \\ 0 & 3 & 0 \\ 1 & 0 & 1 \end{smallmatrix}\right)$ acting on $\mathbb{F}^3$, find $\det \varphi$ via $\varphi(e_1) \wedge \varphi(e_2) \wedge \varphi(e_3)$.

Recognition. Top wedge is 1-dimensional; expand the wedge of columns, keeping only the $e_1 \wedge e_2 \wedge e_3$ term (all repeated-index wedges vanish).

Solution. Columns are $\varphi(e_1) = e_1 + e_3$, $\varphi(e_2) = 3e_2$, $\varphi(e_3) = 2e_1 + e_3$. Then

$$(e_1 + e_3) \wedge 3e_2 \wedge (2e_1 + e_3) = 3\big(e_1 \wedge e_2 \wedge e_3 + e_3 \wedge e_2 \wedge 2e_1\big).$$

Now $e_3 \wedge e_2 \wedge e_1 = -\,e_1 \wedge e_2 \wedge e_3$ (one swap of the outer factors, sign -1), so the bracket is $(1-2)\, e_1 \wedge e_2 \wedge e_3 = -e_1 \wedge e_2 \wedge e_3$, giving $3 \cdot (-1) = -3$. Hence $\det \varphi = -3$. *Sanity check.* Cofactor expansion along the middle row gives $3 \cdot \det \left(\begin{smallmatrix} 1 & 2 \\ 1 & 1 \end{smallmatrix}\right) = 3(1 - 2) = -3$, matching.

Worked Example 11.5.35 (Multiplicativity of det from functoriality)**.** Verify $\det(\varphi\psi) = \det(\varphi) \det(\psi)$ for $\varphi = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, $\psi = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ on $\mathbb{F}^2$, using top wedges.

Recognition. $\wedge^n(\varphi\psi) = \wedge^n(\varphi) \circ \wedge^n(\psi)$, and each $\wedge^n$ acts as a scalar (its determinant) on the line $\wedge^2(V)$.

Solution. $\wedge^2(\psi)$ scales $e_1 \wedge e_2$ by $\det \psi = 1$; $\wedge^2(\varphi)$ scales by $\det \varphi = 2$. Composing scales by $2 \cdot 1 = 2$. Directly, $\varphi\psi = \left(\begin{smallmatrix} 2 & 2 \\ 0 & 1 \end{smallmatrix}\right)$ has $\det = 2$. *Sanity check.* $\det(\varphi\psi) = 2 = \det \varphi \cdot \det \psi = 2 \cdot 1$, exactly the commuting-triangle statement.

Worked Example 11.5.36 (Singular maps and vanishing top wedge)**.** Show that $\varphi\colon \mathbb{F}^3 \to \mathbb{F}^3$ with columns e_1, e_2, $e_1 + e_2$ has $\det \varphi = 0$, directly from the exterior power.

Recognition. $\det \varphi$ is the scalar in $\varphi(e_1) \wedge \varphi(e_2) \wedge \varphi(e_3) = \det(\varphi)\, e_1 \wedge e_2 \wedge e_3$; linearly dependent columns force a vanishing wedge.

Solution. $\varphi(e_3) = e_1 + e_2 = \varphi(e_1) + \varphi(e_2)$, so

$$\varphi(e_1) \wedge \varphi(e_2) \wedge (\varphi(e_1) + \varphi(e_2)) = \varphi(e_1) \wedge \varphi(e_2) \wedge \varphi(e_1) + \varphi(e_1) \wedge \varphi(e_2) \wedge \varphi(e_2) = 0,$$

since each term repeats a factor. Hence $\det \varphi = 0$. *Sanity check.* The third column is the sum of the first two, so the matrix is singular — exactly the case the exterior algebra detects as a vanishing top wedge.

Worked Example 11.5.37 (Determinant of a scalar map)**.** Compute $\det(\lambda\, \mathrm{id}_V)$ for $\dim V = n$ using $\wedge^n$.

Recognition. Each factor scales by λ; with n factors the top wedge scales by λ^n.

Solution. $(\lambda v_1) \wedge \cdots \wedge (\lambda v_n) = \lambda^n\, (v_1 \wedge \cdots \wedge v_n)$, so $\det(\lambda\, \mathrm{id}_V) = \lambda^n$. *Sanity check.* For $n = 2$ this is $\lambda^2 = \det \left(\begin{smallmatrix} \lambda & 0 \\ 0 & \lambda \end{smallmatrix}\right)$, and in general the diagonal matrix λI_n has determinant λ^n, agreeing with the wedge computation.

Remark 11.5.3. The three constructions fit a single template. Each is $T(M)$ modulo the graded ideal that imposes the desired symmetry, and each represents a class of maps out of M:

$T(M)$:	no relations	universal for linear maps into algebras,
$S(M) = T(M)/\langle m \otimes m' - m' \otimes m \rangle$:	$mm' = m'm$	universal for commutative targets,
$\wedge(M) = T(M)/\langle m \otimes m \rangle$:	$m \wedge m = 0$	universal for alternating maps.

For V of dimension n the homogeneous dimensions are n^k, $\binom{n+k-1}{k}$, and $\binom{n}{k}$ respectively, and the top exterior power $\wedge^n(V)$ — the smallest and most rigid piece — is the one-dimensional home of the determinant.

In these exercises R is a commutative ring with 1 and M is an R-module; F is a field and V is a finite dimensional vector space over F.

Exercises (from the text).

1. Prove that if M is a cyclic R-module then $T(M) = S(M)$, i.e., the tensor algebra $T(M)$ is commutative.
2. Fill in the details for the proof of Proposition 33 that $S/I = \bigoplus_{k=0}^{\infty} S_k/I_k$. [Show first that $S_k I_j \subseteq I_{k+j}$. Use this to show that the multiplication $(S_i/I_i)(S_j/I_j) \subseteq S_{i+j}/I_{i+j}$ is well defined, and then check the ring axioms and verify the statements made in the proof of Proposition 33.]
3. Show that the image of the map Sym_2 for the $\mathbb{Z}$-module $\mathbb{Z}$ consists of the 2-tensors $a(1 \otimes 1)$ where a is an even integer. Conclude in particular that the symmetric tensor $1 \otimes 1$ in $\mathbb{Z} \otimes_{\mathbb{Z}} \mathbb{Z}$ is not contained in the image of the map Sym_2.
4. Prove that $m \wedge n_1 \wedge n_2 \wedge \cdots \wedge n_k = (-1)^k (n_1 \wedge n_2 \wedge \cdots \wedge n_k \wedge m)$. In particular, $x \wedge (y \wedge z) = (y \wedge z) \wedge x$ for all $x, y, z \in M$.
5. Prove that if M is a free R-module of rank n then $\wedge^i(M)$ is a free R-module of rank $\binom{n}{i}$ for $i = 0, 1, 2, \ldots$.
6. If A is an R-algebra and $\varphi\colon M \to A$ is an R-module homomorphism with $\varphi(m)^2 = 0$ for all $m \in M$, prove there is a unique R-algebra homomorphism $\Phi\colon \wedge(M) \to A$ such that $\Phi|_M = \varphi$.
7. Let $R = \mathbb{Z}[x, y]$ and $I = (x, y)$.
   (a) Prove that if $ax + by = a'x + b'y$ in R then $a' = a + yf$ and $b' = b - xf$ for some polynomial $f(x, y) \in R$.
   (b) Prove the map $\varphi(ax + by,\, cx + dy) = ad - bc \bmod (x, y)$ in the example following Corollary 37 is a well defined alternating R-bilinear map from $I \times I$ to R/I.
8. Let R be an integral domain and let F be its field of fractions.
   (a) Considering F as an R-module, prove that $\wedge^2 F = 0$.
   (b) Let I be an R-submodule of F (for example, any ideal in R). Prove that $\wedge^i I$ is a torsion R-module for $i \geq 2$ (i.e., for every $x \in \wedge^i I$ there is some nonzero $r \in R$ with $rx = 0$).
   (c) Give an example of an integral domain R and R-module I in F with $\wedge^i I \neq 0$ for every $i \geq 0$ (cf. the example following Corollary 37).
9. Let $R = \mathbb{Z}[G]$ be the group ring of the group $G = \{1, \sigma\}$ of order 2. Let $M = \mathbb{Z}e_1 \oplus \mathbb{Z}e_2$ be a free $\mathbb{Z}$-module of rank 2 with basis e_1 and e_2. Define $\sigma(e_1) = e_1 + 2e_2$ and $\sigma(e_2) = -e_2$. Prove that this makes M into an R-module and that the R-module $\wedge^2 M$ is a group of order 2 with $e_1 \wedge e_2$ as generator.
10. Prove that $z - \frac{1}{k!}\mathrm{Alt}(z) = \frac{1}{k!} \sum_{\sigma \in S_k} \big(z - \epsilon(\sigma)\, \sigma z\big)$ for any k-tensor z and use this to prove that the kernel of the R-module homomorphism $\frac{1}{k!}\mathrm{Alt}$ in Proposition 40 is $\mathcal{A}^k(M)$.
11. Suppose that $-1 \neq 1$ in F. Prove that the image of Alt_k is the unique largest subspace of $T^k(V)$ on which each permutation σ in the symmetric group S_k acts as multiplication by the scalar $\epsilon(\sigma)$.
12.
   (a) Prove that if $f(x, y)$ is an alternating bilinear map on V (i.e., $f(x, x) = 0$ for all $x \in V$) then $f(x, y) = -f(y, x)$ for all $x, y \in V$.
   (b) Suppose that $-1 \neq 1$ in F. Prove that if $f(x, y)$ is a bilinear map on V with $f(x, y) = -f(y, x)$ for all $x, y \in V$ then f is alternating (i.e., $f(x, x) = 0$ for all $x \in V$).
   (c) Suppose that $-1 = 1$ in F. Prove that every alternating bilinear form $f(x, y)$ on V is symmetric (i.e., $f(x, y) = f(y, x)$ for all $x, y \in V$). Prove that there is a symmetric bilinear map on V that is not alternating. [One approach: show that $C^2(V) \subseteq \mathcal{A}^2(V)$ and $C^2(V) \neq \mathcal{A}^2(V)$ by counting dimensions. Alternatively, construct an explicit symmetric map that is not alternating.]

13. Let F be any field in which $-1 \neq 1$ and let V be a vector space over F. Prove that $V \otimes_F V = S^2(V) \oplus \wedge^2(V)$, i.e., that every 2-tensor can be written uniquely as a sum of a symmetric and an alternating tensor.

14. Prove that if M is an R-module direct factor of the R-module N then $T(M)$ (respectively, $S(M)$ and $\wedge(M)$) is an R-subalgebra of $T(N)$ (respectively, $S(N)$ and $\wedge(N)$).

Practice problems.

1. Let V be a finite-dimensional vector space over $\mathbb{F}$ with $\dim V = n$. Compute $\dim V^{\otimes k}$ in terms of n and k, and explain why $T(V) = \bigoplus_{k \geq 0} V^{\otimes k}$ is infinite-dimensional whenever $n \geq 1$.

2. Let V have ordered basis $\{ e_1, e_2, e_3 \}$. Inside the symmetric algebra $S(V)$, write down a basis for the degree-2 component $S^2(V)$ and verify directly that $\dim S^2(V) = \binom{n+k-1}{k}$ with $n = 3$, $k = 2$.

3. With V as in the previous problem, list a basis for $\wedge^2(V)$ and for $\wedge^3(V)$, and confirm the formula $\dim \wedge^k(V) = \binom{n}{k}$. What is $\wedge^k(V)$ for $k > 3$, and why?

4. In the exterior algebra $\wedge(V)$, prove that $v \wedge v = 0$ for every $v \in V$, and deduce that $w \wedge z = -\, z \wedge w$ for all $w, z \in V$. (Begin from the defining relations of $\wedge(V)$.)

5. Let $V = \mathbb{F}^2$ with basis $\{ e_1, e_2 \}$. Compute the product $(2e_1 + 3e_2) \wedge (e_1 - e_2)$ in $\wedge^2(V)$, expressing the answer as a scalar multiple of $e_1 \wedge e_2$.

6. Let $\varphi \colon V \to V$ be the linear map given on the basis $\{ e_1, e_2 \}$ of $V = \mathbb{F}^2$ by $\varphi(e_1) = e_1 + 2e_2$ and $\varphi(e_2) = 3e_1 + 4e_2$. The induced map $\wedge^2(\varphi) \colon \wedge^2(V) \to \wedge^2(V)$ acts on the one-dimensional space $\wedge^2(V)$ as multiplication by a scalar. Compute that scalar and identify it as $\det$ of a matrix.

7. Show that the tensor algebra $T(V)$, the symmetric algebra $S(V)$, and the exterior algebra $\wedge(V)$ are all graded $\mathbb{F}$-algebras: in each case exhibit the grading and verify that the product of a degree-i element with a degree-j element lands in degree $i + j$.

8. Let $\dim V = n$. Prove that the top exterior power $\wedge^n(V)$ is one-dimensional, and that a linear map $\varphi \in \mathrm{End}(V)$ induces multiplication by $\det \varphi$ on $\wedge^n(V)$. Use this to give a basis-free proof that $\det(\psi\varphi) = \det(\psi)\det(\varphi)$.

9. Describe explicitly the surjective algebra homomorphisms $T(V) \twoheadrightarrow S(V)$ and $T(V) \twoheadrightarrow \wedge(V)$, and identify the two-sided ideals that are their kernels. State which ideal is generated by elements $v \otimes w - w \otimes v$ and which by elements $v \otimes v$.

Additional exercises.

1. Let $\dim V = n$. Compute $\sum_{k=0}^{m} \dim S^k(V)$, the dimension of the part of $S(V)$ of degree at most m (note $\dim S(V) = \infty$ for $n \geq 1$), i.e. give a closed form for $\sum_{k=0}^{m} \binom{n+k-1}{k}$, and prove that $\dim \wedge(V) = \sum_{k=0}^{n} \binom{n}{k} = 2^n$.

2. Let $W \subseteq V$ be a subspace with $\dim W = r$ and $\dim V = n$. Prove that the inclusion $W \hookrightarrow V$ induces an injective algebra homomorphism $\wedge(W) \to \wedge(V)$, and that $\wedge^r(W) \to \wedge^r(V)$ is injective onto a one-dimensional subspace. Interpret a nonzero element of $\wedge^r(W)$ as encoding the subspace W.

3. Prove that vectors $v_1, \ldots, v_k \in V$ are linearly independent if and only if $v_1 \wedge v_2 \wedge \cdots \wedge v_k \neq 0$ in $\wedge^k(V)$. Use this to characterize when an element $v_1 \wedge \cdots \wedge v_n \in \wedge^n(V)$ is a basis of $\wedge^n(V)$.

4. Suppose $\mathbb{F}$ has characteristic 0. Construct an explicit $\mathbb{F}$-linear injection $S^k(V) \to V^{\otimes k}$ (a symmetrization splitting of the projection $V^{\otimes k} \to S^k(V)$) and verify on $S^2(V)$ with $\dim V = 2$ that your map is a section of the canonical projection.

5. Let $\varphi \in \mathrm{End}(V)$ with $\dim V = n$. Show that $\mathrm{tr}\big(\wedge^k(\varphi)\big)$ equals the k-th elementary symmetric function of the eigenvalues of φ (over $\mathbb{C}$), and in particular recover $\mathrm{tr}(\wedge^1(\varphi)) = \mathrm{tr}(\varphi)$ and $\mathrm{tr}(\wedge^n(\varphi)) = \det(\varphi)$.

Commutative-diagram exercises.

1. State and prove the universal property of the tensor algebra by completing the diagram below: given any $\mathbb{F}$-algebra A and any $\mathbb{F}$-linear map $f\colon V \to A$, show there is a unique algebra homomorphism $\tilde{f}$ making the triangle commute, where $\iota\colon V \to T(V)$ is the canonical inclusion.

$$\begin{array}{ccc} V & \xhookrightarrow{\iota} & T(V) \\ & \searrow^{f} & \downarrow{\scriptstyle \tilde{f}} \\ & & A \end{array}$$

2. The symmetric algebra solves a mapping problem into *commutative* algebras. Let A be a commutative $\mathbb{F}$-algebra and $f\colon V \to A$ linear. Show the dashed arrow $\bar{f}$ exists uniquely and that the lower triangle commutes, where $\pi\colon T(V) \to S(V)$ is the canonical projection and $\tilde{f}$ is from the previous exercise.

$$\begin{array}{ccccc} V & \xhookrightarrow{\iota} & T(V) & \xrightarrow{\pi} & S(V) \\ & \searrow^{f} & & \searrow^{\tilde{f}} & \downarrow{\scriptstyle \bar{f}} \\ & & & & A \end{array}$$

   State the analogous universal property for $\wedge(V)$ (replacing commutative algebras by algebras in which every $f(v)$ squares to 0).

3. Functoriality. Let $\varphi\colon V \to W$ be linear. Show that φ induces algebra homomorphisms making each square below commute, where the vertical maps are the canonical projections, and conclude that $\wedge$ is a functor (i.e. $\wedge(\psi\varphi) = \wedge(\psi) \wedge (\varphi)$ and $\wedge(\mathrm{id}_V) = \mathrm{id}$).

$$\begin{array}{ccc} T(V) & \xrightarrow{T(\varphi)} & T(W) \\ {\scriptstyle \pi_V}\downarrow & & \downarrow{\scriptstyle \pi_W} \\ \wedge(V) & \xrightarrow[\wedge(\varphi)]{} & \wedge(W) \end{array}$$

4. Let $0 \to U \xrightarrow{i} V \xrightarrow{p} Q \to 0$ be a short exact sequence of finite-dimensional vector spaces, with $\dim U = r$ and $\dim Q = s$. Fix a linear section $\sigma\colon Q \to V$ of p ($p\sigma = \mathrm{id}_Q$) and let the diagonal arrow be $\mu_\sigma(w \otimes \eta) = w \wedge \wedge^s(\sigma)(\eta)$; this map depends on σ. Establish the canonical isomorphism on top exterior powers indicated by the dashed arrow (show that $\mu_\sigma \circ (\wedge^r(i) \otimes \mathrm{id})$ is independent of σ and bijective), and use the diagram to prove $\wedge^{r+s}(V) \cong \wedge^r(U) \otimes \wedge^s(Q)$.

$$\begin{array}{ccc} \wedge^r(U) \otimes \wedge^s(Q) & \overset{\sim}{\dashrightarrow} & \wedge^{r+s}(V) \\ {\scriptstyle \wedge^r(i)\otimes \mathrm{id}}\downarrow & \nearrow_{\mu_\sigma} & \\ \wedge^r(V) \otimes \wedge^s(Q) & & \end{array}$$

5. Connect the top exterior power to the determinant via naturality. For $\varphi \in \mathrm{End}(V)$ with $\dim V = n$, show the square below commutes, where the vertical arrows are the canonical identification of $\wedge^n(V)$ with $\mathbb{F}$ after choosing a basis $e_1 \wedge \cdots \wedge e_n$, and conclude that the scalar by which $\wedge^n(\varphi)$ acts is independent of that choice and equals $\det \varphi$.

$$\begin{array}{ccc} \wedge^n(V) & \xrightarrow{\wedge^n(\varphi)} & \wedge^n(V) \\ {\scriptstyle \sim}\downarrow & & \downarrow{\scriptstyle \sim} \\ \mathbb{F} & \xrightarrow[\cdot\, \det\varphi]{} & \mathbb{F} \end{array}$$

11.6 Matrices, Row Reduction, and Explicit Determinants

Matrices, row reduction, and linear systems

The abstract picture of §11.1–11.2 — vector spaces, linear maps, rank and nullity — has a thoroughly concrete shadow: once bases are fixed, a linear map $T\colon F^n \to F^m$ *is* an $m \times n$ matrix A, and the equation $T(x) = b$ *is* the linear system $AX = B$. Artin develops the computational side first (Chapter 1), and it is worth having in hand as the algorithmic complement to the structure theory. The single tool that does everything below — solving systems, deciding consistency, computing rank, inverting a matrix — is row reduction by elementary matrices.

Definition 11.6.1 (Elementary matrices and row operations)**.** Let F be a field. An *elementary matrix* is an $n \times n$ matrix obtained from the identity I_n by one of three modifications, and *left* multiplication $X \mapsto EX$ performs the corresponding *elementary row operation* on X:

(i) *Transvection.* Put a scalar a in the (i, j) position $(i \neq j)$ of I_n. Then EX adds $a \cdot (\text{row } j)$ to (row i).

(ii) *Swap.* Exchange rows i and j of I_n (zeros on the $(i,i),(j,j)$ diagonal, ones in the $(i,j),(j,i)$ slots). Then EX interchanges (row i) and (row j).

(iii) *Scaling.* Replace one diagonal entry of I_n by a nonzero scalar c. Then EX multiplies (row i) by c.

Lemma 11.6.2 (Elementary matrices are invertible)**.** *Each elementary matrix E is invertible, and E^{-1} is again elementary of the same type. A finite product of elementary matrices is therefore invertible.*

Proof. The inverse operation is itself elementary: "subtract $a \cdot (\text{row } j)$ from (row i)" undoes type (i), the swap undoes itself (type (ii)), and "multiply (row i) by c^{-1}" undoes type (iii). The matrix of the inverse operation is E^{-1}. A product of invertibles is invertible. □

Row reduction of a matrix M means producing $M' = E_k \cdots E_2 E_1 M$ for some sequence of elementary matrices, i.e. applying row operations until no further simplification is useful. Setting $P = E_k \cdots E_1$ (an invertible matrix), we have $M' = PM$; this P records the whole reduction.

Definition 11.6.3 (Row echelon form)**.** A matrix is in *row echelon form* (REF) if:

(a) every zero row lies below every nonzero row;

(b) the first nonzero entry of each nonzero row is 1 (its *pivot*);

(c) the pivot in each row lies strictly to the right of the pivot in the row above;

(d) every entry *above* a pivot is 0 (so the pivot is the only nonzero entry in its column).

Remark 11.6.1. Condition (d) is what Artin builds into "row echelon"; many texts call a matrix satisfying only (a)–(c) row echelon and reserve *reduced* row echelon form (RREF) for the addition of (d). We follow Artin: "REF" below always includes (d), so the form is unique. A *pivot column* is one containing a pivot; the remaining columns are *free*.

Theorem 11.6.4 (Existence of a row echelon form)**.** *Every matrix M can be carried to a matrix in row echelon form by a finite sequence of elementary row operations. The resulting echelon form is uniquely determined by M.*

Proof. Induct on the number of rows. If $M = 0$ it is already echelon. Otherwise let column p be the first nonzero column. Use a type (ii) swap to bring a nonzero entry of column p to the top row, then a type (iii) scaling to normalize it to 1: this is the first pivot. Type (i) operations clear all other entries of column p. The matrix now has block form $\left(\begin{smallmatrix} 1 & * \\ 0 & D \end{smallmatrix}\right)$ with a smaller matrix D below-right; since the columns left of D are zero, operating on D leaves the rest untouched. By induction D reduces to echelon form, after which type (i) operations clear the entries above the new pivots. The four conditions then hold. Uniqueness (which we use but do not prove here) follows because the pivot columns and the coordinates of the free columns are determined by the linear dependencies among the columns of M, which row operations preserve. □

Proposition 11.6.5 (Row operations preserve the solution set)**.** *If $M = [A \mid B]$ is the augmented matrix of the system $AX = B$ and $M' = [A' \mid B'] = PM$ with P invertible, then $AX = B$ and $A'X = B'$ have exactly the same solutions.*

Proof. Because P is invertible and $[A' \mid B'] = [PA \mid PB]$: if $AX = B$ then $A'X = PAX = PB = B'$; conversely if $A'X = B'$ then $AX = P^{-1}A'X = P^{-1}B' = B$. The two equations are interchanged by the invertible P, hence have identical solution sets. □

This is the whole point of reduction: replace $AX = B$ by the visibly solvable $A'X = B'$.

Theorem 11.6.6 (Solving $AX = B$ from echelon form)**.** *Let $[A' \mid B']$ be the row echelon form of the augmented matrix of $AX = B$, with B' a single column.*

(1) The system is consistent *(has a solution) if and only if the last column B' contains no pivot — equivalently, there is no row of the form $[\,0 \;\cdots\; 0 \mid 1\,]$, which would read $0 = 1$.*

(2) When consistent, the free variables (those whose columns carry no pivot) may be assigned arbitrary values, and the pivot variables are then determined uniquely.

In particular a consistent system has a unique solution iff every column of A' is a pivot column.

Proof. A pivot in the last column gives an equation $0 \cdot x_1 + \cdots + 0 \cdot x_n = 1$, impossible, so consistency forces no such pivot. Conversely, if no pivot sits in column B', solve from the bottom up: each nonzero row has its pivot in some column of A', expressing that pivot variable in terms of the free variables to its right; assigning the free variables any values determines the pivot variables in turn. Uniqueness holds exactly when there are no free variables, i.e. when every column of A' is a pivot column. □

Corollary 11.6.7 (Underdetermined homogeneous systems)**.** *A homogeneous system $AX = 0$ of m equations in n unknowns with $m < n$ has a nontrivial solution.*

Proof. The echelon form A' has at most m pivots (one per row), and $m < n$, so some of the n columns are free. Assigning a free variable the value 1 yields a solution $X \neq 0$ with $A'X = 0$, hence $AX = 0$. □

The number r of pivots is the genuinely structural quantity hiding in the algorithm.

Definition 11.6.8 (Rank via echelon form)**.** The *rank* $\operatorname{rank} A$ is the number of pivots (equivalently, of nonzero rows) in any row echelon form of A. For A the matrix of $T\colon F^n \to F^m$ this agrees with $\dim \operatorname{im} T$, and $\operatorname{null} A = n - \operatorname{rank} A = \dim \ker T$ counts the free variables — the concrete face of rank–nullity from §11.2.

Worked Example 11.6.9 (An underdetermined (consistent) system)**.** Solve the system over $\mathbb{Q}$

$$x_1 + x_2 + 2x_3 + x_4 = 5, \qquad x_1 + x_2 + 2x_3 + 6x_4 = 10, \qquad x_1 + 2x_2 + 5x_3 + 2x_4 = 7.$$

Recognition. This is Artin's system (1.2.11): three equations, four unknowns. Reduce the augmented matrix to echelon form; with fewer pivots than unknowns expect a one-parameter family.

Solution. Augment and reduce:

$$\left[\begin{array}{cccc|c} 1 & 1 & 2 & 1 & 5 \\ 1 & 1 & 2 & 6 & 10 \\ 1 & 2 & 5 & 2 & 7 \end{array}\right] \xrightarrow[R_3 - R_1]{R_2 - R_1} \left[\begin{array}{cccc|c} 1 & 1 & 2 & 1 & 5 \\ 0 & 0 & 0 & 5 & 5 \\ 0 & 1 & 3 & 1 & 2 \end{array}\right] \xrightarrow{R_2 \leftrightarrow R_3} \left[\begin{array}{cccc|c} 1 & 1 & 2 & 1 & 5 \\ 0 & 1 & 3 & 1 & 2 \\ 0 & 0 & 0 & 5 & 5 \end{array}\right].$$

Scale R_3 by $\frac{1}{5}$, then clear above each pivot ($R_1 - R_2$, then eliminate column 4):

$$\left[\begin{array}{cccc|c} 1 & 0 & -1 & 0 & 3 \\ 0 & 1 & 3 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 \end{array}\right].$$

Pivots sit in columns $1, 2, 4$; column 3 is free. Setting $x_3 = c$,

$$x_1 = 3 + c, \quad x_2 = 1 - 3c, \quad x_4 = 1, \quad x_3 = c \qquad (c \in \mathbb{Q} \text{ arbitrary}).$$

Check. Substitute into the first equation: $(3 + c) + (1 - 3c) + 2c + 1 = 5$ for all c. The last column carries no pivot, so the system is consistent; rank $= 3 < 4$, giving $4 - 3 = 1$ free parameter — exactly the line of solutions found.

Worked Example 11.6.10 (An inconsistent system)**.** Decide whether $AX = B$ is solvable, where

$$A = \begin{pmatrix} 1 & 6 & 0 & 1 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \qquad B = \begin{pmatrix} 1 \\ 3 \\ 1 \end{pmatrix}.$$

Recognition. Here A is already in echelon form; consistency is decided purely by whether a pivot lands in the augmented (last) column.

Solution. Form the augmented matrix

$$[A \mid B] = \left[\begin{array}{cccc|c} 1 & 6 & 0 & 1 & 1 \\ 0 & 0 & 1 & 2 & 3 \\ 0 & 0 & 0 & 0 & 1 \end{array}\right].$$

The bottom row reads $0x_1 + 0x_2 + 0x_3 + 0x_4 = 1$, i.e. $0 = 1$, which no X can satisfy. A pivot has appeared in the last column, so the system is *inconsistent*: there is no solution. *Check.* Replacing B by $B' = (1, 3, 0)^{\mathsf{T}}$ removes the offending pivot; then with $x_2 = s$, $x_4 = t$ free, $x_1 = 1 - 6s - t$ and $x_3 = 3 - 2t$ solve it. Consistency is a property of B relative to the column space of A, detected by the last-column pivot test.

Method (Inverting a matrix by reduction)**.** To compute A^{-1} for an invertible $n \times n$ matrix A, row reduce the augmented block $[\, A \mid I_n \,]$ until the left block becomes I_n. The right block is then A^{-1}. (If the left block instead develops a zero row, A is not invertible.) Reason: the operations multiply by $P = E_k \cdots E_1$ with $PA = I$, so $P = A^{-1}$; the same P applied to I on the right yields $PI = A^{-1}$.

Theorem 11.6.11 (Characterization of invertibility)**.** *For a square matrix A over F the following are equivalent:*

(a) A can be reduced to I by elementary row operations;

(b) A is a product of elementary matrices;

(c) A is invertible;

(d) $AX = B$ has a unique solution for every B;

(e) the homogeneous system $AX = 0$ has only $X = 0$.

Proof. A square echelon matrix is either I (when it has n pivots, one per column) or has a zero bottom row (fewer than n pivots).

(a)⇒(b): if $E_k \cdots E_1 A = I$ then $A = E_1^{-1} \cdots E_k^{-1}$, a product of elementary matrices since each E_i^{-1} is elementary. (b)⇒(c): a product of invertibles is invertible. (c)⇒(a): if A is invertible so is its echelon form $A' = PA$; an invertible matrix has no zero row, so by the dichotomy $A' = I$. (c)⇒(d): $X = A^{-1}B$ is a solution, and if $AX = AX'$ then $X = X'$ after multiplying by A^{-1}. (d)⇒(e): the case $B = 0$ has the solution $X = 0$, which is then the unique one. (e)⇒(c): if $AX = 0$ forces $X = 0$ there are no free columns, so the echelon form has n pivots and equals I, putting us back at (a)⇒(c). □

Remark 11.6.2 (One-sided inverses suffice). A useful consequence: if a square A has a right inverse B (so $AB = I$) it is invertible with $A^{-1} = B$. Indeed reducing A gives $A' = PA$ in echelon form, whence $A'B = PAB = P$; since P is invertible its bottom row is nonzero, so A' has no zero row and thus $A' = I$, making P a left inverse of A. Now A has both a left and a right inverse, and these coincide ($L = L(AB) = (LA)B = B$). The symmetric argument handles a left inverse.

Worked Example 11.6.12 (Computing an inverse over $\mathbb{Q}$)**.** Invert $A = \begin{pmatrix} 1 & 5 \\ 2 & 6 \end{pmatrix}$ by reduction (Artin's Example 1.2.18).

Recognition. Augment with I_2 and drive the left block to I_2; whatever the right block becomes is A^{-1}.

Solution.

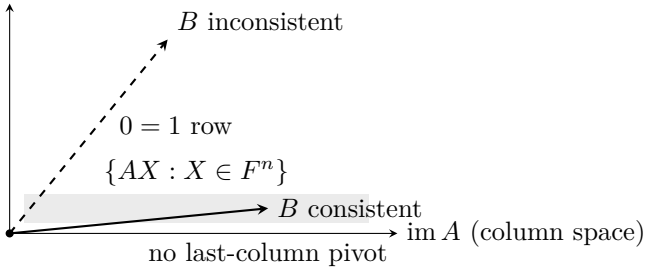
$$[A \mid I] = \left[\begin{array}{cc|cc} 1 & 5 & 1 & 0 \\ 2 & 6 & 0 & 1 \end{array}\right] \xrightarrow{R_2 - 2R_1} \left[\begin{array}{cc|cc} 1 & 5 & 1 & 0 \\ 0 & -4 & -2 & 1 \end{array}\right] \xrightarrow{-\frac{1}{4}R_2} \left[\begin{array}{cc|cc} 1 & 5 & 1 & 0 \\ 0 & 1 & \frac{1}{2} & -\frac{1}{4} \end{array}\right].$$

Clear above the second pivot with $R_1 - 5R_2$:

$$\left[\begin{array}{cc|cc} 1 & 0 & -\frac{3}{2} & \frac{5}{4} \\ 0 & 1 & \frac{1}{2} & -\frac{1}{4} \end{array}\right], \qquad \text{so} \qquad A^{-1} = \begin{pmatrix} -\frac{3}{2} & \frac{5}{4} \\ \frac{1}{2} & -\frac{1}{4} \end{pmatrix}.$$

Check. The 2×2 formula gives $\det A = 6 - 10 = -4$ and $A^{-1} = \frac{1}{-4}\left(\begin{smallmatrix} 6 & -5 \\ -2 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} -3/2 & 5/4 \\ 1/2 & -1/4 \end{smallmatrix}\right)$, matching. And $AA^{-1} = \left(\begin{smallmatrix} 1 & 5 \\ 2 & 6 \end{smallmatrix}\right)\left(\begin{smallmatrix} -3/2 & 5/4 \\ 1/2 & -1/4 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$.

Worked Example 11.6.13 (Rank from echelon form)**.** Find $\operatorname{rank} A$ and $\operatorname{null} A$ for $A = \begin{pmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 3 & 1 & 2 \end{pmatrix}$ over $\mathbb{Q}$.



Recognition. Count pivots in the echelon form; null $= n -$ rank then counts free columns, by rank–nullity.

Solution. Reduce:

$$\begin{pmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 1 & 3 & 1 & 2 \end{pmatrix} \xrightarrow{R_3 - R_1} \begin{pmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 \end{pmatrix} \xrightarrow{R_3 - R_2} \begin{pmatrix} 1 & 2 & 0 & 1 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Two nonzero rows, so $\operatorname{rank} A = 2$; with $n = 4$ columns, $\operatorname{null} A = 4 - 2 = 2$. *Check.* Columns $3, 4$ are free, giving two independent kernel vectors, e.g. $(2, -1, 1, 0)^{\mathsf{T}}$ and $(1, -1, 0, 1)^{\mathsf{T}}$; one verifies $A\,(2, -1, 1, 0)^{\mathsf{T}} = 0$ and $A\,(1, -1, 0, 1)^{\mathsf{T}} = 0$. The count $\operatorname{rank} + \operatorname{null} = 2 + 2 = 4 = \dim \mathbb{Q}^4$ is exactly rank–nullity.

The reduction algorithm has a clean geometric reading: each row operation is an invertible change of the equations, so it slides b within the picture without moving the solution set. The pivots mark the directions A genuinely controls; the free columns are the slack.

Caution. The last-column pivot test decides *consistency*, not uniqueness. A system can be consistent yet have infinitely many solutions (free columns of A', as in the underdetermined example), and can be inconsistent regardless of how many free columns A' has. Keep the two columns of bookkeeping separate: a pivot in B' kills all solutions; a free column in A' multiplies the solutions. Also: over a ring that is not a field do not "divide" carelessly — type (iii) scaling requires the pivot entry to be a *unit*, which is automatic in a field but fails for matrices over a mere ring.

Remark 11.6.3 (Bridge to the abstract chapter). Theorem 11.6.11 is the matrix incarnation of the isomorphism criterion: A invertible $\iff$ the map $T = L_A$ is bijective $\iff \ker T = 0 \iff \operatorname{im} T = F^n$, the $\dim V = n$ case of rank–nullity. The factorization $A = E_1^{-1} \cdots E_k^{-1}$ says $\mathrm{GL}_n(F)$ is *generated by elementary matrices*, the computational shadow of the structure of GL_n studied later. Thus the algorithm of this section and the structure theory of §11.1–11.2 are two views of one object.

Permutations and cycle notation

A *permutation* of the index set $\{1,\dots,n\}$ is a bijection $p\colon \{1,\dots,n\}\to\{1,\dots,n\}$. The set of all such permutations is the symmetric group Sym_n (Artin writes S_n). The advantage of viewing a permutation as a *map* — rather than as a reordered list — is that two permutations compose as functions: the **product** qp means $q\circ p$, "first do p, then q."

Definition 11.6.14 (Cycle notation)**.** A **cycle** $(c_1\,c_2\,\cdots\,c_r)$ denotes the permutation that sends $c_1\mapsto c_2$, $c_2\mapsto c_3$, $\dots$, $c_{r-1}\mapsto c_r$, and $c_r\mapsto c_1$, fixing all unlisted indices. A 2-cycle is a **transposition**. Every permutation is a product of disjoint cycles; one omits 1-cycles (fixed points), and writes the identity as 1.

For example, Artin's permutation p with $p(1)=3$, $p(2)=5$, $p(3)=4$, $p(4)=1$, $p(5)=2$ has cycle form

$$p=(1\,3\,4)(2\,5).$$

Cycle notation is not unique: $(1\,3\,4)=(3\,4\,1)=(4\,1\,3)$, and disjoint cycles may be reordered, so $p=(2\,5)(1\,3\,4)$ as well.

Remark 11.6.4. Because $qp=q\circ p$ is read right-to-left, composing cycles takes practice. With $q=(1\,4\,5\,2)$ and $p=(1\,3\,4)(2\,5)$ one follows each index through p first, then q: $3\overset{p}{\mapsto}4\overset{q}{\mapsto}5$, so qp sends $3\mapsto5$; tracking all indices gives $qp=(1\,3\,5)$, while $pq=(2\,3\,4)$. Composition is *not* commutative.

Worked Example 11.6.15 (Multiplying permutations in cycle notation)**.** With $p=(1\,3\,4)(2\,5)$ and $q=(1\,4\,5\,2)$ in Sym_5, compute qp and confirm $pq\neq qp$.

Recognition. Product means compose right-to-left ($qp=q\circ p$); chase each index through p then through q.

Solution. Apply p then q to each index: $1\overset{p}{\mapsto}3\overset{q}{\mapsto}3$; $3\overset{p}{\mapsto}4\overset{q}{\mapsto}5$; $5\overset{p}{\mapsto}2\overset{q}{\mapsto}1$; and $2\overset{p}{\mapsto}5\overset{q}{\mapsto}2$, $4\overset{p}{\mapsto}1\overset{q}{\mapsto}4$ are fixed. So $qp=(1\,3\,5)$. Reversing the order, pq: $1\overset{q}{\mapsto}4\overset{p}{\mapsto}1$ fixed; $2\overset{q}{\mapsto}1\overset{p}{\mapsto}3$; $3\overset{q}{\mapsto}3\overset{p}{\mapsto}4$; $4\overset{q}{\mapsto}5\overset{p}{\mapsto}2$; so $pq=(2\,3\,4)$. *Check.* $qp=(1\,3\,5)$ moves 1, but $pq=(2\,3\,4)$ fixes 1; the two products differ, so Sym_5 is non-abelian.

The sign of a permutation

To attach a ±1 to a permutation we use its matrix.

Definition 11.6.16 (Permutation matrix)**.** The **permutation matrix** $P=P_p$ of $p\in\mathrm{Sym}_n$ is the matrix that permutes coordinates by p under left multiplication. In terms of the matrix units e_{ij} (a single 1 in position i,j),

$$P_p=\sum_{i=1}^{n}e_{p(i),\,i},$$

so P_p has a single 1 in each row and each column. Equivalently $P_p\,x$ moves the ith entry of x to position $p(i)$.

Proposition 11.6.17 (Permutation matrices, Artin 1.5.10)**.** *Let $p,q\in\mathrm{Sym}_n$ with matrices P,Q.*

(a) A matrix is a permutation matrix iff it has exactly one 1 *in each row and column and* 0 *elsewhere.*

(b) $\det P=\pm1$.

(c) $P_{pq}=P_pP_q$, so $p\mapsto P_p$ is a group homomorphism $\mathrm{Sym}_n\to\mathrm{GL}_n$.

Proof. Part (a) is immediate from $P_p=\sum_i e_{p(i),i}$ and the bijectivity of p. For (c), using $e_{ij}e_{k\ell}=\delta_{jk}e_{i\ell}$,

$$P_pP_q=\Big(\sum_i e_{p(i),i}\Big)\Big(\sum_j e_{q(j),j}\Big)=\sum_{i,j}\delta_{i,\,q(j)}\,e_{p(i),\,j}=\sum_j e_{p(q(j)),\,j}=P_{pq},$$

the surviving terms being those with $i=q(j)$. For (b): a transposition's matrix is an elementary row-swap matrix, with determinant -1; since every permutation is a product of transpositions, $\det P=(-1)^{(\#\text{ swaps})}=\pm1$ by multiplicativity of det (and part (c)). $\square$

Definition 11.6.18 (Sign)**.** The **sign** of p is $\operatorname{sgn}(p) = \det P_p \in \{+1, -1\}$. A permutation is **even** if $\operatorname{sgn}(p) = +1$ and **odd** if $\operatorname{sgn}(p) = -1$.

By Proposition 11.6.17(c) and multiplicativity of the determinant, sgn is a homomorphism: $\operatorname{sgn}(qp) = \operatorname{sgn}(q)\operatorname{sgn}(p)$. A transposition is odd ($\operatorname{sgn} = -1$), so if $p = \tau_1 \cdots \tau_k$ is any factorization into transpositions then $\operatorname{sgn}(p) = (-1)^k$; in particular the parity of k is an invariant of p, even though k itself is not. An r-cycle is a product of $r-1$ transpositions, $(c_1 \cdots c_r) = (c_1\, c_r) \cdots (c_1\, c_3)(c_1\, c_2)$, so sgn of an r-cycle is $(-1)^{r-1}$.

The sign can also be read from **inversions**: an inversion of p is a pair $i < j$ with $p(i) > p(j)$, and $\operatorname{sgn}(p) = (-1)^{\#\text{inversions}}$. (Each adjacent transposition changes the inversion count by ± 1, matching the row-swap computation of $\det P_p$.)

Worked Example 11.6.19 (Sign by three routes)**.** Compute $\operatorname{sgn}(p)$ for $p = (1\,3\,4)(2\,5) \in \mathrm{Sym}_5$ using transpositions, cycle lengths, and inversions.

Recognition. sgn is multiplicative; an r-cycle has sign $(-1)^{r-1}$; or count inversions of the one-line image.

Solution. Transpositions: $(1\,3\,4) = (1\,4)(1\,3)$ (two transpositions, even) and $(2\,5)$ is one transposition (odd), so $\operatorname{sgn}(p) = (+1)(-1) = -1$. *Cycle lengths:* a 3-cycle has sign $(-1)^2 = +1$, a 2-cycle has sign $(-1)^1 = -1$; product $= -1$. *Inversions:* the one-line image is $(p(1), \ldots, p(5)) = (3, 5, 4, 1, 2)$; counting pairs $i < j$ with $p(i) > p(j)$ gives 7 inversions, namely $(1,4), (1,5), (2,3), (2,4), (2,5), (3,4), (3,5)$, and $(-1)^7 = -1$. *Check.* All three routes give $\operatorname{sgn}(p) = -1$, so p is odd.

The four nonzero entries of the 4×4 permutation matrix for $q = (1\,4\,5\,2)$ restricted to $\{1, 2, 4, 5\}$ illustrate the "one 1 per row and column" pattern; the schematic below shows where the 1's sit for the 3-cycle $p = (1\,2\,3)$ (so $P = e_{21} + e_{32} + e_{13}$):

	col 1	col 2	col 3
row 1	0	0	1
row 2	1	0	0
row 3	0	1	0

The complete (Leibniz) expansion of the determinant

Expanding the determinant multilinearly across every row at once produces a closed formula summing over all permutations.

Theorem 11.6.20 (Complete expansion, Artin 1.6.4)**.** *For an $n \times n$ matrix $A = (a_{ij})$,*

$$\det A = \sum_{p \in \mathrm{Sym}_n} \operatorname{sgn}(p)\, a_{1,p(1)}\, a_{2,p(2)} \cdots a_{n,p(n)}.$$

Proof sketch. Write the ith row as $A_i = \sum_j a_{ij} e_j$ (here e_j is the jth standard row vector). Because det is linear in each row separately (Artin 1.4.7), expanding all n rows gives

$$\det A = \sum_{j_1, \ldots, j_n} a_{1 j_1} \cdots a_{n j_n}\, \det\big[e_{j_1}; \ldots; e_{j_n}\big],$$

a sum over all functions $i \mapsto j_i$. A determinant of standard basis rows vanishes when two rows coincide (alternating property), so only the choices where $i \mapsto j_i = p(i)$ is a *permutation* survive. For such a p, $\det[e_{p(1)}; \ldots; e_{p(n)}] = \det P_p^{\mathsf{T}} = \det P_p = \operatorname{sgn}(p)$. Collecting the surviving terms yields the stated formula. □

Remark 11.6.5 (Relation to the exterior-algebra determinant of §11.5). This is the same number produced by the top exterior power. If $V = \mathbb{F}^n$ has basis $e_1, \ldots, e_n$, then $\wedge^n(V)$ is 1-dimensional, spanned by $e_1 \wedge \cdots \wedge e_n$. Feeding the columns $A_1, \ldots, A_n$ of A into the universal alternating n-linear map gives

$$A_1 \wedge \cdots \wedge A_n = (\det A)\, e_1 \wedge \cdots \wedge e_n,$$

which defines $\det A$ intrinsically. Reordering basis wedges with the anticommutativity $e_i \wedge e_j = -e_j \wedge e_i$ produces exactly the sign $\operatorname{sgn}(p)$ on the term indexed by p, recovering Theorem 11.6.20. Thus "alternating n-linear, normalized to 1 on I" (Artin's defining properties 1.4.7) and "the coefficient on the top wedge" are two faces of one object.

For $n = 3$ the six permutations give Artin's expansion (1.6.5),

$$\det A = a_{11}a_{22}a_{33} + a_{12}a_{23}a_{31} + a_{13}a_{21}a_{32} - a_{11}a_{23}a_{32} - a_{12}a_{21}a_{33} - a_{13}a_{22}a_{31},$$

the three positive terms running down the left-to-right diagonals of the augmented block $[\,A \mid A\,]$ and the three negative terms down the right-to-left diagonals.

Caution. The diagonal ("Sarrus") mnemonic from the block $[\,A \mid A\,]$ works *only* for 3×3. For 4×4 and larger it is wrong — the complete expansion has $n!$ terms, not $2n$, and they do not line up along diagonals.

Cofactor (Laplace) expansion

For computation one rarely uses the $n!$-term formula directly; instead one expands along a single row or column.

Theorem 11.6.21 (Expansion by minors, Artin 1.6.1–1.6.2)**.** *Let A_{ij} be the $(n-1) \times (n-1)$ matrix obtained by deleting row i and column j. Then for any fixed row i or any fixed column j,*

$$\det A = \sum_{v=1}^{n} (-1)^{i+v} a_{iv} \det A_{iv} \qquad \textit{(along row } i\textit{)},$$

$$\det A = \sum_{v=1}^{n} (-1)^{v+j} a_{vj} \det A_{vj} \qquad \textit{(along column } j\textit{)}.$$

The signs $(-1)^{i+j}$ form a checkerboard pattern.

Proof sketch. Group the $n!$ terms of Theorem 11.6.20 by the value $v = p(i)$ in the chosen row i. Factoring out a_{iv} from each group, what remains is a signed sum over permutations of the remaining indices — precisely $(-1)^{i+v} \det A_{iv}$, the cofactor. (The sign $(-1)^{i+v}$ records the transpositions needed to move entry (i, v) into the corner before deleting its row and column.) Summing over v recovers $\det A$. Applying the result to A^{T}, whose determinant equals $\det A$, gives the column version. □

Remark 11.6.6. The i, j entry of the **cofactor matrix** is $\operatorname{cof}(A)_{ij} = (-1)^{i+j} \det A_{ji}$ (note the transposed indices: it is the (j, i) cofactor $(-1)^{j+i} \det A_{ji}$ in the sense of the proof above). Artin uses the cofactor matrix to write the inverse: $A^{-1} = \det(A)^{-1} \operatorname{cof}(A)$ when $\det A \neq 0$. For hand computation, expand along whichever row or column has the most zeros.

Worked Example 11.6.22 (A 3×3 determinant, two ways)**.** Compute $\det A$ for $A = \begin{pmatrix} 1 & 1 & 2 \\ 0 & 2 & 1 \\ 1 & 0 & 2 \end{pmatrix}$ by complete expansion and by cofactors.

Recognition. Both Theorem 11.6.20 and Theorem 11.6.21 apply; the row with a zero ($a_{21} = 0$) makes cofactor expansion along row 2 cheapest.

Solution. Complete expansion (1.6.5):

$$\det A = (1)(2)(2) + (1)(1)(1) + (2)(0)(0) - (1)(1)(0) - (1)(0)(2) - (2)(2)(1) = 4 + 1 + 0 - 0 - 0 - 4 = 1.$$

Cofactor along row 2 (signs $-, +, -$):

$$\det A = -0 \cdot \det \begin{pmatrix} 1 & 2 \\ 0 & 2 \end{pmatrix} + 2 \cdot \det \begin{pmatrix} 1 & 2 \\ 1 & 2 \end{pmatrix} - 1 \cdot \det \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} = 0 + 2(0) - 1(-1) = 1.$$

Check. Both methods give $\det A = 1$, so A is invertible over $\mathbb{Q}$ (indeed over $\mathbb{Z}$, since $\det = \pm 1$ would even give $A^{-1} \in \mathrm{M}_3(\mathbb{Z})$).

Worked Example 11.6.23 (The 3×3 Vandermonde determinant)**.** Show $\det V = (b-a)(c-a)(c-b)$ for $V = \begin{pmatrix} 1 & a & a^2 \\ 1 & b & b^2 \\ 1 & c & c^2 \end{pmatrix}$, and read off when the rows are dependent.

Recognition. Use cofactor expansion, or column operations followed by expansion; the answer must vanish exactly when two of a, b, c coincide (two equal rows).

Solution. Subtract row 1 from rows 2 and 3 (this leaves det unchanged) to get

$$\det V = \det \begin{pmatrix} 1 & a & a^2 \\ 0 & b-a & b^2-a^2 \\ 0 & c-a & c^2-a^2 \end{pmatrix} = \det \begin{pmatrix} b-a & b^2-a^2 \\ c-a & c^2-a^2 \end{pmatrix},$$

expanding along column 1. Factor $b^2 - a^2 = (b-a)(b+a)$ and $c^2 - a^2 = (c-a)(c+a)$, then pull $(b-a)$ from row 1 and $(c-a)$ from row 2:

$$\det V = (b-a)(c-a) \det \begin{pmatrix} 1 & b+a \\ 1 & c+a \end{pmatrix} = (b-a)(c-a)\big((c+a)-(b+a)\big) = (b-a)(c-a)(c-b).$$

Check. Setting $a = b$ makes the first factor 0 and indeed rows $1, 2$ of V coincide; the determinant vanishes exactly when two of a, b, c are equal, matching the alternating property of det.

Worked Example 11.6.24 (Sign from the complete expansion of a single term)**.** In a 4×4 matrix, the complete expansion contains the term $a_{1,2}a_{2,4}a_{3,1}a_{4,3}$. Determine its sign.

Recognition. By Theorem 11.6.20 the coefficient is $\operatorname{sgn}(p)$ where p is the permutation with $p(i)$ equal to the second index of $a_{i,\cdot}$.

Solution. The column indices give $p(1) = 2$, $p(2) = 4$, $p(3) = 1$, $p(4) = 3$, i.e. $p = (1\,2\,4\,3)$, a single 4-cycle. A 4-cycle is a product of 3 transpositions, so $\operatorname{sgn}(p) = (-1)^3 = -1$. (Inversion check on $(2, 4, 1, 3)$: pairs $(2,1), (4,1), (4,3)$ are inverted, 3 inversions, $(-1)^3 = -1$.) *Check.* Both the cycle-length rule and the inversion count give $\operatorname{sgn}(p) = -1$, so this term appears with a minus sign in $\det A$.

Remark 11.6.7. The complete expansion is mostly of theoretical value: with $n!$ terms it is impractical for large n, but it exhibits $\det A$ as a *polynomial* in the n^2 entries with coefficients ± 1. Hence if each $a_{ij}(t)$ is a differentiable (or polynomial, or continuous) function of a parameter t, so is $\det A(t)$ — a fact used repeatedly when A varies, e.g. in computing characteristic polynomials.

11.7 Eigenvalues, Characteristic Polynomials, and Triangular Form

Eigenvectors and invariant subspaces

Throughout, $T\colon V \to V$ is a linear operator on a finite-dimensional vector space over a field F, and A denotes its matrix with respect to some basis. The two main tools for analyzing T are invariant subspaces and eigenvectors.

Definition 11.7.1 (Invariant subspace, eigenvector, eigenvalue)**.** A subspace $W \subseteq V$ is **T-invariant** if $T(W) \subseteq W$; then T restricts to an operator $T|_W$ on W. A nonzero vector $v \in V$ is an **eigenvector** of T if

$$T(v) = \lambda v \qquad \text{for some scalar } \lambda \in F,$$

and the scalar λ is the **eigenvalue** attached to v. A nonzero column vector X is an eigenvector of a square matrix A when $AX = \lambda X$, i.e. AX is a scalar multiple of X.

An eigenvector with eigenvalue 1 is a fixed vector; one with eigenvalue 0 is a nonzero element of the nullspace. Over $V = F^n$, a nonzero v is an eigenvector exactly when v and $T(v)$ are parallel. The link to invariant subspaces is immediate: the line Fv spanned by an eigenvector is T-invariant, because $T(cv) = c\lambda v \in Fv$; conversely a T-invariant line is spanned by an eigenvector. *An eigenvector is precisely a basis of a one-dimensional invariant subspace.*

If W is T-invariant and we extend a basis $(w_1, \dots, w_k)$ of W to a basis B of V, the matrix of T acquires the block form

$$[T]_B = \begin{pmatrix} A & B' \\ 0 & D \end{pmatrix},$$

where A is the $k \times k$ matrix of $T|_W$. The case $k = 1$ (an eigenvector v_1 placed first) gives the first column $(\lambda, 0, \dots, 0)^{\mathsf{T}}$.

Proposition 11.7.2 (Similar matrices share eigenvalues)**.** *If $A' = P^{-1}AP$ for an invertible P, then A and A' have the same eigenvalues.*

Proof. Similar matrices represent the same operator T in different bases, and the eigenvalues are an intrinsic feature of T: if $AX = \lambda X$ then $A'(P^{-1}X) = P^{-1}APP^{-1}X = P^{-1}(AX) = \lambda(P^{-1}X)$, and $P^{-1}X \neq 0$. So every eigenvalue of A is one of A', and symmetrically. □

Proposition 11.7.3 (Diagonal matrix = basis of eigenvectors)**.** *The matrix of T in a basis $B = (v_1, \dots, v_n)$ is diagonal if and only if each v_j is an eigenvector. Equivalently, $A \in \mathrm{M}_n(F)$ is similar to a diagonal matrix iff F^n has a basis of eigenvectors of A.*

Proof. If $T(v_j) = \lambda_j v_j$ for all j, the jth column of $[T]_B$ is λ_j in row j and 0 elsewhere, so $[T]_B = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$. Conversely, if $[T]_B$ is diagonal with entries λ_j, then reading off column j gives $T(v_j) = \lambda_j v_j$, so each v_j is an eigenvector. The matrix statement is the same fact applied to $T =$ left multiplication by A, with $P = [B]$ the change-of-basis matrix. □

A linear operator on a *real* space need not have any eigenvector: a rotation R_θ of $\mathbb{R}^2$ through $\theta \neq 0, \pi$ carries no nonzero vector to a parallel one. We will see below that over $\mathbb{C}$ the situation is far better.

The characteristic polynomial

To find eigenvectors one first finds eigenvalues. Rewrite $T(v) = \lambda v$ as $(\lambda I - T)(v) = 0$: a nonzero v is an eigenvector with eigenvalue λ iff v lies in the kernel of $\lambda I - T$. Hence λ is an eigenvalue iff $\lambda I - T$ is singular, iff $\det(\lambda I - A) = 0$. Replacing the unknown λ by an indeterminate t turns this into a polynomial condition.

Definition 11.7.4 (Characteristic polynomial)**.** The **characteristic polynomial** of T (or of its matrix A) is

$$p(t) = \det(tI - A).$$

Proposition 11.7.5 (Basic facts)**.** *Let $p(t) = \det(tI - A)$ for an $n \times n$ matrix A.*

(a) $p(t)$ is a monic polynomial of degree n, and the eigenvalues of T are exactly the roots of $p(t)$ in F.

(b) $p(t)$ does not depend on the choice of basis; it is an invariant of T.

(c) $p(t) = t^n - (\operatorname{tr} A)\, t^{n-1} + \cdots + (-1)^n \det A$, where $\operatorname{tr} A$ is the sum of the diagonal entries.

(d) If A is upper or lower triangular with diagonal entries $a_{11}, \dots, a_{nn}$, then $p(t) = (t - a_{11}) \cdots (t - a_{nn})$; the diagonal entries are the eigenvalues.

Proof. (a) The complete expansion of $\det(tI - A)$ is a sum of products, one entry from each row and column; the leading term comes from the diagonal $(t - a_{11}) \cdots (t - a_{nn})$, giving degree n and leading coefficient 1. The eigenvalue criterion is the singularity computation above together with $\det(\lambda I - A) = p(\lambda)$.

(b) A change of basis replaces A by $A' = P^{-1}AP$, and

$$tI - A' = tI - P^{-1}AP = P^{-1}(tI - A)P,$$

so $\det(tI - A') = \det(P^{-1}) \det(tI - A) \det(P) = \det(tI - A)$.

(c) The t^n and t^{n-1} terms of the expansion come only from the diagonal product $(t - a_{11}) \cdots (t - a_{nn})$, whose expansion contributes $t^n - (a_{11} + \cdots + a_{nn})t^{n-1} + \cdots$; the constant term is $p(0) = \det(-A) = (-1)^n \det A$.

(d) If A is triangular, so is $tI - A$, with diagonal entries $t - a_{ii}$, and the determinant of a triangular matrix is the product of its diagonal entries. □

For a 2×2 matrix $A=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ this reads $p(t)=t^2-(\operatorname{tr}A)\,t+\det A$. Over $\mathbb{C}$ we get existence of eigenvalues for free:

Corollary 11.7.6 (Existence over $\mathbb{C}$; trace and determinant)**.** *Let T act on a finite-dimensional space $V\neq\{0\}$.*

(a) T has at most $n=\dim V$ eigenvalues.

(b) If $F=\mathbb{C}$, then T has at least one eigenvalue, hence at least one eigenvector.

(c) If $\lambda_1,\dots,\lambda_n$ are the eigenvalues of a complex $n\times n$ matrix A (with multiplicity), then $\det A=\lambda_1\cdots\lambda_n$ and $\operatorname{tr}A=\lambda_1+\cdots+\lambda_n$.

Proof. (a) Eigenvalues are roots of $p(t)$, which has degree n, hence at most n roots. (b) By the Fundamental Theorem of Algebra every complex polynomial of positive degree has a root, so $p(t)$ has a root $\lambda\in\mathbb{C}$, and $\lambda I-A$ is then singular. (c) Over $\mathbb{C}$, $p(t)=(t-\lambda_1)\cdots(t-\lambda_n)$; comparing with the form in Proposition 11.7.5(c), the coefficient of t^{n-1} gives $\operatorname{tr}A=\sum\lambda_i$ and the constant term gives $(-1)^n\det A=(-1)^n\prod\lambda_i$. □

Worked Example 11.7.7 (A diagonalizable 2×2 matrix)**.** Diagonalize $A=\left(\begin{smallmatrix} 3 & 2 \\ 1 & 4 \end{smallmatrix}\right)$ over $\mathbb{R}$.

Recognition. Two distinct eigenvalues will force a basis of eigenvectors (Proposition 11.7.3); compute $p(t)$, then solve $(\lambda I-A)X=0$.

Solution. $p(t)=t^2-(\operatorname{tr}A)t+\det A=t^2-7t+10=(t-5)(t-2)$, so the eigenvalues are 5 and 2. For $\lambda=5$: $(5I-A)=\left(\begin{smallmatrix} 2 & -2 \\ -1 & 1 \end{smallmatrix}\right)$ kills $v_1=(1,1)^{\mathsf{T}}$. For $\lambda=2$: $(2I-A)=\left(\begin{smallmatrix} -1 & -2 \\ -1 & -2 \end{smallmatrix}\right)$ kills $v_2=(2,-1)^{\mathsf{T}}$. With $P=[\,v_1\ v_2\,]=\left(\begin{smallmatrix} 1 & 2 \\ 1 & -1 \end{smallmatrix}\right)$ we get $P^{-1}AP=\left(\begin{smallmatrix} 5 & 0 \\ 0 & 2 \end{smallmatrix}\right)$. *Check.* $Av_1=(5,5)^{\mathsf{T}}=5v_1$ and $Av_2=(4,-2)^{\mathsf{T}}=2v_2$; also $\operatorname{tr}A=7=5+2$ and $\det A=10=5\cdot 2$, matching Corollary 11.7.6(c).

Worked Example 11.7.8 (A non-diagonalizable 2×2 matrix)**.** Show the shear $A=\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ is not diagonalizable over any field.

Recognition. A is triangular, so its eigenvalues are read off the diagonal (Proposition 11.7.5(d)); diagonalizability needs a full basis of eigenvectors (Proposition 11.7.3).

Solution. Here $p(t)=(t-1)^2$, so the only eigenvalue is $\lambda=1$ (a double root). The eigenvectors solve $(I-A)X=0$, i.e. $\left(\begin{smallmatrix} 0 & -1 \\ 0 & 0 \end{smallmatrix}\right)X=0$, forcing the second coordinate to vanish: the eigenspace is the single line $F\cdot(1,0)^{\mathsf{T}}$, dimension 1. There is no basis of eigenvectors, so A is not similar to a diagonal matrix. *Check.* If $A=P\,\mathrm{diag}(1,1)P^{-1}$ held, then $A=I$, which is false. So a repeated eigenvalue with a deficient eigenspace genuinely blocks diagonalization.

Worked Example 11.7.9 (Eigenvalues of a triangular 3×3 matrix)**.** Read off the eigenvalues and find an eigenvector of $A=\left(\begin{smallmatrix} 2 & 5 & -1 \\ 0 & 3 & 4 \\ 0 & 0 & 2 \end{smallmatrix}\right)$.

Recognition. For a triangular matrix the diagonal entries are the eigenvalues, with no determinant expansion needed (Proposition 11.7.5(d)).

Solution. The diagonal gives $p(t)=(t-2)^2(t-3)$, so the eigenvalues are 2 (multiplicity 2) and 3. For $\lambda=2$, solve $(2I-A)X=0$: the first standard basis vector $e_1=(1,0,0)^{\mathsf{T}}$ works since the first column of A is $(2,0,0)^{\mathsf{T}}=2e_1$. *Check.* $Ae_1=(2,0,0)^{\mathsf{T}}=2e_1$, and $\operatorname{tr}A=2+3+2=7=2+2+3$ matches the eigenvalue sum.

Triangular and diagonal forms

Theorem 11.7.10 (Triangularization over $\mathbb{C}$)**.** *Let T be a linear operator on a finite-dimensional complex vector space V. Then there is a basis of V in which the matrix of T is upper triangular. Equivalently, every complex $n\times n$ matrix A is similar to an upper triangular matrix: there is $P\in\mathrm{GL}_n(\mathbb{C})$ with $P^{-1}AP$ upper triangular.*

Proof. Induct on $n = \dim V$, the case $n = 1$ being trivial. By Corollary 11.7.6(b), A has an eigenvector v_1 with eigenvalue λ. Extend to a basis $(v_1, \dots, v_n)$; in this basis (equivalently, after conjugating A by $P = [\, v_1 \ \cdots \ v_n \,]$) the matrix takes the block form

$$A' = P^{-1}AP = \begin{pmatrix} \lambda & * \\ 0 & D \end{pmatrix},$$

where D is $(n-1) \times (n-1)$ (the first column is $(\lambda, 0, \dots, 0)^{\mathsf{T}}$ because $Av_1 = \lambda v_1$). By induction there is $Q \in \mathrm{GL}_{n-1}(\mathbb{C})$ with $Q^{-1}DQ$ upper triangular. Set $Q_1 = \left(\begin{smallmatrix} 1 & 0 \\ 0 & Q \end{smallmatrix}\right)$. Then

$$Q_1^{-1}A'Q_1 = \begin{pmatrix} \lambda & * \\ 0 & Q^{-1}DQ \end{pmatrix}$$

is upper triangular, and it equals $(PQ_1)^{-1}A(PQ_1)$. Listing the basis in reverse order yields a lower-triangular form instead. □

Remark 11.7.1. The only feature of $\mathbb{C}$ used is that the characteristic polynomial *splits* into linear factors. Hence the same induction proves: over any field F, if the characteristic polynomial of A is a product of linear factors in F, then A is similar over F to an upper (or lower) triangular matrix. In the induction step one checks that the characteristic polynomial of the block D is $p(t)/(t-\lambda)$, so the splitting hypothesis passes from A to D.

The triangular entries on the diagonal are the eigenvalues (with multiplicity), so triangular form already exhibits all of them at once. We now ask when we can go further and reach a *diagonal* form.

Proposition 11.7.11 (Distinct eigenvalues give independence)**.** *Eigenvectors $v_1, \dots, v_r$ of T belonging to distinct eigenvalues $\lambda_1, \dots, \lambda_r$ are linearly independent.*

Proof. Induct on r; the case $r = 1$ holds because an eigenvector is nonzero. Suppose $a_1v_1 + \cdots + a_rv_r = 0$. Applying T gives a second relation $a_1\lambda_1v_1 + \cdots + a_r\lambda_rv_r = 0$. Multiply the first relation by λ_r and subtract the second:

$$a_1(\lambda_r - \lambda_1)v_1 + \cdots + a_{r-1}(\lambda_r - \lambda_{r-1})v_{r-1} = 0.$$

By induction $v_1, \dots, v_{r-1}$ are independent, so each $a_i(\lambda_r - \lambda_i) = 0$ for $i < r$; since the λ_i are distinct, $\lambda_r - \lambda_i \neq 0$, forcing $a_1 = \cdots = a_{r-1} = 0$. The original relation collapses to $a_rv_r = 0$, and $v_r \neq 0$ gives $a_r = 0$. □

Theorem 11.7.12 (Diagonalizability criterion)**.** *Let T act on an n-dimensional space V over F.*

(a) T is diagonalizable iff V has a basis of eigenvectors of T.

(b) If the characteristic polynomial of T has n distinct roots in F, then T is diagonalizable.

Proof. (a) is Proposition 11.7.3. For (b): the n distinct roots give n eigenvectors, one per eigenvalue, which are independent by Proposition 11.7.11; n independent vectors in an n-dimensional space form a basis, so (a) applies. □

Caution. Distinct eigenvalues are *sufficient* but not *necessary* for diagonalizability: the identity I_n has the single eigenvalue 1 yet is already diagonal. The sharp statement (over a field where the characteristic polynomial splits) is that T is diagonalizable iff its **minimal polynomial** is a product of *distinct* linear factors. Conversely, the shear $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ has minimal polynomial $(t-1)^2$, with a repeated factor, and is not diagonalizable.

Cayley–Hamilton

Theorem 11.7.13 (Cayley–Hamilton)**.** *Every square matrix satisfies its own characteristic polynomial: if $p(t) = \det(tI - A)$, then $p(A) = 0$.*

Proof via triangularization. Work over $\mathbb{C}$ (the general case follows because $p(A) = 0$ is a system of polynomial identities in the entries of A, and the complex case implies it formally over any field). By Theorem 11.7.10 write $A = PUP^{-1}$ with U upper triangular, diagonal entries $\lambda_1, \dots, \lambda_n$; these are the eigenvalues, and $p(t) = (t - \lambda_1) \cdots (t - \lambda_n)$. Since $p(A) = P\,p(U)\,P^{-1}$, it suffices to show $p(U) = (U - \lambda_1 I) \cdots (U - \lambda_n I) = 0$.

Let $e_1, \dots, e_n$ be the standard basis and $W_k = \mathrm{Span}(e_1, \dots, e_k)$. Because U is upper triangular, $U(W_k) \subseteq W_k$, and moreover $(U - \lambda_k I)$ sends W_k into W_{k-1} (the kth column of $U - \lambda_k I$ has a 0 in position k, so $Ue_k - \lambda_k e_k \in W_{k-1}$). Hence the product $(U - \lambda_1 I) \cdots (U - \lambda_n I)$, applied right-to-left, drives $W_n \to W_{n-1} \to \cdots \to W_0 = \{0\}$. Therefore $p(U) = 0$, and $p(A) = 0$. □

Remark 11.7.2 (The continuity / diagonalizable-dense argument). Here is a second proof over $\mathbb{C}$. Matrices with n distinct eigenvalues are *dense* in $\mathrm{M}_n(\mathbb{C})$: the discriminant of the characteristic polynomial is a polynomial in the entries that is not identically zero, so its non-vanishing locus is dense. For such a diagonalizable A, Cayley–Hamilton is immediate — in an eigenbasis A is $\mathrm{diag}(\lambda_1, \dots, \lambda_n)$ and $p(A) = \mathrm{diag}(p(\lambda_1), \dots, p(\lambda_n)) = 0$ since each λ_i is a root of p. The map $A \mapsto p_A(A)$ is a polynomial (hence continuous) function of the entries of A, and it vanishes on the dense diagonalizable set, so it vanishes everywhere.

Worked Example 11.7.14 (Cayley–Hamilton on a 2×2 matrix)**.** Verify $p(A) = 0$ for $A = \left(\begin{smallmatrix} 3 & 2 \\ 1 & 4 \end{smallmatrix}\right)$, and use it to express A^{-1}.

Recognition. By Theorem 11.7.13, A kills $p(t) = t^2 - 7t + 10$; the constant term lets us solve for A^{-1}.

Solution. $A^2 = \left(\begin{smallmatrix} 11 & 14 \\ 7 & 18 \end{smallmatrix}\right)$, so $A^2 - 7A + 10I = \left(\begin{smallmatrix} 11 & 14 \\ 7 & 18 \end{smallmatrix}\right) - \left(\begin{smallmatrix} 21 & 14 \\ 7 & 28 \end{smallmatrix}\right) + \left(\begin{smallmatrix} 10 & 0 \\ 0 & 10 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 0 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. From $A^2 - 7A + 10I = 0$ we get $A(7I - A) = 10I$, hence $A^{-1} = \frac{1}{10}(7I - A) = \frac{1}{10}\left(\begin{smallmatrix} 4 & -2 \\ -1 & 3 \end{smallmatrix}\right)$. *Check.* $A \cdot \frac{1}{10}\left(\begin{smallmatrix} 4 & -2 \\ -1 & 3 \end{smallmatrix}\right) = \frac{1}{10}\left(\begin{smallmatrix} 10 & 0 \\ 0 & 10 \end{smallmatrix}\right) = I$. Correct.

The triangularization proof has a clean geometric skeleton: a complete flag $0 = W_0 \subset W_1 \subset \cdots \subset W_n = V$ adapted to T, with each factor $(T - \lambda_k I)$ stepping down one rung.

$$
\begin{array}{ll}
W_n = V & T(W_k) \subseteq W_k \text{ (invariant flag)} \\
\uparrow & \\
\vdots & (T - \lambda_k I)(W_k) \subseteq W_{k-1} \\
\uparrow & \\
W_2 & \text{so } (T - \lambda_1 I) \cdots (T - \lambda_n I) \\
\uparrow & \\
W_1 & \text{maps } V \to W_{n-1} \to \cdots \to \{0\} \\
\uparrow & \\
W_0 = \{0\} & \Rightarrow\ p(T) = 0
\end{array}
$$

11.8 Orthogonal Matrices, Rotations, and the Matrix Exponential

Orthogonal matrices and rotations

Throughout this section the field of scalars is $\mathbb{R}$, and vectors are real column vectors. The dot product of $X = (x_1, \dots, x_n)^{\mathsf{T}}$ and $Y = (y_1, \dots, y_n)^{\mathsf{T}}$ in $\mathbb{R}^n$ is

$$(X \cdot Y) = x_1 y_1 + \cdots + x_n y_n = X^{\mathsf{T}} Y,$$

the matrix product of a row and a column. The *length* of X is $|X|$ with $|X|^2 = (X \cdot X) = X^{\mathsf{T}} X$, and X is *orthogonal* to Y, written $X \perp Y$, when $(X \cdot Y) = 0$. The dot product is what an orthogonal matrix is built to protect.

Definition 11.8.1 (Orthogonal matrix)**.** A real $n \times n$ matrix A is *orthogonal* if $A^{\mathsf{T}} A = I$; equivalently A is invertible with $A^{-1} = A^{\mathsf{T}}$. The orthogonal matrices form a subgroup $\mathrm{O}(n) \leq \mathrm{GL}_n(\mathbb{R})$, the *orthogonal group*; those with $\det = 1$ form the *special orthogonal group* $\mathrm{SO}(n) \trianglelefteq \mathrm{O}(n)$, of index 2.

Lemma 11.8.2 (Columns are orthonormal)**.** *A matrix A is orthogonal if and only if its columns $A_1, \dots, A_n$ form an orthonormal basis of $\mathbb{R}^n$, i.e. $(A_i \cdot A_j) = \delta_{ij}$.*

Proof. The (i,j) entry of $A^{\mathsf{T}}A$ is $A_i^{\mathsf{T}}A_j = (A_i \cdot A_j)$. Thus $A^{\mathsf{T}}A = I$ if and only if $(A_i \cdot A_j) = \delta_{ij}$ for all i, j, which says exactly that the columns are mutually orthogonal unit vectors. □

Remark 11.8.1. Two consequences are immediate. First, $\det(A^{\mathsf{T}}A) = (\det A)^2 = \det I = 1$, so $\det A = \pm 1$ for every orthogonal A; this is what cuts $\mathrm{O}(n)$ into the two cosets $\mathrm{SO}(n)$ and its complement. Second, a linear operator T on $\mathbb{R}^n$ preserves the dot product (a so-called *orthogonal operator*) if and only if its standard matrix A is orthogonal, because

$$(TX \cdot TY) = (AX)^{\mathsf{T}}(AY) = X^{\mathsf{T}}(A^{\mathsf{T}}A)Y,$$

and this equals $X^{\mathsf{T}}Y = (X \cdot Y)$ for all X, Y exactly when $A^{\mathsf{T}}A = I$. Preserving the dot product is the same as preserving all lengths, since $(X \cdot Y)$ is recovered from lengths by polarization.

The 2×2 case: $\mathrm{SO}(2)$ and $\mathrm{O}(2)$

In the plane the orthogonal group splits cleanly into rotations and reflections, and the determinant is the label that tells them apart.

Theorem 11.8.3 (Classification of 2×2 orthogonal matrices)**.** *Let $A \in \mathrm{O}(2)$.*

1. *If $\det A = 1$, then $A = R_\theta = \begin{pmatrix} c & -s \\ s & c \end{pmatrix}$ with $c = \cos\theta$, $s = \sin\theta$, for some angle θ. This is counterclockwise rotation through θ; these matrices are $\mathrm{SO}(2)$.*
2. *If $\det A = -1$, then $A = \begin{pmatrix} c & s \\ s & -c \end{pmatrix}$. Such an A is the reflection of the plane across the line through the origin making angle $\theta/2$ with the x-axis.*

Proof. The first column of A is a unit vector, so it equals $(c, s)^{\mathsf{T}} = (\cos\theta, \sin\theta)^{\mathsf{T}}$ for some θ. The second column is a unit vector orthogonal to the first, and in $\mathbb{R}^2$ there are exactly two such: $(-s, c)^{\mathsf{T}}$ and $(s, -c)^{\mathsf{T}}$. The first choice gives R_θ, with $\det R_\theta = c^2 + s^2 = 1$; the second gives $\begin{pmatrix} c & s \\ s & -c \end{pmatrix}$, with determinant $-c^2 - s^2 = -1$. This exhausts $\mathrm{O}(2)$ and separates the two cases by the sign of the determinant.

For the rotation, $R_\theta(1,0)^{\mathsf{T}} = (c, s)^{\mathsf{T}}$ and $R_\theta(0,1)^{\mathsf{T}} = (-s, c)^{\mathsf{T}}$ are the standard basis turned counterclockwise by θ. For the reflection $S = \begin{pmatrix} c & s \\ s & -c \end{pmatrix}$ the characteristic polynomial is $t^2 - 1$, so the eigenvalues are $+1$ and -1 with orthogonal eigenvectors; writing a unit vector as $(\cos\alpha, \sin\alpha)^{\mathsf{T}}$ one finds $S(\cos\alpha, \sin\alpha)^{\mathsf{T}} = (\cos(\theta - \alpha), \sin(\theta - \alpha))^{\mathsf{T}}$, which is fixed exactly when $\alpha = \theta/2$. So S fixes the line at angle $\theta/2$ and negates its perpendicular: a reflection across that line. □

Remark 11.8.2. The map $\theta \mapsto R_\theta$ is a homomorphism $\mathbb{R} \to \mathrm{SO}(2)$ with $R_\theta R_\phi = R_{\theta+\phi}$ and kernel $2\pi\mathbb{Z}$, so $\mathrm{SO}(2) \cong \mathbb{R}/2\pi\mathbb{Z}$ is the circle group: rotations add their angles. A product of two reflections has determinant $(-1)(-1) = 1$, hence is a rotation; this is the algebra behind "two mirrors make a turn."

Worked Example 11.8.4 (Reading a 2×2 orthogonal matrix)**.** Classify $A = \frac{1}{2}\begin{pmatrix} 1 & -\sqrt{3} \\ \sqrt{3} & 1 \end{pmatrix}$ and $B = \frac{1}{2}\begin{pmatrix} 1 & \sqrt{3} \\ \sqrt{3} & -1 \end{pmatrix}$.

Recognition. Check det: $+1$ means a rotation R_θ (read θ off $\cos\theta, \sin\theta$); -1 means a reflection (fixed line at angle $\theta/2$).

Solution. For A, $\det A = \frac{1}{4}(1 + 3) = 1$, so $A = R_\theta$ with $\cos\theta = \frac{1}{2}$, $\sin\theta = \frac{\sqrt{3}}{2}$, giving $\theta = 60°$: rotation by $60°$. For B, $\det B = \frac{1}{4}(-1 - 3) = -1$, a reflection; here $\cos\theta = \frac{1}{2}$, $\sin\theta = \frac{\sqrt{3}}{2}$, so $\theta = 60°$ and the mirror line sits at $\theta/2 = 30°$ to the x-axis. Check: $A^{\mathsf{T}}A = I$ since the columns are orthonormal, and $B^2 = I$ as every reflection squares to the identity.

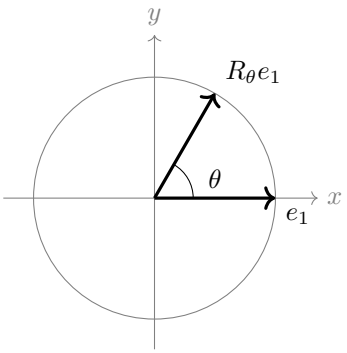


Figure 11.1: R_θ sends $e_1 = (1,0)^\mathsf{T}$ to $(\cos\theta, \sin\theta)^\mathsf{T}$ on the unit circle, turning the plane counterclockwise through θ.

Worked Example 11.8.5 (Composing two reflections is a rotation)**.** Let F_0 be reflection across the x-axis and F_β be reflection across the line at angle β. Show $F_\beta F_0$ is a rotation and find its angle.

Recognition. Each reflection has $\det = -1$, so the product has $\det = +1$ and lies in SO(2); multiply the matrices.

Solution. With $c = \cos 2\beta$, $s = \sin 2\beta$ the reflection matrices are $F_0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$ and $F_\beta = \begin{pmatrix} c & s \\ s & -c \end{pmatrix}$. Then

$$F_\beta F_0 = \begin{pmatrix} c & s \\ s & -c \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} c & -s \\ s & c \end{pmatrix} = R_{2\beta}.$$

So the composite is rotation by 2β, twice the angle between the mirrors. Check: $\det(F_\beta F_0) = (-1)(-1) = 1$ and $\operatorname{tr} = 2\cos 2\beta = 2c$, consistent with $R_{2\beta}$.

Rotations of $\mathbb{R}^3$ and Euler's theorem

A rotation of $\mathbb{R}^3$ should fix an axis and spin the perpendicular plane. Artin makes this the definition, then proves it coincides with SO(3).

Definition 11.8.6 (Rotation of $\mathbb{R}^3$)**.** A *rotation* of $\mathbb{R}^3$ about the origin is a linear operator ρ that fixes a unit vector u (a *pole*) and rotates the 2-dimensional subspace $W = u^\perp$. The line $\mathbb{R}u$ is the *axis*. With $u = e_1$ and an orthonormal basis (e_2, e_3) of W, the matrix has the block form

$$M = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{pmatrix},$$

whose lower-right 2×2 block is the planar rotation R_θ. The pair (u, θ) is the *spin*; note (u, θ) and $(-u, -\theta)$ give the same rotation.

Lemma 11.8.7 (A determinant-one orthogonal 3×3 matrix has eigenvalue 1)**.** *If $M \in \mathrm{SO}(3)$ then 1 is an eigenvalue of M.*

Proof. It suffices to show $\det(M - I) = 0$. For 3×3 matrices $\det(-B) = (-1)^3 \det B = -\det B$, so $\det(I - M) = -\det(M - I)$. Using $\det M = 1$ and $M^\mathsf{T} M = I$,

$$\det(M - I) = \det(M - I)^\mathsf{T} = \det M \cdot \det(M - I)^\mathsf{T} = \det\big(M(M^\mathsf{T} - I)\big) = \det(I - M).$$

Hence $\det(M - I) = \det(I - M) = -\det(M - I)$, forcing $\det(M - I) = 0$. So $M - I$ is singular and 1 is an eigenvalue, with a unit eigenvector u: a candidate pole. □

Theorem 11.8.8 (Euler's theorem)**.** *The 3×3 rotation matrices are exactly the orthogonal 3×3 matrices of determinant 1; that is, the rotations of $\mathbb{R}^3$ are precisely the elements of* SO(3).

Proof. ($\Rightarrow$) If ρ is a rotation with spin (u,θ), build an orthonormal basis $\mathcal{B}$ by appending to u an orthonormal basis of $W = u^{\perp}$. In this basis ρ has the block matrix M' above, which is orthogonal with $\det M' = \det R_\theta = 1$. The change-of-basis matrix $P = [\mathcal{B}]$ has orthonormal columns, so P is orthogonal, and $M = PM'P^{-1}$ is therefore orthogonal with $\det M = \det M' = 1$.

($\Leftarrow$) Conversely let $M \in \mathrm{SO}(3)$ and let T be multiplication by M. By the lemma there is a unit eigenvector u with $Tu = u$. Let $W = u^{\perp}$, a 2-dimensional space. Since T is orthogonal it preserves the dot product, so it sends W to W: for $w \in W$, $(Tw \cdot u) = (Tw \cdot Tu) = (w \cdot u) = 0$. The restriction $T|_W$ is again orthogonal in dimension 2, hence by the planar classification it is a rotation or a reflection. A reflection on W has $\det = -1$, and combined with $Tu = u$ would give $\det M = -1$, contradiction. So $T|_W$ is a rotation: T fixes u and rotates $W = u^{\perp}$, which is exactly a rotation of $\mathbb{R}^3$. □

Corollary 11.8.9 (Trace gives the angle; composites are rotations)**.** *If $M \in \mathrm{SO}(3)$ represents the rotation with spin (u,θ), then*

$$\operatorname{tr} M = 1 + 2\cos\theta.$$

Moreover the composition of any two rotations of $\mathbb{R}^3$ is again a rotation about some axis.

Proof. Choose an orthonormal basis (u, v_2, v_3); in it M is similar to the block matrix M', whose trace is $1 + \cos\theta + \cos\theta = 1 + 2\cos\theta$. Trace is similarity-invariant, so $\operatorname{tr} M = 1 + 2\cos\theta$. For the second statement, $\mathrm{SO}(3)$ is a group, so a product of two of its elements is again in $\mathrm{SO}(3)$, hence a rotation by Euler's theorem. (Geometrically this is not at all obvious: two spins about different axes compose to a single spin about a third.) □

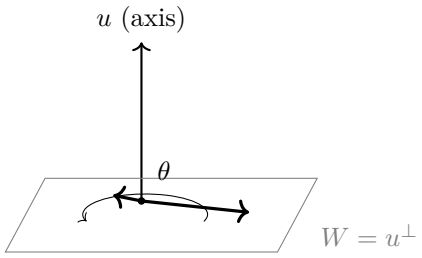

Figure 11.2: A rotation of $\mathbb{R}^3$ fixes the axis $\mathbb{R}u$ pointwise and spins the perpendicular plane $W = u^{\perp}$ through the angle θ (right-hand rule, viewed from the head of u).

Worked Example 11.8.10 (Axis and angle of a 3×3 rotation)**.** Let $M = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$. Confirm $M \in \mathrm{SO}(3)$, then find its axis and angle.

Recognition. Verify $M^{\mathsf{T}}M = I$ and $\det M = 1$; the axis is the $+1$-eigenvector, and θ comes from $\operatorname{tr} M = 1 + 2\cos\theta$.

Solution. The columns are e_2, e_3, e_1, an orthonormal basis, so $M^{\mathsf{T}}M = I$; this is an even permutation (a 3-cycle), so $\det M = 1$ and $M \in \mathrm{SO}(3)$. For the axis solve $Mu = u$: the system makes all coordinates equal, so $u = \frac{1}{\sqrt{3}}(1,1,1)^{\mathsf{T}}$. For the angle, $\operatorname{tr} M = 0 = 1 + 2\cos\theta$, so $\cos\theta = -\frac{1}{2}$ and $\theta = 120^\circ$. Check: M cyclically permutes $e_1 \to e_2 \to e_3 \to e_1$, and $M^3 = I$, consistent with a 120° turn about the main diagonal $(1,1,1)$.

Worked Example 11.8.11 (Reconstructing a rotation matrix from spin)**.** Find the matrix of the rotation about $u = e_3 = (0,0,1)^{\mathsf{T}}$ through $\theta = 90^\circ$, and verify the trace formula.

Recognition. The axis is e_3, so the fixed direction is the third coordinate; put the planar rotation R_{90° in the top-left 2×2 block acting on e_1, e_2.

Solution. With $\cos 90^\circ = 0$, $\sin 90^\circ = 1$,

$$M = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Indeed $Me_3 = e_3$ and the upper-left block rotates the xy-plane by $90°$. Check: $\det M = 1$ and $\operatorname{tr} M = 0 + 0 + 1 = 1 = 1 + 2\cos 90°$, since $\cos 90° = 0$. Also $M^4 = I$, as a quarter turn must satisfy.

Worked Example 11.8.12 (Recovering the angle but not the axis sign)**.** A matrix $M \in \mathrm{SO}(3)$ has $\operatorname{tr} M = 2$. What is its rotation angle, and why is the axis not pinned down by the trace alone?

Recognition. Use $\operatorname{tr} M = 1 + 2\cos\theta$ to solve for $\cos\theta$; remember the spin (u, θ) equals $(-u, -\theta)$.

Solution. $2 = 1 + 2\cos\theta$ gives $\cos\theta = \frac{1}{2}$, so $\theta = \pm 60°$. The trace is a similarity invariant and depends only on $\cos\theta$, so it cannot distinguish θ from $-\theta$ nor select between the two poles $\pm u$; the unsigned angle $60°$ is all the trace sees. Check: rotations by $+60°$ about u and by $-60°$ about u (equivalently $+60°$ about $-u$) both have trace 2 but are inverse to each other, confirming the trace alone is blind to orientation. To fix the axis one solves $Mu = u$.

Caution. The trace gives only $\cos\theta$, hence the angle up to sign. Orthogonality alone is weaker still: $\det = -1$ orthogonal matrices (improper rotations, reflections, rotary reflections) are *not* rotations. Always check $\det = +1$ before invoking Euler's theorem, and find the axis by solving $(M - I)u = 0$ rather than guessing from the trace.

The matrix exponential

The scalar differential equation $\frac{dx}{dt} = ax$ has solutions $x(t) = ce^{at}$, and the entire theory rests on the single fact that $\frac{d}{dt}e^{at} = ae^{at}$. To solve a coupled first-order system $\frac{dX}{dt} = AX$ with A a constant $n \times n$ matrix, we manufacture the same machine one dimension up: a matrix-valued function e^{tA} with $\frac{d}{dt}e^{tA} = Ae^{tA}$. Building it, proving it works, and computing it are the content of this section. Throughout, $A \in \mathrm{M}_n(\mathbb{C})$, and derivatives of vector- or matrix-valued functions of the real variable t are taken entrywise.

Definition 11.8.13 (Matrix exponential)**.** For $A \in \mathrm{M}_n(\mathbb{C})$ the *exponential* of A is the matrix obtained by substituting A for x and id for 1 in the Taylor series of e^x:

$$e^A = \mathrm{id} + \frac{A}{1!} + \frac{A^2}{2!} + \frac{A^3}{3!} + \cdots = \sum_{k=0}^{\infty} \frac{A^k}{k!}.$$

More usefully we exponentiate tA to get the matrix-valued function

$$e^{tA} = \mathrm{id} + \frac{tA}{1!} + \frac{t^2A^2}{2!} + \frac{t^3A^3}{3!} + \cdots = \sum_{k=0}^{\infty} \frac{t^kA^k}{k!}.$$

To make sense of an infinite sum of matrices we measure size with the norm $\|A\| = \left(\sum_{i,j} |a_{ij}|^2\right)^{1/2}$, which is submultiplicative up to a dimensional constant: $\|AB\| \le n\,\|A\|\,\|B\|$, and hence $\|A^k\| \le n^{k-1}\|A\|^k$ for $k \ge 1$.

Theorem 11.8.14 (Convergence and derivative; Artin 5.4.4)**.** *Let $A \in \mathrm{M}_n(\mathbb{C})$.*

(a) The series for e^{tA} converges absolutely, and uniformly on every bounded set of t.

(b) e^{tA} is a differentiable function of t, with $\frac{d}{dt}e^{tA} = Ae^{tA} = e^{tA}A$.

(c) If $A, B \in \mathrm{M}_n(\mathbb{C})$ commute, $AB = BA$, then $e^{A+B} = e^Ae^B$.

Proof. (a) The $k = 0$ term is the constant matrix id, which does not affect convergence. For $k \ge 1$ bound the (i, j) entry of the degree-k term: $|\frac{t^k(A^k)_{ij}}{k!}| \le \frac{|t|^k\,\|A^k\|}{k!} \le \frac{|t|^k\,n^{k-1}\|A\|^k}{k!} = \frac{1}{n} \cdot \frac{(n|t|\,\|A\|)^k}{k!}$. For $|t| \le r$ these are dominated by the constants $m_k = \frac{1}{n} \cdot \frac{(nr\|A\|)^k}{k!}$, and $\sum_k m_k = \frac{1}{n}e^{\,nr\|A\|} < \infty$ by the ratio test. By the Weierstrass M-test each entry series converges absolutely and uniformly on $|t| \le r$.

(b) Each entry of e^{tA} is a power series in t whose term-by-term derivative is again uniformly convergent (same M-test, shifted index), so we may differentiate term by term:

$$\frac{d}{dt}\sum_{k\ge0} \frac{t^kA^k}{k!} = \sum_{k\ge1} \frac{kt^{k-1}A^k}{k!} = \sum_{k\ge1} \frac{t^{k-1}A^k}{(k-1)!} = A\sum_{j\ge0} \frac{t^jA^j}{j!} = Ae^{tA},$$

and the A may be pulled out on either side since it commutes with every A^j, giving also $e^{tA}A$.

(c) When $AB = BA$ the binomial theorem holds: $(A+B)^k = \sum_{i+j=k} \binom{k}{i} A^i B^j$. Substituting and reindexing the absolutely convergent double sum,

$$e^{A+B} = \sum_{k\geq 0} \frac{(A+B)^k}{k!} = \sum_{k\geq 0} \frac{1}{k!} \sum_{i+j=k} \frac{k!}{i!\,j!} A^i B^j = \Big(\sum_{i\geq 0} \frac{A^i}{i!}\Big)\Big(\sum_{j\geq 0} \frac{B^j}{j!}\Big) = e^A e^B.$$

Absolute convergence is what licenses the rearrangement (Cauchy product), which needs no commutativity; $AB = BA$ is used only in the binomial expansion of $(A+B)^k$. □

Corollary 11.8.15 (Artin 5.4.5)**.** *For every $A \in \mathrm{M}_n(\mathbb{C})$ the matrix e^A is invertible, with inverse e^{-A}.*

Proof. A and $-A$ commute, so part (c) gives $e^A e^{-A} = e^{A+(-A)} = e^0 = \mathrm{id}$, and likewise $e^{-A}e^A = \mathrm{id}$. □

Caution. The law $e^{A+B} = e^A e^B$ *requires* $AB = BA$. For $A = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 0 & 0 \\ 1 & 0 \end{smallmatrix}\right)$ one has $AB \neq BA$, and indeed $e^A e^B = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 0 \\ 1 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 1 \end{smallmatrix}\right)$, whereas $e^B e^A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 2 \end{smallmatrix}\right)$, so the two products even disagree with each other — neither can equal the symmetric quantity e^{A+B}.

Solving the linear system

The point of all this is one theorem: the columns of e^{tA} are a complete set of solutions.

Theorem 11.8.16 (Fundamental matrix; Artin 5.4.9)**.** *Let $A \in \mathrm{M}_n(\mathbb{C})$. The columns of e^{tA} form a basis of the solution space of $\frac{dX}{dt} = AX$. Equivalently, every solution is $X(t) = e^{tA}C$ for a unique constant vector $C \in \mathbb{C}^n$; the initial condition $X(0) = X_0$ forces $C = X_0$.*

Proof. By Theorem 11.8.14(b) the matrix e^{tA} satisfies $\frac{d}{dt}e^{tA} = Ae^{tA}$, so each column solves the system; thus $X(t) = e^{tA}C$ is a solution for every constant C. Conversely let $X(t)$ be any solution. Differentiate $e^{-tA}X(t)$ by the product rule, using that A and e^{-tA} commute:

$$\frac{d}{dt}\big(e^{-tA}X(t)\big) = (-A\,e^{-tA})X(t) + e^{-tA}\big(AX(t)\big) = e^{-tA}(-A+A)X(t) = 0.$$

Hence $e^{-tA}X(t)$ is a constant vector C, and $X(t) = e^{tA}C$. Setting $t = 0$ gives $X(0) = e^0 C = C$, so C is uniquely determined (and equals the initial value). The columns are independent because e^{tA} is invertible (its determinant never vanishes). □

Method (Computing e^{tA}.)**.** The series is rarely summed directly. Instead:

- **Diagonal:** if $A = \mathrm{diag}(\lambda_1, \ldots, \lambda_n)$ then $e^{tA} = \mathrm{diag}(e^{\lambda_1 t}, \ldots, e^{\lambda_n t})$, read straight off the series.
- **Diagonalizable:** if $P^{-1}AP = D$ is diagonal, then $A^k = PD^kP^{-1}$, so $e^{tA} = Pe^{tD}P^{-1}$. (Conjugation commutes with the whole series.)
- **Jordan block:** if $A = \lambda\,\mathrm{id} + N$ with N nilpotent ($N^k = 0$), then since $\lambda\,\mathrm{id}$ and N commute, $e^{tA} = e^{\lambda t}e^{tN}$ and $e^{tN} = \mathrm{id} + tN + \cdots + \frac{t^{k-1}}{(k-1)!}N^{k-1}$ is a *finite* sum.
- **Complex eigenvalues:** a pair $\lambda = r \pm si$ contributes real solutions through $e^{(r+si)t} = e^{rt}(\cos st + i \sin st)$; take real and imaginary parts.

Worked Example 11.8.17 (A coupled growth system by diagonalization)**.** Solve $\frac{dX}{dt} = AX$ for $A = \left(\begin{smallmatrix} 3 & 2 \\ 1 & 4 \end{smallmatrix}\right)$, with $X = (x_1, x_2)^{\mathsf{T}}$, then write e^{tA}.

Recognition. A has distinct real eigenvalues, so it is diagonalizable; by the method, $e^{tA} = Pe^{tD}P^{-1}$ with P the eigenvector matrix. Each basic solution is $e^{\lambda t}V$ for an eigenvector V (Artin 5.3.13).

Solution. The characteristic polynomial is $\det(A - \lambda\,\mathrm{id}) = (3-\lambda)(4-\lambda) - 2 = \lambda^2 - 7\lambda + 10 = (\lambda - 5)(\lambda - 2)$, so $\lambda = 5, 2$. For $\lambda = 5$: $(A - 5\,\mathrm{id})V = \left(\begin{smallmatrix} -2 & 2 \\ 1 & -1 \end{smallmatrix}\right)V = 0$ gives $V_1 = (1,1)^{\mathsf{T}}$. For $\lambda = 2$: $\left(\begin{smallmatrix} 1 & 2 \\ 1 & 2 \end{smallmatrix}\right)V = 0$ gives $V_2 = (2,-1)^{\mathsf{T}}$. The two basic solutions are

$$e^{5t}\left(\begin{smallmatrix} 1 \\ 1 \end{smallmatrix}\right), \qquad e^{2t}\left(\begin{smallmatrix} 2 \\ -1 \end{smallmatrix}\right),$$

and the general solution is $X(t) = c_1 e^{5t}(1,1)^{\mathsf{T}} + c_2 e^{2t}(2,-1)^{\mathsf{T}}$. To assemble e^{tA}, set $P = \left(\begin{smallmatrix} 1 & 2 \\ 1 & -1 \end{smallmatrix}\right)$, $P^{-1} = -\frac{1}{3}\left(\begin{smallmatrix} -1 & -2 \\ -1 & 1 \end{smallmatrix}\right) = \frac{1}{3}\left(\begin{smallmatrix} 1 & 2 \\ 1 & -1 \end{smallmatrix}\right)$, $D = \operatorname{diag}(5,2)$:

$$e^{tA} = Pe^{tD}P^{-1} = \frac{1}{3}\left(\begin{smallmatrix} 1 & 2 \\ 1 & -1 \end{smallmatrix}\right)\left(\begin{smallmatrix} e^{5t} & 0 \\ 0 & e^{2t} \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 2 \\ 1 & -1 \end{smallmatrix}\right) = \frac{1}{3}\left(\begin{smallmatrix} e^{5t}+2e^{2t} & 2e^{5t}-2e^{2t} \\ e^{5t}-e^{2t} & 2e^{5t}+e^{2t} \end{smallmatrix}\right).$$

Check. At $t=0$ this is $\frac{1}{3}\left(\begin{smallmatrix} 3 & 0 \\ 0 & 3 \end{smallmatrix}\right) = \mathrm{id}$, as e^0 must be, and differentiating the $(1,1)$ entry gives $\frac{1}{3}(5e^{5t} + 4e^{2t})$, which equals the $(1,1)$ entry of Ae^{tA} — the columns really do solve the system.

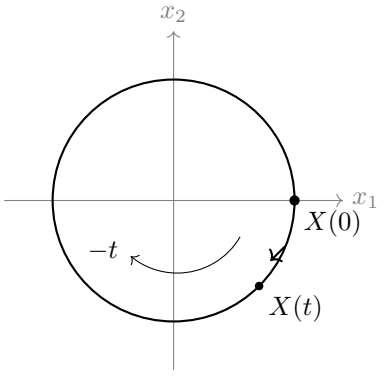
Worked Example 11.8.18 (A defective matrix via a Jordan block)**.** Solve $\frac{dX}{dt} = AX$ for the non-diagonalizable matrix $A = \left(\begin{smallmatrix} 2 & 1 \\ 0 & 2 \end{smallmatrix}\right)$.

Recognition. A has the single eigenvalue 2 with a one-dimensional eigenspace, so it is a Jordan block: write $A = 2\,\mathrm{id} + N$ with $N = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ nilpotent. Use $e^{tA} = e^{2t}e^{tN}$ with e^{tN} a finite sum.

Solution. Here $N^2 = 0$, so $e^{tN} = \mathrm{id} + tN = \left(\begin{smallmatrix} 1 & t \\ 0 & 1 \end{smallmatrix}\right)$. Since $2\,\mathrm{id}$ and N commute,

$$e^{tA} = e^{2t}\left(\begin{smallmatrix} 1 & t \\ 0 & 1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} e^{2t} & te^{2t} \\ 0 & e^{2t} \end{smallmatrix}\right).$$

The columns give the basis of solutions $\left(\begin{smallmatrix} e^{2t} \\ 0 \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} te^{2t} \\ e^{2t} \end{smallmatrix}\right)$; the factor t in the second is the signature of a repeated eigenvalue with a deficient eigenspace. *Check.* $\frac{d}{dt}(te^{2t}) = e^{2t} + 2te^{2t}$, and the system demands $\frac{d}{dt}x_1 = 2x_1 + x_2 = 2te^{2t} + e^{2t}$ for the second column — they match.



Worked Example 11.8.19 (An oscillator from complex eigenvalues)**.** Solve $\frac{dX}{dt} = AX$ for $A = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ and identify the trajectories geometrically.

Recognition. The eigenvalues are non-real, $\lambda = \pm i$ (pure imaginary, $r = 0$). By the method, each contributes $e^{\pm it} = \cos t \pm i \sin t$; take real and imaginary parts of one complex basic solution to get real solutions.

Solution. $\det(A - \lambda\,\mathrm{id}) = \lambda^2 + 1$, so $\lambda = \pm i$. For $\lambda = i$, $(A - i\,\mathrm{id})V = \left(\begin{smallmatrix} -i & 1 \\ -1 & -i \end{smallmatrix}\right)V = 0$ gives $V = (1,i)^{\mathsf{T}}$. The complex basic solution is

$$e^{it}\left(\begin{smallmatrix} 1 \\ i \end{smallmatrix}\right) = (\cos t + i \sin t)\left(\begin{smallmatrix} 1 \\ i \end{smallmatrix}\right) = \left(\begin{smallmatrix} \cos t \\ -\sin t \end{smallmatrix}\right) + i\left(\begin{smallmatrix} \sin t \\ \cos t \end{smallmatrix}\right).$$

By Artin's lemma (5.3.23) the real and imaginary parts each solve the real system, giving the real basis $\left(\begin{smallmatrix} \cos t \\ -\sin t \end{smallmatrix}\right)$, $\left(\begin{smallmatrix} \sin t \\ \cos t \end{smallmatrix}\right)$, i.e. $e^{tA} = \left(\begin{smallmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{smallmatrix}\right)$, the rotation by angle $-t$. *Check.* e^{tA} is orthogonal with $\det = \cos^2 t + \sin^2 t = 1$, so $\|X(t)\|$ is constant: every trajectory is a circle, as a frictionless oscillator should be. The diagram below traces one such orbit.

Worked Example 11.8.20 (Fibonacci numbers as a matrix power)**.** With $F_0 = 0$, $F_1 = 1$, $F_{n+1} = F_n + F_{n-1}$, show $\left(\begin{smallmatrix} F_{n+1} \\ F_n \end{smallmatrix}\right) = Q^n\left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$ for $Q = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, and diagonalize to get Binet's formula.

Recognition. This is the discrete analogue of $\frac{dX}{dt} = AX$: instead of $X(t) = e^{tA}X(0)$ we iterate, $X_n = Q^n X_0$. Diagonalizing Q computes the power exactly as it computes the exponential — $Q^n = PD^nP^{-1}$.

Solution. One step of the recurrence is $\left(\begin{smallmatrix} F_{n+1} \\ F_n \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 1 \\ 1 & 0 \end{smallmatrix}\right)\left(\begin{smallmatrix} F_n \\ F_{n-1} \end{smallmatrix}\right)$, so by induction $\left(\begin{smallmatrix} F_{n+1} \\ F_n \end{smallmatrix}\right) = Q^n\left(\begin{smallmatrix} F_1 \\ F_0 \end{smallmatrix}\right) = Q^n\left(\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right)$. Now $\det(Q - \lambda\,\mathrm{id}) = \lambda^2 - \lambda - 1$, with roots $\varphi = \frac{1+\sqrt{5}}{2}$ and $\psi = \frac{1-\sqrt{5}}{2}$ (note $\varphi\psi = -1$, $\varphi - \psi = \sqrt{5}$). Eigenvectors are $(\varphi, 1)^{\mathsf{T}}$ and $(\psi, 1)^{\mathsf{T}}$, so with $P = \left(\begin{smallmatrix} \varphi & \psi \\ 1 & 1 \end{smallmatrix}\right)$, $D = \mathrm{diag}(\varphi, \psi)$,

$$Q^n = PD^nP^{-1} = \frac{1}{\varphi - \psi}\left(\begin{smallmatrix} \varphi & \psi \\ 1 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} \varphi^n & 0 \\ 0 & \psi^n \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & -\psi \\ -1 & \varphi \end{smallmatrix}\right).$$

Reading off the $(2,1)$ entry of Q^n (which is F_n) gives Binet's formula

$$F_n = \frac{\varphi^n - \psi^n}{\varphi - \psi} = \frac{1}{\sqrt{5}}\left[\left(\tfrac{1+\sqrt{5}}{2}\right)^n - \left(\tfrac{1-\sqrt{5}}{2}\right)^n\right].$$

Check. $n = 5$ gives $\varphi^5 \approx 11.0902$, $\psi^5 \approx -0.0902$, and $(11.0902 + 0.0902)/\sqrt{5} = 11.1803/2.2360 \approx 5 = F_5$. Since $|\psi| < 1$, the ψ^n term decays, so F_n is the nearest integer to $\varphi^n/\sqrt{5}$ — the golden ratio governs the growth, exactly as the dominant eigenvalue governs e^{tA}.

Remark 11.8.3 (The two pictures, side by side). Diagonalization solves both the continuous problem $\frac{dX}{dt} = AX$ and the discrete one $X_{n+1} = QX_n$ by the same move: change to an eigenbasis, where the dynamics decouple into independent scalar channels $e^{\lambda t}$ or λ^n, then change back. The exponential $e^{tA} = Pe^{tD}P^{-1}$ and the power $Q^n = PD^nP^{-1}$ are literally the same formula with $e^{t(\,\cdot\,)}$ replaced by $(\,\cdot\,)^n$. When the eigenvalues are complex, $e^{\lambda t}$ supplies the cos, sin of oscillation and λ^n the rotating powers; when an eigenvalue is defective, the nilpotent part injects a polynomial factor (t in the flow, n in the power). Everything downstream — stability, growth rate, periodicity — is read directly from the eigenvalues of A.

11.9 Bilinear and Hermitian Forms; the Spectral Theorem

Bilinear forms and their matrices

Let V be a real vector space, here always finite-dimensional. The dot product $X \cdot Y = X^{\mathsf{T}}Y = x_1y_1 + \cdots + x_ny_n$ on $\mathbb{R}^n$ is the prototype of a *bilinear form*: a real-valued function of two vector arguments that is linear in each slot separately. Replacing the special features of dot product — symmetry and positive definiteness — by weaker hypotheses produces the symmetric, skew-symmetric, and (over $\mathbb{C}$) Hermitian forms studied here.

Definition 11.9.1 (Bilinear form)**.** A *bilinear form* on a real vector space V is a map $V \times V \to \mathbb{R}$, written $(v, w) \mapsto \langle v, w\rangle$, that is linear in each variable: for all $v_1, v_2, w_1, w_2 \in V$ and $r \in \mathbb{R}$,

$$\langle rv_1, w_1\rangle = r\langle v_1, w_1\rangle, \quad \langle v_1 + v_2, w_1\rangle = \langle v_1, w_1\rangle + \langle v_2, w_1\rangle,$$

and symmetrically in the second slot. Equivalently it is compatible with linear combinations in each variable: $\langle \sum_i x_iv_i,\, w\rangle = \sum_i x_i\langle v_i, w\rangle$ and $\langle v, \sum_j w_jy_j\rangle = \sum_j \langle v, w_j\rangle y_j$ (it is convenient to pull scalars in the second slot out to the right).

The basic example on $\mathbb{R}^n$ is $\langle X, Y\rangle = X^{\mathsf{T}}AY$ for a fixed $n \times n$ matrix A; dot product is the case $A = I$. The next definition shows this example is the only one once a basis is fixed.

Definition 11.9.2 (Matrix of a form)**.** Let $\mathcal{B} = (v_1, \ldots, v_n)$ be a basis of V and $\langle\,,\,\rangle$ a bilinear form. The *matrix of the form with respect to* $\mathcal{B}$ is $A = (a_{ij})$ with

$$a_{ij} = \langle v_i, v_j\rangle.$$

Proposition 11.9.3 (Coordinatization, Artin 8.1.5)**.** *With A the matrix of $\langle\,,\,\rangle$ in the basis $\mathcal{B}$, if X and Y are the coordinate vectors of v and w, then*

$$\langle v, w\rangle = X^{\mathsf{T}}AY.$$

Proof. Write $v = \sum_i v_ix_i$ and $w = \sum_j v_jy_j$. By bilinearity,

$$\langle v, w\rangle = \Big\langle \sum_i v_ix_i,\ \sum_j v_jy_j \Big\rangle = \sum_{i,j} x_i\langle v_i, v_j\rangle y_j = \sum_{i,j} x_ia_{ij}y_j = X^{\mathsf{T}}AY. \qquad \square$$

Definition 11.9.4 (Symmetric and skew-symmetric)**.** A bilinear form is *symmetric* if $\langle v, w\rangle = \langle w, v\rangle$ for all v, w, and *skew-symmetric* if $\langle v, w\rangle = -\langle w, v\rangle$ for all v, w. ("Symmetric form" always means a *bilinear* symmetric form, and likewise for skew-symmetric.)

Lemma 11.9.5 (Symmetry of form $\leftrightarrow$ symmetry of matrix, Artin 8.1.6)**.** *Let A be $n \times n$. The form $X^{\mathsf{T}}AY$ is symmetric — that is, $X^{\mathsf{T}}AY = Y^{\mathsf{T}}AX$ for all X, Y — if and only if $A^{\mathsf{T}} = A$. Consequently a bilinear form is symmetric iff its matrix with respect to one (equivalently every) basis is a symmetric matrix. The analogous statement holds with "symmetric" replaced by "skew-symmetric" and $A^{\mathsf{T}} = -A$.*

Proof. If $A^{\mathsf{T}} = A$, view the scalar $X^{\mathsf{T}}AY$ as a 1×1 matrix equal to its own transpose: $X^{\mathsf{T}}AY = (X^{\mathsf{T}}AY)^{\mathsf{T}} = Y^{\mathsf{T}}A^{\mathsf{T}}X = Y^{\mathsf{T}}AX$, so the form is symmetric. Conversely, taking $X = e_i$, $Y = e_j$ gives $e_i^{\mathsf{T}}Ae_j = a_{ij}$ and $e_j^{\mathsf{T}}Ae_i = a_{ji}$; symmetry of the form forces $a_{ij} = a_{ji}$, i.e. $A^{\mathsf{T}} = A$. The second sentence is then immediate from $\langle v, w\rangle = X^{\mathsf{T}}AY$. The skew case is identical with signs reversed. □

Worked Example 11.9.6 (Writing the matrix of a quadratic form)**.** Find the symmetric matrix A with $q(x, y, z) = X^{\mathsf{T}}AX$ for $q = 2x^2 - 3y^2 + z^2 + 4xy - 6xz + 10yz$, and evaluate q at $(1, -1, 2)$ as $X^{\mathsf{T}}AX$.

Recognition. A quadratic form $q(X) = \langle X, X\rangle$ comes from a *symmetric* matrix A; the diagonal entries are the pure-square coefficients, and each cross term cx_ix_j $(i \neq j)$ is split as $a_{ij} = a_{ji} = c/2$ so that $a_{ij} + a_{ji} = c$.

Solution. The squares give $a_{11} = 2$, $a_{22} = -3$, $a_{33} = 1$. The cross terms $4xy$, $-6xz$, $10yz$ split into halves $a_{12} = a_{21} = 2$, $a_{13} = a_{31} = -3$, $a_{23} = a_{32} = 5$. Hence

$$A = \begin{pmatrix} 2 & 2 & -3 \\ 2 & -3 & 5 \\ -3 & 5 & 1 \end{pmatrix}.$$

At $X = (1, -1, 2)^{\mathsf{T}}$: $AX = (2 - 2 - 6,\ 2 + 3 + 10,\ -3 - 5 + 2)^{\mathsf{T}} = (-6, 15, -6)^{\mathsf{T}}$, and $X^{\mathsf{T}}(AX) = 1(-6)+(-1)(15)+2(-6) = -6-15-12 = -33$. *Check.* Directly $q(1, -1, 2) = 2-3+4+4(-1)-6(2)+10(-2) = 2 - 3 + 4 - 4 - 12 - 20 = -33$. The two agree, and $A = A^{\mathsf{T}}$, as a quadratic form's matrix must be.

Change of basis: congruence

A change of basis transforms the matrix of a form by *congruence* $A \mapsto P^{\mathsf{T}}AP$ — not by the conjugation $P^{-1}AP$ that governs a linear operator. This difference is the whole point: although both operators and forms are recorded by matrices once a basis is chosen, their theories are genuinely distinct.

Proposition 11.9.7 (Change of basis, Artin 8.1.7–8.1.8)**.** *Let A, A' be the matrices of a bilinear form with respect to bases $\mathcal{B}$ and $\mathcal{B}'$, and let P be the change-of-basis matrix, $\mathcal{B}' = \mathcal{B}P$. Then*

$$A' = P^{\mathsf{T}}AP.$$

As P ranges over all invertible matrices, the matrices $P^{\mathsf{T}}AP$ are exactly those representing the same form in different bases. We call A and A' congruent*.*

Proof. Let X, X' be the coordinate vectors of a vector v in the two bases, so $v = \mathcal{B}X = \mathcal{B}'X'$ and $PX' = X$; similarly $PY' = Y$ for w. Then

$$\langle v, w\rangle = X^{\mathsf{T}}AY = (PX')^{\mathsf{T}}A(PY') = X'^{\mathsf{T}}(P^{\mathsf{T}}AP)Y',$$

which identifies $P^{\mathsf{T}}AP$ as the matrix of the form in $\mathcal{B}'$. □

Remark 11.9.1 (Operators versus forms). Under $\mathcal{B}' = \mathcal{B}P$, the matrix of the bilinear form $X^{\mathsf{T}}AY$ changes to $P^{\mathsf{T}}AP$, while the matrix of the linear operator $Y = AX$ changes to $P^{-1}AP$. Since $P^{\mathsf{T}} \neq P^{-1}$ in general, the two new matrices usually differ. Congruence preserves symmetry ($(P^{\mathsf{T}}AP)^{\mathsf{T}} = P^{\mathsf{T}}A^{\mathsf{T}}P = P^{\mathsf{T}}AP$ when $A^{\mathsf{T}} = A$) and rank, but not eigenvalues; conjugation preserves eigenvalues. The two equivalences coincide exactly when P is orthogonal, $P^{\mathsf{T}} = P^{-1}$.

Worked Example 11.9.8 (Effect of a basis change on dot product)**.** Take dot product on $\mathbb{R}^2$ (matrix $A = I$) and the new basis $\mathcal{B}' = \mathcal{B}P$ with $P = \left(\begin{smallmatrix} 1 & \frac{1}{2} \\ 0 & 2 \end{smallmatrix}\right)$. Compute the matrix A' of the form in the new basis and read off $\langle v_1', v_2' \rangle$.

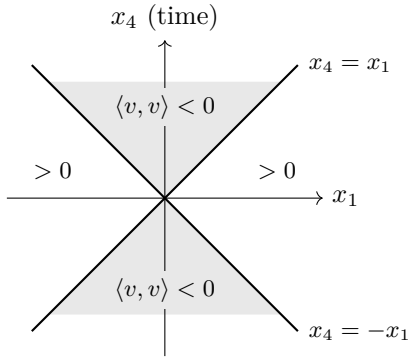
Recognition. Dot product has $A = I$, so under $\mathcal{B}' = \mathcal{B}P$ its matrix becomes $A' = P^{\mathsf{T}} I P = P^{\mathsf{T}} P$ (the congruence rule with $A = I$). The Gram matrix $P^{\mathsf{T}} P$ records the inner products of the new basis vectors.

Solution. Compute

$$A' = P^{\mathsf{T}} P = \begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 5 \end{pmatrix}.$$

So in the new coordinates the form is $\langle X', Y' \rangle = X'^{\mathsf{T}} \left(\begin{smallmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & 5 \end{smallmatrix}\right) Y'$, and the off-diagonal entry gives $\langle v_1', v_2' \rangle = 1$. *Check.* The new basis vectors are $v_1' = (1, 0)$ and $v_2' = (1, 2)$ (columns of P in standard coordinates); directly $v_1' \cdot v_2' = 1 \cdot 1 + 0 \cdot 2 = 1$ and $v_2' \cdot v_2' = 1 + 4 = 5$, matching A'. Note A' is symmetric and positive definite, as congruence of I must produce.

Worked Example 11.9.9 (The Lorentz form is indefinite)**.** On space-time $\mathbb{R}^4$ the *Lorentz form* is $\langle X, Y \rangle = x_1 y_1 + x_2 y_2 + x_3 y_3 - x_4 y_4$ (the coordinate x_4 is "time", the speed of light normalized to 1). Write its matrix, show it is symmetric, and exhibit vectors u, w with $\langle u, u \rangle > 0$ and $\langle w, w \rangle < 0$.



Recognition. The matrix of a form reads its coefficients off the diagonal here, since there are no cross terms. "Indefinite" means $\langle v, v \rangle$ takes both signs — so we just need one spacelike and one timelike vector.

Solution. The matrix in the standard basis is

$$A = \operatorname{diag}(1, 1, 1, -1) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \qquad A^{\mathsf{T}} = A,$$

so the form is symmetric. For $u = (1, 0, 0, 0)$, $\langle u, u \rangle = 1 > 0$ (spacelike); for $w = (0, 0, 0, 1)$, $\langle w, w \rangle = -1 < 0$ (timelike). Thus the form is neither positive nor negative definite: it is indefinite. *Check.* The lightlike vector $\ell = (1, 0, 0, 1)$ has $\langle \ell, \ell \rangle = 1 - 1 = 0$, a nonzero vector of "length" zero — impossible for the positive definite dot product, confirming the Lorentz form is a genuinely different symmetric form.

The light cone $\langle v, v \rangle = 0$ separates the spacelike region $\langle v, v \rangle > 0$ from the timelike region $\langle v, v \rangle < 0$. Suppressing x_2, x_3, the cone in the (x_1, x_4)-plane is the pair of lines $x_4 = \pm x_1$:

Hermitian forms

Over $\mathbb{C}$, naive bilinearity loses positivity: $\langle iX, iX \rangle = i^2 \langle X, X \rangle = -\langle X, X \rangle$ would force the form to change sign. The fix is to make the form *conjugate-linear* in one slot, which restores $\langle v, v \rangle \geq 0$.

Definition 11.9.10 (Hermitian form, Artin 8.3.1)**.** A *Hermitian form* on a complex vector space V is a map $V \times V \to \mathbb{C}$, written $\langle v, w \rangle$, that is conjugate-linear in the first variable, linear in the second, and *Hermitian symmetric*:

$$\langle cv_1, w_1 \rangle = \overline{c}\, \langle v_1, w_1 \rangle, \qquad \langle v_1, cw_1 \rangle = c\, \langle v_1, w_1 \rangle, \qquad \langle w, v \rangle = \overline{\langle v, w \rangle},$$

together with additivity in each slot. Hermitian symmetry forces $\langle v, v \rangle = \overline{\langle v, v \rangle}$, so $\langle v, v \rangle \in \mathbb{R}$ for every v.

The *standard Hermitian form* on $\mathbb{C}^n$ is $\langle X, Y\rangle = X^*Y = \overline{x_1}y_1 + \cdots + \overline{x_n}y_n$, where $X^* = \overline{X}^{\mathsf{T}} = (\overline{x_1}, \ldots, \overline{x_n})$ is the conjugate transpose. Then $\langle X, X\rangle = \sum_i |x_i|^2 > 0$ for $X \neq 0$: writing $x_v = a_v + b_v i$, this is $\sum_v (a_v^2 + b_v^2)$, the squared length of the corresponding real $2n$-vector. The *adjoint* of a complex matrix is $A^* = \overline{A}^{\mathsf{T}}$, with entries $(A^*)_{ij} = \overline{a_{ji}}$; it obeys

$$(cA)^* = \overline{c}\,A^*, \qquad (A+B)^* = A^* + B^*, \qquad (AB)^* = B^*A^*, \qquad A^{**} = A.$$

A square matrix is *Hermitian* (self-adjoint) if $A^* = A$, i.e. $a_{ji} = \overline{a_{ij}}$: the diagonal entries are real and the entries below the diagonal are conjugates of those above. A real matrix is Hermitian iff it is symmetric.

Proposition 11.9.11 (Coordinatization and change of basis, Artin 8.3.8–8.3.10)**.** *Let A be the matrix of a Hermitian form in a basis $\mathcal{B}$, $a_{ij} = \langle v_i, v_j\rangle$. If X, Y are the coordinate vectors of v, w then*

$$\langle v, w\rangle = X^*AY, \qquad A^* = A.$$

Conversely every Hermitian matrix A defines a Hermitian form X^*AY on $\mathbb{C}^n$. Under a change of basis $\mathcal{B}' = \mathcal{B}P$ (with P invertible complex), the matrix transforms by

$$A' = P^*AP.$$

Proof. Expanding $v = \sum_i v_i x_i$, $w = \sum_j v_j y_j$ and using conjugate-linearity in the first slot, $\langle v, w\rangle = \sum_{i,j} \overline{x_i}\, a_{ij}\, y_j = X^*AY$. Hermitian symmetry gives $a_{ji} = \langle v_j, v_i\rangle = \overline{\langle v_i, v_j\rangle} = \overline{a_{ij}}$, i.e. $A^* = A$. For the change of basis, substitute $PX' = X$, $PY' = Y$:

$$X^*AY = (PX')^*A(PY') = X'^*(P^*AP)Y',$$

identifying P^*AP as the new matrix. (Note P^*AP is again Hermitian: $(P^*AP)^* = P^*A^*P^{**} = P^*AP$.) □

Theorem 11.9.12 (Hermitian eigenvalues are real, Artin 8.3.11)**.** *The eigenvalues, trace, and determinant of a Hermitian matrix A are real. In particular the eigenvalues of a real symmetric matrix are real.*

Proof. Since trace and determinant are the sum and product of the eigenvalues, it suffices to prove each eigenvalue real. Let $AX = \lambda X$ with $X \neq 0$. On one hand $X^*AX = X^*(\lambda X) = \lambda\, X^*X$. On the other hand, using $A^* = A$ and $(\lambda X)^* = \overline{\lambda}\, X^*$,

$$X^*AX = (X^*A)X = (X^*A^*)X = (AX)^*X = (\lambda X)^*X = \overline{\lambda}\, X^*X.$$

So $\lambda X^*X = \overline{\lambda}\, X^*X$. As $X^*X = \sum |x_i|^2 > 0$ is a nonzero real, $\lambda = \overline{\lambda}$, i.e. $\lambda \in \mathbb{R}$. A real symmetric matrix, viewed over $\mathbb{C}$, is Hermitian, so its eigenvalues are real as well. □

Worked Example 11.9.13 (Reading a Hermitian matrix and checking realness)**.** Is $A = \left(\begin{smallmatrix} 3 & 1+i \\ 1-i & -2 \end{smallmatrix}\right)$ Hermitian? Compute $\langle X, X\rangle = X^*AX$ for $X = (1,\, i)^{\mathsf{T}}$ and confirm it is real.

Recognition. A matrix is Hermitian iff $A^* = A$, equivalently real diagonal and $a_{21} = \overline{a_{12}}$. For any Hermitian A, X^*AX is automatically real — a good arithmetic check.

Solution. Diagonal entries $3, -2$ are real; off-diagonals satisfy $a_{21} = 1 - i = \overline{1+i} = \overline{a_{12}}$, so $A^* = A$ and A is Hermitian. Now $X = (1, i)^{\mathsf{T}}$, so $X^* = (\overline{1}, \overline{i}) = (1, -i)$. First

$$AX = \begin{pmatrix} 3 & 1+i \\ 1-i & -2 \end{pmatrix}\begin{pmatrix} 1 \\ i \end{pmatrix} = \begin{pmatrix} 3 + (1+i)i \\ (1-i) - 2i \end{pmatrix} = \begin{pmatrix} 2+i \\ 1-3i \end{pmatrix},$$

using $(1+i)i = i + i^2 = -1 + i$. Then

$$X^*AX = (1, -i)\begin{pmatrix} 2+i \\ 1-3i \end{pmatrix} = (2+i) - i(1-3i) = (2+i) - (i - 3i^2) = (2+i) - (3+i) = -1.$$

Check. The result -1 is real, as the theorem guarantees for X^*AX with A Hermitian; its sign being negative also shows this A is not positive definite (consistent with the diagonal entry $-2 < 0$).

Remark 11.9.2 (Unitary change preserves the standard form). A complex matrix P with $P^*P = I$ is *unitary*; equivalently its columns are orthonormal for the standard Hermitian form. Under $\mathcal{B}' = \mathcal{B}P$ the standard form X^*Y becomes $X'^*(P^*P)Y'$, which equals X'^*Y' exactly when P is unitary. Thus a change of basis of $\mathbb{C}^n$ preserves the standard Hermitian form iff the change-of-basis matrix is unitary — the complex analogue of orthogonal matrices preserving dot product on $\mathbb{R}^n$. The unitary matrices form a group $\mathrm{U}(n) \leq \mathrm{GL}_n(\mathbb{C})$.

Orthogonality and the orthogonal complement

Throughout this section V is a finite-dimensional vector space carrying a fixed form $\langle\ ,\ \rangle$ that is either a *symmetric* bilinear form on a real vector space or a *Hermitian* form on a complex vector space. Everything below applies verbatim to both cases; on first reading it is best to picture a symmetric form on a real space and ignore the conjugation bars, since conjugation is the identity on $\mathbb{R}$. We do *not* assume the form is positive definite until the final part. The single organizing idea is orthogonality.

Definition 11.9.14 (Orthogonal vectors and subspaces)**.** Two vectors $v, w \in V$ are **orthogonal**, written $v \perp w$, if $\langle v, w\rangle = 0$. Symmetry (or Hermitian symmetry $\langle w, v\rangle = \overline{\langle v, w\rangle}$) makes this relation symmetric in v and w. For a subspace $W \leq V$ the **orthogonal complement** (or orthogonal space) is

$$W^{\perp} \;=\; \{\, v \in V \;:\; \langle v, w\rangle = 0 \text{ for all } w \in W \,\}.$$

A basis $v_1, \ldots, v_n$ of V is an **orthogonal basis** if $\langle v_i, v_j\rangle = 0$ whenever $i \neq j$; with respect to such a basis the matrix of the form is diagonal.

Remark 11.9.3. When the form is indefinite a *nonzero* vector can be self-orthogonal: $\langle v, v\rangle = 0$ with $v \neq 0$ (a **null vector** of the form is one orthogonal to *all* of V). For the Lorentz form on $\mathbb{R}^4$, $(1, 0, 0, 1)$ is self-orthogonal (but it is not a null vector: the Lorentz form is nondegenerate). So one should resist reading $\perp$ as a metric angle in general and work algebraically with the bare condition $\langle v, w\rangle = 0$.

Definition 11.9.15 (Nullspace and nondegeneracy)**.** The **nullspace** of the form is $N = V^{\perp} = \{\, v \in V : \langle v, V\rangle = 0 \,\}$, the set of null vectors. The form is **nondegenerate** if $N = \{\, 0 \,\}$, i.e. for every $v \neq 0$ there is some v' with $\langle v, v'\rangle \neq 0$; otherwise it is **degenerate**. The form is nondegenerate *on a subspace* W if its restriction to W is nondegenerate.

The matrix criterion is the practical test. Let A be the matrix of the form in some basis, so that $\langle v, w\rangle = X^{*}AY$ where X, Y are coordinate vectors (here $X^{*} = \overline{X}^{\mathsf{T}}$, which is X^{T} in the real case).

Proposition 11.9.16 (Matrix criterion for nondegeneracy)**.** *With A the matrix of the form in a basis:* (a) *v is a null vector iff its coordinate vector Y solves $AY = 0$;* (b) *the form is nondegenerate iff A is invertible.*

Proof. If $AY = 0$ then $X^{*}AY = 0$ for all X, so v is orthogonal to every vector, hence null. Conversely if $AY \neq 0$ then some coordinate $e_i^{*}AY = (AY)_i$ is nonzero, so v is not orthogonal to that basis vector and is not null. This is (a). Since A is invertible iff $AY = 0$ has only the trivial solution, (b) follows from (a). □

A first dividend of nondegeneracy is a cancellation principle for the form, the analogue of "$ax = ay \Rightarrow x = y$."

Proposition 11.9.17 (Testing equality through the form)**.** *If the form is nondegenerate and $\langle v, w\rangle = \langle v', w\rangle$ for* all *$w \in V$, then $v = v'$.*

Proof. The hypothesis says $\langle v - v', w\rangle = 0$ for all w, so $v - v'$ is a null vector. Nondegeneracy forces $v - v' = 0$. □

Worked Example 11.9.18 (Reading off the nullspace from the matrix)**.** Let $V = \mathbb{R}^3$ with the form whose matrix in the standard basis is $A = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix}$. Find the nullspace and decide whether the form is nondegenerate.

Recognition. By Proposition 11.9.16, the nullspace is $\ker A$ and the form is nondegenerate iff $\det A \neq 0$.

Solution. Row reduction gives $\det A = 1\cdot(1-0) - 0 + 1\cdot(0-1) = 0$, so A is singular and the form is *degenerate*. Solving $AY = 0$: rows 1 and 3 both say $y_1 + y_3 = 0$, and row 2 says $y_2 = 0$. Thus $N = \mathrm{Span}\{\, (1, 0, -1) \,\}$, a line of null vectors. *Check.* $\langle (1, 0, -1), (x_1, x_2, x_3)\rangle$ is the first-minus-third entry of $A(x_1, x_2, x_3)^{\mathsf{T}}$ paired suitably; directly $A(1, 0, -1)^{\mathsf{T}} = (0, 0, 0)^{\mathsf{T}}$, confirming $(1, 0, -1) \in N$. Correct.

The orthogonal decomposition $V = W \oplus W^{\perp}$

The central structural theorem says that nondegeneracy on a subspace is *exactly* the condition for that subspace and its complement to split the whole space orthogonally. First a clean reformulation of nondegeneracy on W.

Lemma 11.9.19 (Nondegeneracy on W as a trivial intersection)**.** *The form is nondegenerate on W if and only if $W \cap W^{\perp} = \{0\}$.*

Proof. A vector $w \in W$ lies in $W^{\perp}$ iff $\langle w, w' \rangle = 0$ for all $w' \in W$, i.e. iff w is a null vector of the restricted form. So $W \cap W^{\perp}$ is the nullspace of the restriction, which is $\{0\}$ exactly when the restriction is nondegenerate. □

Theorem 11.9.20 (Orthogonal direct sum)**.** *Let $W \leq V$.*

1. *The form is nondegenerate on W if and only if $V = W \oplus W^{\perp}$.*
2. *If the form is nondegenerate on V and on W, then it is nondegenerate on $W^{\perp}$.*

*When $V = W \oplus W^{\perp}$ with $W \perp W^{\perp}$ we call it the **orthogonal sum** of the two pieces.*

Proof. (1) A direct sum requires $W \cap W^{\perp} = \{0\}$ and $V = W + W^{\perp}$. The first is precisely nondegeneracy on W by Lemma 11.9.19, so it remains to produce, assuming nondegeneracy on W, a decomposition $v = w + u$ with $w \in W$, $u \in W^{\perp}$ for every v. Extend a basis $w_1, \ldots, w_k$ of W to a basis of V and write the matrix of the form in block form $M = \left(\begin{smallmatrix} A & B \\ B^* & D \end{smallmatrix}\right)$, where A is the $k \times k$ matrix of the form on W. Nondegeneracy on W makes A invertible. Change the appended basis vectors by $P = \left(\begin{smallmatrix} I & Q \\ 0 & I \end{smallmatrix}\right)$; the new matrix is P^*MP, whose upper-right block becomes 0 exactly when $Q = -A^{-1}B$. The new appended vectors are then orthogonal to all of W, hence lie in $W^{\perp}$, and together with W they span V. So $V = W + W^{\perp}$.

(2) By (1), $V = W \oplus W^{\perp}$, and in a basis adapted to this splitting the matrix of the form is block-diagonal $\operatorname{diag}(A, A')$ with A the matrix on W and A' the matrix on $W^{\perp}$. Since the form is nondegenerate on V, this block-diagonal matrix is invertible, so each block is invertible; in particular A' is, and the form is nondegenerate on $W^{\perp}$. □

Iterating the construction of a single nonzero-self-product vector yields an orthogonal basis in general.

Theorem 11.9.21 (Existence of an orthogonal basis)**.** *Every symmetric form on a real space, or Hermitian form on a complex space, admits an orthogonal basis.*

Proof. If the form is identically zero every basis is orthogonal. Otherwise there is a vector with $\langle v_1, v_1 \rangle \neq 0$: indeed if $\langle x, y \rangle \neq 0$ then expanding $\langle x + y, x + y \rangle = \langle x, x \rangle + 2\,\mathrm{Re}\langle x, y \rangle + \langle y, y \rangle$ (after scaling y to make $\langle x, y \rangle$ real and nonzero) shows one of the diagonal terms is nonzero. Let $W = \mathrm{Span}\{v_1\}$; the 1×1 matrix $(\langle v_1, v_1 \rangle)$ is invertible, so the form is nondegenerate on W, and by Theorem 11.9.20, $V = W \oplus W^{\perp}$. By induction $W^{\perp}$ has an orthogonal basis $v_2, \ldots, v_n$, and $v_1, \ldots, v_n$ is then an orthogonal basis of V. □

Orthogonal projection and the projection formula

Suppose the form is nondegenerate on W, so $V = W \oplus W^{\perp}$ and each v has a unique expression $v = w + u$ with $w \in W$, $u \in W^{\perp}$.

Definition 11.9.22 (Orthogonal projection)**.** The **orthogonal projection** onto W is the linear map $\pi \colon V \to W$, $\pi(v) = w$, where $v = w + u$ is the decomposition above. Equivalently π is the unique linear map with $\pi(w) = w$ for $w \in W$ and $\pi(u) = 0$ for $u \in W^{\perp}$.

Caution. If the form is *degenerate* on W the projection does not exist: by Lemma 11.9.19 there is a nonzero $x \in W \cap W^{\perp}$, and we would need both $\pi(x) = x$ (as $x \in W$) and $\pi(x) = 0$ (as $x \in W^{\perp}$). Always check nondegeneracy on W before projecting.

Theorem 11.9.23 (Projection formula)**.** *Let the form be nondegenerate on W and let $w_1, \ldots, w_k$ be an* orthogonal *basis of W. Then the orthogonal projection of v onto W is*

$$\pi(v) \;=\; \sum_{i=1}^{k} c_i\, w_i, \qquad c_i = \frac{\langle w_i, v \rangle}{\langle w_i, w_i \rangle}.$$

Proof. Nondegeneracy on W and diagonality of the matrix in an orthogonal basis give $\langle w_i, w_i\rangle \neq 0$, so the c_i make sense. Put $w = \sum_i c_i w_i \in W$; it suffices to show $u = v - w \in W^\perp$, i.e. $\langle w_i, u\rangle = 0$ for each i. Using $\langle w_i, w_j\rangle = 0$ for $i \neq j$,

$$\langle w_i, u\rangle = \langle w_i, v\rangle - \langle w_i, w\rangle = \langle w_i, v\rangle - c_i\langle w_i, w_i\rangle = \langle w_i, v\rangle - \langle w_i, v\rangle = 0.$$

Hence $v = w + u$ with $w \in W$, $u \in W^\perp$, so $\pi(v) = w$. □

Caution. The projection formula is *false* if the spanning vectors of W are not mutually orthogonal — the cross terms $\langle w_i, w_j\rangle$ no longer drop out. Orthogonalize first (next subsection).

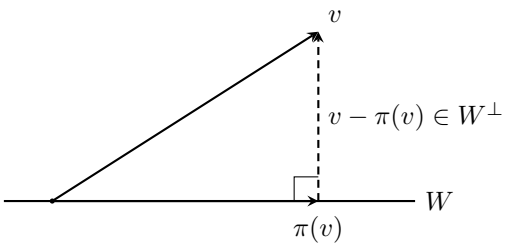
Taking $W = V$ turns the same formula into a recipe for coordinates in an orthogonal basis: if $v_1, \ldots, v_n$ is an orthogonal basis of a nondegenerate V then $v = \sum_i c_i v_i$ with $c_i = \langle v_i, v\rangle / \langle v_i, v_i\rangle$.

Worked Example 11.9.24 (Projection onto a line in $\mathbb{R}^3$)**.** With the dot product on $V = \mathbb{R}^3$, let $W = \mathrm{Span}\{\, w_1 \,\}$, $w_1 = (1,1,1)^\mathsf{T}$. Project $v = (x_1, x_2, x_3)^\mathsf{T}$ onto W.

Recognition. One orthogonal basis vector; apply Theorem 11.9.23 with a single term.

Solution. $\langle w_1, v\rangle = x_1 + x_2 + x_3$ and $\langle w_1, w_1\rangle = 3$, so $\pi(v) = c\, w_1$ with $c = \frac{x_1+x_2+x_3}{3}$. Concretely $\pi(v) = \frac{x_1+x_2+x_3}{3}(1,1,1)^\mathsf{T}$. *Check.* $v - \pi(v)$ should lie in $W^\perp$: $\langle w_1, v - \pi(v)\rangle = (x_1 + x_2 + x_3) - 3c = 0$. Correct.

Worked Example 11.9.25 (Coordinates in an orthogonal basis of $\mathbb{R}^3$)**.** Let $v_1 = (1,1,1)^\mathsf{T}$, $v_2 = (1,-1,0)^\mathsf{T}$, $v_3 = (1,1,-2)^\mathsf{T}$, an orthogonal basis of $\mathbb{R}^3$ for the dot product. Express an arbitrary $v = (x_1, x_2, x_3)^\mathsf{T}$ in this basis.



Recognition. Use the $W = V$ form of the projection formula: $c_i = \langle v_i, v\rangle / \langle v_i, v_i\rangle$.

Solution. Compute the squared lengths: $\langle v_1, v_1\rangle = 3$, $\langle v_2, v_2\rangle = 2$, $\langle v_3, v_3\rangle = 6$. Then

$$c_1 = \frac{x_1 + x_2 + x_3}{3}, \qquad c_2 = \frac{x_1 - x_2}{2}, \qquad c_3 = \frac{x_1 + x_2 - 2x_3}{6},$$

and $v = c_1 v_1 + c_2 v_2 + c_3 v_3$. *Check.* The basis is orthogonal — $\langle v_1, v_2\rangle = 1 - 1 + 0 = 0$, $\langle v_1, v_3\rangle = 1 + 1 - 2 = 0$, $\langle v_2, v_3\rangle = 1 - 1 + 0 = 0$ — so the formula applies. Testing $v = v_2$ gives $c_1 = 0$, $c_2 = 1$, $c_3 = 0$, as it must.

The decomposition $v = \pi(v) + (v - \pi(v))$ is the picture worth carrying: $\pi(v)$ is the shadow of v in W, and $v - \pi(v)$ is the orthogonal residual.

Gram–Schmidt orthonormalization

When the form is *positive definite* ($\langle v, v\rangle > 0$ for all $v \neq 0$) we can both orthogonalize and normalize. A real space with a positive-definite symmetric form is a **Euclidean space**; a complex space with a positive-definite Hermitian form is a **Hermitian space**. The length is $|v| = \sqrt{\langle v, v\rangle}$, and an **orthonormal basis** is an orthogonal basis with $\langle v_i, v_i\rangle = 1$ for all i. In an orthonormal basis the form is just the standard dot product (or standard Hermitian form) on coordinate vectors: $\langle v, w\rangle = X^* Y$.

Corollary 11.9.26 (Positive definite ⇒ split on every subspace)**.** *In a Euclidean or Hermitian space the form is nondegenerate on every subspace W, so $V = W \oplus W^\perp$ for all W.*

Proof. For any nonzero $w \in W$, $\langle w, w\rangle > 0$, so w is not a null vector of the restriction; the restricted nullspace is $\{\, 0 \,\}$, i.e. the form is nondegenerate on W. Apply Theorem 11.9.20. □

Method (Gram–Schmidt: turn any basis into an orthonormal one)**.** *Trigger.* A positive-definite form and a basis $v_1, \dots, v_n$; you want an orthonormal basis spanning the same flags $V_k = \mathrm{Span}\{\, v_1, \dots, v_k \,\}$.

1. Set $u_1 = v_1$, then $w_1 = u_1/|u_1|$.
2. Having orthonormal $w_1, \dots, w_{k-1}$ for V_{k-1}, subtract the projection: $u_k = v_k - \sum_{i=1}^{k-1} \langle w_i, v_k \rangle\, w_i$ (denominators are 1 since the w_i are normalized). Then $u_k \perp V_{k-1}$.
3. Normalize: $w_k = u_k/|u_k|$. After n steps $w_1, \dots, w_n$ is orthonormal and $\mathrm{Span}\{\, w_1, \dots, w_k \,\} = V_k$ for each k.

Corollary 11.9.27 (Gram–Schmidt procedure)**.** *Every Euclidean or Hermitian space has an orthonormal basis; the Method above produces one from any starting basis, with $w_k = u_k/|u_k|$ and $u_k = v_k - \pi_{V_{k-1}}(v_k)$.*

Proof. By the projection formula (Theorem 11.9.23) with the orthonormal basis $w_1, \dots, w_{k-1}$ of V_{k-1}, the vector $\pi_{V_{k-1}}(v_k) = \sum_{i<k} \langle w_i, v_k \rangle w_i$, so $u_k = v_k - \pi_{V_{k-1}}(v_k)$ lies in $V_{k-1}^{\perp}$ and is nonzero because $v_k \notin V_{k-1}$. Positive definiteness gives $|u_k| > 0$, so w_k is defined and is a unit vector orthogonal to $w_1, \dots, w_{k-1}$. By induction the whole set is orthonormal and spans the same flag. □

Worked Example 11.9.28 (Gram–Schmidt in $\mathbb{R}^3$)**.** Apply Gram–Schmidt to $v_1 = (1,1,0)^{\mathsf{T}}$, $v_2 = (1,0,1)^{\mathsf{T}}$, $v_3 = (0,1,1)^{\mathsf{T}}$ in $\mathbb{R}^3$ with the dot product.

Recognition. Corollary 11.9.27: orthogonalize by subtracting projections onto the running orthogonal set, then normalize at the end.

Solution. Start $u_1 = v_1 = (1,1,0)^{\mathsf{T}}$, $|u_1|^2 = 2$. Project v_2: $\langle u_1, v_2 \rangle = 1$, so

$$u_2 = v_2 - \frac{\langle u_1, v_2 \rangle}{\langle u_1, u_1 \rangle} u_1 = (1,0,1)^{\mathsf{T}} - \tfrac{1}{2}(1,1,0)^{\mathsf{T}} = \left(\tfrac{1}{2}, -\tfrac{1}{2}, 1\right)^{\mathsf{T}}, \quad |u_2|^2 = \tfrac{3}{2}.$$

Project v_3 onto $\mathrm{Span}\{\, u_1, u_2 \,\}$: $\langle u_1, v_3 \rangle = 1$, $\langle u_2, v_3 \rangle = -\tfrac{1}{2} + 1 = \tfrac{1}{2}$, so

$$u_3 = v_3 - \frac{1}{2} u_1 - \frac{1/2}{3/2} u_2 = (0,1,1)^{\mathsf{T}} - \tfrac{1}{2}(1,1,0)^{\mathsf{T}} - \tfrac{1}{3}\left(\tfrac{1}{2}, -\tfrac{1}{2}, 1\right)^{\mathsf{T}} = \left(-\tfrac{2}{3}, \tfrac{2}{3}, \tfrac{2}{3}\right)^{\mathsf{T}}.$$

Normalize: $w_1 = \frac{1}{\sqrt{2}}(1,1,0)^{\mathsf{T}}$, $w_2 = \frac{1}{\sqrt{6}}(1,-1,2)^{\mathsf{T}}$ (scaling u_2 by 2), $w_3 = \frac{1}{\sqrt{3}}(-1,1,1)^{\mathsf{T}}$. *Check.* $\langle u_1, u_2 \rangle = \tfrac{1}{2} - \tfrac{1}{2} + 0 = 0$; $\langle u_1, u_3 \rangle = -\tfrac{2}{3} + \tfrac{2}{3} + 0 = 0$; $\langle u_2, u_3 \rangle = -\tfrac{1}{3} - \tfrac{1}{3} + \tfrac{2}{3} = 0$. All three are mutually orthogonal and unit length, so w_1, w_2, w_3 is orthonormal. Correct.

Worked Example 11.9.29 (Projecting onto a plane after orthogonalizing)**.** In $\mathbb{R}^3$ (dot product) let $W = \mathrm{Span}\{\, (1,1,0)^{\mathsf{T}}, (1,0,1)^{\mathsf{T}} \,\}$. Compute the orthogonal projection of $v = (2,0,0)^{\mathsf{T}}$ onto W.

Recognition. W's spanning vectors are *not* orthogonal, so first orthogonalize (reuse u_1, u_2 from the previous example), then apply the projection formula (Theorem 11.9.23).

Solution. From above, an orthogonal basis of W is $u_1 = (1,1,0)^{\mathsf{T}}$ ($|u_1|^2 = 2$) and $u_2 = (\tfrac{1}{2}, -\tfrac{1}{2}, 1)^{\mathsf{T}}$ ($|u_2|^2 = \tfrac{3}{2}$). Then $\langle u_1, v \rangle = 2$, $\langle u_2, v \rangle = 1$, so

$$\pi(v) = \frac{2}{2} u_1 + \frac{1}{3/2} u_2 = (1,1,0)^{\mathsf{T}} + \tfrac{2}{3}\left(\tfrac{1}{2}, -\tfrac{1}{2}, 1\right)^{\mathsf{T}} = \left(\tfrac{4}{3}, \tfrac{2}{3}, \tfrac{2}{3}\right)^{\mathsf{T}}.$$

Check. The residual $v - \pi(v) = (\tfrac{2}{3}, -\tfrac{2}{3}, -\tfrac{2}{3})^{\mathsf{T}}$ must be orthogonal to W. Indeed $\langle (1,1,0)^{\mathsf{T}}, v - \pi(v) \rangle = \tfrac{2}{3} - \tfrac{2}{3} = 0$ and $\langle (1,0,1)^{\mathsf{T}}, v - \pi(v) \rangle = \tfrac{2}{3} - \tfrac{2}{3} = 0$. Correct.

Worked Example 11.9.30 (Length and angle from the form)**.** In a Euclidean space, $\langle v, w \rangle = |v|\,|w| \cos\theta$ defines the angle θ. Find the angle between $v = (1,1,0)^{\mathsf{T}}$ and $w = (1,0,1)^{\mathsf{T}}$ in $\mathbb{R}^3$.

Recognition. Restricting the form to $\mathrm{Span}\{\, v, w \,\}$ makes it a 2-dimensional Euclidean space, where the form reads as the dot product and the law of cosines $\langle v, w \rangle = |v||w| \cos\theta$ holds.

Solution. $\langle v, w \rangle = 1$, $|v| = |w| = \sqrt{2}$, so $\cos\theta = \frac{1}{\sqrt{2} \cdot \sqrt{2}} = \tfrac{1}{2}$, giving $\theta = 60°$. *Check.* $\cos\theta = \tfrac{1}{2} \in [-1, 1]$, consistent with the Cauchy–Schwarz bound $|\langle v, w \rangle| \le |v||w|$ that positive definiteness guarantees; here $1 \le 2$. Correct.

Remark 11.9.4. One often keeps the *orthogonal* (unnormalized) basis $u_1, \dots, u_n$ rather than the orthonormal one: normalizing requires extracting square roots like $\sqrt{2}, \sqrt{6}$, which leaves the field $\mathbb{Q}$, whereas the projection formula already works over any nondegenerate form using the denominators $\langle u_i, u_i \rangle$. The orthonormal basis is the right object only when one genuinely wants lengths and the standard form $\langle v, w \rangle = X^* Y$.

Throughout, V is a finite-dimensional *Hermitian space*: a complex vector space carrying a positive-definite Hermitian form $\langle \cdot, \cdot \rangle$, conjugate-linear in the first slot and linear in the second (as in the definition of a Hermitian form above), with $\langle w, v \rangle = \overline{\langle v, w \rangle}$ and $\langle v, v \rangle > 0$ for $v \neq 0$. We fix an orthonormal basis B throughout, so that the form is the standard one $\langle X, Y \rangle = X^* Y$ on coordinate vectors. For a complex matrix A we write $A^* = \overline{A}^{\mathsf{T}}$ for the conjugate transpose. The goal of this section is Artin's Spectral Theorem: a single hypothesis — that an operator commute with its adjoint — forces an orthonormal eigenbasis, and the two cases worth memorizing (Hermitian and unitary) fall out as corollaries.

The adjoint operator

Definition 11.9.31 (Adjoint)**.** Let T be a linear operator on a Hermitian space V. The *adjoint* T^* is the unique operator satisfying

$$\langle Tv, w \rangle = \langle v, T^* w \rangle \qquad \text{for all } v, w \in V.$$

With respect to an orthonormal basis B, if T has matrix A then T^* has matrix $A^* = \overline{A}^{\mathsf{T}}$. The adjoint obeys

$$(T + U)^* = T^* + U^*, \qquad (TU)^* = U^* T^*, \qquad T^{**} = T.$$

Definition 11.9.32 (Normal, Hermitian, unitary)**.** An operator T on a Hermitian space is

$$\textit{normal} \text{ if } TT^* = T^*T, \qquad \textit{Hermitian} \text{ if } T^* = T, \qquad \textit{unitary} \text{ if } T^*T = \mathrm{id}\,.$$

Correspondingly a matrix A is normal if $A^*A = AA^*$, Hermitian if $A^* = A$, and unitary if $A^* = A^{-1}$. Hermitian operators ($T^* = T$) and unitary operators ($T^* = T^{-1}$) are both normal, since each commutes with its own adjoint; normality is the common umbrella under which the Spectral Theorem is stated.

Proposition 11.9.33 (Forms read off the type of T)**.** *Let T act on a Hermitian space V with adjoint T^*.*

(a) $\langle Tv, w \rangle = \langle v, T^* w \rangle$ and $\langle v, Tw \rangle = \langle T^* v, w \rangle$ for all v, w.

(b) T is normal $\iff$ $\langle Tv, Tw \rangle = \langle T^* v, T^* w \rangle$ for all v, w.

(c) T is Hermitian $\iff$ $\langle Tv, w \rangle = \langle v, Tw \rangle$ for all v, w.

(d) T is unitary $\iff$ $\langle Tv, Tw \rangle = \langle v, w \rangle$ for all v, w (i.e. T preserves the form).

Proof. (a) Let A be the matrix of T in an orthonormal basis and write $v = BX$, $w = BY$. Then $\langle Tv, w \rangle = (AX)^* Y = X^* A^* Y$, while $\langle v, T^* w \rangle = X^* A^* Y$ as well, since T^* has matrix A^*; the two agree. The second identity is the same computation with the roles swapped.

(b) Substitute $T^* v$ for v in the first identity of (a) to get $\langle TT^* v, w \rangle = \langle T^* v, T^* w \rangle$, and substitute Tv for v in the second identity to get $\langle Tv, Tw \rangle = \langle T^* Tv, w \rangle$. If T is normal then $TT^* = T^*T$, so the two left sides agree and $\langle Tv, Tw \rangle = \langle T^* v, T^* w \rangle$. Conversely, if those forms agree for all v, w, then $\langle T^* Tv, w \rangle = \langle TT^* v, w \rangle$ for all w; nondegeneracy of the form forces $T^* Tv = TT^* v$ for all v, i.e. T is normal. Parts (c) and (d) are the same substitution argument applied to $T^* = T$ and $T^* T = \mathrm{id}$ respectively. □

Proposition 11.9.34 (Orthogonal complements of invariant subspaces)**.** *Let W be a subspace of V. If W is T-invariant ($TW \subseteq W$), then $W^\perp$ is T^*-invariant. If W is T^*-invariant, then $W^\perp$ is T-invariant.*

Proof. Suppose $TW \subseteq W$ and let $u \in W^\perp$; we must show $T^* u \in W^\perp$, i.e. $\langle w, T^* u \rangle = 0$ for every $w \in W$. By the Proposition above, $\langle w, T^* u \rangle = \langle Tw, u \rangle$. Since $Tw \in W$ and $u \perp W$, this is 0. Hence $T^* u \in W^\perp$. Because $T^{**} = T$, interchanging the roles of T and T^* gives the second statement. □

Caution. The adjoint depends on the form, not just on T as a linear map: in a *non*-orthonormal basis the matrix of T^* is *not* A^*. All of the identities here are stated in an orthonormal basis, where $\langle X, Y \rangle = X^* Y$; if you change to a skew basis you must conjugate by the Gram matrix. Keep the basis orthonormal and the bookkeeping is automatic.

An eigenvector of T is an eigenvector of T^*

The single computational fact that powers the whole theorem is that, for a *normal* operator, eigenvectors are shared with the adjoint, only with the conjugate eigenvalue. This is where positive-definiteness is used.

Theorem 11.9.35 (Shared eigenvectors)**.** *Let T be normal on a Hermitian space V, and let v be an eigenvector of T with eigenvalue λ. Then v is an eigenvector of T^* with eigenvalue $\overline{\lambda}$.*

Proof. Case $\lambda = 0$. Then $Tv = 0$, and we must show $T^*v = 0$. Since the form is positive definite it suffices to show $\langle T^*v, T^*v\rangle = 0$. By normality (part (b) above), $\langle T^*v, T^*v\rangle = \langle Tv, Tv\rangle = \langle 0, 0\rangle = 0$, so $T^*v = 0$.

General λ. Put $S = T - \lambda\,\mathrm{id}$. Then $Sv = 0$, and $S^* = T^* - \overline{\lambda}\,\mathrm{id}$. One checks directly that S is again normal: $SS^* = (T - \lambda)(T^* - \overline{\lambda})$ and $S^*S = (T^* - \overline{\lambda})(T - \lambda)$ expand to the same thing because $TT^* = T^*T$ and scalars commute with everything. By the case $\lambda = 0$ applied to S, v is in the kernel of S^*: $S^*v = T^*v - \overline{\lambda}\,v = 0$, i.e. $T^*v = \overline{\lambda}\,v$. □

Method (Reduce by one dimension and induct)**.** Given a normal T: pick a unit eigenvector v_1 (it exists over $\mathbb{C}$ since the characteristic polynomial has a root). By Theorem 11.9.35, the line $W = \mathrm{Span}(v_1)$ is T^*-invariant, so by Proposition 11.9.34 its orthogonal complement $W^\perp$ is T-invariant. Restrict T to $W^\perp$ — still normal — and recurse on the smaller space. Reassembling the unit eigenvectors gives an orthonormal eigenbasis.

The spectral theorem

Theorem 11.9.36 (Spectral Theorem for normal operators)**.** *Let T be a normal operator on a Hermitian space V.*

(a) There is an orthonormal basis of V consisting of eigenvectors of T.

(b) (Matrix form) If A is a normal matrix, there is a unitary matrix P such that P^*AP is diagonal.

Proof. (a) Induct on $n = \dim V$; the case $n = 0$ is vacuous. For $n \geq 1$ choose an eigenvector of T (the characteristic polynomial has a root over $\mathbb{C}$) and normalize it to a unit vector v_1, with $Tv_1 = \lambda v_1$. By Theorem 11.9.35, v_1 is also an eigenvector of T^*, so the line $W = \mathrm{Span}(v_1)$ is T^*-invariant. By Proposition 11.9.34, $W^\perp$ is T-invariant, and $V = W \oplus W^\perp$ orthogonally. The restriction of T to the invariant subspace $W^\perp$ is again normal (it has the same adjoint formulas), and $\dim W^\perp = n - 1$. By the inductive hypothesis $W^\perp$ has an orthonormal basis $v_2, \ldots, v_n$ of eigenvectors of T. Adjoining v_1 yields an orthonormal basis $v_1, \ldots, v_n$ of V consisting of eigenvectors of T.

(b) Regard A as the matrix (in the standard orthonormal basis of $\mathbb{C}^n$) of the operator "multiply by A," which is normal. By (a) there is an orthonormal basis B of eigenvectors. The change-of-basis matrix P from the standard basis to B has orthonormal columns, hence is unitary, and the matrix of the operator in the new basis is $P^{-1}AP = P^*AP$, which is diagonal. □

The induction is exactly the orthogonal splitting at each stage; the picture below records one step of the recursion.

$$\begin{array}{ccc} V & \xrightarrow{\;=\;} & W \oplus W^\perp \\ {\scriptstyle T}\downarrow & & \downarrow{\scriptstyle T|_W \,\oplus\, T|_{W^\perp}} \\ V & \xrightarrow[\;=\;]{} & W \oplus W^\perp \end{array}$$

Here $W = \mathrm{Span}(v_1)$ carries the scalar λ and $W^\perp$ is the smaller normal problem fed back into the theorem.

Diagram explanation. Objects: All four nodes are the same vector space V, a finite-dimensional Hermitian space. The top-right and bottom-right nodes are written as a direct-sum decomposition $W \oplus W^\perp$, where $W = \mathrm{Span}(v_1)$ is the line spanned by the chosen unit eigenvector v_1 (it lies in the λ-eigenspace, which may be larger), and $W^\perp$ is its orthogonal complement (a $(n-1)$-dimensional T-invariant subspace).

Arrows: The two horizontal arrows labelled "=" are the *canonical decomposition isomorphisms* $V \xrightarrow{\sim} W \oplus W^\perp$: the top one sends $v \mapsto \mathrm{proj}_W v \oplus \mathrm{proj}_{W^\perp} v$, and the bottom one is the same map on the output copy of V. These are written "=" because the splitting is orthogonal and canonical (no choice beyond v_1). The

left vertical arrow is $T\colon V \to V$. The right vertical arrow is $T|_W \oplus T|_{W^\perp}\colon W \oplus W^\perp \to W \oplus W^\perp$, the block-diagonal restriction: on W it acts as scalar multiplication by λ, and on $W^\perp$ it is the restricted (still normal) operator fed to the next induction step.

What commutes: The square says: applying T and then decomposing equals decomposing first and then applying the block-diagonal restriction. Concretely, for any $v = w + u$ with $w \in W$, $u \in W^\perp$: (T then decompose)$(v) = Tv = Tw + Tu = \lambda w + T|_{W^\perp} u$; (decompose then restrict)$(v) = T|_W(w) \oplus T|_{W^\perp}(u) = \lambda w \oplus T|_{W^\perp} u$. These are the same.

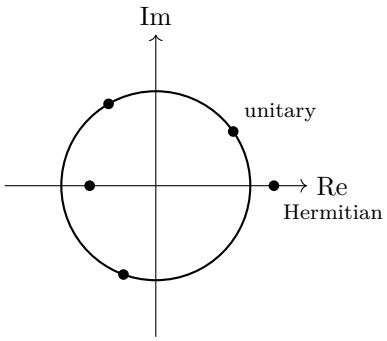
Why it commutes: The key is that both W and $W^\perp$ are T-invariant: W is invariant because v_1 is an eigenvector, and $W^\perp$ is invariant by Proposition 11.9.34 (since W is T^*-invariant by Theorem 11.9.35). Invariance of both summands is exactly what makes T block-diagonal in the decomposition $W \oplus W^\perp$, so the two paths through the square produce the same vector.

Why this matters here: This diagram organizes the inductive step of the proof of the Spectral Theorem (Theorem 11.9.36). Each application of the recursion peels off one eigenvector v_1, splits V into $W \oplus W^\perp$, and reduces the problem from dimension n to dimension $n-1$ on $W^\perp$. The commutativity of the square is the assertion that T respects this splitting, making the restriction to $W^\perp$ well-defined and still normal.

Concrete example: Take $n = 2$ and $A = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 3 \end{smallmatrix}\right)$ acting on $\mathbb{C}^2$ with the standard Hermitian form. Choose $v_1 = e_1$ (eigenvalue $\lambda = 2$); then $W = \mathrm{Span}(e_1)$ and $W^\perp = \mathrm{Span}(e_2)$. The block- diagonal form is $A|_W \oplus A|_{W^\perp} = [2] \oplus [3]$, and the square commutes: $Ae_1 = 2e_1 \in W$, $Ae_2 = 3e_2 \in W^\perp$.

Common pitfall: Students sometimes read the horizontal "=" as asserting that V *is* $W \oplus W^\perp$ as a set, and conclude the diagram is trivially empty content. In fact the two horizontal arrows are doing real work: they encode the fact that the splitting is T-*equivariant*, i.e. that T does not mix the two summands. Without invariance of $W^\perp$, the right vertical arrow would not be well-defined as a map on $W \oplus W^\perp$, and the square would fail.

Takeaway: The point of this diagram is that normality forces the orthogonal complement of each eigenspace to be T-invariant, so T splits into an independent scalar on W and a smaller normal problem on $W^\perp$, making the induction work.



Corollary 11.9.37 (Hermitian operators have real eigenvalues)**.** *Let T be Hermitian ($T^* = T$). Then V has an orthonormal basis of eigenvectors, and every eigenvalue of T is real. In matrix form: a Hermitian matrix A admits a unitary P with P^*AP a* real *diagonal matrix.*

Proof. A Hermitian operator is normal, so Theorem 11.9.36 gives the orthonormal eigenbasis. For reality: if $Tv = \lambda v$ with $v \neq 0$, then by Theorem 11.9.35 also $T^*v = \overline{\lambda}\, v$; but $T^* = T$, so $\overline{\lambda}\, v = Tv = \lambda v$, forcing $\overline{\lambda} = \lambda$, i.e. $\lambda \in \mathbb{R}$. The diagonal of P^*AP is the list of eigenvalues, all real. □

Corollary 11.9.38 (Unitary operators: eigenvalues on the unit circle)**.** *Let T be unitary ($T^*T = \mathrm{id}$). Then V has an orthonormal basis of eigenvectors, and every eigenvalue satisfies $|\lambda| = 1$. In matrix form: a unitary matrix A admits a unitary P with P^*AP diagonal, each diagonal entry of absolute value* 1*.*

Proof. A unitary operator is normal, so we have the eigenbasis. If $Tv = \lambda v$ with $\|v\| = 1$, then by part (d) the form is preserved: $1 = \langle v, v\rangle = \langle Tv, Tv\rangle = \langle \lambda v, \lambda v\rangle = \lambda\overline{\lambda}\,\langle v, v\rangle = |\lambda|^2$, so $|\lambda| = 1$. □

The two corollaries place the eigenvalues on the two distinguished loci of the complex plane: Hermitian eigenvalues lie on the real axis, unitary eigenvalues on the unit circle. (Real symmetric matrices, below, are the real-axis case made real.)

Theorem 11.9.39 (Spectral Theorem for real symmetric matrices)**.** *Let A be a real symmetric matrix ($A^{\mathsf{T}} = A$). Then there is a real orthogonal matrix P (i.e. $P^{\mathsf{T}}P = I$, P real) such that $P^{\mathsf{T}}AP$ is a real diagonal matrix. Equivalently, a symmetric operator on a Euclidean space has an orthonormal eigenbasis, and all its eigenvalues are real. We say A is* orthogonally diagonalizable.

Proof. View the real symmetric A as a complex Hermitian matrix (a real symmetric matrix satisfies $A^* = A^{\mathsf{T}} = A$). By Corollary 11.9.37 its eigenvalues are real, and its characteristic polynomial — a real polynomial — therefore splits over $\mathbb{R}$. Running the induction of Theorem 11.9.36 entirely over $\mathbb{R}$: at each stage pick a real unit eigenvector v_1 (it exists because the real eigenvalue λ gives a real eigenspace $\ker(A - \lambda I) \neq 0$), split $\mathbb{R}^n = \operatorname{Span}(v_1) \oplus \operatorname{Span}(v_1)^{\perp}$ orthogonally, and recurse on the symmetric restriction. The resulting orthonormal eigenbasis is real, and the change-of-basis matrix P assembled from these real orthonormal columns is a real orthogonal matrix with $P^{\mathsf{T}}AP$ diagonal. □

Remark 11.9.5. A clean uniform statement: T is diagonalizable in an orthonormal basis if and only if T is normal. The three named cases impose where the eigenvalues live — the real line (Hermitian/symmetric) or the unit circle (unitary) — but they do not change the diagonalization mechanism, which is normality alone.

Worked examples

Worked Example 11.9.40 (Orthogonally diagonalizing a 2×2 real symmetric matrix)**.** Find a real orthogonal P with $P^{\mathsf{T}}AP$ diagonal, where $A = \left(\begin{smallmatrix} 2 & 1 \\ 1 & 2 \end{smallmatrix}\right)$.

Recognition. A is real symmetric, so Theorem 11.9.39 applies: real eigenvalues, and eigenvectors for distinct eigenvalues are automatically orthogonal. The recipe is: eigenvalues, then unit eigenvectors as the columns of P.

Solution. The characteristic polynomial is $\det(A - \lambda I) = (2-\lambda)^2 - 1 = \lambda^2 - 4\lambda + 3 = (\lambda - 1)(\lambda - 3)$, so $\lambda = 3, 1$. For $\lambda = 3$: $(A - 3I) = \left(\begin{smallmatrix} -1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$ gives eigenvector $(1,1)^{\mathsf{T}}$; for $\lambda = 1$: $\left(\begin{smallmatrix} 1 & 1 \\ 1 & 1 \end{smallmatrix}\right)$ gives $(1,-1)^{\mathsf{T}}$. These are orthogonal (dot product 0); normalize by $1/\sqrt{2}$:

$$P = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}, \qquad P^{\mathsf{T}}AP = \begin{pmatrix} 3 & 0 \\ 0 & 1 \end{pmatrix}.$$

Check. $P^{\mathsf{T}}P = \frac{1}{2}\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, so P is orthogonal; and the trace $2 + 2 = 4 = 3 + 1$ and determinant $4 - 1 = 3 = 3 \cdot 1$ match the diagonal, as they must under conjugation.

Worked Example 11.9.41 (A 3×3 symmetric matrix with a repeated eigenvalue)**.** Orthogonally diagonalize $A = \left(\begin{smallmatrix} 2 & 0 & 0 \\ 0 & 3 & 1 \\ 0 & 1 & 3 \end{smallmatrix}\right)$.

Recognition. Real symmetric again. The block structure (a 1×1 block [2] and the 2×2 block $\left(\begin{smallmatrix} 3 & 1 \\ 1 & 3 \end{smallmatrix}\right)$) lets us diagonalize each block orthogonally and assemble.

Solution. The characteristic polynomial factors as $(2-\lambda)\big[(3-\lambda)^2 - 1\big] = (2-\lambda)(\lambda - 2)(\lambda - 4)$, so the eigenvalues are $\lambda = 4$ and $\lambda = 2$ (the latter a double root). For $\lambda = 4$: solving $(A - 4I)x = 0$ gives $x = (0,1,1)^{\mathsf{T}}$. For the double eigenvalue $\lambda = 2$: $(A - 2I) = \left(\begin{smallmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{smallmatrix}\right)$ has nullspace spanned by $(1,0,0)^{\mathsf{T}}$ and

$(0,1,-1)^{\mathsf{T}}$, already mutually orthogonal and orthogonal to $(0,1,1)^{\mathsf{T}}$. Normalize:

$$P = \begin{pmatrix} 0 & 1 & 0 \\ \frac{1}{\sqrt{2}} & 0 & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & 0 & -\frac{1}{\sqrt{2}} \end{pmatrix}, \qquad P^{\mathsf{T}}AP = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{pmatrix}.$$

Check. The columns are orthonormal (the two $\lambda = 2$ columns and the $\lambda = 4$ column are pairwise orthogonal and unit length), and $\operatorname{tr} A = 2+3+3 = 8 = 4+2+2$, confirming the spectrum. The repeated eigenvalue still gives an orthonormal basis — exactly the content of the theorem beyond "distinct eigenvalues."

Worked Example 11.9.42 (A normal matrix that is neither Hermitian nor real symmetric)**.** Show $A = \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ (real, but not symmetric) is normal, and unitarily diagonalize it; locate its eigenvalues.

Recognition. Normality is $A^*A = AA^*$; here $A^* = A^{\mathsf{T}}$ since A is real. The Spectral Theorem 11.9.36 then guarantees a unitary P with P^*AP diagonal, even though A is not Hermitian.

Solution. Compute $A^{\mathsf{T}} = \left(\begin{smallmatrix} 1 & 1 \\ -1 & 1 \end{smallmatrix}\right)$. Then $A^{\mathsf{T}}A = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right) = AA^{\mathsf{T}}$, so A is normal. The eigenvalues solve $(1-\lambda)^2+1 = 0$, i.e. $\lambda = 1 \pm i$. Eigenvectors: for $\lambda = 1+i$, $(A-(1+i)I) = \left(\begin{smallmatrix} -i & -1 \\ 1 & -i \end{smallmatrix}\right)$ gives $(1,-i)^{\mathsf{T}}$; for $\lambda = 1-i$, $(1,i)^{\mathsf{T}}$. These are orthogonal under the Hermitian form: $\langle (1,-i),(1,i)\rangle = \overline{1}\cdot 1 + \overline{(-i)}\cdot i = 1 + i\cdot i = 1-1 = 0$. Normalize by $1/\sqrt{2}$:

$$P = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}, \qquad P^*AP = \begin{pmatrix} 1+i & 0 \\ 0 & 1-i \end{pmatrix}.$$

Check. $P^*P = I$ (the columns are orthonormal), and $A = \sqrt{2}\left(\begin{smallmatrix} \cos\frac{\pi}{4} & -\sin\frac{\pi}{4} \\ \sin\frac{\pi}{4} & \cos\frac{\pi}{4} \end{smallmatrix}\right)$ is $\sqrt{2}$ times a rotation, so its eigenvalues $\sqrt{2}\,e^{\pm i\pi/4} = 1 \pm i$ sit off both the real axis and the unit circle — normal without being Hermitian or unitary, exactly the generality the theorem buys.

Worked Example 11.9.43 (Reading the type of T off its spectrum)**.** A normal operator T on a Hermitian space has spectrum $\{\,2,\ -3,\ i,\ -i\,\}$. Can T be Hermitian? Unitary? Neither?

Recognition. By Corollaries 11.9.37 and 11.9.38, Hermitian forces all eigenvalues real and unitary forces all $|\lambda| = 1$; a normal T is diagonalizable regardless.

Solution. The eigenvalues $i, -i$ are non-real, so T is *not* Hermitian. The eigenvalues $2, -3$ have $|\lambda| \neq 1$, so T is *not* unitary. It is nonetheless normal (we are told so), hence still orthogonally/unitarily diagonalizable with an orthonormal eigenbasis. *Check.* i and $-i$ lie on the unit circle but off the real axis, while $2, -3$ lie on the real axis but off the circle — the spectrum straddles both special loci, so neither corollary's hypothesis holds, yet the main theorem still does.

Remark 11.9.6. Artin's slogan is worth keeping: "When faced with a Hermitian operator or a Hermitian matrix, it should be an automatic response to apply the Spectral Theorem." Concretely, the moment you see a real symmetric or Hermitian matrix, you already know it is orthogonally/unitarily diagonalizable with real eigenvalues — no further hypothesis is needed, and the eigenvectors for distinct eigenvalues come out orthogonal for free.

Quadratic forms and the principal axis theorem

Throughout, V is a finite-dimensional real vector space and we work with column vectors $X \in \mathbb{R}^n$. A symmetric form on $\mathbb{R}^n$ is recorded by a symmetric matrix A via $\langle X, Y\rangle = X^{\mathsf{T}}AY$, and its associated *quadratic form* is the diagonal restriction $q(X) = X^{\mathsf{T}}AX$. Geometrically, the zero loci of degree-two polynomials are the conics and quadrics, and the whole theory of this section is the statement that, up to a change of variables, only a short list of them occurs.

Definition 11.9.44 (Quadratic form)**.** A **quadratic form** in the variables $x_1, \dots, x_n$ is a polynomial each of whose terms has degree exactly 2. Collecting coefficients into a symmetric matrix $A = (a_{ij})$ (so that the coefficient of x_ix_j with $i \neq j$ is split as $2a_{ij}$), every such form is

$$q(x_1,\dots,x_n) \;=\; \sum_i a_{ii}x_i^2 \;+\; \sum_{i<j} 2a_{ij}\,x_ix_j \;=\; X^{\mathsf{T}}AX, \qquad X = (x_1,\dots,x_n)^{\mathsf{T}}.$$

The matrix A is uniquely determined by q. A general (inhomogeneous) quadratic polynomial is $f(X) = X^{\mathsf{T}}AX + BX + c$ with B a $1 \times n$ row and $c \in \mathbb{R}$.

The half-coefficient convention is exactly the one that makes A symmetric: the form $x_1^2 + 2x_1x_2 - x_2^2$ has matrix $\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, not $\left(\begin{smallmatrix} 1 & 2 \\ 0 & -1 \end{smallmatrix}\right)$.

Theorem 11.9.45 (Principal axes / Spectral Theorem, matrix form)**.** *Let A be a real symmetric $n \times n$ matrix. Then there is an orthogonal matrix P (so $P^{\mathsf{T}}P = I$, i.e. $P^{\mathsf{T}} = P^{-1}$) such that*

$$P^{\mathsf{T}}AP \;=\; \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$$

is diagonal, and the λ_i are the (necessarily real) eigenvalues of A. In the new variables $X = PX'$ the quadratic form becomes a sum of squares $q = \sum_i \lambda_i x_i'^2$ with no cross terms.

Proof. The eigenvalues of a real symmetric matrix are real: if $Av = \lambda v$ with $v \neq 0$ a complex eigenvector, then $\overline{v}^{\mathsf{T}}Av = \lambda\,\overline{v}^{\mathsf{T}}v$, while taking conjugate transpose and using $A^{\mathsf{T}} = A$, $\overline{A} = A$ gives $\overline{v}^{\mathsf{T}}Av = \overline{\lambda}\,\overline{v}^{\mathsf{T}}v$; since $\overline{v}^{\mathsf{T}}v > 0$ we get $\lambda = \overline{\lambda}$. Now argue by induction on n. Pick a real unit eigenvector v_1, $Av_1 = \lambda_1 v_1$. Its orthogonal complement $W = v_1^{\perp}$ is A-invariant: for $w \perp v_1$, $\langle v_1, Aw\rangle = \langle Av_1, w\rangle = \lambda_1\langle v_1, w\rangle = 0$, so $Aw \in W$. The restriction of A to W is again symmetric, so by induction W has an orthonormal basis of eigenvectors; adjoining v_1 gives an orthonormal eigenbasis of $\mathbb{R}^n$. Stacking these as the columns of P makes P orthogonal and $P^{\mathsf{T}}AP$ diagonal. Substituting $X = PX'$, $q = X^{\mathsf{T}}AX = (PX')^{\mathsf{T}}A(PX') = X'^{\mathsf{T}}(P^{\mathsf{T}}AP)X' = \sum_i \lambda_i x_i'^2$. □

Method (Classifying a conic $f = 0$ in the plane)**.** *Trigger.* A quadratic polynomial $f(x_1, x_2) = a_{11}x_1^2 + 2a_{12}x_1x_2 + a_{22}x_2^2 + b_1x_1 + b_2x_2 + c$ is given.

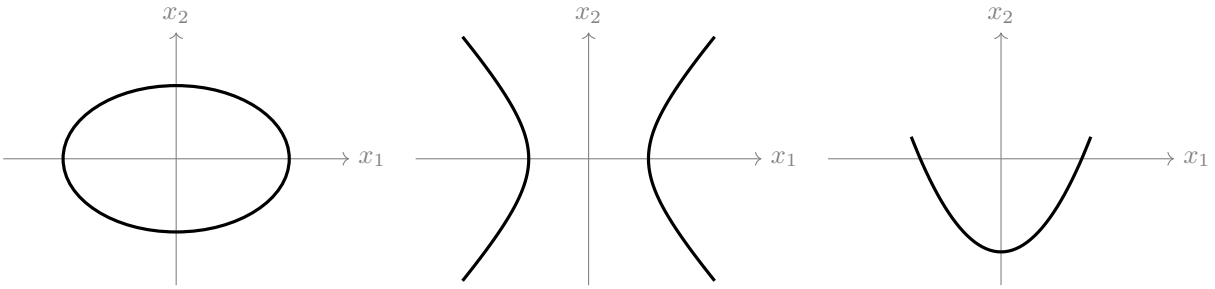
1. Form the symmetric matrix $A = \left(\begin{smallmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{smallmatrix}\right)$ and read off $\det A$. *Sign of* $\det A$ *already decides the type:* $\det A > 0$ (definite) gives an ellipse, $\det A < 0$ (indefinite) a hyperbola, $\det A = 0$ a parabola — up to degenerate cases.

2. Diagonalize: by Theorem 11.9.45 an orthogonal P kills the cross term, leaving $\lambda_1x_1^2 + \lambda_2x_2^2 + b_1'x_1 + b_2'x_2 + c = 0$.

3. Complete the square in each variable with $\lambda_i \neq 0$; this is a translation (see the proof of Theorem 11.9.46) and removes the corresponding linear term.

4. Rescale by a nonzero constant to normalize the constant term to -1 (or, in the parabolic case, to put the equation in the form $a_{11}x_1^2 - x_2 = 0$). Match against the list in Theorem 11.9.46.

Shortcut for type only: if you only need the *type*, arbitrary (not necessarily orthogonal) changes of variable are allowed — they distort an ellipse but never turn it into a hyperbola or a parabola.



Theorem 11.9.46 (Classification of plane conics)**.** *Every nondegenerate conic in $\mathbb{R}^2$ is congruent, by an isometry, to one of the following loci, where $a_{11}, a_{22} > 0$:*

$$\textit{Ellipse: } a_{11}x_1^2 + a_{22}x_2^2 - 1 = 0, \quad \textit{Hyperbola: } a_{11}x_1^2 - a_{22}x_2^2 - 1 = 0, \quad \textit{Parabola: } a_{11}x_1^2 - x_2 = 0.$$

The type and the coefficients are determined by the conic, except that a_{11} and a_{22} may be interchanged in the equation of an ellipse. The remaining loci of a quadratic equation — a pair of lines, a single line, a point, or the empty set — are called degenerate.

Proof. By Theorem 11.9.45 an orthogonal change of variable diagonalizes the quadratic part, so we may assume $f = a_{11}x_1^2 + a_{22}x_2^2 + b_1x_1 + b_2x_2 + c$. If $a_{ii} \neq 0$ the substitution $x_i \mapsto x_i - \frac{b_i}{2a_{ii}}$ (a translation) eliminates b_i and absorbs the change into c; this is completing the square. When both $a_{ii} \neq 0$ we reach $a_{11}x_1^2 + a_{22}x_2^2 + c = 0$. If $c = 0$ the locus is degenerate (a point or a pair of lines); otherwise scale so $c = -1$. If both $a_{ii} < 0$ the locus is empty (degenerate), so at least one is positive; arranging $a_{11} > 0$ gives the ellipse ($a_{22} > 0$) or the hyperbola ($a_{22} < 0$). If instead one eigenvalue vanishes, say $a_{22} = 0$, then f is genuinely quadratic forces $a_{11} \neq 0$; if $b_2 \neq 0$ the substitution $x_2 \mapsto x_2 - c/b_2$ removes the constant and, after scaling, leaves the parabola $a_{11}x_1^2 - x_2 = 0$; if $b_2 = 0$ the locus degenerates to two lines, one line, or empty. □

Remark 11.9.7. The two operations are different in kind. The orthogonal step (principal axes) *rotates* so the axes of the conic align with the coordinate axes; the completing-the-square step *translates* so the center sits at the origin. Together they exhaust the isometry group of the plane up to reflection, which is why congruence classes match the list above.

ellipse: $\det A > 0$ hyperbola: $\det A < 0$ parabola: $\det A = 0$

Worked Example 11.9.47 (Classify a conic by its discriminant)**.** Classify the locus $x_1^2 + 2x_1x_2 - x_2^2 + 2x_1 + 2x_2 - 1 = 0$ (Artin's example).

Recognition. Method "Classifying a conic": the matrix A and $\det A$ decide the type; for type alone an arbitrary change of variable is legal.

Solution. Here $A = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, $B = (2\ 2)$, $c = -1$, and $\det A = -1 - 1 = -2 < 0$, so A is indefinite and the conic is a hyperbola or degenerate. To confirm, use the nonorthogonal change $x_1 \mapsto x_1 - x_2$, $x_2 \mapsto x_2$ to clear the cross term; the polynomial becomes $x_1^2 - 2x_2^2 + 2x_1 - 1 = 0$, and completing the square in x_1 ($x_1^2 + 2x_1 = (x_1+1)^2 - 1$) gives, after a translation and dropping primes, $x_1^2 - 2x_2^2 - 2 = 0$, i.e. $\frac{1}{2}x_1^2 - x_2^2 - 1 = 0$. *Check.* This is the hyperbola form $a_{11}x_1^2 - a_{22}x_2^2 - 1 = 0$ with $a_{11} = \frac{1}{2}$, $a_{22} = 1$, matching the prediction $\det A < 0$. The locus is a hyperbola.

Worked Example 11.9.48 (From eigenvalues to principal axes)**.** Put $q(x_1, x_2) = 5x_1^2 - 4x_1x_2 + 5x_2^2$ into principal-axis form and name the conic $q = 9$.

Recognition. Theorem 11.9.45: diagonalize the symmetric matrix; the diagonal entries are the eigenvalues and the conic type follows from their signs.

Solution. $A = \left(\begin{smallmatrix} 5 & -2 \\ -2 & 5 \end{smallmatrix}\right)$ has characteristic polynomial $(5-\lambda)^2 - 4 = \lambda^2 - 10\lambda + 21 = (\lambda - 3)(\lambda - 7)$, so $\lambda_1 = 3$, $\lambda_2 = 7$. Orthonormal eigenvectors are $\frac{1}{\sqrt{2}}(1,1)^{\mathsf{T}}$ (for 3) and $\frac{1}{\sqrt{2}}(1,-1)^{\mathsf{T}}$ (for 7). With $P = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$ orthogonal, $P^{\mathsf{T}}AP = \operatorname{diag}(3, 7)$ and $q = 3x_1'^2 + 7x_2'^2$. *Check.* $q = 9$ becomes $\frac{x_1'^2}{3} + \frac{x_2'^2}{9/7} = 1$; both coefficients positive, so an ellipse with semi-axes along the lines $x_1 = x_2$ and $x_1 = -x_2$. Eigenvalues both positive $\Rightarrow \det A = 21 > 0$, consistent with "ellipse."

Sylvester's law of inertia

Over $\mathbb{R}$ we may go further than diagonalizing: rescaling each axis lets us reduce every diagonal entry to 1, -1, or 0. What is rescaling-invariant is then only the *number* of each sign.

Theorem 11.9.49 (Normal form; signature)**.** *Let A be a real symmetric $n \times n$ matrix. There is an invertible real matrix Q such that*

$$Q^{\mathsf{T}}AQ \;=\; \begin{pmatrix} I_p & & \\ & -I_m & \\ & & 0_z \end{pmatrix}, \qquad p + m + z = n,$$

with p ones, m minus-ones, and z zeros on the diagonal. The form is nondegenerate iff $z = 0$. The pair (p, m) is the ***signature*** *of the form.*

Proof. By Theorem 11.9.45 an orthogonal P gives $P^{\mathsf{T}}AP = \operatorname{diag}(\lambda_1, \dots, \lambda_n)$. For each i replace the ith basis vector by a scalar multiple: under $v_i \mapsto c_i v_i$ the entry λ_i becomes $c_i^2\lambda_i$. Choosing $c_i = 1/\sqrt{|\lambda_i|}$ when $\lambda_i \neq 0$ normalizes it to $\operatorname{sign}(\lambda_i) = \pm 1$, and $\lambda_i = 0$ stays 0. Folding this diagonal rescaling D into $Q = PD$ yields the stated normal form. Nondegeneracy means $\det A \neq 0$, i.e. no zero eigenvalue, i.e. $z = 0$. □

Theorem 11.9.50 (Sylvester's Law of Inertia)**.** *The signature (p, m) in Theorem 11.9.49 depends only on the congruence class of A, not on the diagonalizing matrix Q. Equivalently, two real symmetric matrices are congruent ($A' = Q^{\mathsf{T}}AQ$ for invertible Q) iff they have the same rank $p + m$ and the same p.*

Proof. The number z of zeros is congruence-invariant because $\operatorname{rank}(Q^{\mathsf{T}}AQ) = \operatorname{rank} A$ for invertible Q, so $p + m = \operatorname{rank} A$ is fixed; it remains to show p is fixed. Realize A as a symmetric form $\beta(X, Y) = X^{\mathsf{T}}AY$. Let p_0 be the largest dimension of a subspace $U \subseteq \mathbb{R}^n$ on which β is *positive definite*, i.e. $\beta(u, u) > 0$ for all $u \neq 0$ in U; this number is defined without reference to any basis, hence is a congruence invariant. In the normal-form basis $v_1, \ldots, v_n$, the span U_+ of the p vectors with $\beta(v_i, v_i) = +1$ is positive definite, so the invariant is $\geq p$. Conversely, if U has dimension $> p$, then U meets the span V_- of the $m + z$ vectors with $\beta(v_i, v_i) \leq 0$ nontrivially (dimensions add to more than n), giving a nonzero $u \in U \cap V_-$ with $\beta(u, u) \leq 0$, contradicting positive-definiteness on U. Hence the invariant equals p, so p is determined by the congruence class. □

Caution. Signature is a *congruence* ($Q^{\mathsf{T}}AQ$) invariant, not a *similarity* ($Q^{-1}AQ$) invariant. Congruence preserves the signs of the eigenvalues but not their magnitudes; similarity preserves the eigenvalues themselves. The two notions agree only when Q is orthogonal, where $Q^{\mathsf{T}} = Q^{-1}$.

Worked Example 11.9.51 (Find a signature)**.** Find the signature of $A = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 2 \end{smallmatrix}\right)$.

Recognition. Theorem 11.9.49: signature counts the positive and negative eigenvalues; either diagonalize or reduce by congruence.

Solution. The eigenvalues come from the block structure: the 2×2 block $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has eigenvalues ± 1, and the last block contributes 2. So the eigenvalues are $1, -1, 2$: one is negative, two positive, none zero. Hence $p = 2$, $m = 1$, $z = 0$, signature $(2, 1)$, and A is congruent to $\operatorname{diag}(1, 1, -1) = I_{2,1}$. *Check.* $\det A = 2 \cdot (0 \cdot 0 - 1 \cdot 1) = -2 \neq 0$ confirms $z = 0$; the sign of $\det A = \lambda_1\lambda_2\lambda_3 = (1)(-1)(2) = -2$ matches an odd number ($m = 1$) of negative eigenvalues.

Worked Example 11.9.52 (Signature by completing squares)**.** Determine the signature of $q(x, y, z) = x^2 + 2xy + 2y^2 + 4yz + 5z^2$ without computing eigenvalues.

Recognition. Theorem 11.9.50 lets us use *any* invertible change of variable; completing squares is a congruence and reads off the signs directly.

Solution. Group around x: $x^2 + 2xy = (x + y)^2 - y^2$, so $q = (x + y)^2 + y^2 + 4yz + 5z^2$. Now group the y terms: $y^2 + 4yz = (y + 2z)^2 - 4z^2$, giving $q = (x + y)^2 + (y + 2z)^2 + z^2$. Set $u = x + y$, $v = y + 2z$, $w = z$ (an invertible substitution). Then $q = u^2 + v^2 + w^2$, all coefficients $+1$. *Check.* Signature $(3, 0)$, so q is positive definite; indeed q is a sum of three real squares, hence ≥ 0 and zero only when $u = v = w = 0$, i.e. $x = y = z = 0$. Congruent to I_3.

Skew-symmetric forms and the symplectic basis

The other side of the bilinear coin: a form with $\langle v, v\rangle = 0$ for every v. Here, unless the form is zero, there is no orthogonal basis at all, yet the classification is even cleaner — there is a single normal form, and rank is forced to be even.

Definition 11.9.53 (Skew-symmetric form)**.** A bilinear form $\langle\,,\,\rangle$ on V is **skew-symmetric** (alternating) if $\langle v, v\rangle = 0$ for all $v \in V$. Over a field of characteristic $\neq 2$ this is equivalent to $\langle u, v\rangle = -\langle v, u\rangle$ for all u, v. Its matrix A satisfies $A^{\mathsf{T}} = -A$ with zero diagonal.

The equivalence over char $\neq 2$ is the expansion $0 = \langle u + v, u + v\rangle = \langle u, u\rangle + \langle u, v\rangle + \langle v, u\rangle + \langle v, v\rangle = \langle u, v\rangle + \langle v, u\rangle$. The basic example is the determinant form $\langle X, Y\rangle = \det\left(\begin{smallmatrix} x_1 & y_1 \\ x_2 & y_2 \end{smallmatrix}\right) = x_1y_2 - x_2y_1$ on $\mathbb{R}^2$, with matrix $S = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$.

Theorem 11.9.54 (Standard symplectic form)**.** *Let $\langle\,,\,\rangle$ be a nondegenerate skew-symmetric form on a vector space V of dimension m over a field F. Then m is even, $m = 2n$, and V has a basis in which the*

matrix of the form is block-diagonal with n copies of $S = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$:

$$S_0 = \begin{pmatrix} S & & \\ & \ddots & \\ & & S \end{pmatrix}.$$

In matrix terms, every invertible skew-symmetric A satisfies $P^{\mathsf{T}}AP = S_0$ for some invertible P.

Proof. Since the form is nondegenerate and $V \neq 0$, choose v_1, v_2 with $\langle v_1, v_2\rangle = c \neq 0$; scaling v_2 by c^{-1} makes $\langle v_1, v_2\rangle = 1$. As $\langle v_1, v_2\rangle \neq 0$ but $\langle v_1, v_1\rangle = \langle v_2, v_2\rangle = 0$, the vectors v_1, v_2 are independent. On the plane $W = \operatorname{Span}\{v_1, v_2\}$ the matrix of the form is exactly S, which is invertible, so the form is nondegenerate on W. Hence $V = W \oplus W^{\perp}$ and the form is nondegenerate on $W^{\perp}$. By induction on dimension, $W^{\perp}$ has a basis $v_3, \ldots, v_m$ putting the form into block form S_0; then $v_1, \ldots, v_m$ is the required basis of V. In particular the construction pairs basis vectors two at a time, so $\dim V$ is even. □

Corollary 11.9.55 (Even rank)**.** *If A is an invertible $m \times m$ skew-symmetric matrix, then m is even. More generally, every skew-symmetric matrix has even rank.*

Proof. The invertible case is immediate from Theorem 11.9.54. In general, restrict the form to a complement of its radical (the set of v with $\langle v, w\rangle = 0$ for all w); the induced form there is nondegenerate skew-symmetric, hence of even dimension equal to $\operatorname{rank} A$. □

Remark 11.9.8. Reordering the symplectic basis as $(v_1, v_3, \ldots, v_{2n-1}; v_2, v_4, \ldots, v_{2n})$ turns S_0 into the more familiar block form $\left(\begin{smallmatrix} 0 & I_n \\ -I_n & 0 \end{smallmatrix}\right)$. Contrast with the symmetric case: symmetric forms have an *orthogonal* basis and a sign-sensitive invariant (the signature), whereas skew forms have a *symplectic* basis, no signs, and a single discrete invariant — the rank, which is always even.

Worked Example 11.9.56 (A symplectic basis on $\mathbb{R}^4$)**.** The form with matrix $A = \left(\begin{smallmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{smallmatrix}\right)$ is skew-symmetric and nondegenerate. Exhibit a symplectic basis.

Recognition. Theorem 11.9.54: peel off a hyperbolic plane $\langle v_1, v_2\rangle = 1$, then repeat on the orthogonal complement.

Solution. Write $e_1, \ldots, e_4$ for the standard basis. From A, $\langle e_1, e_4\rangle = 1$, so take $v_1 = e_1$, $v_2 = e_4$; the plane $W = \operatorname{Span}\{e_1, e_4\}$ carries the matrix S. Its orthogonal complement is $W^{\perp} = \operatorname{Span}\{e_2, e_3\}$, on which $\langle e_2, e_3\rangle = 1$, so take $v_3 = e_2$, $v_4 = e_3$. In the basis (e_1, e_4, e_2, e_3) the form has matrix $S_0 = \operatorname{diag}(S, S)$. *Check.* $\langle v_1, v_2\rangle = \langle e_1, e_4\rangle = 1$, $\langle v_3, v_4\rangle = \langle e_2, e_3\rangle = 1$, and the cross pairings $\langle e_1, e_2\rangle, \langle e_1, e_3\rangle, \langle e_4, e_2\rangle, \langle e_4, e_3\rangle$ are all 0 from A. So $P^{\mathsf{T}}AP = S_0$ with $P = [\, e_1\, e_4\, e_2\, e_3 \,]$.

Worked Example 11.9.57 (No odd-dimensional nondegenerate skew form)**.** Show directly that a 3×3 skew-symmetric matrix is always singular.

Recognition. Corollary 11.9.55: skew matrices have even rank, so a 3×3 one cannot have rank 3.

Solution. For skew A, $\det(A^{\mathsf{T}}) = \det(-A) = (-1)^3 \det A = -\det A$; but $\det(A^{\mathsf{T}}) = \det A$, so $\det A = -\det A$, forcing $2 \det A = 0$, hence $\det A = 0$ over any field of characteristic $\neq 2$. Thus A is singular and its rank is at most 2 — in fact 0 or 2 by even-rank. *Check.* The explicit $A = \left(\begin{smallmatrix} 0 & a & b \\ -a & 0 & c \\ -b & -c & 0 \end{smallmatrix}\right)$ has $\det A = 0$ by direct expansion $(a \cdot (0 \cdot 0 - c \cdot (-b)) - b \cdot ((-a) \cdot (-c) - 0) = abc - abc = 0$ after sign bookkeeping). Consistent with even rank.

Remark 11.9.9. The two normal-form theorems of this section are the linear-algebra core behind the classification of conics and quadrics: diagonalize the symmetric part (principal axes), translate to kill the linear part (complete the square), and the surviving data — the signature on the symmetric side, the even rank on the skew side — is a complete congruence invariant. Sylvester's Law is what makes "signature" well defined, and hence what keeps the types in the short list of conics in Theorem 11.9.46 genuinely distinct (no invertible affine change of variables turns one type into another); exhaustiveness comes from diagonalizing and completing the square.

11.10 The Classical Linear Groups and Lie Algebras

The classical groups

Subgroups of the general linear group GL_n are called *linear groups* or *matrix groups*. The most important ones are the special linear, orthogonal, unitary, and symplectic groups — the *classical groups*. Each is carved out of GL_n by a single algebraic relation that records a piece of geometry: a determinant condition, or the requirement that a matrix preserve a fixed bilinear, Hermitian, or skew form. We collect the definitions, verify the relations make sense, and learn to check membership by hand.

Throughout, P^{T} is the transpose and $P^* = \overline{P}^{\mathsf{T}}$ is the conjugate transpose (Hermitian adjoint) of a complex matrix P; for real P these coincide. We write I for the identity matrix.

Definition 11.10.1 (The real classical groups)**.** Inside $\mathrm{GL}_n = \mathrm{GL}_n(\mathbb{R})$ or $\mathrm{GL}_n(\mathbb{C})$ one singles out:

(SL) the *special linear group* $\mathrm{SL}_n = \{\, P \in \mathrm{GL}_n(\mathbb{R}) : \det P = 1 \,\}$;

(O) the *orthogonal group* $\mathrm{O}_n = \{\, P \in \mathrm{GL}_n(\mathbb{R}) : P^{\mathsf{T}}P = I \,\}$;

(U) the *unitary group* $\mathrm{U}_n = \{\, P \in \mathrm{GL}_n(\mathbb{C}) : P^*P = I \,\}$;

(Sp) the *symplectic group* $\mathrm{Sp}_{2n} = \{\, P \in \mathrm{GL}_{2n}(\mathbb{R}) : P^{\mathsf{T}} S\, P = S \,\}$, where $S = \left(\begin{smallmatrix} 0 & I_n \\ -I_n & 0 \end{smallmatrix}\right)$ is the standard skew-symmetric form on $\mathbb{R}^{2n}$.

Adding the word *special* imposes $\det P = 1$ in addition: the *special orthogonal group* $\mathrm{SO}_n = \mathrm{O}_n \cap \mathrm{SL}_n$ and the *special unitary group* $\mathrm{SU}_n = \mathrm{U}_n \cap \{\det P = 1\}$.

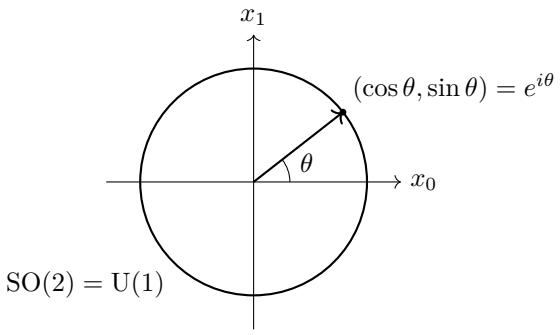
Remark 11.10.1. Each relation says the matrix preserves a form, so each is a group automatically. An orthogonal P preserves the dot product $X^{\mathsf{T}}Y$ on $\mathbb{R}^n$, since $(PX)^{\mathsf{T}}(PY) = X^{\mathsf{T}}P^{\mathsf{T}}PY = X^{\mathsf{T}}Y$. A unitary P preserves the standard Hermitian product X^*Y on $\mathbb{C}^n$. A symplectic P preserves the skew form $X^{\mathsf{T}}SY$ on $\mathbb{R}^{2n}$. The condition $\det P = 1$ likewise picks out the maps preserving signed volume. There are also indefinite analogues: the *Lorentz group* $\mathrm{O}_{3,1} = \{\, P : P^{\mathsf{T}} I_{3,1} P = I_{3,1} \,\}$, and more generally $\mathrm{O}_{p,m}$ for any signature, preserve an indefinite form rather than the positive-definite dot product. The complex orthogonal group ($P^{\mathsf{T}}P = I$ over $\mathbb{C}$) is *not* the unitary group ($P^*P = I$); the defining relations differ.

Proposition 11.10.2 (The defining relations are closed under the group operations)**.** *For each of* $\mathrm{SL}_n, \mathrm{O}_n, \mathrm{U}_n, \mathrm{Sp}_{2n}$*, the defining set is a subgroup of the ambient* GL_n*. Moreover every orthogonal, unitary, or symplectic matrix is invertible, and every orthogonal or unitary matrix has* det *of absolute value* 1*.*

Proof. We argue uniformly; take the orthogonal case, the others being identical with ^{T} replaced by $\cdot^*$ or with the form S inserted. The identity satisfies $I^{\mathsf{T}}I = I$. If $P^{\mathsf{T}}P = I$ and $Q^{\mathsf{T}}Q = I$, then $(PQ)^{\mathsf{T}}(PQ) = Q^{\mathsf{T}}P^{\mathsf{T}}PQ = Q^{\mathsf{T}}Q = I$, so the product is orthogonal; and from $P^{\mathsf{T}}P = I$ we get $P^{-1} = P^{\mathsf{T}}$, whence P is invertible and $(P^{-1})^{\mathsf{T}}P^{-1} = PP^{\mathsf{T}} = I$ (using $P^{\mathsf{T}}P = I \Rightarrow PP^{\mathsf{T}} = I$ for square P), so the inverse is orthogonal. For determinants, $P^{\mathsf{T}}P = I$ gives $\det(P)^2 = \det(P^{\mathsf{T}})\det(P) = \det I = 1$, so $\det P = \pm 1$; in the unitary case $P^*P = I$ gives $\overline{\det P}\,\det P = |\det P|^2 = 1$. The symplectic case uses $P^{\mathsf{T}}SP = S$, and since S is invertible, $\det(P)^2 \det S = \det S$ forces $\det(P)^2 = 1$; in fact one can show $\det P = 1$ always, so the two uses of the letter "S" in $\mathrm{SO}, \mathrm{SU}, \mathrm{Sp}$ do not conflict. □

Remark 11.10.2 (Dimensions and compactness). The *dimension* of a linear group G is, roughly, the number of degrees of freedom of a matrix in G. The full space of real $n \times n$ matrices has dimension n^2; each independent scalar relation cuts the count by one. Thus SL_2 has dimension 3 (the single equation $\det P = 1$ removes one degree of freedom from the four entries). The orthogonal group O_n has dimension $\frac{1}{2}n(n-1)$: the n^2 equations of $P^{\mathsf{T}}P = I$ are symmetric, giving $\binom{n+1}{2}$ independent conditions. The unitary group U_n has dimension n^2 as a real manifold. The groups $\mathrm{O}_n, \mathrm{SO}_n, \mathrm{U}_n, \mathrm{SU}_n$ are *compact*: they are closed (defined by polynomial equations) and bounded (an orthogonal or unitary matrix has columns of length 1, so all entries lie in $[-1, 1]$ or the unit disk). By contrast GL_n, Sp_{2n} and, for $n \geq 2$, SL_n are *not* compact ($\mathrm{SL}_1 = \{1\}$ is trivial) — SL_2 contains $\left(\begin{smallmatrix} t & 0 \\ 0 & t^{-1} \end{smallmatrix}\right)$ with $t \to \infty$.

The circle group



The smallest classical group already has three faces. The unit circle $x_0^2 + x_1^2 = 1$ carries a group structure in several isomorphic guises.

Theorem 11.10.3 (Three incarnations of the circle group)**.** *The following groups are isomorphic, all of dimension* 1*:*

$$\mathrm{SO}(2) \;\cong\; \mathrm{U}(1) \;\cong\; \{\, z \in \mathbb{C} : |z| = 1 \,\}.$$

Explicitly, the rotation matrix $R(\theta) = \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$*, the unit complex number* $e^{i\theta}$*, and the angle* $\theta \bmod 2\pi$ *all describe the same group, with* $R(\theta) \mapsto e^{i\theta}$ *a group isomorphism.*

Proof. The map $\theta \mapsto R(\theta)$ from the additive group $\mathbb{R}/2\pi\mathbb{Z}$ of angles to $\mathrm{SO}(2)$ is a homomorphism, since the angle-addition formulas give $R(\theta)R(\phi) = R(\theta+\phi)$; it is surjective because every 2×2 real orthogonal matrix of determinant 1 has this form (orthonormal columns with the right orientation), and injective modulo 2π. The map $\theta \mapsto e^{i\theta} = \cos\theta + i\sin\theta$ is a homomorphism onto the unit-modulus complex numbers, with the same kernel. A unit complex number is exactly a 1×1 unitary matrix: $\mathrm{U}(1) = \{\, p \in \mathbb{C}^\times : \overline{p}\,p = 1 \,\} = \{\, p : |p| = 1 \,\}$. Composing, $R(\theta) \mapsto e^{i\theta}$ is a well-defined isomorphism. The single parameter θ shows the dimension is 1. □

Worked Example 11.10.4 (Is a given matrix orthogonal, and is it special?)**.** Decide whether $P = \frac{1}{5}\left(\begin{smallmatrix} 3 & -4 \\ 4 & 3 \end{smallmatrix}\right)$ lies in O_2, and if so whether it lies in SO_2.

Recognition. Membership in O_n is the relation $P^{\mathsf{T}}P = I$; "special" adds $\det P = 1$. Compute the product and the determinant directly.

Solution. With $P = \frac{1}{5}\left(\begin{smallmatrix} 3 & -4 \\ 4 & 3 \end{smallmatrix}\right)$, $P^{\mathsf{T}} = \frac{1}{5}\left(\begin{smallmatrix} 3 & 4 \\ -4 & 3 \end{smallmatrix}\right)$, so

$$P^{\mathsf{T}}P = \frac{1}{25}\begin{pmatrix} 3 & 4 \\ -4 & 3 \end{pmatrix}\begin{pmatrix} 3 & -4 \\ 4 & 3 \end{pmatrix} = \frac{1}{25}\begin{pmatrix} 25 & 0 \\ 0 & 25 \end{pmatrix} = I.$$

Hence $P \in \mathrm{O}_2$. Its determinant is $\det P = \frac{1}{25}(3\cdot 3 - (-4)\cdot 4) = \frac{1}{25}(9+16) = 1$, so $P \in \mathrm{SO}_2$. *Check.* $\frac{1}{5}(3,4)$ and $\frac{1}{5}(-4,3)$ are orthonormal columns, and $P = R(\theta)$ with $\cos\theta = \frac{3}{5}, \sin\theta = \frac{4}{5}$ — a genuine rotation, consistent with $\det = 1$.

Worked Example 11.10.5 (A unitary membership check)**.** Show that $P = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & i \\ i & 1 \end{smallmatrix}\right)$ is unitary, and determine whether $P \in \mathrm{SU}_2$.

Recognition. Unitarity is $P^*P = I$ with $P^* = \overline{P}^{\mathsf{T}}$; "special" requires $\det P = 1$. Conjugate, transpose, multiply, then take the determinant.

Solution. Conjugating, $\overline{P} = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & -i \\ -i & 1 \end{smallmatrix}\right)$, and transposing, $P^* = \overline{P}^{\mathsf{T}} = \frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & -i \\ -i & 1 \end{smallmatrix}\right)$ (this P is symmetric). Then

$$P^*P = \frac{1}{2}\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} = \frac{1}{2}\begin{pmatrix} 1-i^2 & i-i \\ -i+i & -i^2+1 \end{pmatrix} = \frac{1}{2}\begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = I,$$

so $P \in \mathrm{U}_2$. But $\det P = \frac{1}{2}(1\cdot 1 - i\cdot i) = \frac{1}{2}(1+1) = 1$, so in fact $P \in \mathrm{SU}_2$. *Check.* $|\det P| = 1$ as the proposition demands for any unitary matrix, and here the value is exactly 1, placing P in the special unitary group.

Worked Example 11.10.6 (Verifying the symplectic relation in Sp_2)**.** With $S = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$, show that every $P \in \mathrm{SL}_2(\mathbb{R})$ satisfies $P^{\mathsf{T}} S\, P = S$, so that $\mathrm{Sp}_2 = \mathrm{SL}_2$.

Recognition. The symplectic condition is $P^{\mathsf{T}} S P = S$. In the 2×2 case the skew form is essentially the determinant, so expect the relation to reduce to $\det P = 1$.

Solution. Let $P = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$. Then

$$P^{\mathsf{T}} S\, P = \begin{pmatrix} a & c \\ b & d \end{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a & c \\ b & d \end{pmatrix} \begin{pmatrix} c & d \\ -a & -b \end{pmatrix} = \begin{pmatrix} 0 & ad - bc \\ bc - ad & 0 \end{pmatrix}.$$

This equals $S = \left(\begin{smallmatrix} 0 & 1 \\ -1 & 0 \end{smallmatrix}\right)$ precisely when $ad - bc = 1$, i.e. when $\det P = 1$. Hence $\mathrm{Sp}_2 = \{\, P : \det P = 1 \,\} = \mathrm{SL}_2(\mathbb{R})$. *Check.* The computation also confirms that any symplectic matrix has determinant 1 (here $\det P = ad - bc = 1$ directly), matching the general fact that $\mathrm{Sp}_{2n} \subseteq \mathrm{SL}_{2n}$.

Caution. Do not confuse the orthogonal relation $P^{\mathsf{T}} P = I$ (real) with the unitary relation $P^* P = I$ (complex): forgetting to conjugate when computing P^* is the most common error in a unitary membership check. Likewise, "$\det P = \pm 1$" for orthogonal matrices does *not* say $P \in \mathrm{SO}_n$; the reflection $\left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ is orthogonal with $\det = -1$, so it lies in $\mathrm{O}_2 \setminus \mathrm{SO}_2$.

SU(2) the unit quaternions

The group $\mathrm{SU}(2)$ of 2×2 complex special unitary matrices is at once an algebraic object — a matrix group — and a geometric one — the unit 3-sphere S^3 in $\mathbb{R}^4$. Reconciling the two pictures organizes every computation in this section, and culminates in an explicit two-to-one map onto the rotation group $\mathrm{SO}(3)$.

Definition 11.10.7 (The special unitary group $\mathrm{SU}(2)$)**.** $\mathrm{SU}(2)$ consists of the complex 2×2 matrices P satisfying $P^* P = I$ and $\det P = 1$, where $P^* = \overline{P}^{\mathsf{T}}$ is the conjugate transpose.

Proposition 11.10.8 (Normal form of an element)**.** *Every element of* $\mathrm{SU}(2)$ *has the form*

$$P = \begin{pmatrix} a & b \\ -\overline{b} & \overline{a} \end{pmatrix}, \qquad a, b \in \mathbb{C}, \quad a\overline{a} + b\overline{b} = 1.$$

Conversely every such matrix lies in $\mathrm{SU}(2)$*.*

Proof. Write $P = \left(\begin{smallmatrix} a & b \\ u & v \end{smallmatrix}\right)$ with $a, b, u, v \in \mathbb{C}$. When $\det P = 1$ the relation $P^* = P^{-1}$ reads

$$\begin{pmatrix} \overline{a} & \overline{u} \\ \overline{b} & \overline{v} \end{pmatrix} = \begin{pmatrix} v & -b \\ -u & a \end{pmatrix},$$

since for a 2×2 matrix of determinant 1 the inverse is $\left(\begin{smallmatrix} v & -b \\ -u & a \end{smallmatrix}\right)$. Comparing entries gives $v = \overline{a}$ and $u = -\overline{b}$, and then $\det P = av - bu = a\overline{a} + b\overline{b} = 1$. The converse is the same computation read backwards. □

Writing $a = x_0 + x_1 i$ and $b = x_2 + x_3 i$ turns the constraint $a\overline{a} + b\overline{b} = 1$ into $x_0^2 + x_1^2 + x_2^2 + x_3^2 = 1$. This is the heart of the section.

Theorem 11.10.9 ($\mathrm{SU}(2)$ is the 3-sphere)**.** *The map $P \mapsto (x_0, x_1, x_2, x_3)$ of Proposition 11.10.8 is a bijection of* $\mathrm{SU}(2)$ *with the unit* 3*-sphere*

$$S^3 = \{\, (x_0, x_1, x_2, x_3) \in \mathbb{R}^4 \mid x_0^2 + x_1^2 + x_2^2 + x_3^2 = 1 \,\}.$$

Under it the identity I is the north pole $e_0 = (1, 0, 0, 0)$, and the remaining standard basis vectors correspond to the quaternion matrices

$$\mathbf{i} = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \qquad \mathbf{j} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad \mathbf{k} = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}.$$

These satisfy $\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = -I$ and $\mathbf{ij} = \mathbf{k}$, $\mathbf{jk} = \mathbf{i}$, $\mathbf{ki} = \mathbf{j}$. The real span of $I, \mathbf{i}, \mathbf{j}, \mathbf{k}$ is the ***quaternion algebra*** *$\mathbb{H}$, and* $\mathrm{SU}(2)$ *is exactly the set of* unit *quaternions.*

Proof. Bijectivity is the substitution above: $(a,b) \leftrightarrow (x_0,x_1,x_2,x_3)$ is a real-linear isomorphism $\mathbb{C}^2 \to \mathbb{R}^4$ carrying the equation $|a|^2+|b|^2=1$ to the sphere equation. A general P in normal form expands as

$$P = x_0 I + x_1\mathbf{i} + x_2\mathbf{j} + x_3\mathbf{k},$$

which one checks against Proposition 11.10.8 entry by entry; setting one x to 1 and the rest to 0 recovers each basis matrix. The relations $\mathbf{ij}=\mathbf{k}$ etc. are direct 2×2 multiplications. □

Remark 11.10.3. That S^3 carries a continuous group law is special: there is no way to make S^2 a topological group, and a theorem of topology says the only spheres of positive dimension admitting continuous group laws are S^1 and S^3 (the 0-sphere $S^0=\{\pm 1\}$ is the group of order 2). The norm $|a|^2+|b|^2=\det P$ is multiplicative, which is why unit quaternions are closed under multiplication.

Latitudes (conjugacy classes) and longitudes (subgroups)

The sphere geometry of S^3 has an exact algebraic meaning inside $\mathrm{SU}(2)$. The horizontal slices $x_0=c$ are the *latitudes*; the great circles through the poles $\pm I$ are the *longitudes*.

Lemma 11.10.10 (Eigenvalues)**.** *For $P\in\mathrm{SU}(2)$ with $P\neq\pm I$, the eigenvalues are complex conjugates of absolute value* 1*. The characteristic polynomial is $t^2-(\operatorname{tr}P)\,t+1=t^2-2x_0t+1$.*

Proof. $\det P=1$ gives the constant term 1, and $\operatorname{tr}P=2x_0$ the linear term. The discriminant is $4x_0^2-4\le 0$ since $-1\le x_0\le 1$ on the sphere, so the roots are conjugate; their product is $\det P=1$, so each has absolute value 1. □

Proposition 11.10.11 (Latitudes are conjugacy classes)**.** *For $-1<c<1$ the latitude $\{x_0=c\}=\{P\in\mathrm{SU}(2)\mid \operatorname{tr}P=2c\}$ is a single conjugacy class. The remaining classes are the singletons $\{I\}$ and $\{-I\}$, which together form the center $Z=\{\pm I\}$.*

Proof. Trace is a conjugacy invariant, so each class lies in one latitude. Conversely, let P have eigenvalues $\lambda,\overline{\lambda}$. Choose a unit eigenvector and complete it to an orthonormal eigenbasis; the change-of-basis matrix Q can be normalized to lie in $\mathrm{SU}(2)$, and then $Q^*PQ=\operatorname{diag}(\lambda,\overline{\lambda})$. Two elements with the same trace have the same eigenvalue pair, hence are both conjugate to the same diagonal matrix, hence to each other. The extreme traces $\operatorname{tr}P=\pm 2$ force $P=\pm I$, which are central. □

The latitude $x_0=0$, where $\operatorname{tr}P=0$, is the **equator** E. An equatorial element is

$$A = x_1\mathbf{i}+x_2\mathbf{j}+x_3\mathbf{k} = \begin{pmatrix} x_1 i & x_2+x_3 i \\ -x_2+x_3 i & -x_1 i \end{pmatrix},$$

which is *trace-zero and skew-Hermitian*: $A^*=-A$. The trace-zero skew-Hermitian 2×2 matrices form a real 3-dimensional space $V=\operatorname{Span}\{\mathbf{i},\mathbf{j},\mathbf{k}\}$, orthogonal to I in $\mathbb{R}^4$, and E is the unit 2-sphere in V.

Proposition 11.10.12 (The equator squares to $-I$)**.** *For $A\in\mathrm{SU}(2)$ the following are equivalent: (i) $A\in E$, i.e. $\operatorname{tr}A=0$; (ii) the eigenvalues of A are i and $-i$; (iii) $A^2=-I$.*

Proof. (i)⇔(ii): the characteristic polynomial $t^2-(\operatorname{tr}A)t+1$ has roots $\pm i$ iff $\operatorname{tr}A=0$. (ii)⇒(iii): if λ is an eigenvalue of A then λ^2 is one of A^2; here $\lambda=\pm i$ gives $\lambda^2=-1$, and the only $\mathrm{SU}(2)$ matrix with eigenvalue -1 is $-I$, so $A^2=-I$. (iii)⇒(ii): $A^2=-I$ forces each eigenvalue to satisfy $\lambda^2=-1$, so $\lambda=\pm i$, and $\det A=1$ pairs them as $i,-i$. □

Proposition 11.10.13 (Longitudes are conjugate subgroups)**.** *Let $A\in E$. The longitude through A is*

$$L_A=\{\ P_\theta=(\cos\theta)\,I+(\sin\theta)\,A \mid 0\le\theta<2\pi\ \}.$$

Each L_A is a subgroup of $\mathrm{SU}(2)$ isomorphic to the circle $\mathrm{SO}(2)$; every $P\neq\pm I$ lies on a unique longitude, while $\pm I$ lie on all of them; and any two longitudes are conjugate.

Proof. Since $A^2 = -I$ (Proposition 11.10.12), the map $\theta \mapsto (\cos\theta)I + (\sin\theta)A$ behaves exactly like $\theta \mapsto e^{i\theta}$: writing $c = \cos\theta$, $s = \sin\theta$ and c', s' for a second angle,

$$(cI + sA)(c'I + s'A) = (cc' - ss')I + (cs' + sc')A = (\cos(\theta+\theta'))I + (\sin(\theta+\theta'))A,$$

by the addition formulas. So L_A is closed under multiplication, contains I ($\theta = 0$), and is closed under inversion ($\theta \mapsto -\theta$); the displayed law is an isomorphism $L_A \cong \mathrm{SO}(2)$. Uniqueness of the longitude through $P \neq \pm I$ is the statement that I and A are determined by P up to sign of A. Finally, by Proposition 11.10.11 any $A \in E$ is conjugate to $\mathbf{i}$, say $\mathbf{i} = QAQ^*$; then $Q(cI + sA)Q^* = cI + s\mathbf{i}$, so L_A is conjugate to $L_{\mathbf{i}}$. □

Remark 11.10.4. Two longitudes are familiar groups. The longitude $L_{\mathbf{i}} = \{\, cI + s\mathbf{i} \,\}$ is the group T of diagonal matrices $\mathrm{diag}(e^{i\theta}, e^{-i\theta})$. The longitude $L_{\mathbf{j}} = \{\, cI + s\mathbf{j} \,\}$ is the group of *real* matrices in $\mathrm{SU}(2)$, namely $\mathrm{SO}(2)$ itself, with $cI + s\mathbf{j}$ representing rotation through $-\theta$.

Worked Example 11.10.14 (A longitude is a one-parameter circle subgroup)**.** Verify directly that $T = \{\, \mathrm{diag}(e^{i\theta}, e^{-i\theta}) \mid \theta \in \mathbb{R} \,\}$ is the longitude $L_{\mathbf{i}}$ and is closed under multiplication.

Recognition. By Proposition 11.10.13 a longitude is $cI + sA$ with $A \in E$; for $A = \mathbf{i}$ we recognize the diagonal torus.

Solution. Compute $(\cos\theta)I + (\sin\theta)\mathbf{i} = \left(\begin{smallmatrix} \cos\theta + i\sin\theta & 0 \\ 0 & \cos\theta - i\sin\theta \end{smallmatrix}\right) = \mathrm{diag}(e^{i\theta}, e^{-i\theta})$, so $L_{\mathbf{i}} = T$. Multiplying, $\mathrm{diag}(e^{i\theta}, e^{-i\theta})\,\mathrm{diag}(e^{i\phi}, e^{-i\phi}) = \mathrm{diag}(e^{i(\theta+\phi)}, e^{-i(\theta+\phi)})$. *Check.* The product sits at angle $\theta + \phi$, matching the addition law $\theta \mapsto \theta + \phi$ of Proposition 11.10.13; and $\mathbf{i}^2 = \mathrm{diag}(i, -i)^2 = \mathrm{diag}(-1, -1) = -I$ as required.

The spin homomorphism $\mathrm{SU}(2) \to \mathrm{SO}(3)$

Because the equator E is a conjugacy class, $\mathrm{SU}(2)$ acts on it by conjugation. Conjugation preserves trace and the skew-Hermitian property, so for $P \in \mathrm{SU}(2)$ the operator

$$\gamma_P \colon V \to V, \qquad \gamma_P(U) = PUP^*$$

maps the 3-dimensional space V of trace-zero skew-Hermitian matrices to itself. The decisive fact is that γ_P is a *rotation*.

Lemma 11.10.15 (Trace recovers the dot product)**.** *For $U, V \in V$ with coordinates in the basis $(\mathbf{i}, \mathbf{j}, \mathbf{k})$, the Euclidean inner product is*

$$\langle U, V \rangle = -\tfrac{1}{2}\,\mathrm{tr}(UV).$$

Proof. Multiplying out $U = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}$ and $V = v_1\mathbf{i} + v_2\mathbf{j} + v_3\mathbf{k}$ with the quaternion relations gives

$$UV = -(u_1v_1 + u_2v_2 + u_3v_3)I + U \times V,$$

where $U \times V$ is the cross product, a trace-zero combination of $\mathbf{i}, \mathbf{j}, \mathbf{k}$. Since $\mathrm{tr}\, I = 2$ and $\mathrm{tr}\,\mathbf{i} = \mathrm{tr}\,\mathbf{j} = \mathrm{tr}\,\mathbf{k} = 0$, we get $\mathrm{tr}(UV) = -2\langle U, V \rangle$. □

Lemma 11.10.16 (γ_P is a rotation)**.** *For every $P \in \mathrm{SU}(2)$, γ_P is an orthogonal operator on V with $\det \gamma_P = 1$, hence a rotation.*

Proof. γ_P is real-linear. It is orthogonal because, using Lemma 11.10.15 and the conjugation-invariance of trace,

$$\langle \gamma_P U, \gamma_P V \rangle = -\tfrac{1}{2}\,\mathrm{tr}(PUP^*\,PVP^*) = -\tfrac{1}{2}\,\mathrm{tr}(PUVP^*) = -\tfrac{1}{2}\,\mathrm{tr}(UV) = \langle U, V \rangle.$$

An orthogonal operator has $\det = \pm 1$. Now $\mathrm{SU}(2) \cong S^3$ is path-connected and $P \mapsto \det \gamma_P$ is continuous into $\{\, \pm 1 \,\}$, so it is constant; at $P = I$, $\gamma_I = \mathrm{id}$ has determinant 1. Hence $\det \gamma_P = 1$ for all P, and by Euler's theorem $\gamma_P \in \mathrm{SO}(3)$. □

Theorem 11.10.17 (The spin double cover)**.** *The rule $P \mapsto \gamma_P$ is a surjective group homomorphism*

$$\gamma \colon \mathrm{SU}(2) \longrightarrow \mathrm{SO}(3),$$

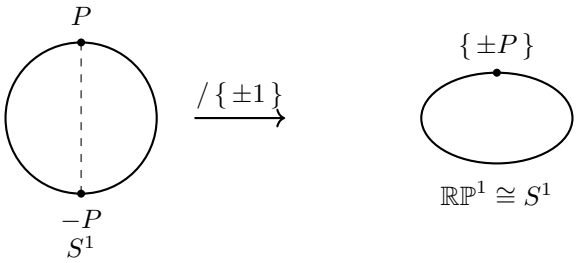
*the **spin homomorphism**, with kernel the center $Z = \{\pm I\}$. It is two-to-one: $\gamma_P = \gamma_{-P}$. Consequently*

$$\mathrm{SO}(3) \;\cong\; \mathrm{SU}(2)/\{\pm I\},$$

and topologically $\mathrm{SO}(3)$ *is real projective 3-space* $\mathbb{RP}^3$*, obtained from* S^3 *by identifying antipodal points. Moreover, if* $P = (\cos\theta)I + (\sin\theta)A$ *with* $A \in E$*, then* γ_P *is the rotation about the pole* A *through angle* 2θ*.*

Proof. Homomorphism: $\gamma_P(\gamma_Q U) = P(QUQ^*)P^* = (PQ)U(PQ)^* = \gamma_{PQ}(U)$, so $\gamma_P\gamma_Q = \gamma_{PQ}$. By Lemma 11.10.16 the image lies in $\mathrm{SO}(3)$.

Kernel: if $\gamma_P = \mathrm{id}$ then $PUP^* = U$, i.e. P commutes with every $U \in E$. Every element of $\mathrm{SU}(2)$ has the form $cI + sB$ with $B \in E$, so P commutes with all of $\mathrm{SU}(2)$, forcing $P \in Z = \{\pm I\}$. Conversely $\pm I$ are central, so $\gamma_{\pm I} = \mathrm{id}$. Thus $\ker\gamma = \{\pm I\}$ and $\gamma_P = \gamma_{-P}$.



Angle, surjectivity: a rotation's angle is a conjugacy invariant of $\mathrm{SO}(3)$ and θ is a conjugacy invariant of $\mathrm{SU}(2)$ (Proposition 11.10.11), so it suffices to compute one representative per class. Take $P = (\cos\theta)I + (\sin\theta)\mathbf{i} = \mathrm{diag}(e^{i\theta}, e^{-i\theta})$. Then $\gamma_P\mathbf{i} = P\mathbf{i}P^* = \mathbf{i}$, so $\mathbf{i}$ is the pole, and

$$\gamma_P\mathbf{j} = P\mathbf{j}P^* = \begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{pmatrix}\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} e^{-i\theta} & 0 \\ 0 & e^{i\theta} \end{pmatrix} = \begin{pmatrix} 0 & e^{2i\theta} \\ -e^{-2i\theta} & 0 \end{pmatrix} = (\cos 2\theta)\mathbf{j} + (\sin 2\theta)\mathbf{k}.$$

In the orthonormal plane $\mathrm{Span}\{\mathbf{j}, \mathbf{k}\}$ orthogonal to the pole $\mathbf{i}$, this is rotation through 2θ. As θ ranges over $[0, \pi]$ the angle 2θ covers every value in $[0, 2\pi)$, so every rotation is hit: γ is surjective. By the first isomorphism theorem $\mathrm{SO}(3) \cong \mathrm{SU}(2)/\{\pm I\}$. Identifying the antipodal pair $\{\pm P\}$ with a point of S^3 identifies $\mathrm{SO}(3)$ with $S^3/\{\pm 1\} = \mathbb{RP}^3$. □

Remark 11.10.5. The factor of 2 in "angle 2θ" is why $\mathrm{SU}(2)$ is the *spin* group: a full 2π rotation in $\mathrm{SO}(3)$ comes from a half-loop $\theta\colon 0 \to \pi$ in $\mathrm{SU}(2)$, while the loop $\theta\colon 0 \to 2\pi$ traverses $\mathrm{SU}(2)$ once but $\mathrm{SO}(3)$ twice. The one-dimensional shadow is the double cover $\mathrm{SO}(2) \to \mathrm{SO}(2)$, $\rho_\theta \mapsto \rho_{2\theta}$, whose every fiber is the antipodal pair $\{\rho_\theta, \rho_{\theta+\pi}\}$.

The double cover $S^3 \to \mathbb{RP}^3$ already shows its character in dimension one, where antipodal identification on the circle gives a circle again:

Worked Example 11.10.18 (The rotation induced by a unit quaternion)**.** Let $P = \frac{1}{\sqrt{2}}\,I + \frac{1}{\sqrt{2}}\,\mathbf{i} \in \mathrm{SU}(2)$. Identify the axis and angle of the rotation $\gamma_P \in \mathrm{SO}(3)$ it induces, and confirm by direct conjugation.

Recognition. Here $P = (\cos\theta)I + (\sin\theta)\mathbf{i}$ with $\theta = \pi/4$ and pole $A = \mathbf{i}$; Theorem 11.10.17 predicts a rotation about the $\mathbf{i}$-axis through $2\theta = \pi/2$.

Solution. With $\theta = \pi/4$, $P = \mathrm{diag}(e^{i\pi/4}, e^{-i\pi/4})$. The pole is fixed: $\gamma_P\mathbf{i} = \mathbf{i}$. Using the boxed computation in the proof with $2\theta = \pi/2$,

$$\gamma_P\mathbf{j} = (\cos\tfrac{\pi}{2})\mathbf{j} + (\sin\tfrac{\pi}{2})\mathbf{k} = \mathbf{k}, \qquad \gamma_P\mathbf{k} = P\mathbf{k}P^* = -\mathbf{j}.$$

So in the basis $(\mathbf{i}, \mathbf{j}, \mathbf{k}) \leftrightarrow \mathbb{R}^3$ the matrix of γ_P is $\left(\begin{smallmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{smallmatrix}\right)$, the rotation by 90° about the $\mathbf{i}$-axis. *Check.* This matrix is orthogonal with determinant 1 and fixes the axis $\mathbf{i}$; squaring P gives $P^2 = \mathrm{diag}(i, -i) = \mathbf{i}$, whose image γ_{P^2} is rotation by π about $\mathbf{i}$ — exactly γ_P^2, consistent.

Worked Example 11.10.19 (The kernel is exactly $\{\pm I\}$)**.** Show that $-I$ acts trivially on V, and that no element of a non-polar latitude can.

Recognition. $\ker\gamma = \{\pm I\}$ by Theorem 11.10.17; the kernel is detected by which P commute with all of E.

Solution. For $P = -I$: $\gamma_{-I}(U) = (-I)U(-I)^* = U$, so $-I \in \ker\gamma$, confirming $\gamma_P = \gamma_{-P}$. Now take any P with $\operatorname{tr} P = 2c$, $-1 < c < 1$, so $P = cI + sB$ with $B \in E$, $s \neq 0$. If P centralized all of E it would centralize $\mathbf{i}, \mathbf{j}, \mathbf{k}$; but $B = x_1\mathbf{i} + x_2\mathbf{j} + x_3\mathbf{k}$ has $\mathbf{i}B - B\mathbf{i} = 2x_2\mathbf{k} - 2x_3\mathbf{j}$, so B commutes with $\mathbf{i}$ only when $B = \pm\mathbf{i}$, and $\pm\mathbf{i}$ does not commute with $\mathbf{j}$ ($\mathbf{ji} = -\mathbf{k} \neq \mathbf{k} = \mathbf{ij}$). Since $s \neq 0$, $P = cI + sB$ commutes with exactly the matrices that B commutes with, so P cannot commute with all of E. *Check.* Only $c = \pm 1$ (forcing $s = 0$, $P = \pm I$) survives, so $\ker\gamma = \{\pm I\}$, a group of order 2, and γ is two-to-one as claimed.

Worked Example 11.10.20 (Composition of induced rotations)**.** Let $P = \operatorname{diag}(e^{i\theta}, e^{-i\theta})$ and $P' = \operatorname{diag}(e^{i\phi}, e^{-i\phi})$. Verify $\gamma_{PP'} = \gamma_P\gamma_{P'}$ and read off the resulting rotation.

Recognition. γ is a homomorphism (Theorem 11.10.17); both P, P' lie on the longitude $L_{\mathbf{i}}$, which γ sends to rotations about the common axis $\mathbf{i}$.

Solution. Since $PP' = \operatorname{diag}(e^{i(\theta+\phi)}, e^{-i(\theta+\phi)})$, Theorem 11.10.17 gives $\gamma_{PP'}$ = rotation about $\mathbf{i}$ through $2(\theta+\phi)$. Separately γ_P rotates by 2θ and $\gamma_{P'}$ by 2ϕ about the same axis $\mathbf{i}$; rotations about a fixed axis add their angles, giving $2\theta + 2\phi$. *Check.* Both routes yield rotation about $\mathbf{i}$ by $2\theta + 2\phi$, so $\gamma_{PP'} = \gamma_P\gamma_{P'}$. The longitude $L_{\mathbf{i}} \cong \mathrm{SO}(2)$ maps onto the circle of rotations about $\mathbf{i}$ by angle-doubling — the 1-dimensional double cover.

Caution. A unit quaternion and the rotation it induces are *not* in bijection: P and $-P$ give the same rotation $\gamma_P = \gamma_{-P}$. So a rotation by angle α about axis A has two "spins" (A, α) and $(-A, -\alpha)$, the antipodal pair $\{\pm P\}$. Tracking the sign is exactly the extra data $\mathrm{SU}(2)$ carries over $\mathrm{SO}(3)$.

Throughout, GL_n denotes $\mathrm{GL}_n(\mathbb{R})$ or $\mathrm{GL}_n(\mathbb{C})$, and the matrix exponential is the convergent series

$$e^A \;=\; I + A + \tfrac{1}{2!}A^2 + \tfrac{1}{3!}A^3 + \cdots \;=\; \sum_{k\geq 0} \tfrac{1}{k!}A^k.$$

A *one-parameter group* in a linear group $G \leq \mathrm{GL}_n$ is a differentiable homomorphism from the additive group $\mathbb{R}^+$ of real numbers into G. The two threads of this section are: every such homomorphism is $t \mapsto e^{tA}$ for a single matrix A (so one-parameter groups are classified by their velocity at the identity), and the set of those velocity matrices — the *tangent space at I* — is a vector space carrying an extra operation, the bracket. That tangent space is the *Lie algebra* of G.

One-parameter groups are exponentials

Theorem 11.10.21 (Artin 9.5.2)**.** *Let A be a real or complex $n \times n$ matrix.*

(a) The map $\varphi\colon \mathbb{R}^+ \to \mathrm{GL}_n$, $\varphi(t) = e^{tA}$, is a group homomorphism.

(b) Conversely, if $\varphi\colon \mathbb{R}^+ \to \mathrm{GL}_n$ is a differentiable map that is a homomorphism, and $A = \varphi'(0)$ is its derivative at the origin, then $\varphi(t) = e^{tA}$ for all t.

Proof. (a) For real r, s the matrices rA and sA commute, so the exponential of a sum is the product of the exponentials, $e^{(r+s)A} = e^{rA}e^{sA}$. Hence $\varphi(r+s) = \varphi(r)\varphi(s)$ and $\varphi(0) = e^0 = I$, so φ is a homomorphism into GL_n (each e^{tA} is invertible, with inverse e^{-tA}).

(b) Since φ is a homomorphism, $\varphi(\Delta t + t) = \varphi(\Delta t)\varphi(t)$ and $\varphi(t) = \varphi(0)\varphi(t)$, so the difference quotient factors:

$$\frac{\varphi(\Delta t + t) - \varphi(t)}{\Delta t} = \frac{\varphi(\Delta t) - \varphi(0)}{\Delta t}\,\varphi(t).$$

Letting $\Delta t \to 0$ gives $\varphi'(t) = \varphi'(0)\varphi(t) = A\,\varphi(t)$. Thus φ solves the matrix differential equation $\frac{d}{dt}\varphi = A\varphi$. The function e^{tA} solves the same equation, and both take the value I at $t = 0$; by uniqueness of solutions to this linear equation, $\varphi(t) = e^{tA}$. □

Remark 11.10.6. The theorem is a bijection $\{\text{one-parameter groups in } \mathrm{GL}_n\} \leftrightarrow \{n \times n \text{ matrices } A\}$, the correspondence being $\varphi \leftrightarrow \varphi'(0)$. So to find the one-parameter groups lying in a subgroup $H \leq \mathrm{GL}_n$ we ask only: for which A is $e^{tA} \in H$ for all t? This single question produces the Lie algebra of H.

Worked Example 11.10.22 (The exponential of a nilpotent and of a rotation generator)**.** Compute e^{tA} for $A = e_{12} = \left(\begin{smallmatrix} 0 & 1 \\ 0 & 0 \end{smallmatrix}\right)$ and for $A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$.

Recognition. Use the series $e^{tA} = \sum_k \frac{t^k}{k!} A^k$ and exploit the structure of the powers of A: nilpotency truncates the series, while the rotation generator cycles like i.

Solution. For $A = e_{12}$ we have $A^2 = 0$, so all but two terms vanish:

$$e^{tA} = I + tA = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}.$$

For $A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ we have $A^2 = -I$, so the even powers give cos and the odd powers give sin:

$$e^{tA} = (\cos t)\, I + (\sin t)\, A = \begin{pmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{pmatrix},$$

the standard parametrization of $\mathrm{SO}(2)$ (Artin 9.5.6(b)). *Check.* e^{tA} for the first A is upper triangular with 1's on the diagonal, hence in SL_2 (trace $A = 0$); the second has $\det e^{tA} = \cos^2 t + \sin^2 t = 1$, as a rotation must.

One-parameter groups in the classical groups

The same computation that read off $\mathrm{SO}(2)$ above pins down which A keep e^{tA} inside the orthogonal, unitary, and special linear groups. Write A^{T} for the transpose and $A^* = \overline{A}^{\mathsf{T}}$ for the conjugate transpose.

Proposition 11.10.23 (Artin 9.5.8, 9.5.10)**.** *(a) If A is real skew-symmetric ($A^{\mathsf{T}} = -A$), then e^A is orthogonal; if A is complex skew-Hermitian ($A^* = -A$), then e^A is unitary.*

(b) The one-parameter groups in $\mathrm{O}(n)$ are exactly the $t \mapsto e^{tA}$ with A real skew-symmetric; those in $\mathrm{U}(n)$ are the $t \mapsto e^{tA}$ with A skew-Hermitian.

(c) The one-parameter groups in SL_n are the $t \mapsto e^{tA}$ with $\operatorname{tr} A = 0$.

Proof. From the series, $(e^A)^* = e^{(A^*)}$, and $(e^A)^{-1} = e^{-A}$. If $A^* = -A$ then $(e^A)^* = e^{-A} = (e^A)^{-1}$, so e^A is unitary; replacing $*$ by transpose gives the orthogonal case. This proves (a). For (b), if A is skew-Hermitian so is tA, so e^{tA} is unitary for all t. Conversely if e^{tA} is unitary for all t, write $e^{tA^*} = e^{-tA}$; differentiating both sides at $t = 0$ gives $A^* = -A$. For (c) we use Lemma 11.10.24 below: if $\operatorname{tr} A = 0$ then $\det e^{tA} = e^{t \operatorname{tr} A} = e^0 = 1$ for all t, so $e^{tA} \in \mathrm{SL}_n$; conversely if $\det e^{tA} = 1$ for all t, then $\frac{d}{dt} e^{t \operatorname{tr} A} = 0$ at $t = 0$, and that derivative is $\operatorname{tr} A$, so $\operatorname{tr} A = 0$. □

Lemma 11.10.24 (Artin 9.5.9)**.** *For any square matrix A, $\det e^A = e^{\operatorname{tr} A}$.*

Proof. Over $\mathbb{C}$, $A = QTQ^{-1}$ with Q invertible and T upper triangular; the diagonal entries $\lambda_1, \dots, \lambda_n$ of T are the eigenvalues of A (with multiplicity). Each power T^k is upper triangular with diagonal entries $\lambda_1^k, \dots, \lambda_n^k$, so e^T is upper triangular with diagonal entries $e^{\lambda_1}, \dots, e^{\lambda_n}$; and $e^A = Qe^TQ^{-1}$ (apply $X \mapsto QXQ^{-1}$ to the series), so $\det e^A = \det e^T$. The trace is the sum of the λ_i and $\det e^T$ is the product of the diagonal entries of e^T, so

$$\det e^A = e^{\lambda_1} \cdots e^{\lambda_n} = e^{\lambda_1 + \cdots + \lambda_n} = e^{\operatorname{tr} A}.$$ □

The Lie algebra as the tangent space at I

Definition 11.10.25 (Artin 9.6)**.** A vector v is *tangent* to a subset $S \subseteq \mathbb{R}^N$ at a point $x \in S$ if there is a differentiable path $\varphi(t)$, defined for small t and lying entirely in S, with $\varphi(0) = x$ and $\varphi'(0) = v$. For a linear group $G \leq \mathrm{GL}_n$, the space of tangent vectors at the identity I is the *Lie algebra* of G, written $\mathrm{Lie}(G)$. Its elements are matrices $\varphi'(0)$ for paths φ in G with $\varphi(0) = I$.

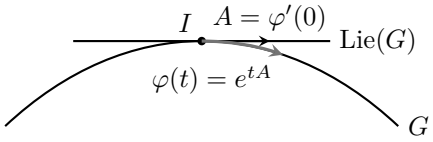
The one-parameter groups already give tangent vectors: for $\varphi(t) = e^{tA}$ we have $\varphi(0) = I$ and $\varphi'(0) = A$, so every such A lies in $\mathrm{Lie}(G)$. The content of the next two propositions is the converse: for the orthogonal and special linear groups, the tangent space contains *nothing more* than the exponential directions, even though there are many non-exponential paths through I.

Proposition 11.10.26 (Artin 9.6.1)**.** $\mathrm{Lie}(\mathrm{O}(n)) = \mathrm{Lie}(\mathrm{SO}(n))$ *is the space of real skew-symmetric matrices.*

Proof. Let φ be a path in $\mathrm{O}(n)$ with $\varphi(0) = I$ and $\varphi'(0) = A$. Orthogonality means $\varphi(t)^{\mathsf{T}}\varphi(t) = I$ identically, so $\frac{d}{dt}\big(\varphi(t)^{\mathsf{T}}\varphi(t)\big) = 0$. By the product rule,

$$0 = \Big(\varphi'(t)^{\mathsf{T}}\varphi(t) + \varphi(t)^{\mathsf{T}}\varphi'(t)\Big)\Big|_{t=0} = A^{\mathsf{T}}I + I^{\mathsf{T}}A = A^{\mathsf{T}} + A,$$

so $A^{\mathsf{T}} = -A$. Conversely every skew-symmetric A is $\varphi'(0)$ for the one-parameter group $\varphi(t) = e^{tA} \subseteq \mathrm{O}(n)$ by Proposition 11.10.23. (The same path stays in the identity component $\mathrm{SO}(n)$, so the two groups share a Lie algebra.) □



Proposition 11.10.27 (Artin 9.6.4)**.** $\mathrm{Lie}(\mathrm{SL}_n)$ *is the space of real trace-zero matrices.*

Proof. If φ is a path in SL_n with $\varphi(0) = I$, $\varphi'(0) = A$, then $\det\varphi(t) = 1$ identically, so $\frac{d}{dt}\det\varphi(t) = 0$. A direct expansion of the determinant (Artin 9.6.2) gives $\frac{d}{dt}\det\varphi(t)\big|_{t=0} = \operatorname{tr} A$, so $\operatorname{tr} A = 0$. Conversely every trace-zero A arises from $e^{tA} \subseteq \mathrm{SL}_n$ by Proposition 11.10.23. □

Remark 11.10.7. The pattern across the classical groups: the defining condition on the group becomes a *linear* condition on the tangent matrices (the derivative of the constraint at I). Skew-Hermitian gives $\mathrm{Lie}(\mathrm{U}(n)) = \mathfrak{u}(n)$, and imposing also trace zero gives $\mathrm{Lie}(\mathrm{SU}(n)) = \mathfrak{su}(n)$. In each case $\mathrm{Lie}(G)$ is a real vector space.

Group	Condition on $M \in G$	Lie algebra $\mathrm{Lie}(G)$
$\mathrm{O}(n)$, $\mathrm{SO}(n)$	$M^{\mathsf{T}}M = I$	$A^{\mathsf{T}} = -A$ (skew-symmetric)
$\mathrm{U}(n)$	$M^*M = I$	$A^* = -A$ (skew-Hermitian)
SL_n	$\det M = 1$	$\operatorname{tr} A = 0$ (trace zero)

The diagram below is the picture behind every one of these proofs: the curve e^{tA} leaves the identity I with velocity A, and the constraint surface G forces that velocity into a linear subspace, the tangent space $\mathrm{Lie}(G)$.

The Lie bracket

Definition 11.10.28 (Artin 9.6.5)**.** On the space of $n \times n$ matrices the *bracket* (or commutator) is

$$[A, B] \;=\; AB - BA.$$

It is zero precisely when A and B commute.

Proposition 11.10.29. *The bracket is bilinear and alternating ($[A, A] = 0$, equivalently $[A, B] = -[B, A]$), and satisfies the* Jacobi identity

$$[A, [B, C]] + [B, [C, A]] + [C, [A, B]] = 0.$$

Moreover, on each classical Lie algebra it restricts to that subspace: if A, B are both trace zero, or both skew-symmetric, then so is $[A, B]$.

Proof. Bilinearity and $[A, A] = AA - AA = 0$ are immediate; expanding $[A + B, A + B] = 0$ then gives $[A, B] = -[B, A]$. For Jacobi, expand each double bracket into the six products $ABC, ACB, \ldots$; for example $[A, [B, C]] = ABC - ACB - BCA + CBA$. Summing the three cyclic terms, every one of the six monomials ABC, $ACB, \ldots$ appears once with a $+$ sign and once with a $-$ sign, so the total is 0. Closure on the classical algebras: $\operatorname{tr}[A, B] = \operatorname{tr}(AB) - \operatorname{tr}(BA) = 0$ since $\operatorname{tr}(AB) = \operatorname{tr}(BA)$; and if $A^{\mathsf{T}} = -A$, $B^{\mathsf{T}} = -B$ then $[A, B]^{\mathsf{T}} = (AB - BA)^{\mathsf{T}} = B^{\mathsf{T}}A^{\mathsf{T}} - A^{\mathsf{T}}B^{\mathsf{T}} = BA - AB = -[A, B]$. □

Definition 11.10.30 (Artin 9.6.7, abstract Lie algebra)**.** An (abstract) *Lie algebra* is a real vector space V together with a bracket $[\,\cdot\,,\cdot\,]\colon V\times V\to V$ that is bilinear, alternating ($[v,v]=0$), and satisfies the Jacobi identity. The matrix bracket makes every $\mathrm{Lie}(G)$ a Lie algebra in this sense.

Method (Compute the Lie algebra of a matrix group)**.** Differentiate the defining equation of G at I. Write a path $\varphi(t)=I+tA+\cdots$, substitute into the constraint (e.g. $\varphi^{\mathsf T}\varphi=I$ or $\det\varphi=1$), and keep the first-order term: it is a *linear* equation in A cutting out $\mathrm{Lie}(G)$. Then equip $\mathrm{Lie}(G)$ with $[A,B]=AB-BA$.

Worked Example 11.10.31 (The Lie algebra $\mathfrak{so}(3)$ and a basis)**.** Determine $\mathrm{Lie}(\mathrm{SO}(3))=\mathfrak{so}(3)$ explicitly and give a basis.

Recognition. By Proposition 11.10.26, $\mathfrak{so}(3)$ is the space of real 3×3 skew-symmetric matrices; count its dimension and pick the standard basis.

Solution. A real 3×3 matrix A with $A^{\mathsf T}=-A$ has zero diagonal and entries below the diagonal determined by those above, so

$$A=\begin{pmatrix}0 & -c & b\\ c & 0 & -a\\ -b & a & 0\end{pmatrix},\qquad a,b,c\in\mathbb{R},$$

a 3-dimensional space. A natural basis is

$$L_1=\begin{pmatrix}0&0&0\\0&0&-1\\0&1&0\end{pmatrix},\quad L_2=\begin{pmatrix}0&0&1\\0&0&0\\-1&0&0\end{pmatrix},\quad L_3=\begin{pmatrix}0&-1&0\\1&0&0\\0&0&0\end{pmatrix},$$

where L_k generates rotation about the k-th coordinate axis. *Check.* Each L_k is skew-symmetric and $A=aL_1+bL_2+cL_3$, so the three L_k span the 3-dimensional $\mathfrak{so}(3)$; and $\dim\mathfrak{so}(3)=\binom{3}{2}=3=\dim\mathrm{SO}(3)$ as a manifold, as it must.

Worked Example 11.10.32 (Brackets of the basis elements of $\mathfrak{so}(3)$)**.** Compute $[L_1,L_2]$, $[L_2,L_3]$, $[L_3,L_1]$ for the basis above.

Recognition. Apply $[A,B]=AB-BA$ to the explicit matrices; by closure (Proposition 11.10.29) each answer is again skew-symmetric, hence a combination of L_1,L_2,L_3.

Solution. Multiply out. For L_1L_2 and L_2L_1,

$$L_1L_2=\begin{pmatrix}0&0&0\\1&0&0\\0&0&0\end{pmatrix},\qquad L_2L_1=\begin{pmatrix}0&1&0\\0&0&0\\0&0&0\end{pmatrix},$$

so

$$[L_1,L_2]=L_1L_2-L_2L_1=\begin{pmatrix}0&-1&0\\1&0&0\\0&0&0\end{pmatrix}=L_3.$$

By the cyclic symmetry of the construction the same computation gives

$$[L_1,L_2]=L_3,\qquad [L_2,L_3]=L_1,\qquad [L_3,L_1]=L_2.$$

Check. The relations are cyclic and alternating ($[L_2,L_1]=-L_3$), exactly the structure constants of the cross product on $\mathbb{R}^3$: under $L_1\leftrightarrow e_1$, $L_2\leftrightarrow e_2$, $L_3\leftrightarrow e_3$ the bracket becomes $[u,v]=u\times v$. So $(\mathfrak{so}(3),[\,\cdot\,,\cdot\,])$ is the cross-product Lie algebra (Artin, Exercise 6.9).

Worked Example 11.10.33 (Jacobi identity, checked on $\mathfrak{so}(3)$)**.** Verify the Jacobi identity for $A=L_1$, $B=L_2$, $C=L_3$ using only the bracket relations.

Recognition. Use $[L_1,L_2]=L_3$ and cyclic permutations, plus $[L_i,L_i]=0$; no matrix multiplication is needed once the structure constants are known.

Solution. Compute the inner brackets first:

$$[B,C]=[L_2,L_3]=L_1,\quad [C,A]=[L_3,L_1]=L_2,\quad [A,B]=[L_1,L_2]=L_3.$$

Then

$$[A,[B,C]] = [L_1, L_1] = 0, \quad [B,[C,A]] = [L_2, L_2] = 0, \quad [C,[A,B]] = [L_3, L_3] = 0,$$

and the sum is 0. *Check.* Consistent with Proposition 11.10.29; equivalently the cross-product identity $u \times (v \times w) + v \times (w \times u) + w \times (u \times v) = 0$ on the standard basis of $\mathbb{R}^3$.

Caution. The bracket is *not* associative: in general $[A,[B,C]] \neq [[A,B],C]$. The Jacobi identity is the correct substitute for associativity, and it is why $[A,A] = 0$, bilinearity, and Jacobi — not commutativity or associativity — are the defining axioms. Also, $\mathrm{Lie}(G)$ records only first-order (t^1) data: distinct group elements can share a tangent vector, and the exponential $A \mapsto e^A$ recovers a one-parameter group but is not in general a bijection onto G.

Remark 11.10.8. Lie algebras are useful precisely because they are vector spaces: linear algebra is easier than the curved geometry of the group. The deep fact, due to Lie, is that many linear groups — in particular the classical groups — are nearly determined by their Lie algebras, so questions about G can be transported to the linear object $\mathrm{Lie}(G)$ and its bracket.

11.11 Graded Problem Bank

Easy

DF 11.1.1 Let $V = \mathbb{R}^n$ and fix $(a_1, \dots, a_n) \in V$. Prove the set of $(x_1, \dots, x_n)$ with $a_1x_1 + \cdots + a_nx_n = 0$ is a subspace; find its dimension and a basis.

DF 11.1.4 Prove the space of real-valued functions on $[a,b]$ $(a < b)$ is an infinite-dimensional vector space over $\mathbb{R}$.

DF 11.1.5 Prove the space of continuous real-valued functions on $[a,b]$ $(a < b)$ is an infinite-dimensional vector space over $\mathbb{R}$.

DF 11.1.8 For $\varphi : V \to V$ linear and fixed $\lambda \in F$, prove the eigenvectors with eigenvalue λ together with 0 form a subspace of V.

DF 11.2.4 Show the matrix of counterclockwise rotation of $\mathbb{R}^2$ by angle θ in the standard basis is $\begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix}$.

DF 11.2.7 Prove that any two similar matrices have the same column rank.

DF 11.2.22 Determine the inverses of $A = \begin{pmatrix} -7 & -1 & -4 \\ 7 & 1 & 3 \\ 1 & 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 1 & 0 & 2 \\ 0 & 2 & 1 & -1 \\ 0 & 2 & 0 & 0 \\ -1 & 1 & 1 & 0 \end{pmatrix}$ using row reduction.

DF 11.2.28 For each list, decide whether the given vectors in $\mathbb{R}^4$ are linearly independent and, if dependent, exhibit an explicit dependence relation: (a)–(d) as in the text.

DF 11.2.29 For each list of vectors in $\mathbb{R}^4$, determine the subspace they span and give a basis for it.

DF 11.2.32 Let $\varphi : \mathbb{R}^4 \to \mathbb{R}^4$ have matrix $A = \begin{pmatrix} 1 & -1 & 0 & 3 \\ -1 & 2 & 1 & -1 \\ -1 & 1 & 0 & -3 \\ 1 & -2 & -1 & 1 \end{pmatrix}$ in the standard basis; find a basis for $\operatorname{im}\varphi$ and for $\ker\varphi$.

DF 11.2.33 Let $\varphi : \mathbb{R}^4 \to \mathbb{R}^2$ satisfy $\varphi(1,0,0,0) = (1,-1)$, $\varphi(1,-1,0,0) = (0,0)$, $\varphi(1,-1,1,0) = (1,-1)$, $\varphi(1,-1,1,-1) = (0,0)$; find a basis for the image and for the kernel.

DF 11.3.2 In V (degree ≤ 5 polynomials over $\mathbb{Q}$ with basis $1, x, \dots, x^5$), show each of the four maps (evaluation at 3; $\int_0^1 p$; $\int_0^1 t^2 p$; $p'(5)$) lies in V^* and write it in the dual basis.

DF 11.4.5 Compute the determinants of $A = \begin{pmatrix} 5 & 4 & 4 \\ -2 & 0 & 2 \\ 3 & 4 & -2 \end{pmatrix}$ and $B = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 4 & 8 \\ 1 & 3 & 9 & 27 \\ 1 & 4 & 16 & 64 \end{pmatrix}$ using row reduction.

Artin 1.2 Determine the products AB and BA for the given matrices A and B.

Artin 1.10 Let D be the diagonal matrix with entries $d_1, \dots, d_n$ and $A = (a_{ij})$ arbitrary $n \times n$; compute DA and AD.

Artin 1.4.1 Evaluate the listed 2×2, 3×3, and 4×4 determinants.

Artin 1.5.1 Write each permutation (12)(13)(14)(15), (123)(234)(345), (1234)(2345), (12)(23)(34)(45)(51) as a product of disjoint cycles.

Artin 3.1.2 Find the inverse of 5 modulo p for $p = 7, 11, 13, 17$.

Artin 3.2.1 Prove that the scalar product of a vector with the zero scalar of F is the zero vector, and that $-w \in W$ whenever w lies in a subspace W.

Artin 3.3.1 Find a basis for the space of $n \times n$ symmetric matrices ($A^{\mathsf{T}} = A$).

Artin 3.3.3 Prove that the three functions x^2, $\cos x$, e^x are linearly independent.

Artin 4.1.2 For $v_1, \dots, v_n \in V$, prove the map $\varphi : F^n \to V$, $\varphi(X) = v_1 x_1 + \cdots + v_n x_n$, is linear.

Artin 4.4.1 For a linear operator T and scalar λ, prove the eigenspace $V(\lambda)$ is a T-invariant subspace.

Artin 4.5.1 Compute the characteristic polynomials and complex eigenvalues/eigenvectors of the three given 2×2 matrices.

Artin 5.4.1 Compute e^A for each of the given matrices A.

Artin 8.3.3 The $n \times n$ Hermitian matrices form a real vector space; find a basis for it.

Artin 8.4.1 What is the inverse of a matrix whose columns are orthogonal?

Artin 8.4.7 Apply the Gram–Schmidt procedure to the basis $(1,1,0)^{\mathsf{T}}, (1,0,1)^{\mathsf{T}}, (0,1,1)^{\mathsf{T}}$ of $\mathbb{R}^3$.

Fraleigh 33.1 Find three bases for $\mathbb{R}^2$ over $\mathbb{R}$, no two of which share a vector.

Fraleigh 33.2 Determine whether $\{(1,1,0), (1,0,1), (0,1,1)\}$ is a basis for $\mathbb{R}^3$ over $\mathbb{R}$.

Fraleigh 33.3 Determine whether $\{(-1,1,2), (2,-3,1), (10,-14,0)\}$ is a basis for $\mathbb{R}^3$ over $\mathbb{R}$.

Fraleigh 33.4 Give a basis for $\mathbb{Z}_{13}$ over $\mathbb{Z}_{13}$.

Fraleigh 33.5 Give a basis for $\{\, a + b\sqrt{2} \mid a, b \in \mathbb{Q} \,\}$ over $\mathbb{Q}$.

Fraleigh 33.8 Give a basis for $\mathbb{C}$ over $\mathbb{R}$.

Fraleigh 33.15 Decide true or false for each of the ten statements (a)–(j) about vectors, scalars, bases, and modules.

Fraleigh 33.19 Generalize Example 33.2 to the vector space F^n of ordered n-tuples over F; exhibit a basis for F^n.

Medium

DF 11.1.2 Let V be the degree-≤ 5 polynomials over $\mathbb{Q}$; prove V is a 6-dimensional $\mathbb{Q}$-space with basis $1, x, \dots, x^5$, and that $1, 1+x, \dots, 1+x+\cdots+x^5$ is also a basis.

DF 11.1.3 Let $\varphi : \mathbb{R}^4 \to \mathbb{R}$ be linear with $\varphi(1,0,0,0) = 1$, $\varphi(1,-1,0,0) = 0$, $\varphi(1,-1,1,0) = 1$, $\varphi(1,-1,1,-1) = 0$; determine $\varphi(a,b,c,d)$.

DF 11.1.7 If $\varphi : V \to V$ is linear on an n-dimensional V with $\varphi^2 = 0$, prove $\operatorname{im}\varphi \subseteq \ker\varphi$ and hence $\operatorname{rank}\varphi \leq n/2$.

DF 11.1.11 Prove that any set of linearly independent vectors of V is contained in a basis of V.

DF 11.1.13 Prove $\mathbb{R}^n \cong \mathbb{R}$ as vector spaces over $\mathbb{Q}$ for all $n \in \mathbb{Z}^+$ (hence as additive abelian groups).

DF 11.2.1 For V the degree-≤ 5 polynomials over $\mathbb{Q}$, determine the transition matrix from $1, x, \dots, x^5$ to $1, 1+x, \dots, 1+x+\cdots+x^5$.

DF 11.2.2 With V as above and $\varphi = d/dx$, determine the matrix of φ with respect to the two bases of the previous exercise.

DF 11.2.3 For degree-$\le n$ polynomials over F, find the transition matrix from $1, x, \dots, x^n$ to $1, x-\lambda, \dots, (x-\lambda)^n$, and conclude the latter is a basis.

DF 11.2.5 Show the $m \times n$ matrix $A = M_{\mathcal{B}}^{\mathcal{E}}(\varphi)$ is nonsingular iff $\varphi : V \to W$ is nonsingular, independent of the chosen bases.

DF 11.2.6 Prove for $\varphi \in \mathrm{Hom}_F(F^n, F^m)$ with natural bases that $\operatorname{im}\varphi$ equals the span of the columns of $M_{\mathcal{B}}^{\mathcal{E}}(\varphi)$, hence $\operatorname{rank}\varphi$ equals the column rank.

DF 11.2.8 For $\varphi : V \to V$ on an n-dimensional V: (a) a basis of eigenvectors gives a diagonal matrix with the eigenvalues on the diagonal; (b) A is similar to a diagonal matrix iff V has a basis of eigenvectors.

DF 11.2.12 In $\mathbb{R}^2$ with basis $v_1 = (1,0)$, $v_2 = (0,1)$ and φ of matrix $\begin{pmatrix} 2 & 1 \\ 0 & 2 \end{pmatrix}$, show $W = \langle v_1 \rangle$ is φ-stable but no φ-invariant W' has $V = W \oplus W'$.

DF 11.2.13 Relate matrices of the same $\varphi : V \to W$ in two pairs of bases: with $P = M_{\mathcal{B}_2}^{\mathcal{B}_1}(I)$, $Q = M_{\mathcal{E}_2}^{\mathcal{E}_1}(I)$, prove $Q^{-1} = M_{\mathcal{E}_1}^{\mathcal{E}_2}(I)$ and $Q^{-1}AP = B$.

DF 11.2.14 Prove "$A \sim C$ iff A can be row reduced to C" is an equivalence relation (row operations are reversible).

DF 11.2.15 Prove two row-equivalent matrices have the same row rank.

DF 11.2.17 Let A, C be in reduced row echelon form; prove that if they are row equivalent then $A = C$.

DF 11.2.20 Determine the solutions of the listed systems of linear equations (a)–(e).

DF 11.2.21 If A, B are row-equivalent $m \times n$ matrices: (a) $AX = 0$ and $BX = 0$ have the same solutions; (b) any dependence among columns of A holds for B; (c) A, B have equally many independent columns.

DF 11.2.30 Compute a basis for the image and kernel of $\varphi : \mathbb{R}^5 \to \mathbb{R}^4$, $\varphi(x,y,z,u,v) = (x+2y+3z+4u+4v,\ -2x-4y+2v,\ x+2y+u-2v,\ x+2y-v)$, via reduced row echelon form.

DF 11.2.34 For $V = \mathrm{M}_2(\mathbb{R})$ and $\varphi = \mathrm{tr} : V \to \mathbb{R}$ (sum of diagonal entries): show the four elementary matrices form a basis, then prove φ linear, find its matrix, and find a basis for $\ker\varphi$.

DF 11.2.37 For V the degree-≤ 6 polynomials over F and $\varphi(f) = f'$, find a basis for $\operatorname{im}\varphi$ and $\ker\varphi$ over each of $F = \mathbb{R}, \mathbb{F}_2, \mathbb{F}_3, \mathbb{F}_5$.

DF 11.2.38 For square matrices A, B, prove $\mathrm{tr}(A \otimes B) = \mathrm{tr}(A)\,\mathrm{tr}(B)$ for the Kronecker product.

DF 11.3.4 If V is infinite-dimensional with basis $\mathcal{A}$, prove $\mathcal{A}^* = \{\, v^* \mid v \in \mathcal{A} \,\}$ does not span V^*.

DF 11.4.1 Formulate and prove the cofactor expansion of $\det A$ along the jth column.

DF 11.4.2 For column vectors $A_1, \dots, A_n \in F^n$ forming the columns of A, prove they are a basis of F^n iff $\det A \neq 0$.

DF 11.5.4 Prove $m \wedge n_1 \wedge \cdots \wedge n_k = (-1)^k (n_1 \wedge \cdots \wedge n_k \wedge m)$; in particular $x \wedge (y \wedge z) = (y \wedge z) \wedge x$.

DF 11.5.12 (a) An alternating bilinear f satisfies $f(x,y) = -f(y,x)$; (b) if $-1 \neq 1$ in F, skew-symmetry implies alternating; (c) if $-1 = 1$, every alternating form is symmetric and some symmetric form is not alternating.

Artin 1.9 When is $(A+B)(A-B) = A^2 - B^2$, and expand $(A+B)^3$, for square matrices A, B.

Artin 1.11 Prove the product of upper triangular matrices is upper triangular.

Artin 1.13 A square matrix A is nilpotent if $A^k = 0$; prove $I + A$ is invertible by exhibiting its inverse.

Artin 1.2.8 Prove that if a product AB of $n \times n$ matrices is invertible, so are both factors.

Artin 1.3.1 A matrix B is symmetric if $B = B^{\mathsf{T}}$; prove BB^{T} and $B + B^{\mathsf{T}}$ are symmetric, and $(A^{-1})^{\mathsf{T}} = (A^{\mathsf{T}})^{-1}$ when A is invertible.

Artin 1.4.5 Use row reduction to prove $\det A^{\mathsf T} = \det A$.

Artin 1.4.6 Prove $\det \begin{pmatrix} A & B \\ 0 & D \end{pmatrix} = (\det A)(\det D)$ for square blocks A, D.

Artin 1.5.3 Prove the inverse of a permutation matrix P is its transpose.

Artin 3.1.1 Prove the numbers $a + b\sqrt{-1}$ with $a, b \in \mathbb{Q}$ form a subfield of $\mathbb{C}$.

Artin 3.1.10 Interpreting entries in $\mathbb{F}_2$, prove the four given 2×2 matrices form a field.

Artin 3.1.11 Prove $\{\, a + bi \mid a, b \in \mathbb{F}_3 \,\}$ is a field with nine elements; discuss whether the same construction works for $\mathbb{F}_5$ and $\mathbb{F}_7$.

Artin 3.2.2 Which of (a) symmetric, (b) invertible, (c) upper-triangular matrices form a subspace of $F^{n\times n}$?

Artin 3.3.4 If A' comes from A by elementary row operations, prove the rows of A and A' span the same space.

Artin 3.3.5 For $V = F^n$, prove every subspace W is the solution space of some homogeneous system $AX = 0$.

Artin 3.3.8 Prove $(v_1, \dots, v_n)$ in F^n is a basis iff the matrix of their coordinate vectors is invertible.

Artin 3.4.1 Show $B = \{\, (1,2,0)^{\mathsf T}, (2,1,2)^{\mathsf T}, (3,1,1)^{\mathsf T} \,\}$ is a basis of $\mathbb{R}^3$, find the coordinates of $(1,2,3)^{\mathsf T}$, and the change-of-basis matrix from B to $B' = \{\, (0,1,0)^{\mathsf T}, (1,0,1)^{\mathsf T}, (2,1,0)^{\mathsf T} \,\}$.

Artin 3.5.1 Prove $\mathbb{R}^{n\times n}$ is the direct sum of the symmetric ($A^{\mathsf T} = A$) and skew-symmetric ($A^{\mathsf T} = -A$) matrices.

Artin 3.5.2 Let W_1 be the $n \times n$ matrices of trace zero; find a subspace W_2 with $\mathbb{R}^{n\times n} = W_1 \oplus W_2$.

Artin 4.1.3 Use the dimension formula to prove the solution space of $AX = 0$ (A an $m \times n$ matrix) has dimension at least $n - m$.

Artin 4.4.3 If W_1, W_2 are T-invariant subspaces, prove $W_1 + W_2$ and $W_1 \cap W_2$ are T-invariant.

Artin 4.4.4 A 2×2 matrix has eigenvector $(1,1)^{\mathsf T}$ with eigenvalue 2 and $(1,2)^{\mathsf T}$ with eigenvalue 3; determine A.

Artin 4.4.6 For P the degree-$\le n$ real polynomials and $D = d/dx$: prove D is nilpotent, find its matrix in a convenient basis, and determine all D-invariant subspaces.

Artin 4.6.1 For A with characteristic polynomial $\prod(t - \lambda_i)$, prove $\operatorname{tr} A = \sum \lambda_i$ and $\det A = \prod \lambda_i$.

Artin 4.6.4 For $A = \begin{pmatrix} 2 & 2 \\ 1 & 2 \end{pmatrix}$ find P with $P^{-1}AP$ diagonal and a formula for A^{30}.

Artin 4.6.5 In each case find a complex P with $P^{-1}AP$ diagonal for the given matrices.

Artin 4.6.7 Prove that if A, B are $n \times n$ and A is nonsingular, then AB is similar to BA.

Artin 4.7.1 Determine the Jordan form of $\begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix}$.

Artin 4.7.2 Prove that $A = \begin{pmatrix} 1 & 1 & 1 \\ -1 & -1 & -1 \\ 1 & 1 & 1 \end{pmatrix}$ satisfies $A^2 = A$ and find its Jordan form.

Artin 5.1.4 Describe geometrically the action of an orthogonal 3×3 matrix of determinant -1.

Artin 5.2.1 Use the Cayley–Hamilton theorem to express A^{-1} via A, $(\det A)^{-1}$, and the coefficients of the characteristic polynomial; verify in the 2×2 case.

Artin 5.4.2 Prove the identity $e^{\operatorname{tr} A} = \det(e^A)$.

Artin 5.4.3 For an eigenvector X of A with eigenvalue λ: (a) if A is invertible, X is an eigenvector of A^{-1} with eigenvalue λ^{-1}; (b) X is an eigenvector of e^A with eigenvalue e^{λ}.

Artin 8.2.2 If symmetric matrices satisfy $A' = P^{\mathsf T}AP$ with P invertible, is $\operatorname{rank} A = \operatorname{rank} A'$?

Artin 8.3.4 Prove that if A is invertible, then A^*A is Hermitian and positive definite.

Artin 8.3.6 Use the characteristic polynomial to prove the eigenvalues of a 2×2 Hermitian matrix are real.

Artin 8.4.3 For real A, prove $B = A^{\mathsf{T}}A$ is positive semidefinite and $\operatorname{rank} B = \operatorname{rank} A$.

Artin 8.4.9 Find an orthonormal basis for the degree-≤ 2 real polynomials under $(f, g) = \int_{-1}^{1} f(x)g(x)\,dx$.

Artin 8.4.10 Prove $(A, B) = \operatorname{tr}(A^{\mathsf{T}}B)$ is positive definite on real $n \times n$ matrices and find an orthonormal basis.

Artin 8.4.11 For subspaces W_1, W_2 with a symmetric bilinear form, prove $(W_1 + W_2)^{\perp} = W_1^{\perp} \cap W_2^{\perp}$, $W \subseteq W^{\perp\perp}$, and $W_1 \subseteq W_2 \implies W_2^{\perp} \subseteq W_1^{\perp}$.

Artin 8.5.1 In a Euclidean space prove (a) the Schwarz inequality, (b) the parallelogram law, (c) $|v| = |w| \implies (v + w) \perp (v - w)$.

Artin 8.6.11 Prove eigenvectors for distinct eigenvalues of a Hermitian matrix A are orthogonal.

Artin 8.6.14 Prove a real symmetric matrix is positive definite iff all its eigenvalues are positive.

Artin 9.1.5 Prove $\mathrm{Sp}_2 = \mathrm{SL}_2$ but $\mathrm{Sp}_4 \neq \mathrm{SL}_4$.

Artin 9.6.1 Verify the Jacobi identity for the bracket $[A, B] = AB - BA$.

Artin 9.8.5 Determine the centers of $\mathrm{SL}_n(\mathbb{R})$ and $\mathrm{SL}_n(\mathbb{C})$.

Fraleigh 33.6 Give a basis over $\mathbb{Q}$ for $\{\, (a + b\sqrt{3})/(c + d\sqrt{3}) \mid a, b, c, d \in \mathbb{Q},\ c + d\sqrt{3} \neq 0 \,\}$.

Fraleigh 33.7 Decide whether $\mathbb{R}$ is finite-dimensional over $\{\, a + b\sqrt{2} \mid a, b \in \mathbb{Q} \,\}$, and if so give a basis.

Fraleigh 33.10 There is a field E with 32 elements; identify the prime subfield and the dimension of E over it.

Fraleigh 33.11 Correct, if needed, the definition: vectors in S span V iff each $\beta \in V$ is uniquely a linear combination of vectors in S.

Fraleigh 33.12 Correct, if needed, the definition: S is linearly independent over F iff the zero vector is not a linear combination of vectors in S.

Fraleigh 33.13 Correct, if needed, the definition: $\dim_F V$ is the minimum number of vectors required to span V.

Fraleigh 33.14 Correct, if needed, the definition: a basis is a set of vectors that span V and are linearly dependent.

Fraleigh 33.16 (a) Define a subspace of V; (b) prove an intersection of subspaces of V is again a subspace.

Fraleigh 33.17 For a collection $S = \{\, \alpha_i \,\}$ in V: (a) define the subspace generated by S; (b) prove it equals the set of finite linear combinations of vectors in S.

Fraleigh 33.18 Define the direct sum $V_1 \oplus \cdots \oplus V_n$ of vector spaces over F and show it is again a vector space over F.

Fraleigh 33.20 Define an isomorphism of a vector space V over F with a vector space V' over the same field F.

Fraleigh 33.21 Prove $\{\, \beta_1, \ldots, \beta_n \,\} \subseteq V$ (finite-dimensional) is a basis iff every vector is uniquely a linear combination of the β_i.

Hard

DF 11.1.6 For $\varphi : V \to V$ linear with $\dim V$ finite, prove there is an integer m with $\operatorname{im} \varphi^m \cap \ker \varphi^m = \{0\}$.

DF 11.1.9 If $v_1, \ldots, v_k$ are eigenvectors of φ for distinct eigenvalues, prove they are linearly independent; conclude an operator on an n-dimensional space has at most n distinct eigenvalues.

DF 11.1.10 Prove every vector space has a basis (the empty set is the basis of the zero space) via Zorn's Lemma.

DF 11.1.12 If F is finite or countable and V is infinite-dimensional over F with basis $\mathcal{B}$, prove $|V| = |\mathcal{B}|$; deduce any two bases have equal cardinality.

DF 11.1.14 For a basis $\mathcal{A}$ of an infinite-dimensional V, prove V is the direct sum of copies of F indexed by $\mathcal{A}$, while the direct product has strictly larger dimension.

DF 11.2.9 If $W \subseteq V$ is φ-stable, φ induces $\varphi|_W$ and $\overline{\varphi}$ on V/W; show both nonsingular implies φ nonsingular; prove the converse in finite dimension and give an infinite-dimensional counterexample.

DF 11.2.10 For an n-dimensional V with φ-stable m-dimensional W: (a) produce a basis giving a block upper triangular matrix; (b) a φ-invariant complement gives block diagonal form; (c) conversely block diagonal form yields φ-invariant W, W' with $V = W \oplus W'$.

DF 11.2.11 For $\varphi : V \to V$ with $\varphi^2 = \varphi$ on finite-dimensional V: (a) $\operatorname{im}\varphi \cap \ker\varphi = 0$; (b) $V = \operatorname{im}\varphi \oplus \ker\varphi$; (c) a basis exists giving a diagonal matrix of 0s and 1s.

DF 11.2.16 Prove by induction that any augmented matrix can be put in reduced row echelon form by elementary row operations.

DF 11.2.18 Prove the row rank of a matrix in reduced row echelon form equals its number of nonzero rows.

DF 11.2.19 Prove the reduced row echelon forms of the augmented matrices

$$\left(\begin{array}{cccccc|c} 1 & 1 & 4 & 8 & 0 & -1 & -1 \\ 1 & 2 & 3 & 9 & 0 & -5 & -2 \\ 0 & -2 & 2 & -2 & 1 & 14 & 3 \\ 1 & 4 & 1 & 11 & 0 & -13 & -4 \end{array}\right) \qquad \left(\begin{array}{cccc|c} 0 & -3 & 3 & 1 & 5 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 2 & -2 & 0 & -3 \end{array}\right)$$

are the two matrices preceding Exercise 16.

DF 11.2.23 (Computing inverses) Show A has inverse B iff the systems $AB_j = e_j$ are solvable; iff A is row equivalent to I; iff $(A \mid I)$ row reduces to $(I \mid B)$.

DF 11.2.24 (Solving systems) For $(A' \mid C')$ the reduced row echelon form of $(A \mid C)$: (a) more zero rows in A' than in $(A' \mid C')$ means no solutions; by (a) we may assume that A' and $(A' \mid C')$ have the same number, r, of nonzero rows (so $r \leq n$, where n is the number of unknowns, i.e. of columns of A); (b) $r = n$ gives a unique solution; (c) $r < n$ gives infinitely many solutions if the field is infinite, with the nonpivotal variables free.

DF 11.2.25 (Spans, independence, dependencies) For vectors $v_1, \ldots, v_n$ with coordinate matrix A and reduced form A', prove the stated criteria (a)–(e) for relations, independent/dependent columns, dimension, and a basis of the span.

DF 11.2.26 For $V = \mathbb{R}^5$ and the five listed vectors $v_1, \ldots, v_5$: verify the reduced row echelon form, conclude $\dim W = 3$ with v_1, v_2, v_4 a basis, and read off all dependence relations.

DF 11.2.27 For a matrix A' in reduced row echelon form: (a) nonzero rows and pivotal columns are independent and nonpivotal columns depend on the pivotal ones; (b) row rank equals column rank.

DF 11.2.27b Use the preceding exercises and Exercise 15 to prove in general that the row rank and column rank of any matrix are equal.

DF 11.2.31 (Image and kernel) For $\varphi : V \to W$ with matrix A and reduced form A': (a) the image has dimension r with the columns of A corresponding to the pivotal columns of A' giving a basis; (b) the kernel is described by $AX = 0$, with φ injective iff rank n and $\dim\ker\varphi = n - r$.

DF 11.2.35 For $V = \mathbb{R}^5$, $W = \mathbb{R}^4$ and the explicit φ, prove A and A' as displayed, conclude $\dim\operatorname{im}\varphi = 3$ with the stated basis, and find the 2-dimensional kernel basis.

DF 11.2.36 For V the degree-≤ 5 rationals and $\varphi(f) = x^2 f'' - 6xf' + 12f$, prove φ is linear and find bases for its image and kernel.

DF 11.2.39 For a subfield $F \subseteq K$ and linear $\psi : V \to W$ of finite-dimensional F-spaces: (a) $1 \otimes \psi$ is K-linear $K \otimes_F V \to K \otimes_F W$; (b) its matrix in the bases $1 \otimes v_i$, $1 \otimes w_j$ equals the matrix of ψ.

DF 11.3.1 For V of finite dimension n over F, prove that $\varphi \mapsto \varphi^*$ (Theorem 11.3.24) is a vector space isomorphism $\operatorname{End}(V) \to \operatorname{End}(V^*)$ but not a ring homomorphism when $n > 1$, and exhibit an F-algebra isomorphism $\operatorname{End}(V) \to \operatorname{End}(V^*)$.

DF 11.3.3 For finite-dimensional V and $\mathrm{Ann}(S) = \{\, f \in V^* \mid f(v) = 0\ \forall v \in S \,\}$ ($S \subseteq V$), prove (a)–(f): subspace, the sum/intersection identities, $W_1 = W_2 \iff \mathrm{Ann}(W_1) = \mathrm{Ann}(W_2)$, span-invariance, the dual-basis description, and $\dim \mathrm{Ann}(W) = \dim V - \dim W$.

DF 11.3.5 If V is infinite-dimensional with basis $\mathcal{A}$, prove V^* is isomorphic to the direct product of copies of F indexed by $\mathcal{A}$, hence $\dim V^* > \dim V$.

DF 11.4.3 For a commutative ring R with 1, an R-module V, and $x_1, \dots, x_n \in V$ with $A(x_1, \dots, x_n)^{\mathsf{T}} = 0$, prove $(\det A)x_i = 0$ for all i.

DF 11.4.4 (Determinants by elimination) Prove the effect of each elementary row operation on $\det A$, that $\det A \neq 0$ iff A row reduces to I, and the formula $\det A = (-1)^s (u_1 \cdots u_t)^{-1}$.

DF 11.4.7 (Minkowski's criterion) If a real $n \times n$ matrix has positive diagonal entries, negative off-diagonal entries, and positive row sums, prove $\det A \neq 0$.

DF 11.5.1 Prove that if M is a cyclic R-module then $T(M) = S(M)$, i.e. the tensor algebra is commutative.

DF 11.5.2 Fill in the proof of Proposition 33 that $S/I = \bigoplus_{k \geq 0} S_k / I_k$, including $S_k I_j \subseteq I_{k+j}$ and well-definedness of multiplication.

DF 11.5.3 Show the image of Sym_2 for the $\mathbb{Z}$-module $\mathbb{Z}$ consists of the 2-tensors $a(1 \otimes 1)$ with a even; conclude $1 \otimes 1$ is not in the image.

DF 11.5.5 Prove that if M is free of rank n then $\wedge^i(M)$ is free of rank $\binom{n}{i}$ for all i.

DF 11.5.6 If A is an R-algebra and $\varphi : M \to A$ is R-linear with $\varphi(m)^2 = 0$ for all $m \in M$, prove there is a unique R-algebra map $\Phi : \wedge(M) \to A$ with $\Phi|_M = \varphi$.

DF 11.5.7 For $R = \mathbb{Z}[x, y]$, $I = (x, y)$: (a) characterize the equality $ax + by = a'x + b'y$; (b) prove the displayed map is a well-defined alternating R-bilinear map $I \times I \to R/I$.

DF 11.5.8 For an integral domain R with fraction field F: (a) $\wedge^2 F = 0$; (b) for a submodule $I \subseteq F$, $\wedge^i I$ is torsion for $i \geq 2$; (c) exhibit R and I with $\wedge^i I \neq 0$ for all i.

DF 11.5.9 For $R = \mathbb{Z}[G]$ with $G = \{1, \sigma\}$ and $M = \mathbb{Z}e_1 \oplus \mathbb{Z}e_2$ with $\sigma(e_1) = e_1 + 2e_2$, $\sigma(e_2) = -e_2$: prove M is an R-module and $\wedge^2 M$ has order 2 generated by $e_1 \wedge e_2$.

DF 11.5.10 Prove $z - \frac{1}{k!}\mathrm{Alt}(z) = \frac{1}{k!}\sum_{\sigma \in S_k}(z - \epsilon(\sigma)\sigma z)$ and use it to identify $\ker\left(\frac{1}{k!}\mathrm{Alt}\right)$ with $\mathcal{A}^k(M)$.

DF 11.5.11 Suppose that $-1 \neq 1$ in F. Prove the image of Alt_k is the unique largest subspace of $T^k(V)$ on which each $\sigma \in S_k$ acts as multiplication by $\epsilon(\sigma)$.

DF 11.5.13 For a field with $-1 \neq 1$, prove $V \otimes_F V = S^2(V) \oplus \wedge^2(V)$: every 2-tensor splits uniquely into symmetric and alternating parts.

DF 11.5.14 Prove that if M is a direct factor of N then $T(M)$ (resp. $S(M)$, $\wedge(M)$) is a subalgebra of $T(N)$ (resp. $S(N)$, $\wedge(N)$).

Artin 1.7 Find a formula for the nth power of the displayed unipotent matrix and prove it by induction.

Artin 1.M.1 For $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ with A invertible and $AC = CA$, prove $\det M = \det(AD - CB)$, and show it can fail when $AC \neq CA$.

Artin 1.M.3 Show $\mathrm{tr}(A + B) = \mathrm{tr}\, A + \mathrm{tr}\, B$, $\mathrm{tr}\, AB = \mathrm{tr}\, BA$, and $\mathrm{tr}\, A = \mathrm{tr}(BAB^{-1})$ for invertible B.

Artin 1.M.4 Prove the equation $AB - BA = I$ has no solution in real $n \times n$ matrices.

Artin 1.M.7 (Vandermonde) Prove det of the 3×3 Vandermonde equals $(a - b)(b - c)(c - a)$, generalize to $n \times n$, and deduce uniqueness of the interpolating polynomial.

Artin 1.M.10 For $m \times n$ and $n \times m$ matrices A, B, prove $I_m - AB$ is invertible iff $I_n - BA$ is invertible.

Artin 3.4.4 For the prime field $\mathbb{F}_p$ and $V = \mathbb{F}_p^2$: (a) the number of bases equals $|\mathrm{GL}_2(\mathbb{F}_p)|$; (b) $|\mathrm{GL}_2(\mathbb{F}_p)| = p(p + 1)(p - 1)^2$ and $|\mathrm{SL}_2(\mathbb{F}_p)| = p(p + 1)(p - 1)$.

Artin 3.5.3 For subspaces $W_1, \dots, W_k$ with $V = \sum W_i$ and the chain of intersection conditions, prove $V = W_1 \oplus \cdots \oplus W_k$.

Artin 3.M.4 For a vector space V over an infinite field, prove V is not the union of finitely many proper subspaces.

Artin 3.M.5 For $\alpha = \sqrt[3]{2}$: (a) prove $1, \alpha, \alpha^2$ are independent over $\mathbb{Q}$; (b) prove the numbers $a + b\alpha + c\alpha^2$ $(a, b, c \in \mathbb{Q})$ form a field.

Artin 4.3.4 For complex $n \times n$ B, prove or disprove that $T(A) = AB - BA$ on the space of all $n \times n$ matrices is singular.

Artin 4.4.8 If every nonzero vector is an eigenvector of T on a finite-dimensional space, prove T is scalar multiplication.

Artin 4.6.8 Prove T is nilpotent iff some basis makes its matrix upper triangular with zero diagonal.

Artin 4.6.10 For $M = \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix}$, prove M is diagonalizable iff A and D are.

Artin 4.7.3 For a complex operator T on a 5-dimensional space with characteristic polynomial $(t - \lambda)^5$ and $\operatorname{rank}(T - \lambda I) = 2$, list the possible Jordan forms.

Artin 4.M.6 Without using the characteristic polynomial, prove an operator on an n-dimensional space has at most n distinct eigenvalues.

Artin 4.M.8 For T on a finite-dimensional complex V: (a) each generalized eigenspace V_λ is T-invariant; (b) V is the direct sum of its generalized eigenspaces.

Artin 5.M.3 Prove that if $\operatorname{tr} A^k = 0$ for all $k > 0$ then the complex matrix A is nilpotent.

Artin 5.M.4 If all eigenvalues of A have absolute value less than 1, prove $I + A + A^2 + \dots$ converges to $(I - A)^{-1}$.

Artin 8.4.21 Prove Sylvester's law: the signature of a symmetric bilinear form is well defined.

Artin 8.5.5 For a unitary P with eigenvectors X_1, X_2 for distinct eigenvalues, prove $X_1 \perp X_2$ under the standard Hermitian form.

Artin 8.6.17 For commuting Hermitian A, B, prove there is a unitary P with P^*AP and P^*BP both diagonal.

Artin 8.6.22 Prove the spectral theorem for symmetric operators.

Artin 8.8.3 For real skew-symmetric S, prove $I + S$ is invertible and $(I - S)(I + S)^{-1}$ is orthogonal.

Artin 8.8.4 For a real skew-symmetric A: (a) prove $\det A \geq 0$; (b) if A has integer entries, prove $\det A$ is a perfect square.

Artin 8.M.7 For a real $m \times n$ matrix A, prove there exist orthogonal $P \in \mathrm{O}_m$, $Q \in \mathrm{O}_n$ with PAQ diagonal and nonnegative entries (singular value decomposition).

Artin 8.M.8 Prove the polar decomposition: every nonsingular matrix A is uniquely $A = UP$ with P positive definite Hermitian and U unitary.

Artin 9.4.8 On $W =$ Hermitian 2×2 matrices: (a) $P \cdot A = PAP^*$ is an action of $\mathrm{SL}_2(\mathbb{C})$; (b) the form $(A, A') = \det(A + A') - \det A - \det A'$ has signature $(1, 3)$, so its negative has the Lorentz signature $(3, 1)$; (c) build a homomorphism $\mathrm{SL}_2(\mathbb{C}) \to \mathrm{O}_{3,1}$ with kernel $\{\pm 1\}$.

Artin 9.8.6 Determine all normal subgroups of $\mathrm{GL}_2(\mathbb{R})$ that contain its center.

Artin 9.M.4 For quaternions $\alpha = a + bi + cj + dk$: (a) compute $\alpha\overline{\alpha}$; (b) every $\alpha \neq 0$ has an inverse; (c) the unit quaternions form a group $\cong \mathrm{SU}_2$.

Chapter 12

Modules over Principal Ideal Domains

12.1 The Basic Theory

Setup: modules over a PID

Throughout this section R is a Principal Ideal Domain (PID): an integral domain in which every ideal is principal. The two motivating examples are $R = \mathbb{Z}$ (where R-modules are exactly abelian groups) and $R = \mathbb{F}[x]$ for a field $\mathbb{F}$ (where, as we shall exploit in 12.2–12.3, an $\mathbb{F}[x]$-module is a vector space V together with a chosen linear operator). The whole point of the theory is that finitely generated modules over a PID admit a clean, complete classification — the same one that yields the structure theorem for finitely generated abelian groups as the case $R = \mathbb{Z}$.

We freely use that in a PID: (i) any two elements a, b have a gcd $d = \gcd(a, b)$ with $(a) + (b) = (d)$; (ii) R is a Unique Factorization Domain; (iii) R is Noetherian (every ascending chain of ideals stabilizes), so submodules of finitely generated modules are again finitely generated.

Definition 12.1.1. An R-module F is *free* on a subset $A \subseteq F$ if for every nonzero $x \in F$ there are unique nonzero $r_1, \dots, r_n \in R$ and distinct $a_1, \dots, a_n \in A$ with $x = r_1 a_1 + \cdots + r_n a_n$. We call A a *basis*. If A is finite of size n then $F \cong R^n$, and n is the *rank* of F.

Remark 12.1.1. Over a commutative ring with $1 \neq 0$ the rank is well defined: $R^n \cong R^m$ forces $n = m$. (Quotient by a maximal ideal $\mathfrak{m}$ to get $(R/\mathfrak{m})^n \cong (R/\mathfrak{m})^m$ as vector spaces over the field $R/\mathfrak{m}$, then compare dimensions.) For a PID this is part of the larger structure below.

A free module of rank m has the universal mapping property: any set map from a basis into an R-module extends uniquely to an R-module homomorphism. Concretely, $\mathrm{Hom}_R(R^m, M) \cong M^m$.

Worked Example 12.1.2 (Free vs. non-free modules)**.** Decide which of the following are free R-modules: (a) $\mathbb{Z}^3$ over $\mathbb{Z}$; (b) $\mathbb{Z}/6\mathbb{Z}$ over $\mathbb{Z}$; (c) $\mathbb{Q}$ over $\mathbb{Z}$; (d) $\mathbb{F}[x]^2$ over $\mathbb{F}[x]$; (e) the ideal $(2) \subseteq \mathbb{Z}$ over $\mathbb{Z}$.

Recognition. Apply the definition directly: a free module is a direct sum of copies of R, equivalently it has a basis. Torsion or "divisibility" obstructions kill freeness.

Solution. (a) Free of rank 3, basis e_1, e_2, e_3. (b) NOT free: every element is killed by 6, but a basis element a must satisfy $ra = 0 \Rightarrow r = 0$ (uniqueness with $r = 0$). (c) NOT free: any two elements $\frac{a}{b}, \frac{c}{d} \in \mathbb{Q}$ satisfy the relation $(cb)\frac{a}{b} - (ad)\frac{c}{d} = 0$, so no two elements are independent; a single element cannot generate $\mathbb{Q}$ (e.g. $\frac{1}{2}$ generates only $\frac{1}{2}\mathbb{Z}$). (d) Free of rank 2. (e) Free of rank 1 with basis $\{2\}$: every element is $2k = k \cdot 2$ uniquely, and $r \cdot 2 = 0 \Rightarrow r = 0$ since $\mathbb{Z}$ is a domain. Sanity check: $(2) \cong \mathbb{Z}$ as $\mathbb{Z}$-modules via $2k \mapsto k$, confirming rank 1.

Submodules of free modules are free

Theorem 12.1.3. *Let R be a PID, let F be a free R-module of finite rank n, and let $N \subseteq F$ be a submodule. Then N is free of rank $m \leq n$, and there is a basis $y_1, \dots, y_n$ of F together with nonzero elements $a_1, \dots, a_m \in R$ such that $a_1 y_1, \dots, a_m y_m$ is a basis of N and $a_1 \mid a_2 \mid \cdots \mid a_m$.*

The "aligned basis" $a_1y_1, \ldots, a_my_m$ is exactly what produces the invariant factors below. The inclusion $N \hookrightarrow F$ becomes diagonal in these coordinates — this is the module-theoretic content of Smith Normal Form.

Worked Example 12.1.4 (An aligned basis in $\mathbb{Z}^2$)**.** Let $F = \mathbb{Z}^2$ and N the subgroup generated by $u = (4, 2)$ and $v = (2, 2)$. Find a basis y_1, y_2 of F and $a_1 \mid a_2$ with a_1y_1, a_2y_2 a basis of N.

Recognition. Theorem 12.1.3: pick generators, run integer row/column operations (change of basis in F and in N) to diagonalize.

Solution. Stack as rows of $A = \begin{pmatrix} 4 & 2 \\ 2 & 2 \end{pmatrix}$. Swap rows: $\begin{pmatrix} 2 & 2 \\ 4 & 2 \end{pmatrix}$; $R_2 - 2R_1$: $\begin{pmatrix} 2 & 2 \\ 0 & -2 \end{pmatrix}$; $C_2 - C_1$: $\begin{pmatrix} 2 & 0 \\ 0 & -2 \end{pmatrix}$; sign-fix to $\mathrm{diag}(2, 2)$. So $a_1 = 2, a_2 = 2$ with $2 \mid 2$, and y_1, y_2 is the basis of F recorded by the column operations. Sanity check: $\det A = 8 - 4 = 4 = a_1a_2$ and $[F : N] = 4$, matching $|\det|$.

Free presentations and Smith normal form

If M is finitely generated by $x_1, \ldots, x_m$, map $R^m \twoheadrightarrow M$ by $e_i \mapsto x_i$; the kernel N of relations is free of rank $\leq m$ (Theorem 12.1.3), say with generators giving a map $R^n \to R^m$ whose matrix is the *relations/presentation matrix* $A \in \mathrm{M}_{m\times n}(R)$. We get an exact sequence, a *free presentation* of M:

$$R^n \xrightarrow{A} R^m \xrightarrow{\pi} M \longrightarrow 0$$

Diagram explanation. Objects: Three R-modules in sequence: R^n is the free module of relations (rank n, one basis vector per relation generator), R^m is the free module of generators (rank m, one basis vector per generator x_i of M), and M is the finitely generated R-module being presented.

Arrows: $A\colon R^n \to R^m$ is the relations map, sending the j-th basis vector e_j of R^n to the j-th relation written as a linear combination of generators; its matrix is the presentation matrix. $\pi\colon R^m \to M$ is the surjective quotient map sending $e_i \mapsto x_i$. The terminal 0 records surjectivity of π.

What commutes: Exactness at R^m: $\mathrm{im}(A) = \ker(\pi)$. In other words, a combination $\sum r_ie_i$ maps to 0 in M if and only if it is a relation, i.e., lies in the column space of A.

Why it commutes: $\pi \circ A$ sends $e_j \mapsto$ the j-th relation expressed in M, which is 0 by construction (the x_i satisfy those relations). Conversely, any $v \in \ker(\pi)$ is an element of R^m whose image in M is 0, meaning it is expressible as a relation, so $v \in \mathrm{im}(A)$.

Why this matters here: This diagram encodes the entire data of M: generators live in R^m and the relations kernel $N = \mathrm{im}(A)$ is free of rank $\leq m$ by Theorem 12.1.3. It is the raw input for Smith Normal Form – diagonalizing A immediately yields the invariant factor decomposition.

Concrete example: $M = \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$, generators x_1, x_2 with relations $2x_1 = 0$, $3x_2 = 0$. Then $A = \mathrm{diag}(2, 3)$, $n = m = 2$, and $M \cong \mathbb{Z}^2/\mathrm{im}(A) = \mathbb{Z}/2 \oplus \mathbb{Z}/3$.

Common pitfall: Students often confuse A as the matrix of a map $R^n \to R^m$ (acting on column vectors of coefficients) with A as the transpose presentation. Be careful: columns of A are the relation vectors in R^m, not rows.

Takeaway: The point of this diagram is that every finitely generated R-module is a cokernel of a matrix A over R, so classifying modules reduces to understanding $\mathrm{coker}(A)$ via Smith Normal Form.

so that $M \cong R^m/\mathrm{im}(A) = \mathrm{coker}(A)$.

Theorem 12.1.5 (Smith Normal Form)**.** *Every $A \in \mathrm{M}_{m\times n}(R)$ over a PID can be written $A = UDV$ with $U \in \mathrm{GL}_m(R)$, $V \in \mathrm{GL}_n(R)$ invertible, and D "diagonal":*

$$D = \mathrm{diag}(a_1, a_2, \ldots, a_r, 0, \ldots, 0), \qquad a_1 \mid a_2 \mid \cdots \mid a_r, \quad a_i \neq 0.$$

The a_i (up to units) are unique; in fact $a_1 \cdots a_k = d_k(A)$ where $d_k(A) = \gcd$ of all $k \times k$ minors of A, so $a_k = d_k(A)/d_{k-1}(A)$ (with $d_0 = 1$).

Changing basis in R^m (left mult. by U) and in R^n (right mult. by V) does not change $\mathrm{coker}(A)$, so:

$$M \cong \mathrm{coker}(A) \cong R^{m-r} \oplus R/(a_1) \oplus \cdots \oplus R/(a_r).$$

The change-of-basis is the commuting square (recall $A = UDV$, so $U^{-1}A = DV$):

$$\begin{array}{ccc} R^n & \xrightarrow{\;A\;} & R^m \\ {\scriptstyle V}\big\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\big\downarrow{\scriptstyle U^{-1}} \\ R^n & \xrightarrow[\;D\;]{} & R^m \end{array}$$

Diagram explanation. Objects: Four copies of free R-modules: the top row has domain R^n and codomain R^m connected by A; the bottom row has the same modules but now connected by the diagonal matrix $D = \mathrm{diag}(a_1, \dots, a_r, 0, \dots, 0)$. The left and right copies of R^n and R^m are literally the same modules, merely viewed in different bases.

Arrows: $A\colon R^n \to R^m$ is the original presentation matrix. $V\colon R^n \xrightarrow{\cong} R^n$ is the map $v \mapsto Vv$ for $V \in \mathrm{GL}_n(R)$ (V is the factor that multiplies A on the right in $A = UDV$), a change of basis in the domain (column operations). $U^{-1}\colon R^m \xrightarrow{\cong} R^m$ is left multiplication by $U^{-1} \in \mathrm{GL}_m(R)$, a change of basis in the codomain (row operations). $D\colon R^n \to R^m$ is the Smith Normal Form diagonal matrix.

What commutes: Going right-then-down equals going down-then-right: $U^{-1} \circ A = D \circ V$, which is exactly the factorization $A = UDV$ rearranged.

Why it commutes: Start with $v \in R^n$. Right path: $v \mapsto Av$ (apply A) then $\mapsto U^{-1}(Av) = (U^{-1}A)v$. Left path: $v \mapsto Vv$ (change basis) then $\mapsto D(Vv) = (DV)v$. These agree because $U^{-1}A = DV$ is exactly Smith's theorem ($A = UDV$).

Why this matters here: Since V and U^{-1} are invertible, $\mathrm{coker}(A) \cong \mathrm{coker}(D)$. The cokernel of D splits as $R/(a_1) \oplus \cdots \oplus R/(a_r) \oplus R^{m-r}$, giving the structure theorem. The diagram makes it transparent that the change of basis does not alter the module being presented.

Concrete example: $A = \begin{pmatrix} 2 & 4 \\ 0 & 6 \end{pmatrix}$ over $\mathbb{Z}$: Smith Normal Form gives $D = \mathrm{diag}(2, 6)$, and $\mathrm{coker}(A) \cong \mathbb{Z}/2 \oplus \mathbb{Z}/6$.

Common pitfall: The two copies of R^n (and R^m) are the SAME module in different coordinate systems, not different modules. The vertical arrows are NOT quotient maps – they are automorphisms (invertible basis changes), which is why $\mathrm{coker}(A) \cong \mathrm{coker}(D)$ exactly, not merely up to some extension.

Takeaway: The point of this diagram is that Smith Normal Form is a change of basis in both domain and codomain simultaneously, leaving the cokernel – the module M – unchanged and converting an arbitrary matrix to a diagonal one.

Worked Example 12.1.6 (Smith Normal Form over $\mathbb{Z}$)**.** Find the Smith Normal Form and the cokernel of $A = \begin{pmatrix} 2 & 4 & 4 \\ -6 & 6 & 12 \\ 10 & 4 & 16 \end{pmatrix}$ over $\mathbb{Z}$.

Recognition. Smith Normal Form via the minor-gcd formula $a_k = d_k/d_{k-1}$, then $\mathrm{coker}(A) \cong \bigoplus \mathbb{Z}/(a_i)$.

Solution. Entry gcd d_1 = gcd of all entries = 2. Compute d_2 = gcd of 2×2 minors. Sample minors: $\det \begin{pmatrix} 2 & 4 \\ -6 & 6 \end{pmatrix} = 36$, $\det \begin{pmatrix} 2 & 4 \\ -6 & 12 \end{pmatrix} = 48$, $\det \begin{pmatrix} 2 & 4 \\ 10 & 4 \end{pmatrix} = -32$, $\det \begin{pmatrix} 4 & 4 \\ 6 & 12 \end{pmatrix} = 24$; $\gcd(36, 48, 32, 24, \dots) = 4$, and one checks no smaller common value, so $d_2 = 4$. Finally $d_3 = |\det A|$: expand $\det A = 2(6 \cdot 16 - 12 \cdot 4) - 4(-6 \cdot 16 - 12 \cdot 10) + 4(-6 \cdot 4 - 6 \cdot 10) = 2(96 - 48) - 4(-96 - 120) + 4(-24 - 60) = 96 + 864 - 336 = 624$. Then $a_1 = d_1 = 2$, $a_2 = d_2/d_1 = 4/2 = 2$, $a_3 = d_3/d_2 = 624/4 = 156$. Check divisibility $2 \mid 2 \mid 156$ (yes). So $D = \mathrm{diag}(2, 2, 156)$ and

$$\mathrm{coker}(A) \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/156\mathbb{Z}.$$

Sanity check: $|\det A| = 624 = 2 \cdot 2 \cdot 156 = a_1 a_2 a_3$, so the group has order 624, consistent.

Worked Example 12.1.7 (A cokernel with free part)**.** Compute $\mathrm{coker}(A)$ for $A = \begin{pmatrix} 6 & 4 \\ 9 & 6 \end{pmatrix} \in \mathrm{M}_2(\mathbb{Z})$ viewed as relations on $\mathbb{Z}^2$.

Recognition. $\det A = 0$ flags a free summand; Smith Normal Form has a trailing 0.

Solution. $\det A = 36 - 36 = 0$. Entry gcd $d_1 = \gcd(6, 4, 9, 6) = 1$, so $a_1 = 1$. Since $\det = 0$, $d_2 = 0$, giving $D = \mathrm{diag}(1, 0)$. Thus $\mathrm{coker}(A) \cong \mathbb{Z}/1\mathbb{Z} \oplus \mathbb{Z}/0\mathbb{Z} \cong 0 \oplus \mathbb{Z} \cong \mathbb{Z}$. Sanity check: rows $(6, 4), (9, 6)$ are parallel ($\frac{3}{2}$ ratio), so $\mathrm{im}(A)$ has rank 1 inside $\mathbb{Z}^2$ and the quotient has free rank $2 - 1 = 1$; the $\mathbb{Z}/1\mathbb{Z} = 0$ factor reflects that $\mathrm{im}(A)$ is "primitive enough" (gcd of entries 1) to contribute no torsion.

Worked Example 12.1.8 (Smith Normal Form over $\mathbb{F}[x]$)**.** Over $R = \mathbb{Q}[x]$ put $A = \begin{pmatrix} x-1 & 0 \\ 0 & (x-1)(x+2) \end{pmatrix}$ into Smith Normal Form.

Recognition. The PID $\mathbb{Q}[x]$ admits the same algorithm; invariant factors must satisfy $a_1 \mid a_2$ after sorting.

Solution. Here it is already diagonal with $a_1 = x-1$, $a_2 = (x-1)(x+2)$ and $x-1 \mid (x-1)(x+2)$, so this IS the Smith Normal Form. Thus $\operatorname{coker}(A) \cong \mathbb{Q}[x]/(x-1) \oplus \mathbb{Q}[x]/\big((x-1)(x+2)\big)$. Sanity check: had we instead been handed $\operatorname{diag}\big((x-1)(x+2),\, x-1\big)$, divisibility fails ($(x-1)(x+2) \nmid x-1$); column/row ops would re-sort to recover $a_1 = x-1,\ a_2 = (x-1)(x+2)$, the unique invariant-factor order.

The fundamental (structure) theorem — invariant factor form

Theorem 12.1.9 (Fundamental Theorem, Invariant Factor Form)**.** *Let R be a PID and M a finitely generated R-module. Then*

$$M \;\cong\; R^r \;\oplus\; R/(a_1) \;\oplus\; R/(a_2) \;\oplus\; \cdots \;\oplus\; R/(a_m),$$

for some integer $r \geq 0$ (the free rank *or* Betti number *of M) and nonzero, nonunit elements $a_1, a_2, \ldots, a_m \in R$ satisfying the divisibility chain*

$$a_1 \mid a_2 \mid \cdots \mid a_m.$$

The integer r and the ideals $(a_1), \ldots, (a_m)$ (equivalently the a_i up to units) are uniquely determined by M. The a_i are the invariant factors *of M.*

Definition 12.1.10. The *torsion submodule* is $\operatorname{Tor}(M) = \{\, x \in M : rx = 0 \text{ for some } r \neq 0 \,\}$. A module is *torsion* if $\operatorname{Tor}(M) = M$ and *torsion-free* if $\operatorname{Tor}(M) = 0$.

In the decomposition above, $\operatorname{Tor}(M) \cong R/(a_1) \oplus \cdots \oplus R/(a_m)$ collects exactly the cyclic factors, and $M/\operatorname{Tor}(M) \cong R^r$ is free. So the free rank r equals $\operatorname{rank}\big(M/\operatorname{Tor}(M)\big)$ and is the number of "infinite" summands.

Corollary 12.1.11. *A finitely generated torsion-free module over a PID is free.*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \operatorname{Tor}(M) & \hookrightarrow & M & \twoheadrightarrow & M/\operatorname{Tor}(M) & \longrightarrow & 0 \\ & & \cong\uparrow & & & & \uparrow\cong & & \\ & & R/(a_1) \oplus \cdots \oplus R/(a_m) & & & & R^r & & \end{array}$$

Diagram explanation. Objects: Top row: five terms of a short exact sequence of R-modules: 0, $\operatorname{Tor}(M)$ (the torsion submodule of M, consisting of all elements killed by some nonzero $r \in R$), M itself, the quotient $M/\operatorname{Tor}(M)$ (torsion-free part), and 0. Bottom row: $R/(a_1) \oplus \cdots \oplus R/(a_m)$ is the direct sum of cyclic torsion factors from the structure theorem, and R^r is the free summand of rank r.

Arrows: Top row left: inclusion $\operatorname{Tor}(M) \hookrightarrow M$ (the natural inclusion of the torsion submodule). Top row right: canonical surjection $M \twoheadrightarrow M/\operatorname{Tor}(M)$. Left vertical: the isomorphism $R/(a_1) \oplus \cdots \oplus R/(a_m) \xrightarrow{\cong} \operatorname{Tor}(M)$ given by the structure theorem. Right vertical: the isomorphism $R^r \xrightarrow{\cong} M/\operatorname{Tor}(M)$ identifying the free part.

What commutes: Exactness at $\operatorname{Tor}(M)$: $\ker(\operatorname{Tor}(M) \to M) = 0$ (injection). Exactness at M: $\operatorname{im}(\operatorname{Tor}(M) \hookrightarrow M) = \ker(M \to M/\operatorname{Tor}(M))$, i.e., $\operatorname{Tor}(M)$ is exactly the kernel of the quotient map. Exactness at $M/\operatorname{Tor}(M)$: $\ker(M/\operatorname{Tor}(M) \to 0) = M/\operatorname{Tor}(M) = \operatorname{im}(M \to M/\operatorname{Tor}(M))$ (surjection). The vertical isom arrows are compatible with the horizontal sequence.

Why it commutes: By definition, $\operatorname{Tor}(M)$ is a submodule of M, so inclusion is injective; the quotient map kills exactly $\operatorname{Tor}(M)$. The structure theorem (Theorem 12.1.9) supplies the explicit isomorphisms vertically, identifying torsion with the cyclic factors and the free part with R^r.

Why this matters here: This diagram cleanly separates the two parts of the structure theorem and shows the sequence SPLITS – since $M/\operatorname{Tor}(M) \cong R^r$ is free (hence projective), the surjection $M \twoheadrightarrow R^r$ has a section, giving $M \cong \operatorname{Tor}(M) \oplus R^r \cong R/(a_1) \oplus \cdots \oplus R/(a_m) \oplus R^r$.

Concrete example: $M = \mathbb{Z} \oplus \mathbb{Z}/2 \oplus \mathbb{Z}/6$. Then $\operatorname{Tor}(M) = \mathbb{Z}/2 \oplus \mathbb{Z}/6$, $M/\operatorname{Tor}(M) = \mathbb{Z}$, and the sequence $0 \to \mathbb{Z}/2 \oplus \mathbb{Z}/6 \to M \to \mathbb{Z} \to 0$ splits via the section $1 \mapsto (1, 0, 0)$.

Common pitfall: Students sometimes confuse $\mathrm{Tor}(M)$ (torsion submodule, a specific subobject of M) with the derived functor $\mathrm{Tor}_R^1(-,-)$ from homological algebra. Here $\mathrm{Tor}(M)$ is simply the set of torsion elements, not a bifunctor.

Takeaway: The point of this diagram is that the structure theorem naturally splits M into a torsion piece (the cyclic $R/(a_i)$ factors) and a free piece (R^r), and the short exact sequence splits because free modules are projective.

The bottom row identifies the two halves of the structure theorem; the sequence splits because R^r is free (hence projective).

Worked Example 12.1.12 (Reading off invariant factors and torsion)**.** Let $M = \mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$. Find the free rank, $\mathrm{Tor}(M)$, and the invariant factors.

Recognition. Theorem 12.1.9: assemble the cyclic torsion factors into a divisibility chain via CRT; the free $\mathbb{Z}$ contributes r.

Solution. Free rank $r = 1$. For the torsion part combine using $\mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \cong \mathbb{Z}/12\mathbb{Z}$ (coprime, CRT). To build the chain $a_1 \mid a_2$: the smallest invariant factor must divide the rest. We have available the primary pieces $\{4, 2\}$ at $p = 2$ and $\{3\}$ at $p = 3$. The largest invariant factor takes the top power from each prime: $4 \cdot 3 = 12$. The next takes remaining top powers: at $p = 2$ the leftover is 2, at $p = 3$ nothing, giving 2. So $a_1 = 2,\ a_2 = 12$ with $2 \mid 12$. Thus

$$\mathrm{Tor}(M) \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}, \qquad M \cong \mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}.$$

Sanity check: order of torsion $= 2 \cdot 12 = 24 = 4 \cdot 2 \cdot 3$. Consistent.

Worked Example 12.1.13 (Number of abelian groups of order 600)**.** How many abelian groups of order 600 are there up to isomorphism, and list their invariant factors.

Recognition. $R = \mathbb{Z}$ case of Theorem 12.1.9: count via partitions of each prime exponent; assemble invariant-factor chains.

Solution. $600 = 2^3 \cdot 3 \cdot 5^2$. Partitions: of 3 (for 2): 3, 2+1, 1+1+1 ($p(3) = 3$); of 1 (for 3): only 1 ($p(1) = 1$); of 2 (for 5): 2, 1+1 ($p(2) = 2$). Total $3 \cdot 1 \cdot 2 = 6$ groups. As invariant factors (align partitions right, multiply column-wise): e.g. for 2-part 2+1, 5-part 1+1, 3-part 1: columns give $a_1 = 2 \cdot 5 = 10$, $a_2 = 4 \cdot 5 \cdot 3 = 60$, so $\mathbb{Z}/10 \oplus \mathbb{Z}/60$. Listing all six in invariant-factor form (each chain $a_1 \mid a_2 \mid \cdots$): $\mathbb{Z}/600$; $\mathbb{Z}/2 \oplus \mathbb{Z}/300$; $\mathbb{Z}/2 \oplus \mathbb{Z}/2 \oplus \mathbb{Z}/150$; $\mathbb{Z}/5 \oplus \mathbb{Z}/120$; $\mathbb{Z}/10 \oplus \mathbb{Z}/60$; $\mathbb{Z}/2 \oplus \mathbb{Z}/10 \oplus \mathbb{Z}/30$. Sanity check: each has product 600, and within each the invariant factors form a divisibility chain ($5 \mid 120$, $10 \mid 60$, $2 \mid 10 \mid 30$).

Elementary divisor (primary) form

Theorem 12.1.14 (Elementary Divisor Form)**.** *With R a PID and M finitely generated,*

$$M \;\cong\; R^r \;\oplus\; R/(p_1^{\alpha_1}) \;\oplus\; R/(p_2^{\alpha_2}) \;\oplus\; \cdots \;\oplus\; R/(p_t^{\alpha_t}),$$

where the p_i are (not necessarily distinct) primes of R and $\alpha_i \geq 1$. The free rank r and the list of prime powers $p_i^{\alpha_i}$ (with multiplicity, up to units) are uniquely determined. These prime powers are the elementary divisors *of M.*

The two forms are equivalent (over any PID) by the Chinese Remainder Theorem: if $a = \prod_j p_j^{\beta_j}$ with the p_j distinct, then $R/(a) \cong \bigoplus_j R/(p_j^{\beta_j})$.

Remark 12.1.2 (Converting between the two lists). *Invariant factors → elementary divisors:* factor each a_i into prime powers and list them. *Elementary divisors → invariant factors:* for each prime p sort its exponents in nondecreasing order and pad with 0's on the LEFT so all primes have the same length; the k-th invariant factor is the product over all primes p of p raised to its k-th exponent. The largest invariant factor a_m is the lcm of all elementary divisors and generates $\mathrm{Ann}(\mathrm{Tor}(M))$ (for $R = \mathbb{Z}$: a_m is the exponent of $\mathrm{Tor}(M)$, not its order).

Worked Example 12.1.15 (Both decompositions of one group)**.** For $G = \mathbb{Z}/8\mathbb{Z}\oplus\mathbb{Z}/4\mathbb{Z}\oplus\mathbb{Z}/9\mathbb{Z}\oplus\mathbb{Z}/3\mathbb{Z}\oplus\mathbb{Z}/5\mathbb{Z}$, list elementary divisors and invariant factors.

Recognition. Theorem 12.1.14 gives elementary divisors directly (already prime powers); the pad-left rule rebuilds invariant factors.

Solution. Elementary divisors: at $p = 2$: $8, 4$; at $p = 3$: $9, 3$; at $p = 5$: 5. Now build invariant factors — longest list has length 2. Pad: p=2 : $(4, 8)$ as exponents $(2, 3)$; p=3 : $(3, 9)$ exponents $(1, 2)$; p=5 : $(\cdot, 5)$ exponents $(0, 1)$. Column 1 (smaller): $4 \cdot 3 \cdot 1 = 12$. Column 2 (larger): $8 \cdot 9 \cdot 5 = 360$. So invariant factors $a_1 = 12,\ a_2 = 360$ with $12 \mid 360$:

$$G \cong \mathbb{Z}/12\mathbb{Z} \oplus \mathbb{Z}/360\mathbb{Z}.$$

Sanity check: $12 \cdot 360 = 4320 = 8 \cdot 4 \cdot 9 \cdot 3 \cdot 5$. Consistent; $a_2 = 360 = \operatorname{lcm}(8, 4, 9, 3, 5)$ is the exponent of G.

Worked Example 12.1.16 (Elementary divisors over $\mathbb{Q}[x]$)**.** A finitely generated torsion $\mathbb{Q}[x]$-module is $M = \mathbb{Q}[x]/(x^2(x-1)) \oplus \mathbb{Q}[x]/(x(x-1)^2)$. Find its elementary divisors and invariant factors.

Recognition. Theorem 12.1.14 with $R = \mathbb{Q}[x]$; primes are monic irreducibles $x,\ x - 1$.

Solution. Split each cyclic factor by CRT: $\mathbb{Q}[x]/(x^2(x-1)) \cong \mathbb{Q}[x]/(x^2) \oplus \mathbb{Q}[x]/(x-1)$; $\mathbb{Q}[x]/(x(x-1)^2) \cong \mathbb{Q}[x]/(x) \oplus \mathbb{Q}[x]/((x-1)^2)$. Elementary divisors: at x: x^2, x; at $x-1$: $(x-1)^2$, $(x-1)$. Invariant factors (pad-left, both length 2): a_1 from smaller powers $x \cdot (x-1)$; a_2 from larger $x^2 \cdot (x-1)^2$. So

$$a_1 = x(x-1), \quad a_2 = x^2(x-1)^2, \qquad a_1 \mid a_2.$$

Sanity check: $a_1 a_2 = x^3(x-1)^3$ matches the product of the two original moduli $x^2(x-1) \cdot x(x-1)^2$.

Uniqueness via p-power counts

The uniqueness in Theorems 12.1.9 and 12.1.14 is proved by extracting invariants of M intrinsically. Two especially useful gadgets, for a prime p of R and the residue field $k = R/(p)$:

Proposition 12.1.17 (Counting via $\dim_k$)**.** *For a finitely generated torsion module M over the PID R, the number of elementary divisors that are powers of p is $\dim_k\big(M/pM\big)$, and more refined counts come from $\dim_k\big(p^j M/p^{j+1}M\big)$. These dimensions are isomorphism invariants, which forces uniqueness of the elementary divisor list.*

Worked Example 12.1.18 (Distinguishing two groups by $\dim_{\mathbb{F}_p}$)**.** Show $G = \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$ and $H = \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/8\mathbb{Z}$ are non-isomorphic even though $|G| = |H| = 16$.

Recognition. Use the invariant $\dim_{\mathbb{F}_2}(M/2M)$ = number of 2-power elementary divisors (rank of the 2-torsion).

Solution. $G/2G$: each $\mathbb{Z}/4$ gives $\mathbb{Z}/4\big/2(\mathbb{Z}/4) \cong \mathbb{Z}/2$, so $\dim_{\mathbb{F}_2}(G/2G) = 2$. $H/2H$: $\mathbb{Z}/2\big/2(\mathbb{Z}/2) = \mathbb{Z}/2$ and $\mathbb{Z}/8\big/2(\mathbb{Z}/8) = \mathbb{Z}/2$, so $\dim_{\mathbb{F}_2}(H/2H) = 2$ also. Tie — go one level deeper with $\dim_{\mathbb{F}_2}(2M/4M)$. For G: $2G = 2\mathbb{Z}/4 \oplus 2\mathbb{Z}/4 \cong \mathbb{Z}/2 \oplus \mathbb{Z}/2$ and $4G = 0$, so $\dim(2G/4G) = 2$. For H: $2H = 0 \oplus 2\mathbb{Z}/8 \cong \mathbb{Z}/4$, $4H = 0 \oplus 4\mathbb{Z}/8 \cong \mathbb{Z}/2$, so $\dim(2H/4H) = \dim(\mathbb{Z}/4\big/\mathbb{Z}/2) = 1$. Since $2 \neq 1$, $G \ncong H$. Sanity check: elementary divisors are $\{4, 4\}$ vs. $\{2, 8\}$ — genuinely different lists, as the invariants detect.

Worked Example 12.1.19 (Uniqueness forces the divisibility order)**.** Explain why $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$ cannot also be written with invariant factors $4, 2$ (i.e. why the chain must be $2 \mid 4$, not $4 \mid 2$).

Recognition. Theorem 12.1.9 fixes invariant factors uniquely AND requires $a_1 \mid a_2$; this is a normalization, not a choice.

Solution. The module $\mathbb{Z}/2 \oplus \mathbb{Z}/4$ has order 8 and exponent (largest order of an element) $= 4$. The largest invariant factor always equals the exponent, so $a_{\max} = 4$; the remaining factor is $8/4 = 2$, and $2 \mid 4$. Writing "$4, 2$" would violate $a_1 \mid a_2$ ($4 \nmid 2$) and is simply not the normal form. Sanity check: as elementary divisors this is $\{2, 4\}$ at $p = 2$; pad-left gives $a_1 = 2, a_2 = 4$ — the unique answer.

Recovering finitely generated abelian groups ($R = \mathbb{Z}$)

Corollary 12.1.20 (Fundamental Theorem of Finitely Generated Abelian Groups)**.** *Every finitely generated abelian group G is isomorphic to*

$$G \cong \mathbb{Z}^r \oplus \mathbb{Z}/(n_1) \oplus \cdots \oplus \mathbb{Z}/(n_s), \qquad n_1 \mid n_2 \mid \cdots \mid n_s,\ n_i \geq 2,$$

and r together with the n_i are uniquely determined; equivalently to a direct sum of cyclic groups of prime-power order whose multiset is unique (elementary divisors).

This is just Theorems 12.1.9 and 12.1.14 specialized to the PID $R = \mathbb{Z}$, where "module" = "abelian group," "free of rank r" = "$\mathbb{Z}^r$," and "invariant factors / elementary divisors" are the classical ones.

Worked Example 12.1.21 (Full classification from a presentation)**.** The abelian group G is generated by x, y, z with relations $3x + y + z = 0$, $x + 3y + z = 0$, $x + y + 3z = 0$. Classify G.

Recognition. Build the relations matrix, take Smith Normal Form (Theorem 12.1.3 + Structure Theorem), read off $G \cong \bigoplus \mathbb{Z}/(a_i) \oplus \mathbb{Z}^r$.

Solution. Relations matrix $A = \begin{pmatrix} 3 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 3 \end{pmatrix}$. Use minor-gcds. $d_1 = 1$ (entry 1 present), so $a_1 = 1$. $\det A$: $\det = 3(9-1) - 1(3-1) + 1(1-3) = 24 - 2 - 2 = 20$, so $d_3 = 20$. For d_2: 2×2 minors include $\det \begin{pmatrix} 3 & 1 \\ 1 & 3 \end{pmatrix} = 8$, $\det \begin{pmatrix} 1 & 1 \\ 3 & 1 \end{pmatrix} = -2$, $\det \begin{pmatrix} 3 & 1 \\ 1 & 1 \end{pmatrix} = 2$; $\gcd(8, 2, \dots) = 2$, so $d_2 = 2$. Hence $a_1 = 1$, $a_2 = d_2/d_1 = 2$, $a_3 = d_3/d_2 = 20/2 = 10$. Drop the unit $a_1 = 1$ (it gives $\mathbb{Z}/1 = 0$):

$$G \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/10\mathbb{Z}, \quad 2 \mid 10.$$

Sanity check: $|\det A| = 20 = 2 \cdot 10 = |G|$, finite (no free part since $\det \neq 0$). Consistent.

Worked Example 12.1.22 (A presentation with infinite part)**.** Classify the abelian group with generators a, b, c and the single relation $2a + 4b + 6c = 0$.

Recognition. One relation on three generators: relations matrix is 1×3; Smith Normal Form has one nonzero entry = gcd of the row, rest of quotient is free.

Solution. $A = \begin{pmatrix} 2 & 4 & 6 \end{pmatrix}$, $d_1 = \gcd(2, 4, 6) = 2$, so Smith Normal Form $= \begin{pmatrix} 2 & 0 & 0 \end{pmatrix}$ and $G \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z} \oplus \mathbb{Z}$. Free rank $= 3 - 1 = 2$.

$$G \cong \mathbb{Z}^2 \oplus \mathbb{Z}/2\mathbb{Z}.$$

Sanity check: the relation is "$2 \cdot (a + 2b + 3c) = 0$." Change basis $a' = a + 2b + 3c$ (extend to a basis of $\mathbb{Z}^3$); the relation becomes $2a' = 0$, leaving two free generators. Matches $\mathbb{Z}^2 \oplus \mathbb{Z}/2\mathbb{Z}$.

Worked Example 12.1.23 (From order data to the group)**.** A finite abelian group G has order 72, contains an element of order 12, and satisfies $\dim_{\mathbb{F}_2}(G/2G) = 2$, $\dim_{\mathbb{F}_3}(G/3G) = 1$. Determine G.

Recognition. Combine the order/exponent constraint (largest invariant factor) with the $\dim_k(G/pG)$ counts of elementary divisors (uniqueness proposition).

Solution. $72 = 2^3 \cdot 3^2$. $\dim_{\mathbb{F}_3}(G/3G) = 1$ means ONE 3-power elementary divisor, so the 3-part is a single $\mathbb{Z}/9$ (since 3^2 must appear). $\dim_{\mathbb{F}_2}(G/2G) = 2$ means TWO 2-power elementary divisors with exponents summing to 3: that is $\{2, 4\}$ (i.e. $2^1, 2^2$). So elementary divisors $= \{4, 2, 9\}$. Build invariant factors: $a_1 = 2$ (smaller 2-power, no 3-part), $a_2 = 4 \cdot 9 = 36$. So $G \cong \mathbb{Z}/2 \oplus \mathbb{Z}/36$. Check the order-12 requirement: exponent $= a_2 = 36$, and $12 \mid 36$, so an element of order 12 exists. Sanity check: $2 \cdot 36 = 72$; $2 \mid 36$. Consistent and unique.

Why submodules of free modules being free underlies everything

The structure theorem is bootstrapped from Theorem 12.1.3: present M as R^m/N, align a basis so $N = \bigoplus a_i R y_i$, and quotient. The picture is the diagonalized presentation:

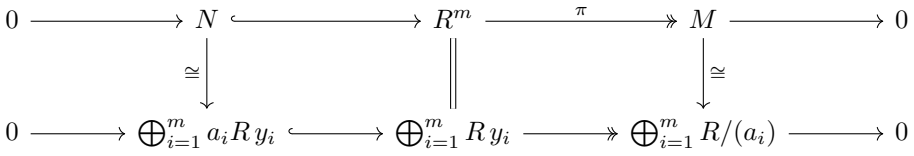


Diagram explanation. Objects: Two parallel short exact sequences. Top: N is the relations submodule (kernel of the presentation surjection π, free of rank $\leq m$ by Theorem 12.1.3), R^m is the free module of generators, and M is the module being classified. Bottom: after Smith Normal Form realigns the basis to $y_1, \ldots, y_m$, the relations submodule becomes $\bigoplus_{i=1}^m a_i R y_i$ (the diagonal submodule), R^m is rewritten as $\bigoplus_{i=1}^m R y_i$ (same module, new basis), and the cokernel is $\bigoplus_{i=1}^m R/(a_i)$.

Arrows: Top row: natural inclusion $N \hookrightarrow R^m$ and projection $\pi : R^m \twoheadrightarrow M$. Bottom row: inclusion $\bigoplus a_i R y_i \hookrightarrow \bigoplus R y_i$ (each $a_i R y_i \subseteq R y_i$) and the coordinatewise quotient. Left vertical: the isomorphism $N \xrightarrow{\cong} \bigoplus a_i R y_i$ given by the aligned-basis theorem (Theorem 12.1.3 produces exactly $a_i y_i$ as basis of N in the y_i coordinates). Middle vertical: equality, since $\bigoplus R y_i = R^m$ with the new basis. Right vertical: the induced isomorphism $M \xrightarrow{\cong} \bigoplus R/(a_i)$, well-defined because the left and middle squares commute.

What commutes: Each square commutes. Left square: the isomorphism $N \cong \bigoplus a_i R y_i$ is chosen to interleave with the same inclusion into $R^m = \bigoplus R y_i$. Right square: the quotient map π composed with $M \cong \bigoplus R/(a_i)$ equals the coordinatewise quotient composed with the identity on R^m. Exactness at each node: $\ker(\hookrightarrow) = 0$ and $\mathrm{im}(\hookrightarrow) = \ker(\text{quotient})$ in both rows.

Why it commutes: Well-definedness of the right vertical arrow $M \cong \bigoplus R/(a_i)$: an element of M is a coset $v + N$ for $v \in R^m$. Writing $v = \sum r_i y_i$ in the new basis, the image in $\bigoplus R/(a_i)$ is $\sum (r_i \bmod a_i)$. Changing the representative by an element of $N = \bigoplus a_i R y_i$ adds multiples of $a_i y_i$, which are 0 in $R/(a_i)$. So the map is well-defined on cosets.

Why this matters here: This double exact sequence is the structural engine of the proof of Theorem 12.1.9. It shows the abstract isomorphism $M \cong \bigoplus R/(a_i)$ is not arbitrary – it is forced by the aligned-basis choice for $N \subseteq R^m$ and is explicit and canonical in those coordinates.

Concrete example: $M = \mathbb{Z}^2/N$ with N generated by $(4, 0)$ and $(0, 6)$. Here $y_1 = e_1, y_2 = e_2$ already diagonalize $N = 4\mathbb{Z} y_1 \oplus 6\mathbb{Z} y_2$, so $M \cong \mathbb{Z}/4 \oplus \mathbb{Z}/6$; but $4 \nmid 6$, so this diagonal form is not yet aligned ($a_1 \mid a_2$ fails). Smith Normal Form gives $a_1 = 2$, $a_2 = 12$, and indeed $\mathbb{Z}/4 \oplus \mathbb{Z}/6 \cong \mathbb{Z}/2 \oplus \mathbb{Z}/12$.

Common pitfall: The middle vertical arrow is an EQUALITY, not a non-trivial isomorphism. Students sometimes think the two copies of R^m are different objects; they are literally the same free module, with the bottom labeling recording the choice of aligned basis $y_1, \ldots, y_m$ from Smith Normal Form.

Takeaway: The point of this diagram is that once the aligned basis $y_1, \ldots, y_m$ is chosen (via Smith Normal Form), the abstract module M becomes transparently equal to $\bigoplus R/(a_i)$ by reading off the quotient coordinate by coordinate.

Reading the right column: $M \cong \bigoplus_i R/(a_i)$, where $a_i = 0$ contributes a free summand R and units a_i contribute 0. Dropping zeros-as-units and grouping the genuine a_i yields exactly the invariant factor decomposition of Theorem 12.1.9.

Worked Example 12.1.24 (Executing the bootstrap by hand)**.** Let $M = \mathbb{Z}^2/N$ where $N = \mathrm{Span}_{\mathbb{Z}}\{(6, 0), (0, 9), (3, 3)\}$. Classify M by aligning a basis.

Recognition. The diagram above: diagonalize the 2×3 relations matrix to Smith Normal Form, then quotient coordinatewise.

Solution. Relations as columns: $A = \begin{pmatrix} 6 & 0 & 3 \\ 0 & 9 & 3 \end{pmatrix}$ (2 generators, 3 relations). $d_1 = \gcd(6, 0, 3, 0, 9, 3) = 3$, so $a_1 = 3$. $d_2 =$ gcd of 2×2 minors: $\det \begin{pmatrix} 6 & 0 \\ 0 & 9 \end{pmatrix} = 54$, $\det \begin{pmatrix} 6 & 3 \\ 0 & 3 \end{pmatrix} = 18$, $\det \begin{pmatrix} 0 & 3 \\ 9 & 3 \end{pmatrix} = -27$; $\gcd(54, 18, 27) = 9$, so $d_2 = 9$ and $a_2 = d_2/d_1 = 9/3 = 3$. Smith Normal Form $\mathrm{diag}(3, 3)$ (the extra relation column is dependent). Hence $M \cong \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$ with invariant factors $3, 3$ ($3 \mid 3$). Sanity check: $|M| = [\mathbb{Z}^2 : N]$. Lattice N contains $(6, 0), (0, 9), (3, 3)$; index $= |\det|$ of a basis of N. From $(3, 3)$ and $(6, 0) = 2(3, 3) - (0, 6)$ get $(0, 6)$, and $\gcd(6, 9) = 3$ gives $(0, 3)$; so N has basis $(3, 3), (0, 3)$, $\det = 9$, index $9 = 3 \cdot 3$. Matches.

Worked Example 12.1.25 (Free rank from a wide presentation)**.** Let $M = \mathbb{Z}^3/N$, $N = \mathrm{Span}_{\mathbb{Z}}\{(2,2,0), (0,2,2)\}$. Find the free rank and torsion of M.

Recognition. Relations matrix is 3×2 (rank ≤ 2), so free rank $\geq 3 - 2 = 1$; diagonalize for the torsion.

Solution. $A = \begin{pmatrix} 2 & 0 \\ 2 & 2 \\ 0 & 2 \end{pmatrix}$. $d_1 = 2$, so $a_1 = 2$. $d_2 =$ gcd of 2×2 minors: $\det \begin{pmatrix} 2 & 0 \\ 2 & 2 \end{pmatrix} = 4$, $\det \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = 4$, $\det \begin{pmatrix} 2 & 2 \\ 0 & 2 \end{pmatrix} = 4$; $d_2 = 4$, $a_2 = 4/2 = 2$. There is no third column, so Smith Normal Form (as a 3×2) is $\mathrm{diag}(2,2)$ followed by a zero row. Thus

$$M \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z},$$

free rank $r = 1$, $\mathrm{Tor}(M) \cong \mathbb{Z}/2 \oplus \mathbb{Z}/2$. Sanity check: N has rank 2 in $\mathbb{Z}^3$, so $M/\mathrm{Tor}(M)$ has rank $3 - 2 = 1$; the two invariant factors $2, 2$ account for the $|\det|$-style torsion of the rank-2 sublattice. Consistent.

Exercises (from the text).

1. Let M be a module over the integral domain R.
   (a) Show that any finite number of elements of M, one of which is torsion, are R-linearly dependent. Conclude that the rank of $\mathrm{Tor}(M)$ is 0, so that in particular any torsion R-module has rank 0.
   (b) Show that the rank of M is the same as the rank of the (torsion free) quotient module $M/\operatorname{Tor} M$.

2. Let M be a module over the integral domain R.
   (a) Suppose that M has rank n and that $x_1, x_2, \ldots, x_n$ is any maximal set of linearly independent elements of M. Let $N = Rx_1 + \cdots + Rx_n$ be the submodule generated by $x_1, x_2, \ldots, x_n$. Prove that N is isomorphic to R^n and that the quotient M/N is a torsion R-module (equivalently, the elements $x_1, \ldots, x_n$ are linearly independent and for any $y \in M$ there is a nonzero element $r \in R$ such that ry can be written as a linear combination $r_1x_1 + \cdots + r_nx_n$ of the x_i).
   (b) Prove conversely that if M contains a submodule N that is free of rank n (i.e., $N \cong R^n$) such that the quotient M/N is a torsion R-module then M has rank n. [Let $y_1, y_2, \ldots, y_{n+1}$ be any $n+1$ elements of M. Use the fact that M/N is torsion to write r_iy_i as a linear combination of a basis for N for some nonzero elements $r_1, \ldots, r_{n+1}$ of R. Use an argument as in the proof of Proposition 3 to see that the r_iy_i, and hence also the y_i, are linearly dependent.]

3. Let R be an integral domain and let A and B be R-modules of ranks m and n, respectively. Prove that the rank of $A \oplus B$ is $m + n$. [Use the previous exercise.]

4. Let R be an integral domain, let M be a module over R and let N be a submodule of M. Suppose M has rank n, N has rank r and the quotient M/N has rank s. Prove that $n = r+s$. [Let $x_1, x_2, \ldots, x_s$ be elements of M whose images in M/N are a maximal set of independent elements and let $x_{s+1}, x_{s+2}, \ldots, x_{s+r}$ be a maximal set of independent elements in N. Prove that $x_1, x_2, \ldots, x_{s+r}$ are linearly independent in M and that for any element $y \in M$ there is a nonzero element $r \in R$ such that ry is a linear combination of these elements. Then use Exercise 2.]

5. Let $R = \mathbb{Z}[x]$ and let $M = (2, x)$ be the ideal generated by 2 and x, considered as a submodule of R. Show that $\{2, x\}$ is not a basis of M. [Find a nontrivial R-linear dependence between these two elements.] Show that the rank of M is 1 but that M is not free of rank 1 (the latter is much harder).

6. Show that if R is an integral domain and M is any nonprincipal ideal of R then M is torsion free of rank 1 but is not a free R-module.

7. Let R be any ring, let $A_1, A_2, \ldots, A_m$ be R-modules and let B_i be a submodule of A_i, $1 \leq i \leq m$. Prove that
$$(A_1 \oplus A_2 \oplus \cdots \oplus A_m)/(B_1 \oplus B_2 \oplus \cdots \oplus B_m) \cong (A_1/B_1) \oplus (A_2/B_2) \oplus \cdots \oplus (A_m/B_m).$$

8. Let R be a P.I.D., let B be a torsion R-module and let p be a prime in R. Prove that if $pb = 0$ for some nonzero $b \in B$, then $\text{Ann}(B) \subseteq (p)$.

9. Give an example of an integral domain R and a nonzero torsion R-module M such that $\text{Ann}(M) = 0$. Prove that if N is a finitely generated torsion R-module then $\text{Ann}(N) \neq 0$.

10. For p a prime in the P.I.D. R and N a torsion R-module prove that the p-primary component of N is a submodule of N and prove that N is the direct sum of its p-primary components (there need not be finitely many of them).

11. Let R be a P.I.D., let a be a nonzero element of R and let $M = R/(a)$. For any prime p of R prove that

$$p^{k-1}M/p^kM \cong \begin{cases} R/(p) & \text{if } k \leq n \\ 0 & \text{if } k > n, \end{cases}$$

where n is the power of p dividing a (so n may be 0).

12. Let R be a P.I.D. and let p be a prime in R.

    (a) Let M be a finitely generated torsion R-module. Use the previous exercise to prove that $p^{k-1}M/p^kM \cong F^{n_k}$ where F is the field $R/(p)$ and n_k is the number of elementary divisors of M which are powers of p^α with $\alpha \geq k$.

    (b) Suppose M_1 and M_2 are isomorphic finitely generated torsion R-modules. Use (a) to prove that, for every $k \geq 0$, M_1 and M_2 have the same number of elementary divisors p^α with $\alpha \geq k$. Prove that this implies that M_1 and M_2 have the same set of elementary divisors.

13. If M is a finitely generated module over the P.I.D. R, describe the structure of $M/\text{Tor}(M)$.

14. Let R be a P.I.D. and let M be a torsion R-module. Prove that M is irreducible (cf. Exercises 9 to 11 of Section 10.3) if and only if $M = Rm$ for any nonzero element $m \in M$ where the annihilator of m is a nonzero prime ideal (p).

15. Prove that if R is a Noetherian ring then R^n is a Noetherian R-module. [Fix a basis of R^n. If M is a submodule of R^n show that the collection of first coordinates of elements of M is a submodule of R hence is finitely generated. Let $m_1, m_2, \ldots, m_k$ be elements of M whose first coordinates generate this submodule of R. Show that any element of M can be written as an R-linear combination of $m_1, m_2, \ldots, m_k$ plus an element of M whose first coordinate is 0. Prove that $M \cap R^{n-1}$ is a submodule of R^{n-1} where R^{n-1} is the set of elements of R^n with first coordinate 0 and then use induction on n.]

16. Prove that M is finitely generated if and only if there is a surjective R-homomorphism $\varphi : R^n \to M$ for some integer n (this is true for any ring R).

17. In Exercises 17–19, R is a Euclidean Domain, $\varphi\colon R^n \to M$ is a surjective R-module homomorphism, $x_1, \ldots, x_n$ is a basis for R^n, and $y_1, \ldots, y_m$ are generators for $\ker\varphi$ (finitely many, by Exercise 15), say $y_i = a_{i1}x_1 + \cdots + a_{in}x_n$ for $i = 1, \ldots, m$. The $m \times n$ matrix (a_{ij}), whose i-th row records the relation y_i, is called a *relations matrix* (it is the transpose of the presentation matrix used in the text above).

    (a) Show that interchanging x_i and x_j in the basis for R^n interchanges the ith column with the jth column in the corresponding relations matrix.

    (b) Show that, for any $a \in R$, replacing the element x_j by $x_j - ax_i$ in the basis for R^n gives another basis for R^n and that the corresponding relations matrix for this basis is the same as the original relations matrix except that a times the jth column is added to the ith column (i.e., the new columns are $\ldots, a_ix_i + \cdots + a_jx_j + \cdots = \cdots + (a_i + aa_j)x_i + \cdots + a_j(x_j - ax_i) + \ldots$).

18. (a) Show that interchanging the generators y_i and y_j of $\ker\varphi$ interchanges the ith row with the jth row in the relations matrix.

    (b) Show that, for any $a \in R$, replacing the element y_j by $y_j - ay_i$ gives another set of generators for $\ker\varphi$ and that the corresponding relations matrix for this choice of generators is the same as the original relations matrix except that $-a$ times the ith row has been added to the jth row.

19. By the previous two exercises we may perform elementary row and column operations on a given relations matrix by choosing different generators for R^n and for $\ker\varphi$. If all relation matrices are the zero matrix then $\ker\varphi = 0$ and $M \cong R^n$. Otherwise let a_1 be the (nonzero) g.c.d. (recall R is a Euclidean Domain) of all the entries in a fixed initial relations matrix for M.

(a) Prove that by elementary row and column operations we may assume a_1 occurs in a relations matrix of the form

$$\begin{pmatrix} a_1 & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{pmatrix}$$

where a_1 divides a_{ij}, $i = 1, 2, \ldots, m$, $j = 1, 2, \ldots, n$.

(b) Prove that there is a relations matrix of the form

$$\begin{pmatrix} a_1 & 0 & \cdots & 0 \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & a_{m2} & \cdots & a_{mn} \end{pmatrix}$$

where a_1 divides all the entries.

(c) Let a_2 be a g.c.d. of all the entries except the element a_1 in the relations matrix in (b). Prove that there is a relations matrix of the form

$$\begin{pmatrix} a_1 & 0 & 0 & \cdots & 0 \\ 0 & a_2 & 0 & \cdots & 0 \\ 0 & 0 & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & a_{m3} & \cdots & a_{mn} \end{pmatrix}$$

where a_1 divides a_2 and a_2 divides all the other entries of the matrix.

(d) Prove that there is a relations matrix of the form $\begin{pmatrix} D & 0 \\ 0 & 0 \end{pmatrix}$ where D is a diagonal matrix with nonzero entries $a_1, a_2, \ldots, a_k$, $k \leq n$, satisfying

$$a_1 \mid a_2 \mid \cdots \mid a_k.$$

Conclude that

$$M \cong R/(a_1) \oplus R/(a_2) \oplus \cdots \oplus R/(a_k) \oplus R^{n-k}.$$

20. Let R be an integral domain with quotient field F and let M be any R-module. Prove that the rank of M equals the dimension of the vector space $F \otimes_R M$ over F.

Practice problems.

1. Let $R = \mathbb{Z}$ and let $M = \mathbb{Z}^4/N$, where N is the subgroup generated by the rows of

$$A = \begin{pmatrix} 2 & 4 & 6 & 0 \\ 0 & 6 & 0 & 12 \\ 4 & 0 & 8 & 8 \end{pmatrix}.$$

Compute the Smith normal form of A, and use it to write M in invariant factor form $\mathbb{Z}^r \oplus \mathbb{Z}/a_1\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/a_m\mathbb{Z}$ with $a_1 \mid a_2 \mid \cdots \mid a_m$. State the free rank r and the order of the torsion submodule.

2. Let $R = \mathbb{Q}[x]$ and let $M = R^3/N$, where N is generated by the rows of

$$\begin{pmatrix} x-1 & 0 & 0 \\ 0 & (x-1)^2 & 0 \\ 0 & 0 & (x-1)^2(x+2) \end{pmatrix}.$$

Find the invariant factors of M as an R-module, and write down its elementary divisor (primary) decomposition. Is M a torsion module?

3. A finite abelian group G has order $2^6 \cdot 3^3$ and is given in elementary divisor form

$$G \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/8\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/9\mathbb{Z}.$$

Convert this primary decomposition into invariant factor form $\mathbb{Z}/a_1\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/a_m\mathbb{Z}$ with $a_1 \mid \cdots \mid a_m$, and verify that a_m equals the exponent of G.

4. Let R be a PID and let $M = R/(a) \oplus R/(b)$ where $a, b \in R$ are nonzero nonunits. Express M in invariant factor form in terms of $d = \gcd(a, b)$ and $\ell = \operatorname{lcm}(a, b)$. Then specialize to $R = \mathbb{Z}$, $a = 12$, $b = 18$, and write out the resulting invariant factors explicitly.

5. Over $R = \mathbb{Z}$, classify up to isomorphism all abelian groups of order $600 = 2^3 \cdot 3 \cdot 5^2$. List each one in invariant factor form, and state how many isomorphism classes there are.

6. Let $A = \begin{pmatrix} 2 & 0 \\ 0 & 9 \end{pmatrix}$ be a presentation matrix over $\mathbb{Z}$ for $M = \mathbb{Z}^2/A\mathbb{Z}^2$. Show directly (without first putting A in Smith normal form) that $M \cong \mathbb{Z}/18\mathbb{Z}$ by exhibiting a generator of order 18, then confirm the answer by computing the Smith normal form of A.

7. Let $R = \mathbb{Q}[x]$ and consider $M = R^2/N$ with N generated by the rows of

$$\begin{pmatrix} x^2+1 & x+1 \\ x+1 & 1 \end{pmatrix}.$$

Compute $\det$ of this matrix, find the Smith normal form over R, and decide whether M is free, torsion, or a nontrivial mix of the two.

8. Suppose M is a finitely generated module over a PID R with invariant factors $a_1 \mid a_2 \mid a_3$ where $a_1 = p$, $a_2 = p^2q$, $a_3 = p^3q^2$ for distinct primes $p, q \in R$ and M has free rank 0. List the elementary divisors of M and compute the number of cyclic primary summands in its decomposition.

Additional exercises.

1. Let R be a PID and let M be a free R-module of rank n. Let $N \subseteq M$ be a submodule. State the theorem that N is free of rank $\leq n$, and prove that N is finitely generated by exhibiting an explicit generating set with at most n elements (you may assume the basis-adapted form: there is a basis $e_1, \ldots, e_n$ of M and elements $a_1 \mid \cdots \mid a_k$ with $a_1e_1, \ldots, a_ke_k$ a basis of N).

2. Let T be the torsion submodule of a finitely generated module M over a PID R. Prove that M/T is free, and prove that the free rank $r = \operatorname{rank}(M/T)$ is uniquely determined by M (i.e. independent of the chosen decomposition $M \cong R^r \oplus (\text{torsion})$). Conclude that two finitely generated R-modules with the same torsion part but different free ranks cannot be isomorphic.

3. Let p be a prime in a PID R and let M be a finitely generated torsion R-module. For each $i \geq 0$ define $d_i = \dim_{R/(p)}\big(p^iM[p]\big)$, where $M[p] = \{\, x \in M : px = 0 \,\}$. Show that the numbers d_i determine, and are determined by, the multiset of powers of p occurring as elementary divisors of M. (This is the uniqueness mechanism for elementary divisors; argue it for a single primary component M on which p is the only relevant prime.)

4. Let $R = \mathbb{Z}$. Give two finitely generated abelian groups G and H that have the same order and the same number of elements of order p for the prime $p = 2$, yet are not isomorphic, OR prove that for $p = 2$ no such pair exists. Justify your answer using the elementary divisor invariants.

5. Let M be a finitely generated module over a PID R with annihilator $\operatorname{Ann}(M) = (a) \neq 0$. Prove that a is (up to a unit) the largest invariant factor a_m, and deduce that M is cyclic if and only if $a_1 = \cdots = a_{m-1}$ are units, i.e. $M \cong R/(a_m)$. Illustrate with $R = \mathbb{Z}$, $M = \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$, by computing $\operatorname{Ann}(M)$ and the invariant factors.

Commutative-diagram exercises.

1. Let R be a PID and let M be finitely generated with a presentation

$$R^m \xrightarrow{A} R^n \xrightarrow{\pi} M \longrightarrow 0$$

exact, where A is an $n \times m$ matrix. Suppose $U \in \mathrm{GL}_n(R)$ and $V \in \mathrm{GL}_m(R)$ put A into Smith normal form $D = UAV = \operatorname{diag}(a_1, \dots, a_k, 0, \dots)$. Draw the commutative diagram relating the two presentations $R^m \xrightarrow{A} R^n$ and $R^m \xrightarrow{D} R^n$ using the vertical isomorphisms induced by U and V, and explain why it shows $M \cong \operatorname{coker}(A) \cong \operatorname{coker}(D) = R^{n-k} \oplus \bigoplus_i R/(a_i)$.

2. Let R be a PID and let

$$0 \longrightarrow T \xrightarrow{\iota} M \xrightarrow{q} M/T \longrightarrow 0$$

be the short exact sequence where T is the torsion submodule of the finitely generated module M. Show this sequence splits by constructing a section $s\colon M/T \to M$ with $q \circ s = \mathrm{id}_{M/T}$, and draw the diagram exhibiting the resulting isomorphism $M \cong T \oplus (M/T)$ (with M/T free).

3. Let R be a PID and let $a \mid b$ in R. Consider the diagram

$$R/(a) \xrightarrow{f} R/(b)$$

where f is the R-module map sending $1 + (a)$ to $c + (b)$. Determine exactly which $c \in R$ make f well defined, and for such c build the commutative diagram with the quotient maps from R showing f is induced by multiplication by c on R. Use this to describe $\operatorname{Hom}_R(R/(a), R/(b))$ as a cyclic R-module.

4. Let $R = \mathbb{Z}$ and consider the map $\varphi\colon \mathbb{Z}^2 \to \mathbb{Z}^2$ given by the matrix $A = \begin{pmatrix} 6 & 0 \\ 0 & 10 \end{pmatrix}$, fitting into

$$\mathbb{Z}^2 \xrightarrow{A} \mathbb{Z}^2 \xrightarrow{\pi} M \longrightarrow 0.$$

Find $U, V \in \mathrm{GL}_2(\mathbb{Z})$ with UAV in Smith normal form, and draw the commutative square with vertical maps V and U relating A to its Smith normal form. Read off M in invariant factor form from the diagram.

5. Let R be a PID, p a prime, and let M be a finitely generated torsion R-module. Consider multiplication by p, fitting into the exact sequence

$$0 \longrightarrow M[p] \longrightarrow M \xrightarrow{p\cdot} M \longrightarrow M/pM \longrightarrow 0.$$

Draw this diagram and prove that $\dim_{R/(p)} M[p] = \dim_{R/(p)} M/pM$ equals the number of elementary divisors of M that are powers of p. (Argue exactness at each spot and count $R/(p)$-dimensions.)

12.2 The Rational Canonical Form

From a linear operator to an $F[x]$-module

Throughout, F is a field, V is a finite-dimensional F-vector space, and $T \in \operatorname{End}(V)$ is a fixed linear transformation. The single most important idea of the section is that the pair (V, T) is exactly the same data as an $F[x]$-module.

Definition 12.2.1 (V as an $F[x]$-module)**.** Given $T \in \mathrm{End}(V)$, make V into a module over the polynomial ring $F[x]$ by letting x act as T: for $p(x) = \sum_{i=0}^{n} a_i x^i \in F[x]$ and $v \in V$,

$$p(x) \cdot v \;:=\; p(T)(v) \;=\; \sum_{i=0}^{n} a_i \, T^i(v).$$

Scalars $a \in F \subseteq F[x]$ act as the original F-scalar multiplication, and $x \cdot v = T(v)$. We denote this module by V_T when the operator must be named.

Remark 12.2.1. The module axioms hold because $F[x]$ is commutative and $p(T)q(T) = (pq)(T)$. Two operators T, S on V give the *same* $F[x]$-module structure iff $T = S$, so no information is lost. Conversely, any $F[x]$-module M that is finite-dimensional *as an F-vector space* arises this way: the action of x is an F-linear map $M \to M$, i.e. an operator. Thus

$$\{\ (V,T) : V \text{ finite-dim'l } F\text{-space},\ T \in \mathrm{End}(V)\ \} \;\longleftrightarrow\; \{\ F[x]\text{-modules finitely generated and torsion}\ \}.$$

The module V_T is a torsion module: by finite dimension some nonzero polynomial kills V (see m_T below), so $\mathrm{Ann}(V_T) \neq 0$.

Remark 12.2.2 (submodules = T-invariant subspaces). A subset $W \subseteq V$ is an $F[x]$-submodule of V_T iff W is an F-subspace with $T(W) \subseteq W$, i.e. a T-invariant subspace. Cyclic submodules are $F[x] \cdot v = \mathrm{Span}_F\{\, v, Tv, T^2v, \dots \}$, the T-cyclic subspace generated by v.

The translation table between the two languages is the backbone of the section:

$$\textbf{operator language} \xleftrightarrow{\text{same data}} F[x]\textbf{-module language}$$

$$T\text{-invariant subspace} \longleftrightarrow F[x]\text{-submodule}$$

$$T\text{-cyclic subspace } F[v] \longleftrightarrow \text{cyclic submodule } F[x]v$$

$$\text{operators } T \cong S \text{ similar} \longleftrightarrow V_T \cong V_S \text{ as } F[x]\text{-modules}$$

Diagram explanation. Objects: The left column holds operator-language objects: a linear operator T on V, a T-invariant subspace $W \subseteq V$, the T-cyclic subspace $F[v] = \mathrm{Span}_F\{v, Tv, T^2v, \dots\}$ spanned by a single vector v, and the relation "T similar to S." The right column holds $F[x]$-module-language counterparts: the module V_T, an $F[x]$-submodule of V_T, a cyclic submodule $F[x]v$, and an isomorphism $V_T \cong V_S$ of $F[x]$-modules.

Arrows: Each horizontal double arrow $\longleftrightarrow$ (the top one is labelled "same data") is a bijective correspondence, not a ring or module homomorphism. The top arrow is the master dictionary: the pair (V,T) is literally the same data as the $F[x]$-module V_T defined by $p(x) \cdot v = p(T)(v)$. The lower three rows specialize that correspondence to subobjects, generators, and isomorphism classes.

What commutes: This is a correspondence diagram, not a composable square, so commutativity means: every row's left-hand entry is the *exact translate* of the right-hand entry under the master bijection at the top. If W is T-invariant, then W with the restricted action is an $F[x]$-submodule, and conversely.

Why it commutes: The module axioms force $x \cdot w = T(w) \in W$ whenever $T(W) \subseteq W$, making W closed under the $F[x]$-action. The T-cyclic span equals $F[x] \cdot v$ because the $F[x]$-action is exactly iterated application of T. Similarity $B = P^{-1}AP$ defines an $F[x]$-isomorphism $V_A \to V_B$ by $v \mapsto P^{-1}v$, and every $F[x]$-isomorphism arises this way.

Why this matters here: This dictionary is the justification for everything that follows: invariant factors, minimal and characteristic polynomials, and the similarity criterion all live in the module language. The diagram tells the reader exactly which operator concept translates to which module concept, so no row of the later theory is mysterious.

Concrete example: For T = rotation by 90° on $\mathbb{Q}^2$ (matrix $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$), the subspace $\{0\}$ is the only proper T-invariant subspace, corresponding to the fact that $V_T \cong \mathbb{Q}[x]/(x^2+1)$ is a simple $\mathbb{Q}[x]$-module with no proper nonzero submodules.

Common pitfall: The horizontal arrows are correspondences, not isomorphisms of rings or modules. Students sometimes read the top arrow as an isomorphism $V \cong V_T$ and wonder what the domain and codomain are. The arrow means: specifying T is equivalent to specifying an $F[x]$-module structure on V; there is no separate map between objects called V and V_T.

Takeaway: The point of this diagram is that the pair (V, T) and the $F[x]$-module V_T are the same mathematical object viewed in two languages, so any theorem about modules over a PID immediately becomes a theorem about linear operators.

Worked Example 12.2.2 (Reading off the module structure of a 2×2 matrix)**.** Let $F = \mathbb{Q}$ and $A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ acting on $V = \mathbb{Q}^2$ with standard basis e_1, e_2. Describe V as a $\mathbb{Q}[x]$-module and find a single generator.

Recognition. Here $T = A$, so x acts as A. A vector v generates V_T as an $F[x]$-module iff $v, Tv, T^2v, \dots$ span V over F; this is the cyclic-submodule description.

Solution. We have $T(e_1) = Ae_1 = e_2$. Thus from the single generator e_1,

$$x \cdot e_1 = e_2, \qquad x^2 \cdot e_1 = Ae_2 = -e_1.$$

So $\{ e_1, x \cdot e_1 \} = \{ e_1, e_2 \}$ already spans V over $\mathbb{Q}$, and $V_T = \mathbb{Q}[x]\, e_1$ is cyclic. Moreover $x^2 e_1 = -e_1$ gives the relation $(x^2 + 1) \cdot e_1 = 0$, and no lower-degree polynomial kills e_1 (else e_1, e_2 would be dependent). Hence

$$V_T \;\cong\; F[x]/(x^2 + 1).$$

Sanity check. As a $\mathbb{Q}$-space $F[x]/(x^2+1)$ has basis $\{ 1, x \}$, dimension $2 = \dim_{\mathbb{Q}} V$. Good.

Worked Example 12.2.3 (A non-cyclic module: the identity operator)**.** Let $T = \mathrm{id}$ on $V = F^2$. Show V_T is *not* cyclic and identify it.

Recognition. Cyclicity means one vector's T-orbit spans. For $T = \mathrm{id}$, $Tv = v$, so the T-cyclic subspace of any v is just Fv, one-dimensional.

Solution. For every $v \in V$, $\mathrm{Span}_F\{ v, Tv, T^2v, \dots \} = \mathrm{Span}_F\{ v \} = Fv \neq V$. So no single vector generates; V_T needs two generators. Since x acts as id, $(x-1)v = 0$ for all v, so V_T is annihilated by $x - 1$ and

$$V_T \;\cong\; F[x]/(x-1) \;\oplus\; F[x]/(x-1).$$

Sanity check. Each summand is 1-dimensional over F; the sum is 2-dimensional $= \dim V$, and the operator on each summand is multiplication by $x \equiv 1$, i.e. the identity. Good.

Invariant factors of a linear transformation

Since $F[x]$ is a PID and V_T is a finitely generated torsion $F[x]$-module, the invariant factor form of the structure theorem (Theorem 12.1.9) applies.

Theorem 12.2.4 (Invariant factor decomposition for V_T)**.** *Let V be a finite-dimensional F-vector space and $T \in \mathrm{End}(V)$. Then there exist monic polynomials $a_1(x), a_2(x), \dots, a_m(x) \in F[x]$, each of degree ≥ 1, with the divisibility chain*

$$a_1(x) \mid a_2(x) \mid \cdots \mid a_m(x),$$

unique with these properties, such that

$$V_T \;\cong\; F[x]/(a_1(x)) \;\oplus\; F[x]/(a_2(x)) \;\oplus\; \cdots \;\oplus\; F[x]/(a_m(x))$$

as $F[x]$-modules. The $a_i(x)$ are the invariant factors *of T.*

Definition 12.2.5 (invariant factors of T and of A)**.** The polynomials $a_1 \mid \cdots \mid a_m$ above are the invariant factors of T. If $A = \mathrm{M}(T)$ is a matrix of T in some basis, the invariant factors of A are those of T; equivalently they are the nonconstant invariant factors (Smith normal form diagonal entries) of the characteristic matrix $xI - A$ over $F[x]$.

Remark 12.2.3. There is a completely mechanical way to obtain the $a_i(x)$: form the $n \times n$ matrix $xI - A$ over the PID $F[x]$ and put it in Smith normal form by elementary row and column operations,

$$xI - A \xrightarrow{\text{row/col ops over } F[x]} \operatorname{diag}\big(1, \dots, 1,\ a_1(x), \dots, a_m(x)\big),$$

where the leading 1's are the units and $a_1 \mid \cdots \mid a_m$ are the nonconstant diagonal entries. This is the operative computation in every example below.

The Smith-normal-form computation is exactly a change of presentation of the module, which we record as a commutative diagram. Writing $R = F[x]$ and presenting V_T by $xI - A$:

$$\begin{array}{ccccccc} R^n & \xrightarrow{xI-A} & R^n & \twoheadrightarrow & V_T & \longrightarrow & 0 \\ \cong\downarrow P & & \cong\downarrow Q & & \| & & \\ R^n & \xrightarrow[D]{} & R^n & \twoheadrightarrow & V_T & \longrightarrow & 0 \end{array}$$

$$D = \operatorname{diag}(1, \dots, 1, a_1, \dots, a_m), \qquad D = Q(xI - A)P^{-1}.$$

Diagram explanation. Objects: All four corner objects are copies of R^n where $R = F[x]$, and the rightmost pair is V_T followed by 0. Each row is a presentation of V_T as a quotient of R^n by the image of a matrix map. The top row uses the original matrix $xI - A$; the bottom row uses the Smith diagonal $D = \operatorname{diag}(1, \dots, 1, a_1, \dots, a_m)$.

Arrows: Top row left: the map $R^n \xrightarrow{xI-A} R^n$ sends a column vector e to $(xI - A)e$, presenting V_T as the cokernel. Bottom row: same shape with D in place of $xI - A$. Left vertical: $P\colon R^n \xrightarrow{\cong} R^n$ is an invertible column-operation matrix (the column operations multiply $xI - A$ on the right by P^{-1}). Right vertical: $Q\colon R^n \xrightarrow{\cong} R^n$ is the row-operation matrix (left-multiplication). The vertical at V_T is the identity; the two 0's are not joined by an arrow.

What commutes: The left square says $Q \circ (xI - A) = D \circ P$, i.e. $D = Q(xI - A)P^{-1}$. The right square says both cokernels coincide: the bottom surjection $R^n \twoheadrightarrow V_T$ is the top one composed with Q^{-1}; its kernel is $Q \cdot \operatorname{im}(xI - A) = \operatorname{im} D$, because the column operations P and row operations Q are both invertible and simply re-express the same lattice of relations.

Why it commutes: For any $e \in R^n$, following top-then-right: $(xI - A)e \mapsto$ its image in V_T. Following left-then-bottom: $Pe \mapsto D(Pe) = Q(xI - A)e \mapsto$ its image in V_T (the cokernel quotient kills $\operatorname{im} D$). Since Q is invertible, $\operatorname{im} D = Q \cdot \operatorname{im}(xI - A)$, and the quotient is unchanged.

Why this matters here: This diagram certifies that the Smith normal form computation really does compute the invariant factors of V_T: changing $xI - A$ to D by invertible row/column ops does not change the cokernel V_T, so the diagonal entries $a_1 \mid \cdots \mid a_m$ are genuine module invariants.

Concrete example: For $A = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$, $xI - A = \operatorname{diag}(x - 2, x - 2)$ is already diagonal with $P = Q = I$ and $D = \operatorname{diag}(x - 2, x - 2)$. The cokernel is $F[x]/(x - 2) \oplus F[x]/(x - 2)$, both rows giving the same V_T.

Common pitfall: Students sometimes think that because the bottom row looks simpler than the top, it must present a different (simpler) module. It presents the *same* module V_T; the diagram's right-hand column's identity arrow is the explicit witness of that equality.

Takeaway: The point of this diagram is that Smith normal form is a change of presentation of V_T, not a change of module, so its diagonal entries are the invariant factors.

Worked Example 12.2.6 (Invariant factors via Smith normal form of $xI - A$)**.** Let $F = \mathbb{Q}$ and $A = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$. Find the invariant factors of A.

Recognition. Reduce $xI - A$ over $\mathbb{Q}[x]$ to Smith normal form; the nonconstant diagonal entries are the invariant factors.

Solution.

$$xI - A = \begin{pmatrix} x - 2 & 0 \\ 0 & x - 2 \end{pmatrix}.$$

This is already diagonal with both entries equal, $a_1 = a_2 = x - 2$ (no unit can be extracted since gcd of the entries is $x - 2$, not 1). The divisibility chain $x - 2 \mid x - 2$ holds. So the invariant factors are

$$a_1(x) = x - 2, \qquad a_2(x) = x - 2,$$

and $V_T \cong F[x]/(x-2) \oplus F[x]/(x-2)$. *Sanity check.* $\sum \deg a_i = 1 + 1 = 2 = \dim_{\mathbb{Q}} V$. The operator is scalar 2, which is non-cyclic in dimension 2 – consistent with two invariant factors.

Worked Example 12.2.7 (A cyclic operator has a single invariant factor)**.** Let $F = \mathbb{Q}$ and $A = \left(\begin{smallmatrix} 0 & -6 \\ 1 & 5 \end{smallmatrix}\right)$. Find the invariant factors.

Recognition. If V_T is cyclic there is exactly one invariant factor $a_1 = m_T = c_T$. We run Smith normal form to confirm.

Solution.

$$xI - A = \begin{pmatrix} x & 6 \\ -1 & x - 5 \end{pmatrix}.$$

The $(2,1)$ entry -1 is a unit. Swap rows, scale, and clear:

$$\begin{pmatrix} -1 & x-5 \\ x & 6 \end{pmatrix} \to \begin{pmatrix} 1 & -(x-5) \\ 0 & 6 + x(x-5) \end{pmatrix} \to \begin{pmatrix} 1 & 0 \\ 0 & x^2 - 5x + 6 \end{pmatrix}.$$

So the single nonconstant invariant factor is

$$a_1(x) = x^2 - 5x + 6 = (x-2)(x-3).$$

Sanity check. $\deg a_1 = 2 = \dim V$, a single invariant factor confirms cyclicity. Indeed $\det(xI - A) = x^2 - 5x + 6 = a_1$, as it must when there is one invariant factor.

Worked Example 12.2.8 (Three invariant factors over $\mathbb{F}_2$)**.** Over $F = \mathbb{F}_2$, suppose the Smith normal form of $xI - A$ for a 4×4 matrix A is $\operatorname{diag}\big(1,\ x+1,\ x+1,\ x^2+1\big)$. List the invariant factors and check the dimension.

Recognition. The invariant factors are the nonconstant diagonal entries, and they must form a divisibility chain $a_1 \mid a_2 \mid a_3$.

Solution. The nonconstant entries are $x+1,\ x+1,\ x^2+1$. Check the chain: over $\mathbb{F}_2$ we have $x^2+1 = (x+1)^2$, so $x+1 \mid x+1 \mid x^2+1$ (over $\mathbb{Q}$ the chain would fail, since $x+1 \nmid x^2+1$ there). Hence

$$a_1 = x + 1, \qquad a_2 = x + 1, \qquad a_3 = x^2 + 1 = (x+1)^2.$$

Sanity check. $\sum \deg a_i = 1{+}1{+}2 = 4 = \dim V$, as it must be for a $4{\times}4$ matrix. (The lesson: $\sum \deg a_i = \dim V$ is the audit that catches an inconsistent SNF.)

Companion matrices and the rational canonical form

To turn the abstract decomposition into a matrix we need a canonical matrix for the operator "multiplication by x" on a single cyclic module $F[x]/(a(x))$.

Definition 12.2.9 (companion matrix)**.** Let $a(x) = x^k + b_{k-1}x^{k-1} + \cdots + b_1 x + b_0 \in F[x]$ be monic of degree $k \geq 1$. Its *companion matrix* is the $k \times k$ matrix

$$C_{a(x)} \;=\; \begin{pmatrix} 0 & 0 & \cdots & 0 & -b_0 \\ 1 & 0 & \cdots & 0 & -b_1 \\ 0 & 1 & \cdots & 0 & -b_2 \\ \vdots & & \ddots & & \vdots \\ 0 & 0 & \cdots & 1 & -b_{k-1} \end{pmatrix}.$$

Proposition 12.2.10 (the operator on a cyclic module is a companion matrix)**.** *On $W = F[x]/(a(x))$ with a monic of degree k, the ordered basis $\bar{1}, \bar{x}, \ldots, \bar{x}^{\,k-1}$ realizes multiplication-by-x as the matrix $C_{a(x)}$. Its characteristic and minimal polynomials are both equal to $a(x)$.*

Definition 12.2.11 (rational canonical form)**.** Let $a_1 \mid \cdots \mid a_m$ be the invariant factors of T. The *rational canonical form* of T (equivalently of A) is the block-diagonal matrix

$$\mathrm{RCF}(T) \;=\; \begin{pmatrix} C_{a_1} & & & \\ & C_{a_2} & & \\ & & \ddots & \\ & & & C_{a_m} \end{pmatrix} \;=\; C_{a_1} \oplus C_{a_2} \oplus \cdots \oplus C_{a_m}.$$

Theorem 12.2.12 (existence and uniqueness of RCF)**.** *Every $A \in \mathrm{M}_n(F)$ is similar to a unique matrix in rational canonical form, the direct sum of the companion matrices of its invariant factors $a_1 \mid \cdots \mid a_m$. In particular, A is similar to* $\mathrm{RCF}(A)$*, and this form depends only on A (not on the field extension or the chosen basis).*

The change of basis that produces the RCF is the operator-language shadow of the $F[x]$-module isomorphism. If P is the matrix whose columns are the chosen basis vectors of the cyclic pieces, then:

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & V \\ {\scriptstyle P^{-1}}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle P^{-1}} \\ V & \xrightarrow[\;P^{-1}AP\;]{} & V \end{array} \qquad P^{-1}AP \;=\; \mathrm{RCF}(A) \;=\; \bigoplus_{i=1}^{m} C_{a_i}.$$

Diagram explanation. Objects: All four objects are the same vector space V (a finite-dimensional F-space). The top row is V in the original coordinates; the bottom row is V in the new basis given by the columns of P (the cyclic-basis vectors of the invariant factor decomposition).

Arrows: The top horizontal is the operator $T\colon V \to V$. The bottom horizontal is $P^{-1}AP\colon V \to V$, the conjugate of $A = \mathrm{M}(T)$ in the new basis, which equals $\mathrm{RCF}(A)$. The two verticals are both the *coordinate-change isomorphism* $P^{-1}\colon V \xrightarrow{\cong} V$ (left side is the domain copy; right side is the codomain copy of the same change of basis).

What commutes: The square commutes: $P^{-1} \circ T = (P^{-1}AP) \circ P^{-1}$. Equivalently, top-then-right equals left-then-bottom: $P^{-1}(Tv) = (P^{-1}AP)(P^{-1}v)$ for all $v \in V$.

Why it commutes: Take any $v \in V$. Top-then-right: $v \overset{T}{\mapsto} Tv \overset{P^{-1}}{\longmapsto} P^{-1}(Tv)$. Left-then-bottom: $v \overset{P^{-1}}{\longmapsto} P^{-1}v \overset{P^{-1}AP}{\longmapsto} (P^{-1}A\cancel{P})(P^{-1}v) = P^{-1}(Av) = P^{-1}(Tv)$. Agreement is immediate from matrix associativity; the key input is that $A = \mathrm{M}(T)$ so $Tv = Av$ in coordinates.

Why this matters here: This diagram is the operator-language certificate that A is *similar* to $\mathrm{RCF}(A)$: the conjugating matrix P exists and is the matrix of cyclic-basis vectors. The existence theorem for the RCF is exactly the assertion that such a P exists for every A.

Concrete example: For $A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ with single invariant factor $x^2 + 1$, the single cyclic generator is e_1 with orbit e_1, e_2, so $P = I$ and $P^{-1}AP = A$ is already in RCF. The square is the identity square, confirming $A = C_{x^2+1}$.

Common pitfall: Both vertical arrows are labelled P^{-1} but they act on *different copies* of V (domain and codomain of T). Students sometimes try to "cancel" P^{-1} from both sides of the square, forgetting that the two copies are logically distinct (input coordinates vs. output coordinates).

Takeaway: The point of this diagram is that conjugating T by the cyclic-basis change-of-coordinates P^{-1} transforms the matrix of T into the block-diagonal rational canonical form, making the module decomposition visible in matrix form.

Worked Example 12.2.13 (Companion matrix of a cubic)**.** Write down the companion matrix of $a(x) = x^3 - 2x^2 + 5x - 7$ over $\mathbb{Q}$, and verify its characteristic polynomial.

Recognition. Direct application of the companion-matrix definition with $b_0 = -7,\ b_1 = 5,\ b_2 = -2$.

Solution.

$$C_a = \begin{pmatrix} 0 & 0 & 7 \\ 1 & 0 & -5 \\ 0 & 1 & 2 \end{pmatrix}.$$

Sanity check. Expand $\det(xI - C_a)$ along the first row:

$$\det\begin{pmatrix} x & 0 & -7 \\ -1 & x & 5 \\ 0 & -1 & x-2 \end{pmatrix} = x\big(x(x-2)+5\big) - 7(1) = x^3 - 2x^2 + 5x - 7 = a(x). \blacksquare$$

Worked Example 12.2.14 (Building the RCF from invariant factors)**.** A 5×5 rational matrix A has three invariant factors, of which $a_1 = x + 3$ and $a_2 = (x + 3)(x - 1)$. Find a_3, then write the RCF.

Recognition. $\sum \deg a_i = \dim V = 5$ and $a_1 \mid a_2 \mid a_3$. The RCF is the direct sum of companion matrices.

Solution. $\deg a_1 = 1$, $\deg a_2 = 2$, so $\deg a_3 = 2$ to reach 5. The chain forces $a_2 \mid a_3$, but $\deg a_2 = \deg a_3 = 2$ and both monic forces $a_3 = a_2 = (x + 3)(x - 1) = x^2 + 2x - 3$. So

$$a_1 = x + 3, \qquad a_2 = a_3 = x^2 + 2x - 3.$$

Companion matrices: $C_{a_1} = (-3)$ and $C_{a_2} = \left(\begin{smallmatrix} 0 & 3 \\ 1 & -2 \end{smallmatrix}\right)$. Hence

$$\mathrm{RCF}(A) = \left(\begin{array}{c|cc|cc} -3 & & & & \\ \hline & 0 & 3 & & \\ & 1 & -2 & & \\ \hline & & & 0 & 3 \\ & & & 1 & -2 \end{array}\right).$$

Sanity check. Total size $1 + 2 + 2 = 5$. $\blacksquare$

Worked Example 12.2.15 (Full computation: matrix to RCF over $\mathbb{Q}$)**.** Find the rational canonical form of $A = \left(\begin{smallmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{smallmatrix}\right)$ over $\mathbb{Q}$.

Recognition. Compute the invariant factors via Smith normal form of $xI - A$, then assemble companion blocks.

Solution.

$$xI - A = \begin{pmatrix} x-1 & -1 & 0 \\ 0 & x-1 & 0 \\ 0 & 0 & x-2 \end{pmatrix}.$$

The $(1, 2)$ entry -1 is a unit; move it to position $(1, 1)$ and use it to clear its row and column. Column-swap $C_1 \leftrightarrow C_2$ and negate C_1 to bring a 1 to $(1, 1)$, then eliminate with $C_2 - (x - 1)C_1$ and $R_2 + (x - 1)R_1$:

$$\to \begin{pmatrix} 1 & x-1 & 0 \\ -(x-1) & 0 & 0 \\ 0 & 0 & x-2 \end{pmatrix} \to \begin{pmatrix} 1 & 0 & 0 \\ 0 & (x-1)^2 & 0 \\ 0 & 0 & x-2 \end{pmatrix}.$$

Now reorder to a divisibility chain. The nonconstant entries are $(x - 1)^2$ and $x - 2$, which are coprime; since $\gcd\big((x-1)^2, x-2\big) = 1$, the block diag $\big((x-1)^2, x-2\big)$ has Smith normal form diag $\big(1, (x-1)^2(x-2)\big)$, so there is one invariant factor

$$a_1(x) = (x-1)^2(x-2) = x^3 - 4x^2 + 5x - 2.$$

So A is cyclic and

$$\mathrm{RCF}(A) = C_{a_1} = \begin{pmatrix} 0 & 0 & 2 \\ 1 & 0 & -5 \\ 0 & 1 & 4 \end{pmatrix}.$$

Sanity check. $c_A(x) = \det(xI - A) = (x - 1)^2(x - 2) = a_1$, and the single invariant factor of degree 3 matches $\dim V = 3$. The Jordan block $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ shows $m_A = (x - 1)^2(x - 2) = c_A$, so the operator is indeed cyclic. $\blacksquare$

Worked Example 12.2.16 (Two invariant factors: a non-cyclic example)**.** Find the RCF of $A = \left(\begin{smallmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 5 \end{smallmatrix}\right)$ over $\mathbb{Q}$.

Recognition. The eigenvalue 2 appears with a 2-dimensional eigenspace, forcing two invariant factors. Confirm by SNF.

Solution. $xI - A = \operatorname{diag}(x-2, x-2, x-5)$. Over $\mathbb{Q}[x]$ we extract the chain: gcd of all entries is 1, then group so divisibility holds. The invariant factors are

$$a_1(x) = x - 2, \qquad a_2(x) = (x-2)(x-5) = x^2 - 7x + 10,$$

since $x - 2 \mid (x-2)(x-5)$ and $\deg a_1 + \deg a_2 = 1 + 2 = 3 = \dim V$. Companion blocks $C_{a_1} = (2)$ and $C_{a_2} = \left(\begin{smallmatrix} 0 & -10 \\ 1 & 7 \end{smallmatrix}\right)$ give

$$\operatorname{RCF}(A) = \left(\begin{array}{c|cc} 2 & & \\ \hline & 0 & -10 \\ & 1 & 7 \end{array}\right).$$

Sanity check. $c_A = (x-2)^2(x-5)$ and the product $a_1 a_2 = (x-2) \cdot (x-2)(x-5) = (x-2)^2(x-5)$ matches. The largest invariant factor $a_2 = (x-2)(x-5)$ equals m_A – correct, since A is diagonalizable with distinct factors. ■

Characteristic and minimal polynomials

Theorem 12.2.17 (char/min polynomials from invariant factors)**.** *Let $T \in \operatorname{End}(V)$ have invariant factors $a_1 \mid a_2 \mid \cdots \mid a_m$. Then*

$$c_T(x) \;=\; \prod_{i=1}^{m} a_i(x) \qquad \text{and} \qquad m_T(x) \;=\; a_m(x),$$

the characteristic polynomial is the product of all invariant factors, and the minimal polynomial is the largest (last) invariant factor.

Corollary 12.2.18. *$\deg c_T = \dim_F V$, $m_T \mid c_T$, and $c_T \mid (m_T)^m$ where m is the number of invariant factors. Consequently c_T and m_T have the same irreducible factors (the distinct prime divisors of a_m). The operator T is cyclic (i.e. V_T is a cyclic $F[x]$-module, $m = 1$) iff $m_T = c_T$.*

Worked Example 12.2.19 (Char and min polynomials from a Smith normal form)**.** The invariant factors of $A \in \mathrm{M}_3(\mathbb{Q})$ are $a_1 = x + 1$, $a_2 = (x+1)(x-3)$. Find c_A, m_A, and decide whether A is diagonalizable over $\mathbb{Q}$.

Recognition. $c_A = \prod a_i$, $m_A = a_2$ (largest). Diagonalizability $\iff$ m_A splits into distinct linear factors.

Solution.

$$c_A = a_1 a_2 = (x+1) \cdot (x+1)(x-3) = (x+1)^2(x-3),$$
$$m_A = a_2 = (x+1)(x-3).$$

m_A is a product of *distinct* linear factors over $\mathbb{Q}$, so A is diagonalizable. *Sanity check.* $\deg c_A = 3 = \dim V$, as it must be for a 3×3 matrix (the degree audit $\sum \deg a_i = \dim V$ is what flags bad data). Contrast: if instead $A \in \mathrm{M}_4(\mathbb{Q})$ had $a_1 = x+1$, $a_2 = (x+1)^2(x-3)$, then $c_A = (x+1)^3(x-3)$ and $m_A = (x+1)^2(x-3)$; since m_A has the repeated factor $(x+1)^2$, that A is *not* diagonalizable. ■

Worked Example 12.2.20 (Recovering invariant factors from c and m)**.** A matrix $A \in \mathrm{M}_6(\mathbb{Q})$ has $c_A(x) = (x-2)^4(x-5)^2$, $m_A(x) = (x-2)^2(x-5)$ and $\dim_{\mathbb{Q}} \ker(A - 2I) = 2$. Determine the invariant factors (hence the RCF block sizes).

Recognition. $a_m = m_A$ is the last invariant factor; the remaining a_i divide it and multiply (with a_m) to c_A. Match prime powers factor-by-factor with descending exponents.

Solution. Work prime-by-prime, listing exponents of $(x-2)$ and $(x-5)$ in each a_i from the largest down, where a_m carries the exponents in m_A, namely $(2, 1)$. For $(x-2)$: total exponent 4 in c_A, top exponent 2; the partitions of 4 with largest part 2 are $2+2$ and $2+1+1$. The number of parts is the number of invariant factors divisible by $x-2$, which equals $\dim \ker(A - 2I) = 2$ (each summand $\mathbb{Q}[x]/(a_i)$ with $(x-2) \mid a_i$ contributes a 1-dimensional kernel of $x-2$), so the partition is $2+2$. For $(x-5)$: total 2, top 1; partition $1+1$. Aligning from the largest factor, $(x-2)$ contributes 2 to a_2 and 2 to a_1, and $(x-5)$ contributes 1 to each:

$$a_1(x) = (x-2)^2(x-5), \qquad a_2(x) = (x-2)^2(x-5) = m_A.$$

(Without the kernel condition, $x-2$, $(x-2)(x-5)$, $(x-2)^2(x-5)$ would fit the same c_A and m_A: the pair (c_A, m_A) alone does not determine the invariant factors.) *Sanity check.* $a_1 \mid a_2$ (equal), product $= (x-2)^4(x-5)^2 = c_A$ ■, largest $= (x-2)^2(x-5) = m_A$ ■, $\sum \deg = 3+3 = 6 = \dim V$ ■. The RCF is $C_{a_1} \oplus C_{a_2}$, two 3×3 blocks.

Worked Example 12.2.21 (Cyclic iff $c = m$)**.** Decide whether $A = \left(\begin{smallmatrix} 3 & 1 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 3 \end{smallmatrix}\right)$ over $\mathbb{Q}$ is cyclic.

Recognition. A is cyclic iff $m_A = c_A$ iff there is a single invariant factor.

Solution. $c_A(x) = (x-3)^3$. For m_A: $(A-3I) = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{smallmatrix}\right)$ is nonzero but $(A-3I)^2 = 0$, so $m_A = (x-3)^2 \neq c_A$. Hence A is *not* cyclic. *Sanity check.* Invariant factors: $a_2 = (x-3)^2 = m_A$, $a_1 = x-3$ (so that $a_1 a_2 = (x-3)^3 = c_A$ and $a_1 \mid a_2$). Two invariant factors $\Rightarrow$ non-cyclic, consistent. ■

Worked Example 12.2.22 (Minimal polynomial of a companion matrix is its char polynomial)**.** Let $a(x) = x^4 + x + 1 \in \mathbb{F}_2[x]$ and $A = C_a$. Show $m_A = c_A = a$, so A is cyclic.

Recognition. A companion matrix has a single invariant factor equal to a, so $m_A = c_A = a$. We may verify directly that $\bar{1}$ has T-orbit spanning.

Solution. With $T =$ multiplication-by-x on $\mathbb{F}_2[x]/(a)$ and generator $\bar{1}$, the orbit $\bar{1}, \bar{x}, \bar{x}^2, \bar{x}^3$ is a basis (degrees 0 through 3), so $\bar{1}$ generates and V_T is cyclic with single invariant factor a. Hence $m_A = c_A = a = x^4 + x + 1$. *Sanity check.* a is irreducible over $\mathbb{F}_2$ (no roots: $a(0) = a(1) = 1$, and it has no quadratic factor since the only irreducible quadratic $x^2 + x + 1$ does not divide it). An irreducible char polynomial of degree 4 forces a single invariant factor of degree $4 = \dim V$. ■

The similarity criterion

Theorem 12.2.23 (similarity $\iff$ same invariant factors)**.** *Let $A, B \in \mathrm{M}_n(F)$. The following are equivalent:*

1. *A and B are similar over F (i.e. $B = P^{-1}AP$ for some invertible $P \in \mathrm{M}_n(F)$);*
2. *$V_A \cong V_B$ as $F[x]$-modules;*
3. *A and B have the same invariant factors;*
4. *A and B have the same rational canonical form;*
5. *$xI - A$ and $xI - B$ have the same Smith normal form over $F[x]$.*

Corollary 12.2.24 (similarity is field-independent)**.** *If $F \subseteq K$ are fields and $A, B \in \mathrm{M}_n(F)$ are similar over K, then they are already similar over F. The rational canonical form, invariant factors, c_A and m_A are unchanged by field extension. (This is why the RCF is "rational": it needs no roots, only the base field F.)*

Worked Example 12.2.25 (Deciding similarity over $\mathbb{Q}$)**.** Are $A = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$ similar over $\mathbb{Q}$?

Recognition. Compare invariant factors (equivalently RCFs). Same char polynomial is necessary but not sufficient.

Solution. Both have $c(x) = (x-1)^2$. But $m_A = (x-1)^2$ (since $A - I \neq 0$) while $m_B = x - 1$ (since $B = I$). Different minimal polynomials $\Rightarrow$ different largest invariant factor $\Rightarrow$ *not* similar. *Sanity check.* A has invariant factor $(x-1)^2$ (cyclic); B has invariant factors $x-1, x-1$. Distinct lists confirm non-similarity, even though $c_A = c_B$. ■

Worked Example 12.2.26 (Similar despite looking different)**.** Show $A = \left(\begin{smallmatrix} 0 & -2 \\ 1 & 3 \end{smallmatrix}\right)$ and $B = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 2 \end{smallmatrix}\right)$ are similar over $\mathbb{Q}$.

Recognition. Compute the invariant factors of each; if identical, they share the RCF and are similar.

Solution. B is diagonal with eigenvalues $1, 2$, so $c_B = (x-1)(x-2)$, $m_B = (x-1)(x-2)$ (distinct eigenvalues $\Rightarrow$ cyclic), single invariant factor $a = (x-1)(x-2) = x^2 - 3x + 2$. For A: $\det(xI - A) = x(x-3) + 2 = x^2 - 3x + 2$ and A is a companion matrix (it equals C_{x^2-3x+2}), so its single invariant factor is also $x^2 - 3x + 2$. Same invariant factor $\Rightarrow$ similar. *Sanity check.* Common RCF is $C_{x^2-3x+2} = \left(\begin{smallmatrix} 0 & -2 \\ 1 & 3 \end{smallmatrix}\right) = A$, so A is already in RCF and B is similar to it (both have RCF C_{x^2-3x+2}). ■

Worked Example 12.2.27 (Counting similarity classes with a given characteristic polynomial)**.** Over $\mathbb{Q}$, how many similarity classes of 4×4 matrices have characteristic polynomial $c(x) = (x-1)^4$?

Recognition. Each class corresponds to one valid invariant-factor chain $a_1 \mid \cdots \mid a_m$ with $\prod a_i = (x-1)^4$. Since the only prime here is $x-1$, this is the same as partitioning the exponent 4 (the parts, in nondecreasing order, are the exponents of $a_1, \ldots, a_m$).

Solution. Invariant factors are powers $(x-1)^{e_1} \mid \cdots \mid (x-1)^{e_m}$ with $e_1 \le \cdots \le e_m$ and $\sum e_i = 4$, each $e_i \ge 1$. These are exactly the partitions of 4:

$$4; \quad 3+1; \quad 2+2; \quad 2+1+1; \quad 1+1+1+1.$$

That is $p(4) = 5$ classes, with largest part e_m giving $m_A = (x-1)^{e_m}$:

$$(x-1)^4; \quad (x-1)^3; \quad (x-1)^2; \quad (x-1)^2; \quad (x-1).$$

Sanity check. The two middle classes $2+2$ and $2+1+1$ share $m_A = (x-1)^2$ yet are distinct (different RCFs: one $C \oplus C$ with two 2-blocks, one with a 2-block and two 1-blocks) – illustrating that (c_A, m_A) does *not* determine the class. ■

Worked Example 12.2.28 (Field-independence in action)**.** $A, B \in \mathrm{M}_2(\mathbb{Q})$ are similar over $\mathbb{C}$. Must they be similar over $\mathbb{Q}$?

Recognition. By the field-independence corollary, similarity over an extension field descends to the base field, because invariant factors are computed entirely in $\mathbb{Q}[x]$.

Solution. Yes. The Smith normal form of $xI - A$ over $\mathbb{Q}[x]$ already determines the invariant factors; passing to $\mathbb{C}[x]$ does not change the SNF (elementary operations over $\mathbb{Q}[x]$ are valid over $\mathbb{C}[x]$, and the monic SNF is unique). So A, B similar over $\mathbb{C} \Rightarrow$ same invariant factors $\Rightarrow$ similar over $\mathbb{Q}$. *Sanity check.* Concretely, $\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ has invariant factor x^2+1, irreducible over $\mathbb{Q}$ but split over $\mathbb{C}$; its RCF over $\mathbb{Q}$ is itself, and no diagonalization over $\mathbb{Q}$ exists, consistent with the form being the same regardless of field. ■

The Cayley–Hamilton theorem

Theorem 12.2.29 (Cayley–Hamilton)**.** *Let $T \in \mathrm{End}(V)$ with characteristic polynomial $c_T(x)$. Then $c_T(T) = 0$; that is, T satisfies its own characteristic polynomial. Equivalently, the minimal polynomial $m_T(x)$ divides $c_T(x)$.*

Remark 12.2.4 (module proof). The structure theorem proof is immediate. With $a_1 \mid \cdots \mid a_m$ the invariant factors, $m_T = a_m$ kills each summand $F[x]/(a_i)$ because $a_i \mid a_m$; hence $m_T(T) = 0$ on all of V. Since $c_T = \prod a_i$ and $a_m \mid \prod a_i$ (it is one of the factors), $m_T \mid c_T$, so $c_T(T) = 0$ as well.

Worked Example 12.2.30 (Verifying Cayley–Hamilton on a 2×2 matrix)**.** Verify $c_A(A) = 0$ for $A = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$ over $\mathbb{Q}$.

Recognition. Cayley–Hamilton guarantees $c_A(A) = 0$; we substitute A into $c_A(x)$ and compute.

Solution. $c_A(x) = \det(xI - A) = (x-1)(x-4) - 6 = x^2 - 5x - 2$. Compute

$$A^2 = \begin{pmatrix} 7 & 10 \\ 15 & 22 \end{pmatrix}, \qquad A^2 - 5A - 2I = \begin{pmatrix} 7 & 10 \\ 15 & 22 \end{pmatrix} - \begin{pmatrix} 5 & 10 \\ 15 & 20 \end{pmatrix} - \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \blacksquare$$

Sanity check. $\operatorname{tr} A = 5$ and $\det A = -2$, matching the coefficients $-(\operatorname{tr} A) = -5$ and $\det A = -2$ in c_A. ■

Worked Example 12.2.31 (Using Cayley–Hamilton to invert a matrix)**.** For $A = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)$, use Cayley–Hamilton to express A^{-1} as a polynomial in A.

Recognition. From $c_A(A) = A^2 - 5A - 2I = 0$ and $\det A \neq 0$, solve for I and divide to isolate A^{-1}.

Solution. $A^2 - 5A - 2I = 0 \Rightarrow A(A - 5I) = 2I \Rightarrow A^{-1} = \frac{1}{2}(A - 5I)$. So

$$A^{-1} = \tfrac{1}{2}\begin{pmatrix} 1-5 & 2 \\ 3 & 4-5 \end{pmatrix} = \begin{pmatrix} -2 & 1 \\ \frac{3}{2} & -\frac{1}{2} \end{pmatrix}.$$

Sanity check. $AA^{-1} = \left(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix}\right)\left(\begin{smallmatrix} -2 & 1 \\ \frac{3}{2} & -\frac{1}{2} \end{smallmatrix}\right) = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$. ■

Worked Example 12.2.32 (Reducing high powers via the minimal polynomial)**.** With $A = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ over $\mathbb{Q}$, compute A^{10} using m_A.

Recognition. $m_A(x) = x^2 + 1$ (it is the invariant factor of this companion matrix), so $A^2 = -I$ and high powers reduce.

Solution. $A^2 = -I \Rightarrow A^{10} = (A^2)^5 = (-I)^5 = -I = \left(\begin{smallmatrix} -1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$. *Sanity check.* A is rotation by $90°$; A^{10} is rotation by $900° \equiv 180°$, which is $-I$. ■

Worked Example 12.2.33 (Cayley–Hamilton does not give the minimal polynomial)**.** For $A = 3I_3$ over $\mathbb{Q}$, contrast $c_A(A) = 0$ with the genuinely smallest relation.

Recognition. Cayley–Hamilton only asserts $c_A(A) = 0$; the minimal polynomial m_A (the last invariant factor) can have much smaller degree.

Solution. $c_A(x) = (x-3)^3$, so Cayley–Hamilton says $(A - 3I)^3 = 0$ – true but weak. The actual minimal polynomial is $m_A(x) = x - 3$ since $A - 3I = 0$ already. The invariant factors are $x-3,\ x-3,\ x-3$. *Sanity check.* $m_A = x - 3$ is the largest invariant factor, $c_A = (x-3)^3$ is the product of all three, and $m_A \mid c_A$. The gap between $\deg m_A = 1$ and $\deg c_A = 3$ is exactly the non-cyclicity ($m = 3$ invariant factors). ■

Connection to Jordan form (a preview)

When F contains all eigenvalues (e.g. $F = \mathbb{C}$), each invariant factor factors into prime powers $(x-\lambda)^k$ – the *elementary divisors* – and the companion block $C_{(x-\lambda)^k}$ is similar to a single Jordan block $J_k(\lambda)$. The RCF and the Jordan form are thus two normal forms for the same $F[x]$-module, read off from the two forms of the structure theorem (invariant factors vs. elementary divisors).

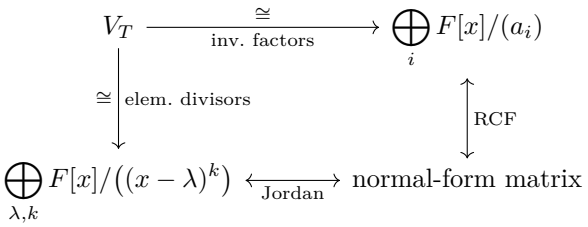

Diagram explanation. Objects: Top-left: the $F[x]$-module V_T (assuming F contains all eigenvalues, e.g. $F = \mathbb{C}$). Top-right: the invariant-factor decomposition $\bigoplus_i F[x]/(a_i)$, where $a_1 \mid \cdots \mid a_m$ are the (not necessarily irreducible) invariant factors. Bottom-left: the elementary-divisor decomposition $\bigoplus_{\lambda,k} F[x]/((x-\lambda)^k)$, where each $(x-\lambda)^k$ is an irreducible (linear) prime-power factor of some a_i. Bottom-right: "normal-form matrix," meaning either the RCF or the Jordan form depending on which path you follow.

Arrows: The top arrow $\cong$ (labelled "inv. factors") is the structure-theorem isomorphism grouping V_T by the monic divisibility chain. The left arrow $\cong$ (labelled "elem. divisors") is the *other* structure-theorem isomorphism, grouping V_T by prime-power factors. The right vertical double arrow (labelled "RCF") records the translation of the top-right decomposition into a matrix: a summand $F[x]/(a_i)$ contributes a companion block C_{a_i} to the RCF. The bottom horizontal double arrow (labelled "Jordan") does the same for the bottom-left decomposition: a summand $F[x]/((x-\lambda)^k)$ contributes a Jordan block $J_k(\lambda)$. The two decompositions are related by regrouping: each a_i factors into prime powers, and vice versa collecting the prime powers of the same a_i reconstitutes $F[x]/(a_i)$ by CRT.

What commutes: Both paths from V_T to the normal-form matrix lead to the same module (up to isomorphism), so the two composites agree: the RCF and Jordan form are two presentations of the same $F[x]$-module data. Concretely, going right-then-down (RCF companion blocks then recognizing Jordan blocks inside each) equals going down-then-right (elementary divisors directly giving Jordan blocks).

Why it commutes: The Chinese Remainder Theorem for $F[x]$ (a PID) gives $F[x]/(a_i) \cong \bigoplus_j F[x]/((p_j)^{e_{ij}})$ when $a_i = \prod_j p_j^{e_{ij}}$ with distinct irreducibles p_j. Each C_{a_i} is therefore similar to $\bigoplus_j J_{e_{ij}}(\lambda_j)$ over F (since $p_j = x - \lambda_j$ over an algebraically closed field). The CRT isomorphism is the explicit commutativity witness.

Why this matters here: This diagram crystallizes the conceptual relationship between the RCF (base-field friendly, always exists) and the Jordan form (requires eigenvalues in F, but finer-grained): they are the same

module decomposition, just expressed with different groupings of the summands. A student who understands this square understands why RCF and Jordan form carry identical information over $\mathbb{C}$.

Concrete example: Let $a_1 = (x-2)$ and $a_2 = (x-2)^2(x-3)$ over $\mathbb{C}$. The RCF path gives blocks C_{a_1} (1×1) and C_{a_2} (3×3). The elementary-divisor path gives $(x-2), (x-2)^2, (x-3)$, yielding Jordan blocks $J_1(2), J_2(2), J_1(3)$. Both produce a 4×4 matrix recording the same $F[x]$-module.

Common pitfall: Students assume the RCF and Jordan form are "the same matrix." They encode the same abstract module but are genuinely different matrices (they coincide only when A is a scalar matrix λI; even a prime-power invariant factor gives different blocks, e.g. $C_{(x-2)^2} = \left(\begin{smallmatrix} 0 & -4 \\ 1 & 4 \end{smallmatrix}\right)$ but $J_2(2) = \left(\begin{smallmatrix} 2 & 1 \\ 0 & 2 \end{smallmatrix}\right)$). The diagram's bottom-right corner is labelled "normal-form matrix" (either form), not a single canonical object.

Takeaway: The point of this diagram is that the invariant-factor and elementary-divisor decompositions of V_T are the same structural data reorganized in two ways, with the RCF and Jordan form as their respective matrix realizations.

Worked Example 12.2.34 (Elementary divisors, RCF, and Jordan form together)**.** Over $\mathbb{C}$, let A have invariant factors $a_1 = (x-2)$, $a_2 = (x-2)^2(x-3)$. List the elementary divisors and write both the Jordan form and the RCF block sizes.

Recognition. Elementary divisors are the prime-power factors of the invariant factors; Jordan blocks correspond to elementary divisors, RCF blocks to invariant factors.

Solution. Factor each invariant factor: $a_1 = (x-2)$ and $a_2 = (x-2)^2(x-3)$. So the elementary divisors are

$$(x-2), \quad (x-2)^2, \quad (x-3).$$

Jordan form: blocks $J_1(2),\ J_2(2),\ J_1(3)$, i.e.

$$J = \begin{pmatrix} 2 & & & \\ & 2 & 1 & \\ & 0 & 2 & \\ & & & 3 \end{pmatrix}.$$

RCF: companion blocks of a_1 (size 1) and a_2 (size 3), so a 1×1 and a 3×3 block. *Sanity check.* $\dim V = \deg a_1 + \deg a_2 = 1 + 3 = 4$, matching the 4 Jordan diagonal entries. $m_A = a_2 = (x-2)^2(x-3)$ records the largest Jordan block at each eigenvalue ($(x-2)^2$ for $\lambda = 2$, $(x-3)$ for $\lambda = 3$). ■

Exercises (from the text).

1. Prove that similar linear transformations of V (or $n\times n$ matrices) have the same characteristic and the same minimal polynomial.
2. Let M be as in Lemma 19. Prove that the minimal polynomial of M is the least common multiple of the minimal polynomials of $A_1, \ldots, A_k$.
3. Prove that two 2×2 matrices over F which are not scalar matrices are similar if and only if they have the same characteristic polynomial.
4. Prove that two 3×3 matrices are similar if and only if they have the same characteristic and the same minimal polynomials. Give an explicit counterexample to this assertion for 4×4 matrices.
5. Prove directly from the fact that the collection of *all* linear transformations of an n dimensional vector space V over F to itself form a vector space over F of dimension n^2 that the minimal polynomial of a linear transformation T has degree at most n^2.
6. Prove that the constant term in the characteristic polynomial of the $n\times n$ matrix A is $(-1)^n \det A$ and that the coefficient of x^{n-1} is the negative of the sum of the diagonal entries of A (the sum of the diagonal entries of A is called the *trace* of A). Prove that $\det A$ is the product of the eigenvalues of A and that the trace of A is the sum of the eigenvalues of A.

7. Determine the eigenvalues of the matrix

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{pmatrix}.$$

8. Verify that the characteristic polynomial of the companion matrix

$$\begin{pmatrix} 0 & 0 & 0 & \dots & 0 & -a_0 \\ 1 & 0 & 0 & \dots & 0 & -a_1 \\ 0 & 1 & 0 & \dots & 0 & -a_2 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -a_{n-1} \end{pmatrix}$$

is

$$x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0.$$

9. Find the rational canonical forms of

$$\begin{pmatrix} 0 & -1 & -1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} c & 0 & -1 \\ 0 & c & 1 \\ -1 & 1 & c \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 422 & 465 & 15 & -30 \\ -420 & -463 & -15 & 30 \\ 840 & 930 & 32 & -60 \\ -140 & -155 & -5 & 12 \end{pmatrix}.$$

10. Find all similarity classes of 6×6 matrices over $\mathbb{Q}$ with minimal polynomial $(x+2)^2(x-1)$ (it suffices to give all lists of invariant factors and write out some of their corresponding matrices).

11. Find all similarity classes of 6×6 matrices over $\mathbb{C}$ with characteristic polynomial $(x^4-1)(x^2-1)$.

12. Find all similarity classes of 3×3 matrices A over $\mathbb{F}_2$ satisfying $A^6 = I$ (compare with the answer we computed over $\mathbb{Q}$). Do the same for 4×4 matrices B satisfying $B^{20} = I$.

13. Prove that the number of similarity classes of 3×3 matrices over $\mathbb{Q}$ with a given characteristic polynomial in $\mathbb{Q}[x]$ is the same as the number of similarity classes over any extension field of $\mathbb{Q}$. Give an example to show that this is not true in general for 4×4 matrices.

14. Determine all possible rational canonical forms for a linear transformation with characteristic polynomial $x^2(x^2+1)^2$.

15. Determine all possible rational canonical forms for all 2×2 rational matrices (i.e., $M_2(\mathbb{Q})$) of precise order 4 (multiplicatively, of course). Do the same if the matrix has entries from $\mathbb{C}$.

16. Show that $x^5 - 1 = (x-1)(x^2 - 4x + 1)(x^2 + 5x + 1)$ in $\mathbb{F}_{19}[x]$. Use this to determine up to similarity all 2×2 matrices with entries from $\mathbb{F}_{19}$ of order **5**.

17. Determine representatives for the conjugacy classes for $GL_3(\mathbb{F}_2)$. [Compare your answer with Theorem 15 and Proposition 14 of Chapter 6.]

18. Let V be a finite dimensional vector space over $\mathbb{Q}$ and suppose T is a nonsingular linear transformation of V such that $T^{-1} = T^2 + T$. Prove that the dimension of V is divisible by 3. If the dimension of V is precisely 3 prove that all such transformations T are similar.

19. Let V be the infinite dimensional real vector space

$$\mathbb{R}^\infty = \{(a_0, a_1, a_2, \ldots) \mid a_0, a_1, a_2, \ldots \in \mathbb{R}\}.$$

Define the map $T : V \to V$ by $T(a_0, a_1, a_2, \ldots) = (0, a_0, a_1, a_2, \ldots)$. Prove that T has no eigenvectors.

20. Let ℓ be a prime and let $\Phi_\ell(x) = \dfrac{x^\ell - 1}{x - 1} = x^{\ell-1} + x^{\ell-2} + \cdots + x + 1 \in \mathbb{Z}[x]$ be the ℓth cyclotomic polynomial, which is irreducible over $\mathbb{Q}$ (Example 4 following Corollary 9.14). This exercise determines the smallest degree of a factor of $\Phi_\ell(x)$ modulo p for any prime p and so in particular determines when $\Phi_\ell(x)$ is irreducible modulo p. This actually determines the complete factorization of $\Phi_\ell(x)$ modulo p — cf. Exercise 8 of Section 13.6.)

    (a) Show that if $p = \ell$ then $\Phi_\ell(x)$ is divisible by $x - 1$ in $\mathbb{F}_p[x]$.

    (b) Suppose $p \neq \ell$ and let f denote the order of p in $\mathbb{F}_\ell^\times$, i.e., f is the smallest power of p with $p^f \equiv 1$ mod ℓ. Show that $m = f$ is the first value of m for which the group $GL_m(\mathbb{F}_p)$ contains an element A of order ℓ. Use the formula for the order of this group at the end of Section 11.1.)

    (c) Show that $\Phi_\ell(x)$ is not divisible by any polynomial of degree smaller than f in $\mathbb{F}_p[x]$ [consider the companion matrix for such a divisor and use (b)]. Let $m_A(x) \in \mathbb{F}_p[x]$ denote the minimal polynomial for the matrix A in (b) and conclude that $m_A(x)$ is irreducible of degree f and divides $\Phi_\ell(x)$ in $\mathbb{F}_p[x]$.

    (d) In particular, prove that $\Phi_\ell(x)$ is irreducible modulo p if and only if $\ell - 1$ is the smallest power of p which is congruent to 1 modulo ℓ, i.e., p is a primitive root modulo ℓ.

21. Prove that the second elementary row and column operation described before Theorem 21 does not change the determinant of the matrix and the first and third elementary operations multiply the determinant by a unit. Conclude from Theorem 21 that the characteristic polynomial of A differs by a unit from the product of the invariant factors of A. Since both these polynomials are monic by definition, conclude that they are equal (this gives an alternate proof of Proposition 20).

22. In Exercises 22–25, V is an n-dimensional vector space over F with basis $e_1, \ldots, e_n$, $A = (a_{ij})$ is an $n \times n$ matrix over F, and T is the linear transformation of V with $T(e_j) = \sum_{i=1}^n a_{ij} e_i$, which makes V an $F[x]$-module. Let $\xi_1, \ldots, \xi_n$ be a basis of the free $F[x]$-module $F[x]^n$ and let $\varphi\colon F[x]^n \to V$ be the surjective $F[x]$-module homomorphism with $\varphi(\xi_i) = e_i$. Show that the elements

$$v_j = -a_{1j}\xi_1 - \cdots - a_{j-1,j}\xi_{j-1} + (x - a_{jj})\xi_j - a_{j+1,j}\xi_{j+1} - \cdots - a_{nj}\xi_n$$

    for $j = 1, 2, \ldots, n$ are elements of the kernel of φ.

23. (a) Show that $x\xi_j = v_j + f_j$ where $f_j \in F\xi_1 + \cdots + F\xi_n$ is an element in the F-vector space spanned by $\xi_1, \ldots, \xi_n$.

    (b) Show that

$$F[x]\xi_1 + \cdots + F[x]\xi_n = (F[x]v_1 + \cdots + F[x]v_n) + (F\xi_1 + \cdots + F\xi_n).$$

24. Show that $v_1, v_2, \ldots, v_n$ generate the kernel of φ. [Use the previous result to show that any element of $\ker \varphi$ is the sum of an element in the module generated by $v_1, v_2, \ldots, v_n$ and an element of the form $b_1\xi_1 + \cdots + b_n\xi_n$ where the b_i are elements of F. Then show that such an element is in $\ker \varphi$ only if all the b_i are 0, since $e_1, \ldots, e_n$ are a basis for V over F.]

25. Show that the generators $v_1, v_2, \ldots, v_n$ of $\ker \varphi$ have corresponding relations matrix

$$\begin{pmatrix} x - a_{11} & -a_{21} & \ldots & -a_{n1} \\ -a_{12} & x - a_{22} & \ldots & -a_{n2} \\ \vdots & \vdots & & \vdots \\ -a_{1n} & -a_{2n} & \ldots & x - a_{nn} \end{pmatrix} = xI - A^t.$$

Practice problems.

1. Let $A = \begin{pmatrix} 2 & -1 \\ 1 & 4 \end{pmatrix} \in \mathrm{M}_2(\mathbb{Q})$. Compute the characteristic polynomial $c_A(x)$ and the minimal polynomial $m_A(x)$, list the invariant factors of A, and write down the rational canonical form of A.

2. Find the companion matrix of the polynomial $p(x) = x^3 - 2x^2 + 5x - 3 \in \mathbb{Q}[x]$. Verify directly that its characteristic polynomial equals $p(x)$.

3. Suppose a 6×6 matrix A over $\mathbb{Q}$ has invariant factors

$$x-1, \qquad (x-1)(x+2), \qquad (x-1)(x+2)^2.$$

Compute $c_A(x)$ and $m_A(x)$, give $\dim_{\mathbb{Q}} V$ where $V = \mathbb{Q}^6$ viewed as an $\mathbb{Q}[x]$-module via A, and write the rational canonical form of A as a block-diagonal matrix of companion matrices.

4. The list $x+1,\ x^2+1,\ (x+1)(x^2+1)$ is proposed as the set of invariant factors of some matrix over $\mathbb{Q}$. Explain why this list is NOT a valid list of invariant factors, and give the smallest correction that makes it valid (keeping the same elementary divisors).

5. Over $\mathbb{F} = \mathbb{Q}$, let $T : V \to V$ be a linear operator with $c_T(x) = (x^2+1)^2$ and $m_T(x) = x^2+1$. Determine all possible lists of invariant factors of T and, for each, write the rational canonical form.

6. Determine whether the matrices

$$A = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 2 \end{pmatrix}, \qquad B = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}$$

are similar over $\mathbb{Q}$ by computing the invariant factors (equivalently the rational canonical form) of each.

7. Let $A \in \mathrm{M}_4(\mathbb{Q})$ have $c_A(x) = (x-3)^4$ and $m_A(x) = (x-3)^2$. List every possible list of invariant factors consistent with this data, and for each give the rational canonical form. State how many similarity classes of such matrices exist.

8. Put the matrix

$$M = xI - \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} x-1 & -1 \\ 0 & x-1 \end{pmatrix} \in \mathrm{M}_2(\mathbb{Q}[x])$$

into Smith normal form over $\mathbb{Q}[x]$, and read off the invariant factors and the rational canonical form of $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$.

9. Use the Cayley–Hamilton theorem to express A^{-1} as a polynomial in A for $A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} \in \mathrm{M}_2(\mathbb{Q})$, after first computing $c_A(x)$.

Additional exercises.

1. Let T be a linear operator on a finite-dimensional $\mathbb{F}$-vector space V, making V an $\mathbb{F}[x]$-module with x acting as T. Prove that V is a torsion $\mathbb{F}[x]$-module, and explain why $\mathrm{Ann}_{\mathbb{F}[x]}(V) = \langle m_T(x) \rangle$. Deduce that $m_T(x)$ divides $c_T(x)$ and that they share the same irreducible factors.

2. Let $A \in \mathrm{M}_n(\mathbb{F})$. Prove that $c_A(x) = m_A(x)$ if and only if A has exactly one invariant factor, if and only if $V = \mathbb{F}^n$ is a cyclic $\mathbb{F}[x]$-module (i.e. there exists v with $V = \mathbb{F}[x]\,v$). Such an A is called nonderogatory; describe its rational canonical form.

3. Let $A \in \mathrm{M}_n(\mathbb{F})$ with invariant factors $a_1(x) \mid a_2(x) \mid \cdots \mid a_k(x)$. Prove the Cayley–Hamilton theorem $c_A(A) = 0$ directly from the relation $m_A(x) = a_k(x)$ and $m_A(x) \mid c_A(x)$, and show that $c_A(x) = a_1(x)a_2(x)\cdots a_k(x)$.

4. Suppose $\mathbb{F} \subseteq K$ is a field extension and $A, B \in \mathrm{M}_n(\mathbb{F})$. Prove that A and B are similar over K if and only if they are similar over $\mathbb{F}$. (Hint: invariant factors are computed by the Smith normal form of $xI - A$ over the PID $\mathbb{F}[x]$, and this computation is unaffected by enlarging the field.)

5. Let T be a nilpotent operator on a 5-dimensional $\mathbb{Q}$-vector space with $m_T(x) = x^3$. Determine all possible lists of invariant factors of T, write the rational canonical form for each, and count the number of similarity classes.

Commutative-diagram exercises.

1. Let V be a finite-dimensional $\mathbb{F}$-vector space and $T \in \mathrm{End}_{\mathbb{F}}(V)$, giving V the structure of an $\mathbb{F}[x]$-module. Let $S \in \mathrm{End}_{\mathbb{F}}(W)$ likewise make W an $\mathbb{F}[x]$-module. Show that an $\mathbb{F}$-linear map $\varphi : V \to W$ is a homomorphism of $\mathbb{F}[x]$-modules if and only if the square

$$\begin{array}{ccc} V & \xrightarrow{T} & V \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\varphi} \\ W & \xrightarrow[S]{} & W \end{array}$$

commutes, i.e. $\varphi T = S\varphi$. Deduce that $A, B \in \mathrm{M}_n(\mathbb{F})$ are similar iff $\mathbb{F}^n_A \cong \mathbb{F}^n_B$ as $\mathbb{F}[x]$-modules.

2. Let $A \in \mathrm{M}_n(\mathbb{F})$ have invariant factors $a_1(x) \mid \cdots \mid a_k(x)$, so the structure theorem gives an $\mathbb{F}[x]$-module isomorphism φ filling in

$$\mathbb{F}^n \xrightarrow[\cong]{\varphi} \bigoplus_{i=1}^{k} \mathbb{F}[x]/\langle a_i(x)\rangle.$$

Show that, under any choice of basis realizing φ, the matrix of the operator $x \cdot (-)$ on the right-hand summand $\mathbb{F}[x]/\langle a_i(x)\rangle$ (with respect to the basis $1, x, \ldots, x^{\deg a_i - 1}$) is the companion matrix of $a_i(x)$, and hence that A is similar to the corresponding rational canonical form.

3. For a fixed monic $p(x) \in \mathbb{F}[x]$ of degree d with companion matrix $C = C(p)$, let $T = x \cdot (-)$ on $U = \mathbb{F}[x]/\langle p(x)\rangle$. Show that the $\mathbb{F}$-linear map $\psi : \mathbb{F}[x]/\langle p(x)\rangle \to U$ sending $\overline{1} \mapsto \overline{1}$ extends to an $\mathbb{F}[x]$-module isomorphism, and that it makes

$$\begin{array}{ccc} \mathbb{F}[x]/\langle p(x)\rangle & \xrightarrow{x\,\cdot} & \mathbb{F}[x]/\langle p(x)\rangle \\ {\scriptstyle\psi}\downarrow{\scriptstyle\cong} & & {\scriptstyle\cong}\downarrow{\scriptstyle\psi} \\ U & \xrightarrow[T]{} & U \end{array}$$

commute. Conclude $m_C(x) = c_C(x) = p(x)$.

4. Let $A, B \in \mathrm{M}_n(\mathbb{F})$ be similar, say $B = P^{-1}AP$ for some invertible P. Writing $\mathbb{F}^n_A$ and $\mathbb{F}^n_B$ for the two $\mathbb{F}[x]$-module structures, show that left multiplication by P^{-1} fits into a commuting square

$$\begin{array}{ccc} \mathbb{F}^n_A & \xrightarrow{A} & \mathbb{F}^n_A \\ {\scriptstyle P^{-1}\cdot}\downarrow & & \downarrow{\scriptstyle P^{-1}\cdot} \\ \mathbb{F}^n_B & \xrightarrow[B]{} & \mathbb{F}^n_B \end{array}$$

and is therefore an $\mathbb{F}[x]$-module isomorphism. Conclude that similar matrices have the same invariant factors and hence the same rational canonical form.

12.3 The Jordan Canonical Form

Throughout this section F is a field, V is a finite-dimensional F-vector space, and $T \in \mathrm{End}_F(V)$ is a linear transformation; we identify T with its matrix $A \in \mathrm{M}_n(F)$ in a chosen basis. As in §12.2 we make V into a module over the polynomial ring $F[x]$ by letting x act as T:

$$p(x) \cdot v \;=\; p(T)\,v, \qquad p(x) \in F[x],\ v \in V.$$

Because $F[x]$ is a P.I.D. and V is a finitely generated torsion $F[x]$-module (it is killed by $c_T(x)$), the structure theorem applies. In §12.2 the invariant-factor decomposition produced the rational canonical form, which exists over *every* field. The Jordan canonical form is what the *elementary divisor* decomposition produces, and it exists precisely when $c_T(x)$ *splits* into linear factors over F — automatically so when F is algebraically closed, e.g. $F = \mathbb{C}$.

Elementary divisors that are prime powers

Recall the elementary divisor form of the structure theorem: a finitely generated torsion $F[x]$-module V decomposes as

$$V \;\cong\; \bigoplus_{i} F[x]/\big(p_i(x)^{a_i}\big),$$

where the $p_i(x)$ are monic irreducibles and the prime powers $p_i(x)^{a_i}$ are the *elementary divisors* of V (equivalently, of T). The minimal polynomial $m_T(x)$ is the least common multiple of the elementary divisors and the characteristic polynomial $c_T(x)$ is their product. When $c_T(x)$ splits over F, every irreducible $p_i(x)$ is *linear*, say $p_i(x) = x - \lambda$, so every elementary divisor has the shape $(x-\lambda)^k$. The key computation is to find the matrix of T on a single cyclic summand $F[x]/\big((x-\lambda)^k\big)$.

Definition 12.3.1 (Jordan block)**.** For $\lambda \in F$ and $k \geq 1$, the *Jordan block* of size k with eigenvalue λ is the $k \times k$ matrix

$$J_k(\lambda) \;=\; \begin{pmatrix} \lambda & 1 & & \\ & \lambda & \ddots & \\ & & \ddots & 1 \\ & & & \lambda \end{pmatrix} \;=\; \lambda I_k + N_k,$$

having λ on the diagonal, 1 on the first superdiagonal, and 0 elsewhere; here $N_k = J_k(0)$ is the nilpotent shift with $N_k^k = 0$ but $N_k^{k-1} \neq 0$.

Proposition 12.3.2 (A cyclic summand is a Jordan block)**.** *The $F[x]$-module $W = F[x]/\big((x-\lambda)^k\big)$ is k-dimensional over F, and with respect to the ordered basis*

$$\bar{e}_1 = \overline{(x-\lambda)^{k-1}}, \quad \bar{e}_2 = \overline{(x-\lambda)^{k-2}}, \quad \ldots, \quad \bar{e}_k = \overline{1},$$

the matrix of multiplication by x (that is, of T) is exactly the Jordan block $J_k(\lambda)$.

Proof. Set $u = x - \lambda$, a nilpotent operator on W with $u^k = 0$, $u^{k-1} \neq 0$. The classes $\bar{e}_j = \overline{u^{k-j}}$ for $j = 1, \ldots, k$ form an F-basis. Since $x = \lambda + u$, we have $x \cdot \bar{e}_j = \lambda\,\bar{e}_j + u \cdot \bar{e}_j$. Now $u \cdot \bar{e}_j = \overline{u^{k-j+1}} = \bar{e}_{j-1}$ for $j \geq 2$, while $u \cdot \bar{e}_1 = \overline{u^k} = 0$. Hence $T\bar{e}_1 = \lambda \bar{e}_1$ and $T\bar{e}_j = \bar{e}_{j-1} + \lambda \bar{e}_j$ for $j \geq 2$, which is column-by-column the matrix $J_k(\lambda) = \lambda I + N_k$. □

Assembling the cyclic summands block-diagonally gives the central definition and existence theorem.

Definition 12.3.3 (Jordan canonical form)**.** A matrix is in *Jordan canonical form* if it is block diagonal,

$$J \;=\; \operatorname{diag}\big(J_{k_1}(\lambda_1),\; J_{k_2}(\lambda_2),\; \ldots,\; J_{k_t}(\lambda_t)\big),$$

each diagonal block a Jordan block. The eigenvalues λ_i need not be distinct: each elementary divisor $(x-\lambda_i)^{k_i}$ contributes one block $J_{k_i}(\lambda_i)$.

Theorem 12.3.4 (Existence and uniqueness of the Jordan form)**.** *Let $A \in \mathrm{M}_n(F)$ and suppose $c_A(x)$ splits into linear factors over F (e.g. F algebraically closed). Then A is similar to a matrix J in Jordan canonical form. The form J is unique up to the order of the blocks: the multiset of Jordan blocks $\{\, J_{k_i}(\lambda_i) \,\}$ is determined by A, being in bijection with the elementary divisors $(x-\lambda_i)^{k_i}$ of A. Two such matrices are similar if and only if they have the same Jordan form up to a rearrangement of blocks.*

Proof. Splitting of $c_A(x)$ forces every irreducible factor of every elementary divisor to be linear, so the elementary divisors are $(x-\lambda_i)^{k_i}$. The structure theorem gives $V \cong \bigoplus_i F[x]/\big((x-\lambda_i)^{k_i}\big)$ as $F[x]$-modules, and Proposition 12.3.2 identifies the matrix of x on the i-th summand as $J_{k_i}(\lambda_i)$. Block-diagonalizing over the summands yields J. Uniqueness of the elementary divisors (structure theorem) is exactly uniqueness of the block multiset; and similarity of matrices is the same as $F[x]$-module isomorphism of the associated modules, which is governed by the elementary divisors. □

The change of basis realizing the similarity is the square below: P is the matrix whose columns are a *Jordan basis* (the bases of the cyclic summands strung together).

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & V \\ {\scriptstyle P^{-1}}\downarrow\cong & & \cong\downarrow{\scriptstyle P^{-1}} \\ V & \xrightarrow[\;J\;]{} & V \end{array} \qquad \text{i.e.} \qquad J = P^{-1}AP.$$

Diagram explanation. Objects: All four corners are the same vector space V over F, but the two on the bottom row are V coordinatized by the Jordan basis, while the two on the top are V coordinatized by the original basis. The square lives inside $\mathrm{End}_F(V)$; every vertex is the same abstract space, only the choice of basis differs.

Arrows: The top horizontal is T (the original linear map, matrix A in the chosen basis). The bottom horizontal is J (the same map in the Jordan basis). The two vertical arrows are both P^{-1}, where $P \in \mathrm{M}_n(F)$ is the change-of-basis matrix whose columns list the Jordan basis vectors; P^{-1} is the coordinate-change isomorphism sending the original-basis expression to the Jordan-basis expression.

What commutes: Going right-then-down equals going down-then-right: $P^{-1} \circ T = J \circ P^{-1}$, i.e. $J = P^{-1}AP$.

Why it commutes: Take any $v \in V$. Top-then-right: T acts on v to give Tv, then P^{-1} recoordinatizes to $P^{-1}(Tv)$. Down-then-right: P^{-1} recoordinatizes v to $P^{-1}v$, then J acts to give $J(P^{-1}v) = P^{-1}AP \cdot P^{-1}v = P^{-1}(Av) = P^{-1}(Tv)$. These agree because $P^{-1}AP = J$ is exactly the relation that defines conjugate matrices.

Why this matters here: This square is the proof in miniature that A is *similar* to J: similarity of matrices is precisely the existence of an invertible P making this square commute. It also shows the Jordan form J is not just an abstract object but a concrete matrix obtained by conjugating A by the Jordan basis matrix P.

Concrete example: For $A = \left(\begin{smallmatrix} 7 & 1 \\ -4 & 3 \end{smallmatrix}\right)$ with Jordan form $J_2(5)$, take any v_2 with $(A - 5I)v_2 \neq 0$ (e.g. $v_2 = e_1$) and $v_1 = (A - 5I)v_2$ (here $v_1 = (2, -4)^{\mathsf{T}}$), so that $Pe_1 = v_1$ and $Pe_2 = v_2$; the square commutes with $P = [v_1 \,|\, v_2]$ and $P^{-1}AP = \left(\begin{smallmatrix} 5 & 1 \\ 0 & 5 \end{smallmatrix}\right)$.

Common pitfall: Students read the vertical arrows as saying "V on top *is different from* V on the bottom." They are the same space; the arrows record a recoordinatization, not an injection. Equality $J = P^{-1}AP$ does not mean $T = J$; it means T and J are conjugate (similar), hence represent the same linear map in two different bases.

Takeaway: The point of this diagram is that similarity of matrices is a basis-change statement, and the Jordan form is the result of choosing the Jordan basis as the new coordinate system.

Reading off invariants from the Jordan form

Once J is known, every classical invariant of A is visible at a glance.

Proposition 12.3.5 (Spectral data from the blocks)**.** *Let $J = \mathrm{diag}\left(J_{k_1}(\lambda_1), \ldots, J_{k_t}(\lambda_t)\right)$ be the Jordan form of A. For a scalar λ, group the blocks with eigenvalue λ and let their sizes be $k^{(1)} \geq k^{(2)} \geq \cdots \geq k^{(m_\lambda)}$. Then:*

1. *the* characteristic polynomial *is $c_A(x) = \prod_\lambda (x - \lambda)^{d_\lambda}$, where $d_\lambda = \sum_j k^{(j)}$ is the sum of the sizes of the λ-blocks (the* algebraic multiplicity*);*
2. *the* minimal polynomial *is $m_A(x) = \prod_\lambda (x - \lambda)^{k^{(1)}}$, the exponent being the size of the* largest *λ-block;*
3. *the* geometric multiplicity $\dim \ker(A - \lambda I) = m_\lambda$ *equals the* number *of λ-blocks;*
4. *A is diagonalizable over $F \iff$ every block has size $1 \iff m_A(x)$ is squarefree (a product of distinct linear factors).*

Proof. Each $J_k(\lambda)$ is upper triangular with λ on the diagonal, so its characteristic polynomial is $(x - \lambda)^k$; multiplying over blocks gives (1). Since $J_k(\lambda) = \lambda I + N_k$ with $N_k^k = 0$, $N_k^{k-1} \neq 0$, the minimal polynomial of one block is $(x - \lambda)^k$, and the minimal polynomial of a block diagonal matrix is the l.c.m. of the block minimal polynomials; grouping by λ gives (2). For (3), $(J_k(\lambda) - \lambda I) = N_k$ has a 1-dimensional kernel, so

each λ-block contributes exactly one eigenvector and $\dim\ker(A-\lambda I)$ counts the λ-blocks. Statement (4) is the case where all $k^{(j)}=1$, equivalent by (2) to m_A squarefree. $\square$

Worked Example 12.3.6 (Reading invariants off a given Jordan form)**.** Let $J=\operatorname{diag}\big(J_3(2),\,J_2(2),\,J_1(2),\,J_2(5)\big)$, an 8×8 matrix over $\mathbb{Q}$. Find $c_J(x)$, $m_J(x)$, the algebraic and geometric multiplicities of each eigenvalue, and decide whether J is diagonalizable.

Recognition. Proposition 12.3.5: every invariant is read directly from the block sizes, grouped by eigenvalue.

Solution. The eigenvalue 2 has blocks of sizes $3,2,1$ and the eigenvalue 5 has a single block of size 2.

- Algebraic multiplicities: $d_2=3+2+1=6$, $d_5=2$. Total $8=n$, a sanity check. Hence $c_J(x)=(x-2)^6(x-5)^2$.
- Minimal polynomial: largest 2-block has size 3, largest 5-block has size 2, so $m_J(x)=(x-2)^3(x-5)^2$.
- Geometric multiplicities: number of 2-blocks $=3$, number of 5-blocks $=1$. So $\dim\ker(J-2I)=3$, $\dim\ker(J-5I)=1$.
- Diagonalizable? No: m_J is not squarefree (it has $(x-2)^3$), equivalently there are blocks of size >1.

Sanity check: $\deg c_J=6+2=8=n$ and $\deg m_J=3+2=5\le 8$, and $m_J\mid c_J$, all as required.

Worked Example 12.3.7 (From elementary divisors to the Jordan form)**.** A $\mathbb{Q}[x]$-module V has elementary divisors $(x-1)^2,\ (x-1),\ (x+3)^3$. Write the Jordan form of the operator "multiplication by x" and its two polynomials.

Recognition. Each elementary divisor $(x-\lambda)^k$ is one Jordan block $J_k(\lambda)$ (Theorem 12.3.4); the polynomials come from Proposition 12.3.5.

Solution. The blocks are $J_2(1),\ J_1(1),\ J_3(-3)$, so

$$J=\operatorname{diag}\big(J_2(1),\,J_1(1),\,J_3(-3)\big)=\begin{pmatrix}1&1&&&&\\&1&&&&\\&&1&&&\\&&&-3&1&\\&&&&-3&1\\&&&&&-3\end{pmatrix}.$$

Then $c_J(x)=(x-1)^{2+1}(x+3)^3=(x-1)^3(x+3)^3$ (degree 6 = size of V), and $m_J(x)=\operatorname{lcm}\big((x-1)^2,(x-1),(x+3)^3\big)=(x-1)^2(x+3)^3$. Sanity check: the eigenvalue 1 has two blocks, so $\dim\ker(J-I)=2$, while -3 has one block.

Generalized eigenspaces

The block structure at a fixed eigenvalue lives inside a single T-invariant subspace.

Definition 12.3.8 (Generalized eigenspace)**.** For an eigenvalue λ of T with algebraic multiplicity d_λ, the *generalized eigenspace* is

$$K_\lambda \;=\; \ker\big((T-\lambda I)^{d_\lambda}\big) \;=\; \{\, v\in V : (T-\lambda I)^k v=0 \text{ for some } k \,\}.$$

Theorem 12.3.9 (Primary / generalized eigenspace decomposition)**.** *If $c_T(x)=\prod_{i=1}^{r}(x-\lambda_i)^{d_i}$ splits over F (distinct λ_i), then*

$$V \;=\; K_{\lambda_1}\oplus K_{\lambda_2}\oplus\cdots\oplus K_{\lambda_r},$$

each K_{λ_i} is T-invariant with $\dim K_{\lambda_i}=d_i$, and the restriction $(T-\lambda_i I)\big|_{K_{\lambda_i}}$ is nilpotent. The Jordan blocks with eigenvalue λ_i are precisely the Jordan form of this nilpotent restriction, shifted by λ_i.

Proof. This is the primary decomposition: K_{λ_i} is the $(x-\lambda_i)$-primary component of the $F[x]$-module V, i.e. the sum of the cyclic summands whose elementary divisor is a power of $(x-\lambda_i)$. The summands corresponding to distinct primes are independent, giving the direct sum, and $\dim K_{\lambda_i}$ is the sum of the sizes of the λ_i-blocks, namely d_i. On K_{λ_i} the operator $x-\lambda_i$ acts as $\bigoplus J_k(0)=$ nilpotent shifts. $\square$

The decomposition is the coproduct/biproduct square: V splits as an internal direct sum and T respects the splitting.

$$\begin{array}{ccc} K_{\lambda_1} \oplus \cdots \oplus K_{\lambda_r} & \xrightarrow{T} & K_{\lambda_1} \oplus \cdots \oplus K_{\lambda_r} \\ \cong\downarrow & & \downarrow\cong \\ V & \xrightarrow[T]{} & V \end{array} \qquad T = \bigoplus_{i=1}^{r} \big(\lambda_i I + N_i\big), \quad N_i \text{ nilpotent.}$$

Diagram explanation. Objects: The bottom row is V as a single $F[x]$-module (with x acting as T). The top row is the same module presented as the internal direct sum $K_{\lambda_1} \oplus \cdots \oplus K_{\lambda_r}$ of its generalized eigenspaces, each K_{λ_i} a T-invariant subspace of dimension d_i (the algebraic multiplicity of λ_i).

Arrows: Both horizontal arrows are T (the same operator on the same underlying set, just expressed in different presentations of V). The two vertical arrows are both the canonical isomorphism $K_{\lambda_1} \oplus \cdots \oplus K_{\lambda_r} \xrightarrow{\sim} V$ sending $(v_1, \ldots, v_r)$ to $v_1 + \cdots + v_r$, which is inverse to the decomposition $V \xrightarrow{\sim} K_{\lambda_1} \oplus \cdots \oplus K_{\lambda_r}$; they exist by the primary decomposition theorem (Chinese Remainder Theorem for $F[x]$-modules).

What commutes: $T \circ (\text{decomp. iso.}) = (\text{decomp. iso.}) \circ T$, i.e. the isomorphism intertwines T on V with T on the direct sum, the latter acting block-diagonally as $\bigoplus_i (\lambda_i I + N_i)$ with N_i nilpotent.

Why it commutes: Each K_{λ_i} is T-invariant (because $(T - \lambda_i I)^{d_i}$ kills it, and T maps each kernel of $(T - \lambda_i I)^k$ to itself). So applying T then decomposing is the same as decomposing then applying T on each summand: a vector $v = v_1 + \cdots + v_r$ with $v_i \in K_{\lambda_i}$ satisfies $Tv = Tv_1 + \cdots + Tv_r$ with $Tv_i \in K_{\lambda_i}$.

Why this matters here: This square is the "global" picture of the Jordan theorem: it says T is block-diagonally $\bigoplus(\lambda_i I + N_i)$, which is the Jordan form statement before choosing bases inside each summand. It organizes the proof of the Jordan canonical form into two steps: (1) split V into the K_{λ_i}; (2) find a Jordan basis inside each nilpotent piece N_i.

Concrete example: For T on $\mathbb{Q}^4$ with $c_T(x) = (x-4)^3(x-5)$, this square shows $V = K_4 \oplus K_5$ with $\dim K_4 = 3$, $\dim K_5 = 1$, and $T|_{K_4} = 4I + N_4$ (nilpotent), $T|_{K_5} = 5I$ (already scalar).

Common pitfall: Students sometimes confuse the direct sum $K_{\lambda_1} \oplus \cdots \oplus K_{\lambda_r}$ with the direct sum of all eigenspaces. The K_{λ_i} are *generalized* eigenspaces (kernels of $(T - \lambda_i I)^{d_i}$, not just $T - \lambda_i I$); the decomposition holds whenever c_T splits, even if T is not diagonalizable.

Takeaway: The point of this diagram is that whenever c_T splits, T block-decomposes along its generalized eigenspaces, reducing the Jordan form problem eigenvalue by eigenvalue to a purely nilpotent problem on each block.

The single-block action makes the nilpotent shift explicit. On $W = F[x]/\big((x-\lambda)^k\big)$ with $u = x - \lambda$, the basis cycles down to zero:

$$\bar{e}_k \xrightarrow{u} \bar{e}_{k-1} \xrightarrow{u} \cdots \xrightarrow{u} \bar{e}_2 \xrightarrow{u} \bar{e}_1 \xrightarrow{u} 0, \qquad u = T - \lambda I.$$

Diagram explanation. Objects: The nodes $\bar{e}_k, \bar{e}_{k-1}, \ldots, \bar{e}_1$ are the F-basis elements of $W = F[x]/\big((x-\lambda)^k\big)$, where $\bar{e}_j = \overline{(x-\lambda)^{k-j}}$. The terminal node 0 is the zero element of W. Each $\bar{e}_j$ is a degree-$(k-j)$ representative of a coset in the quotient module.

Arrows: Every arrow is multiplication by $u = x - \lambda$ (equivalently, the action of $T - \lambda I$ on W). The arrow $\bar{e}_j \xrightarrow{u} \bar{e}_{j-1}$ records $u \cdot \overline{(x-\lambda)^{k-j}} = \overline{(x-\lambda)^{k-j+1}} = \bar{e}_{j-1}$ for $j \geq 2$. The last arrow $\bar{e}_1 \xrightarrow{u} 0$ records $u \cdot \overline{(x-\lambda)^{k-1}} = \overline{(x-\lambda)^k} = \bar{0}$ because $(x-\lambda)^k$ is the defining relation in W.

What commutes: This is a chain, not a square, so commutativity is replaced by termination. The chain is not exact: the composite of two consecutive arrows is u^2, and $u^2 \bar{e}_j = u\bar{e}_{j-1} = \bar{e}_{j-2}$ is nonzero for $j \geq 3$; only the final step $u\bar{e}_1 = 0$ kills the chain. The full nilpotency statement is $u^k = 0$ on W but $u^{k-1} \neq 0$: the chain has exactly k nontrivial steps.

Why it commutes: Each step follows directly from the coset arithmetic in $F[x]/\big((x-\lambda)^k\big)$: multiplying the representative $(x-\lambda)^{k-j}$ by $(x-\lambda)$ gives $(x-\lambda)^{k-j+1}$, which is the representative of $\bar{e}_{j-1}$. The chain terminates at 0 because $(x-\lambda)^k \equiv 0$ in W.

Why this matters here: This chain is a visual proof that the matrix of T on W (in the given basis) is the Jordan block $J_k(\lambda)$: the N_k part (the superdiagonal 1's) is exactly the shift $\bar{e}_j \mapsto \bar{e}_{j-1}$, while λI contributes the diagonal. Understanding this chain is the key step in Proposition 12.3.2 and in building a Jordan basis for any cyclic summand.

Concrete example: Take $k = 3$, $\lambda = 2$, $W = \mathbb{Q}[x]/((x-2)^3)$. Then $\bar{e}_3 = \overline{1}$, $\bar{e}_2 = \overline{x-2}$, $\bar{e}_1 = \overline{(x-2)^2}$, and the chain is $\bar{e}_3 \xrightarrow{u} \bar{e}_2 \xrightarrow{u} \bar{e}_1 \xrightarrow{u} 0$, giving the matrix of $T =$ "multiply by x" as $J_3(2)$.

Common pitfall: Students sometimes reverse the index order and assume $\bar{e}_1$ is the "top" of the chain. In this convention $\bar{e}_k = \overline{1}$ has the *highest* index and u shifts it *down* to $\bar{e}_{k-1}$; the chain decays toward 0, not away from it. Confusing the direction leads to writing the Jordan block transposed (subdiagonal 1's instead of superdiagonal 1's).

Takeaway: The point of this diagram is that the cyclic module $F[x]/((x-\lambda)^k)$ has a basis that $T - \lambda I$ shifts one step at a time until it annihilates, and this shifting pattern is precisely what makes the matrix a Jordan block.

Worked Example 12.3.10 (Generalized eigenspaces by the nullity chain)**.** For $A = \left(\begin{smallmatrix} 7 & 1 \\ -4 & 3 \end{smallmatrix}\right) \in \mathrm{M}_2(\mathbb{Q})$, find the eigenvalues, the generalized eigenspaces, and the Jordan form.

Recognition. c_A has a repeated root, so A may fail to be diagonalizable; use Theorem 12.3.9 and the nullity of powers of $A - \lambda I$.

Solution. $c_A(x) = x^2 - (\operatorname{tr} A)x + \det A = x^2 - 10x + 25 = (x-5)^2$, so the only eigenvalue is $\lambda = 5$ with algebraic multiplicity 2. Compute

$$A - 5I = \begin{pmatrix} 2 & 1 \\ -4 & -2 \end{pmatrix}, \qquad (A-5I)^2 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Thus $\dim\ker(A-5I) = 1$ (rows are dependent) and $\dim\ker(A-5I)^2 = 2$. So $K_5 = \mathbb{Q}^2$ and the nullity chain $0, 1, 2$ jumps by 1 each step: a single Jordan block of size 2. Hence

$$J = J_2(5) = \begin{pmatrix} 5 & 1 \\ 0 & 5 \end{pmatrix}.$$

Sanity check: geometric multiplicity $\dim\ker(A-5I) = 1 =$ number of blocks, and $m_A(x) = (x-5)^2 = c_A(x)$, consistent with one block of full size.

Computing the Jordan form: block sizes from nullities

In practice we do not first compute the rational canonical form. The block sizes at λ are recovered from the nullity sequence of $T - \lambda I$.

Method (Jordan form of a matrix A over a field where c_A splits.)**.** 1. Factor $c_A(x) = \prod_i (x-\lambda_i)^{d_i}$; the λ_i are the eigenvalues with algebraic multiplicities d_i.

2. For each λ set $B = A - \lambda I$ and compute the nullities $r_k = \dim\ker B^{\,k} = n - \operatorname{rank} B^{\,k}$ for $k = 0, 1, 2, \ldots$ until they stabilize ($r_k = d_\lambda$).

3. The number of Jordan blocks of size $\geq k$ is $r_k - r_{k-1}$. Hence the number of blocks of size *exactly* k is $(r_k - r_{k-1}) - (r_{k+1} - r_k) = 2r_k - r_{k-1} - r_{k+1}$.

4. Assemble $\operatorname{diag}(J_k(\lambda), \ldots)$ across all λ.

Caution. The geometric multiplicity $r_1 = \dim\ker(A - \lambda I)$ tells you the *number* of λ-blocks but *not* their sizes. Two operators can share c_A, the eigenvalues, and even the geometric multiplicities yet differ in Jordan form; you must go up the nullity chain. (See the contrast in the next example.)

Worked Example 12.3.11 (Distinguishing forms with equal char. poly)**.** Both A and A' over $\mathbb{Q}$ have $c(x) = (x-2)^4$ and geometric multiplicity $\dim\ker(\cdot - 2I) = 2$. Determine each Jordan form, given the nullity chains $r_\bullet(A) = (0, 2, 4)$ and $r_\bullet(A') = (0, 2, 3, 4)$.

Recognition. Step (3) of the Method: block counts come from *differences* of nullities, not from r_1 alone.

Solution. For A: $r_0, r_1, r_2 = 0, 2, 4$. Blocks of size ≥ 1: $r_1 - r_0 = 2$; size ≥ 2: $r_2 - r_1 = 2$; size ≥ 3: $r_3 - r_2 = 0$ (the chain has stabilized at $r_2 = 4 = d_2$). So two blocks of size 2:

$$J(A) = \operatorname{diag}\big(J_2(2),\, J_2(2)\big) = \begin{pmatrix} 2 & 1 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 1 \\ 0 & 0 & 0 & 2 \end{pmatrix}, \qquad m_A(x) = (x-2)^2.$$

For A': $r_0, r_1, r_2, r_3 = 0, 2, 3, 4$. Blocks of size ≥ 1: 2; size ≥ 2: $r_2 - r_1 = 1$; size ≥ 3: $r_3 - r_2 = 1$; size ≥ 4: $r_4 - r_3 = 0$ (stabilized at $r_3 = 4 = d_2$). So one block of size 3 and one of size 1:

$$J(A') = \operatorname{diag}\big(J_3(2),\, J_1(2)\big) = \begin{pmatrix} 2 & 1 & 0 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix}, \qquad m_{A'}(x) = (x-2)^3.$$

So A and A' share $c(x)$ and the geometric multiplicity $r_1 = 2$ but are not similar: their nullity chains first differ at r_2. (This needs $d_2 \geq 4$: when $d_2 = 3$, the value $r_1 = 2$ forces the partition $3 = 2 + 1$.) Sanity check: in each case $\deg m$ is the largest block size, and the partitions $2 + 2$ and $3 + 1$ both account for all of K_2, of dimension $d_2 = 4$.

Worked Example 12.3.12 (Full computation: a 4×4 matrix over $\mathbb{Q}$)**.** Compute the Jordan form, c_A, m_A, and the generalized eigenspace dimensions of

$$A = \begin{pmatrix} 4 & 1 & 1 & 1 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 5 \end{pmatrix} \in \mathrm{M}_4(\mathbb{Q}).$$

Recognition. A is upper triangular, so read c_A off the diagonal, then run the nullity Method at each eigenvalue.

Solution. The diagonal gives $c_A(x) = (x-4)^3(x-5)$, so $\lambda = 4$ (alg. mult. 3) and $\lambda = 5$ (alg. mult. 1).

At $\lambda = 4$: $B = A - 4I = \left(\begin{smallmatrix} 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{smallmatrix}\right)$. This has rank 2 (rows 1 and 4 are independent, rows 2, 3 zero), so $r_1 = 4 - 2 = 2$. Next $B^2 = \left(\begin{smallmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{smallmatrix}\right)$ has rank 1, so $r_2 = 3$; and $r_3 = 3 = d_4$ stabilizes. Block counts: size ≥ 1 is $r_1 = 2$, size ≥ 2 is $r_2 - r_1 = 1$, size ≥ 3 is $r_3 - r_2 = 0$. So at 4 the blocks are $J_2(4)$, $J_1(4)$.

At $\lambda = 5$: algebraic multiplicity 1 forces a single $J_1(5)$.

Therefore

$$J = \operatorname{diag}\big(J_2(4),\, J_1(4),\, J_1(5)\big) = \begin{pmatrix} 4 & 1 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 5 \end{pmatrix},$$

with $c_A(x) = (x-4)^3(x-5)$ and $m_A(x) = (x-4)^2(x-5)$. The generalized eigenspaces have $\dim K_4 = 3$ and $\dim K_5 = 1$, and $V = K_4 \oplus K_5$. Sanity check: $\dim \ker(A - 4I) = r_1 = 2$ matches the two 4-blocks; $\deg m_A = 3 \leq 4 = \deg c_A$ and $m_A \mid c_A$.

Worked Example 12.3.13 (Full computation from a non-triangular matrix)**.** Find the Jordan form and a Jordan basis for

$$A = \begin{pmatrix} \frac{1}{2} & \frac{3}{2} & \frac{1}{2} \\ -3 & 4 & 3 \\ -\frac{1}{2} & \frac{3}{2} & \frac{3}{2} \end{pmatrix} \in \mathrm{M}_3(\mathbb{Q}).$$

Recognition. No shortcut from the diagonal here; compute c_A, then apply the nullity Method and chase a cyclic vector to build P.

Solution. One computes $c_A(x) = (x-1)^2(x-4)$ (trace $= \frac{1}{2} + 4 + \frac{3}{2} = 6 = 1 + 1 + 4$ and $\det A = 4$, consistent). So $\lambda = 1$ (mult. 2), $\lambda = 4$ (mult. 1).

At $\lambda = 1$: $B = A - I = \begin{pmatrix} -\frac{1}{2} & \frac{3}{2} & \frac{1}{2} \\ -3 & 3 & 3 \\ -\frac{1}{2} & \frac{3}{2} & \frac{1}{2} \end{pmatrix}$ has rank 2, so $r_1 = 1$: a single 1-block. Since $d_1 = 2$, that block has size 2, i.e. $J_2(1)$ (one checks $\dim \ker B^2 = 2$).

At $\lambda = 4$: multiplicity 1 gives $J_1(4)$.

Hence

$$J = \operatorname{diag}\big(J_2(1),\, J_1(4)\big) = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 4 \end{pmatrix}, \quad c_A(x) = (x-1)^2(x-4), \quad m_A(x) = (x-1)^2(x-4).$$

To build P: pick v with $Bv \neq 0$ but $B^2 v = 0$ (a generator of the size-2 chain); then $\{\, Bv,\, v \,\}$ is the Jordan basis of K_1 ordered so that $T(Bv) = 1 \cdot Bv$ and $Tv = Bv + 1 \cdot v$. Adjoin an eigenvector w for $\lambda = 4$. With $P = [\, Bv \mid v \mid w \,]$ one gets $P^{-1}AP = J$. Sanity check: $m_A = c_A$ here because every eigenvalue has a single block (the module is cyclic), matching $\deg m_A = 3 = n$.

Worked Example 12.3.14 (A nilpotent operator: Jordan form is all zeros plus shifts)**.** Let $N = \left(\begin{smallmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{smallmatrix}\right)$ over any field F. Find its Jordan form and verify $N^3 = 0$.

Recognition. Nilpotent means the only eigenvalue is 0; the Jordan form is a direct sum of nilpotent shifts $J_k(0)$, decided by the nullity chain.

Solution. $c_N(x) = x^3$, the single eigenvalue 0. Nullities of N^k: $\operatorname{rank} N = 2 \Rightarrow r_1 = 1$; $N^2 = \left(\begin{smallmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{smallmatrix}\right)$ has rank $1 \Rightarrow r_2 = 2$; $N^3 = 0 \Rightarrow r_3 = 3$. The chain $0, 1, 2, 3$ rises by 1 each step: one block of size 3. So N is already $J_3(0)$ and is its own Jordan form, with $m_N(x) = x^3$. Sanity check: $r_1 = 1$ block, $N^3 = 0$ but $N^2 \neq 0$, matching a single size-3 block.

Powers, polynomials, and functions of a Jordan block

Because $J_k(\lambda) = \lambda I + N$ with N nilpotent and commuting with λI, powers and polynomials expand by the binomial theorem with $N^k = 0$.

Proposition 12.3.15 (Powers of a Jordan block)**.** *For $J = J_k(\lambda) = \lambda I + N$ and $n \geq 0$,*

$$J^n \;=\; \sum_{j=0}^{k-1} \binom{n}{j} \lambda^{\,n-j}\, N^{\,j},$$

so the (p, q) entry of J^n is $\binom{n}{q-p}\lambda^{\,n-(q-p)}$ for $q \geq p$ (and 0 for $q < p$); the superdiagonals of J^n carry the binomial coefficients $\binom{n}{j}\lambda^{\,n-j}$.

Proof. λI and N commute, so the binomial theorem gives $J^n = (\lambda I + N)^n = \sum_{j \geq 0} \binom{n}{j} \lambda^{n-j} N^j$; the sum truncates at $j = k - 1$ since $N^k = 0$. The matrix N^j has 1's on the j-th superdiagonal, which places $\binom{n}{j}\lambda^{n-j}$ there. □

Worked Example 12.3.16 (Computing a power of a Jordan block)**.** Compute $J_3(2)^4$ and $J_2(3)^5$.

Recognition. Proposition 12.3.15: the entries are binomial coefficients times powers of the eigenvalue.

Solution. For $J_3(2)$, $k = 3$, $n = 4$, $\lambda = 2$: diagonal $\binom{4}{0}2^4 = 16$, first superdiagonal $\binom{4}{1}2^3 = 4 \cdot 8 = 32$, second superdiagonal $\binom{4}{2}2^2 = 6 \cdot 4 = 24$. So

$$J_3(2)^4 = \begin{pmatrix} 16 & 32 & 24 \\ 0 & 16 & 32 \\ 0 & 0 & 16 \end{pmatrix}.$$

For $J_2(3)$, $n = 5$, $\lambda = 3$: diagonal $3^5 = 243$, superdiagonal $\binom{5}{1}3^4 = 5 \cdot 81 = 405$, giving $J_2(3)^5 = \left(\begin{smallmatrix} 243 & 405 \\ 0 & 243 \end{smallmatrix}\right)$. Sanity check: $\det J_3(2)^4 = 16^3 = (2^4)^3 = 2^{12} = (\det J_3(2))^4 = (2^3)^4$, consistent.

Worked Example 12.3.17 (Minimal polynomial certifies a polynomial identity)**.** Let $A \in \mathrm{M}_5(\mathbb{C})$ have Jordan form $\mathrm{diag}(J_2(2), J_2(2), J_1(2))$. Show $(A-2I)^2 = 0$ but $A - 2I \neq 0$, and find the smallest N with $(A-2I)^N = 0$.

Recognition. By Proposition 12.3.5, $m_A(x)$ has exponent equal to the largest block size; $m_A(A) = 0$ is the defining vanishing relation.

Solution. All eigenvalues equal 2 and the largest block has size 2, so $m_A(x) = (x-2)^2$. The Cayley–Hamilton/minimal relation gives $(A-2I)^2 = 0$. Since there is a block of size 2, $A - 2I = N \neq 0$ (it has a nonzero superdiagonal entry). The smallest such N is the exponent in m_A, namely $N = 2$. Sanity check: the nullity chain at 2 is $r_1 = 3$ (three blocks), $r_2 = 5$; it stabilizes at $k = 2 = \deg m_A$.

Similarity classification over $\mathbb{C}$

The Jordan form turns the (hard) similarity problem into the (easy) comparison of two block multisets.

Corollary 12.3.18 (Similarity invariants)**.** *Over an algebraically closed field F, two matrices in $\mathrm{M}_n(F)$ are similar iff they have the same Jordan form up to block order, equivalently the same elementary divisors, equivalently the same nullities $\dim\ker(A-\lambda I)^k$ for all λ, k. The number of similarity classes with characteristic polynomial $\prod_i (x-\lambda_i)^{d_i}$ equals $\prod_i p(d_i)$, where $p(d)$ is the number of partitions of d.*

Worked Example 12.3.19 (Counting similarity classes)**.** How many similarity classes of 4×4 complex matrices have characteristic polynomial $c(x) = (x-3)^4$? List their minimal polynomials.

Recognition. Corollary 12.3.18: classes $\leftrightarrow$ partitions of the algebraic multiplicity 4; the minimal polynomial exponent is the largest part.

Solution. With a single eigenvalue 3 of multiplicity 4, the classes correspond to partitions of 4, and $p(4) = 5$:

4	:	$J_4(3)$	$m(x) = (x-3)^4$
$3+1$	:	$J_3(3) \oplus J_1(3)$	$m(x) = (x-3)^3$
$2+2$	:	$J_2(3) \oplus J_2(3)$	$m(x) = (x-3)^2$
$2+1+1$	:	$J_2(3) \oplus J_1(3) \oplus J_1(3)$	$m(x) = (x-3)^2$
$1+1+1+1$	:	$3I_4$	$m(x) = (x-3)$

The geometric multiplicities (number of parts) are $1, 2, 2, 3, 4$ respectively, which distinguishes 2+2 from 2+1+1 (both have $m(x) = (x-3)^2$ but 2 vs. 3 blocks). Sanity check: each partition sums to $4 = \deg c$, and the diagonalizable class is the all-ones partition.

Worked Example 12.3.20 (Are these two matrices similar over $\mathbb{C}$?)**.** Decide whether $A = \left(\begin{smallmatrix} 2 & 1 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{smallmatrix}\right)$ and $A' = \left(\begin{smallmatrix} 2 & 0 & 0 \\ 0 & 2 & 1 \\ 0 & 0 & 2 \end{smallmatrix}\right)$ are similar, and whether either is similar to $B = 2I_3$.

Recognition. Corollary 12.3.18: compare Jordan forms (equivalently the multiset of block sizes).

Solution. Both A and A' are $\mathrm{diag}(J_2(2), J_1(2))$ after reordering the blocks — same multiset $\{2, 1\}$ of sizes — so $A \sim A'$. Indeed each has $c(x) = (x-2)^3$, $m(x) = (x-2)^2$, and $\dim\ker(\cdot - 2I) = 2$. By contrast $B = 2I_3$ is $\mathrm{diag}(J_1(2), J_1(2), J_1(2))$ with three size-1 blocks and $m_B(x) = x - 2$ squarefree, so B is *not* similar to A (different block multiset $\{1, 1, 1\} \neq \{2, 1\}$). Sanity check: $A - 2I \neq 0$ while $B - 2I = 0$, so they cannot be conjugate.

Exercises (from the text).

1. Suppose the vector space V is the direct sum of cyclic $F[x]$-modules whose annihilators are $(x-1)(x^2+1)^2$, (x^4-1) and $(x+1)(x^2-1)$. Determine the invariant factors and elementary divisors for V.
2. Prove that if $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of the $n \times n$ matrix A then $\lambda_1^k, \ldots, \lambda_n^k$ are the eigenvalues of A^k for any $k \geq 0$.
3. Use the method of Example 2 above to determine explicit matrices P_1 and P_2 with $P_1^{-1}BP_1$ and $P_2^{-1}CP_2$ in Jordan canonical form. Use this to explicitly construct a matrix Q which conjugates B into C (proving directly that these matrices are similar).

4. Prove that the Jordan canonical form for the matrix

$$\begin{pmatrix} 9 & 4 & 5 \\ -4 & 0 & -3 \\ -6 & -4 & -2 \end{pmatrix}$$

is that stated at the beginning of this section. Explicitly determine a matrix P which conjugates this matrix to its Jordan canonical form. Explain why this matrix cannot be diagonalized.

5. Compute the Jordan canonical form for the matrix

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & -2 \\ 0 & 1 & 3 \end{pmatrix}.$$

6. Determine which of the following matrices are similar:

$$\begin{pmatrix} -1 & 4 & -4 \\ 2 & -1 & 3 \\ 0 & -4 & 3 \end{pmatrix} \quad \begin{pmatrix} -3 & -4 & 0 \\ 2 & 3 & 0 \\ 8 & 8 & 1 \end{pmatrix} \quad \begin{pmatrix} -3 & 2 & -4 \\ 2 & 1 & 0 \\ 3 & -1 & 3 \end{pmatrix} \quad \begin{pmatrix} -1 & 4 & -4 \\ 0 & -3 & 2 \\ 0 & -4 & 3 \end{pmatrix}.$$

7. Determine the Jordan canonical form for the following matrices:

$$\begin{pmatrix} 5 & 4 & 1 \\ -1 & 0 & 0 \\ -3 & -4 & 1 \end{pmatrix} \quad \begin{pmatrix} 3 & 4 & 2 \\ -2 & -3 & -1 \\ -4 & -4 & -3 \end{pmatrix}.$$

8. Prove that the matrices

$$A = \begin{pmatrix} 5 & 6 & 0 \\ -3 & -4 & 0 \\ -2 & 0 & 1 \end{pmatrix} \qquad B = \begin{pmatrix} 3 & -1 & 2 \\ -10 & 6 & -14 \\ -6 & 3 & -7 \end{pmatrix}$$

are similar. Prove that both A and B can be diagonalized and determine explicit matrices P_1 and P_2 with $P_1^{-1}AP_1$ and $P_2^{-1}BP_2$ in diagonal form.

9. Prove that the matrices

$$A = \begin{pmatrix} -8 & -10 & -1 \\ 7 & 9 & 1 \\ 3 & 2 & 0 \end{pmatrix} \qquad B = \begin{pmatrix} -3 & 2 & -4 \\ 4 & -1 & 4 \\ 4 & -2 & 5 \end{pmatrix}$$

both have $(x-1)^2(x+1)$ as characteristic polynomial but that one can be diagonalized and the other cannot. Determine the Jordan canonical form for both matrices.

10. Find all Jordan canonical forms of 2×2, 3×3 and 4×4 matrices over $\mathbb{C}$.

11. Verify that the characteristic polynomial of

$$A = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ -2 & -2 & 0 & 1 \\ -2 & 0 & -1 & -2 \end{pmatrix}$$

is a product of linear factors over $\mathbb{Q}$. Determine the rational and Jordan canonical forms for A over $\mathbb{Q}$.

12. Determine the Jordan canonical form for the matrix

$$\begin{pmatrix} 1 & 2 & 0 & 0 \\ 0 & 1 & 2 & 0 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

13. Determine the Jordan canonical form for the matrix

$$\begin{pmatrix} 3 & 0 & -2 & -3 \\ 4 & -8 & 14 & -15 \\ 2 & -4 & 7 & -7 \\ 0 & 2 & -4 & 3 \end{pmatrix}.$$

14. Prove that the matrices

$$A = \begin{pmatrix} 2 & 0 & 0 & 0 \\ -4 & -1 & -4 & 0 \\ 2 & 1 & 3 & 0 \\ -2 & 4 & 9 & 1 \end{pmatrix} \qquad B = \begin{pmatrix} 5 & 0 & -4 & -7 \\ 3 & -8 & 15 & -13 \\ 2 & -4 & 7 & -7 \\ 1 & 2 & -5 & 1 \end{pmatrix}$$

are similar.

15. Prove that the matrices

$$A = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix} \qquad B = \begin{pmatrix} 5 & 2 & -8 & -8 \\ -6 & -3 & 8 & 8 \\ -3 & -1 & 3 & 4 \\ 3 & 1 & -4 & -5 \end{pmatrix}$$

both have characteristic polynomial $(x-3)(x+1)^3$. Determine whether they are similar and determine the Jordan canonical form for each matrix.

16. Determine the Jordan canonical form for the matrix

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

and determine a matrix P which conjugates this matrix into its Jordan canonical form.

17. Prove that any matrix A is similar to its transpose A^t.

18. Determine all possible Jordan canonical forms for a linear transformation with characteristic polynomial $(x-2)^3(x-3)^2$.

19. Prove that all $n \times n$ matrices with characteristic polynomial $f(x)$ are similar if and only if $f(x)$ has no repeated factors in its unique factorization in $F[x]$.

20. Show that the following matrices are similar in $M_p(\mathbb{F}_p)$ ($p \times p$ matrices with entries from $\mathbb{F}_p$):

$$\begin{pmatrix} 0 & 0 & \dots & 0 & 1 \\ 1 & 0 & \dots & 0 & 0 \\ 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & \dots & 1 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 1 & 1 & 0 & \dots & 0 & 0 \\ 0 & 1 & 1 & \dots & 0 & 0 \\ 0 & 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & 1 \\ 0 & 0 & 0 & \dots & 0 & 1 \end{pmatrix}.$$

21. Show that if $A^2 = A$ then A is similar to a diagonal matrix which has only 0's and 1's along the diagonal.

22. Prove that an $n \times n$ matrix A with entries from $\mathbb{C}$ satisfying $A^3 = A$ can be diagonalized. Is the same statement true over *any* field F?

23. Suppose A is a 2×2 matrix with entries from $\mathbb{Q}$ for which $A^3 = I$ but $A \neq I$. Write A in rational canonical form and in Jordan canonical form viewed as a matrix over $\mathbb{C}$.

24. Prove there are no 3×3 matrices A over $\mathbb{Q}$ with $A^8 = I$ but $A^4 \neq I$.

25. Determine the Jordan canonical form for the $n \times n$ matrix over $\mathbb{Q}$ whose entries are all equal to 1.

26. Determine the Jordan canonical form for the $n \times n$ matrix over $\mathbb{F}_p$ whose entries are all equal to 1 (the answer depends on whether or not p divides n).

27. Determine the Jordan canonical form for the $n \times n$ matrix over $\mathbb{Q}$ whose entries are all equal to 1 except that the entries along the main diagonal are all equal to 0.

28. Determine the Jordan canonical form for the $n \times n$ matrix over $\mathbb{F}_p$ whose entries are all equal to 1 except that the entries along the main diagonal are all equal to 0.

29. Suppose V_i is the generalized eigenspace of T corresponding to eigenvalue λ_i. For any $k \geq 0$, prove that the nullity of $T - \lambda_i$ on the subspace $(T - \lambda_i)^k V_i$ is the same as the nullity of $T - \lambda_i$ on $(T - \lambda_i)^k V$ and equals the number of Jordan blocks for T with eigenvalue λ_i and size greater than k (so for $k = 0$ this gives the number of Jordan blocks).

30. Let λ be an eigenvalue of the linear transformation T on the finite dimensional vector space V over the field F. Let $r_k = \dim_F (T - \lambda)^k V$ be the rank of the linear transformation $(T - \lambda)^k$ on V. For any $k \geq 1$, prove that $r_{k-1} - 2r_k + r_{k+1}$ is the number of Jordan blocks of T corresponding to λ of size k [use Exercise 12 in Section 1]. (This gives an efficient method for determining the Jordan canonical form for T by computing the ranks of the matrices $(A - \lambda I)^k$ for a matrix A representing T, cf. Exercise 31(a) in Section 11.2.)

31. Let N be an $n \times n$ matrix with coefficients in the field F. The matrix N is said to be *nilpotent* if some power of N is the zero matrix, i.e., $N^k = 0$ for some k. Prove that any nilpotent matrix is similar to a block diagonal matrix whose blocks are matrices with 1's along the first superdiagonal and 0's elsewhere.

32. Prove that if N is an $n \times n$ nilpotent matrix then in fact $N^n = 0$.

33. Let A be a strictly upper triangular $n \times n$ matrix (all entries on and below the main diagonal are zero). Prove that A is nilpotent.

34. Prove that the trace of a nilpotent $n \times n$ matrix is 0 (recall the trace of a matrix is the sum of the diagonal elements).

35. For $0 \leq i \leq n$, let d_i be the g.c.d. of the determinants of the $i \times i$ minors of $xI - A$, for A as in Theorem 21 (take the 0×0 minor to be 1). Prove that the ith element along the diagonal of the Smith Normal Form for A is d_i/d_{i-1}. [Show these g.c.d.s do not change under elementary row and column operations.]

36. Let $V = \mathbb{C}^n$ be the usual n-dimensional vector space of n-tuples $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ of complex numbers. Let T be the linear transformation defined by setting $T(\alpha_1, \alpha_2, \ldots, \alpha_n)$ equal to $(0, \alpha_1, \alpha_2, \ldots, \alpha_{n-1})$. Determine the Jordan canonical form for T.

37. Let J be a Jordan block of size n with eigenvalue λ over $\mathbb{C}$.

    (a) Prove that the Jordan canonical form for the matrix J^2 is the Jordan block of size n with eigenvalue λ^2 if $\lambda \neq 0$.

    (b) If $\lambda = 0$ prove that the Jordan canonical form for J^2 has two blocks (with eigenvalues 0) of size $\dfrac{n}{2}, \dfrac{n}{2}$ if n is even and of size $\dfrac{n-1}{2}, \dfrac{n+1}{2}$ if n is odd.

38. Determine necessary and sufficient conditions for a matrix $A \in M_n(\mathbb{C})$ to have a square root, i.e., for there to exist another matrix $B \in M_n(\mathbb{C})$ such that $A = B^2$. [Suppose B is in Jordan canonical form and consider the Jordan canonical form for B^2 using the previous exercise.]

39. Let J be a Jordan block of size n with eigenvalue λ over a field F of characteristic 2. Determine the Jordan canonical form for the matrix J^2. Determine necessary and sufficient conditions for a matrix $A \in M_n(F)$ to have a square root, i.e., for there to exist another matrix $B \in M_n(F)$ such that $A = B^2$.

40. Prove that for all $A, B \in M_n(K)$ and all $\alpha \in K$

    (a) $\|A + B\| \leq \|A\| + \|B\|$

(b) $\|AB\| \leq \|A\| \cdot \|B\|$

(c) $\|\alpha A\| = |\alpha| \cdot \|A\|$.

41. Let R be the radius of convergence of the real or complex power series $G(x)$ (where $R = \infty$ if $G(x)$ converges for all $x \in K$).

(a) Prove that if $\|A\| < R$ then $G(A)$ converges.

(b) Deduce that for *all* matrices the following power series converge:

$$\sin(A) = A - \frac{A^3}{3!} + \frac{A^5}{5!} - \cdots + (-1)^k \frac{A^{2k+1}}{(2k+1)!} + \cdots$$

$$\cos(A) = I - \frac{A^2}{2!} + \frac{A^4}{4!} - \cdots + (-1)^k \frac{A^{2k}}{(2k)!} - \cdots$$

$$\exp(A) = I + A + \frac{A^2}{2!} + \frac{A^3}{3!} + \cdots + \frac{A^k}{k!} + \cdots$$

where I is the $n \times n$ identity matrix.

42. Let P be a nonsingular $n \times n$ matrix.

(a) Prove that $PG(At)P^{-1} = G(PAtP^{-1}) = G(PAP^{-1}t)$. (This implies that, up to a change of basis, it suffices to compute $G(At)$ for matrices A in canonical form.) [Take limits of partial sums to get the first equality. The second equality is immediate because the matrix tI commutes with every matrix.]

(b) Prove that if A is the direct sum of matrices $A_1, A_2, \ldots, A_m$, then $G(At)$ is the direct sum of the matrices $G(A_1t), G(A_2t), \ldots, G(A_mt)$.

(c) Show that if Z is the diagonal matrix with entries $z_1, z_2, \ldots, z_n$ then $G(Zt)$ is the diagonal matrix with entries $G(z_1t), G(z_2t), \ldots, G(z_nt)$.

43. Prove that if A and B are *commuting* matrices then $\exp(A+B) = \exp(A)\exp(B)$. [Treat A and B as commuting indeterminates and deduce this by comparing the power series on the left hand side with the product of the two power series on the right hand side.]

44. Use the preceding exercise to show that if M is any matrix and λ is any element of K then

$$\exp(\lambda It + M) = e^{\lambda t}\exp(M).$$

45. Let N be the $r \times r$ matrix with 1's along the first superdiagonal and zeros elsewhere. Compute the exponential of the following nilpotent $r \times r$ matrix:

$$\text{if } Nt = \begin{pmatrix} 0 & t & & & \\ & 0 & t & & \\ & & \ddots & \ddots & \\ & & & & t \\ & & & & 0 \end{pmatrix} \text{ then } \exp(Nt) = \begin{pmatrix} 1 & t & \frac{t^2}{2!} & \cdots & \cdots & \frac{t^{r-1}}{(r-1)!} \\ & 1 & t & \frac{t^2}{2!} & & \vdots \\ & & \ddots & \ddots & \ddots & \vdots \\ & & & \ddots & \ddots & \frac{t^2}{2!} \\ & & & & 1 & t \\ & & & & & 1 \end{pmatrix}.$$

Deduce that if J is the $r \times r$ elementary Jordan matrix with eigenvalue λ then

$$\exp(Jt) = \begin{pmatrix} e^{\lambda t} & te^{\lambda t} & \frac{t^2}{2!}e^{\lambda t} & \cdots & \cdots & \frac{t^{r-1}}{(r-1)!}e^{\lambda t} \\ & e^{\lambda t} & te^{\lambda t} & \frac{t^2}{2!}e^{\lambda t} & & \vdots \\ & & \ddots & \ddots & \ddots & \vdots \\ & & & \ddots & \ddots & \frac{t^2}{2!}e^{\lambda t} \\ & & & & e^{\lambda t} & te^{\lambda t} \\ & & & & & e^{\lambda t} \end{pmatrix}.$$

[To do the first part use the observation that since Nt is a nilpotent matrix, $\exp(Nt)$ is a *polynomial* in Nt, i.e., all but a finite number of the terms in the power series are zero. To compute the exponential of Jt write Jt as $\lambda It + Nt$ and use Exercise 44 with $M = Nt$.]

46. For the 4×4 matrices D and P given in Example 3 of this section:

$$D = \begin{pmatrix} 1 & 2 & -4 & 4 \\ 2 & -1 & 4 & -8 \\ 1 & 0 & 1 & -2 \\ 0 & 1 & -2 & 3 \end{pmatrix} \qquad P = \begin{pmatrix} 0 & 1 & 2 & 0 \\ 2 & 0 & -2 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

show that, for $E = \exp(P^{-1}DP)$,

$$E = \begin{pmatrix} e & e & 0 & 0 \\ 0 & e & 0 & 0 \\ 0 & 0 & e & e \\ 0 & 0 & 0 & e \end{pmatrix} \quad \text{and} \quad \exp(D) = \begin{pmatrix} e & 2e & -4e & 4e \\ 2e & -e & 4e & -8e \\ e & 0 & e & -2e \\ 0 & e & -2e & 3e \end{pmatrix}.$$

47. Compute the exponential of each of the following matrices:

    (a) the matrix A in Example 2 of this section

    (b) the matrix in Exercise 4 (where you computed the Jordan canonical form and a change of basis matrix)

    (c) the matrix in Exercise 16.

48. Show that $\exp(0) = I$ (here 0 is the zero matrix and I is the identity matrix). Deduce that $\exp(A)$ is nonsingular with inverse $\exp(-A)$ for all matrices $A \in M_n(K)$.

49. Prove that $\det(\exp(A)) = e^{\mathrm{tr}(A)}$, where $\mathrm{tr}(A)$ is the trace of A (the sum of the diagonal entries of A).

50. Fix any $A \in M_n(K)$. Prove that the map

$$K \to GL_n(K) \qquad \text{defined by} \qquad t \mapsto \exp(At)$$

    is a group homomorphism (here K is the additive group of the field). (Note how this generalizes the familiar exponential map from K to $K^\times$, which is the $n = 1$ case. The subgroup $\{\exp(At) \mid t \in K\}$ is called a *1-parameter subgroup* of $GL_n(K)$. These subgroups and the exponential map play an important role in the theory of *Lie groups* — $GL_n(K)$ being a particular example of a Lie group.)

51. Establish the following properties of derivatives:

    (a) If $G(t) = \sum_{k=0}^{\infty} a_k t^k$ then $\dfrac{d}{dt}G(At) = A\sum_{k=1}^{\infty} k a_k (At)^{k-1}$.

    (b) If v is an $n \times 1$ matrix with (constant) entries from K then

$$\frac{d}{dt}\big(G(At)v\big) = \left(\frac{d}{dt}G(At)\right)v.$$

52. Deduce from part (a) of the preceding exercise that

$$\frac{d}{dt}\exp(At) = A\exp(At).$$

53. Prove that $\exp(At)$ is a fundamental matrix of $(*)$ and that if C is the $n \times 1$ constant vector whose entries are $y_1(0), \ldots, y_n(0)$ then $y(t) = \exp(At)C$ is the particular solution to the system $(*)$ satisfying the initial condition $y(0) = C$. (Note how this generalizes the 1-dimensional result that the single differential equation $y' = ay$ has e^{at} as a basis for the 1-dimensional space of solutions and the unique solution to this differential equation satisfying the initial condition $y(0) = c$ is $y = ce^{at}$.) [Use the preceding exercises.]

54. Prove that if M is a fundamental matrix of $(*)$ and if Q is a nonsingular matrix in $M_n(K)$, then MQ is also a fundamental matrix of $(*)$. (The columns of MQ are linear combinations of the columns of M.)

55. In each of Parts (a) to (c) find a fundamental matrix for the system $(*)$, where the coefficient matrix A of $(*)$ is specified.

    (a) A is the matrix in Part (a) of Exercise 47.

    (b) A is the matrix in Part (b) of Exercise 47.

    (c) A is the matrix in Part (c) of Exercise 47.

56. Consider the system $(*)$ whose coefficient matrix A is the matrix D listed in Exercise 46 (and whose fundamental matrix was computed just before the preceding exercise). Find the particular solution to $(*)$ that satisfies the initial condition $y_i(0) = 1$ for $i = 1, 2, 3, 4$.

57. Prove that the matrix, A, of coefficients of the system of n first order equations obtained from $(**)$ is the transpose of the companion matrix of the polynomial $x^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0$.

58. Use the above methods to find a basis for the vector space of solutions to the following differential equations

    (a) $y''' - 3y' + 2y = 0$

    (b) $y'''' + 4y''' + 6y'' + 4y' + y = 0$.

59. Prove that the solution of $(*)$ given by $y_i(t) = 0$ for all $i \in \{1, \ldots, n\}$ (i.e., the zero solution) is globally asymptotically stable if all the eigenvalues of A have negative real parts. [For those unfamiliar with the behavior of the complex exponential function, assume all eigenvalues are real (hence are negative real numbers). Use the explicit nature of the solutions to show that they all tend to zero as $t \to \infty$.]

Practice problems.

1. Let T be a linear operator on a 5-dimensional vector space over $\mathbb{C}$ whose elementary divisors are $(x-2)^3$ and $(x-2)^2$. Write down the Jordan canonical form of T, and read off $c_T(x)$ and $m_T(x)$.

2. Suppose $A \in \mathrm{M}_4(\mathbb{C})$ has characteristic polynomial $c_A(x) = (x-3)^4$ and minimal polynomial $m_A(x) = (x-3)^2$. List all possible Jordan canonical forms of A (up to ordering of the Jordan blocks), and for each give the corresponding list of elementary divisors.

3. Let T be the operator on $\mathbb{C}^6$ given by the Jordan form $J = \operatorname{diag}\big(J_3(1),\, J_2(1),\, J_1(4)\big)$, where $J_k(\lambda)$ denotes the $k \times k$ Jordan block with eigenvalue λ. Determine the eigenvalues of T, the dimension of each eigenspace $\ker(T - \lambda\ \mathrm{id})$, and the dimension of each generalized eigenspace.

4. Compute the Jordan canonical form of

$$A = \begin{pmatrix} 5 & 1 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 5 \end{pmatrix} \in \mathrm{M}_3(\mathbb{C}),$$

   and find $m_A(x)$ and $c_A(x)$.

5. Two matrices $A, B \in \mathrm{M}_4(\mathbb{C})$ both have $c(x) = (x-7)^2(x+1)^2$ and $m(x) = (x-7)(x+1)^2$. Are A and B necessarily similar over $\mathbb{C}$? Justify your answer by exhibiting their Jordan forms.

6. For each integer $k \geq 1$, let $N = J_k(0)$ be the $k \times k$ nilpotent Jordan block. Compute $\operatorname{rank}(N^j)$ for $0 \leq j \leq k$, and explain how the sequence $\dim\ker(N^j)$ determines that N has a single Jordan block.

7. Let $A \in \mathrm{M}_n(\mathbb{C})$ be diagonalizable. Show that every elementary divisor of A has the form $(x-\lambda)^1$, and conclude that the Jordan canonical form of A is diagonal.

8. Find the Jordan canonical form of

$$A = \begin{pmatrix} 2 & 1 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & 2 \end{pmatrix},$$

   by first computing $\dim\ker(A - 2\ \mathrm{id})$ and $\dim\ker\big((A - 2\ \mathrm{id})^2\big)$.

9. Suppose T is an operator on a finite-dimensional $\mathbb{C}$-vector space with $m_T(x) = (x-\lambda)^m$ for a single scalar λ. Show that the size of the largest Jordan block of T equals m, and that $T - \lambda\,\mathrm{id}$ is nilpotent.

Additional exercises.

1. Let T act on a vector space of dimension 7 over $\mathbb{C}$ with eigenvalues $\lambda = 0$ and $\lambda = 5$. Given $\dim\ker(T) = 3$, $\dim\ker(T^2) = 5$, $\dim\ker(T^3) = 6$, $\dim\ker(T^4) = 6$, and $\dim\ker(T - 5\,\mathrm{id}) = 1$, $\dim\ker\big((T-5\,\mathrm{id})^2\big) = 1$, determine the complete list of Jordan block sizes for each eigenvalue and write the Jordan canonical form.
2. Let $A \in \mathrm{M}_n(\mathbb{C})$ with $A^2 = A$ (an idempotent). Using the theory of elementary divisors over $\mathbb{C}$, prove that A is similar to a diagonal matrix whose diagonal entries are 0's and 1's, and express the number of 1's in terms of $\operatorname{rank}(A)$.
3. Prove that a matrix $A \in \mathrm{M}_n(\mathbb{C})$ and its transpose A^{T} have the same Jordan canonical form, and hence are similar over $\mathbb{C}$. (Suggestion: show $J_k(\lambda)$ is similar to $J_k(\lambda)^{\mathsf{T}}$.)
4. Let $\lambda \in \mathbb{C}$ and let $N = J_k(\lambda) - \lambda\,\mathrm{id}$. For an operator T on V with single eigenvalue λ, show that the number of Jordan blocks of size $\geq j$ equals $\dim\ker\big((T-\lambda\,\mathrm{id})^{j}\big) - \dim\ker\big((T-\lambda\,\mathrm{id})^{j-1}\big)$, and use this to recover all block sizes from the ranks of the powers of $T - \lambda\,\mathrm{id}$.
5. Determine, up to similarity over $\mathbb{C}$, all $A \in \mathrm{M}_3(\mathbb{C})$ satisfying $A^3 = \mathrm{id}$ but $A \neq \mathrm{id}$. List the possible Jordan forms and the corresponding elementary divisors.

Commutative-diagram exercises.

1. Let V be a finite-dimensional $\mathbb{C}$-vector space and $T \in \mathrm{End}(V)$ with single eigenvalue λ, and set $N = T - \lambda\,\mathrm{id}$. For each $j \geq 0$ the inclusions of $\ker(N^{j+1})$ and $\ker(N^j)$ into V and the action of N fit into the diagram

$$\begin{array}{ccc} \ker(N^{j+1}) & \xrightarrow{\;N\;} & \ker(N^{j}) \\ \big\downarrow & & \big\downarrow \\ V & \xrightarrow{\;N\;} & V \end{array}$$

   Verify that the diagram commutes, that the top arrow $N\colon \ker(N^{j+1}) \to \ker(N^j)$ is well defined, and explain how the ranks of these maps recover the Jordan block sizes of T.

2. Let $V = V_1 \oplus V_2$ be the decomposition of V into generalized eigenspaces for an operator $T \in \mathrm{End}(V)$ over $\mathbb{C}$ with two distinct eigenvalues, and let $\pi_i\colon V \to V_i$ be the projections. Show that T commutes with each π_i, i.e. that for each i the square

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & V \\ {\scriptstyle\pi_i}\big\downarrow & & \big\downarrow{\scriptstyle\pi_i} \\ V_i & \xrightarrow{\;T|_{V_i}\;} & V_i \end{array}$$

   commutes, and conclude that the Jordan canonical form of T is block-diagonal with respect to $V_1 \oplus V_2$.

3. Let $\varphi\colon V \to W$ be an isomorphism of finite-dimensional $\mathbb{C}$-vector spaces and let $T \in \mathrm{End}(V)$, $S \in \mathrm{End}(W)$ satisfy $S\varphi = \varphi T$, so that

$$\begin{array}{ccc} V & \xrightarrow{\;T\;} & V \\ {\scriptstyle\varphi}\big\downarrow{\scriptstyle\cong} & & {\scriptstyle\cong}\big\downarrow{\scriptstyle\varphi} \\ W & \xrightarrow{\;S\;} & W \end{array}$$

   commutes. Prove that S and T have the same elementary divisors, hence the same Jordan canonical form. Explain why similarity of matrices is exactly this situation with $W = V$ and φ a change of basis.

4. Let $T \in \mathrm{End}(V)$ over $\mathbb{C}$ and fix an eigenvalue λ with $N = T - \lambda\,\mathrm{id}$. The block N restricts to a chain of maps on the kernel filtration; for a fixed j the diagram

$$\begin{array}{ccc} \ker(N^{j})/\ker(N^{j-1}) & \xrightarrow{\;\overline{N}\;} & \ker(N^{j-1})/\ker(N^{j-2}) \\ {\scriptstyle\text{basis}}\big\uparrow & & \big\uparrow{\scriptstyle\text{basis}} \\ \{\,\text{blocks of size} \geq j\,\} & \xrightarrow{\;\text{(shift)}\;} & \{\,\text{blocks of size} \geq j-1\,\} \end{array}$$

indicates the induced map $\overline{N}$ on successive quotients; each vertical arrow matches the blocks listed below it with a basis of the quotient above it (for each block, the image of one vector of a Jordan basis). Prove $\overline{N}$ is injective, and deduce the inequality $\dim\big(\ker(N^j)/\ker(N^{j-1})\big) \le \dim\big(\ker(N^{j-1})/\ker(N^{j-2})\big)$ on the number of Jordan blocks of size $\ge j$.

12.4 Smith Normal Form by Row and Column Operations

Modules by generators and relations

Fix a commutative ring R. Left multiplication by an $m \times n$ matrix A over R defines a homomorphism of R-modules

$$R^n \xrightarrow{A} R^m,$$

whose image AR^n consists of all R-linear combinations of the columns of A. We say the quotient module

$$V \;=\; R^m/AR^n$$

is *presented* by A, and call A a *presentation matrix* for any module isomorphic to it. The rows of A correspond to a chosen set of generators $v_1, \dots, v_m$ of V (the images of the standard basis of R^m), and the columns of A to a complete set of *relations* among them.

Definition 12.4.1 (Presentation matrix)**.** Let V be an R-module with generators $v_1, \dots, v_m$. A column $Y = (y_1, \dots, y_m)^{\mathsf{T}} \in R^m$ with $v_1y_1 + \cdots + v_my_m = 0$ in V is a *relation*. If A is an $m \times n$ matrix whose columns are a complete set of relations — meaning every relation is an R-combination of them — then the map $R^m/AR^n \to V$, $e_i \mapsto v_i$, is an isomorphism, and A is a presentation matrix for V.

Remark 12.4.1. The cyclic group $\mathbb{Z}/5\mathbb{Z}$ is presented over $\mathbb{Z}$ by the 1×1 matrix $[5]$, since $\mathbb{Z}/5\mathbb{Z} = \mathbb{Z}^1/5\mathbb{Z}^1$. More generally a finite abelian group with generators $v_1, \dots, v_m$ and relations read off as the columns of an integer matrix A is exactly $\mathbb{Z}^m/A\mathbb{Z}^n$. The same matrix recipe works verbatim with $R = F[t]$ in place of $\mathbb{Z}$.

Because the choice of generators and relations is not unique, many matrices present the same module. The following operations do not change the isomorphism class — they are the engine of the whole computation.

Proposition 12.4.2 (Operations preserving the presented module)**.** *Let A be an $m \times n$ presentation matrix for V. Each of the following A' presents the same module V:*

1. *$A' = QA$ with $Q \in \mathrm{GL}_m(R)$ (a row change of basis in R^m);*
2. *$A' = AP$ with $P \in \mathrm{GL}_n(R)$ (a column change of basis in R^n);*
3. *A' obtained by deleting a zero column (a trivial relation);*
4. *A' obtained by deleting a row and column that meet at an entry 1 whose row and column are otherwise zero (a generator forced to vanish).*

Proof. Operations (i) and (ii) replace A by QAP with Q, P invertible; these are changes of basis in R^m and R^n, so the cokernel R^m/AR^n is unchanged up to isomorphism. A zero column is the relation $0 = 0$, which says nothing, so (iii) omits it. In (iv) a column equal to e_i is the relation $v_i = 0$; the generator v_i is then useless and its occurrence in other relations is irrelevant, so deleting row i and that column changes neither V nor its presentation. □

The invertible matrices over R that we may use for Q and P are the products of *elementary* matrices: row/column swaps, scaling a row or column by a unit of R, and adding an R-multiple of one row (or column) to another. Over a field every nonzero scalar is a unit and one diagonalizes freely; over $\mathbb{Z}$ the only units are ± 1, and over $F[t]$ the units are the nonzero constants. The point of Smith normal form is that these restricted operations still suffice to diagonalize.

Smith normal form over $\mathbb{Z}$

Theorem 12.4.3 (Diagonalization of integer matrices)**.** *Let A be an $m \times n$ integer matrix. There exist products Q and P of elementary integer matrices so that*

$$A' \;=\; QAP \;=\; \begin{pmatrix} d_1 & & & & \\ & d_2 & & & \\ & & \ddots & & \\ & & & d_k & \\ & & & & 0 \end{pmatrix}$$

is diagonal with positive entries $d_1, d_2, \ldots, d_k$ satisfying the divisibility chain $d_1 \mid d_2 \mid \cdots \mid d_k$. The diagonal need not reach the bottom right corner: if k is less than m and n, the diagonal is padded with zeros.

Proof (the algorithm). Assume $A \neq 0$. The strategy is to maneuver a smallest entry into the upper left corner, clear its row and column, and recurse on what remains; termination rides on a strictly decreasing positive integer.

Step 1. By permuting rows and columns, move a nonzero entry of smallest absolute value to position $(1,1)$; multiply row 1 by -1 if needed so that $a_{11} > 0$.

Step 2. To clear the first column, for each $i > 1$ divide with remainder $a_{i1} = a_{11}q + r$ with $0 \leq r < a_{11}$, and subtract $q \cdot$ (row 1) from row i. This replaces a_{i1} by r. If $r \neq 0$ then $r < a_{11}$, so return to Step 1 (with a strictly smaller pivot). If $r = 0$ a zero has been produced. Repeat with column operations to clear the first row.

Step 3. Once a_{11} is the only nonzero entry in its row and column, suppose some entry b of the remaining block is not divisible by a_{11}. Add that column to column 1; this puts b in the first column, and Step 2's division produces a remainder r with $0 < r < a_{11}$, sending us back to Step 1.

Every return to Step 1 strictly decreases the positive pivot a_{11}, so it can happen only finitely often; the process terminates with a_{11} dividing every entry of the remaining block and being the unique nonzero entry of its row and column. Setting $d_1 = a_{11}$ and recursing on the $(m-1) \times (n-1)$ block yields the diagonal form, and Step 3 guarantees $d_1 \mid d_2 \mid \cdots$. □

Remark 12.4.2. The same proof works over any ring where division with remainder makes the pivot decrease along a well-ordered measure: over $\mathbb{Z}$ that measure is $|a_{11}|$, and over $F[t]$ it is the *degree* of the pivot polynomial. The four-matrix relationship $A' = QAP$ is summarized by the square below, where each arrow is labelled by the matrix defining it.

$$\begin{array}{ccc} R^n & \xrightarrow{\;A\;} & R^m \\ {\scriptstyle P^{-1}}\downarrow\cong & & \cong\downarrow{\scriptstyle Q} \\ R^n & \xrightarrow[\;A'\;]{} & R^m \end{array} \qquad \text{i.e.} \qquad A' = QAP, \quad Q, P \text{ invertible.}$$

Diagram explanation. Objects: All four nodes are the same free R-module ($R = \mathbb{Z}$ or $R = F[t]$ as the context dictates), just viewed in two different bases. The top row uses the *original* bases of R^n (domain) and R^m (codomain); the bottom row uses the *new* bases obtained by the invertible changes P and Q.

Arrows: The top horizontal arrow is the original matrix map $A\colon R^n \to R^m$, $v \mapsto Av$. The bottom horizontal arrow is the Smith-normal-form map $A'\colon R^n \to R^m$, $v \mapsto A'v$. The left vertical arrow is $P^{-1}\colon R^n \to R^n$, an invertible (basis-change) map marked $\cong$; it re-expresses domain vectors in the new basis. The right vertical arrow is $Q\colon R^m \to R^m$, also invertible, re-expressing codomain vectors. Both vertical maps are isomorphisms, not mere inclusions.

What commutes: The square says: going right then down equals going down then right. Explicitly, $Q \circ A = A' \circ P^{-1}$, which is the matrix equation $QA = A'P^{-1}$, rearranged to $A' = QAP$.

Why it commutes: Start with any $v \in R^n$. Along the top-then-right path: $v \mapsto Av \mapsto Q(Av) = QAv$. Along the left-then-bottom path: $v \mapsto P^{-1}v \mapsto A'(P^{-1}v) = QAPP^{-1}v = QAv$. These are equal because

$A' = QAP$, i.e. we *defined* A' to be QAP for the invertible Q, P produced by the Smith algorithm; the diagram simply records this definition as a path equality.

Why this matters here: This square is the key organizing picture for the whole Smith-form argument. It shows that replacing A by $A' = QAP$ is not a trick but a *change of basis*: the module $\operatorname{coker} A = R^m/AR^n$ and the module $\operatorname{coker} A' = R^m/A'R^n$ are isomorphic (via Q on the codomain), so the presented module is unchanged. The diagram makes this conceptual point immediate.

Concrete example: Take $R = \mathbb{Z}$, $m = n = 2$, $A = \left(\begin{smallmatrix} 2 & 6 \\ 4 & 18 \end{smallmatrix}\right)$. With $Q = \left(\begin{smallmatrix} 1 & 0 \\ -2 & 1 \end{smallmatrix}\right)$ and $P = \left(\begin{smallmatrix} 1 & -3 \\ 0 & 1 \end{smallmatrix}\right)$ (both products of elementary matrices: Q performs $R_2 \mapsto R_2 - 2R_1$ and P performs $C_2 \mapsto C_2 - 3C_1$), $QAP = \left(\begin{smallmatrix} 2 & 0 \\ 0 & 6 \end{smallmatrix}\right)$ is diagonal with $2 \mid 6$, and the square commutes: $Q(Av) = A'(P^{-1}v)$ for every $v \in \mathbb{Z}^2$.

Common pitfall: Students often read the vertical arrows as inclusions or think $P = Q$. They are *independent* basis changes: P acts on the domain R^n and Q acts on the codomain R^m; in general $m \neq n$ and there is no reason to expect $P = Q$ or even that they have the same size. Also, the commutativity records a definition ($A' := QAP$), not a condition that must be separately verified once Q and P are chosen.

Takeaway: The point of this diagram is that Smith normal form A' is simply the original map A expressed in new bases for both domain and codomain, so the presented module R^m/AR^n is isomorphic to the far simpler diagonal quotient $R^m/A'R^n$.

Recovering the abelian group

A diagonal presentation matrix reads off the module instantly, because a diagonal relation only couples each generator to itself.

Theorem 12.4.4 (Structure theorem, via Smith form)**.** *Let V be a finitely generated abelian group, presented by an integer matrix in the diagonal form of Theorem 12.4.3 (delete any $d_i = 1$ and any zero column first). Then*

$$V \;\cong\; \mathbb{Z}/d_1\mathbb{Z} \oplus \mathbb{Z}/d_2\mathbb{Z} \oplus \cdots \oplus \mathbb{Z}/d_k\mathbb{Z} \oplus \mathbb{Z}^r,$$

with $d_1 \mid d_2 \mid \cdots \mid d_k$ and $d_i > 1$; the d_i are the invariant factors *and r (the number of zero rows, i.e. generators with no relation) is the free rank. The group is finite iff $r = 0$.*

Proof. After diagonalizing, V is generated by $v_1, \ldots, v_m$ subject precisely to the relations $d_1v_1 = 0, \ \ldots, \ d_kv_k = 0$ (the columns of A'), with $v_{k+1}, \ldots, v_m$ unconstrained. Let C_j be the cyclic subgroup generated by v_j: for $j \leq k$ it is $\mathbb{Z}/d_j\mathbb{Z}$, and for $j > k$ it is infinite cyclic, $\cong \mathbb{Z}$. These generate V. If $w_1 + \cdots + w_m = 0$ with $w_j = v_jy_j \in C_j$, then Y is a relation, hence an integer combination of the columns of A'; this forces $d_j \mid y_j$ for $j \leq k$ and $y_j = 0$ for $j > k$, so each $w_j = 0$. The summands are therefore independent and $V = \bigoplus_j C_j$. Dropping any $d_j = 1$ removes a trivial summand $\mathbb{Z}/1\mathbb{Z} = 0$. □

Worked Example 12.4.5 (Diagonalizing an integer matrix (Artin 14.4.4))**.** Bring $A = \left(\begin{smallmatrix} 1 & 2 & 3 \\ 0 & 4 & 6 \\ 0 & 6 & 6 \end{smallmatrix}\right)$ to Smith normal form and read off the abelian group it presents.

Recognition. Theorem 12.4.3: pivot is already 1 at the top left, so clear its row and column, then recurse on the lower-right 2×2 block.

Solution. The entry $a_{11} = 1$ divides everything, so clear the first row by column operations $C_2 \mapsto C_2 - 2C_1$, $C_3 \mapsto C_3 - 3C_1$ (the first column is already clear):

$$\begin{pmatrix} 1 & 2 & 3 \\ 0 & 4 & 6 \\ 0 & 6 & 6 \end{pmatrix} \longrightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 4 & 6 \\ 0 & 6 & 6 \end{pmatrix}.$$

Now work on $\left(\begin{smallmatrix} 4 & 6 \\ 6 & 6 \end{smallmatrix}\right)$. Move a smallest entry; $C_2 \mapsto C_2 - C_1$ gives $\left(\begin{smallmatrix} 4 & 2 \\ 6 & 0 \end{smallmatrix}\right)$, then swap columns: with smallest entry 2 in the corner the first column is already clear, and $C_2 \mapsto C_2 - 2C_1$ gives $\left(\begin{smallmatrix} 2 & 0 \\ 0 & 6 \end{smallmatrix}\right)$ (and $2 \mid 6$). Hence

$$A' = QAP = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 6 \end{pmatrix}, \qquad d_1 = 1,\ d_2 = 2,\ d_3 = 6.$$

Dropping the $d_1 = 1$ summand, $V \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$. Check: the divisibility $1 \mid 2 \mid 6$ holds, the product $1 \cdot 2 \cdot 6 = 12$ equals $|\det A|$ (expanding, $\det A = 1 \cdot (24 - 36) = -12$), and $|V| = 2 \cdot 6 = 12$ matches.

Worked Example 12.4.6 (From a relation matrix to $\mathbb{Z}/4\mathbb{Z}$ (Artin 14.5.4))**.** The abelian group generated by v_1, v_2, v_3 with the complete set of relations $3v_1+2v_2+v_3 = 8v_1+4v_2+2v_3 = 7v_1+6v_2+2v_3 = 9v_1+6v_2+v_3 = 0$ is presented by the matrix whose columns are these coefficient vectors. Identify the group.

Recognition. Use Proposition 12.4.2: a row/column equal to a standard basis vector lets us delete a generator, collapsing the matrix.

Solution. The presentation matrix is

$$A = \begin{pmatrix} 3 & 8 & 7 & 9 \\ 2 & 4 & 6 & 6 \\ 1 & 2 & 2 & 1 \end{pmatrix}.$$

The third row has a leading 1 (column 1). Clear the rest of that row (column operations) and of that column (row operations), then use the entry 1 to delete generator v_3 and its column (operation (iv)). After clearing one is left, by repeated reductions, with a single relation: the matrix collapses to the 1×1 matrix [4]. (Concretely, column reductions drive the block to $\left(\begin{smallmatrix} 2 & 1 \\ \cdot & \cdot \end{smallmatrix}\right)$, the 1 deletes another generator, and a final division leaves [4].) Hence

$$V \cong \mathbb{Z}/4\mathbb{Z}.$$

Check: A has rank 3, the number of generators, so V has no free part (by contrast, the 2×1 matrix $\left(\begin{smallmatrix} 4 \\ 0 \end{smallmatrix}\right)$ presents $\mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}$, its zero row being a free generator); thus V is finite cyclic of order 4, and indeed gcd of the 3×3 minors of A equals 4.

Smith normal form over $F[t]$

The integer algorithm transports to the polynomial ring $F[t]$ because the division algorithm is available there: the role of $|a_{11}|$ is played by $\deg a_{11}$, and the units (which we may use to scale) are the nonzero constants of F, so we normalize each pivot to be *monic*.

Theorem 12.4.7 (Diagonalization over $F[t]$)**.** *Let A be an $m \times n$ matrix over $R = F[t]$, F a field. There exist products Q, P of elementary R-matrices with $A' = QAP$ diagonal, each nonzero diagonal entry d_i a monic polynomial, and $d_1 \mid d_2 \mid \cdots \mid d_k$. Consequently a finitely generated $F[t]$-module V decomposes as*

$$V \;\cong\; F[t]/(d_1) \oplus \cdots \oplus F[t]/(d_k) \oplus F[t]^{\,r}, \qquad d_1 \mid d_2 \mid \cdots \mid d_k,$$

the d_i being monic of positive degree (the invariant factors of V).

Proof. Run the algorithm of Theorem 12.4.3 with the degree as the size measure. Step 1 moves a nonzero entry of *least degree* to the corner and scales it monic by a unit of F; Step 2 uses polynomial division $a_{i1} = a_{11}q + r$ with $\deg r < \deg a_{11}$ (or $r = 0$) and subtracts $q \cdot$ (row 1); Step 3 imports a non-divisible entry into the first column. Each restart strictly lowers $\deg a_{11}$, a nonnegative integer, so the process halts. The cokernel description and the divisibility chain follow exactly as over $\mathbb{Z}$, with $F[t]/(1) = 0$ dropped; the free part $F[t]^r$ vanishes precisely when V is finite-dimensional over F. □

Worked Example 12.4.8 (Diagonalizing a polynomial matrix (Artin 14.8.2))**.** Over $R = F[t]$ reduce

$$A = \begin{pmatrix} t^2 - 3t + 1 & t - 2 \\ (t-1)^3 & t^2 - 3t + 2 \end{pmatrix}$$

to Smith normal form, and identify the module $V = R^2/AR^2$.

Recognition. Theorem 12.4.7: hunt for the lowest-degree entry to act as pivot; here a degree-1 entry can be turned into a constant, which is a unit.

Solution. The entry $t - 2$ has the least degree. Using column operations one produces a unit (nonzero constant) in a corner — this happens exactly because the gcd of all entries is 1. Swapping it into position $(1, 1)$ and clearing its row and column by the algorithm gives

$$A \;\longrightarrow\; \begin{pmatrix} 1 & 0 \\ 0 & t^3 - 3t^2 + 2t \end{pmatrix}.$$

Drop the row and column of the 1 (Proposition 12.4.2(iv)): V is presented by the 1×1 matrix $[\,g\,]$ with $g(t) = t^3 - 3t^2 + 2t = t(t-1)(t-2)$. Hence $V \cong F[t]/(g)$ is cyclic, and since the factors are pairwise coprime,

$$V \cong F[t]/(t) \,\oplus\, F[t]/(t-1) \,\oplus\, F[t]/(t-2).$$

Check: $\dim_F V = \deg g = 3$, matching the sum $1+1+1$ of the degrees of the three coprime factors; and the single invariant factor g has degree $3 = \dim_F V$, consistent with V being cyclic.

Worked Example 12.4.9 (Invariant factors of a 2×2 polynomial matrix)**.** Over $R = \mathbb{Q}[t]$ put $A = \left(\begin{smallmatrix} t & 0 \\ 0 & t^2 \end{smallmatrix}\right)$ into Smith normal form and decompose $V = R^2/AR^2$. Contrast with $B = \left(\begin{smallmatrix} t & 0 \\ 0 & t-1 \end{smallmatrix}\right)$.

Recognition. Theorem 12.4.7: the diagonal entries are not yet in a divisibility chain unless $d_1 \mid d_2$; if not, fix it with the gcd–lcm trick.

Solution. For A the entries are already diagonal with $t \mid t^2$, so it is in Smith form with invariant factors $d_1 = t$, $d_2 = t^2$. Thus

$$V \cong \mathbb{Q}[t]/(t) \,\oplus\, \mathbb{Q}[t]/(t^2),$$

which is *not* cyclic ($t \mid t^2$ but the two summands persist). For B the diagonal entries t and $t-1$ are coprime, so $t \nmid t-1$ and B is not yet in Smith form. Add column 2 to column 1, then use $\gcd(t, t-1) = 1$: row/column operations produce

$$B \;\longrightarrow\; \begin{pmatrix} 1 & 0 \\ 0 & t(t-1) \end{pmatrix},$$

so $W = R^2/BR^2 \cong \mathbb{Q}[t]/(t(t-1)) \cong \mathbb{Q}[t]/(t) \oplus \mathbb{Q}[t]/(t-1)$ is cyclic with single invariant factor $t(t-1)$. Check: $\dim_{\mathbb{Q}} V = 1+2 = 3 = \deg(t \cdot t^2)$, and $\dim_{\mathbb{Q}} W = 2 = \deg(t(t-1))$; in both cases the dimension equals the sum of the degrees of the invariant factors.

Caution. A diagonal matrix is *not* automatically in Smith normal form: the divisibility chain $d_1 \mid d_2 \mid \cdots$ must hold. The matrix $\left(\begin{smallmatrix} 6 & 0 \\ 0 & 4 \end{smallmatrix}\right)$ presents $\mathbb{Z}/6\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$, but $6 \nmid 4$, so this is not the invariant-factor form. Reduce it: the correct Smith form has $d_1 = \gcd(6,4) = 2$ and $d_2 = \operatorname{lcm}(6,4) = 12$, giving $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}$ (same group of order 24, now in the canonical chain $2 \mid 12$). The same caution applies over $F[t]$ with gcd and lcm of polynomials.

Remark 12.4.3. The two cases of Theorem 12.4.4 and Theorem 12.4.7 are one theorem run over two principal ideal domains. Over $\mathbb{Z}$ the invariant factors d_i are positive integers and V is a finite abelian group (plus a free part); over $F[t]$ they are monic polynomials and V is the data of a linear operator T acting as multiplication by t on a finite-dimensional space. Smith normal form is the single computational device that delivers both the invariant-factor decomposition of a finite abelian group and the rational canonical form of a matrix.

12.5 Jordan Form via Generalized Eigenvectors

Jordan form via generalized eigenvectors

The module derivation of §12.3 produces the Jordan form abstractly, as the elementary-divisor decomposition of V over $F[x]$. Artin gives a hands-on route that never mentions $F[x]$: build the Jordan basis one *chain* at a time out of generalized eigenvectors, reduce the problem to a nilpotent operator, and read the block sizes off the dimensions $\dim \ker(T-\lambda)^i$. Throughout, V is a finite-dimensional vector space over a field F and $T \in \operatorname{End}(V)$; we abbreviate $T - \lambda I$ to $T - \lambda$. We assume the characteristic polynomial $c_T(x)$ splits over F (automatic over $F = \mathbb{C}$); Artin notes this hypothesis is the only place complex scalars are used.

Definition 12.5.1 (Generalized eigenvector and its exponent)**.** A *generalized eigenvector* with eigenvalue λ of T is a nonzero vector x such that $(T-\lambda)^k x = 0$ for some $k > 0$. Its *exponent* is the smallest integer $d \geq 1$ with $(T-\lambda)^d x = 0$. An ordinary eigenvector is the case $d = 1$.

The single observation behind everything is that applying $T - \lambda$ to a generalized eigenvector lowers its exponent by exactly one, so iterating walks x down a ladder to zero. Setting $u_j = (T-\lambda)^j x$ records the rungs.

Proposition 12.5.2 (A Jordan chain spans a T-invariant block)**.** *Let x be a generalized eigenvector of T with eigenvalue λ and exponent d. For $0 \le j \le d-1$ put $u_j = (T-\lambda)^j x$, and let $\mathcal{B} = (u_0, u_1, \dots, u_{d-1})$, $X = \operatorname{Span}\mathcal{B}$. Then X is T-invariant, $\mathcal{B}$ is a basis of X, and the matrix of $T|_X$ in the* reversed *ordered basis $(u_{d-1}, u_{d-2}, \dots, u_0)$ is the Jordan block $J_d(\lambda)$.*

Proof. Because $(T-\lambda)u_j = u_{j+1}$ and $T = \lambda + (T-\lambda)$, we get the action

$$Tu_j = \lambda u_j + u_{j+1} \ (j < d-1), \qquad Tu_{d-1} = \lambda u_{d-1}, \qquad (T-\lambda)^d x = 0.$$

Every Tu_j lies in X, so X is T-invariant. For independence, suppose a nontrivial combination $y = c_j u_j + \cdots + c_{d-1}u_{d-1}$ with leading index j (so $c_j \neq 0$) vanished. Applying $(T-\lambda)^{d-1-j}$ kills every term of higher index and sends u_j to $c_j u_{d-1} = c_j (T-\lambda)^{d-1} x \neq 0$, since x has exponent d. Thus $y \neq 0$, so $\mathcal{B}$ is independent and a basis. Reading the displayed action with the basis listed bottom-up, $u_{d-1} \mapsto u_{d-1}$ scaled by λ and each later u_j acquiring the predecessor u_{j+1}, is column-by-column the matrix $J_d(\lambda) = \lambda I + N_d$, with λ on the diagonal and 1's on the superdiagonal. □

A list $(u_{d-1}, \dots, u_1, u_0)$ as above is a *Jordan chain* of length d: its bottom vector u_{d-1} is a genuine eigenvector, and each vector maps under $T-\lambda$ to the one below it, the last to 0. The diagram is the whole story of a single block.

$$u_0 \xrightarrow{T-\lambda} u_1 \xrightarrow{T-\lambda} \cdots \xrightarrow{T-\lambda} u_{d-1} \xrightarrow{T-\lambda} 0$$

Since the bottom of any chain is an honest eigenvector, every eigenvalue of a generalized eigenvector is a root of $c_T(x)$ (Artin's Corollary 4.7.4).

Diagram explanation. Objects: Each node is a vector in V: $u_j = (T-\lambda)^j x$ for $0 \le j \le d-1$ is a generalized eigenvector with eigenvalue λ and exponent $d-j$ (it is killed by $(T-\lambda)^{d-j}$ but not by any lower power). The terminal node 0 is the zero vector of V, included to record that $(T-\lambda)u_{d-1} = 0$, i.e. u_{d-1} is an ordinary eigenvector.

Arrows: Every arrow labelled $T-\lambda$ is the linear operator $T - \lambda \operatorname{id}_V : V \to V$ applied once. Arrow $u_j \to u_{j+1}$ records the identity $(T-\lambda)u_j = u_{j+1}$; the final arrow $u_{d-1} \to 0$ records $(T-\lambda)u_{d-1} = 0$. These are not a quotient or induced map – they are the original operator evaluated at specific vectors, so no well-definedness check is needed.

What commutes: The sequence is linear (not a square), so the relevant condition is: each arrow carries u_j to exactly u_{j+1}, and the last arrow annihilates u_{d-1}. In exact-sequence language, $\ker(T-\lambda)|_{u_j} = \{0\}$ for $j < d-1$ (each map is injective on the one-dimensional span of u_j), while $u_{d-1} \in \ker(T-\lambda)$.

Why it commutes: Chase the definition: $u_0 = x$, $u_1 = (T-\lambda)x$, $u_2 = (T-\lambda)^2 x$, and so on. Along the top path, one application of $T-\lambda$ sends $u_j = (T-\lambda)^j x$ to $(T-\lambda)^{j+1}x = u_{j+1}$. The chain terminates because x has exponent d: $(T-\lambda)^d x = 0$, so $(T-\lambda)u_{d-1} = (T-\lambda)^d x = 0$.

Why this matters here: This diagram is the entire structural content of the Jordan chain proposition: it shows that the d vectors $u_0, \dots, u_{d-1}$ form a linearly ordered "ladder" under $T-\lambda$, which is exactly the T-action on a Jordan block $J_d(\lambda)$. The rest of the proof (independence of the u_j, T-invariance of their span) unpacks what the diagram compresses.

Concrete example: Take $V = \mathbb{C}^3$, $T = J_3(2)$, $\lambda = 2$, $x = e_3$. Then $T - 2I = N_3$ (the nilpotent 3×3 shift: $N_3 e_1 = 0$ and $N_3 e_j = e_{j-1}$ for $j \ge 2$). The chain is $e_3 \xrightarrow{N_3} e_2 \xrightarrow{N_3} e_1 \xrightarrow{N_3} 0$, corresponding to $u_0 = e_3$, $u_1 = e_2$, $u_2 = e_1$, $d = 3$. The reversed basis (e_1, e_2, e_3) gives back $J_3(2)$ column by column.

Common pitfall: Students sometimes read the arrows as "u_j is sent to u_{j+1} by T," forgetting the $-\lambda$ shift. The operator acting is $T-\lambda$, not T: in the reversed-basis matrix Tu_{d-j} picks up both the scalar λu_{d-j} and the predecessor u_{d-j+1}, which is why the diagonal is λ, not 0. Confusing T with $T-\lambda$ would give the wrong matrix.

Takeaway: The point of this diagram is that $T-\lambda$ walks every Jordan chain stepwise to zero in exactly d steps, making the chain a concrete realization of the abstract Jordan block $J_d(\lambda)$ as a basis of an invariant subspace.

Theorem 12.5.3 (Jordan decomposition; reduction to the nilpotent case)**.** *Let $T \in \mathrm{End}(V)$ with $c_T(x)$ split over F. There is a basis $\mathcal{B}$ of V in which the matrix of T is block diagonal,*

$$J = \operatorname{diag}\big(J_{d_1}(\lambda_1), \dots, J_{d_r}(\lambda_r)\big), \qquad \textstyle\sum_i d_i = \dim V,$$

each block a Jordan block; equivalently every $A \in \mathrm{M}_n(F)$ with split $c_A(x)$ satisfies $P^{-1}AP = J$ for some invertible P. The form J is unique up to the order of the blocks.

Proof sketch (Filippov, after Artin). Induct on $\dim V$, assuming the result for T restricted to any proper invariant subspace. Fix an eigenvalue λ and replace T by $T - \lambda$; this changes no Jordan structure and makes 0 an eigenvalue, so it suffices to build a Jordan basis when 0 is an eigenvalue. Let $K_i = \ker T^i$ and $U_i = \operatorname{im} T^i$. The chains $K_1 \subseteq K_2 \subseteq \cdots$ and $U_1 \supseteq U_2 \supseteq \cdots$ stabilize at some m; put $K = K_m$, $U = U_m$. Both are T-invariant, and $V = K \oplus U$: if $z \in K \cap U$ then $z = T^m v$ and $T^m z = 0$, so $T^{2m}v = 0$; but $K_{2m} = K_m$ forces $T^m v = z = 0$. Since 0 is an eigenvalue, $K \neq 0$, so U is a proper invariant subspace and induction handles $T|_U$. On K the operator T is *nilpotent* ($T^m|_K = 0$), and the remaining content is the nilpotent case.

For a nilpotent T on K, let $N = \ker T$, $W = \operatorname{im} T$. Then $\dim W < \dim K$, so by induction $T|_W$ has Jordan generators $w_1, \dots, w_s$. Lift each to v_i with $Tv_i = w_i$; the chains through the v_i are independent and stack the w_i-chains with one extra rung, after which vectors of N are adjoined to extend these chains to a basis of K (every $v \in K$ differs by an element of N from a vector in the span of the chains, since T maps that span onto W), each added vector giving a 1×1 zero block. Reassembling the λ-blocks for every eigenvalue gives J. Uniqueness follows because the numbers $\dim \ker(T - \lambda)^i$ are similarity invariants and (next subsection) determine the block sizes. □

Remark 12.5.1. The decomposition $V = K \oplus U$ in the proof is the generalized-eigenspace splitting at λ: $K = \ker(T - \lambda)^m$ is the generalized eigenspace K_λ, on which $T - \lambda$ is nilpotent, and U collects the other eigenvalues. The whole space is the direct sum of the K_λ, and the Jordan blocks at λ are exactly the blocks of the nilpotent $T - \lambda$ on K_λ, shifted by λI.

Block sizes from kernel dimensions

We never need an explicit Jordan basis to know the *shape* of J. Fix λ, set $B = T - \lambda$, and let $k_i = \dim \ker B^i$, so $0 = k_0 \leq k_1 \leq k_2 \leq \cdots$ until they stabilize at the algebraic multiplicity d_λ. For a *single* $d \times d$ block with eigenvalue λ, the shift $B = N_d$ has $\dim \ker N_d^i = \min(i, d)$. Summing over all λ-blocks gives the key count.

Method (Block sizes at λ from the kernel-dimension sequence.)**.** Compute $k_i = \dim \ker(T - \lambda)^i = n - \operatorname{rank}(T - \lambda)^i$ for $i = 0, 1, 2, \dots$ until k_i stabilizes. Then:

- the number of Jordan blocks of size $\geq j$ at λ is $k_j - k_{j-1}$;
- hence the number of blocks of size *exactly* j is $(k_j - k_{j-1}) - (k_{j+1} - k_j) = 2k_j - k_{j-1} - k_{j+1}$.

In particular $k_1 = \dim \ker(T - \lambda)$ is the *number* of λ-blocks (the geometric multiplicity), and the smallest i with $k_i = k_{i+1}$ is the size of the largest λ-block (the exponent of $(x - \lambda)$ in m_T).

Caution. The geometric multiplicity k_1 alone counts the blocks but not their sizes: two operators can share c_T, the eigenvalues, and even k_1, yet differ in Jordan form. You must climb the sequence $k_1, k_2, \dots$. The increments $k_j - k_{j-1}$ are nonincreasing in j – they are the column heights of a Young-diagram of the partition – so a jump larger than the one before it signals an arithmetic slip (equal consecutive jumps are allowed).

Worked Example 12.5.4 (Two nilpotent matrices that look alike (Artin's example))**.** Over $\mathbb{Q}$, contrast

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \qquad B = \begin{pmatrix} 1 & -1 & 1 \\ 2 & -2 & 2 \\ 1 & -1 & 1 \end{pmatrix}.$$

Both are nilpotent with $c(x) = x^3$. Find each Jordan form.

Recognition. Nilpotent means the only eigenvalue is 0; apply the Method with $\lambda = 0$, i.e. tabulate $k_i = \dim \ker A^i$.

Solution. For A: $A^2 = \left(\begin{smallmatrix} 0&0&1\\0&0&0\\0&0&0 \end{smallmatrix}\right) \neq 0$ but $A^3 = 0$. Ranks $\operatorname{rank} A = 2$, $\operatorname{rank} A^2 = 1$, $\operatorname{rank} A^3 = 0$ give $k_1, k_2, k_3 = 1, 2, 3$. The sequence rises by 1 each step, so there is one block of size ≥ 1 and one of size ≥ 2 and one of size ≥ 3: a single 3×3 block, $J(A) = J_3(0) = A$ itself. A generator is any v with $A^2 v \neq 0$, e.g. $v = e_3$, giving the chain $(v, Av, A^2 v) = (e_3, e_2, e_1)$.

For B: a short computation gives $B^2 = 0$, so $\operatorname{rank} B = 1$ (its rows are all multiples of $(1, -1, 1)$) and $k_1, k_2 = 2, 3$. Thus there are $k_1 = 2$ blocks, and $k_2 - k_1 = 1$ block of size ≥ 2: one 2×2 and one 1×1,

$$J(B) = \operatorname{diag}\big(J_2(0), J_1(0)\big) = \begin{pmatrix} 0&1&0\\0&0&0\\0&0&0 \end{pmatrix}.$$

A Jordan basis: take $v = e_1$ (so $Bv \neq 0$), giving the length-2 chain (v, Bv); then adjoin a vector of $\ker B$ independent from Bv, e.g. $v' = e_2 + e_3$, for the 1×1 block. Sanity check: $\deg m_A = 3$ (one block) versus $\deg m_B = 2$ (largest block); the two matrices are *not* similar though $c_A = c_B = x^3$.

Worked Example 12.5.5 (Building J from kernel-dimension data alone)**.** A linear operator T on a 7-dimensional complex space has the single eigenvalue $\lambda = 3$, and the kernel dimensions $k_i = \dim \ker (T - 3)^i$ are

$$k_1 = 3, \quad k_2 = 5, \quad k_3 = 6, \quad k_4 = 7, \quad k_5 = 7.$$

Determine the Jordan form of T.

Recognition. Apply the Method: differences of the k_i give the number of blocks of each size; no matrix entries are needed.

Solution. Set $k_0 = 0$. Number of blocks of size $\geq j$ is $k_j - k_{j-1}$:

$$\geq 1 : \ 3, \quad \geq 2 : \ 2, \quad \geq 3 : \ 1, \quad \geq 4 : \ 1, \quad \geq 5 : \ 0.$$

So blocks of size exactly 1: $3 - 2 = 1$; exactly 2: $2 - 1 = 1$; exactly 3: $1 - 1 = 0$; exactly 4: $1 - 0 = 1$. The block sizes are therefore $4, 2, 1$, a partition of 7, and

$$J = \operatorname{diag}\big(J_4(3), J_2(3), J_1(3)\big).$$

Reading off invariants: $c_T(x) = (x - 3)^7$, the largest block has size 4 so $m_T(x) = (x - 3)^4$, and the geometric multiplicity is $k_1 = 3$ (three blocks). Sanity check: $4 + 2 + 1 = 7 = \dim V$; the increments $k_j - k_{j-1} = 3, 2, 1, 1$ are nonincreasing as required, and the stabilization index 4 equals the largest block size $= \deg m_T$.

Worked Example 12.5.6 (A full computation: 4×4 over $\mathbb{Q}$)**.** Find the Jordan form, c_A, and m_A of

$$A = \begin{pmatrix} 2&1&0&0\\0&2&1&0\\0&0&2&0\\0&0&0&2 \end{pmatrix} \in \mathrm{M}_4(\mathbb{Q}).$$

Recognition. A is upper triangular, so c_A is read off the diagonal; then run the Method at the single eigenvalue using $B = A - 2I$.

Solution. The diagonal gives $c_A(x) = (x - 2)^4$, the lone eigenvalue 2 with algebraic multiplicity 4. Put

$$B = A - 2I = \begin{pmatrix} 0&1&0&0\\0&0&1&0\\0&0&0&0\\0&0&0&0 \end{pmatrix}, \qquad B^2 = \begin{pmatrix} 0&0&1&0\\0&0&0&0\\0&0&0&0\\0&0&0&0 \end{pmatrix}, \qquad B^3 = 0.$$

Ranks $\operatorname{rank} B = 2$, $\operatorname{rank} B^2 = 1$, $\operatorname{rank} B^3 = 0$ give $k_1, k_2, k_3 = 2, 3, 4$. Blocks of size ≥ 1: 2; size ≥ 2: $k_2 - k_1 = 1$; size ≥ 3: $k_3 - k_2 = 1$; size ≥ 4: 0. So one block of size 3 and one of size 1:

$$J = \operatorname{diag}\big(J_3(2), J_1(2)\big) = \begin{pmatrix} 2&1&0&0\\0&2&1&0\\0&0&2&0\\0&0&0&2 \end{pmatrix},$$

with $c_A(x) = (x-2)^4$ and $m_A(x) = (x-2)^3$ (largest block size 3). The chain for the big block starts at any v with $B^2 v \neq 0$, say $v = e_3$, yielding $(v, Bv, B^2v) = (e_3, e_2, e_1)$; the size-1 block is the eigenvector e_4. Sanity check: $k_1 = 2$ matches the two blocks, $\deg m_A = 3 \leq 4 = \deg c_A$, and $m_A \mid c_A$.

Remark 12.5.2 (Diagonalizability). Reading the Method off the simplest data: T is diagonalizable iff every block has size 1, iff $k_1 = d_\lambda$ for every eigenvalue (the sequence stabilizes immediately), iff m_T is squarefree, iff every generalized eigenvector is an ordinary eigenvector (Artin's Corollary 4.7.13). The chain picture makes the last equivalence visible: a block of size > 1 has a top vector u_0 that is a generalized eigenvector but, since $(T-\lambda)u_0 = u_1 \neq 0$, not an eigenvector.

12.6 Graded Problem Bank

Easy

DF 12.1.5 For $R = \mathbb{Z}[x]$ and $M = (2, x)$ as a submodule of R, show $\{2, x\}$ is not a basis of M, and show M has rank 1 but is not free of rank 1.

DF 12.1.8 For a PID R, a torsion R-module B, and a prime p, prove that if $pb = 0$ for some nonzero $b \in B$ then $\mathrm{Ann}(B) \subseteq (p)$.

DF 12.1.13 If M is a finitely generated module over the PID R, describe the structure of $M/\operatorname{Tor}(M)$.

DF 12.1.16 Prove that M is finitely generated iff there is a surjective R-homomorphism $\varphi : R^n \to M$ for some n (true for any ring R).

DF 12.2.1 Prove that similar linear transformations of V (or $n \times n$ matrices) have the same characteristic and the same minimal polynomial.

DF 12.2.7 Determine the eigenvalues of the matrix $\begin{pmatrix} 0&1&0&0\\0&0&1&0\\0&0&0&1\\1&0&0&0 \end{pmatrix}$.

DF 12.2.8 Verify that the characteristic polynomial of the companion matrix of $x^n + a_{n-1}x^{n-1} + \cdots + a_0$ is $x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$.

DF 12.2.9 Find the rational canonical forms of $\begin{pmatrix} 0&-1&-1\\0&0&0\\0&0&0 \end{pmatrix}$, $\begin{pmatrix} c&0&-1\\0&c&1\\-1&1&c \end{pmatrix}$, and $\begin{pmatrix} 422&465&15&-30\\-420&-463&-15&30\\840&930&32&-60\\-140&-155&-5&12 \end{pmatrix}$.

DF 12.3.1 For V the direct sum of cyclic $F[x]$-modules with annihilators $(x-1)(x^2+1)^2$, (x^4-1), $(x+1)(x^2-1)$, determine the invariant factors and elementary divisors of V.

DF 12.3.2 Prove that if $\lambda_1, \ldots, \lambda_n$ are the eigenvalues of the $n \times n$ matrix A then $\lambda_1^k, \ldots, \lambda_n^k$ are the eigenvalues of A^k for any $k \geq 0$.

DF 12.3.5 Compute the Jordan canonical form of $\begin{pmatrix} 1&0&0\\0&0&-2\\0&1&3 \end{pmatrix}$.

DF 12.3.6 Determine which of the matrices $\begin{pmatrix} -1&4&-4\\2&-1&3\\0&-4&3 \end{pmatrix}$, $\begin{pmatrix} -3&-4&0\\2&3&0\\8&8&1 \end{pmatrix}$, $\begin{pmatrix} -3&2&-4\\2&1&0\\3&-1&3 \end{pmatrix}$, $\begin{pmatrix} -1&4&-4\\0&-3&2\\0&-4&3 \end{pmatrix}$ are similar.

DF 12.3.7 Determine the Jordan canonical form of $\begin{pmatrix} 5&4&1\\-1&0&0\\-3&-4&1 \end{pmatrix}$ and of $\begin{pmatrix} 3&4&2\\-2&-3&-1\\-4&-4&-3 \end{pmatrix}$.

DF 12.3.12 Determine the Jordan canonical form of $\begin{pmatrix} 1&2&0&0\\0&1&2&0\\0&0&1&2\\0&0&0&1 \end{pmatrix}$.

DF 12.3.18 Prove that any matrix A is similar to its transpose A^t.

DF 12.3.21 Show that if $A^2 = A$ then A is similar to a diagonal matrix with only 0's and 1's on the diagonal.

DF 12.3.34 Prove that the trace of a nilpotent $n \times n$ matrix is 0.

DF 12.3.37 For T on $V = \mathbb{C}^n$ defined by $T(\alpha_1, \ldots, \alpha_n) = (0, \alpha_1, \ldots, \alpha_{n-1})$, determine the Jordan canonical form of T.

DF 12.3.41 Show that $\exp(0) = I$ and deduce that $\exp(A)$ is nonsingular with inverse $\exp(-A)$ for all $A \in \mathrm{M}_n(K)$.

DF 12.3.42 Prove that $\det(\exp(A)) = e^{\operatorname{tr}(A)}$.

Artin 4.4.1 Reduce each of $\left(\begin{smallmatrix} 3 & 1 & -4 \\ 2 & -3 & 1 \\ -4 & 6 & -2 \end{smallmatrix}\right)$ (and the second matrix of the exercise) to diagonal form by integer row and column operations.

Artin 4.4.4 Find a basis for the $\mathbb{Z}$-module of integer solutions of $x + 2y + 3z = 0$, $x + 4y + 9z = 0$.

Artin 4.4.8 Use invertible row and column operations in the ring $\mathbb{Z}[i]$ of Gauss integers to diagonalize the matrix $\left(\begin{smallmatrix} 3 & 2+i \\ 2-i & 9 \end{smallmatrix}\right)$.

Artin 4.5.2 Identify the abelian group presented by the integer matrix $\left(\begin{smallmatrix} 3 & 1 & 2 \\ 1 & 1 & 1 \\ 2 & 3 & 6 \end{smallmatrix}\right)$.

Artin 4.7.1 Find a direct sum of cyclic groups isomorphic to the abelian group presented by the matrix $\left(\begin{smallmatrix} 2 & 2 & 2 \end{smallmatrix}\right)$.

Artin 4.7.2 Write the abelian group generated by x, y with the single relation $3x + 4y = 0$ as a direct sum of cyclic groups.

Artin 4.7.5 Determine the number of isomorphism classes of abelian groups of order 400.

Artin 4.8.1 For the operator T on $\mathbb{C}^2$ with matrix $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$, decide whether the corresponding $\mathbb{C}[t]$-module is cyclic.

Artin Jordan 7.1 Determine the Jordan form of the matrix $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ (the operator 1's above the diagonal).

Artin Jordan 7.2 Prove that $A = \left(\begin{smallmatrix} 1 & 1 & 1 \\ -1 & -1 & -1 \\ 1 & 1 & 1 \end{smallmatrix}\right)$ is idempotent ($A^2 = A$) and find its Jordan form.

Artin Jordan 7.5 Determine the Jordan form of a matrix A all of whose eigenvectors are multiples of a single vector.

Artin Jordan 7.8 Decide whether every complex square matrix A is similar to its transpose.

Medium

DF 12.1.1 For a module M over an integral domain R: (a) show that any finite number of elements of M, one of which is torsion, are R-linearly dependent, so $\operatorname{Tor}(M)$ has rank 0; (b) show $\operatorname{rank}(M) = \operatorname{rank}(M/\operatorname{Tor} M)$.

DF 12.1.3 For an integral domain R and R-modules A, B of ranks m, n, prove that $\operatorname{rank}(A \oplus B) = m + n$.

DF 12.1.6 Show that if R is an integral domain and M is any nonprincipal ideal of R, then M is torsion free of rank 1 but not a free R-module.

DF 12.1.7 For a ring R, modules A_i and submodules $B_i \le A_i$, prove $(A_1 \oplus \cdots \oplus A_m)/(B_1 \oplus \cdots \oplus B_m) \cong (A_1/B_1) \oplus \cdots \oplus (A_m/B_m)$.

DF 12.1.9 Give an integral domain R and a nonzero torsion module M with $\operatorname{Ann}(M) = 0$; prove that a finitely generated torsion module N has $\operatorname{Ann}(N) \neq 0$.

DF 12.1.11 For a PID R, nonzero $a \in R$, $M = R/(a)$, and a prime p, prove $p^{k-1}M/p^kM \cong R/(p)$ for $k \le n$ and 0 for $k > n$, where n is the power of p dividing a.

DF 12.1.14 For a PID R and torsion module M, prove M is irreducible iff $M = Rm$ for any nonzero $m \in M$ with $\operatorname{Ann}(m)$ a nonzero prime ideal (p).

DF 12.1.17 (a) Show interchanging x_i, x_j in the basis for R^n interchanges columns i, j of the relations matrix; (b) show replacing x_j by $x_j - ax_i$ gives a new basis adding a times column j to column i.

DF 12.1.18 (a) Show interchanging generators y_i, y_j of $\ker\varphi$ interchanges rows i, j; (b) show replacing y_j by $y_j - ay_i$ adds $-a$ times row i to row j.

DF 12.1.19 For a Euclidean domain R, establish the Smith-form reduction by elementary row and column operations: (a)–(d) reduce a relations matrix to $\left(\begin{smallmatrix} D & 0 \\ 0 & 0 \end{smallmatrix}\right)$ with $D = \operatorname{diag}(a_1, \ldots, a_k)$, $a_1 \mid a_2 \mid \cdots \mid a_k$, concluding $M \cong R/(a_1) \oplus \cdots \oplus R/(a_k) \oplus R^{n-k}$.

DF 12.2.2 For M block-diagonal with blocks $A_1, \ldots, A_k$, prove the minimal polynomial of M is the least common multiple of the minimal polynomials of the A_i.

DF 12.2.3 Prove two 2×2 matrices over F that are not scalar are similar iff they have the same characteristic polynomial.

DF 12.2.5 Prove directly, from the fact that all linear transformations of an n-dimensional V form an F-space of dimension n^2, that the minimal polynomial of T has degree at most n^2.

DF 12.2.6 Prove the constant term of the characteristic polynomial of A is $(-1)^n \det A$ and the coefficient of x^{n-1} is $-\operatorname{tr}(A)$; deduce $\det A$ and $\operatorname{tr}(A)$ are the product and sum of the eigenvalues.

DF 12.2.10 Find all similarity classes of 6×6 matrices over $\mathbb{Q}$ with minimal polynomial $(x+2)^2(x-1)$.

DF 12.2.11 Find all similarity classes of 6×6 matrices over $\mathbb{C}$ with characteristic polynomial $(x^4-1)(x^2-1)$.

DF 12.2.14 Determine all possible rational canonical forms for a linear transformation with characteristic polynomial $x^2(x^2+1)^2$.

DF 12.2.15 Determine all rational canonical forms for 2×2 rational matrices of exact multiplicative order 4; do the same for entries in $\mathbb{C}$.

DF 12.2.19 Verify the elements $v_j = -a_{1j}\xi_1 - \cdots + (x - a_{jj})\xi_j - \cdots - a_{nj}\xi_n$ lie in $\ker \varphi$.

DF 12.2.20 (a) Show $x\xi_j = v_j + f_j$ with f_j in the F-span of $\xi_1, \ldots, \xi_n$; (b) show $F[x]\xi_1 + \cdots + F[x]\xi_n = (F[x]v_1 + \cdots + F[x]v_n) + (F\xi_1 + \cdots + F\xi_n)$.

DF 12.2.22 Show that the generators $v_1, \ldots, v_n$ of $\ker \varphi$ have relations matrix $xI - A^t$.

DF 12.3.3 Use the method of Example 2 to find explicit P_1, P_2 putting B, C in Jordan form, and construct Q conjugating B into C.

DF 12.3.4 Prove the Jordan canonical form of $\begin{pmatrix} 9 & 4 & 5 \\ -4 & 0 & -3 \\ -6 & -4 & -2 \end{pmatrix}$ is as stated, find P conjugating it to Jordan form, and explain why it cannot be diagonalized.

DF 12.3.8 Prove $A = \begin{pmatrix} 5 & 6 & 0 \\ -3 & -4 & 0 \\ -2 & 0 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 3 & -1 & 2 \\ -10 & 6 & -14 \\ -6 & 3 & -7 \end{pmatrix}$ are similar, both diagonalizable, and determine P_1, P_2 diagonalizing them.

DF 12.3.9 Prove $A = \begin{pmatrix} -8 & -10 & -1 \\ 7 & 9 & 1 \\ 3 & 2 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} -3 & 2 & -4 \\ 4 & -1 & 4 \\ 4 & -2 & 5 \end{pmatrix}$ share characteristic polynomial $(x-1)^2(x+1)$ but only one is diagonalizable; find both Jordan forms.

DF 12.3.10 Find all Jordan canonical forms of 2×2, 3×3, and 4×4 matrices over $\mathbb{C}$.

DF 12.3.11 Verify the characteristic polynomial of $\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ -2 & -2 & 0 & 1 \\ -2 & 0 & -1 & -2 \end{pmatrix}$ splits over $\mathbb{Q}$, and find its rational and Jordan canonical forms over $\mathbb{Q}$.

DF 12.3.13 Determine the Jordan canonical form of $\begin{pmatrix} 3 & 0 & -2 & -3 \\ 4 & -8 & 14 & -15 \\ 2 & -4 & 7 & -7 \\ 0 & 2 & -4 & 3 \end{pmatrix}$.

DF 12.3.14 Prove $A = \begin{pmatrix} 2 & 0 & 0 & 0 \\ -4 & -1 & -4 & 0 \\ 2 & 1 & 3 & 0 \\ -2 & 4 & 9 & 1 \end{pmatrix}$ and $B = \begin{pmatrix} 5 & 0 & -4 & -7 \\ 3 & -8 & 15 & -13 \\ 2 & -4 & 7 & -7 \\ 1 & 2 & -5 & 1 \end{pmatrix}$ are similar.

DF 12.3.15 Show $A = \begin{pmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{pmatrix}$ and $B = \begin{pmatrix} 5 & 2 & -8 & -8 \\ -6 & -3 & 8 & 8 \\ -3 & -1 & 3 & 4 \\ 3 & 1 & -4 & -5 \end{pmatrix}$ have characteristic polynomial $(x-3)(x+1)^3$; decide similarity and find both Jordan forms.

DF 12.3.16 Determine the Jordan canonical form of $\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}$ and a matrix P conjugating it into Jordan form.

DF 12.3.19 Determine all possible Jordan canonical forms for a linear transformation with characteristic polynomial $(x-2)^3(x-3)^2$.

DF 12.3.22 Prove that $A^3 = A$ over $\mathbb{C}$ implies A is diagonalizable; decide whether the same holds over an arbitrary field.

DF 12.3.23 For a 2×2 rational matrix A with $A^3 = I$, $A \neq I$, write A in rational canonical form and in Jordan canonical form over $\mathbb{C}$.

DF 12.3.24 Prove there are no 3×3 matrices A over $\mathbb{Q}$ with $A^8 = I$ but $A^4 \neq I$.

DF 12.3.25 Determine the Jordan canonical form of the $n \times n$ all-ones matrix over $\mathbb{Q}$.

DF 12.3.26 Determine the Jordan canonical form of the $n \times n$ all-ones matrix over $\mathbb{F}_p$ (depending on whether $p \mid n$).

DF 12.3.27 Determine the Jordan canonical form of the $n \times n$ matrix over $\mathbb{Q}$ with all entries 1 except 0's on the main diagonal.

DF 12.3.28 Determine the Jordan canonical form of the $n \times n$ matrix over $\mathbb{F}_p$ with all entries 1 except 0's on the main diagonal.

DF 12.3.31 Prove that any nilpotent matrix is similar to a block-diagonal matrix whose blocks have 1's on the first superdiagonal and 0's elsewhere.

DF 12.3.32 Prove that if N is an $n \times n$ nilpotent matrix then $N^n = 0$.

DF 12.3.33 Prove that a strictly upper-triangular $n \times n$ matrix is nilpotent.

DF 12.3.36 Compute the Jordan canonical form of the linear transformation $T(\alpha_1, \ldots, \alpha_n) = (0, \alpha_1, \ldots, \alpha_{n-1})$ on $V = \mathbb{C}^n$.

DF 12.3.38 For a Jordan block J of size n with eigenvalue λ over $\mathbb{C}$: (a) if $\lambda \neq 0$, show J^2 has Jordan form a single block of size n with eigenvalue λ^2; (b) if $\lambda = 0$, show J^2 splits into two blocks of sizes determined by the parity of n.

DF 12.3.40 For a Jordan block J of size n with eigenvalue λ over a field of characteristic 2, determine the Jordan form of J^2 and necessary and sufficient conditions for $A \in \mathrm{M}_n(F)$ to have a square root.

DF 12.3.43 For $A \in \mathrm{M}_n(K)$, prove $t \mapsto \exp(At)$ is a homomorphism from the additive group K into $GL_n(K)$ (a 1-parameter subgroup).

DF 12.3.47 Compute the exponentials of the matrices in Example 2, in Exercise 4, and in Exercise 16 of this section.

DF 12.3.50 Use the methods of the section to find a basis for the solution space of (a) $y''' - 3y' + 2y = 0$ and (b) $y'''' + 4y''' + 6y'' + 4y' + y = 0$.

Artin 4.4.3 Determine all integer solutions of $AX = 0$ for $A = \left(\begin{smallmatrix} 4 & 7 & 2 \\ 2 & 4 & 6 \end{smallmatrix}\right)$, and find a basis for the integer vectors B such that $AX = B$ has a solution.

Artin 4.4.5 For complex α, β, γ, determine when $\{\ell\alpha + m\beta + n\gamma \mid \ell, m, n \in \mathbb{Z}\}$ is a lattice in the complex plane.

Artin 4.4.6 For φ given by multiplication by an integer matrix A, show $\operatorname{im}\varphi$ has finite index iff A is nonsingular, and that the index is then $|\det A|$.

Artin 4.4.7 For an integer column vector $A = (a_1, \ldots, a_n)^t$ with gcd $= d$, prove there is $P \in GL_n(\mathbb{Z})$ with $PA = (d, 0, \ldots, 0)^t$.

Artin 4.5.1 For $R = \mathbb{Z}[\delta]$ with $\delta = \frac{1+\sqrt{-3}}{2}$, determine a presentation matrix as R-module for the ideal $(2, 1 + \delta)$.

Artin 4.6.2 Find an example of a ring R and an ideal I of R that is not finitely generated.

Artin 4.7.3 Write as a direct sum of cyclic groups the abelian group on x, y, z with relations (a) $3x + 2y + 8z = 0$, $2x + 4z = 0$; (b) $x + y = 0$, $2x = 0$, $4x + 2z = 0$, $4x + 2y + 2z = 0$; (c) $2x + y = 0$, $x - y + 3z = 0$; (d) $7x + 5y + 2z = 0$, $3x + 3y = 0$, $13x + 11y + 2z = 0$.

Artin 4.7.6 For coprime positive integers a, b, manipulate the diagonal matrix with entries a, b to prove $C_{ab} \cong C_a \oplus C_b$; discuss dropping coprimality.

Artin 4.7.7 For $R = \mathbb{Z}[i]$ and V on generators v_1, v_2 with relations $(1 + i)v_1 + (2 - i)v_2 = 0$, $3v_1 + 5iv_2 = 0$, write V as a direct sum of cyclic R-modules.

Artin 4.7.8 For $F = \mathbb{F}_p$, determine for which primes p the additive group F^1 admits a $\mathbb{Z}[i]$-module structure, and likewise F^2.

Artin 4.7.9 Show that a $\mathbb{Z}[i]$-module is the same as an abelian group V with a homomorphism $\varphi : V \to V$ satisfying $\varphi \circ \varphi = -\mathrm{id}$.

Artin 4.8.2 For a $\mathbb{C}[t]$-module of the form $\mathbb{C}[t]/(t-a)^n$, show there is a $\mathbb{C}$-basis in which the matrix of the corresponding operator is a Jordan block.

Artin 4.8.3 For $R = F[x]$ and $V = Rv$ with relation $(x^3 + 3x + 2)v = 0$, choose an F-basis and find the matrix of multiplication by x.

Artin 4.8.4 For an $F[t]$-module V with F-basis $(v_1, \dots, v_n)$ and B the matrix of T, prove $A = tI - B$ is a presentation matrix for the module.

Artin Jordan 7.3 For a 5-dimensional complex V and operator T with characteristic polynomial $(t-\lambda)^5$ and $\mathrm{rank}(T-\lambda I) = 2$, determine the possible Jordan forms of T.

Artin Jordan 7.4 (a) Determine all possible Jordan forms for a matrix with characteristic polynomial $(t+2)^2(t-5)^5$; (b) the same when the $\lambda = -2$ eigenspace is 1-dimensional and the $\lambda = 5$ eigenspace is 2-dimensional.

Artin Jordan 7.6 Determine all invariant subspaces of a linear operator whose Jordan form is a single block.

Artin Jordan 7.7 Decide whether every complex square matrix A with $A^2 = A$ is diagonalizable.

Artin Jordan 7.9 Find a 2×2 matrix over $\mathbb{F}_p$ with a power equal to the identity and an eigenvalue in $\mathbb{F}_p$, but which is not diagonalizable.

Hard

DF 12.1.2 For an integral domain R and module M of rank n: (a) for a maximal independent set $x_1, \dots, x_n$ with $N = Rx_1 + \cdots + Rx_n$, prove $N \cong R^n$ and M/N is torsion; (b) conversely, if M contains a free submodule $N \cong R^n$ with M/N torsion, prove M has rank n.

DF 12.1.4 For an integral domain R, module M of rank n, and submodule N of rank r with M/N of rank s, prove $n = r + s$.

DF 12.1.10 For a prime p in a PID R and torsion module N, prove the p-primary component is a submodule and N is the direct sum of its p-primary components (possibly infinitely many).

DF 12.1.12 For a PID R and prime p: (a) for finitely generated torsion M, prove $p^{k-1}M/p^kM \cong F^{n_k}$, $F = R/(p)$, n_k = number of elementary divisors p^α with $\alpha \geq k$; (b) deduce isomorphic finitely generated torsion modules have the same elementary divisors.

DF 12.1.15 Prove that if R is Noetherian then R^n is a Noetherian R-module.

DF 12.1.20 For an integral domain R with quotient field F and any R-module M, prove $\mathrm{rank}(M) = \dim_F(F \otimes_R M)$.

DF 12.2.4 Prove two 3×3 matrices are similar iff they share characteristic and minimal polynomials; give an explicit 4×4 counterexample.

DF 12.2.12 Find all similarity classes of 3×3 matrices A over $\mathbb{F}_2$ with $A^6 = I$, and of 4×4 matrices A with $A^{20} = I$.

DF 12.2.13 Prove the number of similarity classes of 3×3 matrices over $\mathbb{Q}$ with a given characteristic polynomial equals the number over any extension of $\mathbb{Q}$; give a 4×4 counterexample.

DF 12.2.16 Show $x^5 - 1 = (x-1)(x^2 - 4x + 1)(x^2 + 5x + 1)$ in $\mathbb{F}_{19}[x]$ and determine up to similarity all 2×2 matrices over $\mathbb{F}_{19}$ of order 5.

DF 12.2.17 Determine representatives for the conjugacy classes of $GL_3(\mathbb{F}_2)$.

DF 12.2.18 For a nonsingular T on a finite-dimensional $\mathbb{Q}$-space with $T^{-1} = T^2 + T$, prove $3 \mid \dim V$; if $\dim V = 3$, prove all such T are similar.

DF 12.2.21 For $V = \mathbb{R}^\infty$ and the shift $T(a_0, a_1, \dots) = (0, a_0, a_1, \dots)$, prove T has no eigenvectors.

DF 12.2.23 For primes ℓ and p and $\Phi_\ell(x) = (x^\ell - 1)/(x-1)$ the ℓth cyclotomic polynomial: (a) if $p = \ell$, show $(x-1) \mid \Phi_\ell$ in $\mathbb{F}_p[x]$; (b)–(c) for $p \neq \ell$ and $f = \mathrm{ord}_{\mathbb{F}_\ell^\times}(p)$, show Φ_ℓ has no factor of degree $< f$ mod p and an irreducible factor of degree f; (d) deduce Φ_ℓ is irreducible mod p iff p is a primitive root mod ℓ.

DF 12.2.24 Prove the second elementary row and column operation does not change the determinant and the first and third elementary operations multiply it by a unit; conclude the characteristic polynomial of A equals the product of its invariant factors (an alternate proof of Proposition 20).

DF 12.2.25 Show that $v_1, \ldots, v_n$ generate $\ker \varphi$.

DF 12.3.17 Show that the cyclic-permutation matrix and the single Jordan block (all eigenvalue 1) are similar in $\mathrm{M}_p(\mathbb{F}_p)$.

DF 12.3.20 Prove that all $n \times n$ matrices with characteristic polynomial $f(x)$ are similar iff $f(x)$ has no repeated factor in $F[x]$.

DF 12.3.29 For the generalized eigenspace V_i of T at λ_i, prove that for all $k \geq 0$ the nullity of $T - \lambda_i$ on $(T-\lambda_i)^k V_i$ equals that on $(T-\lambda_i)^k V$ and equals the number of Jordan blocks of T with eigenvalue λ_i and size $> k$.

DF 12.3.30 For $r_k = \dim_F (T-\lambda)^k V$, prove $r_{k-1} - 2r_k + r_{k+1}$ is the number of Jordan blocks for λ of size exactly k.

DF 12.3.35 For $0 \leq i \leq n$, let d_i be the gcd of the $i \times i$ minors of $xI - A$; prove the ith diagonal entry of the Smith Normal Form of A is d_i/d_{i-1}.

DF 12.3.39 Determine necessary and sufficient conditions for $A \in \mathrm{M}_n(\mathbb{C})$ to have a square root B with $A = B^2$.

DF 12.3.44 For $A, B \in \mathrm{M}_n(K)$ and $\alpha \in K$, prove the operator-norm inequalities $\|A+B\| \leq \|A\| + \|B\|$, $\|AB\| \leq \|A\| \cdot \|B\|$, $\|\alpha A\| = |\alpha| \cdot \|A\|$.

DF 12.3.45 For $G(x)$ a power series with radius of convergence R: (a) prove $\|A\| < R$ implies $G(A)$ converges; (b) deduce $\sin(A)$, $\cos(A)$, $\exp(A)$ converge for all A.

DF 12.3.46 For nonsingular P: (a) prove $P\,G(At)\,P^{-1} = G(PAtP^{-1}) = G(PAP^{-1}t)$; (b) if $A = A_1 \oplus \cdots \oplus A_m$, then $G(At) = G(A_1 t) \oplus \cdots \oplus G(A_m t)$; (c) for diagonal $Z = \mathrm{diag}(z_i)$, $G(Zt) = \mathrm{diag}(G(z_i t))$.

DF 12.3.48 Prove that for commuting matrices A, B, $\exp(A+B) = \exp(A)\exp(B)$.

DF 12.3.49 Use the preceding to show $\exp(\lambda I t + M) = e^{\lambda t}\exp(M)$ for any matrix M and $\lambda \in K$.

DF 12.3.51 Compute $\exp(Nt)$ for the $r \times r$ nilpotent superdiagonal matrix N, and deduce the formula for $\exp(Jt)$ where J is the $r \times r$ Jordan block with eigenvalue λ.

DF 12.3.52 For the 4×4 matrices D, P of Example 3, verify the stated E and the value of $\exp(D)$.

DF 12.3.53 Establish the derivative formulas: (a) $\frac{d}{dt}G(At) = A\sum_{k\geq 1} k a_k (At)^{k-1}$; (b) $\frac{d}{dt}(G(At)v) = (\frac{d}{dt}G(At))v$ for constant v.

DF 12.3.54 Deduce from the preceding that $\frac{d}{dt}\exp(At) = A\exp(At)$.

DF 12.3.55 Prove $\exp(At)$ is a fundamental matrix of the linear system $(*)$ and that $y(t) = \exp(At)C$ is the solution with $y(0) = C$.

DF 12.3.56 Prove that if M is a fundamental matrix of $(*)$ and Q is nonsingular then MQ is also a fundamental matrix.

DF 12.3.57 In each of (a)–(c) find a fundamental matrix for the system $(*)$ whose coefficient matrix is the matrix in the corresponding part of Exercise 47.

DF 12.3.58 For the coefficient matrix $A = D$ of Exercise 46, find the particular solution to $(*)$ with $y_i(0) = 1$ for $i = 1, 2, 3, 4$.

DF 12.3.59 Prove that the coefficient matrix A of the first-order system obtained from $(**)$ is the transpose of the companion matrix of $x^n + a_{n-1}x^{n-1} + \cdots + a_0$.

DF 12.3.60 Prove that the zero solution of $(*)$ is globally asymptotically stable if all eigenvalues of A have negative real parts.

Artin 4.3.3 Use permanence of identities to prove that the trace of the operator $f(M) = AMB$ on $R^{m\times n}$ is $(\operatorname{tr} A)(\operatorname{tr} B)$.

Artin 4.4.9 Use diagonalization to prove that if $L \subseteq M$ are lattices then $[M : L] = \Delta(L)/\Delta(M)$.

Artin 4.6.1 For $V \subseteq \mathbb{C}^n$ the common zero locus of an infinite set of polynomials, prove there is a finite subset with the same zero locus.

Artin 4.9.5 For $R = \mathbb{Z}[\sqrt{-5}]$ and the module V presented by the matrix A, prove the residue of A in R/P has rank 1 for every prime ideal P, yet V is not free.

Artin M.1 In how many ways can the additive group $\mathbb{Z}/5\mathbb{Z}$ be given the structure of a module over the Gaussian integers $\mathbb{Z}[i]$?

Artin M.2 Classify the finitely generated modules over the ring $\mathbb{Z}/(6)$.

Artin M.4 When an integer 2×2 matrix A is diagonalized as $Q^{-1}AP$, determine how unique P and Q are.

Artin M.6 (a) Describe the orbits of right multiplication by $G = GL_2(\mathbb{Z})$ on the 2×2 integer matrices; (b) show every integer matrix A admits invertible integer P with AP in Hermite normal form.

Artin Jordan M.7 (Powers of an operator) For K_r, W_r the kernel and image of T^r: (a) show $K_1 \subseteq K_2 \subseteq \cdots$ and $W_1 \supseteq W_2 \supseteq \cdots$; (b) find all implications among $K_r = K_{r+1}$, $W_r = W_{r+1}$, $W_r \cap K_r = 0$, $W_r + K_r = V$ in finite dimension; (c) do the same in infinite dimension.

Artin Jordan M.8 For T on a finite-dimensional complex V and eigenvalue λ, let V_λ be the generalized eigenspace: (a) prove V_λ is T-invariant; (b) prove V is the direct sum of its generalized eigenspaces.

Chapter 13

Field Theory

13.1 Basic Theory of Field Extensions

Fields, characteristic, and the prime subfield

A *field* is a commutative ring F with $1 \neq 0$ in which every nonzero element is a unit, so $F^\times = F \setminus \{0\}$ is an abelian group under multiplication. For each integer $n \geq 1$ write $n \cdot 1_F = 1_F + \cdots + 1_F$ (n summands). There is a unique ring homomorphism $\varphi\colon \mathbb{Z} \to F$ with $\varphi(n) = n \cdot 1_F$, and its kernel is a prime ideal of $\mathbb{Z}$ (the image lies in a field, hence is an integral domain). Thus $\ker\varphi = (0)$ or $\ker\varphi = (p)$ for a prime p.

Definition 13.1.1. The *characteristic* of a field F, written $\operatorname{char}(F)$, is the smallest positive integer p with $p \cdot 1_F = 0$ if such p exists, and is 0 otherwise. If $\operatorname{char}(F) = p > 0$ then p is prime.

Definition 13.1.2. The *prime subfield* of F is the subfield generated by 1_F, i.e. the smallest subfield of F. It is isomorphic to $\mathbb{Q}$ if $\operatorname{char}(F) = 0$ and to $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ if $\operatorname{char}(F) = p$.

Indeed, if $\operatorname{char}(F) = p$ then $\operatorname{im}\varphi \cong \mathbb{Z}/(p) = \mathbb{F}_p$ is already a field, so it is the prime subfield. If $\operatorname{char}(F) = 0$ then φ is injective, extends to $\operatorname{Frac}(\mathbb{Z}) = \mathbb{Q} \hookrightarrow F$, and the image is the prime subfield. Every field is therefore a vector space over its prime subfield, and the universal map φ out of $\mathbb{Z}$ factors through $\mathbb{Z}/\ker\varphi$:

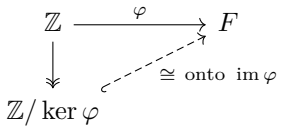

Diagram explanation. Objects: Three objects: the ring of integers $\mathbb{Z}$ (the universal domain of characteristic), the quotient ring $\mathbb{Z}/\ker\varphi$ (either $\mathbb{Z}/(0) \cong \mathbb{Z}$ or $\mathbb{Z}/(p) \cong \mathbb{F}_p$), and the target field F. The quotient $\mathbb{Z}/\ker\varphi$ is itself either $\mathbb{Z}$ (when $\operatorname{char}(F) = 0$, extended to $\mathbb{Q}$) or a prime field $\mathbb{F}_p$ (when $\operatorname{char}(F) = p$).

Arrows: (1) $\varphi\colon \mathbb{Z} \to F$, $n \mapsto n \cdot 1_F$, is the unique unital ring homomorphism from $\mathbb{Z}$ to F; its existence and uniqueness follow from $\mathbb{Z}$ being the initial object among unital rings. (2) $\mathbb{Z} \twoheadrightarrow \mathbb{Z}/\ker\varphi$ is the canonical surjective quotient map sending n to its coset $n + \ker\varphi$. (3) $\mathbb{Z}/\ker\varphi \hookrightarrow F$ is the induced injective map given by the First Isomorphism Theorem; it maps isomorphically onto $\operatorname{im}\varphi = \mathbb{Z} \cdot 1_F$, which is the prime subfield $\mathbb{F}_p$ when $\operatorname{char}(F) = p$; when $\operatorname{char}(F) = 0$ it is a copy of $\mathbb{Z}$ (not a field) whose fraction field $\mathbb{Q}$ is the prime subfield.

What commutes: The triangle commutes: $\varphi = \iota \circ \pi$, where $\pi\colon \mathbb{Z} \twoheadrightarrow \mathbb{Z}/\ker\varphi$ is the quotient and $\iota\colon \mathbb{Z}/\ker\varphi \hookrightarrow F$ is the induced injection. In symbols, for all $n \in \mathbb{Z}$: $\iota(\pi(n)) = \iota(n + \ker\varphi) = \varphi(n) = n \cdot 1_F$.

Why it commutes: Well-definedness of ι: if $n \equiv m \pmod{\ker\varphi}$ then $n - m \in \ker\varphi$, so $\varphi(n - m) = (n - m) \cdot 1_F = 0$ in F, hence $\varphi(n) = \varphi(m)$. The induced map ι is thus well defined on cosets, and injectivity follows because $\ker\iota = \{n + \ker\varphi : \varphi(n) = 0\} = \ker\varphi/\ker\varphi = \{0\}$.

Why this matters here: This diagram encodes the classification of prime subfields in one picture. The author places it here to show that F contains a canonical copy of its prime subfield determined solely by $\ker\varphi$: either

$\mathbb{Q}$ (characteristic 0) or $\mathbb{F}_p$ (characteristic p). Every subsequent result about field extensions implicitly uses this baseline embedding.

Concrete example: Take $F = \mathbb{F}_5$. Then $\varphi\colon \mathbb{Z} \to \mathbb{F}_5$ has $\ker\varphi = (5)$, so $\mathbb{Z}/\ker\varphi = \mathbb{Z}/5\mathbb{Z} = \mathbb{F}_5$, and the induced map is the identity $\mathbb{F}_5 \hookrightarrow \mathbb{F}_5$. The triangle says: send n to n mod 5 directly, or factor through the quotient and then include — same result.

Common pitfall: Students often think the bottom-left object $\mathbb{Z}/\ker\varphi$ is just notation for $\mathbb{F}_p$. In characteristic 0, $\ker\varphi = (0)$ so $\mathbb{Z}/\ker\varphi \cong \mathbb{Z}$, and the map to F extends further to $\mathbb{Q} \hookrightarrow F$ (not shown, but implicit). The diagram itself covers both cases uniformly; do not read $\mathbb{Z}/\ker\varphi$ as always finite.

Takeaway: The point of this diagram is that every field F receives the integers via a unique ring map, and the prime subfield is determined by whether $\ker\varphi$ is trivial or a prime ideal: it is the image $\operatorname{im}\varphi \cong \mathbb{F}_p$ when $\ker\varphi = (p)$, and the fraction field $\mathbb{Q}$ of the image $\operatorname{im}\varphi \cong \mathbb{Z}$ when $\ker\varphi = (0)$.

Worked Example 13.1.3 (Reading off characteristic and prime subfield)**.** Give $\operatorname{char}(F)$ and the prime subfield for: (a) $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$; (b) $\mathbb{F}_5$; (c) $\mathbb{F}_{25} = \mathbb{F}_5[x]/(x^2+2)$; (d) the rational function field $\mathbb{F}_2(t)$; (e) $\mathbb{F}_7(t)$.

Recognition. Apply the definitions: find the least $p > 0$ with $p \cdot 1 = 0$, then the prime subfield is $\mathbb{Q}$ (char 0) or $\mathbb{F}_p$ (char p).

Solution. (a) char = 0 for all three since $n \cdot 1 \neq 0$ for $n \geq 1$; prime subfield $\mathbb{Q}$. (b) char = 5, prime subfield $\mathbb{F}_5$ (all of it). (c) char = 5: the subfield $\mathbb{F}_5 \cdot 1$ has $5 \cdot 1 = 0$, and adjoining a root of x^2+2 does not change that $5 \cdot 1 = 0$; prime subfield $\mathbb{F}_5$. (d) char = 2 because $2 \cdot 1 = 0$ already in the constants $\mathbb{F}_2 \subseteq \mathbb{F}_2(t)$; prime subfield $\mathbb{F}_2$ (the field is infinite but has characteristic 2). (e) char = 7, prime subfield $\mathbb{F}_7$. Sanity check: in characteristic p the Freshman's Dream $(a+b)^p = a^p + b^p$ holds; e.g. in $\mathbb{F}_2(t)$, $(1+t)^2 = 1+t^2$, confirming char = 2.

Worked Example 13.1.4 (No field of characteristic 4)**.** Show there is no field of characteristic 4, and more generally that $\operatorname{char}(F)$ is 0 or prime.

Recognition. The image of $\mathbb{Z}$ inside a field is an integral domain, so $\ker\varphi = (n)$ forces $\mathbb{Z}/(n)$ to be a domain, i.e. $n = 0$ or n prime.

Solution. If $\operatorname{char}(F) = n = ab$ with $1 < a, b < n$, then $(a \cdot 1)(b \cdot 1) = (ab) \cdot 1 = n \cdot 1 = 0$ in the field F, so $a \cdot 1 = 0$ or $b \cdot 1 = 0$ (no zero divisors), contradicting minimality of n. Hence n is prime (or 0). Sanity check: $\mathbb{Z}/4\mathbb{Z}$ is a ring of "characteristic 4" but not a field, since $2 \cdot 2 = 0$ shows 2 is a zero divisor.

Field extensions and the degree

Definition 13.1.5. If $F \subseteq K$ are fields we call K an *extension* of F, written K/F. Since K is a vector space over F, the *degree* of the extension is

$$[K : F] = \dim_F K,$$

the dimension of K as an F-vector space. The extension is *finite* if $[K : F] < \infty$ and *infinite* otherwise.

Worked Example 13.1.6 (Degrees of some standard extensions)**.** Compute $[K : F]$ for: (a) $\mathbb{C}/\mathbb{R}$; (b) $\mathbb{R}/\mathbb{Q}$; (c) $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$; (d) $\mathbb{F}_{p^n}/\mathbb{F}_p$; (e) $F(t)/F$ for a field F.

Recognition. $[K : F] = \dim_F K$; exhibit an F-basis (or show none is finite).

Solution. (a) $\{1, i\}$ is an $\mathbb{R}$-basis of $\mathbb{C}$, so $[\mathbb{C} : \mathbb{R}] = 2$. (b) $[\mathbb{R} : \mathbb{Q}] = \infty$ (uncountable, hence infinite-dimensional over countable $\mathbb{Q}$). (c) $\{1, \sqrt{2}\}$ is a $\mathbb{Q}$-basis: every element of $\mathbb{Q}(\sqrt{2})$ is $a + b\sqrt{2}$ uniquely, so the degree is 2. (d) $\mathbb{F}_{p^n}$ has p^n elements; as an $\mathbb{F}_p$-vector space of dimension d it has p^d elements, so $d = n$, i.e. $[\mathbb{F}_{p^n} : \mathbb{F}_p] = n$. (e) $1, t, t^2, \ldots$ are F-linearly independent in $F(t)$, so $[F(t) : F] = \infty$. Sanity check: $|\mathbb{F}_{p^n}| = p^{[\mathbb{F}_{p^n} : \mathbb{F}_p]}$ is the master count for finite fields, used constantly below.

Simple extensions $F(\alpha)$ and quotients $F[x]/(p(x))$

For α in an extension K/F, the smallest subfield of K containing F and α is denoted $F(\alpha)$; the smallest subring is $F[\alpha]$. An extension of the form $K = F(\alpha)$ is called *simple* and α a *primitive element*. The engine that produces such extensions abstractly is the following theorem of Kronecker.

Theorem 13.1.7 (13.4 / 13.1, on $F[x]/(p(x))$)**.** *Let F be a field and $p(x) \in F[x]$ irreducible. Then $K = F[x]/(p(x))$ is a field containing (an isomorphic copy of) F, and the class $\theta = x + (p(x))$ is a root of p in K. If $\deg p = n$, then*

$$1,\ \theta,\ \theta^2,\ \ldots,\ \theta^{n-1}$$

is an F-basis of K, so $[K : F] = n = \deg p$, and $K = F(\theta)$.

The construction is exactly a quotient of the polynomial ring: $F \hookrightarrow F[x] \twoheadrightarrow F[x]/(p(x))$, where $(p(x))$ is maximal because p is irreducible in the PID $F[x]$. The composite $F \to K$ is injective (it is a field map), giving the tower below; "evaluation at θ" is the reverse description $F[x] \to K$, $x \mapsto \theta$.

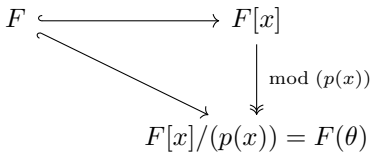

Diagram explanation. Objects: Three objects: the base field F, the polynomial ring $F[x]$ (a PID), and the quotient field $K = F[x]/(p(x)) = F(\theta)$ produced by Kronecker's theorem. The quotient is a field because $p(x)$ is irreducible, making $(p(x))$ a maximal ideal in $F[x]$.

Arrows: (1) $F \hookrightarrow F[x]$ is the natural inclusion of constant polynomials, an injective ring map. (2) $F[x] \twoheadrightarrow F[x]/(p(x))$ is the canonical surjective quotient map $f(x) \mapsto f(x) + (p(x))$. (3) $F \hookrightarrow F[x]/(p(x))$ is the composite of the two, sending $a \in F$ to $a + (p(x))$; it is injective because any field map is injective (the kernel is an ideal of F, which has no nonzero proper ideals).

What commutes: The triangle commutes: the diagonal arrow equals the composite of the horizontal inclusion followed by the vertical quotient. For $a \in F$: down-right path gives $a \mapsto a + (p(x))$; right-then-down path gives $a \mapsto a \in F[x] \mapsto a + (p(x))$. Same result.

Why it commutes: Well-definedness is trivial here (the constant a has no dependence on x, so reducing mod $(p(x))$ leaves it unchanged). Injectivity of the diagonal arrow follows from the general fact that field homomorphisms are injective: $a + (p(x)) = 0$ would mean $p(x) \mid a$, impossible for a nonzero constant a since $\deg p \geq 1$.

Why this matters here: The diagram visualizes why Kronecker's construction "contains F": F embeds into the quotient via the diagonal, so we are genuinely extending F, not just creating an abstract ring. The quotient field $F(\theta)$ is the smallest field over F in which p has a root — the diagram records that F sits inside it canonically.

Concrete example: Take $F = \mathbb{Q}$, $p(x) = x^2 - 2$. Then $F[x]/(p(x)) = \mathbb{Q}[x]/(x^2 - 2) \cong \mathbb{Q}(\sqrt{2})$. The inclusion $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt{2})$ is the diagonal arrow; the quotient map sends $a + bx \mapsto a + b\theta$ with $\theta^2 = 2$.

Common pitfall: Students sometimes think the quotient map $F[x] \twoheadrightarrow F[x]/(p(x))$ is an isomorphism or that $F[x]/(p(x))$ contains $F[x]$ as a subring. It does not: the quotient collapses the entire ideal $(p(x))$ to zero. The correct statement is only that F (the constants) survives injectively.

Takeaway: The point of this diagram is that forming the quotient $F[x]/(p(x))$ is a clean two-step construction — include F into its polynomial ring, then collapse the ideal generated by p — and the base field F embeds into the result by either path.

Worked Example 13.1.8 (Building $\mathbb{F}_4$ as $\mathbb{F}_2[x]/(x^2 + x + 1)$)**.** Construct a field of 4 elements and write out its addition/multiplication structure.

Recognition. Kronecker's theorem: $x^2 + x + 1$ is irreducible over $\mathbb{F}_2$ (no root in $\mathbb{F}_2$), so $\mathbb{F}_2[x]/(x^2 + x + 1)$ is a field of degree 2, hence 4 elements.

Solution. Let $\theta = x + (x^2 + x + 1)$, so $\theta^2 = \theta + 1$ (from $\theta^2 + \theta + 1 = 0$, using $-1 = 1$). Basis $\{1, \theta\}$ gives the four elements $0, 1, \theta, \theta + 1$. Multiplication: $\theta \cdot \theta = \theta + 1$, $\theta(\theta + 1) = \theta^2 + \theta = (\theta + 1) + \theta = 1$, so $\theta^{-1} = \theta + 1$. Thus $\mathbb{F}_4^\times = \{1, \theta, \theta + 1\}$ is cyclic of order 3 generated by θ. Sanity check: $|\mathbb{F}_4| = 2^2 = 4 = 2^{[K:\mathbb{F}_2]}$ with $[K : \mathbb{F}_2] = \deg(x^2 + x + 1) = 2$.

Worked Example 13.1.9 ($\mathbb{Q}[x]/(x^2-2)$ versus $\mathbb{Q}[x]/(x^2+1)$)**.** Identify these two quotient fields concretely and give a basis.

Recognition. Both moduli are irreducible over $\mathbb{Q}$ (no rational roots), so each quotient is a degree-2 field with basis $1, \theta$.

Solution. For x^2-2: $\theta^2 = 2$, so the map $\theta \mapsto \sqrt{2}$ gives $\mathbb{Q}[x]/(x^2-2) \cong \mathbb{Q}(\sqrt{2})$, basis $\{1, \sqrt{2}\}$. For x^2+1: $\theta^2 = -1$, so $\theta \mapsto i$ gives $\mathbb{Q}[x]/(x^2+1) \cong \mathbb{Q}(i)$, basis $\{1, i\}$. Both have degree 2 over $\mathbb{Q}$ but are non-isomorphic: an isomorphism $\mathbb{Q}(i) \to \mathbb{Q}(\sqrt{2})$ would send i to a square root of -1 in $\mathbb{Q}(\sqrt{2}) \subseteq \mathbb{R}$, and there is none. Sanity check: $(a+b\sqrt{2})(a-b\sqrt{2}) = a^2 - 2b^2 \in \mathbb{Q}$ exhibits inverses in $\mathbb{Q}(\sqrt{2})$; $(a+bi)(a-bi) = a^2+b^2$ does so in $\mathbb{Q}(i)$.

Worked Example 13.1.10 (A cubic: $\mathbb{Q}[x]/(x^3-2)$)**.** Show $K = \mathbb{Q}[x]/(x^3-2)$ is a field of degree 3 over $\mathbb{Q}$ and rationalize $1/(\theta^2+1)$.

Recognition. x^3-2 is irreducible over $\mathbb{Q}$ (Eisenstein at 2, or no rational root), so $[K:\mathbb{Q}] = 3$ with basis $1, \theta, \theta^2$, $\theta^3 = 2$.

Solution. $K \cong \mathbb{Q}(\sqrt[3]{2})$ via $\theta \mapsto \sqrt[3]{2}$. To invert θ^2+1, find $a + b\theta + c\theta^2$ with $(\theta^2+1)(a+b\theta+c\theta^2) = 1$. Expanding with $\theta^3 = 2$ (so $\theta^4 = 2\theta$): θ^2+1 times the unknown $= (a+2b) + (b+2c)\theta + (a+c)\theta^2$ after reduction; setting this $= 1$ gives $a+2b = 1$, $b+2c = 0$, $a+c = 0$. Solving: $a = -c$ and $b = -2c$, so $a+2b = -c-4c = -5c = 1 \Rightarrow c = -\frac{1}{5}$, $a = \frac{1}{5}$, $b = \frac{2}{5}$. Hence $(\theta^2+1)^{-1} = \frac{1}{5} + \frac{2}{5}\theta - \frac{1}{5}\theta^2 = \frac{1}{5}(1 + 2\theta - \theta^2)$. Sanity check: degree is 3, matching $\deg(x^3-2) = 3$; and the inverse lies in the $\mathbb{Q}$-span of $1, \theta, \theta^2$ as it must. One verifies $(\theta^2+1)\cdot\frac{1}{5}(1+2\theta-\theta^2) = 1$ directly using $\theta^3 = 2$.

Worked Example 13.1.11 (Same degree, different irreducible)**.** Build a field of 8 elements as $\mathbb{F}_2[x]/(x^3+x+1)$ and find θ^{-1}.

Recognition. x^3+x+1 has no root in $\mathbb{F}_2$ ($0^3+0+1 = 1$, $1+1+1 = 1$), and a cubic with no root is irreducible, so the quotient is a field of degree 3, with $2^3 = 8$ elements.

Solution. $\theta^3 = \theta + 1$ (since $\theta^3 + \theta + 1 = 0$, char 2). Then $\theta \cdot \theta^2 = \theta^3 = \theta + 1$, and we seek θ^{-1}: from $\theta^3 + \theta + 1 = 0$ write $\theta(\theta^2+1) = 1$, so $\theta^{-1} = \theta^2 + 1$. Basis $\{1, \theta, \theta^2\}$. Sanity check: $|\mathbb{F}_8| = 2^3 = 8 = 2^{\deg p}$, and $\mathbb{F}_8^\times$ is cyclic of order 7; indeed θ is a generator since 7 is prime so every nonidentity unit has order 7.

Algebraic and transcendental elements; the minimal polynomial

Definition 13.1.12. Let K/F be an extension and $\alpha \in K$. We call α *algebraic over* F if α is a root of some nonzero $p(x) \in F[x]$, and *transcendental over* F otherwise. The extension K/F is *algebraic* if every element of K is algebraic over F.

Consider the evaluation homomorphism $\mathrm{ev}_\alpha \colon F[x] \to K$, $f(x) \mapsto f(\alpha)$, with image $F[\alpha]$. Then α is algebraic over F iff $\ker(\mathrm{ev}_\alpha) \neq (0)$.

Theorem 13.1.13 (13.9, 13.11, minimal polynomial)**.** *Let α be algebraic over F. Then there is a unique monic irreducible polynomial $m_{\alpha,F}(x) \in F[x]$ with $m_{\alpha,F}(\alpha) = 0$; it generates the kernel of* ev_α*, i.e.* $\ker(\mathrm{ev}_\alpha) = (m_{\alpha,F}(x))$*. A polynomial $g(x) \in F[x]$ satisfies $g(\alpha) = 0$ iff $m_{\alpha,F}(x) \mid g(x)$. Moreover the evaluation map induces an isomorphism*

$$F[x]/(m_{\alpha,F}(x)) \xrightarrow{\ \cong\ } F[\alpha] = F(\alpha),$$

so $F[\alpha]$ is already a field, and

$$[F(\alpha) : F] = \deg m_{\alpha,F}(x).$$

Because $F[x]$ is a PID, the nonzero ideal $\ker(\mathrm{ev}_\alpha)$ is generated by a single monic polynomial $m_{\alpha,F}$; it is irreducible because the image $F[\alpha] \subseteq K$ is a domain, so the ideal is prime, hence (in a PID, for a nonzero proper ideal) maximal. The First Isomorphism Theorem then gives the square:

$$\begin{array}{ccc} F[x] & \xrightarrow{\ \mathrm{ev}_\alpha\ } & K \\ {\scriptstyle \mathrm{mod}\ (m_{\alpha,F})}\downarrow & & \uparrow \\ F[x]/(m_{\alpha,F}(x)) & \xrightarrow[\cong]{\ \overline{\mathrm{ev}_\alpha}\ } & F(\alpha) \end{array}$$

Diagram explanation. Objects: Four objects: the polynomial ring $F[x]$ (top-left), the ambient extension field K (top-right), the quotient ring $F[x]/(m_{\alpha,F}(x))$ (bottom-left, a field because $m_{\alpha,F}$ is irreducible), and the simple extension $F(\alpha) \subseteq K$ (bottom-right). The bottom row and the inclusion $F(\alpha) \hookrightarrow K$ together identify $F(\alpha)$ as the concrete subfield generated by α.

Arrows: (1) $\mathrm{ev}_\alpha \colon F[x] \to K$, $f(x) \mapsto f(\alpha)$, is the evaluation map; its image is $F[\alpha]$. (2) $F[x] \twoheadrightarrow F[x]/(m_{\alpha,F}(x))$ is the surjective quotient map, collapsing multiples of $m_{\alpha,F}$. (3) $\overline{\mathrm{ev}_\alpha} \colon F[x]/(m_{\alpha,F}(x)) \xrightarrow{\cong} F(\alpha)$ is the induced isomorphism from the First Isomorphism Theorem, sending $f + (m_{\alpha,F}) \mapsto f(\alpha)$. (4) $F(\alpha) \hookrightarrow K$ is the canonical inclusion of the subfield.

What commutes: The square commutes: $\mathrm{ev}_\alpha = \iota \circ \overline{\mathrm{ev}_\alpha} \circ \pi$, where π is the quotient and ι the inclusion. Concretely: for $f(x) \in F[x]$, going right gives $f(\alpha)$; going down then right then up gives $\overline{\mathrm{ev}_\alpha}(f + (m_{\alpha,F})) = f(\alpha)$, then ι includes it back into K.

Why it commutes: Well-definedness of $\overline{\mathrm{ev}_\alpha}$: if $f \equiv g \pmod{m_{\alpha,F}}$ then $m_{\alpha,F} \mid (f-g)$, so $f(\alpha) - g(\alpha) = (f-g)(\alpha) = 0$ in K (since $m_{\alpha,F}(\alpha) = 0$). Thus the coset representative does not matter, and $\overline{\mathrm{ev}_\alpha}$ is well defined. Injectivity: $\ker \overline{\mathrm{ev}_\alpha} = \{f + (m_{\alpha,F}) : f(\alpha) = 0\} = \ker(\mathrm{ev}_\alpha)/(m_{\alpha,F}) = \{0\}$, because $\ker(\mathrm{ev}_\alpha) = (m_{\alpha,F})$.

Why this matters here: This is the structural heart of the minimal-polynomial theorem. It shows $F[\alpha] = F(\alpha)$ (the ring generated by α is already a field) and gives the degree formula $[F(\alpha) : F] = \deg m_{\alpha,F}$ by identifying $F(\alpha)$ with a quotient of known dimension. Without the diagram, these facts look separate; the square unifies them as one isomorphism.

Concrete example: Take $F = \mathbb{Q}$, $\alpha = \sqrt{2}$, $K = \mathbb{R}$, $m_{\alpha,\mathbb{Q}}(x) = x^2 - 2$. Then ev_α sends $a + bx + \cdots$ to $a + b\sqrt{2} + \cdots$; the quotient $\mathbb{Q}[x]/(x^2-2)$ has basis $\{1, x + (x^2-2)\}$; and $\overline{\mathrm{ev}_\alpha}$ maps $a + bx + (x^2-2) \mapsto a + b\sqrt{2}$, an isomorphism $\mathbb{Q}[x]/(x^2-2) \xrightarrow{\cong} \mathbb{Q}(\sqrt{2})$.

Common pitfall: The bottom map is an isomorphism between the abstract quotient and the concrete subfield $F(\alpha)$, not between $F[x]$ and K. The top map ev_α need not be surjective onto K (e.g. $F[x] \to \mathbb{R}$ via $x \mapsto \sqrt{2}$ has image only $\mathbb{Q}(\sqrt{2})$, far smaller than $\mathbb{R}$). Do not confuse the surjectivity of the quotient map with any surjectivity onto K.

Takeaway: The point of this diagram is that the First Isomorphism Theorem converts the abstract quotient $F[x]/(m_{\alpha,F})$ into the concrete subfield $F(\alpha)$, simultaneously proving $F[\alpha]$ is a field and computing its degree over F.

Worked Example 13.1.14 (Minimal polynomials over $\mathbb{Q}$)**.** Find $m_{\alpha,\mathbb{Q}}(x)$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ for: (a) $\alpha = \sqrt{2}$; (b) $\alpha = \sqrt[3]{2}$; (c) $\alpha = i$; (d) $\alpha = \zeta_3$ (primitive cube root of 1); (e) $\alpha = \sqrt{2} + \sqrt{2}$, i.e. $2\sqrt{2}$.

Recognition. The minimal polynomial is the monic irreducible with α as a root; produce a monic annihilator and check irreducibility (Eisenstein, rational root test, or cyclotomic).

Solution. (a) $\sqrt{2}$: $x^2 - 2$, irreducible (Eisenstein $p = 2$), degree 2. (b) $\sqrt[3]{2}$: $x^3 - 2$, Eisenstein at 2, degree 3. (c) i: $x^2 + 1$, no real root, degree 2. (d) ζ_3: $\Phi_3(x) = x^2 + x + 1$, irreducible over $\mathbb{Q}$, degree 2. (e) $2\sqrt{2}$ satisfies $x^2 = 8$, so $x^2 - 8$, irreducible (no rational root, as 8 is not a square in $\mathbb{Q}$; Eisenstein at 2 does not apply since $2^2 \mid 8$), degree 2; note $\mathbb{Q}(2\sqrt{2}) = \mathbb{Q}(\sqrt{2})$. Sanity check: in each case $\deg m_{\alpha,\mathbb{Q}} = [\mathbb{Q}(\alpha) : \mathbb{Q}]$, matching the basis $1, \alpha, \ldots, \alpha^{n-1}$.

Worked Example 13.1.15 (Minimal polynomial depends on the base field)**.** Compute $m_{\sqrt{2},F}(x)$ over $F = \mathbb{Q}$, over $F = \mathbb{Q}(\sqrt{2})$, and over $F = \mathbb{R}$.

Recognition. The minimal polynomial generates $\ker(\mathrm{ev}_{\sqrt{2}})$ *over the chosen* F; enlarging F can only shrink the degree.

Solution. Over $\mathbb{Q}$: $x^2 - 2$ (degree 2). Over $\mathbb{Q}(\sqrt{2})$: $\sqrt{2} \in F$, so $x - \sqrt{2}$ (degree 1). Over $\mathbb{R}$: again $x - \sqrt{2}$ (degree 1). Sanity check: $[F(\sqrt{2}) : F] = \deg m_{\sqrt{2},F}$ gives $2, 1, 1$ respectively; and $F(\sqrt{2}) = F$ exactly when the degree is 1.

Worked Example 13.1.16 (Frobenius-flavored minimal polynomial over $\mathbb{F}_p$)**.** Find $m_{\theta,\mathbb{F}_2}(x)$ for θ a root of $x^2 + x + 1$ inside $\mathbb{F}_4$, and verify θ^2 is the other root.

Recognition. Over $\mathbb{F}_2$, θ generates $\mathbb{F}_4$, so its minimal polynomial is the degree-2 irreducible it satisfies.

Solution. $m_{\theta,\mathbb{F}_2}(x) = x^2 + x + 1$. Its roots are θ and θ^2: indeed $\theta^2 = \theta + 1$ and $(\theta^2)^2 + \theta^2 + 1 = \theta^4 + \theta^2 + 1$. Since $\theta^3 = 1$ (as $\theta \in \mathbb{F}_4^\times$ of order 3), $\theta^4 = \theta$, giving $\theta + \theta^2 + 1 = \theta + (\theta + 1) + 1 = 0$. So θ, θ^2 are the two

roots; the Frobenius $x \mapsto x^2$ permutes them. Sanity check: product of roots $= \theta \cdot \theta^2 = \theta^3 = 1 =$ constant term, and sum $= \theta + \theta^2 = 1 =$ minus the linear coefficient (char 2), matching Vieta.

Worked Example 13.1.17 (A transcendental element)**.** Show t is transcendental over F in $F(t)$, and contrast $F(t)/F$ with $F(\alpha)/F$ for α algebraic.

Recognition. Transcendental means $\ker(\mathrm{ev}_t) = (0)$: no nonzero polynomial relation. Then $F[t] \cong F[x]$ as rings (not a field), and $F(t) = \mathrm{Frac}(F[t])$.

Solution. If $\sum c_i t^i = 0$ in $F(t)$ with not all $c_i = 0$, that is a nontrivial polynomial identity in the indeterminate t, impossible. So ev_t is injective and t is transcendental. Then $[F(t) : F] = \infty$ (the powers $1, t, t^2, \ldots$ are independent), whereas an algebraic α gives the *finite* degree $\deg m_{\alpha,F}$ with $F[\alpha] = F(\alpha)$ already a field. Sanity check: for algebraic α, $F[\alpha] = F(\alpha)$; for transcendental t, $F[t] \neq F(t)$ (e.g. $1/t \notin F[t]$), the structural fault line between the two cases.

Worked Example 13.1.18 (Degree and minimal polynomial of $\sqrt[4]{2}$)**.** Find $m_{\sqrt[4]{2},\mathbb{Q}}(x)$ and the degree, then locate $\sqrt{2}$ in the tower.

Recognition. Eisenstein gives irreducibility of $x^4 - 2$; the basis $1, \alpha, \alpha^2, \alpha^3$ has $\alpha^2 = \sqrt{2}$, exhibiting an intermediate field.

Solution. $\alpha = \sqrt[4]{2}$ satisfies $x^4 - 2 = 0$, irreducible by Eisenstein at 2, so $m_{\alpha,\mathbb{Q}}(x) = x^4 - 2$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 4$. Since $\alpha^2 = \sqrt{2}$, we have $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2}) \subseteq \mathbb{Q}(\alpha)$ with $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}(\sqrt{2})] = 2$ (as α satisfies $x^2 - \sqrt{2}$ over $\mathbb{Q}(\sqrt{2})$, irreducible there). Sanity check: $4 = 2 \cdot 2 = [\mathbb{Q}(\alpha) : \mathbb{Q}(\sqrt{2})]\,[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}]$, the tower law previewing 13.2.

Adjoining a root: realizing $F(\alpha)$ abstractly

Kronecker's theorem and the minimal-polynomial theorem are two sides of one coin. Given *any* monic irreducible $p(x) \in F[x]$, the field $F[x]/(p(x))$ is an extension in which p acquires a root θ, and there $m_{\theta,F} = p$. Conversely, given an algebraic α inside some K, the abstract field $F[x]/(m_{\alpha,F})$ is isomorphic to the concrete subfield $F(\alpha) \subseteq K$ via $x \mapsto \alpha$. This lets us compare two roots of the same irreducible polynomial through a common abstract model:

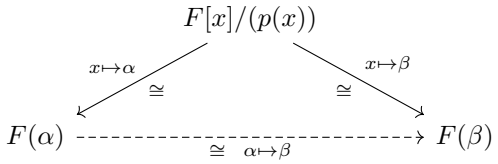

Diagram explanation. Objects: Three objects: the abstract quotient field $F[x]/(p(x))$ at the top (the common abstract model), and the two concrete simple extensions $F(\alpha)$ and $F(\beta)$ at the bottom, each living inside some larger field K where p splits.

Arrows: (1) Left: the evaluation isomorphism $F[x]/(p(x)) \xrightarrow{\cong} F(\alpha)$, sending $x + (p(x)) \mapsto \alpha$; it is an isomorphism by the minimal-polynomial theorem since $p = m_{\alpha,F}$. (2) Right: the evaluation isomorphism $F[x]/(p(x)) \xrightarrow{\cong} F(\beta)$, sending $x + (p(x)) \mapsto \beta$. (3) Bottom dashed: the composite isomorphism $F(\alpha) \xrightarrow{\cong} F(\beta)$, $\alpha \mapsto \beta$, obtained by composing the left inverse with the right map; it fixes F pointwise.

What commutes: The triangle commutes: composing the left arrow's inverse with the right arrow gives the bottom dashed map. Explicitly, for $f(x) \in F[x]$: $f(\alpha) \mapsto f + (p) \mapsto f(\beta)$, so the field isomorphism sends $f(\alpha) \mapsto f(\beta)$.

Why it commutes: Both evaluation maps are well defined on cosets because $p(\alpha) = 0 = p(\beta)$, so if $f \equiv g \pmod{p}$ then $p \mid (f - g)$, giving $f(\alpha) = g(\alpha)$ and $f(\beta) = g(\beta)$. The composite is an isomorphism because it is a composition of isomorphisms. It fixes F: a constant $c \in F$ satisfies $c \mapsto c + (p) \mapsto c$, unchanged.

Why this matters here: Two roots of the same irreducible polynomial always generate isomorphic extensions over F — the abstract quotient $F[x]/(p(x))$ is their common "canonical form". This diagram is the rigorous reason the text can speak of "the" splitting field up to isomorphism, and it foreshadows the Galois group:

the automorphisms of $F(\alpha)/F$ are exactly the composites $\alpha \mapsto \beta$ for the roots β of p that lie in $F(\alpha)$ (for these $F(\beta) = F(\alpha)$); a root $\beta \notin F(\alpha)$ gives an isomorphism onto a different field, as in the example below, so $F(\alpha)/F$ can have fewer automorphisms than p has roots.

Concrete example: $F = \mathbb{Q}$, $p(x) = x^3 - 2$, $\alpha = \sqrt[3]{2}$ (real), $\beta = \zeta_3 \sqrt[3]{2}$ (complex). Both $\mathbb{Q}(\alpha)$ and $\mathbb{Q}(\beta)$ are isomorphic to $\mathbb{Q}[x]/(x^3 - 2)$ via $x \mapsto \alpha$ and $x \mapsto \beta$ respectively. The bottom dashed map $\mathbb{Q}(\alpha) \to \mathbb{Q}(\beta)$, $\sqrt[3]{2} \mapsto \zeta_3 \sqrt[3]{2}$, is a field isomorphism fixing $\mathbb{Q}$, though as subsets of $\mathbb{C}$ they differ ($\mathbb{Q}(\alpha) \subseteq \mathbb{R}$, $\mathbb{Q}(\beta) \not\subseteq \mathbb{R}$).

Common pitfall: Abstract isomorphism of fields does not mean equality as subfields of an ambient field. The dashed arrow is a field-theoretic isomorphism, not the identity map; in the cubic example the two subfields of $\mathbb{C}$ are genuinely different sets. Confusing the abstract isomorphism with set-equality is a common error when working with Galois embeddings.

Takeaway: The point of this diagram is that any two roots of the same irreducible polynomial produce isomorphic simple extensions, with the abstract quotient $F[x]/(p(x))$ serving as a universal model from which each concrete extension is a specialization.

Worked Example 13.1.19 (Conjugate roots give isomorphic fields)**.** Let $\alpha = \sqrt[3]{2}$ and $\beta = \zeta_3 \sqrt[3]{2}$, the two being roots of $x^3 - 2$. Show $\mathbb{Q}(\alpha) \cong \mathbb{Q}(\beta)$ as abstract fields, but $\mathbb{Q}(\alpha) \neq \mathbb{Q}(\beta)$ inside $\mathbb{C}$.

Recognition. Both are $\cong \mathbb{Q}[x]/(x^3 - 2)$ by Kronecker, so they are abstractly isomorphic via $\alpha \mapsto \beta$; equality as subsets of $\mathbb{C}$ is a separate, finer question.

Solution. Since $x^3 - 2$ is irreducible, $\mathbb{Q}(\alpha) \cong \mathbb{Q}[x]/(x^3 - 2) \cong \mathbb{Q}(\beta)$ by the diagram above, with the isomorphism $\alpha \mapsto \beta$. But $\alpha = \sqrt[3]{2} \in \mathbb{R}$ while $\beta = \zeta_3 \sqrt[3]{2} \notin \mathbb{R}$, so as subfields of $\mathbb{C}$ they differ ($\mathbb{Q}(\alpha) \subseteq \mathbb{R}$, $\mathbb{Q}(\beta) \not\subseteq \mathbb{R}$). Sanity check: both have degree $[\cdot : \mathbb{Q}] = 3$, consistent with the shared minimal polynomial; abstract isomorphism does not imply equality of embeddings.

Worked Example 13.1.20 (Two presentations of the same field $\mathbb{F}_4$)**.** Show $\mathbb{F}_2[x]/(x^2 + x + 1)$ is isomorphic to any field with 4 elements, and that "the" field $\mathbb{F}_4$ is well defined up to isomorphism.

Recognition. Any 4-element field L has char $= 2$ and $[L : \mathbb{F}_2] = 2$, so $L = \mathbb{F}_2(\theta)$ with $\theta \notin \mathbb{F}_2$ a root of the unique irreducible quadratic $x^2 + x + 1$.

Solution. If $|L| = 4$ then $\theta \in L \setminus \mathbb{F}_2$ satisfies a degree-2 monic irreducible over $\mathbb{F}_2$; the only such polynomial is $x^2 + x + 1$ ($x^2, x^2 + 1, x^2 + x$ all factor). Hence $L \cong \mathbb{F}_2[x]/(x^2 + x + 1)$, so all 4-element fields are isomorphic. Sanity check: there is exactly one monic irreducible quadratic over $\mathbb{F}_2$, so exactly one field of order 4 up to isomorphism, justifying the notation $\mathbb{F}_4$.

Worked Example 13.1.21 (When $F[\alpha]$ is already a field)**.** For $\alpha = \sqrt{2}$, verify directly that $\mathbb{Q}[\sqrt{2}] = \mathbb{Q}(\sqrt{2})$ by inverting a general element.

Recognition. The theorem says $F[\alpha] = F(\alpha)$ for algebraic α since $F[x]/(m_{\alpha,F})$ is a field; here we confirm it by hand.

Solution. Take $a + b\sqrt{2} \neq 0$ ($a, b \in \mathbb{Q}$). Then $(a + b\sqrt{2})(a - b\sqrt{2}) = a^2 - 2b^2 \neq 0$ (else $\sqrt{2} = a/b \in \mathbb{Q}$). So

$$(a + b\sqrt{2})^{-1} = \frac{a - b\sqrt{2}}{a^2 - 2b^2} \in \mathbb{Q}[\sqrt{2}],$$

showing every nonzero element of $\mathbb{Q}[\sqrt{2}]$ is invertible *inside* $\mathbb{Q}[\sqrt{2}]$. Hence $\mathbb{Q}[\sqrt{2}] = \mathbb{Q}(\sqrt{2})$. Sanity check: this matches $\mathbb{Q}[x]/(x^2 - 2)$ being a field because $x^2 - 2$ is irreducible (maximal ideal), no separate "form the fraction field" step needed.

Remark 13.1.1. The split between algebraic and transcendental elements is precisely the split between $\ker(\mathrm{ev}_\alpha)$ being a nonzero (maximal) ideal versus the zero ideal. In the algebraic case $F[\alpha] = F[x]/(m_{\alpha,F})$ is a field of finite degree $\deg m_{\alpha,F}$; in the transcendental case $F[\alpha] \cong F[x]$ is a polynomial ring and $F(\alpha) \cong F(x)$ is an infinite extension. Section 13.2 promotes the single-generator degree formula $[F(\alpha) : F] = \deg m_{\alpha,F}$ into the multiplicative tower law $[K : F] = [K : E]\,[E : F]$.

Exercises (from the text).

1. Show that $p(x) = x^3 + 9x + 6$ is irreducible in $\mathbb{Q}[x]$. Let θ be a root of $p(x)$. Find the inverse of $1 + \theta$ in $\mathbb{Q}(\theta)$.

2. Show that x^3-2x-2 is irreducible over $\mathbb{Q}$ and let θ be a root. Compute $(1+\theta)(1+\theta+\theta^2)$ and $\dfrac{1+\theta}{1+\theta+\theta^2}$ in $\mathbb{Q}(\theta)$.

3. Show that x^3+x+1 is irreducible over $\mathbb{F}_2$ and let θ be a root. Compute the powers of θ in $\mathbb{F}_2(\theta)$.

4. Prove directly that the map $a+b\sqrt{2}\mapsto a-b\sqrt{2}$ is an isomorphism of $\mathbb{Q}(\sqrt{2})$ with itself.

5. Suppose α is a rational root of a monic polynomial in $\mathbb{Z}[x]$. Prove that α is an integer.

6. Show that if α is a root of $a_nx^n+a_{n-1}x^{n-1}+\cdots+a_1x+a_0$ then $a_n\alpha$ is a root of the monic polynomial $x^n+a_{n-1}x^{n-1}+a_na_{n-2}x^{n-2}+\cdots+a_n^{n-2}a_1x+a_n^{n-1}a_0$.

7. Prove that x^3-nx+2 is irreducible for $n\neq -1,3,5$.

8. Prove that x^5-ax-1 is irreducible over $\mathbb{Z}$ unless $a=0$, 2 or -1. The first two correspond to linear factors, the third corresponds to the factorization $(x^2-x+1)(x^3+x^2-1)$.

Practice problems.

1. Let $\alpha=\sqrt{2}+\sqrt{5}$. Show that α is algebraic over $\mathbb{Q}$, find its minimal polynomial $m_{\alpha,\mathbb{Q}}(x)$, and compute $[\mathbb{Q}(\alpha):\mathbb{Q}]$.

2. Determine the characteristic and the prime subfield of each of the following fields: $\mathbb{Q}$, $\mathbb{Z}/7\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z}[x]/(x^3+x+1)$, and $\mathrm{Frac}(\mathbb{Z}/3\mathbb{Z}[t])$ (the field of rational functions in t over $\mathbb{Z}/3\mathbb{Z}$).

3. Let $F=\mathbb{Z}/3\mathbb{Z}$ and $p(x)=x^2+1\in F[x]$. Verify that $p(x)$ is irreducible over F, describe the field $K=F[x]/(p(x))$ explicitly (give $|K|$ and a basis as an F-vector space), and exhibit a root of $p(x)$ in K.

4. Compute the minimal polynomial of $\zeta_3=e^{2\pi i/3}$ over $\mathbb{Q}$, and separately the minimal polynomial of $\sqrt[3]{2}$ over $\mathbb{Q}$. Then decide whether x^3-2 remains irreducible over $\mathbb{Q}(\zeta_3)$, and justify your answer using degrees.

5. Let α be a root of $f(x)=x^3-x-1\in\mathbb{Q}[x]$. Show f is irreducible over $\mathbb{Q}$, so $[\mathbb{Q}(\alpha):\mathbb{Q}]=3$, and express α^4 and $(\alpha+1)^{-1}$ as $\mathbb{Q}$-linear combinations of the basis $1,\alpha,\alpha^2$.

6. Decide which of the following are algebraic and which are transcendental over the stated base field, with justification: (a) π over $\mathbb{Q}$; (b) π over $\mathbb{Q}(\pi^2)$; (c) the function t over $\mathbb{Q}$ inside $\mathrm{Frac}(\mathbb{Q}[t])$; (d) $\sqrt{1+\sqrt{2}}$ over $\mathbb{Q}$.

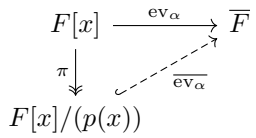
7. Let K/F be a field extension with $[K:F]$ finite. Prove that every element of K is algebraic over F, and that for each $\alpha\in K$ one has $\deg m_{\alpha,F}(x)\le[K:F]$. Show by example that the inequality can be strict.

8. For $F=\mathbb{Z}/2\mathbb{Z}$, list all monic irreducible polynomials of degree 2 and of degree 3 in $F[x]$, and use them to construct fields with 4 and with 8 elements as quotients $F[x]/(p(x))$.

Additional exercises.

1. Let $\alpha=\sqrt[4]{2}$. Build the tower $\mathbb{Q}\subseteq\mathbb{Q}(\sqrt{2})\subseteq\mathbb{Q}(\alpha)$, compute the degree of each step, and use the tower to conclude $[\mathbb{Q}(\alpha):\mathbb{Q}]=4$. Find $m_{\alpha,\mathbb{Q}}(x)$ and $m_{\alpha,\mathbb{Q}(\sqrt{2})}(x)$.

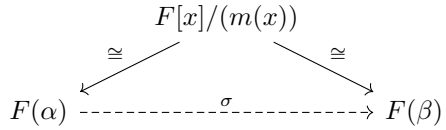
2. Compute the cyclotomic polynomials $\Phi_5(x)$, $\Phi_8(x)$, and $\Phi_{12}(x)$ from the factorization $x^n-1=\prod_{d\mid n}\Phi_d(x)$, and state $[\mathbb{Q}(\zeta_n):\mathbb{Q}]=\varphi(n)$ for each.



3. Let $K=\mathbb{Q}(\sqrt{2},\sqrt{3})$. Show $[K:\mathbb{Q}]=4$, exhibit a $\mathbb{Q}$-basis, prove $K=\mathbb{Q}(\sqrt{2}+\sqrt{3})$ (a simple extension), and find $m_{\sqrt{2}+\sqrt{3},\mathbb{Q}}(x)$.

4. Let F be a field with $\mathrm{char}\,F=p>0$. Prove the Frobenius map $\varphi\colon x\mapsto x^p$ is a ring homomorphism $F\to F$, that it is injective, and that it is the identity on the prime subfield $\mathbb{Z}/p\mathbb{Z}$. Give an example where φ is not surjective.

5. Determine whether $\cos(20^\circ)$ is constructible by showing it satisfies $8x^3-6x-1=0$, proving this cubic is irreducible over $\mathbb{Q}$, and concluding $[\mathbb{Q}(\cos 20^\circ):\mathbb{Q}]=3$; explain why a degree that is not a power of 2 rules out constructibility.



Commutative-diagram exercises.

1. Let $p(x) \in F[x]$ be irreducible of degree n and let $\overline{F}$ be an algebraic closure with $\alpha \in \overline{F}$ a root of p. Draw the diagram exhibiting the evaluation homomorphism $\mathrm{ev}_\alpha \colon F[x] \to \overline{F}$ factoring through $F[x]/(p(x))$, and prove the induced map is an isomorphism onto $F(\alpha)$:

   Identify $\ker(\mathrm{ev}_\alpha)$ and explain why $\overline{\mathrm{ev}_\alpha}$ lands in $F(\alpha)$.

2. Let $\alpha, \beta \in \overline{F}$ both have the same minimal polynomial $m(x) = m_{\alpha,F}(x) = m_{\beta,F}(x)$ over F. Show there is a field isomorphism $\sigma \colon F(\alpha) \to F(\beta)$ fixing F pointwise and sending $\alpha \mapsto \beta$, by completing the diagram:

   State precisely what each diagonal isomorphism is and why σ fixes F.

3. Let $p(x) \in F[x]$ be irreducible and let $\iota \colon F \hookrightarrow F[x]/(p(x))$ be the canonical inclusion. Show that any F-algebra homomorphism out of $F[x]/(p(x))$ into an F-algebra A corresponds bijectively to a choice of root of p in A, by interpreting the universal property as the diagram:

   where $j \colon F \to A$ is the structure map; specify the data determining ψ and the constraint it must satisfy.

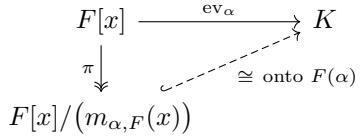
4. Let $\mathrm{char}\, F = p > 0$ and let $\varphi \colon F \to F$ be the Frobenius $x \mapsto x^p$. For a finite extension K/F, show φ extends to $\Phi \colon K \to K$ and that the square

   commutes. Conclude Φ is φ-semilinear, and explain why Φ being an isomorphism is equivalent to K being a perfect field.

13.2 Algebraic Extensions

Algebraic and transcendental elements

Throughout, F is a field and K/F is an extension, i.e. F is a subfield of K. Recall from 13.1 that K is in particular an F-vector space, and the *degree* $[K : F] = \dim_F K$ measures the size of the extension; K/F is *finite* if $[K : F] < \infty$.



Definition 13.2.1. Let K/F be an extension and $\alpha \in K$. We say α is *algebraic over* F if there is a nonzero polynomial $f(x) \in F[x]$ with $f(\alpha) = 0$; otherwise α is *transcendental over* F. The extension K/F is *algebraic* if every element of K is algebraic over F.

If α is algebraic over F, then among all nonzero polynomials in $F[x]$ vanishing at α there is a unique monic one of least degree, the *minimal polynomial* $m_{\alpha,F}(x)$. It is irreducible over F, and $f(\alpha) = 0$ (for

$f \in F[x]$) iff $m_{\alpha,F}(x) \mid f(x)$. We write $\deg \alpha := \deg m_{\alpha,F}(x)$ for the *degree of α over F*. The evaluation homomorphism $x \mapsto \alpha$ realizes

$$F(\alpha) \;\cong\; F[x]/\big(m_{\alpha,F}(x)\big),$$

the picture from 13.1 that we now use repeatedly:

The kernel of ev_α is exactly $(m_{\alpha,F})$, so π induces the dashed isomorphism onto $F(\alpha) = F[\alpha] \subseteq K$.

Diagram explanation. Objects: Three nodes. Top-left: $F[x]$, the polynomial ring over F (an integral domain, hence a ring with no zero-divisors). Top-right: K, the ambient field extension of F that contains α. Bottom-left: $F[x]/(m_{\alpha,F}(x))$, the quotient ring – in fact a field, because $m_{\alpha,F}$ is irreducible, so $(m_{\alpha,F})$ is maximal.

Arrows: (i) $\mathrm{ev}_\alpha : F[x] \to K$, the evaluation-at-$\alpha$ ring homomorphism, sending $f(x) \mapsto f(\alpha)$; its image is $F[\alpha] = F(\alpha)$ since α is algebraic. (ii) $\pi : F[x] \twoheadrightarrow F[x]/(m_{\alpha,F}(x))$, the canonical surjective quotient map, sending $f(x) \mapsto f(x) + (m_{\alpha,F})$. (iii) The dashed arrow $F[x]/(m_{\alpha,F}) \to K$: the induced map (isomorphism onto $F(\alpha)$) that the first isomorphism theorem delivers.

What commutes: The triangle commutes: $\mathrm{ev}_\alpha = \widetilde{\mathrm{ev}}_\alpha \circ \pi$, where $\widetilde{\mathrm{ev}}_\alpha$ is the dashed induced map. In other words, evaluating f at α directly equals first reducing f mod $m_{\alpha,F}$, then evaluating the coset.

Why it commutes: Take $f(x) \in F[x]$. Going right: $f(x) \mapsto f(\alpha)$. Going down then diagonally: $f(x) \mapsto f(x) + (m_{\alpha,F}) \mapsto f(\alpha)$. These agree by definition of the induced map: it sends the coset $f + (m_{\alpha,F})$ to $f(\alpha)$. Well-definedness: if $f \equiv g \pmod{m_{\alpha,F}}$, then $m_{\alpha,F} \mid (f - g)$, so $(f - g)(\alpha) = 0$ (since $m_{\alpha,F}(\alpha) = 0$), giving $f(\alpha) = g(\alpha)$. The coset representative does not affect the output.

Why this matters here: This triangle is the key structural fact underlying Proposition 13.4: the isomorphism $F(\alpha) \cong F[x]/(m_{\alpha,F})$ identifies $[F(\alpha) : F]$ with $\deg m_{\alpha,F}$, because the quotient ring has F-basis $\{1, \bar{x}, \bar{x}^2, \ldots, \bar{x}^{n-1}\}$, the same n elements as $\{1, \alpha, \ldots, \alpha^{n-1}\}$.

Concrete example: Take $F = \mathbb{Q}$, $\alpha = \sqrt{2}$, $K = \mathbb{R}$. Then $m_{\alpha,\mathbb{Q}} = x^2 - 2$, and the triangle gives $\mathbb{Q}(\sqrt{2}) \cong \mathbb{Q}[x]/(x^2 - 2)$. The coset $\bar{x}$ maps to $\sqrt{2}$; evaluating $3x + 1$ at $\sqrt{2}$ equals evaluating the coset $3\bar{x} + 1$ at $\sqrt{2}$, giving $3\sqrt{2} + 1$.

Common pitfall: Students often think the dashed isomorphism is $F[x]/(m_{\alpha,F}) \to K$ (the whole field K). It is only onto $F(\alpha) \subseteq K$; the triangle's upper-right node is K because that is where ev_α lands, but the dashed arrow hits only the subfield $F(\alpha)$.

Takeaway: The point of this diagram is that every simple algebraic extension $F(\alpha)$ is concretely and canonically isomorphic to the quotient ring $F[x]/(m_{\alpha,F})$, which makes its F-dimension equal to $\deg m_{\alpha,F}$.

Proposition 13.2.2 (13.4 of 13.1, recalled)**.** *Let α be algebraic over F with $\deg \alpha = n$. Then*

$$[F(\alpha) : F] = n, \qquad \textit{with } F\textit{-basis } 1, \alpha, \alpha^2, \ldots, \alpha^{n-1}.$$

In particular $F(\alpha)/F$ is finite, hence (as we show below) algebraic.

Worked Example 13.2.3 (Degrees of standard algebraic numbers)**.** Find $m_{\alpha,\mathbb{Q}}(x)$, $\deg \alpha$, and an explicit basis of $\mathbb{Q}(\alpha)$ for (a) $\alpha = \sqrt{2}$; (b) $\alpha = \sqrt[3]{2}$; (c) $\alpha = \zeta_3$ (primitive cube root of unity); (d) $\alpha = \zeta_5$.

Recognition. Proposition above: produce a monic polynomial killing α, verify irreducibility over $\mathbb{Q}$ (Eisenstein, or cyclotomic Φ_n), then $[\mathbb{Q}(\alpha) : \mathbb{Q}] = \deg \alpha$ with basis $1, \alpha, \ldots, \alpha^{\deg \alpha - 1}$.

Solution. (a) $m = x^2 - 2$, irreducible by Eisenstein at 2; deg = 2, basis $1, \sqrt{2}$. (b) $m = x^3 - 2$, Eisenstein at 2; deg = 3, basis $1, \sqrt[3]{2}, \sqrt[3]{4}$. (c) ζ_3 satisfies $x^3 - 1 = (x - 1)(x^2 + x + 1)$ and $\zeta_3 \neq 1$, so $m = \Phi_3(x) = x^2 + x + 1$; deg = 2, basis $1, \zeta_3$. (d) $m = \Phi_5(x) = x^4 + x^3 + x^2 + x + 1$ (irreducible: substitute $x = y + 1$ and apply Eisenstein at 5); deg = 4, basis $1, \zeta_5, \zeta_5^2, \zeta_5^3$. Sanity check: in each case $\deg m_{\alpha,\mathbb{Q}} = \dim_{\mathbb{Q}} \mathbb{Q}(\alpha)$, e.g. $\mathbb{Q}(\zeta_5)$ has $\mathbb{Q}$-dimension $\varphi(5) = 4$, matching.

Worked Example 13.2.4 (Minimal polynomial depends on the base field)**.** Compute $m_{\sqrt{2},F}(x)$ for $F = \mathbb{Q}$, $F = \mathbb{Q}(\sqrt{2})$, and $F = \mathbb{Q}(\sqrt{3})$; in each case give $[F(\sqrt{2}) : F]$.

Recognition. The minimal polynomial is taken *over the stated base*; enlarging the base can only shrink the degree (the old minimal polynomial still vanishes, so the new one divides it).

Solution. Over $\mathbb{Q}$: $m = x^2 - 2$, degree 2. Over $\mathbb{Q}(\sqrt{2})$: $\sqrt{2} \in F$ already, so $m = x - \sqrt{2}$, degree 1 and $F(\sqrt{2}) = F$. Over $\mathbb{Q}(\sqrt{3})$: is $\sqrt{2} \in \mathbb{Q}(\sqrt{3})$? If $\sqrt{2} = a + b\sqrt{3}$ with $a, b \in \mathbb{Q}$, squaring gives $2 = a^2 + 3b^2 + 2ab\sqrt{3}$, forcing $ab = 0$; neither $a = 0$ (then $2 = 3b^2$, impossible in $\mathbb{Q}$) nor $b = 0$ (then $2 = a^2$, impossible) works, so $\sqrt{2} \notin \mathbb{Q}(\sqrt{3})$. Hence $x^2 - 2$ stays irreducible over $\mathbb{Q}(\sqrt{3})$, $m = x^2 - 2$, degree 2. Sanity check: each $m_{\sqrt{2},F}$ divides $x^2 - 2$ (which still vanishes at $\sqrt{2}$), so the degrees $2, 1, 2$ are all at most 2, as they must be.

Worked Example 13.2.5 (A transcendental element)**.** Show $\alpha = \pi$ is transcendental over $\mathbb{Q}$ but algebraic over $\mathbb{R}$, and that t is transcendental over F in $K = F(t)$, the field of rational functions.

Recognition. Algebraic = root of a nonzero polynomial over the base. Transcendence over $\mathbb{Q}$ is the (deep) Lindemann theorem; transcendence of the indeterminate t is immediate from the definition of $F(t)$.

Solution. Over $\mathbb{R}$: π is a root of $x - \pi \in \mathbb{R}[x]$, so algebraic of degree 1, $\mathbb{R}(\pi) = \mathbb{R}$. Over $\mathbb{Q}$: by Lindemann no nonzero $f \in \mathbb{Q}[x]$ has $f(\pi) = 0$, so π is transcendental; consequently $\mathbb{Q}(\pi) \cong \mathbb{Q}(t)$, the rational function field, and $[\mathbb{Q}(\pi) : \mathbb{Q}] = \infty$. For $t \in F(t)$: a relation $\sum c_i t^i = 0$ with $c_i \in F$ not all zero would be a nonzero polynomial identity in the indeterminate t, impossible; so t is transcendental, $[F(t) : F] = \infty$. Sanity check: a transcendental element generates an infinite-dimensional extension $F(\alpha) \cong F(t)$, never a finite one.

Proposition 13.2.6. *Let $\alpha \in K$. Then α is algebraic over F if and only if the simple extension $F(\alpha)/F$ is finite. More precisely, α is algebraic of degree n iff $[F(\alpha) : F] = n < \infty$.*

Worked Example 13.2.7 (Algebraic $\Leftrightarrow$ finite simple extension)**.** Use the proposition to decide algebraicity of $\alpha = \sqrt{2} + \sqrt{3}$ over $\mathbb{Q}$ without first guessing its minimal polynomial.

Recognition. If we can trap α inside a finite extension of $\mathbb{Q}$, then $\mathbb{Q}(\alpha)$ is finite (it is a subspace), so α is algebraic; the degree must divide that of the trapping field.

Solution. Put $L = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Each generator is algebraic of degree 2, and we will see $[L : \mathbb{Q}] = 4 < \infty$. Since $\alpha = \sqrt{2} + \sqrt{3} \in L$, the subspace $\mathbb{Q}(\alpha) \subseteq L$ is finite-dimensional, so α is algebraic with $[\mathbb{Q}(\alpha) : \mathbb{Q}] \mid 4$. To pin it down: $\alpha^2 = 5 + 2\sqrt{6}$, so $\sqrt{6} \in \mathbb{Q}(\alpha)$; then $\alpha \cdot \sqrt{6} = \sqrt{12} + \sqrt{18} = 2\sqrt{3} + 3\sqrt{2}$, and combined with $\alpha = \sqrt{2} + \sqrt{3}$ we solve $\sqrt{2}, \sqrt{3} \in \mathbb{Q}(\alpha)$, giving $\mathbb{Q}(\alpha) = L$ and $\deg \alpha = 4$. Indeed $m_{\alpha,\mathbb{Q}}(x) = x^4 - 10x^2 + 1$. Sanity check: $\deg m = 4 = [L : \mathbb{Q}]$, consistent with $\mathbb{Q}(\alpha) = L$.

The tower law: multiplicativity of degrees

Theorem 13.2.8 (13.14)**.** *Let $F \subseteq E \subseteq K$ be fields. Then*

$$[K : F] = [K : E]\,[E : F],$$

in the sense that $[K : F]$ is finite iff both $[K : E]$ and $[E : F]$ are finite, and then equality holds. If $\alpha_1, \ldots, \alpha_m$ is an F-basis of E and $\beta_1, \ldots, \beta_n$ is an E-basis of K, then $\{\alpha_i \beta_j\}_{i,j}$ is an F-basis of K.

The product of bases is the conceptual content; we display the tower with its degrees:

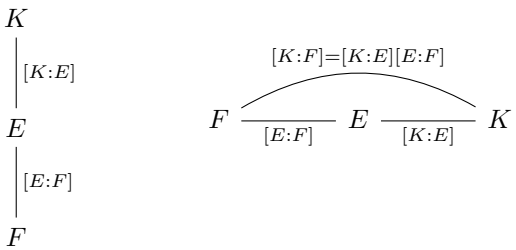


Diagram explanation. Objects: Three field nodes in both views: F (the base field), E (an intermediate field, $F \subseteq E$), and K (the top field, $E \subseteq K$). Each is a field; the edges record the degree $[\,\cdot : \cdot\,] = \dim$ of the upper field as a vector space over the lower.

Arrows: All arrows here are drawn as dashes (inclusions labelled only by their degrees), not arbitrary ring homomorphisms. Each dash A–B labeled d means $[B : A] = d$, i.e. B has dimension d as an A-vector space. Left diagram: a vertical chain $F \subset E \subset K$ with the two step-degrees on the edges. Right diagram: a horizontal chain F–E–K with the same edge labels, plus a bent-left arc from F to K labeled with the product $[K : F] = [K : E][E : F]$, visually asserting the multiplicativity.

What commutes: The key equality is $[K : F] = [K : E] \cdot [E : F]$: the two-step product equals the direct degree. In the right diagram this is the equality of the bent arc label with the product of the two straight-edge labels.

Why it commutes: If $\{\alpha_i\}_{i=1}^m$ is an F-basis of E and $\{\beta_j\}_{j=1}^n$ is an E-basis of K, then every element of K writes as $\sum_j e_j\beta_j$ with $e_j \in E$, and each $e_j = \sum_i c_{ij}\alpha_i$ with $c_{ij} \in F$; substituting gives $\sum_{i,j} c_{ij}\alpha_i\beta_j$, so $\{\alpha_i\beta_j\}$ spans K over F. Independence follows similarly. Hence $\dim_F K = mn$.

Why this matters here: This pair of diagrams summarizes Theorem 13.14 visually. It is the primary computational tool in the section: every degree calculation in the worked examples below is an instance – adjoin one generator at a time, read off the degree of its minimal polynomial over the current field, then multiply.

Concrete example: $F = \mathbb{Q}$, $E = \mathbb{Q}(\sqrt{2})$, $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Then $[E : F] = 2$, $[K : E] = 2$, and the tower law gives $[K : \mathbb{Q}] = 4$, with F-basis $\{1, \sqrt{2}, \sqrt{3}, \sqrt{6}\} = \{1 \cdot 1, \sqrt{2} \cdot 1, 1 \cdot \sqrt{3}, \sqrt{2} \cdot \sqrt{3}\}$ exactly as in the worked example below.

Common pitfall: The dash arrows here are not arbitrary ring or field homomorphisms; they represent inclusion together with a degree label. Students sometimes read the diagram as if the arrows are projections or quotient maps, but they are merely recording "E is a degree-d extension of F".

Takeaway: The point of this diagram is that the degree of a tower of field extensions multiplies at each step, so computing $[K : F]$ reduces to multiplying the degrees of successive one-generator adjunctions.

Worked Example 13.2.9 (A degree-4 biquadratic tower)**.** With $F = \mathbb{Q}$, $E = \mathbb{Q}(\sqrt{2})$, $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, compute all three degrees and exhibit the basis $\{\alpha_i\beta_j\}$.

Recognition. Theorem 13.14: build K one generator at a time and multiply degrees; the tensor of bases gives the basis of K.

Solution. $[E : F] = 2$ with basis $1, \sqrt{2}$ (minimal poly $x^2 - 2$). Over E, is $\sqrt{3} \in E$? No, by the argument of an earlier example, so $x^2 - 3$ stays irreducible over E and $[K : E] = 2$ with basis $1, \sqrt{3}$. Thus

$$[K : \mathbb{Q}] = [K : E]\,[E : F] = 2 \cdot 2 = 4,$$

with F-basis $\{1 \cdot 1,\ 1 \cdot \sqrt{3},\ \sqrt{2} \cdot 1,\ \sqrt{2} \cdot \sqrt{3}\} = \{1, \sqrt{3}, \sqrt{2}, \sqrt{6}\}$. Sanity check: $\dim_{\mathbb{Q}} \mathbb{Q}(\sqrt{2}, \sqrt{3}) = 4$ and the four listed elements are linearly independent over $\mathbb{Q}$, confirming the basis.

This biquadratic extension is *not* a simple tower: $\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$ has Galois group the Klein four-group, so it has *three* intermediate quadratic fields, not one. Besides $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{3})$ there is a third, $\mathbb{Q}(\sqrt{6})$, the fixed field of the automorphism $\sqrt{2} \mapsto -\sqrt{2},\ \sqrt{3} \mapsto -\sqrt{3}$ (which fixes the product $\sqrt{6} = \sqrt{2}\sqrt{3}$). The full subfield lattice, each covering edge of relative degree 2:

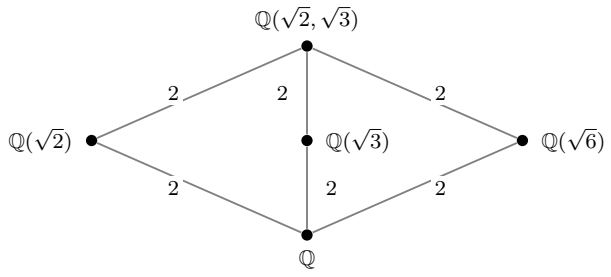

Diagram explanation. Objects: Five field nodes: $\mathbb{Q}$ at the bottom; the three intermediate quadratic subfields $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{3})$, $\mathbb{Q}(\sqrt{6})$ in the middle row; and $\mathbb{Q}(\sqrt{2},\sqrt{3})$ at the top. Each node is a subfield of $\mathbb{C}$; the lattice is ordered by inclusion.

Arrows: Six undirected edges, each labeled 2, recording a degree-2 inclusion: $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt{2})$, $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt{3})$, $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt{6})$ (bottom three), and $\mathbb{Q}(\sqrt{2}) \hookrightarrow \mathbb{Q}(\sqrt{2},\sqrt{3})$, $\mathbb{Q}(\sqrt{3}) \hookrightarrow \mathbb{Q}(\sqrt{2},\sqrt{3})$, $\mathbb{Q}(\sqrt{6}) \hookrightarrow \mathbb{Q}(\sqrt{2},\sqrt{3})$ (top three). Every edge carries the same degree 2, confirming six degree-2 inclusions.

What commutes: Every pair of paths from $\mathbb{Q}$ to $\mathbb{Q}(\sqrt{2},\sqrt{3})$ composes to the same total degree $4 = 2 \cdot 2$ (tower law). For instance, $\mathbb{Q} \subset \mathbb{Q}(\sqrt{2}) \subset \mathbb{Q}(\sqrt{2},\sqrt{3})$ gives $2 \cdot 2 = 4$, and $\mathbb{Q} \subset \mathbb{Q}(\sqrt{6}) \subset \mathbb{Q}(\sqrt{2},\sqrt{3})$ also gives $2 \cdot 2 = 4$, consistent with $[\mathbb{Q}(\sqrt{2},\sqrt{3}) : \mathbb{Q}] = 4$.

Why it commutes: $\mathbb{Q}(\sqrt{2},\sqrt{3})/\mathbb{Q}$ has Galois group the Klein four-group V_4 (generated by $\sigma : \sqrt{2} \mapsto -\sqrt{2}$, $\tau : \sqrt{3} \mapsto -\sqrt{3}$). The three intermediate fields correspond to the three index-2 subgroups of V_4, each fixing one of $\sqrt{2}$, $\sqrt{3}$, $\sqrt{6} = \sqrt{2}\sqrt{3}$. By the fundamental theorem (or direct computation) each has degree 2 over $\mathbb{Q}$ and degree 2 below $\mathbb{Q}(\sqrt{2},\sqrt{3})$.

Why this matters here: The diagram illustrates that a degree-4 extension can have three distinct intermediate quadratic fields, not just one, destroying the naive expectation that a "two-step" tower is unique. It directly prepares for the tower law worked examples and for the discussion of the Galois group being non-cyclic (V_4, not $\mathbb{Z}/4\mathbb{Z}$).

Concrete example: Take the automorphism $\sigma\tau : \sqrt{2} \mapsto -\sqrt{2}, \sqrt{3} \mapsto -\sqrt{3}$. It fixes $\sqrt{6} = \sqrt{2}\sqrt{3}$ and its fixed field is exactly $\mathbb{Q}(\sqrt{6})$, the third intermediate field. All three arise symmetrically from the three non-trivial elements of V_4.

Common pitfall: Students often expect only two intermediate subfields (one from each generator). The key subtlety is that $\mathbb{Q}(\sqrt{6}) \neq \mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{6}) \neq \mathbb{Q}(\sqrt{3})$, but $\sqrt{6} \in \mathbb{Q}(\sqrt{2},\sqrt{3})$ anyway; a product of two adjoined elements can generate a third distinct intermediate field.

Takeaway: The point of this diagram is that $\mathbb{Q}(\sqrt{2},\sqrt{3})/\mathbb{Q}$ is a biquadratic (Klein four) extension with three distinct quadratic subfields, showing that degree-4 extensions are not always generated by a single quadratic adjunction repeated.

Worked Example 13.2.10 (Degree 6 and an immediate non-membership)**.** Let $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ (the splitting field of $x^3 - 2$). Compute $[K : \mathbb{Q}]$ two ways and deduce $\sqrt[3]{2} \notin \mathbb{Q}(\zeta_3)$.

Recognition. Build the tower in two orders; the tower law forces the two products to agree, and a degree that does not divide the total rules out membership.

Solution. Order 1: $[\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 3$ ($x^3 - 2$, Eisenstein). Then ζ_3 has degree ≤ 2 over $\mathbb{Q}(\sqrt[3]{2})$; since $\zeta_3 \notin \mathbb{R} \supseteq \mathbb{Q}(\sqrt[3]{2})$, its degree is exactly 2 (minimal poly $x^2 + x + 1$). So $[K : \mathbb{Q}] = 2 \cdot 3 = 6$. Order 2: $[\mathbb{Q}(\zeta_3) : \mathbb{Q}] = 2$ ($\Phi_3 = x^2 + x + 1$); then $[K : \mathbb{Q}(\zeta_3)] \leq 3$ (as $\sqrt[3]{2}$ is a root of $x^3 - 2$) and the product must equal 6, forcing $[K : \mathbb{Q}(\zeta_3)] = 3$, i.e. $x^3 - 2$ is irreducible over $\mathbb{Q}(\zeta_3)$ and $\sqrt[3]{2} \notin \mathbb{Q}(\zeta_3)$. Sanity check: $6 = 2 \cdot 3 = 3 \cdot 2$ both ways; and $3 \nmid 2 = [\mathbb{Q}(\zeta_3) : \mathbb{Q}]$ already shows $\sqrt[3]{2}$ (degree 3) cannot lie in $\mathbb{Q}(\zeta_3)$.

Worked Example 13.2.11 (Degree forces irreducibility)**.** Show $\sqrt[3]{2} \notin \mathbb{Q}(\sqrt{2})$ and, more generally, that $[F(\alpha) : F] = p$ prime forces $\alpha \notin E$ for any field $E \supseteq F$ with $[E : F] < p$.

Recognition. The degree $[F(\alpha) : F]$ must be divisible by $[E : F]$ for any intermediate E (tower law). If $\alpha \in E$ then $F(\alpha) \subseteq E$, constraining degrees.

Solution. If $\sqrt[3]{2} \in \mathbb{Q}(\sqrt{2})$ then $\mathbb{Q}(\sqrt[3]{2}) \subseteq \mathbb{Q}(\sqrt{2})$, so by the tower law $3 = [\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}]$ divides $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$, false; hence $\sqrt[3]{2} \notin \mathbb{Q}(\sqrt{2})$. General statement: if $\alpha \in E$ then $F(\alpha) \subseteq E$, so $p = [F(\alpha) : F]$ divides $[E : F] < p$, impossible for a prime p unless $[E : F] = 0$, which cannot happen; contradiction. Sanity check: this is the standard "prime degree blocks proper subfields" argument — a degree-p simple extension has no intermediate fields strictly between F and $F(\alpha)$.

Worked Example 13.2.12 (A tower over a finite field)**.** In $\mathbb{F}_2 \subseteq \mathbb{F}_4 \subseteq \mathbb{F}_{16}$ verify the tower law and identify the degrees.

Recognition. For finite fields $\mathbb{F}_{p^n}$, $[\mathbb{F}_{p^n} : \mathbb{F}_p] = n$, and $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^n}$ iff $d \mid n$; degrees of subfield towers multiply.

Solution. $[\mathbb{F}_4 : \mathbb{F}_2] = 2$ and $[\mathbb{F}_{16} : \mathbb{F}_2] = 4$. The tower law gives $[\mathbb{F}_{16} : \mathbb{F}_4] = 4/2 = 2$, consistent with $\mathbb{F}_4 \subseteq \mathbb{F}_{16}$ since $2 \mid 4$. Concretely, $\mathbb{F}_4 = \mathbb{F}_2[x]/(x^2 + x + 1)$ and one builds $\mathbb{F}_{16}$ as a degree-2 extension of $\mathbb{F}_4$. Sanity check: $|\mathbb{F}_{16}| = 16 = 4^2 = (2^2)^2$, and $\dim_{\mathbb{F}_2} \mathbb{F}_{16} = 4 = 2 \cdot 2 = [\mathbb{F}_{16} : \mathbb{F}_4][\mathbb{F}_4 : \mathbb{F}_2]$.

Finite extensions are algebraic and finitely generated

Theorem 13.2.13 (13.17)**.** *The extension K/F is finite if and only if K is generated over F by finitely many algebraic elements; that is, $K = F(\alpha_1, \ldots, \alpha_n)$ with each α_i algebraic over F. Consequently every finite extension is algebraic.*

The two halves: a finite extension is generated by any F-basis (finitely many elements, each algebraic since trapped in a finite extension); conversely $F(\alpha_1, \ldots, \alpha_n)$ is finite by iterating the tower law along

$$F \subseteq F(\alpha_1) \subseteq F(\alpha_1, \alpha_2) \subseteq \cdots \subseteq F(\alpha_1, \ldots, \alpha_n) = K,$$

each step finite because α_{i+1} is algebraic over the (larger) preceding field.

Worked Example 13.2.14 (Every element of a finite extension is algebraic)**.** Let $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, $[K : \mathbb{Q}] = 4$. Show $\gamma = 1 + \sqrt{2} + \sqrt{6}$ is algebraic over $\mathbb{Q}$ and bound its degree.

Recognition. Theorem 13.17: $K/\mathbb{Q}$ finite $\Rightarrow$ algebraic; the degree of any $\gamma \in K$ divides $[K : \mathbb{Q}]$.

Solution. Since $[K : \mathbb{Q}] = 4 < \infty$, $K/\mathbb{Q}$ is algebraic, so γ is algebraic. Moreover $\mathbb{Q}(\gamma) \subseteq K$, so $[\mathbb{Q}(\gamma) : \mathbb{Q}] \mid 4$, i.e. $\deg \gamma \in \{1, 2, 4\}$. As $\gamma \notin \mathbb{Q}$ (it involves $\sqrt{2}$) the degree is 2 or 4. The powers $1, \gamma, \gamma^2, \gamma^3, \gamma^4$ live in the 4-dimensional space K, so are $\mathbb{Q}$-dependent; that dependence is a degree-≤ 4 polynomial relation, explicitly producing $m_{\gamma,\mathbb{Q}}$. Sanity check: any concrete element of a 4-dimensional extension has at most 4 linearly independent powers, guaranteeing a vanishing polynomial of degree ≤ 4.

Worked Example 13.2.15 (A finitely generated tower built step by step)**.** Compute $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}]$ via the chain $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2}) \subseteq \mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$.

Recognition. Iterate the tower law: each adjunction of an algebraic element multiplies the degree by the degree of its minimal polynomial *over the current field*.

Solution. $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$. Over $E = \mathbb{Q}(\sqrt{2})$, $\sqrt[3]{2}$ satisfies $x^3 - 2$; this is irreducible over E since $3 \nmid [E : \mathbb{Q}] = 2$ rules out a root or factor (a proper factor would give $\sqrt[3]{2}$ degree 1 or 2 over E, hence $[E(\sqrt[3]{2}) : \mathbb{Q}] \in \{2, 4\}$, which is not divisible by $3 = [\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}]$ although $\mathbb{Q}(\sqrt[3]{2}) \subseteq E(\sqrt[3]{2})$). So $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : E] = 3$ and $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}] = 3 \cdot 2 = 6$. Sanity check: 6 is divisible by both $2 = [\mathbb{Q}(\sqrt{2}) : \mathbb{Q}]$ and $3 = [\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}]$, as the tower law requires; note $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) = \mathbb{Q}(\sqrt[6]{2})$ since $\sqrt[6]{2} = \sqrt{2}/\sqrt[3]{2}$ lies in the field, while conversely $\sqrt{2} = (\sqrt[6]{2})^3$ and $\sqrt[3]{2} = (\sqrt[6]{2})^2$, so $\sqrt[6]{2}$ generates both.

Worked Example 13.2.16 (Composite degree bound for $F(\alpha, \beta)$)**.** If $[F(\alpha) : F] = m$ and $[F(\beta) : F] = n$ with $\gcd(m, n) = 1$, show $[F(\alpha, \beta) : F] = mn$. Apply to $\sqrt{2}$ ($m = 2$) and $\sqrt[3]{2}$ ($n = 3$).

Recognition. Tower law twice: m, n each divide $[F(\alpha, \beta) : F]$, while $[F(\alpha, \beta) : F] \leq mn$; coprimality pins the value.

Solution. Both $F(\alpha)$ and $F(\beta)$ sit inside $L = F(\alpha, \beta)$, so $m \mid [L : F]$ and $n \mid [L : F]$; since $\gcd(m, n) = 1$, $mn \mid [L : F]$. Conversely $[L : F] = [L : F(\alpha)][F(\alpha) : F] \leq n \cdot m$ because β has degree $\leq n$ over the larger field $F(\alpha)$. Hence $[L : F] = mn$. For $\sqrt{2}, \sqrt[3]{2}$ over $\mathbb{Q}$: $m = 2, n = 3$, gcd $= 1$, so $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}] = 6$, agreeing with the previous example. Sanity check: the displayed lattice has $[L : F(\alpha)] = mn/m = n$ and $[L : F(\beta)] = mn/n = m$, both consistent.

The lattice $F(\alpha, \beta)$ with its degree labels (here $m = 2, n = 3$) commutes:

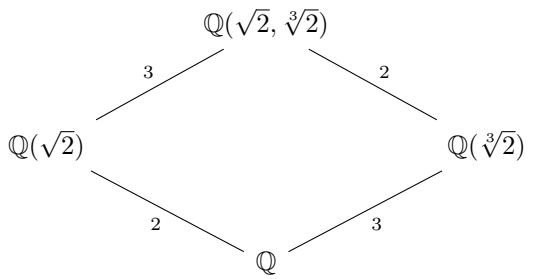

Diagram explanation. Objects: Four field nodes arranged as a diamond: $\mathbb{Q}$ at the bottom (base field), $\mathbb{Q}(\sqrt{2})$ at the lower-left (a degree-2 extension of $\mathbb{Q}$), $\mathbb{Q}(\sqrt[3]{2})$ at the lower-right (a degree-3 extension of $\mathbb{Q}$), and $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$ at the top (the composite, a degree-6 extension of $\mathbb{Q}$).

Arrows: Four undirected solid edges (inclusions), each carrying a degree label. Bottom-left: $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt{2})$, degree 2. Bottom-right: $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt[3]{2})$, degree 3. Top-left: $\mathbb{Q}(\sqrt{2}) \hookrightarrow \mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$, degree 3 (because $\sqrt[3]{2}$ has degree 3 even over the larger field $\mathbb{Q}(\sqrt{2})$, since $3 \nmid 2$). Top-right: $\mathbb{Q}(\sqrt[3]{2}) \hookrightarrow \mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$, degree 2.

What commutes: The two paths from $\mathbb{Q}$ to $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$ both give total degree 6: left path $2 \cdot 3 = 6$, right path $3 \cdot 2 = 6$. This is the tower law applied twice, and the two products must agree because both equal $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}] = 6$.

Why it commutes: Going left then up: $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] \cdot [\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}(\sqrt{2})] = 2 \cdot 3 = 6$. Going right then up: $[\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] \cdot [\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}(\sqrt[3]{2})] = 3 \cdot 2 = 6$. The coprimality of 2 and 3 forces $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}] = 6$, and both paths produce this same value; neither path is "preferred".

Why this matters here: This diamond summarizes the result of the "composite degree bound" worked example: when $\gcd(m, n) = 1$, $[F(\alpha, \beta) : F] = mn$, and the cross-degrees are exactly n (over $F(\alpha)$) and m (over $F(\beta)$). The diagram makes visible that the two generators "see" each other's degree when passing through the other subfield.

Concrete example: The diagram as drawn: $m = [\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$ and $n = [\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 3$. The top degree $6 = 2 \cdot 3$; the top-left edge has degree 3 (degree of $\sqrt[3]{2}$ over $\mathbb{Q}(\sqrt{2})$) and the top-right edge has degree 2 (degree of $\sqrt{2}$ over $\mathbb{Q}(\sqrt[3]{2})$). Every edge label is explained by the coprimality.

Common pitfall: Students sometimes read the top-left label 3 as the degree of $\sqrt[3]{2}$ over $\mathbb{Q}$, not over $\mathbb{Q}(\sqrt{2})$. The degree of an element depends on the base field: over $\mathbb{Q}$ it is still 3, but the label on the edge $\mathbb{Q}(\sqrt{2}) \to \mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$ measures algebraicity over $\mathbb{Q}(\sqrt{2})$, not over $\mathbb{Q}$.

Takeaway: The point of this diagram is that when two algebraic elements have coprime degrees over F, the composite field has degree equal to the product, and the two intermediate subfields appear as symmetric "struts" of a diamond with cross-degrees swapped.

The algebraic closure of F in K; transitivity

Theorem 13.2.17 (13.19)**.** *Let K/F be any extension. The set*

$$\overline{F}^{K} := \{\, \alpha \in K : \alpha \text{ is algebraic over } F \,\}$$

of elements of K algebraic over F is a subfield of K containing F.

Remark 13.2.1. The point: if α, β are algebraic over F, then $F(\alpha, \beta)/F$ is finite (Theorem 13.17), hence algebraic, so $\alpha \pm \beta$, $\alpha\beta$, and α/β (for $\beta \neq 0$) — all elements of $F(\alpha, \beta)$ — are again algebraic over F. Closure under the field operations follows with no need to exhibit minimal polynomials.

Worked Example 13.2.18 (Sum and product of algebraic numbers are algebraic)**.** Show directly that $\sqrt{2} + \sqrt[3]{2}$ and $\sqrt{2} \cdot \sqrt[3]{2}$ are algebraic over $\mathbb{Q}$, and bound their degrees.

Recognition. Theorem 13.19 / the remark: both lie in $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$, a finite (hence algebraic) extension; degrees divide $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}] = 6$.

Solution. $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$ has degree 6 over $\mathbb{Q}$ and is algebraic, so $\sqrt{2} + \sqrt[3]{2}$ and $\sqrt{2}\sqrt[3]{2} = 2^{1/2+1/3} = 2^{5/6} = \sqrt[6]{32}$ are algebraic with degree dividing 6. In fact $2^{5/6}$ has minimal polynomial $x^6 - 32$, so degree exactly 6: Eisenstein at 2 does not apply ($2^2 \mid 32$), but $(2^{5/6})^5 = 16\sqrt[6]{2}$ puts $\sqrt[6]{2}$, of degree 6 by Eisenstein on $x^6 - 2$, inside $\mathbb{Q}(2^{5/6})$. Sanity check: $\deg(2^{5/6}) = 6 = [\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}]$, so $\mathbb{Q}(2^{5/6}) = \mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$, consistent with $2^{5/6}$ generating the whole field.

Worked Example 13.2.19 (The field of algebraic numbers)**.** Let $\overline{\mathbb{Q}} \subseteq \mathbb{C}$ be the set of complex numbers algebraic over $\mathbb{Q}$. Show $\overline{\mathbb{Q}}$ is a field, and that $[\overline{\mathbb{Q}} : \mathbb{Q}] = \infty$ even though $\overline{\mathbb{Q}}/\mathbb{Q}$ is algebraic.

Recognition. Theorem 13.19 gives the subfield structure. For the degree, exhibit elements of unbounded degree, so no finite bound on $\dim_{\mathbb{Q}}$ can hold.

Solution. By Theorem 13.19 (with $K = \mathbb{C}$, $F = \mathbb{Q}$), $\overline{\mathbb{Q}}$ is a subfield of $\mathbb{C}$. It is algebraic over $\mathbb{Q}$ by definition. But $\sqrt[n]{2} \in \overline{\mathbb{Q}}$ has degree n over $\mathbb{Q}$ for every n (Eisenstein at 2 on $x^n - 2$), so $\overline{\mathbb{Q}}$ contains subfields of every finite degree; thus $[\overline{\mathbb{Q}} : \mathbb{Q}] = \infty$. Sanity check: "algebraic" does not imply "finite" — an infinite algebraic extension is exactly one that is algebraic yet of infinite degree, and $\overline{\mathbb{Q}}$ is the prototype.

Worked Example 13.2.20 (Algebraic closure inside $\mathbb{R}$)**.** Describe $\overline{\mathbb{Q}}^{\mathbb{R}}$, the elements of $\mathbb{R}$ algebraic over $\mathbb{Q}$ (the real algebraic numbers), and verify it is a field strictly between $\mathbb{Q}$ and $\mathbb{R}$.

Recognition. Theorem 13.19 with $K = \mathbb{R}$. Strictness on both ends needs one algebraic irrational and one transcendental real.

Solution. The set of real algebraic numbers is a subfield of $\mathbb{R}$ by Theorem 13.19. It strictly contains $\mathbb{Q}$ (e.g. $\sqrt{2}$) and is strictly contained in $\mathbb{R}$ (e.g. π is transcendental, so $\pi \notin \overline{\mathbb{Q}}^{\mathbb{R}}$). Sanity check: $\overline{\mathbb{Q}}^{\mathbb{R}} = \overline{\mathbb{Q}} \cap \mathbb{R}$, the real part of the algebraic numbers; it is countable while $\mathbb{R}$ is uncountable, re-confirming proper containment.

Theorem 13.2.21 (13.20)**.** *If K/E is algebraic and E/F is algebraic, then K/F is algebraic. (Algebraicity is transitive.)*

The proof in one line: given $\alpha \in K$, it satisfies a polynomial $a_n x^n + \cdots + a_0$ with $a_i \in E$; each a_i is algebraic over F, so $E_0 := F(a_0, \ldots, a_n)$ is finite over F (Theorem 13.17), and α is algebraic over E_0, whence $E_0(\alpha)/E_0$ is finite. The tower

$$F \subseteq E_0 \subseteq E_0(\alpha)$$

is finite over F, so α is algebraic over F.

$$\begin{array}{rl} E_0(\alpha) & \alpha \text{ alg. over } E_0 \\ \Big| \, {<}\infty & \\ E_0 = F(a_0, \ldots, a_n) & a_i \text{ alg. over } F \\ \Big| \, {<}\infty & \\ F & \end{array}$$

Diagram explanation. Objects: Three field nodes in a vertical tower. Bottom: F, the ground field. Middle: $E_0 = F(a_0, \ldots, a_n)$, the field obtained by adjoining the finitely many coefficients a_i of the minimal polynomial of α over E to F; it is a finite extension of F because each $a_i \in E$ is algebraic over F (Theorem 13.17). Top: $E_0(\alpha)$, the extension of E_0 by α, which is finite because α is a root of the nonzero polynomial $a_n x^n + \cdots + a_0$, whose coefficients lie in E_0 (being algebraic over the larger field E would not suffice by itself).

Arrows: Two undirected solid edges (inclusions), each labeled $< \infty$: (i) $E_0 \subseteq E_0(\alpha)$, recording $[E_0(\alpha) : E_0] < \infty$ (since α is algebraic over E_0, its minimal polynomial over E_0 has finite degree); (ii) $F \subseteq E_0$, recording $[E_0 : F] < \infty$ (since E_0 is generated over F by finitely many algebraic elements $a_0, \ldots, a_n$). The annotations to the right explain why each step is finite.

What commutes: The relevant conclusion is not a path equality but the multiplicativity: $[E_0(\alpha) : F] = [E_0(\alpha) : E_0] \cdot [E_0 : F] < \infty$. The tower law turns two finite steps into a finite total, meaning α lies in a finite extension of F, hence is algebraic over F.

Why it commutes: Start from $\alpha \in K$, algebraic over E with minimal polynomial $a_n x^n + \cdots + a_0 \in E[x]$. The a_i are algebraic over F (given E/F algebraic), so $E_0 := F(a_0, \ldots, a_n)$ is finite over F (Theorem 13.17). Then α satisfies a polynomial with coefficients in E_0, so $E_0(\alpha)/E_0$ is finite. Both steps are finite, so the tower law gives $E_0(\alpha)/F$ finite, forcing α algebraic over F.

Why this matters here: This diagram is the proof-in-a-picture of Theorem 13.20: algebraicity is transitive. It makes vivid why the two-step argument works – you cannot directly conclude $\alpha \in K$ is algebraic over F just from K/E algebraic and E/F algebraic, but by constructing the finite intermediate E_0 you reduce to the tower law.

Concrete example: Let $F = \mathbb{Q}$, $E = \mathbb{Q}(\sqrt{2})$, $\alpha = \sqrt{1+\sqrt{2}} \in K = E(\alpha)$. Then $a_0 = -(1+\sqrt{2})$, $a_1 = 0$, $a_2 = 1$ (from $\alpha^2 - (1+\sqrt{2}) = 0$), $E_0 = \mathbb{Q}(\sqrt{2}) = E$, $[E_0 : F] = 2$, $[E_0(\alpha) : E_0] = 2$, total $[K : \mathbb{Q}] = 4$, and α is algebraic over $\mathbb{Q}$ (satisfies $x^4 - 2x^2 - 1 = 0$).

Common pitfall: One might hope to directly write a polynomial for α over F from its polynomial over E, but the coefficients $a_i \in E$ are not in F. The diagram reminds you that you must first absorb the a_i into the base by forming E_0, only then can you apply the tower law.

Takeaway: The point of this diagram is that transitivity of algebraicity follows from the tower law: by pulling the coefficients of the minimal polynomial into the base, one constructs a finite tower over F that traps α, proving α algebraic over F.

Worked Example 13.2.22 (A two-step algebraic tower is algebraic)**.** Let $E = \mathbb{Q}(\sqrt{2})$ and $K = E(\sqrt{1+\sqrt{2}})$. Show $K/\mathbb{Q}$ is algebraic and compute $[K : \mathbb{Q}]$.

Recognition. Theorem 13.20: $\sqrt{1+\sqrt{2}}$ is algebraic over E and E is algebraic over $\mathbb{Q}$, so $K/\mathbb{Q}$ is algebraic; the tower law gives the degree.

Solution. $\sqrt{2}$ is algebraic over $\mathbb{Q}$ ($x^2 - 2$), so $E/\mathbb{Q}$ is algebraic with $[E : \mathbb{Q}] = 2$. Next $\beta = \sqrt{1+\sqrt{2}}$ satisfies $x^2 - (1+\sqrt{2})$ over E, irreducible since $1+\sqrt{2}$ is not a square in E (a square $a+b\sqrt{2}$ would need $\sqrt{1+\sqrt{2}} \in E \subseteq \mathbb{R}$ with E of degree 2; checking $E = \mathbb{Q}(\sqrt{2})$ shows no solution). So $[K : E] = 2$ and, by transitivity/tower law, $K/\mathbb{Q}$ is algebraic with $[K : \mathbb{Q}] = 2 \cdot 2 = 4$. Sanity check: $\beta^2 = 1+\sqrt{2} \Rightarrow (\beta^2 - 1)^2 = 2 \Rightarrow \beta^4 - 2\beta^2 - 1 = 0$, so β satisfies $x^4 - 2x^2 - 1 \in \mathbb{Q}[x]$ (Eisenstein-free but irreducible over $\mathbb{Q}$), confirming $\deg_{\mathbb{Q}} \beta = 4 = [K : \mathbb{Q}]$.

Worked Example 13.2.23 (Algebraic over algebraic, with nested radicals)**.** Show $\gamma = \sqrt[3]{5+\sqrt{2}}$ is algebraic over $\mathbb{Q}$ and find $m_{\gamma,\mathbb{Q}}(x)$.

Recognition. Transitivity (13.20): γ is algebraic over $E = \mathbb{Q}(\sqrt{2})$, which is algebraic over $\mathbb{Q}$; clear denominators/radicals to get a $\mathbb{Q}$-polynomial.

Solution. Over $E = \mathbb{Q}(\sqrt{2})$, $\gamma^3 = 5+\sqrt{2}$, so γ satisfies $x^3 - (5+\sqrt{2})$, algebraic over E. Since $E/\mathbb{Q}$ is algebraic, $\gamma/\mathbb{Q}$ is algebraic by Theorem 13.20. To get a $\mathbb{Q}$-polynomial, isolate the radical: $\gamma^3 - 5 = \sqrt{2} \Rightarrow (\gamma^3 - 5)^2 = 2 \Rightarrow \gamma^6 - 10\gamma^3 + 25 = 2$, hence

$$m_{\gamma,\mathbb{Q}}(x) \mid x^6 - 10x^3 + 23.$$

This sextic is irreducible over $\mathbb{Q}$: since $\sqrt{2} = \gamma^3 - 5 \in \mathbb{Q}(\gamma)$ we have $\mathbb{Q}(\gamma) = E(\gamma)$; and $x^3 - (5+\sqrt{2})$ has no root in E (if $(a+b\sqrt{2})^3 = 5+\sqrt{2}$ with $a, b \in \mathbb{Q}$, applying $\sqrt{2} \mapsto -\sqrt{2}$ and multiplying gives $(a^2 - 2b^2)^3 = 23$, impossible in $\mathbb{Q}$), so this cubic is irreducible over E and $[\mathbb{Q}(\gamma) : \mathbb{Q}] = [E(\gamma) : E]\,[E : \mathbb{Q}] = 3 \cdot 2 = 6$. Hence $m_{\gamma,\mathbb{Q}}(x) = x^6 - 10x^3 + 23$ and $[\mathbb{Q}(\gamma) : \mathbb{Q}] = 6$. Sanity check: $6 = 3 \cdot 2 = [E(\gamma) : E][E : \mathbb{Q}]$, matching the tower law and the degree of the found polynomial.

Worked Example 13.2.24 (Composite of two algebraic extensions is algebraic)**.** Inside $\mathbb{C}$, let $E_1 = \mathbb{Q}(\sqrt[3]{2})$ and $E_2 = \mathbb{Q}(\zeta_3)$. Show the composite $E_1E_2 = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ is algebraic over $\mathbb{Q}$ and finite, with degree 6.

Recognition. The composite is generated by finitely many algebraic elements, so Theorem 13.17 makes it finite (hence algebraic); the tower law and coprime degrees fix the value.

Solution. $E_1E_2 = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ is generated by the algebraic elements $\sqrt[3]{2}$ (degree 3) and ζ_3 (degree 2). By Theorem 13.17 it is finite over $\mathbb{Q}$, hence algebraic. Degrees 3 and 2 are coprime, so as in an earlier example $[E_1E_2 : \mathbb{Q}] = 3 \cdot 2 = 6$. Sanity check: this composite is precisely the splitting field of $x^3 - 2$ over $\mathbb{Q}$, whose degree we computed independently as 6 — the two computations agree.

The composite/lattice picture (commuting inclusions, $\zeta = \zeta_3$):

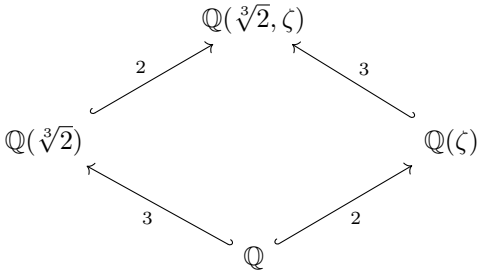

Diagram explanation. Objects: Four field nodes: $\mathbb{Q}$ (base field), $\mathbb{Q}(\sqrt[3]{2})$ (lower-left; degree-3 extension of $\mathbb{Q}$ generated by the real cube root of 2), $\mathbb{Q}(\zeta)$ with $\zeta = \zeta_3$ (lower-right; degree-2 extension of $\mathbb{Q}$, the cyclotomic field generated by a primitive cube root of unity), and $\mathbb{Q}(\sqrt[3]{2}, \zeta)$ (top; the composite, degree-6 extension of $\mathbb{Q}$, also the splitting field of $x^3 - 2$ over $\mathbb{Q}$).

Arrows: Four hooked inclusion arrows. Bottom-left: $\mathbb{Q} \hookrightarrow \mathbb{Q}(\sqrt[3]{2})$, degree 3. Bottom-right: $\mathbb{Q} \hookrightarrow \mathbb{Q}(\zeta)$, degree 2. Top-left: $\mathbb{Q}(\sqrt[3]{2}) \hookrightarrow \mathbb{Q}(\sqrt[3]{2}, \zeta)$, degree 2 (since $\zeta \notin \mathbb{Q}(\sqrt[3]{2}) \subseteq \mathbb{R}$ and $[\mathbb{Q}(\zeta) : \mathbb{Q}] = 2$, so ζ contributes a degree-2 step). Top-right: $\mathbb{Q}(\zeta) \hookrightarrow \mathbb{Q}(\sqrt[3]{2}, \zeta)$, degree 3 (since $\sqrt[3]{2}$ has degree 3 over $\mathbb{Q}(\zeta)$, as $x^3 - 2$ is irreducible over $\mathbb{Q}(\zeta)$ by the degree-6 computation). All arrows are inclusions (field embeddings), hence injective.

What commutes: Both paths from $\mathbb{Q}$ to $\mathbb{Q}(\sqrt[3]{2}, \zeta)$ compute the same total degree: $3 \cdot 2 = 6$ (left-then-up) and $2 \cdot 3 = 6$ (right-then-up). This is not a commutativity of map composites in the usual sense but a consistency of the tower law: $[\mathbb{Q}(\sqrt[3]{2}, \zeta) : \mathbb{Q}] = 6$ regardless of which chain of subfields you use.

Why it commutes: The cross-degrees are forced by coprimality: $\gcd(2, 3) = 1$, so $[\mathbb{Q}(\sqrt[3]{2}, \zeta) : \mathbb{Q}] = 2 \cdot 3 = 6$ (coprime-degree composite formula). Knowing the total and the bottom degrees pins the top edges: $6/3 = 2$ on the left, $6/2 = 3$ on the right. More directly, $\zeta \notin \mathbb{R} \supseteq \mathbb{Q}(\sqrt[3]{2})$, so $[\mathbb{Q}(\sqrt[3]{2}, \zeta) : \mathbb{Q}(\sqrt[3]{2})] = 2$; and $x^3 - 2$ is irreducible over $\mathbb{Q}(\zeta)$ because a reducible cubic has a root, and a root of $x^3 - 2$ in $\mathbb{Q}(\zeta)$ would generate a degree-3 subfield of the degree-2 field $\mathbb{Q}(\zeta)$, impossible as $3 \nmid 2$.

Why this matters here: This diagram is the visual payoff of the "composite of two algebraic extensions" worked example. It also sets up the splitting-field construction of $x^3 - 2$ (the full splitting field needs both $\sqrt[3]{2}$ and a primitive cube root of unity) and shows the degree-6 result two ways, preparing the reader for the Galois group S_3 of order 6 in later chapters.

Concrete example: The three roots of $x^3 - 2$ are $\sqrt[3]{2}$, $\zeta\sqrt[3]{2}$, $\zeta^2\sqrt[3]{2}$. All three lie in $\mathbb{Q}(\sqrt[3]{2}, \zeta)$, confirming it is indeed the splitting field; and $|S_3| = 6 = [\mathbb{Q}(\sqrt[3]{2}, \zeta) : \mathbb{Q}]$, as the fundamental theorem of Galois theory predicts.

Common pitfall: Students sometimes assume $\mathbb{Q}(\sqrt[3]{2}, \zeta) = \mathbb{Q}(\sqrt[3]{2}) \cdot \mathbb{Q}(\zeta)$ has degree at most $\max(2, 3) = 3$. The composite is not the union; it contains products like $\zeta\sqrt[3]{2}$ that are in neither subfield, and its degree is the product $2 \cdot 3 = 6$ (coprimality forces equality, not just divisibility).

Takeaway: The point of this diagram is that the splitting field of $x^3 - 2$ is a degree-6 diamond composite of a degree-3 real extension and a degree-2 cyclotomic extension, with cross-degrees 2 and 3 swapped compared to the bottom, as required by the tower law.

Looking ahead: constructibility (deferred to 13.3)

The degree theory above already settles the classical impossibility results, whose full geometric setup we defer to 13.3. The principle: a real number α is *constructible* (by straightedge and compass from a unit length) only if it lies in a tower

$$\mathbb{Q} = F_0 \subseteq F_1 \subseteq \cdots \subseteq F_k, \qquad [F_{i+1} : F_i] = 2,$$

so $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ must be a power of 2. This single divisibility fact, via the tower law, resolves the ancient problems — previewed here, proved in 13.3.

Worked Example 13.2.25 (Doubling the cube is impossible)**.** Explain why $\sqrt[3]{2}$ is not constructible.

Recognition. Constructible $\Rightarrow [\mathbb{Q}(\alpha) : \mathbb{Q}]$ is a power of 2 (tower of quadratic extensions). A degree not of that form is an obstruction.

Solution. $[\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 3$, which is not a power of 2. By the principle above, $\sqrt[3]{2}$ is not constructible, so the cube cannot be doubled with straightedge and compass. Sanity check: $3 = \deg(x^3 - 2)$ and $3 \nmid 2^k$ for any k, exactly the divisibility failure.

Worked Example 13.2.26 (Trisecting a 60° angle is impossible)**.** Show $\cos 20°$ is not constructible, so a general angle cannot be trisected.

Recognition. Reduce trisection to a degree-3 algebraic obstruction via the triple-angle identity, then apply the power-of-2 criterion.

Solution. The identity $\cos 3\theta = 4\cos^3\theta - 3\cos\theta$ at $\theta = 20^\circ$ (so $3\theta = 60^\circ$, $\cos 60^\circ = \frac{1}{2}$) gives $4\cos^3 20^\circ - 3\cos 20^\circ = \frac{1}{2}$, i.e. with $\alpha = \cos 20^\circ$, $8\alpha^3 - 6\alpha - 1 = 0$. The polynomial $8x^3 - 6x - 1$ has no rational root (rational root test: $\pm 1, \pm\frac{1}{2}, \pm\frac{1}{4}, \pm\frac{1}{8}$ all fail), so it is irreducible over $\mathbb{Q}$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 3$. Since 3 is not a power of 2, $\cos 20^\circ$ is not constructible; hence the 60° angle cannot be trisected. Sanity check: 60° is itself constructible ($\cos 60^\circ = \frac{1}{2} \in \mathbb{Q}$), so the obstruction is exactly the degree-3 jump introduced by trisection.

Worked Example 13.2.27 (Squaring the circle is impossible)**.** Explain why a square of area equal to a given disk cannot be constructed.

Recognition. Constructible numbers are algebraic (each $F_i/\mathbb{Q}$ is finite, hence algebraic). A transcendental target is therefore unreachable.

Solution. Squaring the circle of radius 1 requires constructing a length $\sqrt{\pi}$, hence π. But every constructible number is algebraic over $\mathbb{Q}$ (it lies in a finite tower over $\mathbb{Q}$), while π is transcendental (Lindemann). So $\sqrt{\pi}$ is not constructible and the circle cannot be squared. Sanity check: here the obstruction is not a wrong *degree* but the failure of algebraicity altogether — transcendence is the strongest possible barrier.

Exercises (from the text).

1. Let $\mathbb{F}$ be a finite field of characteristic p. Prove that $|\mathbb{F}| = p^n$ for some positive integer n.
2. Let $g(x) = x^2 + x - 1$ and let $h(x) = x^3 - x + 1$. Obtain fields of 4, 8, 9 and 27 elements by adjoining a root of $f(x)$ to the field F where $f(x) = g(x)$ or $h(x)$ and $F = \mathbb{F}_2$ or $\mathbb{F}_3$. Write down the multiplication tables for the fields with 4 and 9 elements and show that the nonzero elements form a cyclic group.
3. Determine the minimal polynomial over $\mathbb{Q}$ for the element $1 + i$.
4. Determine the degree over $\mathbb{Q}$ of $2 + \sqrt{3}$ and of $1 + \sqrt[3]{2} + \sqrt[3]{4}$.
5. Let $F = \mathbb{Q}(i)$. Prove that $x^3 - 2$ and $x^3 - 3$ are irreducible over F.
6. Prove directly from the definitions that the field $F(\alpha_1, \alpha_2, \ldots, \alpha_n)$ is the composite of the fields $F(\alpha_1), F(\alpha_2), \ldots, F(\alpha_n)$.
7. Prove that $\mathbb{Q}(\sqrt{2} + \sqrt{3}) = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ [one inclusion is obvious, for the other consider $(\sqrt{2} + \sqrt{3})^2$, etc.]. Conclude that $[\mathbb{Q}(\sqrt{2} + \sqrt{3}) : \mathbb{Q}] = 4$. Find an irreducible polynomial satisfied by $\sqrt{2} + \sqrt{3}$.
8. Let F be a field of characteristic $\neq 2$. Let D_1 and D_2 be elements of F, neither of which is a square in F. Prove that $F(\sqrt{D_1}, \sqrt{D_2})$ is of degree 4 over F if $D_1 D_2$ is not a square in F and is of degree 2 over F otherwise. When $F(\sqrt{D_1}, \sqrt{D_2})$ is of degree 4 over F the field is called a *biquadratic extension* of F.
9. Let F be a field of characteristic $\neq 2$. Let a, b be elements of the field F with b not a square in F. Prove that a necessary and sufficient condition for $\sqrt{a + \sqrt{b}} = \sqrt{m} + \sqrt{n}$ for some m and n in F is that $a^2 - b$ is a square in F. Use this to determine when the field $\mathbb{Q}(\sqrt{a + \sqrt{b}})$ $(a, b \in \mathbb{Q})$ is biquadratic over $\mathbb{Q}$.
10. Determine the degree of the extension $\mathbb{Q}(\sqrt{3 + 2\sqrt{2}})$ over $\mathbb{Q}$.
11. (a) Let $\sqrt{3 + 4i}$ denote the square root of the complex number $3 + 4i$ that lies in the first quadrant and let $\sqrt{3 - 4i}$ denote the square root of $3 - 4i$ that lies in the fourth quadrant. Prove that $[\mathbb{Q}(\sqrt{3 + 4i} + \sqrt{3 - 4i}) : \mathbb{Q}] = 1$.
    (b) Determine the degree of the extension $\mathbb{Q}(\sqrt{1 + \sqrt{-3}} + \sqrt{1 - \sqrt{-3}})$ over $\mathbb{Q}$.
12. Suppose the degree of the extension K/F is a prime p. Show that any subfield E of K containing F is either F or K.
13. Suppose $F = \mathbb{Q}(\alpha_1, \alpha_2, \ldots, \alpha_n)$ where $\alpha_i^2 \in \mathbb{Q}$ for $i = 1, 2, \ldots, n$. Prove that $\sqrt[3]{2} \notin F$.
14. Prove that if $[F(\alpha) : F]$ is odd then $F(\alpha) = F(\alpha^2)$.
15. A field F is said to be *formally real* if -1 is not expressible as a sum of squares in F. Let F be a formally real field, let $f(x) \in F[x]$ be an irreducible polynomial of odd degree and let α be a root of $f(x)$. Prove that $F(\alpha)$ is also formally real. [Pick a counterexample of minimal degree. Show that $-1 + f(x)g(x) = (p_1(x))^2 + \cdots + (p_m(x))^2$ for some $p_i(x), g(x) \in F[x]$ where $g(x)$ has odd degree $< \deg f$.

Show that some root β of g has odd degree over F and $F(\beta)$ is not formally real, violating the minimality of α.]

16. Let K/F be an algebraic extension and let R be a ring contained in K and containing F. Show that R is a subfield of K containing F.

17. Let $f(x)$ be an irreducible polynomial of degree n over a field F. Let $g(x)$ be any polynomial in $F[x]$. Prove that every irreducible factor of the composite polynomial $f(g(x))$ has degree divisible by n.

18. Let k be a field and let $k(x)$ be the field of rational functions in x with coefficients from k. Let $t \in k(x)$ be the rational function $\dfrac{P(x)}{Q(x)}$ with relatively prime polynomials $P(x)$, $Q(x) \in k[x]$, with $Q(x) \neq 0$ and $P(x)$, $Q(x)$ not both constant (so $t \notin k$). Then $k(x)$ is an extension of $k(t)$ and to compute its degree it is necessary to compute the minimal polynomial with coefficients in $k(t)$ satisfied by x.

    (a) Show that the polynomial $P(X) - tQ(X)$ in the variable X and coefficients in $k(t)$ is irreducible over $k(t)$ and has x as a root. [By Gauss' Lemma this polynomial is irreducible in $(k(t))[X]$ if and only if it is irreducible in $(k[t])[X]$. Then note that $(k[t])[X] = (k[X])[t]$.]

    (b) Show that the degree of $P(X) - tQ(X)$ as a polynomial in X with coefficients in $k(t)$ is the maximum of the degrees of $P(x)$ and $Q(x)$.

    (c) Show that $[k(x) : k(t)] = [k(x) : k(\dfrac{P(x)}{Q(x)})] = \max(\deg P(x), \deg Q(x))$.

19. Let K be an extension of F of degree n.

    (a) For any $\alpha \in K$ prove that α acting by left multiplication on K is an F-linear transformation of K.

    (b) Prove that K is isomorphic to a subfield of the ring of $n \times n$ matrices over F, so the ring of $n \times n$ matrices over F contains an isomorphic copy of *every* extension of F of degree $\leq n$.

20. Show that if the matrix of the linear transformation "multiplication by α" considered in the previous exercise is A then α is a root of the characteristic polynomial for A. This gives an effective procedure for determining an equation of degree n satisfied by an element α in an extension of F of degree n. Use this procedure to obtain the monic polynomial of degree 3 satisfied by $\sqrt[3]{2}$ and by $1 + \sqrt[3]{2} + \sqrt[3]{4}$.

21. Let $K = \mathbb{Q}(\sqrt{D})$ for some squarefree integer D. Let $\alpha = a + b\sqrt{D}$ be an element of K. Use the basis $1, \sqrt{D}$ for K as a vector space over $\mathbb{Q}$ and show that the matrix of the linear transformation "multiplication by α" on K considered in the previous exercises has the matrix $\begin{pmatrix} a & bD \\ b & a \end{pmatrix}$. Prove directly that the map $a + b\sqrt{D} \mapsto \begin{pmatrix} a & bD \\ b & a \end{pmatrix}$ is an isomorphism of the field K with a subfield of the ring of 2×2 matrices with coefficients in $\mathbb{Q}$.

22. Let K_1 and K_2 be two finite extensions of a field F contained in the field K. Prove that the F-algebra $K_1 \otimes_F K_2$ is a field if and only if $[K_1K_2 : F] = [K_1 : F][K_2 : F]$.

Practice problems.

1. Let $\alpha = \sqrt{2} + \sqrt[3]{2}$. Show that α is algebraic over $\mathbb{Q}$ by exhibiting a tower $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2}) \subseteq \mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$, compute $[\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) : \mathbb{Q}]$ via multiplicativity, and give an upper bound on $\deg m_{\alpha,\mathbb{Q}}(x)$.

2. Compute the minimal polynomial $m_{\alpha,\mathbb{Q}}(x)$ where $\alpha = \sqrt{3 + 2\sqrt{2}}$. (Hint: simplify the nested radical first.) Determine $[\mathbb{Q}(\alpha) : \mathbb{Q}]$.

3. Let $E = \mathbb{Q}(\sqrt{2})$ and $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Verify directly that $\sqrt{3} \notin E$, conclude $[K : E] = 2$, and use $[K : \mathbb{Q}] = [K : E]\,[E : \mathbb{Q}]$ to find $[K : \mathbb{Q}]$. Exhibit an explicit $\mathbb{Q}$-basis of K.

4. Let ζ_5 be a primitive 5th root of unity. Compute $\Phi_5(x)$, find $[\mathbb{Q}(\zeta_5) : \mathbb{Q}]$, and show that $\cos(2\pi/5) \in \mathbb{Q}(\zeta_5)$ with $[\mathbb{Q}(\cos(2\pi/5)) : \mathbb{Q}] = 2$.

5. Inside $\mathbb{C}$, let α be a root of $x^3 - x - 1$ and β a root of $x^2 - 5$. Show $x^3 - x - 1$ is irreducible over $\mathbb{Q}$, then determine $[\mathbb{Q}(\alpha, \beta) : \mathbb{Q}]$, justifying that $\beta \notin \mathbb{Q}(\alpha)$.

6. Suppose $[K : \mathbb{Q}] = 6$ and $\alpha \in K$ satisfies $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 3$. Use multiplicativity of degrees to determine all possible values of $[K : \mathbb{Q}(\alpha)]$, and explain why no element of K can have degree 4 over $\mathbb{Q}$.

7. Let $F \subseteq E \subseteq K$ with E/F algebraic and K/E algebraic. Prove that an arbitrary $\gamma \in K$ is algebraic over F by showing $F(\gamma)$ sits inside a finite extension of F (transitivity of algebraicity). Identify exactly where you use that the coefficients of $m_{\gamma,E}(x)$ are finite in number.

8. Find the splitting field L of $x^4 - 2$ over $\mathbb{Q}$ inside $\mathbb{C}$, compute $[L : \mathbb{Q}]$, and describe L as $\mathbb{Q}(\sqrt[4]{2}, i)$. Build the degree tower $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt[4]{2}) \subseteq L$.

9. Let $\alpha = \sqrt[3]{2}\,\zeta_3$ where ζ_3 is a primitive cube root of unity. Show α is algebraic over $\mathbb{Q}$, find $m_{\alpha,\mathbb{Q}}(x)$, and determine whether $\mathbb{Q}(\alpha) = \mathbb{Q}(\sqrt[3]{2})$.

Additional exercises.

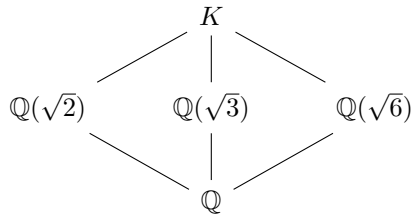
1. Let K/F be a finite extension with $[K : F]$ prime. Prove $K = F(\alpha)$ for every $\alpha \in K \setminus F$, and conclude K has no fields strictly between F and K.

2. Let A denote the set of elements of $\mathbb{C}$ algebraic over $\mathbb{Q}$ (the algebraic closure of $\mathbb{Q}$ in $\mathbb{C}$). Prove A is a subfield of $\mathbb{C}$ by showing that for $\alpha, \beta \in A$ the elements $\alpha \pm \beta$, $\alpha\beta$, and α^{-1} (for $\alpha \neq 0$) all lie in the finite extension $\mathbb{Q}(\alpha, \beta)$. Then explain why $[A : \mathbb{Q}] = \infty$ by exhibiting $\sqrt[n]{2} \in A$ for all n.

3. Let p be a prime and $F = \mathbb{F}_p(t)$ the field of rational functions in t over $\mathbb{F}_p$. Consider α a root of $x^p - t$. Show $m_{\alpha,F}(x) = x^p - t = (x - \alpha)^p$ in $F(\alpha)[x]$, that $[F(\alpha) : F] = p$, and that this extension is not separable.

4. Let K/F be finite. Prove that K/F is algebraic and finitely generated by algebraic elements, and conversely that if $K = F(\alpha_1, \ldots, \alpha_n)$ with each α_i algebraic over F, then K/F is finite. State the degree bound $[K : F] \leq \prod_i \deg m_{\alpha_i,F}(x)$ and give an example where the inequality is strict.

5. Let $\alpha = \zeta_7 + \zeta_7^{-1}$ where ζ_7 is a primitive 7th root of unity. Compute $[\mathbb{Q}(\zeta_7) : \mathbb{Q}]$, show $[\mathbb{Q}(\zeta_7) : \mathbb{Q}(\alpha)] = 2$, and determine $m_{\alpha,\mathbb{Q}}(x)$ together with $[\mathbb{Q}(\alpha) : \mathbb{Q}]$.

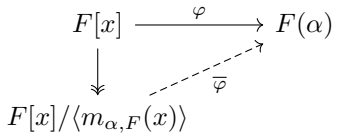


Commutative-diagram exercises.

1. Let $F \subseteq E \subseteq K$ be a tower of finite extensions. Draw the inclusion diagram and annotate each arrow with its degree, then state the equation that the diagram encodes.

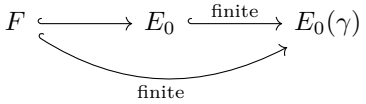
$$F \xhookrightarrow{[E:F]} E \xhookrightarrow{[K:E]} K$$

   Verify the relation $[K : F] = [K : E] \cdot [E : F]$ for $F = \mathbb{Q}$, $E = \mathbb{Q}(\sqrt{2})$, $K = \mathbb{Q}(\sqrt{2}, \sqrt[3]{5})$.



2. Consider the lattice of subfields of $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Complete the diamond, labeling every edge with its degree.

   Show there are no other intermediate fields and explain how multiplicativity of degrees forces every edge label.



3. Let α be algebraic over F with $\deg m_{\alpha,F}(x) = n$. The evaluation map $\varphi\colon F[x] \to F(\alpha)$, $f(x) \mapsto f(\alpha)$, factors through the quotient by the ideal generated by $m_{\alpha,F}(x)$. Fill in the dashed isomorphism and

justify it.

State why $\overline{\varphi}$ is an isomorphism of fields and what this says about $[F(\alpha):F]$.

4. Let E/F and K/E be algebraic, with $\gamma \in K$. Use the diagram to organize a proof that γ is algebraic over F (transitivity). Here $E_0 = F(c_0, \dots, c_{m-1})$ is generated by the coefficients $c_i \in E$ of $m_{\gamma,E}(x)$.

Argue that E_0/F is finite and $E_0(\gamma)/E_0$ is finite, hence $[E_0(\gamma):F] < \infty$ and γ is algebraic over F.

13.3 Classical Straightedge and Compass Constructions

Constructible points and the constructible plane

We work in the Euclidean plane, which we identify with $\mathbb{R}^2$. We are given two points, which we may take to be $(0,0)$ and $(1,0)$; equivalently we are handed the real numbers 0 and 1. The allowed operations are those of an unmarked straightedge and a compass:

1. Through any two already-constructed points we may draw the straight line joining them (straightedge).
2. With center an already-constructed point and radius equal to the distance between two already-constructed points we may draw a circle (compass).
3. New points are the intersections of two such lines, a line and a circle, or two circles.

Definition 13.3.1. A point $P \in \mathbb{R}^2$ is *constructible* if it can be obtained from $(0,0)$ and $(1,0)$ by a finite sequence of the operations above. A real number α is a *constructible number* if $|\alpha|$ is the distance between two constructible points; equivalently, if the point $(\alpha, 0)$ is constructible.

Because we can drop perpendiculars and erect them, a point (a,b) is constructible if and only if both coordinates a and b are constructible numbers. Thus the whole theory reduces to the arithmetic of the set of constructible real numbers. Our first goal is to show this set is a field closed under one further operation, taking square roots of positive elements.

Theorem 13.3.2. *The set of constructible real numbers is a subfield of $\mathbb{R}$ containing $\mathbb{Q}$. Moreover it is closed under the operation $\alpha \mapsto \sqrt{\alpha}$ for $\alpha > 0$.*

The proof is a sequence of geometric constructions, one for each field operation, plus a construction of square roots. We record the constructions because the worked examples below trace the algebra they hide.
Addition and subtraction. Given lengths a and b laid off on a common line from a constructible origin, marking off b beyond the end of a (with the compass) produces $a+b$; marking it back produces $a-b$. So 0 and 1 generate all of $\mathbb{Z}$, and hence $\mathbb{Q}$ once we have division.
Multiplication and division. These use similar triangles. Place O, and on one ray mark A with $OA = 1$ and B with $OB = a$; on a second ray through O mark C with $OC = b$. Draw AC, and through B the line parallel to AC meeting the second ray at D. By similar triangles $OD/OC = OB/OA$, i.e. $OD = ab$. Replacing the role of the unit gives b/a similarly. Hence the constructible numbers form a field.
Square roots. Given $a > 0$, lay off $AB = a$ and $BC = 1$ on a line, draw the circle with diameter AC, and erect the perpendicular to AC at B, meeting the circle at D. Thales' theorem makes $\angle ADC$ a right angle, and the altitude relation in a right triangle gives $BD^2 = AB \cdot BC = a$, so $BD = \sqrt{a}$.

The multiplication construction (and, with the roles of 1 and a exchanged, division) is summarized by the following parallel-projection square; each arrow records a similar-triangle ratio.

$$\begin{array}{ccc} OA = 1 & \xrightarrow{\times a} & OB = a \\ {\scriptstyle \times b}\downarrow & & \downarrow{\scriptstyle \times b} \\ OC = b & \xrightarrow[\times a]{} & OD = ab \end{array}$$

Diagram explanation. Objects: Each node is a *length* (a constructible real number), labelled by a line-segment name: $OA = 1$ (the unit), $OB = a$, $OC = b$, and $OD = ab$. All four are points on two rays from the origin O in the Euclidean plane; they are not abstract elements of a ring but literal distances.

Arrows: Each arrow is a *scaling map*: the horizontal arrows scale by a (multiply by a, implemented via the similar-triangle construction with the unit ray) and the vertical arrows scale by b. The label $\times a$ or $\times b$ names the ratio captured by similar triangles; there is no algebra assumed, only ruler-and-compass geometry.

What commutes: Going right then down gives $1 \xrightarrow{\times a} a \xrightarrow{\times b} ab$; going down then right gives $1 \xrightarrow{\times b} b \xrightarrow{\times a} ab$. Both paths land at $OD = ab$, so $(\times b) \circ (\times a) = (\times a) \circ (\times b)$.

Why it commutes: Multiplication of real numbers is commutative. Geometrically: the parallel-projection construction producing ab from the unit is symmetric in a and b by the symmetry of similar triangles under interchange of the two rays. Element-chase: starting from length 1, right-then-down gives a then ab; down-then-right gives b then $ba = ab$.

Why this matters here: This square summarises *why* multiplication (and, with the roles of 1 and a exchanged, division) can be performed with straightedge and compass; addition and subtraction need only the compass. Specifically it shows that constructible lengths are closed under multiplication, the crucial non-trivial step in proving the constructible numbers form a field (Theorem about the constructible field above).

Concrete example: Take $a = 2$, $b = 3$: the unit segment, the segment of length 2 (double the unit), the segment of length 3, and their product 6 are all constructible from the unit by the parallel-projection recipe. The square records $2 \cdot 3 = 3 \cdot 2 = 6$ geometrically.

Common pitfall: Students read the arrows as inclusions or field homomorphisms. They are not: they are geometric scaling operations on lengths, not ring maps between number fields. The diagram lives in Euclidean geometry, not in a commutative-algebra category.

Takeaway: The point of this diagram is that the commutativity of real multiplication can be witnessed purely by parallel projection, confirming that the similar-triangle construction of ab is well-defined independently of which leg plays the role of a.

The algebraic translation: towers of quadratic extensions

The key idea is to track, after each construction step, the field generated over $\mathbb{Q}$ by the coordinates of all points constructed so far. Suppose at some stage all coordinates lie in a field $F \subseteq \mathbb{R}$. A new point is the intersection of two of the following: lines $ax + by + c = 0$ and circles $x^2 + y^2 + dx + ey + f = 0$ whose coefficients lie in F (they are built from the F-coordinates of old points). We solve for the new coordinates.

- *Two lines:* solving two linear equations over F gives a point with coordinates in F. No new numbers.
- *Line and circle:* substitute the line into the circle to get a quadratic over F in one variable; the new coordinates lie in F or in a quadratic extension $F(\sqrt{u})$ with $u \in F$.
- *Two circles:* subtracting the two circle equations cancels the quadratic terms and leaves a line (the radical axis) over F; this reduces to the line-and-circle case.

In every case the coordinates of the new point lie in F or in a degree-2 extension of F. Iterating gives the central structural theorem.

Theorem 13.3.3. *If α is a constructible real number, then there is a finite tower of fields*

$$\mathbb{Q} = F_0 \subseteq F_1 \subseteq F_2 \subseteq \cdots \subseteq F_m \subseteq \mathbb{R}$$

with $\alpha \in F_m$ and $[F_i : F_{i-1}] = 2$ for every i. In particular $[F_m : \mathbb{Q}] = 2^m$ is a power of 2.

The tower is the heart of the matter, displayed as a chain of quadratic steps.

$$\mathbb{Q} \overset{2}{\text{———}} F_1 \overset{2}{\text{———}} F_2 \overset{2}{\text{———}} \cdots \overset{2}{\text{———}} F_m \ni \alpha$$

Diagram explanation. Objects: Each node is a *subfield of* $\mathbb{R}$: $\mathbb{Q}$ (the rationals), and a chain of intermediate real fields $F_1, F_2, \ldots, F_m$, each containing the previous. The notation $F_m \ni \alpha$ records that the target constructible number α lives in the last field.

Arrows: Each undirected edge between F_{i-1} and F_i labelled 2 is a *field extension of degree* 2: $F_i = F_{i-1}(\sqrt{u_i})$ for some $u_i \in F_{i-1}$, $u_i > 0$, and $[F_i : F_{i-1}] = 2$. The plain edges (no arrowheads) indicate an inclusion (no function formula, just containment) rather than a surjection.

What commutes: This is a linear chain, not a square, so commutativity is trivial: following all steps left-to-right passes through $\mathbb{Q} \subseteq F_1 \subseteq \cdots \subseteq F_m$. The key equality is the multiplicativity of degrees: $[F_m : \mathbb{Q}] = \prod_{i=1}^{m} [F_i : F_{i-1}] = 2^m$.

Why it commutes: The tower law for field extensions: for a chain $K \subseteq L \subseteq M$ of finite extensions, $[M : K] = [M : L] \cdot [L : K]$. Applied m times, each factor $= 2$, so the total degree is 2^m.

Why this matters here: This diagram is the structural heart of the theorem on constructible numbers (Theorem on the tower). It displays exactly *why* the degree $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ must divide 2^m: because $\alpha \in F_m$ and the tower from $\mathbb{Q}$ to F_m has m quadratic steps. Every constructibility argument traces back to the existence of such a chain.

Concrete example: For $\alpha = \sqrt{1+\sqrt{2}}$: the tower is $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2}) \subseteq \mathbb{Q}(\sqrt{1+\sqrt{2}})$, so $m = 2$ and $[F_2 : \mathbb{Q}] = 2^2 = 4$, matching the computation in the worked example on $\sqrt{1+\sqrt{2}}$.

Common pitfall: Students assume $F_m = \mathbb{Q}(\alpha)$. In general F_m can be strictly larger: the tower provides a field containing α, and $\mathbb{Q}(\alpha)$ is only a subfield. The degree $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ *divides* 2^m, which is all the corollary needs.

Takeaway: The point of this diagram is that every constructible number sits inside a tower of m successive quadratic extensions of $\mathbb{Q}$, forcing its degree over $\mathbb{Q}$ to divide 2^m and hence to be a power of 2.

Combining Theorem 13.3.3 with the multiplicativity of degrees in a tower, $[F_m : \mathbb{Q}] = [F_m : F_{m-1}] \cdots [F_1 : \mathbb{Q}]$, yields the necessary condition we will use to prove impossibility.

Corollary 13.3.4. *If α is a constructible real number, then α is algebraic over $\mathbb{Q}$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}] = \deg m_{\alpha,\mathbb{Q}}(x)$ is a power of 2.*

Proof. By Theorem 13.3.3, $\alpha \in F_m$ with $[F_m : \mathbb{Q}] = 2^m$. Since $\mathbb{Q} \subseteq \mathbb{Q}(\alpha) \subseteq F_m$, the tower law gives $[F_m : \mathbb{Q}] = [F_m : \mathbb{Q}(\alpha)]\,[\mathbb{Q}(\alpha) : \mathbb{Q}]$, so $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ divides 2^m and is therefore a power of 2. □

Remark 13.3.1. The condition is *necessary* but not sufficient: there exist non-constructible numbers α with $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ a power of 2, because membership in a 2-power-degree field is not the same as membership in a field reached by a tower of *quadratic* extensions of $\mathbb{Q}$. (The precise sufficient condition requires Galois theory: α is constructible iff the Galois closure of $\mathbb{Q}(\alpha)$ over $\mathbb{Q}$ has degree a power of 2.) For the classical impossibility proofs the necessary condition is all we need.

Pictorially, the lattice of fields under a single new constructible point is a small square: the base field F, the two coordinate extensions, and their compositum, each step of degree 1 or 2.

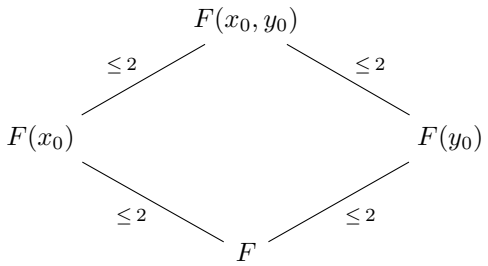


Diagram explanation. Objects: Four *real subfields*: the base field F (the field of coordinates of all previously constructed points), the two intermediate fields $F(x_0)$ and $F(y_0)$ obtained by adjoining one coordinate of a new constructible point (x_0, y_0), and the compositum $F(x_0, y_0)$ containing both.

Arrows: Each undirected dash-edge labelled ≤ 2 is a *field extension of degree at most* 2: the inclusion $F \hookrightarrow F(x_0)$ records that x_0 satisfies a quadratic equation over F (from the line-or-circle intersection analysis), and similarly $F \hookrightarrow F(y_0)$. The top edges record that once x_0 is known, y_0 satisfies a quadratic over $F(x_0)$ (and vice versa), giving at most one more quadratic step.

What commutes: The two paths from F to $F(x_0, y_0)$ agree: $F \subseteq F(x_0) \subseteq F(x_0, y_0)$ and $F \subseteq F(y_0) \subseteq F(x_0, y_0)$ both produce the same compositum. The degree relation is $[F(x_0, y_0) : F] \leq 2$ (both coordinates lie in the single field $F(\sqrt{u})$ of the line-and-circle analysis), with the total obtained either way by multiplying the two steps.

Why it commutes: Both extension chains generate the same subfield of $\mathbb{R}$ (the smallest field over F containing both x_0 and y_0), so they must agree at the top. This follows from the universal property of the compositum: $F(x_0, y_0)$ is the join of $F(x_0)$ and $F(y_0)$ in the lattice of subfields of $\mathbb{R}$.

Why this matters here: This diagram encodes the *inductive step* of the tower theorem: one new constructible point adds at most one quadratic extension, yielding $[F(x_0, y_0) : F] \mid 2$. Iterating over all construction steps builds the full tower, and the diagram shows which field lattice arises from a single step.

Concrete example: Starting from $F = \mathbb{Q}$, the point $P = (\frac{1}{2}, \frac{\sqrt{3}}{2})$ from the two-unit-circles example gives $F(x_0) = \mathbb{Q}$ (since $x_0 = \frac{1}{2} \in \mathbb{Q}$) and $F(y_0) = \mathbb{Q}(\sqrt{3})$, degree 2; the compositum is $\mathbb{Q}(\sqrt{3})$, a single step.

Common pitfall: The labels ≤ 2 on the edges are upper bounds, not equalities in general. If $x_0 \in F$ already (e.g. line-line intersection), then $[F(x_0) : F] = 1$ and the diamond degenerates. In fact it always degenerates: since $[F(x_0, y_0) : F] \leq 2$, each of $F(x_0)$ and $F(y_0)$ equals F or $F(x_0, y_0)$, so the four edges never all have degree 2 (a total degree 4 cannot occur).

Takeaway: The point of this diagram is that each new constructible point contributes at most one quadratic extension step to the tower, so the total degree over $\mathbb{Q}$ remains a power of 2 after any finite sequence of constructions.

Worked examples: constructible numbers and the tower

Worked Example 13.3.5 ($\sqrt{2}$ is constructible)**.** Show $\sqrt{2}$ is a constructible number and exhibit its tower.

Recognition. Theorem 13.3.2 (closure under square roots) constructs it geometrically; Corollary 13.3.4 predicts its degree is a power of 2.

Solution. The diagonal of the unit square has length $\sqrt{1^2 + 1^2} = \sqrt{2}$, so laying off the diagonal gives $(\sqrt{2}, 0)$: it is constructible. Algebraically take the tower $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2})$. Here $m_{\sqrt{2},\mathbb{Q}}(x) = x^2 - 2$ is irreducible (Eisenstein at 2, or no rational root), so $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2 = 2^1$, a single quadratic step. *Sanity check.* $2 = 2^1$ is a power of 2, consistent with Corollary 13.3.4.

Worked Example 13.3.6 (A two-step tower: $\sqrt{1 + \sqrt{2}}$)**.** Decide whether $\alpha = \sqrt{1 + \sqrt{2}}$ is constructible and find $[\mathbb{Q}(\alpha) : \mathbb{Q}]$.

Recognition. Closure of constructible numbers under $+$ and $\sqrt{\ }$ (Theorem 13.3.2); then check the degree against Corollary 13.3.4.

Solution. Build it up: $\sqrt{2}$ is constructible (previous example), so $1 + \sqrt{2} \in \mathbb{Q}(\sqrt{2})$ is constructible and positive, hence $\alpha = \sqrt{1 + \sqrt{2}}$ is constructible. The tower is $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2}) \subseteq \mathbb{Q}(\alpha)$, each step quadratic: $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$, and α satisfies $x^2 - (1 + \sqrt{2})$ over $\mathbb{Q}(\sqrt{2})$, irreducible there since $1 + \sqrt{2}$ is not a square in the real field $\mathbb{Q}(\sqrt{2})$ (its conjugate $1 - \sqrt{2} < 0$, so $1 + \sqrt{2}$ cannot be a square of an element of $\mathbb{Q}(\sqrt{2})$). Thus $[\mathbb{Q}(\alpha) : \mathbb{Q}(\sqrt{2})] = 2$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 2 \cdot 2 = 4$. *Sanity check.* Over $\mathbb{Q}$, α satisfies $(x^2 - 1)^2 = 2$, i.e. $x^4 - 2x^2 - 1 = 0$; this quartic is irreducible over $\mathbb{Q}$ (no rational roots, and it has no quadratic factorization over $\mathbb{Q}$ because $\pm\sqrt{2} \notin \mathbb{Q}$). Degree $4 = 2^2$, a power of 2. ■

Worked Example 13.3.7 (The tower hidden in intersecting circles)**.** Two unit circles centered at $(0, 0)$ and $(1, 0)$ meet at a point P. Find the coordinates of P and the field they generate over $\mathbb{Q}$.

Recognition. Two-circles case of the analysis preceding Theorem 13.3.3: subtract equations to get the radical axis, then intersect with a circle (a quadratic over the current field).

Solution. The circles are $x^2+y^2=1$ and $(x-1)^2+y^2=1$. Subtracting, $2x-1=0$, the radical axis $x=\frac{1}{2}$ (a line over $\mathbb{Q}$). Substituting into the first circle, $y^2=1-\frac{1}{4}=\frac{3}{4}$, so $y=\frac{\sqrt{3}}{2}$. Thus $P=\left(\frac{1}{2},\frac{\sqrt{3}}{2}\right)$ and the coordinate field is $\mathbb{Q}(\sqrt{3})$, reached by the single quadratic step $\mathbb{Q}\subseteq\mathbb{Q}(\sqrt{3})$. *Sanity check.* $m_{\sqrt{3},\mathbb{Q}}(x)=x^2-3$, so $[\mathbb{Q}(\sqrt{3}):\mathbb{Q}]=2$, a power of 2; indeed P is the standard ruler-and-compass construction of an equilateral triangle on the unit segment, angle $60°$. ■

Worked Example 13.3.8 (A non-constructible algebraic number)**.** Show $\beta=2^{1/3}$ is *not* constructible, working only from Corollary 13.3.4.

Recognition. Corollary 13.3.4: a constructible number has degree a power of 2 over $\mathbb{Q}$; contrapositive rules β out.

Solution. The minimal polynomial of $2^{1/3}$ over $\mathbb{Q}$ is $m_{\beta,\mathbb{Q}}(x)=x^3-2$, irreducible by Eisenstein at 2. Hence $[\mathbb{Q}(\beta):\mathbb{Q}]=3$. Since 3 is not a power of 2, β is not constructible. *Sanity check.* If it were constructible, $3\mid 2^m$ for some m, impossible. ■(This is exactly the doubling-the-cube obstruction, developed below.)

Worked Example 13.3.9 (Degree obstruction with a degree-6 number)**.** Is $\gamma=\sqrt[3]{2}+\sqrt{2}$ constructible?

Recognition. Corollary 13.3.4 plus the tower law to compute $[\mathbb{Q}(\gamma):\mathbb{Q}]$.

Solution. Note $\mathbb{Q}(\gamma)=\mathbb{Q}(\sqrt[3]{2},\sqrt{2})$: clearly $\gamma\in\mathbb{Q}(\sqrt[3]{2},\sqrt{2})$, and conversely one can solve for $\sqrt{2}$ and $\sqrt[3]{2}$ from γ (the field $\mathbb{Q}(\gamma)$ contains both summands by a short computation). By the tower law, $[\mathbb{Q}(\sqrt[3]{2},\sqrt{2}):\mathbb{Q}]=[\mathbb{Q}(\sqrt[3]{2},\sqrt{2}):\mathbb{Q}(\sqrt[3]{2})]\cdot[\mathbb{Q}(\sqrt[3]{2}):\mathbb{Q}]=2\cdot 3=6$ (the first factor is 2 since x^2-2 stays irreducible over the real cubic field $\mathbb{Q}(\sqrt[3]{2})$, which contains no $\sqrt{2}$). So $[\mathbb{Q}(\gamma):\mathbb{Q}]=6$. *Sanity check.* 6 is not a power of 2, so γ is not constructible. The cube root alone already poisons the degree. ■

Impossibility of the three classical problems

Theorem 13.3.10 (Doubling the cube is impossible)**.** *There is no straightedge-and-compass construction producing, from an edge of a cube, the edge of a cube with twice the volume.*

Proof. Taking the given edge as the unit, the new edge has length β with $\beta^3=2$, i.e. $\beta=2^{1/3}$. Its minimal polynomial over $\mathbb{Q}$ is x^3-2 (Eisenstein), so $[\mathbb{Q}(\beta):\mathbb{Q}]=3$, not a power of 2. By Corollary 13.3.4, β is not constructible. □

Theorem 13.3.11 (Trisecting a general angle is impossible)**.** *There is no construction that trisects an arbitrary constructible angle. In particular the angle* $60°$ *cannot be trisected.*

Proof. An angle θ is constructible iff the point $(\cos\theta,\sin\theta)$, equivalently the number $\cos\theta$, is constructible. The angle $60°$ is constructible (Example with the two unit circles). Trisecting it means constructing $\cos 20°$. The triple-angle identity $\cos 3\theta=4\cos^3\theta-3\cos\theta$ with $\theta=20°$ and $\cos 60°=\frac{1}{2}$ gives, for $\alpha=\cos 20°$,

$$4\alpha^3-3\alpha=\tfrac{1}{2},\qquad\text{i.e.}\qquad 8\alpha^3-6\alpha-1=0.$$

Put $u=2\alpha$; then $u^3-3u-1=0$. This cubic has no rational root (candidates ±1 fail), hence is irreducible over $\mathbb{Q}$, so $[\mathbb{Q}(u):\mathbb{Q}]=3$ and likewise $[\mathbb{Q}(\alpha):\mathbb{Q}]=3$. Since 3 is not a power of 2, $\cos 20°$ is not constructible by Corollary 13.3.4; the trisection is impossible. □

Theorem 13.3.12 (Squaring the circle is impossible)**.** *There is no construction producing a square whose area equals that of a given circle.*

Proof. Taking the circle to have radius 1 (area π), the desired square has side $\sqrt{\pi}$. If $\sqrt{\pi}$ were constructible then so would π be (the constructible numbers form a field, Theorem 13.3.2), hence π would be algebraic over $\mathbb{Q}$ by Corollary 13.3.4. But Lindemann's theorem asserts π is transcendental over $\mathbb{Q}$. This contradiction shows $\sqrt{\pi}$ is not constructible. □

Remark 13.3.2. Doubling the cube and trisecting 60° are pure degree obstructions: the target has degree 3. Squaring the circle is deeper – it fails not on a degree count but because π is not even algebraic, so it lies outside *every* finite tower over $\mathbb{Q}$. The transcendence of π (Lindemann, 1882) is the only non-algebraic input to this entire section.

The trisection failure can be read off a single tower diagram: the unattainable field $\mathbb{Q}(\cos 20°)$ sits at degree 3 over $\mathbb{Q}$, which no chain of quadratic steps can reach.

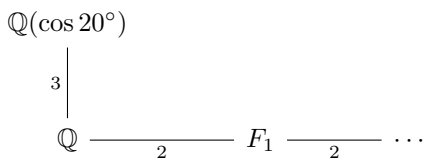

Diagram explanation. Objects: Three kinds of nodes: the target field $\mathbb{Q}(\cos 20°)$ (the smallest subfield of $\mathbb{R}$ containing the number we wish to construct), the base field $\mathbb{Q}$, and a (hypothetical) quadratic tower $\mathbb{Q} \subseteq F_1 \subseteq \cdots$ of the kind that every constructible number must lie inside.

Arrows: The vertical dash labelled 3 is the field extension $\mathbb{Q} \subset \mathbb{Q}(\cos 20°)$ of degree 3: $\cos 20°$ satisfies the cubic $8x^3 - 6x - 1$ (after the substitution $u = 2\cos 20°$, cleared as $u^3 - 3u - 1$), which is irreducible over $\mathbb{Q}$. The horizontal dashes labelled 2 are the quadratic steps in any constructible tower – the only steps that ruler-and-compass allows.

What commutes: Nothing commutes: the point of this diagram is a *non- commutativity.* If $\cos 20°$ were constructible it would lie in some F_m with $[F_m : \mathbb{Q}] = 2^m$; then the tower law would force $3 = [\mathbb{Q}(\cos 20°) : \mathbb{Q}]$ to divide 2^m, which is impossible for any m. The two branches of the diagram *cannot meet*, and that impossibility is the proof.

Why it commutes: It does not – and the failure of the two branches to connect is exactly the content of the impossibility theorem. The left branch has degree 3; any chain of quadratic steps from $\mathbb{Q}$ gives degree 2^m; since $3 \nmid 2^m$ for any m, no tower from the right side can ever reach $\mathbb{Q}(\cos 20°)$ on the left.

Why this matters here: This diagram is the geometric summary of the proof that trisecting 60° is impossible. It makes the abstract degree argument visual: the field $\mathbb{Q}(\cos 20°)$ sits at an odd-degree level that no sequence of degree-2 steps from $\mathbb{Q}$ can reach, so the trisection cannot be accomplished by straightedge and compass.

Concrete example: Compare to $\cos 30° = \frac{\sqrt{3}}{2} \in \mathbb{Q}(\sqrt{3})$, degree $2 = 2^1$ over $\mathbb{Q}$. Here the left branch would be labelled 2, which does divide 2^1, and indeed 30° is constructible (the trisection of 90° works, as the following worked example explains).

Common pitfall: Students read the diagram as saying $\mathbb{Q}(\cos 20°)$ and F_1 are somehow equal or comparable. The point is the opposite: they live in incompatible worlds (degree 3 vs. degree 2, and neither degree divides the other), so by the tower law no inclusion between them can exist.

Takeaway: The point of this diagram is that the field $\mathbb{Q}(\cos 20°)$ has degree 3 over $\mathbb{Q}$, while every constructible field sits in a tower of degree 2^m, and since $3 \nmid 2^m$, trisecting 60° is impossible.

Worked examples: impossibility proofs

Worked Example 13.3.13 (Why 90° *can* be trisected)**.** Explain why 90° can be trisected even though a general angle cannot.

Recognition. The trisection obstruction (Theorem 13.3.11) is about a *specific* target $\cos(\theta/3)$; for special θ the target may have 2-power degree.

Solution. Trisecting 90° asks for 30°, i.e. for $\cos 30° = \frac{\sqrt{3}}{2}$. This lies in $\mathbb{Q}(\sqrt{3})$, with $[\mathbb{Q}(\sqrt{3}) : \mathbb{Q}] = 2$, a power of 2, and indeed 30° is constructible (bisect 60°). No contradiction with Theorem 13.3.11: that theorem only denies a *universal* trisection and uses 60° as a single counterexample. *Sanity check.* Degree $2 = 2^1$; constructibility confirmed. ■

Worked Example 13.3.14 (Doubling via a degree count from a tower)**.** Suppose someone claims to construct $2^{1/3}$ inside $\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$. Refute it.

Recognition. Tower law plus Corollary 13.3.4: $2^{1/3}$ has degree 3, which cannot divide the degree of a multiquadratic field.

Solution. The field $K = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$ has $[K : \mathbb{Q}] = 2^3 = 8$ (each surd is a new quadratic step; they are independent since the relevant radicands are non-squares with distinct prime support). If $2^{1/3} \in K$ then $\mathbb{Q}(2^{1/3}) \subseteq K$, so by the tower law $3 = [\mathbb{Q}(2^{1/3}) : \mathbb{Q}]$ divides $[K : \mathbb{Q}] = 8$. But $3 \nmid 8$. Contradiction. *Sanity check.* No subfield of a 2-power-degree field can have degree 3. ■

Worked Example 13.3.15 (A constructible special angle: 72°)**.** Decide whether 72° is constructible, and connect it to the regular pentagon.

Recognition. Constructibility of $\cos 72°$ via its known closed form; degree check against Corollary 13.3.4.

Solution. One has $\cos 72° = \dfrac{\sqrt{5}-1}{4}$, which lies in $\mathbb{Q}(\sqrt{5})$, degree 2 over $\mathbb{Q}$. So 72° is constructible, and the regular pentagon (5 sides) can be built. This is the case $n = 5$ of the regular-n-gon problem below. *Sanity check.* $[\mathbb{Q}(\sqrt{5}) : \mathbb{Q}] = 2 = 2^1$; numerically $\frac{\sqrt{5}-1}{4} \approx 0.309 = \cos 72°$. ■

Worked Example 13.3.16 (Squaring the circle, contrapositive form)**.** Show that if π were a root of some $x^2 - q$ with $q \in \mathbb{Q}$, the circle could be squared; conclude what Lindemann's theorem rules out.

Recognition. Theorem 13.3.12 and the field-closure Theorem 13.3.2.

Solution. If $\pi = \sqrt{q}$ with $q \in \mathbb{Q}_{>0}$, then π would be constructible (square root of a constructible number), hence so would $\sqrt{\pi} = q^{1/4}$ (another square root), and the side of the equal-area square would be constructible. Lindemann's theorem forbids exactly this by making π transcendental, so no such algebraic description of π exists. *Sanity check.* The obstruction is not a parity-of-degree issue but the total absence of any minimal polynomial for π. ■

Worked Example 13.3.17 (Degree 4 does not imply constructible)**.** Critique the (false) reasoning "$[\mathbb{Q}(\alpha) : \mathbb{Q}] = 4$ is a power of 2, so α is constructible."

Recognition. The Remark after Corollary 13.3.4: the power-of-2 condition is necessary, not sufficient.

Solution. Power-of-2 degree is necessary, so it cannot prove non-constructibility, but it also cannot prove constructibility. A number of degree 4 is constructible iff it actually lies in a tower of quadratic extensions, which holds iff the Galois closure of $\mathbb{Q}(\alpha)$ has 2-power degree. There are degree-4 numbers whose Galois closure has degree 24 (Galois group S_4); those are not constructible despite the degree being 4. *Sanity check.* The correct test is on the Galois closure, not on $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ alone. ■

Constructibility of the regular n-gon

Inscribing a regular n-gon in the unit circle is the same as constructing the point $(\cos \frac{2\pi}{n}, \sin \frac{2\pi}{n})$, i.e. the primitive n-th root of unity $\zeta_n = e^{2\pi i/n}$ in the plane. So the n-gon is constructible iff ζ_n is a constructible point, which (taking coordinates) happens iff $\cos \frac{2\pi}{n}$ is a constructible number.

Proposition 13.3.18. *The regular n-gon is constructible if and only if ζ_n is constructible. A* necessary *condition is that $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n)$ be a power of 2.*

Proof. The first sentence is the discussion above. For the degree condition, recall the cyclotomic field $\mathbb{Q}(\zeta_n)$ has $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \deg \Phi_n(x) = \varphi(n)$, with $\Phi_n(x)$ irreducible over $\mathbb{Q}$. If ζ_n is constructible then, as a point with constructible coordinates, both $\cos \frac{2\pi}{n}$ and $\sin \frac{2\pi}{n}$ are constructible, so $\zeta_n \in \overline{\mathbb{Q}}$ lies in a field reached by a tower of quadratics; in particular $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n)$ is a power of 2 by Corollary 13.3.4 applied in $\mathbb{C}$. □

The cyclotomic tower over $\mathbb{Q}$ is the natural home for this discussion:

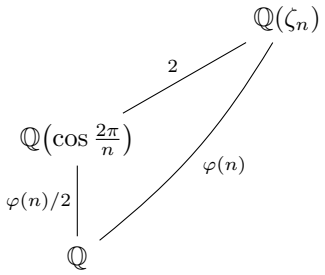

Diagram explanation. Objects: Three *subfields of* $\mathbb{C}$: the rationals $\mathbb{Q}$; the *maximal real subfield* $\mathbb{Q}(\cos\frac{2\pi}{n})$ of the n-th cyclotomic field; and the full *cyclotomic field* $\mathbb{Q}(\zeta_n)$, where $\zeta_n = e^{2\pi i/n}$ is a primitive n-th root of unity.

Arrows: Three inclusion arrows: (i) the left vertical, $\mathbb{Q} \hookrightarrow \mathbb{Q}(\cos\frac{2\pi}{n})$, of degree $\varphi(n)/2$; (ii) the diagonal, $\mathbb{Q}(\cos\frac{2\pi}{n}) \hookrightarrow \mathbb{Q}(\zeta_n)$, of degree 2 (because ζ_n satisfies the quadratic $z^2 - 2\cos\frac{2\pi}{n}\, z + 1$ over $\mathbb{Q}(\cos\frac{2\pi}{n})$); (iii) the bent arrow, $\mathbb{Q} \hookrightarrow \mathbb{Q}(\zeta_n)$, of degree $\varphi(n)$ (the degree of the cyclotomic polynomial Φ_n).

What commutes: The two paths from $\mathbb{Q}$ to $\mathbb{Q}(\zeta_n)$ agree: going via the maximal real subfield gives degree $\frac{\varphi(n)}{2} \cdot 2 = \varphi(n)$, matching the direct arrow. Formally: $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = [\mathbb{Q}(\zeta_n) : \mathbb{Q}(\cos\frac{2\pi}{n})] \cdot [\mathbb{Q}(\cos\frac{2\pi}{n}) : \mathbb{Q}] = 2 \cdot \frac{\varphi(n)}{2} = \varphi(n)$.

Why it commutes: The tower law for field extensions. The key fact that makes the top step exactly degree 2 is that $\zeta_n = \cos\frac{2\pi}{n} + i\sin\frac{2\pi}{n}$ and $\bar{\zeta}_n = \zeta_n^{-1}$ have the same real part, so $\mathbb{Q}(\zeta_n) = \mathbb{Q}(\cos\frac{2\pi}{n})(i\sin\frac{2\pi}{n})$, a degree-2 extension of the real subfield (since $(i\sin\frac{2\pi}{n})^2 = \cos^2\frac{2\pi}{n} - 1$ lies in the real subfield, while $i\sin\frac{2\pi}{n} \notin \mathbb{R}$ for $n > 2$).

Why this matters here: This diagram records the key structural decomposition used to decide constructibility of regular n-gons: the n-gon is constructible iff ζ_n is constructible iff $\cos\frac{2\pi}{n}$ is constructible iff $\varphi(n)/2$ is a power of 2 (equivalently $\varphi(n)$ is a power of 2). The diagram makes all the degree arithmetic transparent.

Concrete example: For $n = 5$: $\varphi(5) = 4$, so $[\mathbb{Q}(\cos\frac{2\pi}{5}) : \mathbb{Q}] = 2$ and $[\mathbb{Q}(\zeta_5) : \mathbb{Q}(\cos\frac{2\pi}{5})] = 2$. Both steps are quadratic, the tower is $\mathbb{Q} \subset \mathbb{Q}(\sqrt{5}) \subset \mathbb{Q}(\zeta_5)$, and the regular pentagon is constructible.

Common pitfall: Students confuse $\mathbb{Q}(\zeta_n)$ with $\mathbb{Q}(\cos\frac{2\pi}{n})$ and forget the top step of degree 2. The real subfield is a *proper* subfield of $\mathbb{Q}(\zeta_n)$ whenever $n > 2$; ζ_n is *not* real for $n > 2$, so it is genuinely a degree-2 extension.

Takeaway: The point of this diagram is that the cyclotomic field $\mathbb{Q}(\zeta_n)$ decomposes as a degree-2 extension of its maximal real subfield, so constructibility of the n-gon reduces to whether the real subfield's degree $\varphi(n)/2$ is a power of 2.

Here $\mathbb{Q}(\cos\frac{2\pi}{n})$ is the maximal real subfield, of index 2 in $\mathbb{Q}(\zeta_n)$ (since ζ_n satisfies the quadratic $z^2 - 2\cos\frac{2\pi}{n}\, z + 1$ over it), so its degree over $\mathbb{Q}$ is $\varphi(n)/2$. The n-gon is constructible iff $\varphi(n)$ is a power of 2 (this turns out to be sufficient as well, by Galois theory: a 2-power-degree *abelian* extension is reached by a tower of quadratics). Writing $\varphi(n)$ as a power of 2 leads to Gauss's classification.

Theorem 13.3.19 (Gauss–Wantzel)**.** *The regular n-gon is constructible if and only if $n = 2^a p_1 p_2 \cdots p_r$ with $a \geq 0$ and $p_1, \ldots, p_r$ distinct Fermat primes, i.e. primes of the form $2^{2^k} + 1$.*

This follows from the criterion that $\varphi(n)$ be a power of 2. Writing $n = 2^a q_1^{e_1} \cdots q_s^{e_s}$ with distinct odd primes q_j, we have $\varphi(n) = \varphi(2^a) \prod_j q_j^{e_j - 1}(q_j - 1)$, a power of 2 exactly when every $e_j = 1$ (otherwise $q_j \mid \varphi(n)$) and every $q_j - 1$ is a power of 2, i.e. each q_j is a Fermat prime. For $n = 2^a p_1 \cdots p_r$ with distinct odd primes p_i the divisor relations among n, the p_i, and $\varphi(n)$ are displayed below.

$$\begin{array}{ccc} n = 2^a p_1 \cdots p_r & \xrightarrow{\ \varphi\ } & \varphi(n) = \varphi(2^a) \prod_i (p_i - 1) \\ \Big| & & \Big| \\ p_i \mid n & \xrightarrow[p_i = 2^{2^k}+1]{} & p_i - 1 = 2^{2^k} \end{array}$$

Diagram explanation. Objects: The four nodes are *arithmetic expressions*, not fields: the top-left is the integer $n = 2^a p_1 \cdots p_r$ (with the p_i distinct odd prime divisors); the top-right is $\varphi(n) = \varphi(2^a)\prod_i (p_i - 1)$; the bottom-left is a single odd prime factor p_i of n; and the bottom-right is $p_i - 1$.

Arrows: The top arrow applies the *Euler totient function* φ: $n \mapsto \varphi(n) = \varphi(2^a)\prod_i (p_i - 1)$ (using multiplicativity of φ, $\varphi(p) = p - 1$, and $\varphi(2^a) = 2^{a-1}$ for $a \geq 1$, $\varphi(1) = 1$). The left vertical dash is the divisibility relation $p_i \mid n$, and the right one records that $p_i - 1$ divides $\varphi(n)$. The bottom arrow asserts the *Fermat prime condition*: $p_i = 2^{2^k} + 1$, which forces $p_i - 1 = 2^{2^k}$, a power of 2.

What commutes: The diagram is a *logic square*, not a function square. The commutativity reads: $\varphi(n)$ is a power of 2 (top-right) *if and only if* every odd prime factor p_i satisfies $p_i - 1 = 2^{2^k}$ (bottom-right). Going top-then-bottom: $n \xrightarrow{\varphi} \varphi(n)$, and requiring $\varphi(n) = 2^m$ forces each factor $p_i - 1$ to be a power of 2. Going left-then-right: each $p_i \mid n$ with $p_i - 1 = 2^{2^k}$ contributes a pure 2-power factor to $\varphi(n)$.

Why it commutes: By the multiplicativity $\varphi(n) = \varphi(2^a)\prod_i (p_i - 1)$: the only way the product $\prod_i (p_i - 1)$ can be a pure power of 2 is if each factor $p_i - 1$ is a power of 2. And $p_i - 1 = 2^j$ with p_i prime forces j itself to be a power of 2 (if j had an odd factor $d > 1$, then $p_i = 2^j + 1$ would be divisible by $2^{j/d} + 1$, contradicting primality).

Why this matters here: This diagram organises the *Gauss–Wantzel classification*: the regular n-gon is constructible iff $\varphi(n)$ is a power of 2, and the diagram shows that this condition forces every odd prime factor of n to be a Fermat prime $2^{2^k} + 1$. It is the arithmetic engine behind the theorem.

Concrete example: $n = 15 = 3 \cdot 5$: $p_1 = 3 = 2^{2^0} + 1$ and $p_2 = 5 = 2^{2^1} + 1$ are both Fermat primes, so $\varphi(15) = (3-1)(5-1) = 8 = 2^3$, and the 15-gon is constructible. For $n = 7$: $p_1 = 7$ and $7 - 1 = 6 = 2 \cdot 3$ is not a power of 2, so $\varphi(7) = 6$ is not a power of 2, and the 7-gon is not constructible.

Common pitfall: Students forget the factor $\varphi(2^a)$ from the power-of-2 part of n and think a factor of 2 in n can "fix" a bad odd prime. The factor $\varphi(2^a)$ ($= 2^{a-1}$ for $a \geq 1$, $= 1$ for $a = 0$) is always a power of 2, so powers of 2 in n are harmless; only the odd primes p_i can destroy the power-of-2 property.

Takeaway: The point of this diagram is that the constructibility condition $\varphi(n) = 2^m$ propagates down to each odd prime factor of n, forcing it to be a Fermat prime; together with the fact that an odd prime p with $p^2 \mid n$ would divide $\varphi(n)$, this gives the complete classification of constructible regular polygons.

Worked examples: regular n-gons

Worked Example 13.3.20 (The pentagon $n = 5$)**.** Decide constructibility of the regular pentagon.

Recognition. Proposition 13.3.18 / Gauss–Wantzel (Theorem 13.3.19): check $\varphi(5)$ and whether 5 is a Fermat prime.

Solution. $\varphi(5) = 4 = 2^2$, a power of 2; equivalently $5 = 2^{2^1} + 1$ is the Fermat prime F_1. So the regular pentagon *is* constructible. Concretely $\cos\frac{2\pi}{5} = \frac{\sqrt{5}-1}{4} \in \mathbb{Q}(\sqrt{5})$, degree 2 over $\mathbb{Q}$. *Sanity check.* The tower is $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{5}) \subseteq \mathbb{Q}(\zeta_5)$ with steps $2, 2$, total $\varphi(5) = 4$. ■

Worked Example 13.3.21 (The heptagon $n = 7$)**.** Decide constructibility of the regular 7-gon.

Recognition. Theorem 13.3.19: is 7 a Fermat prime? Equivalently is $\varphi(7)$ a power of 2?

Solution. $\varphi(7) = 6 = 2 \cdot 3$, *not* a power of 2; and $7 - 1 = 6$ is not a power of 2, so 7 is not a Fermat prime. Hence the regular heptagon is *not* constructible. The number $\cos\frac{2\pi}{7}$ has minimal polynomial $8x^3 + 4x^2 - 4x - 1$ over $\mathbb{Q}$, degree 3. *Sanity check.* Degree 3 is not a power of 2, matching Corollary 13.3.4. ■

Worked Example 13.3.22 (The 9-gon and angle trisection)**.** Decide constructibility of the regular nonagon ($n = 9$) and connect it to Theorem 13.3.11.

Recognition. Gauss–Wantzel with a repeated prime; relation to trisecting 120°.

Solution. $\varphi(9) = 6$, not a power of 2 (here $9 = 3^2$ has the odd prime 3 squared, which already violates the "distinct primes to the first power" condition of Theorem 13.3.19). So the nonagon is not constructible. This is precisely the trisection obstruction: the nonagon needs the angle $\frac{2\pi}{9} = 40°$, i.e. the trisection of the constructible angle 120°, and $\cos 40°$ has degree 3 over $\mathbb{Q}$. *Sanity check.* Same cubic obstruction as $\cos 20°$ in Theorem 13.3.11; degree 3. ■

Worked Example 13.3.23 (The 15-gon $n = 15$)**.** Decide constructibility of the regular 15-gon and exhibit the construction idea.

Recognition. Theorem 13.3.19: $15 = 3 \cdot 5$, distinct odd primes; check each is Fermat.

Solution. Both $3 = 2^{2^0}+1$ (F_0) and $5 = 2^{2^1}+1$ (F_1) are Fermat primes, and $\varphi(15) = \varphi(3)\varphi(5) = 2 \cdot 4 = 8 = 2^3$, a power of 2. So the 15-gon is constructible. Construction idea: since $\frac{2}{5} - \frac{1}{3} = \frac{6-5}{15} = \frac{1}{15}$, the angle $\frac{2\pi}{15}$ is a $\mathbb{Z}$-combination of the constructible angles $\frac{2\pi}{3}$ and $\frac{2\pi}{5}$, so it too is constructible. *Sanity check.* $\varphi(15) = 8 = 2^3$ is a power of 2. ■

Worked Example 13.3.24 (The 17-gon $n = 17$ (Gauss))**.** Decide constructibility of the regular 17-gon.

Recognition. Theorem 13.3.19: is 17 a Fermat prime?
