Solution. $17 = 2^{2^2} + 1 = 2^4 + 1$ is the Fermat prime F_2, and $\varphi(17) = 16 = 2^4$, a power of 2. So the regular 17-gon is constructible – Gauss's celebrated discovery of 1796. The tower $\mathbb{Q} \subseteq \cdots \subseteq \mathbb{Q}(\zeta_{17})$ has 4 quadratic steps, and $\cos\frac{2\pi}{17}$ lies in the unique real subfield of degree $\varphi(17)/2 = 8$ over $\mathbb{Q}$. *Sanity check.* $16 = 2^4$; four square roots suffice to express $\cos\frac{2\pi}{17}$. ■

Worked Example 13.3.25 (A composite with a bad factor: $n = 14$)**.** Decide constructibility of the regular 14-gon.

Recognition. Theorem 13.3.19: $14 = 2 \cdot 7$; the odd part is 7.

Solution. $\varphi(14) = \varphi(2)\varphi(7) = 1 \cdot 6 = 6$, not a power of 2; equivalently the odd prime 7 dividing 14 is not a Fermat prime. Hence the 14-gon is not constructible. The factor of 2 (bisection, always allowed) cannot rescue the bad odd prime 7. *Sanity check.* A regular $2k$-gon is constructible iff the regular k-gon is (bisect each arc); since the 7-gon fails, so does the 14-gon. ■

Exercises (from the text).

1. Prove that it is impossible to construct the regular 9-gon.
2. Prove that Archimedes' construction actually trisects the angle θ. [Note the isosceles triangles in Figure 5 to prove that $\beta = \gamma = 2\alpha$.]
3. Prove that Conway's construction indicated in the text actually constructs $2k^{1/3}$ and $2k^{2/3}$. [One method: let (x, y) be the coordinates of the point C, a the distance from B to C and b the distance from A to D; use similar triangles to prove (a) $\frac{y}{1} = \frac{\sqrt{1-k^2}}{1+a}$, (b) $\frac{x}{a} = \frac{b+k}{1+a}$, (c) $\frac{y}{x-k} = \frac{\sqrt{1-k^2}}{3k}$, and also show that (d) $(1-k^2) + (b+k)^2 = (1+a)^2$; solve these equations for a and b.]
4. The construction of the regular 7-gon amounts to the constructibility of $\cos(2\pi/7)$. We shall see later (Section 14.5 and Exercise 2 of Section 14.7) that $\alpha = 2\cos(2\pi/7)$ satisfies the equation $x^3 + x^2 - 2x - 1 = 0$. Use this to prove that the regular 7-gon is not constructible by straightedge and compass.
5. Use the fact that $\alpha = 2\cos(2\pi/5)$ satisfies the equation $x^2 + x - 1 = 0$ to conclude that the regular 5-gon is constructible by straightedge and compass.

Practice problems.

1. Show directly from the closure properties that $\sqrt{2} + \sqrt[4]{5}$ is a constructible real number by exhibiting it as an element built from $\mathbb{Q}$ using $+, -, \times, \div$ and square roots. Then write down a tower

$$\mathbb{Q} = F_0 \subseteq F_1 \subseteq F_2 \subseteq \cdots \subseteq F_k$$

   with each $[F_{i+1} : F_i] = 2$ such that $\sqrt{2} + \sqrt[4]{5} \in F_k$, and state the resulting upper bound on $[\mathbb{Q}(\sqrt{2} + \sqrt[4]{5}) : \mathbb{Q}]$ forced by the power-of-2 criterion.

2. For each real number α below, compute $m_{\alpha,\mathbb{Q}}(x)$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}]$, and decide whether α is constructible: (a) $\alpha = \sqrt[3]{2}$; (b) $\alpha = \sqrt{1+\sqrt{3}}$; (c) $\alpha = \cos 20°$. In each case justify a verdict of non-constructibility using only the necessary condition that $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ be a power of 2, and a verdict of constructibility by building α from $\mathbb{Q}$ with field operations and square roots.

3. Let $\alpha = \sqrt{2+\sqrt{2}}$. Prove that α is constructible by finding its minimal polynomial over $\mathbb{Q}$, computing $[\mathbb{Q}(\alpha):\mathbb{Q}]$, and exhibiting an explicit tower of degree-2 extensions from $\mathbb{Q}$ up to $\mathbb{Q}(\alpha)$.

4. Prove that the regular 9-gon is not constructible. Specifically, show $\cos 40^\circ$ has $[\mathbb{Q}(\cos 40^\circ):\mathbb{Q}] = 3$, and explain why this rules out trisecting the 120° angle with straightedge and compass, hence the general angle.

5. Decide, with full justification, which of the following points $(x,y) \in \mathbb{R}^2$ are constructible from the base set $\{(0,0),(1,0)\}$: (a) $(\sqrt{6},\,0)$; (b) $(\sqrt[3]{7},\,1)$; (c) $\big(\cos(\pi/8),\,\sin(\pi/8)\big)$; (d) $\big(\pi,\,0\big)$.

6. Let α be a root of $x^4 - 4x^2 + 1$. Show this polynomial is the minimal polynomial of $\alpha = \sqrt{2+\sqrt{3}}$ over $\mathbb{Q}$, deduce $[\mathbb{Q}(\alpha):\mathbb{Q}] = 4$, and conclude α is constructible. Then explain why $[\mathbb{Q}(\beta):\mathbb{Q}] = 4$ alone is *not* sufficient to conclude β is constructible, by giving (with proof) a β of degree 4 over $\mathbb{Q}$ whose splitting field has degree not a power of 2 over $\mathbb{Q}$.

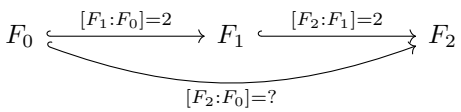
7. Compute the cyclotomic polynomials $\Phi_5(x)$, $\Phi_7(x)$, and $\Phi_{15}(x)$ from the factorization identity $x^n - 1 = \prod_{d\mid n} \Phi_d(x)$. Using $[\mathbb{Q}(\zeta_n):\mathbb{Q}] = \varphi(n)$, decide for each $n \in \{5,7,15\}$ whether the regular n-gon is constructible.

8. Suppose $\beta \in \mathbb{R}$ is constructible and $m_{\beta,\mathbb{Q}}(x) = x^3 + ax + b$ has degree 3. Derive a contradiction, and use it to give a one-line proof that $\sqrt[3]{2}$ is not constructible (so the cube cannot be doubled).

Additional exercises.

1. (Trisection of a constructible angle.) An angle θ is called constructible when $(\cos\theta, \sin\theta)$ is a constructible point. Using the identity $\cos\theta = 4\cos^3(\theta/3) - 3\cos(\theta/3)$, prove that θ is trisectible by straightedge and compass if and only if the cubic $4t^3 - 3t - \cos\theta$ is reducible over $\mathbb{Q}(\cos\theta)$. Apply this to show 90° *is* trisectible but 60° is not.

2. Let K be the field of all constructible real numbers. Prove that K is a subfield of $\mathbb{R}$ that is closed under taking square roots of its nonnegative elements, that $\mathbb{Q} \subseteq K$, and that every element of K is algebraic over $\mathbb{Q}$ with $[\mathbb{Q}(\alpha):\mathbb{Q}]$ a power of 2. Then prove $[K:\mathbb{Q}]$ is infinite by exhibiting elements of arbitrarily large 2-power degree.



3. Prove that $\sqrt[4]{2}$ is constructible but $\sqrt[3]{2}\cdot\sqrt{2}$ is not, and reconcile this with the fact that both numbers are built only from 2, integer roots, and field operations. Identify precisely which step fails the square-root closure / power-of-2 criterion.

4. Let p be an odd prime. Prove that if the regular p-gon is constructible then p is a Fermat prime, i.e. $p = 2^{2^k} + 1$ for some $k \geq 0$. (Use $[\mathbb{Q}(\zeta_p):\mathbb{Q}] = p - 1$ and the power-of-2 criterion; you need not prove the converse.) Determine which of $p \in \{3,5,7,11,13,17\}$ give a constructible p-gon.

5. Show that squaring the circle is impossible: a square with area equal to that of a unit circle would have side $\sqrt{\pi}$. Assuming π is transcendental over $\mathbb{Q}$, prove that $\sqrt{\pi}$ is not constructible, carefully stating which property of constructible numbers is being contradicted.

Commutative-diagram exercises.

1. Let $\alpha = \sqrt{2+\sqrt{3}}$ with $F_0 = \mathbb{Q}$, $F_1 = \mathbb{Q}(\sqrt{3})$, $F_2 = \mathbb{Q}(\alpha)$. Fill in the degree-2 tower and the inclusion maps so that the triangle commutes, and label each arrow with the relevant extension degree:

   Compute the missing degree from multiplicativity of degrees in a tower, and explain how the diagram certifies constructibility of α.

2. Let $\zeta = \zeta_5$ be a primitive 5th root of unity and let $\eta = \zeta + \zeta^{-1} = 2\cos 72^\circ$. Complete the inclusion diagram with all extension degrees, where all fields sit inside $\mathbb{C}$ and all of them except $\mathbb{Q}(\zeta)$ inside $\mathbb{R}$:

$$\begin{array}{ccccc} \mathbb{Q} & \hookrightarrow & \mathbb{Q}(\eta) & \hookrightarrow & \mathbb{Q}(\zeta) \\ \| & & \| & & \| \\ \mathbb{Q} & \hookrightarrow & \mathbb{Q}(\cos 72^\circ) & \hookrightarrow & \mathbb{Q}(\zeta) \end{array}$$

Label every horizontal arrow with its degree (using $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = \varphi(5)$), justify the vertical equalities (note $\mathbb{Q}(\eta) = \mathbb{Q}(\cos 72^\circ)$ since $\eta = 2\cos 72^\circ$), and conclude that the regular pentagon is constructible.

3. Consider the map $\sigma\colon \mathbb{Q}(\sqrt{2}) \to \mathbb{Q}(\sqrt{2})$ given by $a + b\sqrt{2} \mapsto a - b\sqrt{2}$. Show $\sigma \in \mathrm{Aut}(\mathbb{Q}(\sqrt{2}))$, and verify commutativity of the square below, in which the horizontal arrows are σ and the vertical arrows are the identity id:

$$\begin{array}{ccc} \mathbb{Q}(\sqrt{2}) & \xrightarrow{\sigma} & \mathbb{Q}(\sqrt{2}) \\ {\scriptstyle \mathrm{id}}\downarrow & & \downarrow{\scriptstyle \mathrm{id}} \\ \mathbb{Q}(\sqrt{2}) & \xrightarrow{\sigma} & \mathbb{Q}(\sqrt{2}) \end{array}$$

and prove $\sigma^2 = \mathrm{id}$, so $\langle \sigma \rangle \cong \mathbb{Z}/2\mathbb{Z}$ realizes the single degree-2 step $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{2})$ of a constructibility tower.

4. For $\alpha = \sqrt[3]{2}$, the cubic $x^3 - 2$ has no constructibility tower. Display the obstruction as a failure to factor the degree through powers of 2: complete the diagram by inserting the (nonexistent for $\sqrt[3]{2}$) intermediate field and labeling the arrow that cannot have degree 2,

$$\begin{array}{ccc} \mathbb{Q} & \xhookrightarrow{[\mathbb{Q}(\sqrt[3]{2}):\mathbb{Q}]=3} & \mathbb{Q}(\sqrt[3]{2}) \\ \downarrow & \nearrow{\scriptstyle ?} & \\ L & & \end{array}$$

Explain why no field L with $\mathbb{Q} \subsetneq L \subsetneq \mathbb{Q}(\sqrt[3]{2})$ exists, and how the diagram encodes the impossibility of doubling the cube.

13.4 Splitting Fields and Algebraic Closures

The previous sections built a single algebraic extension $F(\alpha)$ one element at a time. We now ask for an extension large enough to contain *all* the roots of a given polynomial. Such a field lets the polynomial dissolve completely into linear factors, and it turns out to be essentially unique. Pushing the construction to its limit produces the algebraic closure $\overline{F}$, a field in which every polynomial over F (indeed over $\overline{F}$ itself) splits.

Splitting fields

Definition 13.4.1 (splitting field)**.** Let F be a field and let $f(x) \in F[x]$ be a nonconstant polynomial. An extension field K of F is called a *splitting field* for $f(x)$ over F if

1. $f(x)$ factors completely into linear factors (*splits*) in $K[x]$, i.e.

$$f(x) = a\,(x - \alpha_1)(x - \alpha_2)\cdots(x - \alpha_n), \qquad a \in F,\ \alpha_i \in K,$$

and

2. K is generated over F by the roots of $f(x)$, i.e. $K = F(\alpha_1, \ldots, \alpha_n)$.

The second condition forces K to be the *smallest* field containing F in which f splits: any subfield of K that contains F and over which f splits must contain all the α_i, hence equals K. More generally a splitting field for a *set* of polynomials over F is a field over which each member splits and which is generated over F by all of their roots.

Remark 13.4.1. The roots α_i need not be distinct, and the generating set is exactly the *distinct* roots. Discarding repeated factors does not change the splitting field: f and its radical (the product of its distinct irreducible factors) have the same root set, hence the same splitting field.

Theorem 13.4.2 (existence of splitting fields)**.** *For any field F and any nonconstant $f(x) \in F[x]$ there exists a splitting field K of $f(x)$ over F.*

Proof. Induct on $n = \deg f$. If $n = 1$ then f is already linear and $K = F$ works. Assume $n > 1$ and the result for all fields and all polynomials of degree $< n$. Let $p(x)$ be an irreducible factor of $f(x)$ in $F[x]$. By Kronecker's theorem (Section 13.1) the field $E = F[x]/(p(x))$ is an extension of F containing a root α of p, hence of f. Over E we may write $f(x) = (x - \alpha)g(x)$ with $g(x) \in E[x]$ of degree $n - 1$. By induction g has a splitting field K over E; thus g (and therefore f) splits in $K[x]$, and K is generated over E, hence over F, by the roots of f. So K is a splitting field for f over F. □

The inductive construction adjoins one root, drops the degree by one, and repeats. The next diagram shows the single step of Kronecker's construction (Section 13.1) that fuels the induction: evaluation $x \mapsto \alpha$ realizes $F(\alpha)$ as a quotient of the polynomial ring.

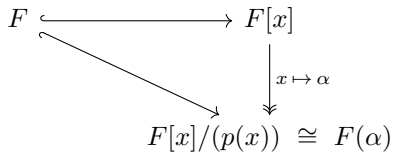


Diagram explanation. Objects: Three objects: the base field F (top-left corner); the polynomial ring $F[x]$ (top-right), an integral domain whose elements are formal polynomials over F; and the quotient ring $F[x]/(p(x))$, identified via an isomorphism with the simple extension $F(\alpha)$ (bottom-right), a field because $p(x)$ is irreducible.

Arrows: The horizontal top arrow $F \hookrightarrow F[x]$ is the canonical ring inclusion sending $a \mapsto a$ (constant polynomials). The vertical arrow $F[x] \twoheadrightarrow F[x]/(p(x))$ is the quotient (evaluation) epimorphism $f(x) \mapsto f(\alpha)$, which kills $p(x)$ and every multiple of $p(x)$. The diagonal arrow $F \hookrightarrow F(\alpha)$ is the inclusion of the base field into the extension, the composite of the other two restricted to F.

What commutes: The triangle commutes: the inclusion $F \hookrightarrow F(\alpha)$ equals the composite $F \hookrightarrow F[x] \twoheadrightarrow F[x]/(p(x)) \cong F(\alpha)$. In symbols, for $a \in F$: $a \mapsto a$ (via the diagonal) equals $a \mapsto a \mapsto a + (p(x))$ (via top then down).

Why it commutes: Take any $a \in F$. Along the top-then-down path: a is first viewed as the constant polynomial $a \in F[x]$, then mapped to its coset $a + (p(x))$, which corresponds to $a \in F(\alpha)$ under the isomorphism (constant polynomials are untouched by reduction mod p). Along the diagonal: a maps directly to itself in $F(\alpha)$. These agree because p has no effect on constants (the degree of p is at least 1, so $p \nmid a$). Well-definedness of the quotient map: since $p(x)$ is irreducible hence generates a maximal ideal, the ring $F[x]/(p(x))$ is a field, and the map $f(x) \mapsto f(\alpha)$ is well-defined on cosets because any two representatives of the same coset differ by a multiple of p, which evaluates to 0 at α.

Why this matters here: This is the single step of Kronecker's theorem fueling the inductive existence proof for splitting fields. It shows concretely how adjoining a root α of an irreducible $p(x)$ is equivalent to forming the quotient $F[x]/(p(x))$, making the abstract construction tangible and the diagram the "why it works" picture.

Concrete example: Take $F = \mathbb{Q}$, $p(x) = x^2 - 2$, $\alpha = \sqrt{2}$. Then $F[x]/(x^2 - 2) \cong \mathbb{Q}(\sqrt{2})$; the quotient map sends $x \mapsto \sqrt{2}$ and identifies $a + bx + (x^2 - 2)$ with $a + b\sqrt{2}$.

Common pitfall: Students confuse the quotient map with an isomorphism: $F[x] \twoheadrightarrow F[x]/(p(x))$ is surjective but NOT injective (it kills the ideal $(p(x))$). The isomorphism is only at the bottom, between the quotient and $F(\alpha)$.

Takeaway: The point of this diagram is that every simple algebraic extension $F(\alpha)$ is concretely realized as a polynomial ring modulo an irreducible, making the tower construction for splitting fields algorithmic.

Proposition 13.4.3 (degree bound)**.** *If K is a splitting field of $f(x) \in F[x]$ with $\deg f = n$, then*

$$[K : F] \;\le\; n!.$$

Proof. Following the existence proof, the first adjunction $F \subseteq F(\alpha)$ has degree $\deg m_{\alpha,F}(x) \le n$, where α is the chosen root; indeed $m_{\alpha,F} \mid f$, so this degree is at most n. Over $F(\alpha)$ the cofactor g has degree $n-1$, and by induction its splitting field over $F(\alpha)$ has degree at most $(n-1)!$. By the tower law (Section 13.2),

$$[K : F] = [K : F(\alpha)]\,[F(\alpha) : F] \;\le\; (n-1)! \cdot n = n!.$$

□

Here is the tower that the proof manufactures, with the running degree bounds attached to each edge.

$$F \xrightarrow{\;\le n\;} F(\alpha_1) \xrightarrow{\;\le n-1\;} F(\alpha_1, \alpha_2) \xrightarrow{\;\cdots\;} K = F(\alpha_1, \ldots, \alpha_n)$$

Diagram explanation. Objects: A linear chain of field extensions: the base field F on the left; the successive adjunction fields $F(\alpha_1)$, $F(\alpha_1, \alpha_2)$, ...; and the splitting field $K = F(\alpha_1, \ldots, \alpha_n)$ on the right. Each node is a field, and each arrow is an extension of fields of the indicated degree bound.

Arrows: Each undirected edge from E to $E(\alpha_k)$ represents the field extension obtained by adjoining one root α_k of the remaining cofactor. The label $\le n-k+1$ over the k-th arrow is the bound on $[E(\alpha_k) : E]$, coming from the degree of the cofactor $g_{k-1}(x)$ at that stage. The arrows are not ring maps but field extensions (inclusions).

What commutes: There is no commutativity condition here; the diagram is a chain, not a square. The key relation is multiplicativity of degrees via the tower law: $[K : F] = [K : F(\alpha_1, \ldots, \alpha_{n-1})] \cdots [F(\alpha_1) : F]$. Each factor is bounded by the label on the corresponding edge.

Why it commutes: Applying the tower law (Section 13.2) step by step: $[K : F] \le (n) \cdot (n-1) \cdots (1) = n!$. At each step the degree $[F(\alpha_1, \ldots, \alpha_k) : F(\alpha_1, \ldots, \alpha_{k-1})]$ is at most the degree of the cofactor of f remaining after $k-1$ roots are removed, which drops by 1 at each step because each new root is a root of the cofactor.

Why this matters here: This diagram organizes the degree-bound proof visually: it makes transparent that the bound $n!$ arises from the telescoping product, one factor per adjunction, each bounded by the decreasing degree of the cofactor. Without the diagram the induction step could feel opaque.

Concrete example: For $f(x) = x^3 - 2$ over $\mathbb{Q}$: the chain is $\mathbb{Q} \xrightarrow{\le 3} \mathbb{Q}(\sqrt[3]{2}) \xrightarrow{\le 2} K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$, giving $[K : \mathbb{Q}] \le 6 = 3!$; in fact equality holds here.

Common pitfall: The bounds $\le n$, $\le n-1$, ... are upper bounds, not equalities. In the $x^4 - 1$ example, the actual degrees are 2, 1, 1, 1 (since f is mostly split over $\mathbb{Q}$), far below $4! = 24$.

Takeaway: The point of this diagram is that the $n!$ degree bound is a straightforward telescoping product whose factors come directly from reading off the decreasing degree of the cofactor at each adjunction step.

Worked Example 13.4.4 (Splitting field of $x^2 - 2$ over $\mathbb{Q}$)**.** Find the splitting field K of $f(x) = x^2 - 2$ over $\mathbb{Q}$ and compute $[K : \mathbb{Q}]$.

Recognition. The splitting field is generated by the roots of f. Here f is irreducible over $\mathbb{Q}$ (Eisenstein at 2), so the degree bound $\le 2!$ applies and we expect a small extension.

Solution. The roots are $\pm\sqrt{2}$. Adjoining one root already gives the other, since $-\sqrt{2} \in \mathbb{Q}(\sqrt{2})$. Thus

$$K = \mathbb{Q}(\sqrt{2}, -\sqrt{2}) = \mathbb{Q}(\sqrt{2}), \qquad x^2 - 2 = (x - \sqrt{2})(x + \sqrt{2}) \text{ in } K[x].$$

Because $m_{\sqrt{2},\mathbb{Q}}(x) = x^2 - 2$ has degree 2, $[K : \mathbb{Q}] = 2$. *Sanity check.* $2 \le 2! = 2$, with equality, as the single quadratic adjunction already splits f entirely.

Worked Example 13.4.5 (Splitting field of $x^3 - 2$ over $\mathbb{Q}$)**.** Find the splitting field K of $f(x) = x^3 - 2$ over $\mathbb{Q}$ and its degree.

Recognition. f is irreducible (Eisenstein at 2), so one real root gives a degree-3 subextension; the complex roots force adjoining ζ_3. Expect $[K : \mathbb{Q}] \le 3! = 6$.

Solution. The roots are $\sqrt[3]{2},\ \zeta_3\sqrt[3]{2},\ \zeta_3^2\sqrt[3]{2}$ where $\zeta_3 = e^{2\pi i/3}$ is a primitive cube root of unity. Thus

$$K = \mathbb{Q}\big(\sqrt[3]{2},\, \zeta_3\sqrt[3]{2},\, \zeta_3^2\sqrt[3]{2}\big) = \mathbb{Q}\big(\sqrt[3]{2},\, \zeta_3\big).$$

Now $[\mathbb{Q}(\sqrt[3]{2}):\mathbb{Q}]=3$ (cubic minimal polynomial) and ζ_3 is a root of x^2+x+1, irreducible over $\mathbb{Q}(\sqrt[3]{2})\subset\mathbb{R}$ since $\zeta_3\notin\mathbb{R}$. By the tower law

$$[K:\mathbb{Q}]=[K:\mathbb{Q}(\sqrt[3]{2})]\,[\mathbb{Q}(\sqrt[3]{2}):\mathbb{Q}]=2\cdot 3=6.$$

Sanity check. $6=3!$, the maximum, reflecting that the three roots are as "independent" as possible.

The lattice of subfields produced in the last example sits inside K as follows, with edges labelled by their degrees over the field below.

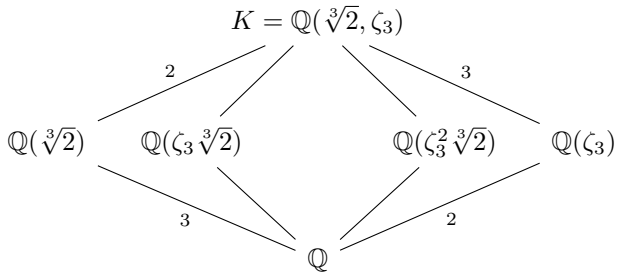

Diagram explanation. Objects: Six fields arranged in a diamond lattice. At the top: $K=\mathbb{Q}(\sqrt[3]{2},\zeta_3)$, the splitting field of x^3-2 of degree 6 over $\mathbb{Q}$. In the middle row: the three intermediate fields $\mathbb{Q}(\sqrt[3]{2})$ (real cubic), $\mathbb{Q}(\zeta_3\sqrt[3]{2})$ and $\mathbb{Q}(\zeta_3^2\sqrt[3]{2})$ (the two complex conjugate cubics), and $\mathbb{Q}(\zeta_3)$ (quadratic cyclotomic). At the bottom: $\mathbb{Q}$.

Arrows: Each dash arrow represents a field inclusion/extension. The label on each edge is the degree of that extension. From $\mathbb{Q}$: $[\mathbb{Q}(\sqrt[3]{2}):\mathbb{Q}]=3$, $[\mathbb{Q}(\zeta_3):\mathbb{Q}]=2$. From the cubic fields to K: degree 2 (must adjoin ζ_3). From $\mathbb{Q}(\zeta_3)$ to K: degree 3 (must adjoin $\sqrt[3]{2}$). The middle-row fields $\mathbb{Q}(\zeta_3\sqrt[3]{2})$ and $\mathbb{Q}(\zeta_3^2\sqrt[3]{2})$ connect to K and to $\mathbb{Q}$ by unlabelled dashes (degrees 2 and 3, as for $\mathbb{Q}(\sqrt[3]{2})$).

What commutes: Every path from $\mathbb{Q}$ to K has the same total degree 6: by the tower law, upward paths all multiply to 6. For instance, $3\cdot 2=6$ (left branch) and $2\cdot 3=6$ (right branch).

Why it commutes: The tower law $[K:\mathbb{Q}]=[K:E][E:\mathbb{Q}]$ applies to each intermediate field E. Since $[K:\mathbb{Q}]=6$ is fixed, the edge degrees must multiply consistently regardless of the path. The commutativity encodes nothing more than the multiplicativity of degrees in towers.

Why this matters here: This diagram consolidates the x^3-2 example: it shows at a glance the three degree-3 subfields (generated by the three roots), the unique degree-2 subfield $\mathbb{Q}(\zeta_3)$, and how they all sit inside the degree-6 splitting field. It gives intuition for the Galois group S_3 acting on these subfields.

Concrete example: The diagram itself is the example: for $f(x)=x^3-2$ over $\mathbb{Q}$, the three roots $\sqrt[3]{2}$, $\zeta_3\sqrt[3]{2}$, $\zeta_3^2\sqrt[3]{2}$ generate three distinct but $\mathbb{Q}$-isomorphic cubic subfields, united only inside K.

Common pitfall: The middle-row fields $\mathbb{Q}(\sqrt[3]{2})$, $\mathbb{Q}(\zeta_3\sqrt[3]{2})$, $\mathbb{Q}(\zeta_3^2\sqrt[3]{2})$ are pairwise distinct as subsets of $\mathbb{C}$ (one is real, two are not), but they are all isomorphic as abstract fields over $\mathbb{Q}$. Do not read the lattice as saying they are equal or that the edges between them have degree 1.

Takeaway: The point of this diagram is that the splitting field of x^3-2 sits in a lattice whose left side passes through the real root and whose right side passes through the primitive cube root of unity, with the total degree 6 read off from any directed path up.

Worked Example 13.4.6 (Splitting field of x^4-2 over $\mathbb{Q}$)**.** Determine K and $[K:\mathbb{Q}]$ for $f(x)=x^4-2$.

Recognition. Eisenstein at 2 gives irreducibility. The real fourth root gives a degree-4 subextension; the non-real roots are produced by multiplying by i, so we expect to adjoin i as well.

Solution. The roots are $\pm\sqrt[4]{2},\ \pm i\sqrt[4]{2}$, so $K=\mathbb{Q}(\sqrt[4]{2},\,i)$. We have $[\mathbb{Q}(\sqrt[4]{2}):\mathbb{Q}]=4$, and i satisfies x^2+1, irreducible over $\mathbb{Q}(\sqrt[4]{2})\subset\mathbb{R}$. Hence

$$[K:\mathbb{Q}]=[K:\mathbb{Q}(\sqrt[4]{2})]\,[\mathbb{Q}(\sqrt[4]{2}):\mathbb{Q}]=2\cdot 4=8.$$

Sanity check. $8\le 24=4!$; the degree is not the full $4!$ because the four roots satisfy the relation $(\sqrt[4]{2})(i\sqrt[4]{2})/(\sqrt[4]{2})^2=i$, cutting the symmetry down.

Worked Example 13.4.7 (Splitting field of $(x^2-2)(x^2-3)$ over $\mathbb{Q}$)**.** Find K and $[K:\mathbb{Q}]$ for $f(x) = (x^2-2)(x^2-3)$.

Recognition. A product splits exactly when each factor splits; the splitting field is generated by the union of the root sets.

Solution. The roots are $\pm\sqrt{2}, \pm\sqrt{3}$, so $K = \mathbb{Q}(\sqrt{2},\sqrt{3})$. Since $\sqrt{3} \notin \mathbb{Q}(\sqrt{2})$ (else $\sqrt{3} = a + b\sqrt{2}$ leads to a contradiction on comparing rational parts), $x^2 - 3$ stays irreducible over $\mathbb{Q}(\sqrt{2})$, giving

$$[K:\mathbb{Q}] = [K:\mathbb{Q}(\sqrt{2})]\,[\mathbb{Q}(\sqrt{2}):\mathbb{Q}] = 2 \cdot 2 = 4.$$

Sanity check. The biquadratic field $\mathbb{Q}(\sqrt{2},\sqrt{3})$ has the four automorphisms $\sqrt{2} \mapsto \pm\sqrt{2}$, $\sqrt{3} \mapsto \pm\sqrt{3}$, matching $[K:\mathbb{Q}] = 4$.

Worked Example 13.4.8 (A reducible polynomial: x^4-1 over $\mathbb{Q}$)**.** Compute the splitting field of $f(x) = x^4-1$ over $\mathbb{Q}$.

Recognition. f factors over $\mathbb{Q}$ as $(x-1)(x+1)(x^2+1)$; only the last factor needs a genuine extension.

Solution. The roots are $1, -1, i, -i$. The rational roots contribute nothing new, and $\mathbb{Q}(i)$ already contains $-i$. Hence

$$K = \mathbb{Q}(i), \qquad [K:\mathbb{Q}] = \deg(x^2+1) = 2.$$

Sanity check. The naive bound $4! = 24$ is enormous compared with the actual degree 2; the bound is far from sharp precisely because f is highly reducible over $\mathbb{Q}$.

Worked Example 13.4.9 (Splitting field over $\mathbb{F}_p$: $x^p - x$)**.** Show that the splitting field of $f(x) = x^p - x$ over $\mathbb{F}_p$ is $\mathbb{F}_p$ itself.

Recognition. Fermat's little theorem says every element of $\mathbb{F}_p$ is a root; a degree-p polynomial has at most p roots.

Solution. For each $a \in \mathbb{F}_p$, $a^p = a$, so $f(a) = 0$. The p distinct elements of $\mathbb{F}_p$ are thus all p roots, giving

$$x^p - x = \prod_{a \in \mathbb{F}_p} (x - a) \quad \text{in } \mathbb{F}_p[x].$$

So f already splits in $\mathbb{F}_p$ and $K = \mathbb{F}_p$, $[K:\mathbb{F}_p] = 1$. *Sanity check.* This is the prototype showing $\mathbb{F}_q$ is the splitting field of $x^q - x$; here $q = p$ and the splitting field is the prime field.

Extending isomorphisms; uniqueness

The key to uniqueness is that a splitting field is determined by its construction up to isomorphism, no matter which root we adjoin first. The mechanism is the extension of a base-field isomorphism across the tower.

Theorem 13.4.10 (extending isomorphisms to splitting fields)**.** *Let $\varphi : F \to F'$ be an isomorphism of fields. Let $f(x) \in F[x]$ and let $f'(x) = \varphi(f)(x) \in F'[x]$ be the polynomial obtained by applying φ to the coefficients of f. If K is a splitting field of f over F and K' is a splitting field of f' over F', then φ extends to an isomorphism $\sigma : K \to K'$, i.e. $\sigma|_F = \varphi$.*

$$\begin{array}{ccc} K & \overset{\sigma}{\underset{\cong}{\dashrightarrow}} & K' \\ \uparrow & & \uparrow \\ F & \xrightarrow[\cong]{\varphi} & F' \end{array}$$

Diagram explanation. Objects: Four fields in a square. Bottom-left: F, the base field. Bottom-right: F', another field isomorphic to F. Top-left: K, a splitting field of $f(x) \in F[x]$. Top-right: K', a splitting field of $f'(x) = \varphi(f)(x) \in F'[x]$.

Arrows: The bottom horizontal arrow $\varphi : F \xrightarrow{\cong} F'$ is a given isomorphism between base fields. The two vertical arrows $F \hookrightarrow K$ and $F' \hookrightarrow K'$ are the canonical field inclusions (splitting fields contain their base).

The top horizontal dashed arrow $\sigma : K \xrightarrow{\cong} K'$ is the extension of φ whose existence is the content of the theorem; it is dashed to indicate it is what we are constructing.

What commutes: The square commutes: $\sigma \circ \iota = \iota' \circ \varphi$, where $\iota : F \hookrightarrow K$ and $\iota' : F' \hookrightarrow K'$ are the inclusions. In plain terms, $\sigma|_F = \varphi$: restricting the extension σ to the base field recovers φ.

Why it commutes: The inductive construction of σ is built to extend φ at each step. At the base case $[K : F] = 1$, $\sigma = \varphi$. In the inductive step, we extend φ to $\varphi_1 : F(\alpha) \to F'(\alpha')$, and the induction hypothesis extends φ_1 to σ; at each step the restriction to the ground field is preserved. The commutativity is thus the induction hypothesis carried through.

Why this matters here: This square is the conceptual core of splitting field uniqueness. Setting $F' = F$, $\varphi = \mathrm{id}_F$ gives the corollary that any two splitting fields of f over F are F-isomorphic; the dashed σ is that isomorphism.

Concrete example: Take $F = \mathbb{Q}$, $\varphi = \mathrm{id}_{\mathbb{Q}}$, $f = x^3 - 2$. The two splitting fields $K_A = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ and $K_B = \mathbb{Q}(\sqrt[3]{2}e^{2\pi i/3}, \zeta_3)$ (constructed by a different root ordering) are connected by a σ that permutes roots and fixes $\mathbb{Q}$.

Common pitfall: The dashed arrow does not mean σ is not a legitimate isomorphism; it means σ is the arrow being *asserted to exist* by the theorem. Once the theorem is proved, σ is as concrete as φ.

Takeaway: The point of this diagram is that a base-field isomorphism φ always lifts to an isomorphism of splitting fields, so the splitting field construction is functorial up to isomorphism.

Proof. Induct on $[K : F]$. If $[K : F] = 1$ then f splits already in F, so f' splits in F', $K' = F'$, and $\sigma = \varphi$ works. Otherwise pick an irreducible factor $p(x)$ of f in $F[x]$ of degree > 1, with a root $\alpha \in K$, and let $p'(x) = \varphi(p)(x)$, an irreducible factor of f' with a root $\alpha' \in K'$. The isomorphism φ induces

$$F(\alpha) \;\cong\; F[x]/(p(x)) \;\xrightarrow{\widetilde{\varphi}}\; F'[x]/(p'(x)) \;\cong\; F'(\alpha'), \qquad \alpha \mapsto \alpha',$$

an isomorphism $\varphi_1 : F(\alpha) \to F'(\alpha')$ restricting to φ on F. Now K is a splitting field of f over $F(\alpha)$ and K' a splitting field of f' over $F'(\alpha')$, with $[K : F(\alpha)] < [K : F]$. By induction φ_1 extends to $\sigma : K \to K'$, completing the step. □

The inner square that does the work — propagating φ across the first adjunction via the polynomial-ring quotients — is the following.

$$\begin{array}{ccc} F[x]/(p(x)) & \xrightarrow[\cong]{\widetilde{\varphi}} & F'[x]/(p'(x)) \\ \cong\downarrow & & \downarrow\cong \\ F(\alpha) & \xrightarrow[\cong]{\varphi_1} & F'(\alpha') \end{array}$$

Diagram explanation. Objects: Four rings/fields in a commutative square. Top-left: $F[x]/(p(x))$, a field (since p is irreducible over F), the algebraic model of $F(\alpha)$. Top-right: $F'[x]/(p'(x))$, similarly a field (since φ carries irreducibles to irreducibles and p' is irreducible over F'). Bottom-left: $F(\alpha)$, the subfield of K generated by F and the root α. Bottom-right: $F'(\alpha')$, the corresponding subfield of K'.

Arrows: The top horizontal arrow $\widetilde{\varphi} : F[x]/(p(x)) \xrightarrow{\cong} F'[x]/(p'(x))$ is the map induced by φ on coefficients: $f(x) + (p(x)) \mapsto \varphi(f)(x) + (p'(x))$. The left vertical arrow $F[x]/(p(x)) \xrightarrow{\cong} F(\alpha)$ evaluates $x \mapsto \alpha$. The right vertical arrow $F'[x]/(p'(x)) \xrightarrow{\cong} F'(\alpha')$ evaluates $x \mapsto \alpha'$. The bottom arrow $\varphi_1 : F(\alpha) \xrightarrow{\cong} F'(\alpha')$ is defined as the composite, sending $\alpha \mapsto \alpha'$ and restricting to φ on F.

What commutes: The square commutes: $\varphi_1 \circ \mathrm{ev}_\alpha = \mathrm{ev}_{\alpha'} \circ \widetilde{\varphi}$, where ev denotes the evaluation isomorphisms. Concretely: $\varphi_1(f(\alpha)) = \varphi(f)(\alpha')$ for any $f(x) \in F[x]$.

Why it commutes: Well-definedness of $\widetilde{\varphi}$ on cosets: if $f(x) \equiv g(x) \pmod{p(x)}$, then $\varphi(f)(x) \equiv \varphi(g)(x) \pmod{p'(x)}$, because φ is a ring isomorphism sending p to p'. The commutativity then follows by chasing: a coset $f + (p)$ goes right to $\varphi(f) + (p')$ and then down to $\varphi(f)(\alpha')$; going down first gives $f(\alpha)$, then $\varphi_1(f(\alpha))$; these agree because φ_1 is defined to act on coefficients via φ.

Why this matters here: This inner square is the inductive engine of the extension-of-isomorphisms theorem: it shows concretely how φ transfers across a single adjunction, promoting the base isomorphism to $\varphi_1 : F(\alpha) \to F'(\alpha')$ on which the induction can continue.

Concrete example: Take $F = \mathbb{Q}$, $\varphi = \mathrm{id}_{\mathbb{Q}}$, $p(x) = x^2 - 2$, $\alpha = \sqrt{2}$, $\alpha' = -\sqrt{2}$, $p'(x) = x^2 - 2$. Then $\widetilde{\varphi}$ is the identity on $\mathbb{Q}[x]/(x^2 - 2)$, but the two vertical isomorphisms send x to $\sqrt{2}$ and $-\sqrt{2}$ respectively, giving $\varphi_1 : \sqrt{2} \mapsto -\sqrt{2}$, the nontrivial automorphism of $\mathbb{Q}(\sqrt{2})$.

Common pitfall: The map $\widetilde{\varphi}$ on the top is induced by φ on coefficients and is NOT the same as evaluation at α; the vertical arrows do the evaluation. Confusing them makes the well-definedness check impossible to see.

Takeaway: The point of this diagram is that an isomorphism of base fields φ induces a canonical isomorphism of the adjoined-root fields via coefficient transport, reducing the inductive step to a one-level square.

Corollary 13.4.11 (uniqueness of splitting fields)**.** *Any two splitting fields of $f(x) \in F[x]$ over F are isomorphic by an isomorphism fixing F pointwise (an F-isomorphism).*

Proof. Apply the theorem with $F' = F$ and $\varphi = \mathrm{id}_F$. Then $f' = f$, and any two splitting fields K, K' satisfy $\sigma : K \to K'$ with $\sigma|_F = \mathrm{id}_F$. □

Worked Example 13.4.12 (Counting extensions of an isomorphism)**.** Let $F = \mathbb{Q}$ and $f(x) = x^3 - 2$ with splitting field $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$. Take $\varphi = \mathrm{id}_{\mathbb{Q}}$. How many isomorphisms $\sigma : K \to K$ extend φ?

Recognition. The extension theorem with $F' = F$ produces F-automorphisms; the number of choices at each adjunction is the number of roots of the relevant irreducible polynomial in K.

Solution. Adjoining a root of $x^3 - 2$ admits 3 choices ($\sqrt[3]{2}, \zeta_3\sqrt[3]{2}, \zeta_3^2\sqrt[3]{2}$); adjoining a root of $x^2 + x + 1$ over that field admits 2 choices (ζ_3, ζ_3^2). So there are $3 \cdot 2 = 6$ extensions. Since $[K : \mathbb{Q}] = 6$, every F-embedding is an automorphism, and $|\mathrm{Aut}(K/\mathbb{Q})| = 6$. *Sanity check.* The count $6 = [K : \mathbb{Q}]$ matches the fact that $K/\mathbb{Q}$ is a Galois extension with $\mathrm{Aut}(K/\mathbb{Q}) \cong S_3$.

Worked Example 13.4.13 (Two constructions of the same splitting field)**.** Verify that adjoining the roots of $x^2 - 2$ in either order yields F-isomorphic splitting fields over $\mathbb{Q}$.

Recognition. The uniqueness corollary guarantees an F-isomorphism between any two splitting fields; here we exhibit it explicitly.

Solution. Construction A: $K_A = \mathbb{Q}[x]/(x^2 - 2)$ with class $\overline{x} =: \beta$, $\beta^2 = 2$. Construction B: $K_B = \mathbb{Q}(\sqrt{2}) \subset \mathbb{R}$. The map $\beta \mapsto \sqrt{2}$ defines an F-isomorphism $K_A \to K_B$ fixing $\mathbb{Q}$, since both are 2-dimensional with the single relation $t^2 = 2$. *Sanity check.* The other choice $\beta \mapsto -\sqrt{2}$ is the second F-isomorphism, corresponding to the nontrivial automorphism of $\mathbb{Q}(\sqrt{2})$; there are exactly $[K : \mathbb{Q}] = 2$ of them.

Worked Example 13.4.14 (Extending a nontrivial automorphism of the base field)**.** Let $\varphi : \mathbb{Q}(\sqrt{2}) \to \mathbb{Q}(\sqrt{2})$ be the nontrivial automorphism $\sqrt{2} \mapsto -\sqrt{2}$. Extend it across the splitting field of $f(x) = x^2 - \sqrt{2}$.

Recognition. Here $f' = \varphi(f) = x^2 + \sqrt{2}$; the extension theorem gives an isomorphism of the two splitting fields.

Solution. A root of f is $\alpha = 2^{1/4}$ with $\alpha^2 = \sqrt{2}$; a root of f' is α' with $(\alpha')^2 = -\sqrt{2}$, e.g. $\alpha' = i\,2^{1/4}$. The extension σ sends $2^{1/4} \mapsto i\,2^{1/4}$ and restricts to φ on $\mathbb{Q}(\sqrt{2})$. Indeed $\sigma(\alpha)^2 = \sigma(\alpha^2) = \varphi(\sqrt{2}) = -\sqrt{2} = (\alpha')^2$, consistent. *Sanity check.* The splitting field of f is $K = \mathbb{Q}(\sqrt{2})(2^{1/4}) = \mathbb{Q}(2^{1/4})$, a real degree-4 field, while that of f' is $K' = \mathbb{Q}(\sqrt{2}, i\,2^{1/4})$, also of degree 4; the map σ is the promised $\cong$ between them. Adjoining *all* four roots of $x^4 - 2$, i.e. the roots of both $x^2 - \sqrt{2}$ and $x^2 + \sqrt{2}$, gives the larger degree-8 field $\mathbb{Q}(2^{1/4}, i)$ of the earlier $x^4 - 2$ example.

Worked Example 13.4.15 (Uniqueness over a finite field)**.** Show that any two splitting fields of $x^4 - x$ over $\mathbb{F}_2$ are isomorphic, and identify the field.

Recognition. By the uniqueness corollary the splitting field is unique up to $\mathbb{F}_2$-isomorphism; we identify it concretely.

Solution. Over $\mathbb{F}_2$, $x^4 - x = x(x - 1)(x^2 + x + 1)$. The quadratic $x^2 + x + 1$ is irreducible over $\mathbb{F}_2$, so its roots lie in $\mathbb{F}_2[x]/(x^2 + x + 1) = \mathbb{F}_4$. Thus $K = \mathbb{F}_4$, the unique field of 4 elements, and $[K : \mathbb{F}_2] = 2$. *Sanity check.* $\mathbb{F}_4 = \{\, 0, 1, \omega, \omega^2 \,\}$ where $\omega^2 + \omega + 1 = 0$; this is exactly the splitting field of $x^4 - x$, and its uniqueness is the uniqueness of $\mathbb{F}_4$.

Algebraic closures

Definition 13.4.16 (algebraically closed; algebraic closure)**.** A field K is *algebraically closed* if every nonconstant polynomial $f(x) \in K[x]$ has a root in K (equivalently, splits completely in $K[x]$). A field $\overline{F}$ is an *algebraic closure* of F if $\overline{F}$ is algebraic over F and $\overline{F}$ is algebraically closed.

Remark 13.4.2. Equivalently, $\overline{F}$ is a splitting field over F of the set of *all* polynomials in $F[x]$. The condition that $\overline{F}$ be algebraic over F keeps it minimal: $\overline{F}$ adds only roots of F-polynomials, nothing transcendental.

Lemma 13.4.17. *If $\overline{F}$ is algebraic over F and every polynomial in $F[x]$ splits in $\overline{F}$, then $\overline{F}$ is algebraically closed (hence an algebraic closure of F).*

Proof. Let $g(x) \in \overline{F}[x]$ be nonconstant with a root β in some extension of $\overline{F}$. Then β is algebraic over $\overline{F}$, which is algebraic over F; by transitivity of algebraicity β is algebraic over F. Its minimal polynomial $m_{\beta,F}(x) \in F[x]$ splits in $\overline{F}$ by hypothesis, so $\beta \in \overline{F}$. Thus every such g has a root in $\overline{F}$, which is therefore algebraically closed. □

Theorem 13.4.18 (existence of an algebraic closure)**.** *Every field F has an algebraic closure $\overline{F}$, and $\overline{F}$ is unique up to F-isomorphism.*

Proof sketch. Existence (Kronecker + Zorn). One builds a field in which every nonconstant $f \in F[x]$ acquires a root. Introduce an indeterminate x_f for each such f and form the polynomial ring $R = F[\,x_f : f\,]$. The ideal I generated by all $f(x_f)$ is proper (a finite subset of the $f(x_f)$ would otherwise have no common root, contradicting the existence of splitting fields for the corresponding finite product). By Zorn's lemma I lies in a maximal ideal $\mathfrak{m}$; then $F_1 = R/\mathfrak{m}$ is a field over F in which every $f \in F[x]$ has a root. Iterating gives a tower $F \subseteq F_1 \subseteq F_2 \subseteq \cdots$ whose union $\overline{F}$ is algebraically closed; the subfield of elements algebraic over F is an algebraic closure. *Uniqueness.* Any two algebraic closures are splitting fields over F of the same (infinite) set of polynomials; the extension-of-isomorphisms theorem, applied through a Zorn's-lemma argument over the partially ordered set of partial F-isomorphisms, yields an F-isomorphism between them. □

Worked Example 13.4.19 ($\mathbb{C}$ is an algebraic closure of $\mathbb{R}$ but not of $\mathbb{Q}$)**.** Decide whether $\mathbb{C}$ is an algebraic closure of $\mathbb{R}$ and of $\mathbb{Q}$.

Recognition. An algebraic closure must be both algebraically closed and *algebraic* over the base field.

Solution. $\mathbb{C}$ is algebraically closed (Fundamental Theorem of Algebra), and $[\mathbb{C} : \mathbb{R}] = 2$ is finite, so $\mathbb{C}$ is algebraic over $\mathbb{R}$: thus $\overline{\mathbb{R}} = \mathbb{C}$. Over $\mathbb{Q}$, however, $\mathbb{C}$ contains transcendental numbers such as π, so $\mathbb{C}$ is *not* algebraic over $\mathbb{Q}$ and is not $\overline{\mathbb{Q}}$. *Sanity check.* $\overline{\mathbb{Q}}$ is the field of algebraic numbers, a countable proper subfield of $\mathbb{C}$, whereas $\mathbb{C}$ is uncountable.

Worked Example 13.4.20 ($\overline{\mathbb{Q}}$ is infinite-dimensional over $\mathbb{Q}$)**.** Show that $[\overline{\mathbb{Q}} : \mathbb{Q}] = \infty$.

Recognition. If the closure were finite over $\mathbb{Q}$ it could not contain roots of arbitrarily high-degree irreducibles.

Solution. For each n, $x^n - 2$ is irreducible over $\mathbb{Q}$ (Eisenstein), so $\overline{\mathbb{Q}}$ contains $\sqrt[n]{2}$ with $[\mathbb{Q}(\sqrt[n]{2}) : \mathbb{Q}] = n$. Hence $[\overline{\mathbb{Q}} : \mathbb{Q}] \geq n$ for every n, forcing $[\overline{\mathbb{Q}} : \mathbb{Q}] = \infty$. *Sanity check.* Consistent with $\overline{\mathbb{Q}}$ being algebraic yet of infinite degree; algebraicity does not bound the degree.

Worked Example 13.4.21 (The algebraic closure of $\mathbb{F}_p$)**.** Describe $\overline{\mathbb{F}_p}$ in terms of the finite fields $\mathbb{F}_{p^n}$.

Recognition. Each $\mathbb{F}_{p^n}$ is the splitting field of $x^{p^n} - x$ over $\mathbb{F}_p$; the closure must contain all of them.

Solution. Since $\mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n}$ iff $m \mid n$, the finite fields form a directed system, and

$$\overline{\mathbb{F}_p} = \bigcup_{n \geq 1} \mathbb{F}_{p^n}.$$

This union is algebraic over $\mathbb{F}_p$ (each element lies in some $\mathbb{F}_{p^n}$) and algebraically closed (any polynomial over it has coefficients in some $\mathbb{F}_{p^n}$, hence splits in a larger $\mathbb{F}_{p^m}$ inside the union). *Sanity check.* $\overline{\mathbb{F}_p}$ is countable and has no finite degree over $\mathbb{F}_p$, mirroring $\overline{\mathbb{Q}}$ over $\mathbb{Q}$.

Worked Example 13.4.22 (No finite field is algebraically closed)**.** Prove that a finite field $\mathbb{F}_q$ is never algebraically closed.

Recognition. An algebraically closed field must contain a root of every polynomial; we manufacture one with no root.

Solution. List the elements $\mathbb{F}_q = \{ a_1, \dots, a_q \}$ and set

$$g(x) = 1 + \prod_{i=1}^{q} (x - a_i).$$

Then $g(a_i) = 1 \neq 0$ for every i, so g has no root in $\mathbb{F}_q$. Hence $\mathbb{F}_q$ is not algebraically closed. *Sanity check.* This is why $\overline{\mathbb{F}_p}$ must be infinite — it is the increasing union of all the finite $\mathbb{F}_{p^n}$.

Worked Example 13.4.23 (Embedding into the closure via the extension theorem)**.** Show that any algebraic extension E/F embeds into a fixed algebraic closure $\overline{F}$ over F.

Recognition. This is the extension-of-isomorphisms theorem applied to $\varphi = \mathrm{id}_F$ together with the algebraic-closedness of $\overline{F}$.

Solution. Each $\alpha \in E$ is algebraic over F, so $m_{\alpha,F}(x)$ splits in $\overline{F}$. Extending id_F root-by-root (Zorn over partial embeddings) gives an F-embedding $\iota : E \hookrightarrow \overline{F}$. *Sanity check.* Taking for E a second algebraic closure $\overline{F}'$ of F gives an F-embedding $\overline{F}' \hookrightarrow \overline{F}$; it is onto, since its image is algebraically closed and $\overline{F}$ is algebraic over it. This recovers the uniqueness of the algebraic closure up to F-isomorphism.

The Frobenius endomorphism organizes the finite-field tower whose union is $\overline{\mathbb{F}_p}$. On each $\mathbb{F}_{p^n}$ it is the map $x \mapsto x^p$, an $\mathbb{F}_p$-automorphism whose fixed field is the prime field $\mathbb{F}_p$.

$$\begin{array}{ccc} \mathbb{F}_{p^n} & \xrightarrow{x \mapsto x^p} & \mathbb{F}_{p^n} \\ \downarrow & & \downarrow \\ \overline{\mathbb{F}_p} & \xrightarrow{x \mapsto x^p} & \overline{\mathbb{F}_p} \end{array}$$

Diagram explanation. Objects: Four fields. Top-left and top-right are both $\mathbb{F}_{p^n}$ (the unique field of p^n elements); they appear as separate copies to indicate the domain and codomain of the Frobenius. Bottom-left and bottom-right are both $\overline{\mathbb{F}_p}$ (the algebraic closure), again as domain and codomain.

Arrows: The top horizontal arrow is the Frobenius endomorphism $\phi_n : \mathbb{F}_{p^n} \to \mathbb{F}_{p^n}$, $x \mapsto x^p$, a field automorphism of $\mathbb{F}_{p^n}$ (since $\mathbb{F}_{p^n}$ is finite). The bottom horizontal arrow is the Frobenius automorphism $\phi : \overline{\mathbb{F}_p} \to \overline{\mathbb{F}_p}$, $x \mapsto x^p$, which is a well-defined automorphism of the algebraic closure fixing $\mathbb{F}_p$. The two vertical arrows are the canonical inclusions $\mathbb{F}_{p^n} \hookrightarrow \overline{\mathbb{F}_p}$, which exist because the algebraic closure contains every finite field $\mathbb{F}_{p^n}$ as a subfield.

What commutes: The square commutes: $\phi \circ \iota = \iota \circ \phi_n$, where $\iota : \mathbb{F}_{p^n} \hookrightarrow \overline{\mathbb{F}_p}$ is the inclusion. Concretely: for $x \in \mathbb{F}_{p^n}$, (x^p) computed in $\mathbb{F}_{p^n}$ equals (x^p) computed in $\overline{\mathbb{F}_p}$ after including.

Why it commutes: The Frobenius $x \mapsto x^p$ is defined by the same formula in both $\mathbb{F}_{p^n}$ and $\overline{\mathbb{F}_p}$; the inclusion ι is a ring homomorphism, so $\iota(x^p) = \iota(x)^p$. The commutativity is therefore the naturality of the Frobenius map with respect to field inclusions: the formula is the same formula, and inclusions commute with taking p-th powers in characteristic p.

Why this matters here: This square records that the Frobenius on $\overline{\mathbb{F}_p}$ restricts correctly to the Frobenius on each layer $\mathbb{F}_{p^n}$. It is the naturality statement organizing the tower $\mathbb{F}_p \subset \mathbb{F}_{p^{2!}} \subset \mathbb{F}_{p^{3!}} \subset \cdots$ whose union is $\overline{\mathbb{F}_p}$, and it justifies using the single symbol ϕ for the global Frobenius.

Concrete example: For $p = 2$, $n = 2$: $\mathbb{F}_4 = \{0, 1, \omega, \omega^2\}$ with $\omega^2 + \omega + 1 = 0$. The Frobenius on $\mathbb{F}_4$ squares: $\omega \mapsto \omega^2$, $\omega^2 \mapsto \omega^4 = \omega$. Inside $\overline{\mathbb{F}_2}$, squaring does the same thing, and the inclusion sees ω as an element of $\overline{\mathbb{F}_2}$: $(\omega)^2 = \omega^2$ whether we work in $\mathbb{F}_4$ or $\overline{\mathbb{F}_2}$.

Common pitfall: The Frobenius on $\overline{\mathbb{F}_p}$ is an automorphism of infinite order; on $\mathbb{F}_{p^n}$ it has order exactly n (since $x \mapsto x^{p^n} = x$ for all $x \in \mathbb{F}_{p^n}$ by Fermat). Do not conflate the global Frobenius with the finite-order restriction.

Takeaway: The point of this diagram is that the Frobenius endomorphism is natural with respect to field inclusions, so the single map $x \mapsto x^p$ on $\overline{\mathbb{F}_p}$ simultaneously restricts to the automorphism of each $\mathbb{F}_{p^n}$ that generates $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)$.

Cyclotomic splitting fields

The splitting field of $x^n - 1$ over $\mathbb{Q}$ is the *cyclotomic field* $\mathbb{Q}(\zeta_n)$, where $\zeta_n = e^{2\pi i/n}$ is a primitive n-th root of unity. Its degree is $\varphi(n)$, the degree of the cyclotomic polynomial $\Phi_n(x) = \prod_{\gcd(k,n)=1}(x - \zeta_n^k)$, the minimal polynomial of ζ_n over $\mathbb{Q}$.

Worked Example 13.4.24 (Splitting field of $x^n - 1$ over $\mathbb{Q}$)**.** Identify the splitting field of $f(x) = x^n - 1$ over $\mathbb{Q}$ and its degree.

Recognition. The roots are the n-th roots of unity, all powers of a single primitive root ζ_n, so one adjunction suffices.

Solution. The roots are $1, \zeta_n, \zeta_n^2, \ldots, \zeta_n^{n-1}$, all lying in $\mathbb{Q}(\zeta_n)$. Thus $K = \mathbb{Q}(\zeta_n)$ and

$$[K : \mathbb{Q}] = \deg \Phi_n(x) = \varphi(n).$$

Sanity check. For $n = 4$, $\varphi(4) = 2$ and $K = \mathbb{Q}(i)$, recovering the earlier $x^4 - 1$ example; for $n = 3$, $\varphi(3) = 2$ and $K = \mathbb{Q}(\zeta_3)$.

Worked Example 13.4.25 (The degree-divisor lattice for $\mathbb{Q}(\zeta_{12})$)**.** Compute $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}]$ and locate the subfields $\mathbb{Q}(\zeta_d)$ for $d \mid 12$.

Recognition. Subfields of $\mathbb{Q}(\zeta_n)$ include $\mathbb{Q}(\zeta_d)$ for each $d \mid n$, with $\mathbb{Q}(\zeta_d) \subseteq \mathbb{Q}(\zeta_n)$, mirroring the divisor lattice.

Solution. $\varphi(12) = 4$, so $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}] = 4$. The relevant divisors give $\mathbb{Q}(\zeta_1) = \mathbb{Q}(\zeta_2) = \mathbb{Q}$, $\mathbb{Q}(\zeta_3)$ of degree 2, $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$ of degree 2, and $\mathbb{Q}(\zeta_{12})$ of degree 4. *Sanity check.* $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(\zeta_3, \zeta_4) = \mathbb{Q}(\sqrt{-3}, i)$, a biquadratic field of degree $4 = 2 \cdot 2$, consistent with $\varphi(12) = 4$.

The containments among cyclotomic fields follow the divisibility lattice of the indices. Here is the portion for $\mathbb{Q}(\zeta_{12})$, with each edge labelled by its relative degree.

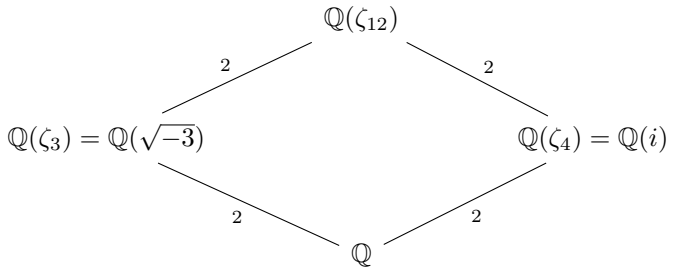

Diagram explanation. Objects: Four fields in a diamond. At the top: the cyclotomic field $\mathbb{Q}(\zeta_{12})$ of degree $\varphi(12) = 4$ over $\mathbb{Q}$, the splitting field of $x^{12} - 1$. In the middle: $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, a degree-2 subfield generated by a primitive cube root of unity (equivalently by $\sqrt{-3}$); and $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$, a degree-2 subfield generated by a primitive 4th root of unity. At the bottom: $\mathbb{Q}$.

Arrows: Each dash arrow is a field inclusion; the edge labels are the relative degrees. From $\mathbb{Q}$: $[\mathbb{Q}(\zeta_3) : \mathbb{Q}] = \varphi(3) = 2$ and $[\mathbb{Q}(\zeta_4) : \mathbb{Q}] = \varphi(4) = 2$. From the middle fields to the top: $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}(\zeta_3)] = 2$ and $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}(\zeta_4)] = 2$.

What commutes: All paths from $\mathbb{Q}$ to $\mathbb{Q}(\zeta_{12})$ give total degree 4: $2 \cdot 2 = 4$ via either branch. The tower law multiplies correctly along each directed path.

Why it commutes: $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(\zeta_3, \zeta_4)$ is the compositum. Since $\mathbb{Q}(\zeta_3) \cap \mathbb{Q}(\zeta_4) = \mathbb{Q}$ (one field is $\mathbb{Q}(\sqrt{-3})$, the other $\mathbb{Q}(i)$, with different discriminants), the degrees multiply: $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}] = [\mathbb{Q}(\zeta_3) : \mathbb{Q}] \cdot [\mathbb{Q}(\zeta_4) : \mathbb{Q}] = 4$. Each upper edge has degree 2 by the tower law, since the total degree is 4 and each lower edge is 2.

Why this matters here: This diamond illustrates the compositum structure of $\mathbb{Q}(\zeta_{12})$: the cyclotomic field for a composite index is built from the cyclotomic fields for its prime-power divisors. It also previews the structure theorem $\mathrm{Gal}(\mathbb{Q}(\zeta_{12})/\mathbb{Q}) \cong (\mathbb{Z}/12\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, whose subgroups correspond to the intermediate fields.

Concrete example: The diagram itself is the running example: the biquadratic field $\mathbb{Q}(\sqrt{-3}, i) = \mathbb{Q}(\zeta_{12})$ with two of its three quadratic subfields; the third, $\mathbb{Q}(\sqrt{3})$ (note $\sqrt{3} = -i\sqrt{-3}$), is not of the form $\mathbb{Q}(\zeta_d)$ and is not drawn.

Common pitfall: The label "$\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$" may suggest these are obviously equal, but the equality requires the identity $\zeta_3 = (-1 + \sqrt{-3})/2$. Do not assume that containments among cyclotomic fields are obvious without verifying the explicit root expressions.

Takeaway: The point of this diagram is that $d \mid e$ gives $\mathbb{Q}(\zeta_d) \subseteq \mathbb{Q}(\zeta_e)$ with relative degree $\varphi(e)/\varphi(d)$. The full subfield lattice of a cyclotomic field $\mathbb{Q}(\zeta_n)$ is in general larger than these cyclotomic subfields (here it also contains $\mathbb{Q}(\sqrt{3})$): it corresponds to the subgroup lattice of $(\mathbb{Z}/n\mathbb{Z})^\times$, not to the divisor lattice of n.

Worked Example 13.4.26 (Splitting field of $x^6 - 1$ over $\mathbb{F}_5$)**.** Find the splitting field of $x^6 - 1$ over $\mathbb{F}_5$.

Recognition. Over $\mathbb{F}_p$ the splitting field of $x^n - 1$ is the smallest $\mathbb{F}_{p^d}$ whose multiplicative group has order divisible by n (for $\gcd(n, p) = 1$): the least d with $n \mid p^d - 1$.

Solution. Here $p = 5$, $n = 6$, $\gcd(6, 5) = 1$. We need the least d with $6 \mid 5^d - 1$. Since $5^1 - 1 = 4$, $5^2 - 1 = 24 = 6 \cdot 4$, we get $d = 2$. Thus the splitting field is $\mathbb{F}_{25}$ and $[\mathbb{F}_{25} : \mathbb{F}_5] = 2$. *Sanity check.* $\mathbb{F}_{25}^\times$ is cyclic of order 24, which is divisible by 6, so it contains all 6 sixth roots of unity — and 24 is the smallest such order among $4, 24, \ldots$.

Worked Example 13.4.27 (Constructibility via splitting-field degrees)**.** Use the degree of a splitting field to decide whether the regular 7-gon is constructible by straightedge and compass.

Recognition. A point is constructible only if it lies in a tower of quadratic extensions, so its degree over $\mathbb{Q}$ must be a power of 2; the relevant degree here is $[\mathbb{Q}(\zeta_7) : \mathbb{Q}] = \varphi(7)$.

Solution. $\varphi(7) = 6$, so $[\mathbb{Q}(\zeta_7) : \mathbb{Q}] = 6$, which is not a power of 2. A constructible ζ_7 would force $6 \mid 2^k$, impossible. Hence the regular 7-gon is *not* constructible. *Sanity check.* By contrast $\varphi(17) = 16 = 2^4$, and indeed the regular 17-gon is constructible (Gauss), confirming the criterion that a regular n-gon is constructible iff $\varphi(n)$ is a power of 2.

Worked Example 13.4.28 ($\Phi_p(x)$ and the prime cyclotomic field)**.** For prime p, identify $\Phi_p(x)$ and the degree $[\mathbb{Q}(\zeta_p) : \mathbb{Q}]$.

Recognition. For prime p, $x^p - 1 = (x - 1)\Phi_p(x)$, and Φ_p is the minimal polynomial of ζ_p.

Solution. Dividing out the rational root gives

$$\Phi_p(x) = \frac{x^p - 1}{x - 1} = x^{p-1} + x^{p-2} + \cdots + x + 1,$$

irreducible over $\mathbb{Q}$ (Eisenstein after the substitution $x \mapsto x + 1$). Hence $[\mathbb{Q}(\zeta_p) : \mathbb{Q}] = \deg \Phi_p = p - 1 = \varphi(p)$. *Sanity check.* For $p = 5$, $\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$ and the degree is $4 = \varphi(5)$, matching the general formula $\varphi(p) = p - 1$.

The basic cyclotomic tower over $\mathbb{Q}$, the source of all the above, is the single adjunction below, with the evaluation map realizing $\mathbb{Q}(\zeta_n)$ as a quotient of $\mathbb{Q}[x]$ by Φ_n.

$$\mathbb{Q} \hookrightarrow \mathbb{Q}[x] \xrightarrow{x \mapsto \zeta_n} \mathbb{Q}[x]/(\Phi_n(x)) \;\cong\; \mathbb{Q}(\zeta_n)$$

Diagram explanation. Objects: Three objects in a horizontal chain. Left: $\mathbb{Q}$, the rational field, the base. Middle: $\mathbb{Q}[x]$, the polynomial ring over $\mathbb{Q}$, a PID whose elements are formal polynomials. Right: $\mathbb{Q}[x]/(\Phi_n(x))$, the quotient by the ideal generated by the n-th cyclotomic polynomial $\Phi_n(x)$, identified (via an isomorphism) with the cyclotomic field $\mathbb{Q}(\zeta_n)$; this field has degree $\varphi(n)$ over $\mathbb{Q}$.

Arrows: The first arrow $\mathbb{Q} \hookrightarrow \mathbb{Q}[x]$ is the canonical inclusion of $\mathbb{Q}$ into its polynomial ring (constants as degree-0 polynomials). The second arrow $\mathbb{Q}[x] \twoheadrightarrow \mathbb{Q}[x]/(\Phi_n(x))$ is the quotient epimorphism $f(x) \mapsto f(x) + (\Phi_n(x))$,

which sends x to the coset $x + (\Phi_n)$, corresponding to ζ_n under the isomorphism. The composite is the inclusion $\mathbb{Q} \hookrightarrow \mathbb{Q}(\zeta_n)$.

What commutes: The composite of the two arrows, restricted to $\mathbb{Q}$, equals the canonical inclusion $\mathbb{Q} \hookrightarrow \mathbb{Q}(\zeta_n)$: for any $q \in \mathbb{Q}$, $q \mapsto q \in \mathbb{Q}[x] \mapsto q + (\Phi_n) = q \in \mathbb{Q}(\zeta_n)$ (constants pass through unaltered).

Why it commutes: Well-definedness of the quotient map: two polynomials in the same coset mod (Φ_n) evaluate identically at ζ_n, because $\Phi_n(\zeta_n) = 0$ by definition. The quotient epimorphism is therefore the unique ring map $\mathbb{Q}[x] \to \mathbb{Q}(\zeta_n)$ sending $x \mapsto \zeta_n$, and it factors as shown. The isomorphism $\mathbb{Q}[x]/(\Phi_n) \cong \mathbb{Q}(\zeta_n)$ holds because Φ_n is irreducible over $\mathbb{Q}$ (by Eisenstein or direct proof), making (Φ_n) a maximal ideal.

Why this matters here: This chain is the cyclotomic analogue of the Kronecker construction: it gives an algebraic model for $\mathbb{Q}(\zeta_n)$ that is purely ring-theoretic (quotient of $\mathbb{Q}[x]$) and avoids any appeal to $\mathbb{C}$. It also shows that $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \deg \Phi_n = \varphi(n)$, the key degree formula for cyclotomic fields.

Concrete example: For $n = 3$: $\Phi_3(x) = x^2 + x + 1$, irreducible over $\mathbb{Q}$. The chain is $\mathbb{Q} \hookrightarrow \mathbb{Q}[x] \twoheadrightarrow \mathbb{Q}[x]/(x^2 + x + 1) \cong \mathbb{Q}(\zeta_3)$ with degree $2 = \varphi(3)$. The coset $x + (x^2 + x + 1)$ represents $\zeta_3 = e^{2\pi i/3}$.

Common pitfall: The map $\mathbb{Q}[x] \twoheadrightarrow \mathbb{Q}[x]/(\Phi_n(x))$ is surjective but NOT injective; the kernel is the ideal $(\Phi_n(x))$, which contains many nonzero polynomials (all multiples of Φ_n). Do not confuse the quotient map with the isomorphism between the quotient and $\mathbb{Q}(\zeta_n)$.

Takeaway: The point of this diagram is that the cyclotomic field $\mathbb{Q}(\zeta_n)$ is algebraically modelled as $\mathbb{Q}[x]/(\Phi_n(x))$, making the degree formula $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n)$ a direct consequence of the irreducibility of Φ_n.

Exercises (from the text).

1. Determine the splitting field and its degree over $\mathbb{Q}$ for $x^4 - 2$.
2. Determine the splitting field and its degree over $\mathbb{Q}$ for $x^4 + 2$.
3. Determine the splitting field and its degree over $\mathbb{Q}$ for $x^4 + x^2 + 1$.
4. Determine the splitting field and its degree over $\mathbb{Q}$ for $x^6 - 4$.
5. Let K be a finite extension of F. Prove that K is a splitting field over F if and only if every irreducible polynomial in $F[x]$ that has a root in K splits completely in $K[x]$. [Use Theorems 8 and 27.]
6. Let K_1 and K_2 be finite extensions of F contained in the field K, and assume both are splitting fields over F.
   (a) Prove that their composite K_1K_2 is a splitting field over F.
   (b) Prove that $K_1 \cap K_2$ is a splitting field over F. [Use the preceding exercise.]

Practice problems.

1. Find the splitting field K of $f(x) = x^3 - 5$ over $\mathbb{Q}$ inside $\mathbb{C}$, and compute $[K : \mathbb{Q}]$. Exhibit a $\mathbb{Q}$-basis of K and verify that $[K : \mathbb{Q}]$ divides $3!$.
2. Let $f(x) = x^4 - 2 \in \mathbb{Q}[x]$. Determine its splitting field K over $\mathbb{Q}$, find $[K : \mathbb{Q}]$, and explain why $[K : \mathbb{Q}] < 4!$ even though f is irreducible of degree 4.
3. Compute the degree over $\mathbb{Q}$ of the splitting field of $g(x) = (x^2 - 2)(x^2 - 3)(x^2 - 5)$. Show that the three quadratic subextensions are pairwise distinct and identify a primitive element.
4. Let p be an odd prime. Show that the splitting field of $x^p - 1$ over $\mathbb{Q}$ is $\mathbb{Q}(\zeta_p)$ and that its degree over $\mathbb{Q}$ equals $\varphi(p) = p - 1$. Identify the minimal polynomial $m_{\zeta_p,\mathbb{Q}}(x)$.
5. Find the splitting field of $x^4 + 1$ over $\mathbb{Q}$ and over $\mathbb{Q}(i)$ separately, computing the degree in each case. Relate $x^4 + 1$ to a cyclotomic polynomial $\Phi_n(x)$ and state n.
6. Working over $\mathbb{F}_2$, factor $x^4 + x + 1$ into irreducibles, decide whether it is separable, and determine the splitting field as $\mathbb{F}_{2^m}$ for the correct m. How many roots does it have in $\mathbb{F}_{16}$?

7. Let $f(x) = x^p - t \in \mathbb{F}_p(t)[x]$, where t is transcendental over $\mathbb{F}_p$. Show f is irreducible, that its splitting field over $\mathbb{F}_p(t)$ has degree p, and that f has a single root of multiplicity p (so f is inseparable). Identify that root.

8. Determine the splitting field of $x^6 - 1$ over $\mathbb{Q}$ and over $\mathbb{F}_7$. Compute $\Phi_6(x)$ and use it to find $[\mathbb{Q}(\zeta_6) : \mathbb{Q}]$.

9. Give an example of an irreducible cubic $f \in \mathbb{Q}[x]$ whose splitting field has degree 6 over $\mathbb{Q}$, and a second irreducible cubic whose splitting field has degree 3. Justify both degree computations using the discriminant.

Additional exercises.

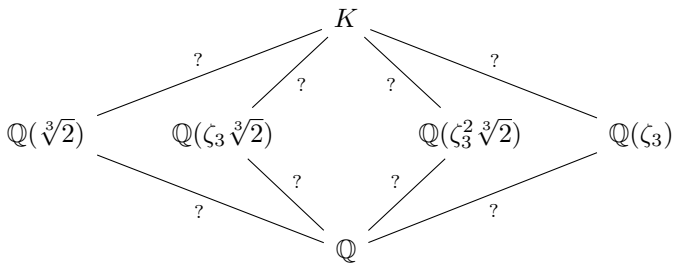
1. Let $f \in F[x]$ have degree n and let K be a splitting field of f over F. Prove by induction on n that $[K : F] \le n!$, and show that $[K : F]$ divides $n!$ when f is separable. Where does the bound $n!$ come from?

2. Let $\overline{F}$ be an algebraic closure of F and let $f \in F[x]$ be nonconstant. Prove that f splits completely into linear factors over $\overline{F}$, and that the subfield generated over F by the roots of f inside $\overline{F}$ is, up to F-isomorphism, the unique splitting field of f. State precisely which extension theorem delivers the uniqueness.

3. Suppose $\varphi\colon F \to F'$ is a field isomorphism, $f \in F[x]$, and $f' = \varphi(f) \in F'[x]$ is its image under the induced map on polynomials. Let K split f over F and K' split f' over F'. Prove that φ extends to an isomorphism $\Phi\colon K \to K'$, and count the number of such extensions when f is separable.

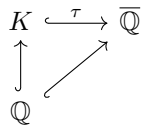
4. Let F be a field that is algebraically closed. Prove that F is infinite. (Hint: if $F = \{a_1, \dots, a_n\}$ were finite, consider $1 + \prod_{i=1}^{n}(x - a_i)$.) Conclude that no finite field is algebraically closed, but each finite field $\mathbb{F}_q$ still has an algebraic closure $\overline{\mathbb{F}_q} = \bigcup_{m \ge 1} \mathbb{F}_{q^{m!}}$.

5. Use Zorn's Lemma to outline a proof that every field F has an algebraic closure: form the poset of algebraic extensions of F inside a sufficiently large field, verify chains have upper bounds, and argue a maximal element $\overline{F}$ is algebraically closed. Identify the one step where Kronecker's construction of $F[x]/(p(x))$ is needed.



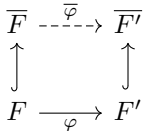
Commutative-diagram exercises.

1. Let $\varphi\colon F \xrightarrow{\sim} F'$ be a field isomorphism, $p \in F[x]$ irreducible with root α in some extension, and β a root of $p' = \varphi(p)$. Show the isomorphism $\sigma\colon F(\alpha) \to F'(\beta)$ extending φ and sending $\alpha \mapsto \beta$ makes the square below commute, where the verticals are the inclusions.



$$\begin{array}{ccc} F & \xrightarrow{\ \varphi\ } & F' \\ \downarrow & & \downarrow \\ F(\alpha) & \xrightarrow{\ \sigma\ } & F'(\beta) \end{array}$$

   Then explain how iterating this square over the roots of f builds the extension $\Phi\colon K \to K'$ of splitting fields.



2. Let K be the splitting field of $x^3 - 2$ over $\mathbb{Q}$, so $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$. Fill in the lattice of intermediate fields below with the correct degrees on each edge (each edge labelled by $[\cdot : \cdot]$), and identify which $\mathbb{Q}$-embeddings $K \to \overline{\mathbb{Q}}$ realize each non-real cube root of 2.

3. Let $\overline{\mathbb{Q}}$ be a fixed algebraic closure of $\mathbb{Q}$ and let $K \subseteq \overline{\mathbb{Q}}$ be a splitting field of $f \in \mathbb{Q}[x]$. Show that any $\mathbb{Q}$-embedding $\tau\colon K \to \overline{\mathbb{Q}}$ has image $\tau(K) = K$, i.e. the embedding below necessarily restricts to an automorphism of K. Explain why this fails if K is replaced by a non-splitting subfield such as $\mathbb{Q}(\sqrt[3]{2})$.

4. Let $\varphi\colon F \xrightarrow{\sim} F'$ be an isomorphism, $\overline{F}$ and $\overline{F'}$ chosen algebraic closures. Prove φ extends to an isomorphism $\overline{\varphi}\colon \overline{F} \to \overline{F'}$ making the square commute, and explain why $\overline{\varphi}$ is generally not unique.

Specialize to $F = F' = \mathbb{Q}$ with $\varphi = \mathrm{id}$ and describe what the extensions $\overline{\varphi}$ are in terms of $\mathrm{Aut}(\overline{\mathbb{Q}})$.

13.5 Separable and Inseparable Extensions

The formal derivative and repeated roots

Whether a polynomial has a repeated root can be detected purely algebraically, without ever leaving the field, by means of the *formal derivative*. This is the engine of the entire section.

Definition 13.5.1. Let F be a field and $f(x) = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \in F[x]$. The *(formal) derivative* of f is

$$D_x f(x) \;=\; n\,a_n x^{n-1} + (n-1)a_{n-1}x^{n-2} + \cdots + a_1 \;\in\; F[x],$$

where the integer coefficients k are interpreted as $k \cdot 1_F = 1_F + \cdots + 1_F$.

Remark 13.5.1. D_x is purely formal: there is no limit. One checks directly from the definition that it is F-linear and obeys the product rule $D_x(fg) = (D_x f)g + f(D_x g)$. In $\mathrm{char}\, F = p$ the factor $k \cdot 1_F$ can vanish, which is the source of every surprise in this section: for example $D_x(x^p) = p\,x^{p-1} = 0$.

Definition 13.5.2. A nonzero polynomial $f(x) \in F[x]$ has a *repeated root* α (in a splitting field) if $(x-\alpha)^2 \mid f(x)$, i.e. the multiplicity of α is at least 2. We call f *separable* if it has no repeated roots in a splitting field, and *inseparable* otherwise.

The link between repeated roots and the derivative is the following criterion, which lets us test separability inside $F[x]$ with the Euclidean algorithm.

Proposition 13.5.3. *A polynomial f has a repeated root α if and only if α is also a root of $D_x f$; equivalently, f has a repeated root if and only if $\gcd\big(f,\, D_x f\big)$ has positive degree. In particular f is separable if and only if $\gcd\big(f,\, D_x f\big) = 1$.*

Remark 13.5.2. The point is that $\gcd(f, D_x f)$ may be computed in $F[x]$ itself, and the gcd is unchanged under field extension. So separability is detected without factoring f and without naming a single root.

Worked Example 13.5.4 (Separability of two quadratics over $\mathbb{Q}$)**.** Decide whether $f(x) = x^2 - 2$ and $g(x) = x^2 - 2x + 1$ in $\mathbb{Q}[x]$ are separable.

Recognition. Compute D_x and apply $\gcd(f, D_x f) = 1$ iff separable; this avoids locating the roots.

Solution. For f: $D_x f = 2x$, and $\gcd(x^2 - 2,\, 2x) = \gcd(x^2 - 2,\, x) = 1$ since $x \nmid (x^2 - 2)$ (the constant term $-2 \neq 0$). So f is separable; indeed its roots $\pm\sqrt{2}$ are distinct. For g: $D_x g = 2x - 2 = 2(x-1)$, and $\gcd\big((x-1)^2,\, 2(x-1)\big) = x - 1$ has positive degree, so g is inseparable. Sanity check: $g = (x-1)^2$ literally has 1 as a double root.

Worked Example 13.5.5 (A cubic with a double root)**.** Test $f(x) = x^3 - 3x + 2 \in \mathbb{Q}[x]$ for repeated roots.

Recognition. Use $\gcd(f, D_x f)$; a nontrivial gcd both flags inseparability and *names* the repeated root.

Solution. $D_x f = 3x^2 - 3 = 3(x^2 - 1)$. Run the Euclidean algorithm: $x^3 - 3x + 2 = x \cdot (x^2 - 1) + (-2x + 2)$, then $x^2 - 1 = \big(-\frac{1}{2}x - \frac{1}{2}\big)(-2x + 2) + 0$, so $\gcd(f, D_x f) = x - 1$ (up to a unit). Hence f is inseparable and $x = 1$ is the repeated root. Sanity check: $f = (x - 1)^2(x + 2)$, confirming the double root at 1 and the simple root at -2.

Worked Example 13.5.6 (Cyclotomic-type polynomial over $\mathbb{Q}$)**.** Show $f(x) = x^n - 1 \in \mathbb{Q}[x]$ is separable for every $n \geq 1$.

Recognition. Over $\mathbb{Q}$ we have $\operatorname{char} \mathbb{Q} = 0$, so $D_x f$ is genuinely nonzero of degree $n - 1$; compute the gcd.

Solution. $D_x f = nx^{n-1}$. Since $x \nmid (x^n - 1)$ (constant term -1), $\gcd(x^n - 1,\, nx^{n-1}) = \gcd(x^n - 1,\, x^{n-1}) = 1$. Thus $x^n - 1$ has n distinct roots, namely the n-th roots of unity ζ_n^k. Sanity check: in $\mathbb{C}$ the roots $e^{2\pi ik/n}$ $(0 \leq k < n)$ are visibly distinct, matching $\deg f = n$ distinct roots.

Worked Example 13.5.7 (Separability fails in characteristic p)**.** Over $\mathbb{F}_p(t)$ (rational functions in an indeterminate t), show that $f(x) = x^p - t$ is inseparable.

Recognition. The criterion $\gcd(f, D_x f) = 1$ still applies, but now $D_x f$ may vanish because $\operatorname{char} = p$.

Solution. $D_x f = p\, x^{p-1} = 0$ in $\mathbb{F}_p(t)[x]$. Then $\gcd(f, 0) = f$ has positive degree, so f is inseparable. In fact, if α is a root in a splitting field then $\alpha^p = t$, and the Frobenius identity gives $x^p - t = x^p - \alpha^p = (x - \alpha)^p$, a single root of multiplicity p. Sanity check: f is irreducible over $\mathbb{F}_p(t)$ (Eisenstein at the prime t), yet it is inseparable – the first concrete inseparable irreducible polynomial.

Separable and inseparable irreducible polynomials

For irreducible polynomials the gcd test simplifies dramatically, because an irreducible $p(x)$ shares a common factor with $D_x p$ only if $D_x p = 0$.

Corollary 13.5.8 (Separability of irreducible polynomials)**.** *Let F be a field and let $p(x) \in F[x]$ be irreducible.*

(1) *If $\operatorname{char} F = 0$, then $p(x)$ is separable. More generally, $p(x)$ is inseparable if and only if $D_x p = 0$.*

(2) *If $\operatorname{char} F = p > 0$, then $D_x p = 0$ if and only if $p(x) = g(x^p)$ for some $g(x) \in F[x]$, i.e. every exponent appearing in p is a multiple of p.*

In general, a polynomial is separable if and only if it is a product of distinct (pairwise non-associate) irreducible polynomials, each of which is separable.

Proof. If p is irreducible then $\gcd(p, D_x p)$ is either 1 or p (up to units), since the only monic divisors of p are 1 and p. Now $\deg D_x p < \deg p$, so $\gcd(p, D_x p) = p$ forces $D_x p = 0$. Thus p is inseparable iff $D_x p = 0$. If $\operatorname{char} F = 0$ and p is nonconstant, the leading term $na_n x^{n-1}$ of $D_x p$ has $na_n \neq 0$, so $D_x p \neq 0$ and p is separable. If $\operatorname{char} F = p$, then $D_x p = \sum k a_k x^{k-1} = 0$ forces $ka_k = 0$, i.e. $a_k = 0$ whenever $p \nmid k$; the surviving exponents are multiples of p, so $p(x) = g(x^p)$. □

Worked Example 13.5.9 (Every irreducible over $\mathbb{Q}$ is separable)**.** Explain why $m_{\alpha,\mathbb{Q}}(x)$ is automatically separable for every algebraic $\alpha \in \overline{\mathbb{Q}}$, and illustrate with $\alpha = \sqrt[3]{2}$.

Recognition. $\operatorname{char} \mathbb{Q} = 0$, so the corollary applies to the irreducible minimal polynomial.

Solution. By the corollary, an irreducible polynomial over a char 0 field is separable. For $\alpha = \sqrt[3]{2}$, $m_{\alpha,\mathbb{Q}} = x^3 - 2$ with $D_x(x^3 - 2) = 3x^2$, and $\gcd(x^3 - 2, 3x^2) = 1$. Hence the three roots $\sqrt[3]{2},\ \zeta_3\sqrt[3]{2},\ \zeta_3^2\sqrt[3]{2}$ are distinct, where $\zeta_3 = e^{2\pi i/3}$. Sanity check: $[\mathbb{Q}(\sqrt[3]{2}, \zeta_3) : \mathbb{Q}] = 6$, the splitting field of a degree-3 separable polynomial, consistent with 3 distinct roots and $[\mathbb{Q}(\zeta_3) : \mathbb{Q}] = 2$.

Worked Example 13.5.10 (The exponent pattern $g(x^p)$)**.** Over $F = \mathbb{F}_p(t)$, verify directly that $p(x) = x^{2p} - t\, x^p + t$ has $D_x p = 0$ and exhibit the g with $p(x) = g(x^p)$.

Recognition. Use part (2): $D_x p = 0$ iff every exponent is divisible by p.

Solution. Every exponent ($2p$, p, and 0) is a multiple of p, so each term of $D_x p$ carries a factor $p \equiv 0$; hence $D_x p = 0$. Writing $g(y) = y^2 - t\, y + t$ gives $p(x) = g(x^p)$. Sanity check: substituting $y = x^p$ and using $D_x g(x^p) = g'(x^p) \cdot p x^{p-1} = 0$ recovers $D_x p = 0$ the slow way.

Worked Example 13.5.11 (An inseparable irreducible polynomial in detail)**.** Show $p(x) = x^p - t$ is irreducible over $F = \mathbb{F}_p(t)$ but inseparable, and compute the multiplicity of its unique root.

Recognition. Combine the $g(x^p)$ criterion with the Frobenius factorization.

Solution. Here $p(x) = g(x^p)$ with $g(y) = y - t$, so $D_x p = 0$ and p is inseparable. Irreducibility: t is a prime in the PID $\mathbb{F}_p[t]$ and Eisenstein at t applies. If $\alpha^p = t$ in a splitting field, then $x^p - t = (x - \alpha)^p$ by Frobenius, so α has multiplicity p. Sanity check: $\deg p = p$ equals the single root's multiplicity, the extreme opposite of $x^n - 1$, which had n multiplicity-1 roots.

Perfect fields

A field over which every irreducible polynomial is separable is the well-behaved case. The corollary already covers $\operatorname{char} 0$; we now isolate the $\operatorname{char} p$ obstruction.

Definition 13.5.12. A field F is *perfect* if either $\operatorname{char} F = 0$, or $\operatorname{char} F = p > 0$ and the Frobenius map $F \to F$, $a \mapsto a^p$, is surjective (equivalently $F = F^p$). For $\operatorname{char} p$ fields, perfection says every element has a p-th root in F.

Proposition 13.5.13. *Every irreducible polynomial over a perfect field F is separable; hence a polynomial in $F[x]$ is separable if and only if it is a product of distinct (pairwise non-associate) irreducible polynomials. Every field of characteristic 0 and every finite field is perfect.*

Sketch. Suppose $\operatorname{char} F = p$ and some irreducible $p(x)$ were inseparable, so $p(x) = g(x^p) = \sum b_k x^{pk}$. If F is perfect, write $b_k = c_k^p$. Then by the Frobenius identity $\left(\sum c_k x^k\right)^p = \sum c_k^p x^{pk} = p(x)$, exhibiting $p(x)$ as a p-th power, contradicting irreducibility. The field $\mathbb{F}_p(t)$ is *not* perfect because $t \notin F^p$, which is exactly why $x^p - t$ exists. □

The Frobenius endomorphism is the central player and deserves its own diagram.

$$\begin{array}{ccc} F & \xrightarrow{\varphi\colon a \mapsto a^p} & F \\ \big\downarrow & & \big\downarrow \\ \overline{F} & \xrightarrow[a \mapsto a^p]{} & \overline{F} \end{array}$$

Diagram explanation. Objects: All four nodes are fields. The top-left and top-right are both F, a field of characteristic p. The bottom-left and bottom-right are both $\overline{F}$, the algebraic closure of F.

Arrows: The top horizontal arrow is the Frobenius endomorphism $\varphi : F \to F$, $a \mapsto a^p$, restricted to F. The bottom horizontal arrow is the same p-power map on $\overline{F}$, $a \mapsto a^p$. The two vertical arrows are the canonical field inclusions $\iota : F \hookrightarrow \overline{F}$; they are injective field homomorphisms that embed every element of F into the larger algebraically closed field.

What commutes: The square commutes: applying φ then including, versus including then applying the p-power map on $\overline{F}$, give the same result: $\iota \circ \varphi = \varphi_{\overline{F}} \circ \iota$, i.e. for every $a \in F$, $(\iota \circ \varphi)(a) = a^p = (\varphi_{\overline{F}} \circ \iota)(a)$.

Why it commutes: Take $a \in F$. Along the top-then-right path: $a \overset{\varphi}{\mapsto} a^p \overset{\iota}{\mapsto} a^p \in \overline{F}$. Along the left-then-bottom path: $a \overset{\iota}{\mapsto} a \in \overline{F} \overset{\varphi_{\overline{F}}}{\longmapsto} a^p$. Both land at the same $a^p \in \overline{F}$. The formula $a \mapsto a^p$ is literally the same operation on both F and $\overline{F}$; the square commutes by definition of both maps.

Why this matters here: The diagram records that Frobenius on F is the restriction of the Frobenius on $\overline{F}$. This is used immediately after: if φ is injective on F (which it is, as a nonzero field map), and F is finite so injective implies surjective, then $\varphi \in \operatorname{Aut}(F)$. The naturality square is the precise reason we can move freely between F and $\overline{F}$ when analyzing φ.

Concrete example: For $F = \mathbb{F}_p$ and $\overline{F} = \overline{\mathbb{F}_p}$: the top Frobenius sends $a \mapsto a^p = a$ (Fermat), so $\varphi = \mathrm{id}$ on $\mathbb{F}_p$; the bottom Frobenius on $\overline{\mathbb{F}_p}$ sends $a \mapsto a^p$, and the square says the identity on $\mathbb{F}_p$ matches the restriction of this map to $\mathbb{F}_p$.

Common pitfall: Students sometimes read the diagram as saying $F = \overline{F}$ because the top and bottom objects "look the same." The two horizontal maps are the same formula, but F and $\overline{F}$ are genuinely different fields (unless F is already algebraically closed); the vertical inclusions are strict embeddings when $F \neq \overline{F}$.

Takeaway: The point of this diagram is that the Frobenius p-power map is natural with respect to field extensions, so its properties on F (injectivity, bijectivity when F is finite) follow from properties of the same map on the larger field $\overline{F}$.

Because $(a+b)^p = a^p + b^p$ and $(ab)^p = a^p b^p$ in $\operatorname{char} p$, the map φ is a ring homomorphism; being a nonzero map of fields it is injective. When F is finite, an injective self-map is automatically bijective, so $\varphi \in \operatorname{Aut}(F)$.

Worked Example 13.5.14 ($\mathbb{F}_p$ is perfect via Fermat)**.** Show the prime field $\mathbb{F}_p$ is perfect.

Recognition. Need: Frobenius $a \mapsto a^p$ is surjective on $\mathbb{F}_p$.

Solution. By Fermat's little theorem $a^p = a$ for all $a \in \mathbb{F}_p$, so Frobenius is the identity map id, which is certainly surjective. Hence $\mathbb{F}_p = \mathbb{F}_p^p$ and $\mathbb{F}_p$ is perfect. Sanity check: every $a \in \mathbb{F}_p$ is its own p-th root, the strongest possible form of "has a p-th root".

Worked Example 13.5.15 ($\mathbb{F}_p(t)$ is imperfect)**.** Show $\mathbb{F}_p(t)$ is not perfect and identify an element with no p-th root.

Recognition. Perfection in $\operatorname{char} p$ means $F = F^p$; find an element outside F^p.

Solution. The image $F^p = \mathbb{F}_p(t)^p$ consists of p-th powers; a rational function $r(t)^p$ only involves exponents of t divisible by p. Thus $t \notin F^p$, so Frobenius is not surjective and F is imperfect. Sanity check: the missing p-th root of t is exactly the root of the inseparable irreducible $x^p - t$.

The Frobenius and finite fields $\mathbb{F}_{p^n}$

The Frobenius automorphism organizes the entire theory of finite fields.

Theorem 13.5.16. *For every prime p and integer $n \geq 1$ there exists a field with exactly p^n elements, unique up to isomorphism, denoted $\mathbb{F}_{p^n}$. It is precisely the splitting field over $\mathbb{F}_p$ of*

$$x^{p^n} - x,$$

and equals the set of its roots, i.e. the fixed field of the iterated Frobenius $\varphi^n : a \mapsto a^{p^n}$.

Idea. Let K be a splitting field of $f(x) = x^{p^n} - x$ over $\mathbb{F}_p$. Since $D_x f = p^n x^{p^n - 1} - 1 = -1$, we have $\gcd(f, D_x f) = 1$, so f is separable and has exactly p^n distinct roots in K. The roots are closed under $+$, $-$, $\cdot$, and inverses (using the Frobenius identities), hence form a subfield with p^n elements; this subfield is all of K. Uniqueness follows because any field with p^n elements has multiplicative group of order $p^n - 1$, so each nonzero a satisfies $a^{p^n - 1} = 1$, whence every element is a root of $x^{p^n} - x$ – it is a splitting field of that polynomial, and splitting fields are unique up to isomorphism. □

Theorem 13.5.17. *The multiplicative group $\mathbb{F}_{p^n}^\times$ is cyclic of order $p^n - 1$.*

Idea. $\mathbb{F}_{p^n}^\times$ is a finite abelian group; in any field the equation $x^d = 1$ has at most d solutions, which forces the group to be cyclic. A generator is called a *primitive element.* □

The containment $\mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n}$ is governed by divisibility of the exponents, exactly mirroring the subfield/degree dictionary.

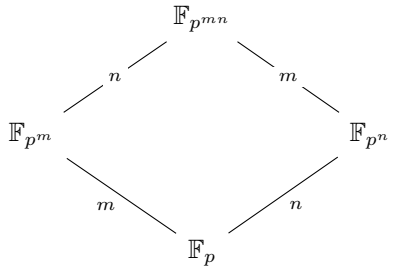


Diagram explanation. Objects: Four finite fields, all of characteristic p. At the bottom is the prime field $\mathbb{F}_p$. At the middle level on the left is $\mathbb{F}_{p^m}$ and on the right $\mathbb{F}_{p^n}$ (subfields of degree m and n over $\mathbb{F}_p$, respectively). At the top is $\mathbb{F}_{p^{mn}}$, which contains both; it is their compositum exactly when $\gcd(m,n)=1$ (in general the compositum is $\mathbb{F}_{p^{\mathrm{lcm}(m,n)}}$, which can be smaller).

Arrows: Each edge denotes a field inclusion $\subseteq$ (a subfield embedding). The edges are labeled by the degree of the extension: the left lower edge $\mathbb{F}_p \subset \mathbb{F}_{p^m}$ has degree m; the right lower edge $\mathbb{F}_p \subset \mathbb{F}_{p^n}$ has degree n; the left upper edge $\mathbb{F}_{p^m} \subset \mathbb{F}_{p^{mn}}$ has degree $[\mathbb{F}_{p^{mn}} : \mathbb{F}_{p^m}] = n$; the right upper edge $\mathbb{F}_{p^n} \subset \mathbb{F}_{p^{mn}}$ has degree $[\mathbb{F}_{p^{mn}} : \mathbb{F}_{p^n}] = m$.

What commutes: The degree-tower law holds along every path from $\mathbb{F}_p$ to $\mathbb{F}_{p^{mn}}$: going via $\mathbb{F}_{p^m}$ gives degree $m \cdot n$, and going via $\mathbb{F}_{p^n}$ also gives degree $n \cdot m$. Both paths compute $[\mathbb{F}_{p^{mn}} : \mathbb{F}_p] = mn$, confirming the diagram is consistent.

Why it commutes: $\mathbb{F}_{p^k}$ is the unique subfield of $\overline{\mathbb{F}_p}$ of order p^k; it exists and is unique because it is the splitting field of $x^{p^k} - x$. The containment $\mathbb{F}_{p^k} \subseteq \mathbb{F}_{p^\ell}$ holds iff $k \mid \ell$, and then $[\mathbb{F}_{p^\ell} : \mathbb{F}_{p^k}] = \ell/k$. The degree labels in the diagram are all special cases of this rule: $[\mathbb{F}_{p^{mn}} : \mathbb{F}_{p^m}] = mn/m = n$ and $[\mathbb{F}_{p^{mn}} : \mathbb{F}_{p^n}] = mn/n = m$.

Why this matters here: The diagram makes the divisibility-governs-containment rule visually explicit, bridging the abstract theorem that $\mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n} \Leftrightarrow m \mid n$ to the concrete tower-degree formula. It also sets up the general compositum claim $\mathbb{F}_{p^m}\mathbb{F}_{p^n} = \mathbb{F}_{p^{\mathrm{lcm}(m,n)}}$.

Concrete example: Take $p = 2$, $m = 2$, $n = 3$, so $\gcd(2,3) = 1$ and the top is $\mathbb{F}_{64} = \mathbb{F}_{2^6}$. The diagram becomes: $\mathbb{F}_2 \subset \mathbb{F}_4$ (degree 2), $\mathbb{F}_2 \subset \mathbb{F}_8$ (degree 3), $\mathbb{F}_4 \subset \mathbb{F}_{64}$ (degree 3), $\mathbb{F}_8 \subset \mathbb{F}_{64}$ (degree 2). Both paths from $\mathbb{F}_2$ to $\mathbb{F}_{64}$ give total degree 6.

Common pitfall: The top field $\mathbb{F}_{p^{mn}}$ is the compositum $\mathbb{F}_{p^m}\mathbb{F}_{p^n}$ only when $\gcd(m,n) = 1$. In general the compositum is $\mathbb{F}_{p^{\mathrm{lcm}(m,n)}}$, which can be strictly smaller than $\mathbb{F}_{p^{mn}}$. For example, $m = n = 2$ gives the compositum $\mathbb{F}_{p^2}$, not $\mathbb{F}_{p^4}$.

Takeaway: The point of this diagram is that the subfield structure of finite fields is completely controlled by divisibility of exponents, so the degree of any subfield tower can be read off by arithmetic on the exponents alone.

The top vertex $\mathbb{F}_{p^{mn}}$ contains the compositum $\mathbb{F}_{p^m}\mathbb{F}_{p^n} = \mathbb{F}_{p^{\mathrm{lcm}(m,n)}}$ and equals it exactly when $\gcd(m,n) = 1$; the upper edges are labeled by the relative degrees $[\mathbb{F}_{p^{mn}} : \mathbb{F}_{p^m}] = n$ and $[\mathbb{F}_{p^{mn}} : \mathbb{F}_{p^n}] = m$. More generally, $\mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n}$ if and only if $m \mid n$, and then $[\mathbb{F}_{p^n} : \mathbb{F}_{p^m}] = n/m$.

Worked Example 13.5.18 (Building $\mathbb{F}_4$ explicitly)**.** Construct $\mathbb{F}_4 = \mathbb{F}_{2^2}$ and verify $\mathbb{F}_4^\times$ is cyclic.

Recognition. $\mathbb{F}_4$ is the splitting field of $x^4 - x$ over $\mathbb{F}_2$; equivalently $\mathbb{F}_2[x]/(p)$ for an irreducible quadratic p.

Solution. Over $\mathbb{F}_2$, $x^4 - x = x(x+1)(x^2+x+1)$, and $x^2 + x + 1$ is the unique irreducible quadratic. Set $\mathbb{F}_4 = \mathbb{F}_2(\alpha)$ with $\alpha^2 + \alpha + 1 = 0$, so $\mathbb{F}_4 = \{0, 1, \alpha, \alpha+1\}$ with $[\mathbb{F}_4 : \mathbb{F}_2] = 2$. Then $\alpha^2 = \alpha + 1$, $\alpha^3 = \alpha \cdot \alpha^2 = \alpha^2 + \alpha = 1$, so α has order $3 = |\mathbb{F}_4^\times|$ and generates the cyclic group. Sanity check: the four roots of $x^4 - x$ are exactly $0, 1, \alpha, \alpha+1$, matching $|\mathbb{F}_4| = 4$.

Worked Example 13.5.19 (The subfield lattice of $\mathbb{F}_{2^6}$)**.** List all subfields of $\mathbb{F}_{64} = \mathbb{F}_{2^6}$ and their degrees over $\mathbb{F}_2$.

Recognition. Subfields $\mathbb{F}_{2^m} \subseteq \mathbb{F}_{2^6}$ correspond to divisors $m \mid 6$.

Solution. The divisors of 6 are $1, 2, 3, 6$, giving subfields

$$\mathbb{F}_2 \subset \mathbb{F}_4 \subset \mathbb{F}_{64}, \qquad \mathbb{F}_2 \subset \mathbb{F}_8 \subset \mathbb{F}_{64},$$

with $\mathbb{F}_4 = \mathbb{F}_{2^2}$, $\mathbb{F}_8 = \mathbb{F}_{2^3}$. Degrees over $\mathbb{F}_2$ are $1, 2, 3, 6$, and e.g. $[\mathbb{F}_{64} : \mathbb{F}_8] = 6/3 = 2$. Sanity check: $\mathbb{F}_4$ and $\mathbb{F}_8$ are incomparable since $2 \nmid 3$ and $3 \nmid 2$, and their compositum is all of $\mathbb{F}_{2^{\mathrm{lcm}(2,3)}} = \mathbb{F}_{2^6}$.

Worked Example 13.5.20 ($\mathbb{F}_{p^n}$ as the fixed field of φ^n)**.** Show $a \in \overline{\mathbb{F}_p}$ lies in $\mathbb{F}_{p^n}$ if and only if $a^{p^n} = a$.

Recognition. Use that $\mathbb{F}_{p^n}$ is exactly the root set of $x^{p^n} - x$, the fixed points of φ^n.

Solution. If $a \in \mathbb{F}_{p^n}$ then $a^{p^n - 1} = 1$ (for $a \neq 0$) or $a = 0$, so $a^{p^n} = a$. Conversely $a^{p^n} = a$ says a is a root of $x^{p^n} - x$, whose root set is $\mathbb{F}_{p^n}$. Hence $\mathbb{F}_{p^n} = \{a : \varphi^n(a) = a\}$. Sanity check: for $n = 1$ this is Fermat's $a^p = a$ characterizing $\mathbb{F}_p$, the bottom of the tower.

Worked Example 13.5.21 (Why $x^9 - x$ gives $\mathbb{F}_9$)**.** Identify the splitting field of $x^9 - x$ over $\mathbb{F}_3$ and its degree.

Recognition. $x^{p^n} - x$ with $p = 3$, $n = 2$ has splitting field $\mathbb{F}_{p^n} = \mathbb{F}_9$.

Solution. $x^9 - x = x^{3^2} - x$, so its splitting field is $\mathbb{F}_9 = \mathbb{F}_{3^2}$ with $[\mathbb{F}_9 : \mathbb{F}_3] = 2$. Take β with $\beta^2 + 1 = 0$ (since $x^2 + 1$ is irreducible over $\mathbb{F}_3$); then $\mathbb{F}_9 = \mathbb{F}_3(\beta)$. Sanity check: $D_x(x^9 - x) = -1$, so $x^9 - x$ is separable with exactly 9 roots, equal to all of $\mathbb{F}_9$.

Inseparable and purely inseparable extensions

In $\operatorname{char} p$ the failure of separability is controlled by the prime p: every inseparable irreducible polynomial becomes, after enough Frobenius pullbacks, a separable one composed with x^{p^k}.

Proposition 13.5.22. *Let* $\operatorname{char} F = p$ *and let* $p(x) \in F[x]$ *be irreducible. Then there is a unique integer* $k \geq 0$ *and a separable irreducible* $p_{\text{sep}}(x) \in F[x]$ *with*

$$p(x) = p_{\text{sep}}\big(x^{p^k}\big).$$

Every root of p *has the same multiplicity* p^k*, called the* inseparable degree*; the number of distinct roots is* $\deg p_{\text{sep}}$*, the* separable degree*.*

Definition 13.5.23. Let $\operatorname{char} F = p$. An element α algebraic over F is *purely inseparable* over F if $m_{\alpha,F}(x) = x^{p^k} - a$ for some $a \in F$ and $k \geq 0$, equivalently $\alpha^{p^k} \in F$. An extension K/F is *purely inseparable* if every element of K is purely inseparable over F.

The minimal polynomial of a purely inseparable element factors as a single repeated root via Frobenius, which we display as a degenerate splitting picture.

$$F \hookrightarrow F(\alpha) = F[x]/\big(x^{p^k} - a\big) \xhookrightarrow{x \mapsto \alpha} \overline{F} \ \ni \ \alpha, \quad \alpha^{p^k} = a$$

where $x^{p^k} - a = (x - \alpha)^{p^k}$ has the *single* root α of multiplicity p^k.

Diagram explanation. Objects: Three objects in a chain. On the left is F, a field of characteristic p. In the middle is the quotient ring $F[x]/(x^{p^k} - a)$, which equals the simple extension $F(\alpha)$ because $x^{p^k} - a = m_{\alpha,F}(x)$ is irreducible over F (by the definition of purely inseparable; having the single root α does not by itself force irreducibility, e.g. $x^p - t^p = (x - t)^p$ over $\mathbb{F}_p(t)$). On the right is $\overline{F}$, the algebraic closure, which contains the unique root α satisfying $\alpha^{p^k} = a$.

Arrows: The left arrow $F \hookrightarrow F(\alpha)$ is the canonical inclusion of the base field into the simple extension, sending $c \in F$ to the class $[c]$. The right arrow $F(\alpha) \to \overline{F}$ is the evaluation/root map $x \mapsto \alpha$: it sends the class $[f(x)]$ in the quotient to $f(\alpha) \in \overline{F}$. Well-definedness: since $\alpha^{p^k} = a$, the relation $x^{p^k} - a = 0$ holds at α, so representatives differing by a multiple of $x^{p^k} - a$ are sent to the same image; the map is well-defined.

What commutes: The sequence is not a commutativity assertion but a factorization chain: the composite $F \hookrightarrow F(\alpha) \to \overline{F}$ is the canonical embedding $F \hookrightarrow \overline{F}$. There are no two competing paths here; the diagram displays the factorization of $F \to \overline{F}$ through the intermediate $F(\alpha)$.

Why it commutes: The composite sends $c \in F$ first to $[c] \in F[x]/(x^{p^k} - a)$, then to $c \in \overline{F}$ (since $c = f(\alpha)$ for the constant polynomial $f = c$). This is exactly the inclusion $F \hookrightarrow \overline{F}$, confirming the chain is consistent.

Why this matters here: The diagram makes precise the meaning of "$F(\alpha)$ is generated by the unique root α of $x^{p^k} - a$." It shows that the algebraic object $F[x]/(x^{p^k} - a)$ and the geometric object "F with α adjoined in $\overline{F}$" are two names for the same thing. The annotation $\alpha^{p^k} = a$ records the defining relation, and $x^{p^k} - a = (x - \alpha)^{p^k}$ records the inseparability: one root, multiplicity p^k.

Concrete example: Take $F = \mathbb{F}_p(t)$, $a = t$, $k = 1$: then $F(\alpha) = \mathbb{F}_p(t)[x]/(x^p - t)$, $\alpha = t^{1/p}$, and the chain is $\mathbb{F}_p(t) \hookrightarrow \mathbb{F}_p(t^{1/p}) \to \overline{\mathbb{F}_p(t)}$. The single root $\alpha = t^{1/p}$ has multiplicity p in $x^p - t = (x - t^{1/p})^p$.

Common pitfall: The right-hand map $F(\alpha) \to \overline{F}$ is a specific embedding, not an isomorphism: $F(\alpha)$ is a degree-p^k extension of F, while $\overline{F}$ is much larger. Students sometimes assume the diagram says $F(\alpha) \cong \overline{F}$.

Also, well-definedness of the right arrow requires checking that α actually satisfies $x^{p^k} - a$; without $\alpha^{p^k} = a$, the map to $\overline{F}$ is not defined.

Takeaway: The point of this diagram is that a purely inseparable extension $F(\alpha)/F$ has only one conjugate of α (itself), so adjoining α creates an extension whose sole root lives in $\overline{F}$ with full multiplicity p^k and no distinct siblings.

Worked Example 13.5.24 (A purely inseparable degree-p extension)**.** Over $F = \mathbb{F}_p(t)$, show $\alpha = \sqrt[p]{t}$ generates a purely inseparable extension and compute $[F(\alpha) : F]$.

Recognition. Match $m_{\alpha,F}$ to the pattern $x^{p^k} - a$ of the definition.

Solution. Here $\alpha^p = t \in F$, and $m_{\alpha,F}(x) = x^p - t$ is irreducible (Eisenstein at t). So α is purely inseparable with $k = 1$ and $[F(\alpha) : F] = p$. The unique conjugate of α is α itself, with multiplicity p. Sanity check: separable degree $= \deg p_{\text{sep}} = 1$ (one distinct root) times inseparable degree $p^1 = p$ equals deg $= p$.

Worked Example 13.5.25 (Separable and inseparable degree split)**.** Over $F = \mathbb{F}_2(t)$, factor $p(x) = x^4 - t^2$ through Frobenius and read off the separable and inseparable degrees of its irreducible factor.

Recognition. These degrees are defined only for irreducible polynomials, so factor first; then use $p_{\text{sep}}(x^{p^k})$ with $p = 2$ on the irreducible factor, the inseparable part being the largest x^{2^k} pullback.

Solution. $x^4 - t^2 = (x^2)^2 - t^2 = (x^2 - t)(x^2 + t)$, but in char 2, $x^2 + t = x^2 - t$, so $x^4 - t^2 = (x^2 - t)^2$. With $x^2 - t$ irreducible and inseparable (it is $g(x^2)$, $g(y) = y - t$), write $x^2 - t = p_{\text{sep}}(x^2)$ where $p_{\text{sep}}(y) = y - t$. Thus over the irreducible factor $x^2 - t$: separable degree 1, inseparable degree $2^1 = 2$. Sanity check: the single root $\alpha = \sqrt{t}$ of $x^2 - t$ has multiplicity 2, and $(x - \alpha)^2 = x^2 - t$ since $2\alpha = 0$.

Worked Example 13.5.26 (Counting distinct roots via separable degree)**.** Let char $F = 3$ and suppose an irreducible $p(x) \in F[x]$ satisfies $p(x) = q(x^9)$ with q separable irreducible of degree 2. How many distinct roots does p have, and what is $\deg p$?

Recognition. Inseparable degree $= p^k = 3^2 = 9$ (since $x^9 = x^{3^2}$); separable degree $= \deg q$.

Solution. The number of distinct roots equals the separable degree $\deg q = 2$. Each occurs with multiplicity equal to the inseparable degree $3^2 = 9$. Hence $\deg p =$ (distinct roots) $\times$ (multiplicity) $= 2 \cdot 9 = 18$. Sanity check: $\deg p = \deg\big(q(x^9)\big) = 9 \cdot \deg q = 18$, the same number computed directly.

Corollary 13.5.27. *Over a perfect field every algebraic extension is separable, and the only purely inseparable extension is the trivial one F/F. In particular, finite fields and* char 0 *fields have no nontrivial purely inseparable extensions.*

Worked Example 13.5.28 (No inseparability over $\mathbb{F}_p$)**.** Explain why no algebraic extension of $\mathbb{F}_p$ is inseparable, despite char $= p$.

Recognition. $\mathbb{F}_p$ (indeed every finite field) is perfect, so the previous corollary forbids inseparable behavior.

Solution. Every finite field F satisfies $F = F^p$ (Frobenius is a bijection on a finite field), so F is perfect; by the corollary every algebraic extension of F is separable. The inseparable phenomena require an *infinite* char p field such as $\mathbb{F}_p(t)$, where t lacks a p-th root. Sanity check: over $\mathbb{F}_p$, $x^{p^n} - x$ – the master polynomial of all finite fields – is separable, so finite extensions $\mathbb{F}_{p^n}/\mathbb{F}_p$ are separable of degree n.

Exercises (from the text).

1. Prove that the derivative D_x of a polynomial satisfies $D_x(f(x) + g(x)) = D_x(f(x)) + D_x(g(x))$ and $D_x(f(x)g(x)) = D_x(f(x))g(x) + f(x)D_x(g(x))$ for any two polynomials $f(x)$ and $g(x)$.
2. Find all irreducible polynomials of degrees 1, 2 and 4 over $\mathbb{F}_2$ and prove that their product is $x^{16} - x$.
3. Prove that d divides n if and only if $x^d - 1$ divides $x^n - 1$. [Note that if $n = qd + r$ then $x^n - 1 = (x^{qd+r} - x^r) + (x^r - 1)$.]
4. Let $a > 1$ be an integer. Prove for any positive integers n, d that d divides n if and only if $a^d - 1$ divides $a^n - 1$ (cf. the previous exercise). Conclude in particular that $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^n}$ if and only if d divides n.

5. For any prime p and any nonzero $a \in \mathbb{F}_p$ prove that $x^p - x + a$ is irreducible and separable over $\mathbb{F}_p$. [For the irreducibility: One approach—prove first that if α is a root then $\alpha + 1$ is also a root. Another approach—suppose it's reducible and compute derivatives.]

6. Prove that $x^{p^n} - 1 = \prod_{0 \neq \alpha \in \mathbb{F}_{p^n}} (x - \alpha)$. Conclude that $\prod_{0 \neq \alpha \in \mathbb{F}_{p^n}} \alpha = (-1)^{p^n}$ so the product of the nonzero elements of a finite field is $+1$ if $p = 2$ and -1 if p is odd. For p odd and $n = 1$ derive *Wilson's Theorem*: $(p-1)! \equiv -1 \pmod{p}$.

7. Suppose K is a field of characteristic p which is not a perfect field: $K \neq K^p$. Prove there exist irreducible inseparable polynomials over K. Conclude that there exist inseparable finite extensions of K.

8. Prove that $f(x)^p = f(x^p)$ for any polynomial $f(x) \in \mathbb{F}_p[x]$.

9. Show that the binomial coefficient $\binom{pn}{pi}$ is the coefficient of x^{pi} in the expansion of $(1+x)^{pn}$. Working over $\mathbb{F}_p$ show that this is the coefficient of $(x^p)^i$ in $(1+x^p)^n$ and hence prove that $\binom{pn}{pi} \equiv \binom{n}{i} \pmod{p}$.

10. Let $f(x_1, x_2, \ldots, x_n) \in \mathbb{Z}[x_1, x_2, \ldots, x_n]$ be a polynomial in the variables $x_1, x_2, \ldots, x_n$ with integer coefficients. For any prime p prove that the polynomial

$$f(x_1, x_2, \ldots, x_n)^p - f(x_1^p, x_2^p, \ldots, x_n^p) \in \mathbb{Z}[x_1, x_2, \ldots, x_n]$$

has all its coefficients divisible by p.

11. Suppose $K[x]$ is a polynomial ring over the field K and F is a subfield of K. If F is a perfect field and $f(x) \in F[x]$ has no repeated irreducible factors in $F[x]$, prove that $f(x)$ has no repeated irreducible factors in $K[x]$.

Practice problems.

1. For each polynomial, compute the formal derivative $f'(x)$, then use $\gcd(f, f')$ to decide whether f has a repeated root in $\overline{F}$.
   (a) $f(x) = x^4 - 2x^2 + 1$ over $\mathbb{Q}$.
   (b) $f(x) = x^3 - 3x + 2$ over $\mathbb{Q}$.
   (c) $f(x) = x^5 + x^4 + x^3 + x^2 + x + 1$ over $\mathbb{Q}$.

2. Work over $\mathbb{F} = \mathbb{Z}/3\mathbb{Z}$. Let $f(x) = x^6 + x^3 + 1$.
   (a) Compute $f'(x)$ and observe that it is the zero polynomial in $\mathbb{F}[x]$. Explain, without factoring f, why $f' = 0$ means f is a polynomial in x^3, and why this forces every root of f in $\overline{\mathbb{F}}$ to be repeated.
   (b) Show that $f(x) = (x-1)^6$ in $\mathbb{F}[x]$, and reconcile this with your derivative computation. (Hint: $x^6 + x^3 + 1 = (x^3 - 1)^2$, and $x^3 - 1 = (x-1)^3$ over $\mathbb{F}$.)

3. Let p be a prime and consider $g(x) = x^p - a \in \mathbb{F}_p(t)[x]$ where $\mathbb{F}_p(t)$ is the rational function field and $a = t$.
   (a) Compute $g'(x)$ and conclude $\gcd(g, g') = g$.
   (b) Show $g(x) = (x - t^{1/p})^p$ over a splitting field, and explain why every root of g is repeated. This is the standard example of an inseparable irreducible polynomial.

4. Determine the number of distinct roots of $x^{16} - x$ over $\mathbb{F}_2$, and prove that this polynomial equals the product of all monic irreducible polynomials in $\mathbb{F}_2[x]$ whose degree divides 4. List the possible degrees of those irreducible factors.

5. Inside a fixed algebraic closure $\overline{\mathbb{F}_2}$, decide which of $\mathbb{F}_4$, $\mathbb{F}_8$, $\mathbb{F}_{16}$ contain $\mathbb{F}_4$ as a subfield. State the general containment rule for $\mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n}$ and prove the direction $m \mid n \implies \mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n}$ using that $\mathbb{F}_{p^n}$ is the splitting field of $x^{p^n} - x$.

6. Let α be a generator of the cyclic group $\mathbb{F}_{16}^\times$.
   (a) Compute $|\alpha|$ and $|\mathbb{F}_{16}^\times|$.

(b) Determine $[\mathbb{F}_2(\alpha):\mathbb{F}_2]$ and deduce $m_{\alpha,\mathbb{F}_2}(x)$ has degree 4.

(c) How many distinct generators does $\mathbb{F}_{16}^{\times}$ have? Express your answer using φ.

7. Let $\sigma:\mathbb{F}_{p^n}\to\mathbb{F}_{p^n}$ be the Frobenius endomorphism $x\mapsto x^p$.

(a) Prove σ is a field homomorphism, i.e. verify $\sigma(x+y)=\sigma(x)+\sigma(y)$ and $\sigma(xy)=\sigma(x)\sigma(y)$, citing the binomial coefficients $\binom{p}{k}\equiv 0 \pmod p$ for $0<k<p$.

(b) Show σ is injective, hence bijective on the finite field $\mathbb{F}_{p^n}$.

(c) Identify the fixed field $\{\,x\in\mathbb{F}_{p^n}:\sigma(x)=x\,\}$ and compute its size.

(d) Show σ has order n as an element of $\mathrm{Aut}(\mathbb{F}_{p^n})$, i.e. $\sigma^n=\mathrm{id}$ but $\sigma^d\neq\mathrm{id}$ for $0<d<n$.

8. Let $K=\mathbb{F}_p(t^{1/p},u^{1/p})$ where t,u are independent transcendentals over $\mathbb{F}_p$ and $F=\mathbb{F}_p(t,u)$.

(a) Show each of $t^{1/p},u^{1/p}$ is purely inseparable over F and compute $[F(t^{1/p}):F]$.

(b) Compute $[K:F]$.

(c) Show $x^p-t\in F[x]$ is irreducible, and conclude F is not a perfect field.

9. Decide whether each irreducible polynomial is separable. Justify each answer by either citing perfectness of the ground field or computing $\gcd(f,f')$.

(a) x^3-2 over $\mathbb{Q}$.

(b) x^4+x+1 over $\mathbb{F}_2$.

(c) x^p-t over $\mathbb{F}_p(t)$.

(d) $\Phi_7(x)$ over $\mathbb{Q}$, where Φ_7 is the 7th cyclotomic polynomial.

Additional exercises.

1. (Perfect fields.) A field F of characteristic p is *perfect* iff the Frobenius map $x\mapsto x^p$ is surjective on F, i.e. $F=F^p$. Prove that every finite field is perfect, and prove that every field of characteristic 0 is perfect (vacuously, by showing every irreducible polynomial there is separable). Then exhibit one imperfect field with proof.

2. (Counting irreducibles.) Let N_d be the number of monic irreducible polynomials of degree d in $\mathbb{F}_p[x]$. Using $x^{p^n}-x=\prod_{d\mid n}\big(\text{product of monic irreducibles of degree } d\big)$, derive the degree identity $p^n=\sum_{d\mid n} d\,N_d$. Use it to compute N_1,N_2,N_3,N_4 for $p=2$ explicitly.

3. (Separable degree of a tower.) Let $F=\mathbb{F}_3(t)$, and let α be a root of $x^9-t\in F[x]$ and $\beta=\alpha^3$, so $\beta^3=t$.

(a) Show $m_{\beta,F}(x)=x^3-t$ and $m_{\alpha,F(\beta)}(x)=x^3-\beta$, each purely inseparable.

(b) Compute $[F(\alpha):F]$ and explain why no element of $F(\alpha)\setminus F$ is separable over F.

4. (Multiplicity of a root.) Let $f(x)\in F[x]$ and $\alpha\in\overline{F}$. Prove that α is a root of f of multiplicity ≥ 2 iff $f(\alpha)=f'(\alpha)=0$. Then determine, over $\mathbb{F}_5$, the multiplicity of $x=2$ as a root of $f(x)=x^4-3x^3+x^2+4$.

5. (Splitting field as fixed locus.) Prove that $\mathbb{F}_{p^n}$ is precisely the set of roots of $x^{p^n}-x$ in $\overline{\mathbb{F}_p}$, and that these p^n roots are all distinct. Deduce both the existence and the uniqueness (inside a fixed $\overline{\mathbb{F}_p}$) of the field with p^n elements. Where in the argument is separability of $x^{p^n}-x$ used?

Commutative-diagram exercises.

1. Let $\sigma:\mathbb{F}_{p^n}\to\mathbb{F}_{p^n}$ be the Frobenius $x\mapsto x^p$ and let $\iota:\mathbb{F}_p\hookrightarrow\mathbb{F}_{p^n}$ be the inclusion. Draw the square

$$\begin{array}{ccc} \mathbb{F}_p & \xrightarrow{\ \iota\ } & \mathbb{F}_{p^n} \\ {\scriptstyle \mathrm{id}}\downarrow & & \downarrow{\scriptstyle \sigma} \\ \mathbb{F}_p & \xrightarrow[\ \iota\ ]{} & \mathbb{F}_{p^n} \end{array}$$

and prove it commutes (i.e. σ restricts to the identity on the prime field). Explain why this exhibits σ as an $\mathbb{F}_p$-algebra automorphism.

2. For $m \mid n$, let σ be the Frobenius on $\mathbb{F}_{p^n}$. Consider

$$\begin{array}{ccc} \mathbb{F}_{p^n} & \xrightarrow{\sigma^m} & \mathbb{F}_{p^n} \\ {\scriptstyle\subseteq}\big\downarrow & & \big\downarrow{\scriptstyle\subseteq} \\ \overline{\mathbb{F}_p} & \xrightarrow[x\mapsto x^{p^m}]{} & \overline{\mathbb{F}_p} \end{array}$$

Show the diagram commutes, and prove that the fixed field of σ^m on $\mathbb{F}_{p^n}$ equals $\mathbb{F}_{p^m}$. Conclude $\mathbb{F}_{p^m}$ is the unique subfield of $\mathbb{F}_{p^n}$ of degree m over $\mathbb{F}_p$.

3. Let F have characteristic p and let $\alpha \in \overline{F}$, $\alpha \notin F$, be purely inseparable over F with $\alpha^p = a \in F$. Let $K = F(\alpha)$ and consider the Frobenius maps making the square

$$\begin{array}{ccc} F & \xrightarrow{\subseteq} & K \\ {\scriptstyle x\mapsto x^p}\big\downarrow & & \big\downarrow{\scriptstyle x\mapsto x^p} \\ F & \xrightarrow[\subseteq]{} & K \end{array}$$

Show this commutes, and use it to prove $K^p \subseteq F$, hence $[K : F] = p$. Why does this force $m_{\alpha,F}(x) = x^p - a$?

4. Let E be the splitting field of $x^{p^n} - x$ over $\mathbb{F}_p$ and let $\varphi : E \to E$ be the Frobenius. Given a tower $\mathbb{F}_p \subseteq \mathbb{F}_{p^d} \subseteq E$ with $d \mid n$, fill in and prove commutativity of

$$\begin{array}{ccc} \mathbb{F}_{p^d} & \xrightarrow{\subseteq} & E \\ {\scriptstyle\varphi^d}\big\downarrow & & \big\downarrow{\scriptstyle\varphi^d} \\ \mathbb{F}_{p^d} & \xrightarrow[\subseteq]{} & E \end{array}$$

where the left arrow is the identity on $\mathbb{F}_{p^d}$. Explain how this realizes $\mathrm{Aut}(E/\mathbb{F}_p)$ as the cyclic group $\langle\varphi\rangle$ of order n, with $\mathrm{Aut}(E/\mathbb{F}_{p^d}) = \langle\varphi^d\rangle$.

5. Let $F = \mathbb{F}_p(t)$ and $K = F(t^{1/p})$, a purely inseparable extension. Writing $\beta = t^{1/p}$, show there is exactly one F-algebra homomorphism $K \to \overline{F}$ by completing

$$\begin{array}{ccc} F & \xrightarrow{\subseteq} & K \\ & {\scriptstyle\subseteq}\searrow & \big\downarrow{\scriptstyle\exists!\,\psi} \\ & & \overline{F} \end{array}$$

Prove ψ must send $\beta \mapsto \beta$ because $x^p - t = (x - \beta)^p$ has β as its only root. Contrast this with the separable case, where the number of such extensions equals the number of distinct roots of $m_{\beta,F}(x)$.

13.6 Cyclotomic Polynomials and Extensions

Roots of unity and the group μ_n

Fix a positive integer n and work inside an algebraic closure $\overline{\mathbb{Q}}$ (or, more generally, inside $\overline{F}$ for a field F whose characteristic does not divide n). An element ζ with $\zeta^n = 1$ is an *n-th root of unity*. The set of all such elements is

$$\mu_n = \{\, \zeta \in \overline{\mathbb{Q}} : \zeta^n = 1 \,\},$$

the set of roots of $x^n - 1$. Since $x^n - 1$ and its derivative nx^{n-1} are coprime when $\mathrm{char}\,\overline{\mathbb{Q}} \nmid n$, the polynomial $x^n - 1$ is separable and has exactly n distinct roots, so $|\mu_n| = n$.

Proposition 13.6.1 (μ_n is cyclic)**.** *The set μ_n is a subgroup of the multiplicative group $\overline{\mathbb{Q}}^\times$, and it is cyclic of order n. In $\mathbb{C}$ one has*

$$\mu_n = \{\, e^{2\pi i k/n} : 0 \le k \le n-1 \,\},$$

and $\mu_n = \langle e^{2\pi i/n} \rangle$.

Remark 13.6.1. μ_n is a finite subgroup of the multiplicative group of a field; every finite subgroup of $F^\times$ is cyclic, which re-proves cyclicity without reference to $\mathbb{C}$. Thus $\mu_n \cong \mathbb{Z}/n\mathbb{Z}$ as abelian groups.

Definition 13.6.2. A generator of the cyclic group μ_n is a *primitive n-th root of unity*; we write a fixed choice as ζ_n. In $\mathbb{C}$ we take $\zeta_n = e^{2\pi i/n}$. An element ζ_n^a is primitive (i.e. has order exactly n) if and only if $\gcd(a,n) = 1$, so the number of primitive n-th roots of unity is $\varphi(n)$.

The picture to keep in mind is that μ_n sits as the vertices of a regular n-gon on the unit circle, with the primitive roots being exactly those vertices that, starting from 1 and stepping by that root, sweep out all n vertices.

Worked Example 13.6.3 (Listing μ_n and its generators for small n)**.** For $n = 1, 2, 3, 4, 6$ list $\mu_n \subset \mathbb{C}$ and identify the primitive roots.

Recognition. Use $\mu_n = \{\, e^{2\pi i k/n} \,\}$; primitive roots are the ζ_n^a with $\gcd(a,n) = 1$, and there are $\varphi(n)$ of them.

Solution. $\mu_1 = \{\, 1 \,\}$ (primitive: 1). $\mu_2 = \{\, 1, -1 \,\}$ (primitive: -1; $\varphi(2) = 1$). $\mu_3 = \{\, 1, \omega, \omega^2 \,\}$ with $\omega = e^{2\pi i/3} = \frac{-1+\sqrt{-3}}{2}$ (primitive: ω, ω^2; $\varphi(3) = 2$). $\mu_4 = \{\, 1, i, -1, -i \,\}$ (primitive: $i, -i$; $\varphi(4) = 2$). $\mu_6 = \{\, \pm 1, \pm\omega, \pm\omega^2 \,\}$ with primitive roots $e^{\pm\pi i/3} = \frac{1\pm\sqrt{-3}}{2}$ (so $\varphi(6) = 2$). Sanity check: in each case $\#\{\text{primitive}\} = \varphi(n)$, and $1 + \varphi(2) + \varphi(3) + \varphi(4) + \varphi(6)$ correctly counts $1, 1, 2, 2, 2$.

Worked Example 13.6.4 (Which powers of ζ_{12} are primitive)**.** Inside $\mu_{12} = \langle \zeta_{12} \rangle$, determine which ζ_{12}^a are primitive 12-th roots of unity, and identify the order of ζ_{12}^8.

Recognition. ζ_{12}^a has order $12/\gcd(a,12)$; it is primitive of order 12 iff $\gcd(a,12) = 1$.

Solution. The units mod 12 are $a \in \{\, 1, 5, 7, 11 \,\}$, so the primitive 12-th roots are $\zeta_{12}, \zeta_{12}^5, \zeta_{12}^7, \zeta_{12}^{11}$, and $\varphi(12) = 4$. For $a = 8$: $\gcd(8,12) = 4$, so ζ_{12}^8 has order $12/4 = 3$, i.e. it is a primitive cube root of unity. Sanity check: $(\zeta_{12}^8)^3 = \zeta_{12}^{24} = 1$ and $(\zeta_{12}^8)^1 = \zeta_{12}^8 \neq 1$, confirming order 3.

The cyclotomic polynomial $\Phi_n(x)$

Definition 13.6.5. The *n-th cyclotomic polynomial* is the monic polynomial whose roots are exactly the primitive n-th roots of unity:

$$\Phi_n(x) = \prod_{\substack{1 \le a \le n \\ \gcd(a,n)=1}} \left(x - \zeta_n^a\right) = \prod_{\zeta \text{ primitive}} (x - \zeta).$$

Its degree is the number of primitive n-th roots of unity, namely $\deg \Phi_n = \varphi(n)$.

Grouping the n roots of $x^n - 1$ according to their exact order partitions μ_n into the sets of primitive d-th roots for each divisor $d \mid n$. This is the engine behind every computation in the section.

Theorem 13.6.6 (factorization of $x^n - 1$)**.** *For every $n \ge 1$,*

$$x^n - 1 = \prod_{d \mid n} \Phi_d(x).$$

Consequently, taking degrees, $n = \sum_{d \mid n} \varphi(d)$.

This product formula doubles as a recursion: knowing Φ_d for all proper divisors $d \mid n$ lets us recover Φ_n by division,

$$\Phi_n(x) = \frac{x^n - 1}{\prod_{\substack{d \mid n \\ d < n}} \Phi_d(x)}.$$

Theorem 13.6.7 (integer coefficients)**.** *For every $n \geq 1$, $\Phi_n(x) \in \mathbb{Z}[x]$; it is a monic polynomial of degree $\varphi(n)$ with integer coefficients.*

Sketch. Induct on n using the recursion. For $n = 1$, $\Phi_1(x) = x - 1 \in \mathbb{Z}[x]$. For the inductive step, $g(x) = \prod_{d|n,\, d<n} \Phi_d(x)$ is monic in $\mathbb{Z}[x]$, and it divides $x^n - 1$ in $\mathbb{C}[x]$; division of one monic integer polynomial by another monic integer polynomial yields a quotient in $\mathbb{Z}[x]$ (the division algorithm stays inside $\mathbb{Z}[x]$ when the divisor is monic). Hence $\Phi_n(x) = (x^n - 1)/g(x) \in \mathbb{Z}[x]$. □

Worked Example 13.6.8 (Building Φ_n by the divisor recursion, $n \leq 6$)**.** Compute $\Phi_1, \ldots, \Phi_6$ from $x^n - 1 = \prod_{d|n} \Phi_d(x)$.

Recognition. Apply $\Phi_n = (x^n - 1)/\prod_{d|n,\, d<n} \Phi_d$ in increasing n.

Solution. $\Phi_1 = x - 1$. From $x^2 - 1 = \Phi_1\Phi_2$: $\Phi_2 = \frac{x^2-1}{x-1} = x + 1$. From $x^3 - 1 = \Phi_1\Phi_3$: $\Phi_3 = \frac{x^3-1}{x-1} = x^2 + x + 1$. From $x^4 - 1 = \Phi_1\Phi_2\Phi_4$: $\Phi_4 = \frac{x^4-1}{(x-1)(x+1)} = \frac{x^4-1}{x^2-1} = x^2 + 1$. From $x^5 - 1 = \Phi_1\Phi_5$: $\Phi_5 = x^4 + x^3 + x^2 + x + 1$. From $x^6 - 1 = \Phi_1\Phi_2\Phi_3\Phi_6$: $\Phi_6 = \dfrac{x^6 - 1}{(x-1)(x+1)(x^2+x+1)} = \dfrac{x^6 - 1}{(x^2-1)(x^2+x+1)} = x^2 - x + 1$. Sanity check on degrees: $\varphi(1, 2, 3, 4, 5, 6) = 1, 1, 2, 2, 4, 2$, matching the degrees obtained; and $\sum_{d|6} \varphi(d) = \varphi(1) + \varphi(2) + \varphi(3) + \varphi(6) = 1 + 1 + 2 + 2 = 6$.

Worked Example 13.6.9 (The prime-power formula Φ_{p^k})**.** Show $\Phi_p(x) = 1 + x + \cdots + x^{p-1}$ for p prime, and more generally $\Phi_{p^k}(x) = \Phi_p\big(x^{p^{k-1}}\big) = 1 + x^{p^{k-1}} + x^{2p^{k-1}} + \cdots + x^{(p-1)p^{k-1}}$.

Recognition. The only divisors of p^k are $1, p, \ldots, p^k$, so the recursion telescopes.

Solution. For $n = p$ prime the proper divisors are just $d = 1$, so $\Phi_p(x) = \frac{x^p-1}{x-1} = 1 + x + \cdots + x^{p-1}$. For $n = p^k$, the proper divisors are $1, p, \ldots, p^{k-1}$, and $\prod_{j=0}^{k-1} \Phi_{p^j}(x) = x^{p^{k-1}} - 1$ (telescoping product of the Φ_{p^j} gives $x^{p^{k-1}} - 1$). Hence

$$\Phi_{p^k}(x) = \frac{x^{p^k} - 1}{x^{p^{k-1}} - 1} = \frac{y^p - 1}{y - 1} = 1 + y + \cdots + y^{p-1}, \qquad y = x^{p^{k-1}},$$

which is the claimed formula. Sanity check ($p = 2, k = 3$): $\Phi_8(x) = \Phi_2(x^4) = x^4 + 1$, and indeed $\deg \Phi_8 = \varphi(8) = 4$. Sanity check ($p = 3, k = 2$): $\Phi_9(x) = \Phi_3(x^3) = x^6 + x^3 + 1$, degree $\varphi(9) = 6$.

Worked Example 13.6.10 (A nontrivial value: Φ_{12} and a check at $x = 1$)**.** Compute $\Phi_{12}(x)$ and verify $\Phi_n(1)$ for $n > 1$ equals p if $n = p^k$ is a prime power and 1 otherwise.

Recognition. Use $\Phi_{12} = (x^{12} - 1)/\prod_{d|12,\, d<12} \Phi_d$, or the rules $\Phi_{2m}(x) = \Phi_m(-x)$ for odd $m > 1$ and $\Phi_{2m}(x) = \Phi_m(x^2)$ for even m, which give $\Phi_{12}(x) = \Phi_6(x^2) = \Phi_3(-x^2)$.

Solution. The proper divisors of 12 are $1, 2, 3, 4, 6$ with product $\Phi_1\Phi_2\Phi_3\Phi_4\Phi_6 = (x^6 - 1)(x^2 + 1)$ (degree $6 + 2 = 8$). Then

$$\Phi_{12}(x) = \frac{x^{12} - 1}{(x^6 - 1)(x^2 + 1)} = \frac{x^6 + 1}{x^2 + 1} = x^4 - x^2 + 1,$$

of degree $\varphi(12) = 4$. Sanity check at $x = 1$: $\Phi_{12}(1) = 1 - 1 + 1 = 1$, consistent with 12 not a prime power; whereas $\Phi_8(1) = 1^4 + 1 = 2 = p$ and $\Phi_9(1) = 1 + 1 + 1 = 3 = p$ for the prime powers $8 = 2^3$, $9 = 3^2$.

Irreducibility over $\mathbb{Q}$ and the degree of $\mathbb{Q}(\zeta_n)$

Theorem 13.6.11 (irreducibility of Φ_n)**.** *For every $n \geq 1$ the cyclotomic polynomial $\Phi_n(x)$ is irreducible over $\mathbb{Q}$. Equivalently, $\Phi_n(x)$ is the minimal polynomial over $\mathbb{Q}$ of any primitive n-th root of unity: $m_{\zeta_n,\mathbb{Q}}(x) = \Phi_n(x)$.*

Idea. By Gauss's Lemma it suffices to show Φ_n is irreducible in $\mathbb{Z}[x]$. Suppose $\Phi_n = fg$ with f the (monic, integral) minimal polynomial of a fixed primitive root ζ. One shows that for every prime $p \nmid n$, if ζ is a root of f then ζ^p is again a root of f (using that $f(x^p) \equiv f(x)^p \pmod p$, the p-th power map being a ring homomorphism in characteristic p that fixes $\mathbb{F}_p$, so $f(\zeta^p) \equiv f(\zeta)^p \equiv 0$ forces a repeated root unless ζ^p is a root of f). Iterating, every ζ^a with $\gcd(a, n) = 1$ is a root of f, so f has all $\varphi(n)$ primitive roots; thus $f = \Phi_n$ and g is a unit. □

Definition 13.6.12. The field $\mathbb{Q}(\zeta_n)$ obtained by adjoining a primitive n-th root of unity to $\mathbb{Q}$ is the *cyclotomic field* of n-th roots of unity.

Corollary 13.6.13 (degree of the cyclotomic field)**.** $[\mathbb{Q}(\zeta_n):\mathbb{Q}] = \deg \Phi_n = \varphi(n)$*, with* $\mathbb{Q}$*-basis*

$$\{\,1, \zeta_n, \zeta_n^2, \ldots, \zeta_n^{\varphi(n)-1}\,\}.$$

The field $\mathbb{Q}(\zeta_n)$ is the splitting field of $x^n - 1$ over $\mathbb{Q}$ (all of μ_n lies in the cyclic group $\langle \zeta_n \rangle$), so it is in particular a normal, separable extension of $\mathbb{Q}$.

Worked Example 13.6.14 (Degree of $\mathbb{Q}(\zeta_5)$ and a basis)**.** Find $[\mathbb{Q}(\zeta_5):\mathbb{Q}]$, the minimal polynomial of ζ_5, and express ζ_5^4 in the standard basis.

Recognition. Corollary: $[\mathbb{Q}(\zeta_5):\mathbb{Q}] = \varphi(5)$ and $m_{\zeta_5,\mathbb{Q}} = \Phi_5$; reduce higher powers via $\Phi_5(\zeta_5) = 0$.

Solution. $\varphi(5) = 4$, so $[\mathbb{Q}(\zeta_5):\mathbb{Q}] = 4$ with $m_{\zeta_5,\mathbb{Q}}(x) = \Phi_5(x) = x^4 + x^3 + x^2 + x + 1$ and basis $\{\,1, \zeta_5, \zeta_5^2, \zeta_5^3\,\}$. Although ζ_5^4 would naively be the fourth basis vector, the relation $\Phi_5(\zeta_5) = 0$ gives $\zeta_5^4 = -1 - \zeta_5 - \zeta_5^2 - \zeta_5^3$, already in the 4-dimensional standard basis. Sanity check: multiplying that relation by ζ_5 and using $\zeta_5^5 = 1$ returns $1 = -\zeta_5 - \zeta_5^2 - \zeta_5^3 - \zeta_5^4$, the same relation, confirming consistency.

Worked Example 13.6.15 ($\mathbb{Q}(\zeta_3)$ as a quadratic field)**.** Identify $\mathbb{Q}(\zeta_3)$ explicitly and compute its degree.

Recognition. $\zeta_3 = \omega$ has minimal polynomial $\Phi_3(x) = x^2 + x + 1$, degree $\varphi(3) = 2$.

Solution. Since $\omega = \frac{-1+\sqrt{-3}}{2}$, we get $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, an imaginary quadratic field, and $[\mathbb{Q}(\zeta_3):\mathbb{Q}] = 2 = \varphi(3)$. Sanity check: ω satisfies $x^2 + x + 1 = 0$, i.e. $2\omega + 1 = \sqrt{-3}$, so $\sqrt{-3} \in \mathbb{Q}(\zeta_3)$ and conversely $\omega = \frac{-1+\sqrt{-3}}{2} \in \mathbb{Q}(\sqrt{-3})$; the two fields coincide. Likewise $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$ with $[\mathbb{Q}(i):\mathbb{Q}] = 2 = \varphi(4)$.

Worked Example 13.6.16 (A tower inside a cyclotomic field: $\mathbb{Q} \subset \mathbb{Q}(\sqrt{5}) \subset \mathbb{Q}(\zeta_5)$)**.** Show $\mathbb{Q}(\sqrt{5})$ is the unique quadratic subfield of $\mathbb{Q}(\zeta_5)$ and verify the tower degrees multiply.

Recognition. $[\mathbb{Q}(\zeta_5):\mathbb{Q}] = 4$; by the tower law any intermediate field E has $[E:\mathbb{Q}] \mid 4$. The Gauss period $\zeta_5 + \zeta_5^4$ generates a quadratic subfield.

Solution. Put $\eta = \zeta_5 + \zeta_5^{-1} = 2\cos(2\pi/5)$. From $\Phi_5(\zeta_5) = 0$, dividing by ζ_5^2 gives $\zeta_5^2 + \zeta_5^{-2} + \zeta_5 + \zeta_5^{-1} + 1 = 0$, i.e. $(\eta^2 - 2) + \eta + 1 = 0$, so $\eta^2 + \eta - 1 = 0$ and $\eta = \frac{-1+\sqrt{5}}{2}$. Hence $\mathbb{Q}(\eta) = \mathbb{Q}(\sqrt{5})$, with $[\mathbb{Q}(\sqrt{5}):\mathbb{Q}] = 2$. It is the only quadratic subfield: $\mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q}) \cong (\mathbb{Z}/5\mathbb{Z})^\times$ is cyclic of order 4 (generated by the class of 2; see Chapter 14), so it has exactly one subgroup of index 2, and by the Galois correspondence exactly one subfield of degree 2 over $\mathbb{Q}$. Then

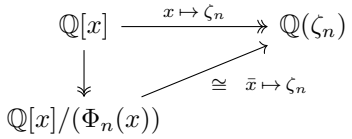
$$[\mathbb{Q}(\zeta_5):\mathbb{Q}] = [\mathbb{Q}(\zeta_5):\mathbb{Q}(\sqrt{5})] \cdot [\mathbb{Q}(\sqrt{5}):\mathbb{Q}] = 2 \cdot 2 = 4.$$

Sanity check: the intermediate degree 2 correctly divides 4, and ζ_5 is a root of $x^2 - \eta x + 1$ over $\mathbb{Q}(\sqrt{5})$ (since $\zeta_5 + \zeta_5^{-1} = \eta$, $\zeta_5 \cdot \zeta_5^{-1} = 1$), a genuine quadratic, confirming $[\mathbb{Q}(\zeta_5):\mathbb{Q}(\sqrt{5})] = 2$.

Worked Example 13.6.17 (Compositum of cyclotomic fields)**.** Compute $[\mathbb{Q}(\zeta_3, \zeta_4):\mathbb{Q}]$ and identify $\mathbb{Q}(\zeta_3, \zeta_4)$ as a single cyclotomic field.

Recognition. Use $\mathbb{Q}(\zeta_m, \zeta_n) = \mathbb{Q}(\zeta_{\mathrm{lcm}(m,n)})$ and, when $\gcd(m,n) = 1$, multiplicativity $\varphi(mn) = \varphi(m)\varphi(n)$.

Solution. Since $\gcd(3,4) = 1$, $\mathrm{lcm}(3,4) = 12$ and $\zeta_3\zeta_4$ is a primitive 12-th root, so $\mathbb{Q}(\zeta_3, \zeta_4) = \mathbb{Q}(\zeta_{12})$. Then $[\mathbb{Q}(\zeta_{12}):\mathbb{Q}] = \varphi(12) = \varphi(3)\varphi(4) = 2 \cdot 2 = 4$. Sanity check: $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$ are distinct quadratic fields, so their compositum has degree $2 \cdot 2 = 4$ over $\mathbb{Q}$ (the two square roots $\sqrt{-3}, i$ are independent), matching $\varphi(12) = 4$; note $\sqrt{3} = \sqrt{-3}/i \in \mathbb{Q}(\zeta_{12})$ as well.



Worked Example 13.6.18 (When ζ_n generates the same field for different n)**.** Explain why $\mathbb{Q}(\zeta_n) = \mathbb{Q}(\zeta_{2n})$ when n is odd, illustrated by $n = 3$.

Recognition. For n odd, $\varphi(2n) = \varphi(2)\varphi(n) = \varphi(n)$, and $-\zeta_n$ is a primitive $2n$-th root of unity.

Solution. If n is odd then $\gcd(2,n) = 1$, so $\varphi(2n) = \varphi(n)$, hence $[\mathbb{Q}(\zeta_{2n}):\mathbb{Q}] = [\mathbb{Q}(\zeta_n):\mathbb{Q}]$. Moreover $-\zeta_n$ has order $\mathrm{lcm}(2,n) = 2n$, so $\zeta_{2n} \in \langle -\zeta_n \rangle \subseteq \mathbb{Q}(\zeta_n)$ and the fields coincide. For $n = 3$: $\mathbb{Q}(\zeta_6) = \mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, both of degree 2. Sanity check: $\Phi_6(x) = x^2 - x + 1$ and $\Phi_3(x) = x^2 + x + 1$ satisfy $\Phi_6(x) = \Phi_3(-x)$, confirming $\zeta_6 = -\zeta_3^k$ and equality of fields.

Commutative diagrams

Adjoining ζ_n as a quotient of $\mathbb{Q}[x]$ (the evaluation map). Adjoining a primitive root realizes $\mathbb{Q}(\zeta_n)$ as a quotient of the polynomial ring by the irreducible Φ_n:

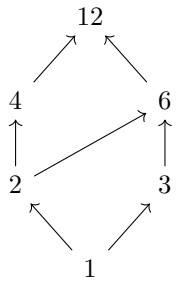
The evaluation homomorphism $f(x) \mapsto f(\zeta_n)$ has kernel (Φ_n) because $\Phi_n = m_{\zeta_n,\mathbb{Q}}$ is irreducible, so the induced map is an isomorphism onto $\mathbb{Q}(\zeta_n)$, of dimension $\varphi(n)$ over $\mathbb{Q}$.

Diagram explanation. Objects: Three nodes: the polynomial ring $\mathbb{Q}[x]$ (upper left), the cyclotomic field $\mathbb{Q}(\zeta_n)$ (upper right), and the quotient ring $\mathbb{Q}[x]/(\Phi_n(x))$ (lower left). All three are $\mathbb{Q}$-algebras; the quotient is a field because Φ_n is irreducible over $\mathbb{Q}$.

Arrows: The top horizontal arrow is the evaluation homomorphism $\mathrm{ev}_{\zeta_n} : f(x) \mapsto f(\zeta_n)$, a surjective $\mathbb{Q}$-algebra map onto $\mathbb{Q}(\zeta_n)$. The left vertical arrow is the canonical quotient projection $\pi\colon \mathbb{Q}[x] \twoheadrightarrow \mathbb{Q}[x]/(\Phi_n(x))$, sending f to its residue class $\bar{f}$; it is surjective by construction. The diagonal arrow is the induced isomorphism $\bar{\varphi}\colon \mathbb{Q}[x]/(\Phi_n(x)) \xrightarrow{\sim} \mathbb{Q}(\zeta_n)$, $\bar{x} \mapsto \zeta_n$.

What commutes: The triangle commutes: $\bar{\varphi} \circ \pi = \mathrm{ev}_{\zeta_n}$, i.e. evaluating f at ζ_n equals first reducing mod Φ_n then applying $\bar{\varphi}$.

Why it commutes: Take $f(x) \in \mathbb{Q}[x]$. Along the top: $f \mapsto f(\zeta_n)$. Along the left-then-diagonal: $f \mapsto \bar{f} \mapsto \bar{\varphi}(\bar{f}) = f(\zeta_n)$ (since $\bar{\varphi}$ is defined by $\bar{x} \mapsto \zeta_n$, it evaluates residue classes at ζ_n). Well-definedness of $\bar{\varphi}$: if $f \equiv g \pmod{\Phi_n}$, then $f - g = \Phi_n \cdot h$, so $f(\zeta_n) - g(\zeta_n) = \Phi_n(\zeta_n)h(\zeta_n) = 0$ because ζ_n is a root of Φ_n. Thus different coset representatives give the same value, and $\bar{\varphi}$ is well-defined.



Why this matters here: This is the First Isomorphism Theorem applied to the evaluation map. It identifies $\mathbb{Q}(\zeta_n)$ concretely as $\mathbb{Q}[x]/(\Phi_n)$, which simultaneously proves $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \deg \Phi_n = \varphi(n)$ and gives the explicit $\mathbb{Q}$-basis $\{1, \zeta_n, \ldots, \zeta_n^{\varphi(n)-1}\}$.

Concrete example: For $n = 5$: $\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$, and $\bar{\varphi}\colon \mathbb{Q}[x]/(x^4 + x^3 + x^2 + x + 1) \xrightarrow{\sim} \mathbb{Q}(\zeta_5)$, $\bar{x} \mapsto \zeta_5$. The residue $\bar{x}^4 = -1 - \bar{x} - \bar{x}^2 - \bar{x}^3$ maps to $\zeta_5^4 = -1 - \zeta_5 - \zeta_5^2 - \zeta_5^3$.

Common pitfall: Students often treat the diagonal isomorphism as the same map as the evaluation arrow rather than a *distinct* induced map. The top arrow goes from $\mathbb{Q}[x]$ (not the quotient), and the diagonal arrow is the unique map through the quotient; without first checking $\ker(\mathrm{ev}_{\zeta_n}) = (\Phi_n)$, there is no guarantee the diagonal map is well-defined or injective.

Takeaway: The point of this diagram is that $\mathbb{Q}(\zeta_n)$ is not merely abstractly isomorphic to $\mathbb{Q}[x]/(\Phi_n)$ but is *the* quotient forced by the First Isomorphism Theorem once you know the evaluation kernel is exactly the ideal (Φ_n).

The divisor diagram $x^n - 1 = \prod_{d|n} \Phi_d$ for $n = 12$. Each divisor $d \mid n$ contributes the factor Φ_d, and the lattice of divisors organizes the factorization. For $n = 12$:

$$x^{12} - 1 = \Phi_1\Phi_2\Phi_3\Phi_4\Phi_6\Phi_{12}.$$

Reading the divisor lattice top-down, the degrees add: $\sum_{d|12} \varphi(d) = 1 + 1 + 2 + 2 + 2 + 4 = 12 = \deg(x^{12} - 1)$.

The divisor lattice of 12 governs the factorization of $x^{12} - 1$, but the *subfield* lattice of $\mathbb{Q}(\zeta_{12})$ is a different object. Since $\varphi(12) = 4$ and $\zeta_{12} = e^{2\pi i/12} = \frac{\sqrt{3}}{2} + \frac{i}{2}$ gives $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(i, \sqrt{3})$, the Galois group is Klein four,

so there are *three* quadratic subfields: $\mathbb{Q}(i) = \mathbb{Q}(\zeta_4)$, $\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$, and $\mathbb{Q}(\sqrt{3})$. (Note $i \cdot \sqrt{3} = \sqrt{-3}$, so any two of these three square roots generate the third.) Each covering edge has relative degree 2:

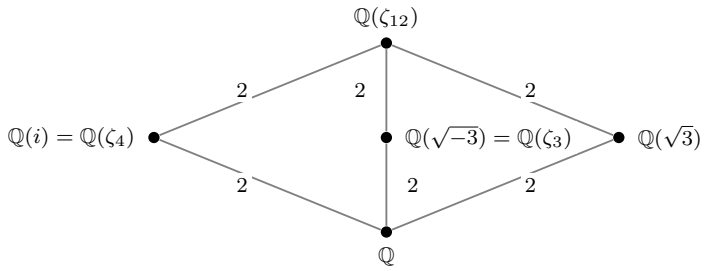


Diagram explanation. Objects: Five nodes arranged as a diamond with an extra middle level: the base field $\mathbb{Q}$ (bottom), three intermediate quadratic subfields $\mathbb{Q}(i) = \mathbb{Q}(\zeta_4)$, $\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$, and $\mathbb{Q}(\sqrt{3})$ (middle row), and the top field $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(i, \sqrt{3})$ (top). All are subfields of $\mathbb{C}$ and finite extensions of $\mathbb{Q}$.

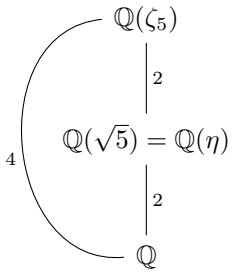
Arrows: Each edge represents an inclusion of fields (a field extension of degree 2). The six edges divide into two levels: three lower edges from $\mathbb{Q}$ up to each quadratic subfield, and three upper edges from each quadratic subfield up to $\mathbb{Q}(\zeta_{12})$. Every edge carries degree label 2, expressing that each extension is quadratic.

What commutes: The tower law: for each quadratic subfield E, $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}] = [\mathbb{Q}(\zeta_{12}) : E] \cdot [E : \mathbb{Q}] = 2 \cdot 2 = 4$. All three paths from $\mathbb{Q}$ to $\mathbb{Q}(\zeta_{12})$ through a middle node give the same total degree 4.

Why it commutes: Since $\varphi(12) = 4$ and $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(i, \sqrt{3})$, the Galois group $\mathrm{Gal}(\mathbb{Q}(\zeta_{12})/\mathbb{Q}) \cong (\mathbb{Z}/12\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ (Klein four), which has exactly three subgroups of index 2, each corresponding to one of the three quadratic subfields by the Galois correspondence. The degree product $2 \cdot 2 = 4$ follows from the tower law applied to any such subgroup.



Why this matters here: This diagram visually separates two distinct lattice structures: the divisor lattice of 12 (which organizes the factorization of $x^{12} - 1$) and the subfield lattice of $\mathbb{Q}(\zeta_{12})$ (which is controlled by the Galois group). The point made in the text is that these are *different* objects, and the subfield lattice has only three intermediate fields at level 2 (not six divisors).

Concrete example: The relation $i \cdot \sqrt{3} = \sqrt{-3}$ explains why knowing any two of i, $\sqrt{3}$, $\sqrt{-3}$ gives the third: $\mathbb{Q}(i, \sqrt{3})$ already contains $\sqrt{-3} = i\sqrt{3}$, and each pair of the three quadratic subfields generates $\mathbb{Q}(\zeta_{12})$ over $\mathbb{Q}$.

Common pitfall: Students confuse this subfield lattice with the divisor lattice of 12. The divisor lattice has six nodes $(1, 2, 3, 4, 6, 12)$ and represents factors Φ_d of $x^{12} - 1$; the subfield lattice shown here has five nodes and represents actual field extensions, organized by the Galois group, not by divisibility.

Takeaway: The point of this diagram is that $\mathbb{Q}(\zeta_{12})$ sits above *three* distinct quadratic subfields simultaneously, each reachable by a degree-2 step, reflecting the Klein-four Galois group rather than the richer divisor lattice of 12.

The tower $\mathbb{Q} \subset \mathbb{Q}(\sqrt{5}) \subset \mathbb{Q}(\zeta_5)$ with degrees. The Gauss period $\eta = \zeta_5 + \zeta_5^{-1}$ produces the quadratic subfield, and the tower law multiplies degrees:

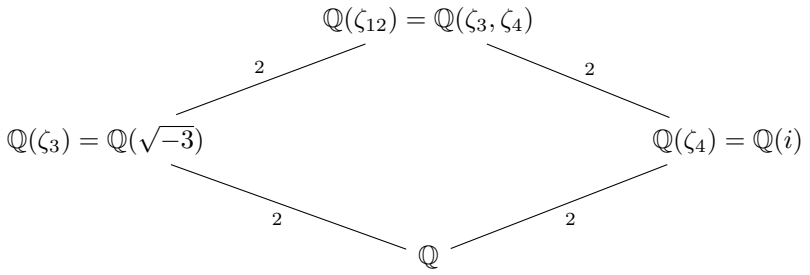
Here $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = [\mathbb{Q}(\zeta_5) : \mathbb{Q}(\sqrt{5})] \cdot [\mathbb{Q}(\sqrt{5}) : \mathbb{Q}] = 2 \cdot 2 = 4 = \varphi(5)$.

Diagram explanation. Objects: Three fields arranged in a vertical chain: $\mathbb{Q}$ at the bottom, the real quadratic field $\mathbb{Q}(\sqrt{5}) = \mathbb{Q}(\eta)$ (where $\eta = \zeta_5 + \zeta_5^{-1} = 2\cos(2\pi/5)$ is the Gauss period) in the middle, and the cyclotomic field $\mathbb{Q}(\zeta_5)$ at the top. All three are subfields of $\mathbb{C}$.

Arrows: The two short vertical dashes represent field inclusions with degree labels: $[\mathbb{Q}(\sqrt{5}) : \mathbb{Q}] = 2$ (lower dash) and $[\mathbb{Q}(\zeta_5) : \mathbb{Q}(\sqrt{5})] = 2$ (upper dash). The long curved arrow on the left records the composite degree $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = 4$ directly from base to top.

What commutes: The tower law: $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = [\mathbb{Q}(\zeta_5) : \mathbb{Q}(\sqrt{5})] \cdot [\mathbb{Q}(\sqrt{5}) : \mathbb{Q}] = 2 \cdot 2 = 4$. The two-step product on the right equals the direct degree on the left.

Why it commutes: The Gauss period $\eta = \zeta_5 + \zeta_5^{-1}$ satisfies $\eta^2 + \eta - 1 = 0$ (derived from $\Phi_5(\zeta_5) = 0$ by dividing by ζ_5^2), so $[\mathbb{Q}(\eta) : \mathbb{Q}] = 2$ and $\eta = \frac{-1+\sqrt{5}}{2} \in \mathbb{Q}(\sqrt{5})$. Then ζ_5 satisfies $x^2 - \eta x + 1 = 0$ over $\mathbb{Q}(\sqrt{5})$ (Vieta: $\zeta_5 + \zeta_5^{-1} = \eta$, $\zeta_5\zeta_5^{-1} = 1$), giving the upper degree 2. Multiplying: $2 \cdot 2 = 4 = \varphi(5)$.



Why this matters here: The diagram makes the intermediate Galois structure visible. Rather than citing $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = \varphi(5) = 4$ as a bare number, the tower shows *why* the degree factors as $2 \cdot 2$: there is a real quadratic subfield generated by the classical Gauss period, and adjoining ζ_5 over it is another quadratic step.

Concrete example: $\eta = \zeta_5 + \zeta_5^4 = 2\cos(72°) = \frac{-1+\sqrt{5}}{2} \approx 0.618$, so $\mathbb{Q}(\sqrt{5}) = \mathbb{Q}(\eta) \subset \mathbb{R}$, while $\mathbb{Q}(\zeta_5) \not\subset \mathbb{R}$; the upper quadratic step is genuinely complex.

Common pitfall: Students may think the bent arrow labelled 4 is an arrow in the opposite direction or a separate map. It is a single field inclusion $\mathbb{Q} \hookrightarrow \mathbb{Q}(\zeta_5)$ of degree 4, drawn bent solely to display the composite degree next to the diagram; it does not represent a fourth-degree polynomial or a new object.

Takeaway: The point of this diagram is that the degree-4 extension $\mathbb{Q}(\zeta_5)/\mathbb{Q}$ factors as two quadratic steps through the Gauss-period subfield $\mathbb{Q}(\sqrt{5})$, exhibiting the internal structure of the cyclotomic tower.

Compositum of $\mathbb{Q}(\zeta_3)$ and $\mathbb{Q}(\zeta_4)$ inside $\mathbb{Q}(\zeta_{12})$. Distinct quadratic cyclotomic fields meet only in $\mathbb{Q}$, and their compositum is again cyclotomic:

Since $\gcd(3, 4) = 1$, $\varphi(12) = \varphi(3)\varphi(4) = 4$, matching $[\mathbb{Q}(\zeta_3, \zeta_4) : \mathbb{Q}] = 4$ obtained by multiplying the two independent quadratic steps.

Diagram explanation. Objects: Four fields in a diamond: $\mathbb{Q}$ at the bottom, the two quadratic cyclotomic fields $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$ on the left and right at middle height, and the cyclotomic field $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(\zeta_3, \zeta_4)$ at the top. All four are subfields of $\mathbb{C}$.

Arrows: Each edge is a field inclusion. The two lower edges carry degree label 2: $[\mathbb{Q}(\zeta_3) : \mathbb{Q}] = \varphi(3) = 2$ and $[\mathbb{Q}(\zeta_4) : \mathbb{Q}] = \varphi(4) = 2$. The two upper edges also carry degree 2: $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}(\zeta_3)] = 2$ and $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}(\zeta_4)] = 2$, since $\mathbb{Q}(\zeta_{12}) = \mathbb{Q}(\zeta_3, \zeta_4)$ is a degree-2 extension of each quadratic base.

What commutes: Both paths from $\mathbb{Q}$ to $\mathbb{Q}(\zeta_{12})$ through a middle node give total degree $2 \cdot 2 = 4 = \varphi(12)$: $[\mathbb{Q}(\zeta_{12}) : \mathbb{Q}] = [\mathbb{Q}(\zeta_{12}) : \mathbb{Q}(\zeta_3)] \cdot [\mathbb{Q}(\zeta_3) : \mathbb{Q}] = 2 \cdot 2$, and likewise through $\mathbb{Q}(\zeta_4)$.

Why it commutes: Because $\gcd(3, 4) = 1$, $\mathbb{Q}(\zeta_3) \cap \mathbb{Q}(\zeta_4) = \mathbb{Q}$ (the two quadratic subfields are distinct and intersect only at the base). By the compositum degree formula for linearly disjoint extensions, $[\mathbb{Q}(\zeta_3, \zeta_4) : \mathbb{Q}] = [\mathbb{Q}(\zeta_3) : \mathbb{Q}] \cdot [\mathbb{Q}(\zeta_4) : \mathbb{Q}] = 4$. The multiplicativity $\varphi(12) = \varphi(3)\varphi(4)$ is exactly this linear-disjointness statement at the level of degrees.

Why this matters here: The diagram encodes the compositum construction: two cyclotomic fields with coprime indices are linearly disjoint over $\mathbb{Q}$, so their join $\mathbb{Q}(\zeta_3, \zeta_4) = \mathbb{Q}(\zeta_{12})$ has the product degree. This justifies the identification $\mathbb{Q}(\zeta_m, \zeta_n) = \mathbb{Q}(\zeta_{\mathrm{lcm}(m,n)})$ and the multiplicativity of φ for coprime arguments.

Concrete example: The product $\zeta_3 \cdot \zeta_4$ has order $\mathrm{lcm}(3, 4) = 12$, so $\zeta_3\zeta_4$ is a primitive 12-th root of unity (namely ζ_{12}^7) and $\zeta_{12} = (\zeta_3\zeta_4)^7 \in \mathbb{Q}(\zeta_3, \zeta_4)$, confirming the top field is $\mathbb{Q}(\zeta_{12})$. Meanwhile $\sqrt{-3} = 2\zeta_3 + 1 = \zeta_3 - \zeta_3^{-1}$ and $i = \zeta_4$, and $\sqrt{-3}/i = \sqrt{3} \in \mathbb{Q}(\zeta_{12})$.

Common pitfall: Students sometimes assume that because both $\mathbb{Q}(\zeta_3)$ and $\mathbb{Q}(\zeta_4)$ are quadratic over $\mathbb{Q}$, their compositum has degree 2 (confusing join with meet). The correct degree is 4, not 2, precisely because the two quadratic extensions are *distinct* (they generate different square roots: $\sqrt{-3}$ vs. i) and hence linearly disjoint.

Takeaway: The point of this diagram is that two cyclotomic fields whose indices are coprime meet only at $\mathbb{Q}$, so their compositum has the product degree, which is the diagrammatic content of the identity $\varphi(mn) = \varphi(m)\varphi(n)$ for $\gcd(m, n) = 1$.

The Frobenius in the irreducibility proof. Over $\mathbb{F}_p$ with $p \nmid n$, reduction mod p intertwines a polynomial with the Frobenius $x \mapsto x^p$, which is what forces $\zeta \mapsto \zeta^p$ to preserve the set of roots of the minimal polynomial:

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\text{mod } p} & \mathbb{F}_p[x] \\ {\scriptstyle f \mapsto f(\zeta)}\downarrow & & \downarrow{\scriptstyle \bar{f} \mapsto \bar{f}(\bar{\zeta}^p) = \bar{f}(\bar{\zeta})^p} \\ \mathbb{Z}[\zeta] & \xrightarrow[a \mapsto \bar{a}^p]{} & \overline{\mathbb{F}_p} \end{array}$$

The relation $\bar{f}(x)^p = \bar{f}(x^p)$ in $\mathbb{F}_p[x]$ is exactly the statement that the p-power map is a ring homomorphism in characteristic p; pulling back, ζ a root of f implies ζ^p is a root of f, which iterated over all primes $p \nmid n$ delivers all $\varphi(n)$ primitive roots and hence the irreducibility of Φ_n.

Diagram explanation. Objects: Four nodes: the integer polynomial ring $\mathbb{Z}[x]$ (upper left), the polynomial ring over $\mathbb{F}_p$ (upper right), the ring $\mathbb{Z}[\zeta] \subset \overline{\mathbb{Q}}$ generated by the root of unity ζ (lower left), and the algebraic closure $\overline{\mathbb{F}_p}$ (lower right). The top row consists of polynomial rings; the bottom row consists of the rings in which they are evaluated.

Arrows: The top horizontal arrow is reduction mod p: $\mathbb{Z}[x] \to \mathbb{F}_p[x]$, $f \mapsto \bar{f}$ (coefficients reduced mod p). The left vertical arrow is evaluation: $f \mapsto f(\zeta) \in \mathbb{Z}[\zeta]$ at the fixed root of unity ζ. Fix a ring homomorphism $\mathbb{Z}[\zeta] \to \overline{\mathbb{F}_p}$, $a \mapsto \bar{a}$ (divide by a maximal ideal of $\mathbb{Z}[\zeta]$ containing p; the quotient is a finite field of characteristic p, which embeds in $\overline{\mathbb{F}_p}$); no such map exists on all of $\overline{\mathbb{Q}}$, where p is invertible. The bottom horizontal arrow is this reduction followed by the Frobenius, $a \mapsto \bar{a}^p$. The right vertical arrow is evaluation at $\bar{\zeta}^p$: $\bar{f} \mapsto \bar{f}(\bar{\zeta}^p) = \bar{f}(\bar{\zeta})^p$, using that $x \mapsto x^p$ is a ring map in characteristic p fixing $\mathbb{F}_p$.

What commutes: The square commutes: reducing f mod p and evaluating at $\bar{\zeta}^p$ gives the same result as evaluating f at ζ, reducing, and then applying Frobenius. Formally: $\overline{f(\zeta)}^p = \bar{f}(\bar{\zeta}^p)$ where $\bar{\zeta}$ is the image of ζ in $\overline{\mathbb{F}_p}$.

Why it commutes: In characteristic p, $(a + b)^p = a^p + b^p$ (Freshman's dream), so $\bar{f}(x)^p = \bar{f}(x^p)$ for any $\bar{f} \in \mathbb{F}_p[x]$. Therefore $\overline{f(\zeta)^p} = \overline{f(\zeta)}^p$ while $\bar{f}(\bar{\zeta}^p) = \bar{f}(\bar{\zeta})^p$; these coincide because $\overline{f(\zeta)} = \bar{f}(\bar{\zeta})$ (evaluation commutes with reduction).

Why this matters here: This is the key step in the irreducibility proof of Φ_n. If f is the minimal polynomial of a primitive root ζ over $\mathbb{Q}$ and $p \nmid n$, the diagram shows $\bar{f}(\bar{\zeta}) = 0$ implies $\bar{f}(\bar{\zeta}^p) = 0$ in $\overline{\mathbb{F}_p}$. Lifting back: $f(\zeta^p)$ must be 0 (no repeated roots since $p \nmid n$), so ζ^p is also a root of f. Iterating over all primes $p \nmid n$ forces every ζ^a with $\gcd(a, n) = 1$ into f, giving $f = \Phi_n$.

Concrete example: Take $n = 5$, $p = 2$, $\zeta = \zeta_5$. The minimal polynomial is $f = \Phi_5 = x^4 + x^3 + x^2 + x + 1$. Reducing mod 2: $\bar{f} = x^4 + x^3 + x^2 + x + 1 \in \mathbb{F}_2[x]$. The diagram gives $\bar{f}(\bar{\zeta}_5^2) = \bar{f}(\bar{\zeta}_5)^2 = 0$, so ζ_5^2 is also a root of Φ_5 mod 2, which is correct.

Common pitfall: Students sometimes think this diagram directly proves Φ_n is irreducible. It does not: it proves that *if* ζ is a root of the minimal polynomial f, then so is ζ^p for every prime $p \nmid n$. The irreducibility follows only after observing that iterating Frobenius over all such primes generates all $\varphi(n)$ primitive roots, forcing $\deg f = \varphi(n) = \deg \Phi_n$.

Takeaway: The point of this diagram is that reduction mod p intertwines evaluation with the Frobenius, turning the abstract statement "ζ^p is conjugate to ζ" into the concrete ring identity $\bar{f}(x)^p = \bar{f}(x^p)$ in characteristic p.

Exercises (from the text).

1. Suppose m and n are relatively prime positive integers. Let ζ_m be a primitive m^{th} root of unity and let ζ_n be a primitive n^{th} root of unity. Prove that $\zeta_m\zeta_n$ is a primitive mn^{th} root of unity.

2. Let ζ_n be a primitive n^{th} root of unity and let d be a divisor of n. Prove that ζ_n^d is a primitive $(n/d)^{\text{th}}$ root of unity.

3. Prove that if a field contains the nth roots of unity for n odd then it also contains the $2n^{\text{th}}$ roots of unity.

4. Prove that if $n = p^k m$ where p is a prime and m is relatively prime to p then there are precisely m distinct n^{th} roots of unity over a field of characteristic p.

5. Prove there are only a finite number of roots of unity in any finite extension K of $\mathbb{Q}$.

6. Prove that for n odd, $n > 1$, $\Phi_{2n}(x) = \Phi_n(-x)$.

7. Use the Möbius Inversion formula indicated in Section 14.3 to prove

$$\Phi_m(x) = \prod_{d|m} (x^d - 1)^{\mu(m/d)}.$$

8. Let ℓ be a prime and let $\Phi_\ell(x) = \dfrac{x^\ell - 1}{x - 1} = x^{\ell-1} + x^{\ell-2} + \cdots + x + 1 \in \mathbb{Z}[x]$ be the ℓth cyclotomic polynomial, which is irreducible over $\mathbb{Z}$ by Theorem 41. This exercise determines the factorization of $\Phi_\ell(x)$ modulo p for any prime p. Let ζ denote any fixed primitive ℓ^{th} root of unity.

   (a) Show that if $p = \ell$ then $\Phi_\ell(x) = (x-1)^{\ell-1} \in \mathbb{F}_\ell[x]$.

   (b) Suppose $p \neq \ell$ and let f denote the order of p mod ℓ, i.e., f is the smallest power of p with $p^f \equiv 1 \pmod{\ell}$. Use the fact that $\mathbb{F}_{p^n}^\times$ is a cyclic group to show that $n = f$ is the smallest power of p with $\zeta \in \mathbb{F}_{p^n}$. Conclude that the minimal polynomial of ζ over $\mathbb{F}_p$ has degree f.

   (c) Show that $\mathbb{F}_p(\zeta) = \mathbb{F}_p(\zeta^a)$ for any integer a not divisible by ℓ. [One inclusion is obvious. For the other, show that $\zeta = (\zeta^a)^b$ where b is the multiplicative inverse of a mod ℓ.] Conclude using (b) that, in $\mathbb{F}_p[x]$, $\Phi_\ell(x)$ is the product of $\frac{\ell-1}{f}$ distinct irreducible polynomials of degree f.

   (d) In particular, prove that, viewed in $\mathbb{F}_p[x]$, $\Phi_7(x) = x^6 + x^5 + \cdots + x + 1$ is the product of two irreducible cubics: $x^3 + x + 1$ and $x^3 + x^2 + 1$ for $p = 2$; is a product of three quadratics for $p = 6 \pmod 7$, a product of 2 irreducible cubics for $p = 2, 4 \pmod 7$, and is irreducible for $p = 3, 5 \pmod 7$.

9. Suppose A is an $n \times n$ matrix over $\mathbb{C}$ for which $A^k = I$ for some integer $k \geq 1$. Show that A can be diagonalized. Show that the matrix $A = \begin{pmatrix} 1 & \alpha \\ 0 & 1 \end{pmatrix}$ where α is an element of a field of characteristic p satisfies $A^p = I$ and cannot be diagonalized if $\alpha \neq 0$.

10. Let φ denote the Frobenius map $x \mapsto x^p$ on the finite field $\mathbb{F}_{p^n}$. Prove that φ gives an isomorphism of $\mathbb{F}_{p^n}$ to itself (such an isomorphism is called an *automorphism*). Prove that φ^n is the identity map but that no lower power of φ is the identity.

11. Let φ denote the Frobenius map $x \mapsto x^p$ on the finite field $\mathbb{F}_{p^n}$ as in the previous exercise. Determine the rational canonical form over $\mathbb{F}_p$ for φ considered as an $\mathbb{F}_p$-linear transformation of the n-dimensional $\mathbb{F}_p$-vector space $\mathbb{F}_{p^n}$.

12. Let φ denote the Frobenius map $x \mapsto x^p$ on the finite field $\mathbb{F}_{p^n}$ as in the previous exercise. Determine the Jordan canonical form (over a field containing all the eigenvalues) for φ considered as an $\mathbb{F}_p$-linear transformation of the n-dimensional $\mathbb{F}_p$-vector space $\mathbb{F}_{p^n}$.

13. (*Wedderburn's Theorem on Finite Division Rings*) This exercise outlines a proof (following Witt) of Wedderburn's Theorem that a finite division ring D is a field (i.e., is commutative).

   (a) Let Z denote the center of D (i.e., the elements of D which commute with every element of D). Prove that Z is a field containing $\mathbb{F}_p$ for some prime p. If $Z = \mathbb{F}_q$ prove that D has order q^n for some integer n [D is a vector space over Z].

   (b) The nonzero elements $D^\times$ of D form a multiplicative group. For any $x \in D^\times$ show that the elements of D which commute with x form a division ring which contains Z. Show that this division ring is of order q^m for some integer m and that $m < n$ if x is not an element of Z.

(c) Show that the class equation (Theorem 4.7) for the group $D^\times$ can be written as

$$q^n - 1 = (q-1) + \sum_{i=1}^{r} \frac{q^n - 1}{|C_{D^\times}(x_i)|}$$

where $x_1, x_2, \ldots, x_r$ are representatives of the distinct conjugacy classes in $D^\times$ not contained in the center of $D^\times$. Conclude from (b) that for each i, $|C_{D^\times}(x_i)| = q^{m_i} - 1$ for some $m_i < n$.

(d) Prove that since $\dfrac{q^n-1}{q^{m_i}-1}$ is an integer (namely, the index $|D^\times : C_{D^\times}(x_i)|$) then m_i divides n (cf. Exercise 4 of Section 5). Conclude that $\Phi_n(x)$ divides $\frac{x^n-1}{x^{m_i}-1}$ and hence that the integer $\Phi_n(q)$ divides $(q^n-1)/(q^{m_i}-1)$ for $i = 1, 2, \ldots, r$.

(e) Use parts (c) and (d) to imply that $\Phi_n(q) = \prod_{\zeta \text{ primitive}} (q - \zeta)$ divides $q-1$. Prove that $|q-\zeta| > q-1$ (complex absolute value) for any root of unity $\zeta \neq 1$ [note that 1 is the closest point on the unit circle in $\mathbb{C}$ to the point q on the real line]. Conclude that $n = 1$, i.e., that $D = Z$ is a field.

14. Given any monic polynomial $P(x) \in \mathbb{Z}[x]$ of degree at least one show that there are infinitely many distinct prime divisors of the integers

$$P(1), P(2), P(3), \ldots, P(n), \ldots.$$

[Suppose $p_1, p_2, \ldots, p_k$ are the only primes dividing the values $P(n)$, $n = 1, 2, \ldots$. Let N be an integer with $P(N) = a \neq 0$. Show that $Q(x) = a^{-1}P(N + ap_1p_2 \ldots p_k x)$ is an element of $\mathbb{Z}[x]$ and that $Q(n) \equiv 1 \pmod{p_1p_2 \ldots p_k}$ for $n = 1, 2, \ldots$. Conclude that there is some integer M such that $Q(M)$ has a prime factor different from $p_1, p_2, \ldots, p_k$ and hence that $P(N + ap_1p_2 \ldots p_k M)$ has a prime factor different from $p_1, p_2, \ldots, p_k$.]

15. Let p be an odd prime not dividing m and let $\Phi_m(x)$ be the mth cyclotomic polynomial. Suppose $a \in \mathbb{Z}$ satisfies $\Phi_m(a) \equiv 0 \pmod{p}$. Prove that a is relatively prime to p and that the order of a in $(\mathbb{Z}/p\mathbb{Z})^\times$ is precisely m. [Since

$$x^m - 1 = \prod_{d|m} \Phi_d(x) = \Phi_m(x) \prod_{\substack{d|m \\ d<m}} \Phi_d(x)$$

we see first that $a^m - 1 \equiv 0 \pmod{p}$ i.e., $a^m \equiv 1 \pmod{p}$. If the order of a mod p were less than m, then $a^d \equiv 1 \pmod{p}$ for some d dividing m, so then $\Phi_d(a) \equiv 0 \pmod{p}$ for some $d < m$, then $x^m - 1$ would have a as a multiple root mod p, a contradiction.]

16. Let $a \in \mathbb{Z}$. Show that if p is an odd prime dividing $\Phi_m(a)$ then either p divides m or $p \equiv 1 \pmod{m}$.

17. Prove there are infinitely many primes p with $p \equiv 1 \pmod{m}$.

Practice problems.

1. Compute the cyclotomic polynomial $\Phi_n(x)$ explicitly for each $n \in \{1, 2, 3, 4, 6, 8, 12\}$ by using the factorization $x^n - 1 = \prod_{d|n} \Phi_d(x)$ and polynomial division. Verify in each case that $\deg \Phi_n = \varphi(n)$.

2. Let $\zeta_5 = e^{2\pi i/5}$ be a primitive 5th root of unity. Write down the minimal polynomial $m_{\zeta_5,\mathbb{Q}}(x)$, state the degree $[\mathbb{Q}(\zeta_5) : \mathbb{Q}]$, and explain why $\{1, \zeta_5, \zeta_5^2, \zeta_5^3\}$ is a $\mathbb{Q}$-basis of $\mathbb{Q}(\zeta_5)$.

3. Using only the formula $\Phi_p(x) = 1 + x + \cdots + x^{p-1}$ for a prime p and the relation $\Phi_{p^k}(x) = \Phi_p\left(x^{p^{k-1}}\right)$, write out $\Phi_9(x)$, $\Phi_{25}(x)$, and $\Phi_{27}(x)$ in full. Confirm $\deg \Phi_{p^k} = p^{k-1}(p-1) = \varphi(p^k)$ in each case.

4. Show directly that the group μ_{12} of 12th roots of unity in $\mathbb{C}^\times$ is cyclic of order 12, and list all of its generators (the primitive 12th roots of unity). Check that the number of generators equals $\varphi(12)$.

5. For $n = 15$, compute $\Phi_{15}(x)$ from $\Phi_{15}(x) = \dfrac{(x^{15}-1)(x-1)}{(x^3-1)(x^5-1)}$, and verify that the resulting polynomial has integer coefficients of degree $\varphi(15) = 8$.

6. Determine the degree $[\mathbb{Q}(\zeta_n) : \mathbb{Q}]$ for $n = 7, 9, 16, 20$. For each n, decide whether $\mathbb{Q}(\zeta_n)$ contains a subfield of degree 2 over $\mathbb{Q}$, justifying your answer in terms of $\varphi(n)$.

7. Decide whether the regular n-gon is constructible by straightedge and compass for $n = 5, 7, 9, 15, 17$. For each, compute $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n)$ and state explicitly whether it is a power of 2, drawing the corresponding conclusion about constructibility of ζ_n.

8. Prove that $\zeta_3 = e^{2\pi i/3}$ satisfies $\zeta_3^2 + \zeta_3 + 1 = 0$, and use this to express $\mathbb{Q}(\zeta_3)$ concretely as $\mathbb{Q}(\sqrt{-3})$. Identify $[\mathbb{Q}(\zeta_3) : \mathbb{Q}]$ and exhibit the nontrivial element of $\mathrm{Aut}(\mathbb{Q}(\zeta_3)/\mathbb{Q})$ as a map permuting the primitive cube roots of unity.

9. Show that $\mathbb{Q}(\zeta_8)$ contains both $\sqrt{2}$ and i, and conclude that $\mathbb{Q}(\zeta_8) = \mathbb{Q}(\sqrt{2}, i)$. Compute $[\mathbb{Q}(\zeta_8) : \mathbb{Q}]$ two ways: as $\varphi(8)$, and as the degree of the tower $\mathbb{Q} \subset \mathbb{Q}(i) \subset \mathbb{Q}(i, \sqrt{2})$.

Additional exercises.

1. Let p be an odd prime. Using $\Phi_p(x) = 1 + x + \cdots + x^{p-1}$ and the substitution $x \mapsto x + 1$, prove that $\Phi_p(x)$ is irreducible over $\mathbb{Q}$ via Eisenstein's criterion at p. Conclude $[\mathbb{Q}(\zeta_p) : \mathbb{Q}] = p - 1$.

2. Prove that for every $n > 1$ the constant term of $\Phi_n(x)$ equals 1 (in particular $\Phi_p(0) = 1$ for a prime p, since $\Phi_p(x) = 1 + x + \cdots + x^{p-1}$). Show separately that $\Phi_p(1) = p$ for a prime p. (Hint: in the identity $x^n - 1 = \prod_{d \mid n} \Phi_d(x)$ the constant term of the left side is $-1 = \Phi_1(0) \prod_{d \mid n,\, d>1} \Phi_d(0)$; with $\Phi_1(0) = -1$, induct on the proper divisors $d \mid n$ to force $\Phi_n(0) = 1$.)

3. Show that the splitting field over $\mathbb{Q}$ of $x^{12} - 1$ is exactly $\mathbb{Q}(\zeta_{12})$, compute its degree over $\mathbb{Q}$, and verify $x^{12} - 1 = \Phi_1\Phi_2\Phi_3\Phi_4\Phi_6\Phi_{12}$ by multiplying out the right-hand side.

4. Let $q = p^f$ be a prime power and let n be a positive integer with $\gcd(n, p) = 1$. Prove that $x^n - 1$ is separable over $\mathbb{F}_q$ (i.e. has no repeated roots in $\overline{\mathbb{F}_q}$), and explain why $\mu_n \subset \overline{\mathbb{F}_q}^{\times}$ is cyclic of order n. Then determine the smallest f for which $\mathbb{F}_{p^f}$ contains all nth roots of unity, in terms of the order of p modulo n.

5. Working over $\mathbb{F}_2$, factor $\Phi_5(x) = 1 + x + x^2 + x^3 + x^4$ into irreducibles in $\mathbb{F}_2[x]$. Relate the degrees of the irreducible factors to the multiplicative order of 2 modulo 5, and use this to find $[\mathbb{F}_2(\zeta_5) : \mathbb{F}_2]$.

Commutative-diagram exercises.

1. Let $\zeta = \zeta_n$. There is a canonical isomorphism $\mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \cong (\mathbb{Z}/n\mathbb{Z})^{\times}$ sending an automorphism σ to the unit a with $\sigma(\zeta) = \zeta^a$. Verify that this map is a group homomorphism by checking that the square below commutes, where the vertical maps send σ to its unit a (componentwise on the left), the bottom map is multiplication of the corresponding units and the top map is composition $\sigma, \tau \mapsto \sigma \circ \tau$.

$$\begin{array}{ccc} \mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \times \mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) & \xrightarrow{\ \circ\ } & \mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \\ \downarrow & & \downarrow \\ (\mathbb{Z}/n\mathbb{Z})^{\times} \times (\mathbb{Z}/n\mathbb{Z})^{\times} & \xrightarrow{(a,b) \mapsto ab} & (\mathbb{Z}/n\mathbb{Z})^{\times} \end{array}$$

   Then specialize to $n = 5$ and exhibit the resulting isomorphism with the cyclic group $(\mathbb{Z}/5\mathbb{Z})^{\times} \cong \mathbb{Z}/4\mathbb{Z}$ explicitly.

2. For $d \mid n$, inclusion of roots of unity gives $\mu_d \subseteq \mu_n$ and a corresponding field inclusion $\mathbb{Q}(\zeta_d) \subseteq \mathbb{Q}(\zeta_n)$ (take $\zeta_d = \zeta_n^{n/d}$). Show that every $\sigma \in \mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ maps $\mathbb{Q}(\zeta_d)$ onto itself, so that restriction $\sigma \mapsto \sigma|_{\mathbb{Q}(\zeta_d)}$ is a homomorphism $\mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \to \mathrm{Aut}(\mathbb{Q}(\zeta_d)/\mathbb{Q})$, and that the diagram below commutes, where the vertical maps are the isomorphisms of the previous exercise and the bottom map is reduction mod d, the surjection $(\mathbb{Z}/n\mathbb{Z})^{\times} \to (\mathbb{Z}/d\mathbb{Z})^{\times}$.

$$\begin{array}{ccc} \mathrm{Aut}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) & \xrightarrow{\sigma \mapsto \sigma|_{\mathbb{Q}(\zeta_d)}} & \mathrm{Aut}(\mathbb{Q}(\zeta_d)/\mathbb{Q}) \\ \cong\downarrow & & \downarrow\cong \\ (\mathbb{Z}/n\mathbb{Z})^{\times} & \xrightarrow[\mathrm{mod}\ d]{} & (\mathbb{Z}/d\mathbb{Z})^{\times} \end{array}$$

   Illustrate with $d = 3$, $n = 12$, computing both unit groups and the reduction map.

3. Let p be a prime not dividing n and consider reduction of coefficients modulo p, the ring map $\mathbb{Z}[x] \to \mathbb{F}_p[x]$. Since $\Phi_n(x) \in \mathbb{Z}[x]$, it has a well-defined image $\overline{\Phi_n}(x) \in \mathbb{F}_p[x]$. Show that the square commutes, where the top map is the divisor-product factorization over $\mathbb{Z}$ and the bottom is the same factorization over $\mathbb{F}_p$, and the vertical maps are coefficient reduction:

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{x^n-1 \mapsto \prod_{d\mid n} \Phi_d} & \mathbb{Z}[x] \\ {\scriptstyle \bmod p}\downarrow & & \downarrow{\scriptstyle \bmod p} \\ \mathbb{F}_p[x] & \xrightarrow[x^n-1 \mapsto \prod_{d\mid n} \overline{\Phi_d}]{} & \mathbb{F}_p[x] \end{array}$$

Use commutativity to explain why $x^n - 1$ remains separable over $\mathbb{F}_p$ exactly when $p \nmid n$.

4. Let $K = \mathbb{Q}(\zeta_8)$ with the three quadratic subfields $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{-2})$ corresponding to the three index-2 subgroups of $(\mathbb{Z}/8\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. Draw the lattice of intermediate fields as a commutative diagram of inclusions:

Label each edge with its relative degree, confirm the top-to-bottom degree is $\varphi(8) = 4$, and match each intermediate field to its corresponding subgroup of $(\mathbb{Z}/8\mathbb{Z})^\times$.

13.7 Finding the Minimal Polynomial

Finding the minimal polynomial

Let α be an element of an extension field K of F, and suppose α is algebraic over F. Its *minimal polynomial* (Artin says *irreducible polynomial*) is the monic polynomial of lowest degree in $F[x]$ having α as a root; equivalently it is the unique monic generator of the ideal of all polynomials in $F[x]$ that vanish at α. The degree of this polynomial is $[F(\alpha) : F]$. We record two general computational methods for producing it, following Artin, together with the one subtlety that separates "a polynomial with α as a root" from "*the* minimal polynomial."

Method (Two ways to capture an algebraic α.)**. Method 1 (linear dependence among powers).** Compute the powers $1, \alpha, \alpha^2, \ldots$ inside K, simplifying as you go, until you spot a linear relation $c_n\alpha^n + \cdots + c_1\alpha + c_0 = 0$ with $c_i \in F$. Then α is a root of $c_nx^n + \cdots + c_1x + c_0$.
Method 2 (expand the product of conjugates). If you can guess the full set of roots $\alpha = \alpha_1, \alpha_2, \ldots, \alpha_k$ that the minimal polynomial ought to have, expand $(x - \alpha_1)(x - \alpha_2)\cdots(x - \alpha_k)$; the irrational parts cancel and the product lands in $F[x]$.

The first method always works in principle; the second works only when the conjugates are guessable (Artin: "sometimes, though not very often"). Both rest on the same finiteness fact.

Lemma 13.7.1 (Artin 15.4.2)**.** (a) *A linear dependence relation $c_n\alpha^n + \cdots + c_1\alpha + c_0 = 0$ among powers of α means exactly that α is a root of $c_nx^n + \cdots + c_1x + c_0 \in F[x]$.*
(b) *Let α, β be algebraic over F with degrees d_1, d_2. The d_1d_2 monomials $\alpha^i\beta^j$ with $0 \le i < d_1$ and $0 \le j < d_2$ span $F(\alpha, \beta)$ as an F-vector space.*

Proof. Part (a) is the definition of "root" read backwards: substituting $x = \alpha$ into $\sum c_ix^i$ recovers the given relation. For (b), since α and β are algebraic over F we have $F(\alpha, \beta) = F[\alpha, \beta]$, the ring of polynomial expressions in α, β. Every such expression reduces, using $\alpha^{d_1} \in \mathrm{Span}_F(1, \ldots, \alpha^{d_1-1})$ and $\beta^{d_2} \in \mathrm{Span}_F(1, \ldots, \beta^{d_2-1})$ from the two minimal polynomials, to an F-combination of the listed monomials. Hence those d_1d_2 monomials span. $\square$

This is what powers Method 1 for a sum $\alpha+\beta$: inside the space $F(\alpha,\beta)$, of dimension at most d_1d_2, the powers $1,(\alpha+\beta),(\alpha+\beta)^2,\dots,(\alpha+\beta)^{d_1d_2}$ are d_1d_2+1 vectors, hence dependent, and a dependence relation hands us a polynomial of degree at most d_1d_2 with $\alpha+\beta$ as a root.

Worked Example 13.7.2 ($\sqrt{2}+\sqrt{3}$ by powers (Method 1))**.** Find a polynomial over $\mathbb{Q}$ with root $\gamma=\sqrt{2}+\sqrt{3}$.

Recognition. Method 1 / Lemma 13.7.1(a): compute powers of γ in $\mathbb{Q}(\sqrt{2},\sqrt{3})$ and hunt for a relation. The simplifying species here are $\sqrt{6}$ and rationals.

Solution. Compute, simplifying each time:

$$\gamma^2=(\sqrt{2}+\sqrt{3})^2=2+2\sqrt{6}+3=5+2\sqrt{6},\qquad \gamma^4=(5+2\sqrt{6})^2=25+20\sqrt{6}+24=49+20\sqrt{6}.$$

We never need γ^1 or γ^3, because we can already eliminate $\sqrt{6}$ between γ^2 and γ^4. From $\gamma^2=5+2\sqrt{6}$ we get $2\sqrt{6}=\gamma^2-5$, so $20\sqrt{6}=10(\gamma^2-5)$, and substituting into $\gamma^4=49+20\sqrt{6}$:

$$\gamma^4=49+10(\gamma^2-5)=10\gamma^2-1,\qquad \text{i.e.}\qquad \gamma^4-10\gamma^2+1=0.$$

So γ is a root of $g(x)=x^4-10x^2+1$. *Check.* Numerically $\gamma\approx 1.414+1.732=3.146$, and $3.146^4-10\cdot 3.146^2+1\approx 97.9-99.0+1\approx 0$. ■

Worked Example 13.7.3 ($\sqrt{2}+\sqrt{3}$ by conjugates (Method 2))**.** Recover the same polynomial by guessing the conjugates of $\gamma=\sqrt{2}+\sqrt{3}$.

Recognition. Method 2: the natural conjugates flip the signs of $\sqrt{2}$ and $\sqrt{3}$ independently, giving four candidate roots; expand the product (Artin 15.4.3).

Solution. Guess the four roots

$$\gamma_1=\sqrt{2}+\sqrt{3},\quad \gamma_2=\sqrt{2}-\sqrt{3},\quad \gamma_3=-\sqrt{2}+\sqrt{3},\quad \gamma_4=-\sqrt{2}-\sqrt{3}.$$

Pair them so the cross terms cancel:

$$(x-\gamma_1)(x-\gamma_4)=x^2-(\sqrt{2}+\sqrt{3})^2=x^2-(5+2\sqrt{6}),$$
$$(x-\gamma_2)(x-\gamma_3)=x^2-(\sqrt{2}-\sqrt{3})^2=x^2-(5-2\sqrt{6}).$$

Multiplying these two,

$$\big(x^2-5-2\sqrt{6}\big)\big(x^2-5+2\sqrt{6}\big)=(x^2-5)^2-(2\sqrt{6})^2=x^4-10x^2+25-24=x^4-10x^2+1,$$

the same $g(x)$. The $\sqrt{6}$ disappeared because we multiplied a number by its conjugate. *Check.* The constant term is $(5-2\sqrt{6})(5+2\sqrt{6})=25-24=1$, matching the $+1$ in $g(x)$. ■

So far we have only produced *a* polynomial with γ as a root. Whether it is the *minimal* polynomial is a separate question, and here is the catch.

Caution. The polynomial you find may be reducible. A linear dependence among $1,\alpha,\dots,\alpha^n$ produces a degree-n polynomial with α as a root, but the minimal polynomial is the *lowest-degree* such polynomial. The dependence you happen to write down need not be the shortest one. To be sure you have the minimal polynomial by this method, work in an actual *monomial basis* of K over F and take the *first* dependence: if n is the least integer for which $1,\alpha,\dots,\alpha^n$ are dependent, then $n=[F(\alpha):F]$ and that relation, divided by its leading coefficient, is the minimal polynomial. Counting dimensions alone is not enough unless α generates K: for $\alpha=\sqrt{2}$ in $K=\mathbb{Q}(\sqrt{2},\sqrt{3})$ the five powers $1,\alpha,\dots,\alpha^4$ satisfy $\alpha^4-4=0$, but $x^4-4=(x^2-2)(x^2+2)$ is reducible.

The cure is Lemma 13.7.1(b) used carefully: the d_1d_2 monomials $\alpha^i\beta^j$ *span*, but they need not be *independent*. When they are independent they form a basis, and then (for F of characteristic 0, such as $\mathbb{Q}$; in characteristic p this can fail) the degree of $\gamma=\alpha+\beta$ over F is genuinely d_1d_2 and the polynomial you extracted is minimal. When they are dependent, the true basis is smaller, and the minimal polynomial has smaller degree than d_1d_2.

Worked Example 13.7.4 (When $\sqrt{2}, \sqrt{3}$ are independent: g is minimal)**.** Show that $g(x) = x^4 - 10x^2 + 1$ is the actual minimal polynomial of $\gamma = \sqrt{2} + \sqrt{3}$ over $\mathbb{Q}$.

Recognition. Pitfall test: check that the four monomials $\sqrt{2}^{\,i}\sqrt{3}^{\,j}$, $0 \le i, j < 2$, are a genuine basis of $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, so that $[K : \mathbb{Q}] = 4$.

Solution. Here $\alpha = \sqrt{2}$, $\beta = \sqrt{3}$, each of degree $d_1 = d_2 = 2$ over $\mathbb{Q}$. The four monomials are

$$1, \quad \sqrt{2}, \quad \sqrt{3}, \quad \sqrt{2}\,\sqrt{3} = \sqrt{6}.$$

These are linearly independent over $\mathbb{Q}$: $\sqrt{3} \notin \mathbb{Q}(\sqrt{2})$ since $\sqrt{2}$ generates a field whose only quadratic surd is $\sqrt{2}$ up to rational multiples, so $[\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}(\sqrt{2})] = 2$ and by the tower law $[K : \mathbb{Q}] = 2 \cdot 2 = 4$. Thus the four monomials form a basis, K has dimension 4, and the powers $1, \gamma, \gamma^2, \gamma^3, \gamma^4$ (five vectors) admit exactly one dependence, of degree 4. Hence $g(x) = x^4 - 10x^2 + 1$ has minimal degree and *is* the minimal polynomial; in particular it is irreducible over $\mathbb{Q}$, so $\mathbb{Q}(\gamma) = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. *Check.* g has no rational root (candidates ± 1 give -8) and no factorization into two rational quadratics $x^2 + ax + b$, $x^2 - ax + c$ with $a, b, c \in \mathbb{Q}$, since matching coefficients gives $a(c - b) = 0$, $b + c - a^2 = -10$, $bc = 1$: if $a = 0$ then b, c are the irrational roots $-5 \pm 2\sqrt{6}$ of $y^2 + 10y + 1$, and if $b = c = \pm 1$ then $a^2 = 12$ or $a^2 = 8$, so $a \notin \mathbb{Q}$; degree $4 = [K : \mathbb{Q}]$. ■

Worked Example 13.7.5 (When monomials are *not* independent: $\sqrt[3]{2}$)**.** Let $f(x) = x^3 - 2$ with roots $\alpha_1 = \sqrt[3]{2}$, $\alpha_2 = \omega\sqrt[3]{2}$, $\alpha_3 = \omega^2\sqrt[3]{2}$, where $\omega = e^{2\pi i/3}$. Inside $K = \mathbb{Q}(\alpha_1, \alpha_2)$, decide whether the nine monomials $\alpha_1^i \alpha_2^j$, $0 \le i, j < 3$, form a basis, and find the right monomial basis (Artin 15.4.4(b)).

Recognition. Pitfall again: Lemma 13.7.1(b) gives nine *spanning* monomials, but $[K : \mathbb{Q}]$ may be smaller than 9, so they are dependent; build the honest basis through a tower.

Solution. Each α_i has degree 3 over $\mathbb{Q}$ (Eisenstein on $x^3 - 2$). Set $F = \mathbb{Q}$, $L = \mathbb{Q}(\alpha_1)$, $K = \mathbb{Q}(\alpha_1, \alpha_2)$. Over L the polynomial f already has the root α_1, so it factors $f(x) = (x - \alpha_1)q(x)$ with q quadratic; α_2 is a root of q, hence has degree at most 2 over L, and exactly 2 because $L = \mathbb{Q}(\alpha_1) \subset \mathbb{R}$ while $\alpha_2 \notin \mathbb{R}$. So $\{\, 1, \alpha_2 \,\}$ is a basis of K over L, and combining with the $\mathbb{Q}$-basis $\{\, 1, \alpha_1, \alpha_1^2 \,\}$ of L, the *six* monomials

$$\alpha_1^i \alpha_2^j, \qquad 0 \le i < 3,\ 0 \le j < 2,$$

form a basis of K over $\mathbb{Q}$. Thus $[K : \mathbb{Q}] = 6$, not 9: the original nine monomials were dependent. If you want a monomial basis to extract minimal polynomials in K, use this six-element one. *Check.* $[K : \mathbb{Q}] = [K : L]\,[L : \mathbb{Q}] = 2 \cdot 3 = 6$, and indeed $K = \mathbb{Q}(\sqrt[3]{2}, \omega)$ is the splitting field of $x^3 - 2$, degree 6. ■

The towers behind the two well-behaved cases sit in the same square-shaped lattice: the base F, the two intermediate fields $F(\alpha)$ and $F(\beta)$, and the compositum $F(\alpha, \beta)$ on top. When the monomials $\alpha^i \beta^j$ are independent the two side-steps have coprime-compatible degrees and the top degree is the product $d_1 d_2$.

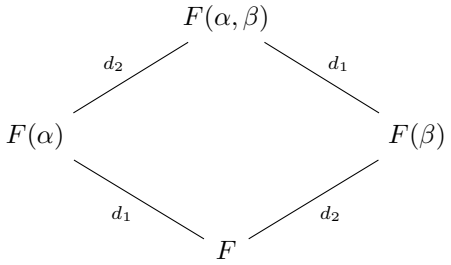


Diagram explanation. Objects: Four fields arranged in a diamond: F (bottom, the base field), $F(\alpha)$ (lower-left, the simple extension by α, a field of degree d_1 over F), $F(\beta)$ (lower-right, degree d_2 over F), and $F(\alpha, \beta)$ (top, the compositum of the two intermediate fields).

Arrows: All four edges are undirected dashes, representing field-extension inclusions. The two lower edges carry degree labels: $F \hookrightarrow F(\alpha)$ has degree d_1 and $F \hookrightarrow F(\beta)$ has degree d_2. The two upper edges carry the *swapped* labels: $F(\alpha) \hookrightarrow F(\alpha, \beta)$ has degree d_2 and $F(\beta) \hookrightarrow F(\alpha, \beta)$ has degree d_1. The swap is the content of the diagram, not a coincidence.

What commutes: Both paths from F to $F(\alpha,\beta)$ give the same total degree. Left path: $[F(\alpha,\beta):F(\alpha)]\cdot[F(\alpha):F] = d_2 \cdot d_1$. Right path: $[F(\alpha,\beta):F(\beta)]\cdot[F(\beta):F] = d_1 \cdot d_2$. Both equal $d_1 d_2$, which is $[F(\alpha,\beta):F]$.

Why it commutes: The tower law $[E:F] = [E:L]\,[L:F]$ for any tower $F \subseteq L \subseteq E$ forces both products to equal the same quantity $[F(\alpha,\beta):F]$. The swap of labels (d_1 and d_2 trade sides) holds precisely because α has degree d_1 over F, and when $\alpha^i\beta^j$ are F-linearly independent the extension $F(\alpha) \hookrightarrow F(\alpha,\beta)$ still requires a basis of size d_2 (the monomials β^j reduce to exactly d_2 independent vectors over $F(\alpha)$).

Why this matters here: The diagram certifies the pitfall test. To know that the polynomial of degree $d_1 d_2$ produced by Method 1 is genuinely minimal for $\alpha+\beta$, we need $[F(\alpha,\beta):F] = d_1 d_2$. This lattice encodes exactly that equality, and it holds if and only if the monomials $\alpha^i\beta^j$ are independent.

Concrete example: Take $F = \mathbb{Q}$, $\alpha = \sqrt{2}$ ($d_1 = 2$), $\beta = \sqrt{3}$ ($d_2 = 2$). The four fields are $\mathbb{Q} \subset \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{3}) \subset \mathbb{Q}(\sqrt{2},\sqrt{3})$, each intermediate step of degree 2, total degree 4. Both paths through the diamond give $2 \cdot 2 = 4$, confirming $g(x) = x^4 - 10x^2 + 1$ has degree equal to $[\mathbb{Q}(\sqrt{2},\sqrt{3}):\mathbb{Q}]$ and is therefore minimal.

Common pitfall: Students assume the upper-edge degrees are also d_1 and d_2 in the obvious order (left side d_1, right side d_2), but the diagram shows them *swapped*. More seriously: the labels are only correct when independence holds. If α and β satisfy a hidden relation over F (as $\sqrt[3]{2}$ and $\omega\sqrt[3]{2}$ do), then $[F(\alpha,\beta):F] < d_1 d_2$ and the upper-edge degrees are smaller than the labels suggest; the diagram would not apply.

Takeaway: The point of this diagram is that the tower law forces both routes around the diamond to give the same total degree $d_1 d_2$, and (for F of characteristic 0) this equality is exactly what certifies that a degree-$d_1 d_2$ polynomial found by the power-counting method is the true minimal polynomial of $\alpha+\beta$ over F.

Worked Example 13.7.6 (A primitive element by both methods)**.** Let $\theta = \sqrt{2}+\sqrt[3]{2}$. Show $\mathbb{Q}(\theta) = \mathbb{Q}(\sqrt{2},\sqrt[3]{2})$ and find a degree-6 polynomial over $\mathbb{Q}$ with root θ, by Method 1 (powers) and by Method 2 (conjugates).

Recognition. Method 1: θ lives in $K = \mathbb{Q}(\sqrt{2},\sqrt[3]{2})$ of degree $[K:\mathbb{Q}] = 2\cdot 3 = 6$ (the monomials $\sqrt{2}^{\,i}\sqrt[3]{2}^{\,j}$ with $i<2$, $j<3$ are a basis by the tower law, the surds having coprime degrees), so $1,\theta,\dots,\theta^6$ are seven vectors in a 6-dimensional space and must be dependent. Method 2: the six conjugates flip $\sqrt{2} \mapsto \pm\sqrt{2}$ and rotate $\sqrt[3]{2} \mapsto \omega^k\sqrt[3]{2}$.

Solution. That θ is primitive: the conjugates of θ are the six numbers $\pm\sqrt{2}+\omega^k\sqrt[3]{2}$ ($k=0,1,2$); they are pairwise distinct, so θ has six distinct conjugates and therefore degree 6 over $\mathbb{Q}$. Since $\mathbb{Q}(\theta) \subseteq K$ and both have degree 6, $\mathbb{Q}(\theta) = K$.

Method 2 (conjugates). Group the six factors by the cube-root rotation:

$$m_\theta(x) = \prod_{k=0}^{2} \big(x - \sqrt{2} - \omega^k\sqrt[3]{2}\big)\big(x + \sqrt{2} - \omega^k\sqrt[3]{2}\big).$$

The inner pair is $\big((x-\omega^k\sqrt[3]{2}) - \sqrt{2}\big)\big((x-\omega^k\sqrt[3]{2}) + \sqrt{2}\big) = (x-\omega^k\sqrt[3]{2})^2 - 2$. Writing $u = x^2-2$ does not quite separate variables, but expanding $\prod_k\big((x-\omega^k\sqrt[3]{2})^2 - 2\big)$ and using $\prod_k(y-\omega^k\sqrt[3]{2}) = y^3-2$ collapses all the ω's. Carrying out the expansion gives the rational polynomial

$$m_\theta(x) = x^6 - 6x^4 - 4x^3 + 12x^2 - 24x - 4.$$

Method 1 (powers). Equivalently, write each power θ^j in the monomial basis $\{\sqrt{2}^{\,i}\sqrt[3]{2}^{\,j}\}$ and solve the 7-vectors-in-6-dimensions linear system; the unique dependence is the same degree-6 relation. Because the monomial basis has exactly six elements, the relation it forces has degree 6, so by the pitfall test m_θ is the genuine minimal polynomial (degree $6 = [\mathbb{Q}(\theta):\mathbb{Q}]$), not a reducible by-product. *Check.* $\deg m_\theta = 6 = [K:\mathbb{Q}]$; numerically $\theta \approx 1.414 + 1.260 = 2.674$ and $2.674^6 - 6\cdot 2.674^4 - 4\cdot 2.674^3 + 12\cdot 2.674^2 - 24\cdot 2.674 - 4 \approx 0$. ■

Remark 13.7.1. The two methods are dual faces of the same vector-space fact. Method 1 reads off a dependence among powers and trusts a *monomial basis* to certify its degree; Method 2 names the conjugates and lets the field automorphisms do the cancellation. When you can guess the conjugates, Method 2 is faster and self-certifying (a product of $[F(\alpha):F]$ distinct conjugates is automatically the minimal polynomial). When you cannot, Method 1 always terminates – provided you take the *first* dependence among $1,\alpha,\alpha^2,\dots$ (a basis of K lets you detect it), so that the reducible-relation pitfall cannot pass off a proper multiple of the minimal polynomial as the minimal polynomial.

13.8 Constructible Regular Polygons

Constructible numbers and quadratic towers

A point of the plane is *constructible* if it can be reached from the two starting points $(0,0)$ and $(1,0)$ in finitely many ruler-and-compass steps: draw the line through two constructed points, draw the circle centered at one constructed point through another, and take intersections of constructed lines and circles. The ruler is a straight-edge only – it may not measure. Following Artin, we translate this geometry into field theory and then settle exactly which regular polygons can be drawn.

Definition 13.8.1. A real number a is *constructible* if the point $(a,0)$ is constructible. Since perpendiculars and lengths can be marked off, a is constructible iff it is a coordinate of some constructible point, iff some pair of constructible points lies at distance $|a|$.

The single algebraic fact behind everything is that one construction step never costs more than a square root.

Proposition 13.8.2 (Lines and circles over a field)**.** *Let $F \subseteq \mathbb{R}$ be a subfield and let p_0, p_1 be points with coordinates in F. The line through p_0, p_1 has a linear equation with coefficients in F, and the circle centered at p_0 through p_1 has a quadratic equation with coefficients in F. If A, B are two such lines or circles, then every (real) intersection point of A and B has coordinates either in F or in a real quadratic extension $F' = F(\sqrt{D})$ with $D \in F$, $D > 0$.*

Proof. The line through (a_0,b_0) and (a_1,b_1) is the locus of $(a_1-a_0)(y-b_0) = (b_1-b_0)(x-a_0)$, and the circle through (a_1,b_1) centered at (a_0,b_0) is $(x-a_0)^2+(y-b_0)^2 = (a_1-a_0)^2+(b_1-b_0)^2$; both have coefficients in F. Intersecting two lines solves a linear system over F, so the point stays in F. Intersecting a line with a circle: use the linear equation to eliminate one variable, leaving a single quadratic $\alpha x^2+\beta x+\gamma = 0$ with $\alpha,\beta,\gamma \in F$; its real solutions lie in $F(\sqrt{D})$ with discriminant $D = \beta^2 - 4\alpha\gamma \in F$. Two circles look quartic, but subtracting their equations cancels the x^2 and y^2 terms, giving a *linear* equation; this reduces to the line-circle case (and reflects that two circles meet in at most two points, not four). □

Running this one step at a time, with the multiplicativity of degree, yields Artin's Theorem 15.5.6.

Theorem 13.8.3 (Constructible points lie in a 2-tower)**.** *If p is a constructible point, then there is a chain of subfields of $\mathbb{R}$*

$$\mathbb{Q} = F_0 \subseteq F_1 \subseteq F_2 \subseteq \cdots \subseteq F_n = K,$$

with $[F_{i+1} : F_i] = 2$ for each i, such that the coordinates of p lie in K. In particular $[K:\mathbb{Q}]$ is a power of 2.

Proof. The given points $(0,0),(1,0)$ have coordinates in $\mathbb{Q} = F_0$. Suppose every point constructed so far has coordinates in some F_i. The next step draws a line or circle through two such points; by the Proposition its equation has coefficients in F_i, so F_i does not change. Any new intersection point then has coordinates in F_i, or in a real quadratic extension $F_{i+1} = F_i(\sqrt{D})$ with $[F_{i+1}:F_i] = 2$. After finitely many steps the coordinates of p lie in the top field $K = F_n$, and $[K:\mathbb{Q}] = \prod_i [F_{i+1}:F_i] = 2^n$. □

Corollary 13.8.4 (Degree obstruction)**.** *If $a \in \mathbb{R}$ is constructible, then a is algebraic over $\mathbb{Q}$ and $[\mathbb{Q}(a):\mathbb{Q}]$ is a power of 2.*

Proof. By Theorem 13.8.3, $a \in K$ with $[K:\mathbb{Q}] = 2^n$. Since $\mathbb{Q}(a) \subseteq K$, the tower law gives $[\mathbb{Q}(a):\mathbb{Q}] \mid [K:\mathbb{Q}] = 2^n$, so $[\mathbb{Q}(a):\mathbb{Q}]$ is itself a power of 2. □

Caution. The converse of the Corollary is *false*: there are real numbers of degree 4 over $\mathbb{Q}$ that are not constructible. A power-of-2 degree is necessary but not sufficient; full sufficiency needs the entire 2-tower, which is what the Galois-theoretic side (below) supplies. Do not claim "$[\mathbb{Q}(a):\mathbb{Q}] = 2^k$ implies a constructible" – it takes a normal 2-tower.

The obstruction already kills several classical problems. We record the trisection impossibility verbatim from Artin, then turn to polygons.

Worked Example 13.8.5 (Trisecting 60° is impossible)**.** Show $\cos 20°$ is not constructible, so the 60° angle cannot be trisected by ruler and compass.

Recognition. An angle θ is constructible iff $\cos\theta$ is a constructible number; apply the degree obstruction (Corollary 13.8.4).

Solution. Let $\alpha = 2\cos\theta = e^{i\theta} + e^{-i\theta}$ with $\theta = \pi/9$. Then $e^{3i\theta} + e^{-3i\theta} = 2\cos(\pi/3) = 1$, and expanding,

$$\alpha^3 = (e^{i\theta} + e^{-i\theta})^3 = e^{3i\theta} + 3e^{i\theta} + 3e^{-i\theta} + e^{-3i\theta} = 1 + 3\alpha,$$

so α is a root of $x^3 - 3x - 1$. This cubic has no rational (hence no integer) root, so it is irreducible over $\mathbb{Q}$ and $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 3$. Thus $[\mathbb{Q}(\cos 20°) : \mathbb{Q}] = 3$ is not a power of 2, so $\cos 20°$ is not constructible. Since 60° is easy to construct, a general trisection would construct 20°; impossible. *Check.* $3 \nmid$ any power of 2, matching the obstruction exactly.

Which regular n-gons: the prime obstruction

Constructing the regular n-gon is the same as constructing the angle $2\pi/n$, equivalently the point $\zeta_n = e^{2\pi i/n} = (\cos\frac{2\pi}{n}, \sin\frac{2\pi}{n})$ in the plane. The relevant degree is governed by Euler's φ through the cyclotomic field $\mathbb{Q}(\zeta_n)$, whose degree over $\mathbb{Q}$ is $\varphi(n)$.

Lemma 13.8.6 (Real vs. full cyclotomic degree)**.** *Let $\zeta = \zeta_n$ and let $\beta = \zeta + \zeta^{-1} = 2\cos\frac{2\pi}{n}$ be the real part data. For $n \geq 3$, $\mathbb{Q}(\beta) = \mathbb{Q}(\zeta) \cap \mathbb{R}$ is the maximal real subfield, $[\mathbb{Q}(\zeta) : \mathbb{Q}(\beta)] = 2$, and*

$$[\mathbb{Q}(\beta) : \mathbb{Q}] = \tfrac{1}{2}\varphi(n).$$

Hence the regular n-gon is constructible only if $\varphi(n)$ is a power of 2.

Proof. ζ satisfies $\zeta^2 - \beta\zeta + 1 = 0$ over $\mathbb{Q}(\beta)$, a non-real quadratic relation, so $[\mathbb{Q}(\zeta) : \mathbb{Q}(\beta)] = 2$ (it is 2, not 1, because $\zeta \notin \mathbb{R}$ while $\beta \in \mathbb{R}$). With $[\mathbb{Q}(\zeta) : \mathbb{Q}] = \varphi(n)$ the tower law gives $[\mathbb{Q}(\beta) : \mathbb{Q}] = \varphi(n)/2$. If the n-gon is constructible then β (and $\cos\frac{2\pi}{n}$) is a constructible real number, so by Corollary 13.8.4 the degree $\varphi(n)/2$ is a power of 2; therefore $\varphi(n)$ is a power of 2. □

For prime $n = p$ this pins down the allowed primes, following Artin's 7-gon argument and Corollary 15.5.9.

Corollary 13.8.7 (Prime polygons force Fermat primes)**.** *Let p be an odd prime. If the regular p-gon is constructible, then $p = 2^{2^k} + 1$ for some $k \geq 0$, i.e. p is a* Fermat prime.

Proof. Here $\varphi(p) = p - 1$, and ζ_p is a root of the irreducible $x^{p-1} + \cdots + x + 1$, so $[\mathbb{Q}(\zeta_p) : \mathbb{Q}] = p - 1$. If the p-gon is constructible, then by Lemma 13.8.6 the number $\varphi(p) = p - 1$ is a power of 2, say $p = 2^m + 1$. If m had an odd factor $d > 1$, write $m = de$; then $2^e + 1$ divides $2^m + 1$ properly (since $x + 1 \mid x^d + 1$ for odd d with $x = 2^e$), contradicting primality of $2^m + 1$. Hence m has no odd factor, $m = 2^k$, and $p = 2^{2^k} + 1$. □

Remark 13.8.1. The known Fermat primes are

$$F_0 = 3, \quad F_1 = 5, \quad F_2 = 17, \quad F_3 = 257, \quad F_4 = 65537,$$

($2^{2^k} + 1$ for $k = 0, 1, 2, 3, 4$). No further Fermat prime is known; $F_5 = 2^{32} + 1$ is composite. So the only odd primes presently known to give a constructible p-gon are $3, 5, 17, 257, 65537$.

Worked Example 13.8.8 (The heptagon (7-gon) is not constructible)**.** Show the regular 7-gon cannot be drawn with ruler and compass.

Recognition. Apply the prime test: 7 would have to be a Fermat prime, i.e. $\varphi(7) = 6$ would have to be a power of 2.

Solution. $\varphi(7) = 6$, so $[\mathbb{Q}(\zeta_7) : \mathbb{Q}] = 6$ and the real subfield has degree $6/2 = 3$ over $\mathbb{Q}$. Since 3 is not a power of 2, $\cos\frac{2\pi}{7}$ is not constructible. (Artin's direct form: if the 7-gon were constructible, $\zeta_7 \in K(i)$ for some real K with $[K : \mathbb{Q}] = 2^k$, giving $[K(i) : \mathbb{Q}] = 2^{k+1}$; but $[\mathbb{Q}(\zeta_7) : \mathbb{Q}] = 6 \nmid 2^{k+1}$, a contradiction.) *Check.* $7 = 2^2 + 1 + 2$ is *not* of the form $2^{2^k} + 1$, and indeed 6 has the odd factor 3.

Worked Example 13.8.9 (The 9-gon (nonagon) is not constructible)**.** Show the regular 9-gon cannot be constructed, even though 9 is not prime.

Recognition. Now $n = 9$ is a prime power; use $\varphi(n)$ directly via Lemma 13.8.6.

Solution. $\varphi(9) = 9 - 3 = 6$, so $[\mathbb{Q}(\zeta_9) : \mathbb{Q}] = 6$ and $[\mathbb{Q}(\cos\frac{2\pi}{9}) : \mathbb{Q}] = 3$, not a power of 2. Hence the 9-gon is not constructible. This is exactly the trisection obstruction in disguise: constructing the 9-gon would construct $2\pi/9 = 40°$, hence $20°$, the angle shown impossible above. *Check.* The real generator $2\cos\frac{2\pi}{9}$ satisfies the same kind of irreducible cubic ($x^3 - 3x + 1$), degree 3.

The Gauss-Wantzel characterization

The degree condition is also sufficient, by the converse direction. We first record that the constructible numbers are closed under field operations and square roots (Artin's Lemma 15.5.11), which lets a quadratic tower be realized geometrically.

Theorem 13.8.10 (Constructible numbers form a $\sqrt{}$-closed field)**.** *The constructible real numbers form a subfield $\mathcal{C} \subseteq \mathbb{R}$, and if $a \in \mathcal{C}$ with $a > 0$ then $\sqrt{a} \in \mathcal{C}$. Consequently, if $\mathbb{Q} = F_0 \subseteq \cdots \subseteq F_n = K \subseteq \mathbb{R}$ is a tower with each $[F_{i+1} : F_i] = 2$, then every element of K is constructible.*

Sketch. Addition and subtraction mark off lengths along a line. Multiplication and division use similar right triangles: with sides $r = 1, s = a$ and $r' = b$ one constructs $s' = ab$, and with $r = a, s = 1, r' = 1$ one constructs $s' = a^{-1}$. For $\sqrt{a}$, inscribe a right triangle in the circle of diameter $1 + a$ (a triangle on a diameter is right-angled); the altitude to the hypotenuse has length $\sqrt{a}$. Thus $\mathcal{C}$ is a subfield closed under square roots. A degree-2 step $F_{i+1} = F_i(\sqrt{D})$ adjoins one square root of an already constructible D, so by induction every element of the top field K is constructible. □

Theorem 13.8.11 (Gauss-Wantzel)**.** *The regular n-gon is constructible with ruler and compass if and only if*

$$n = 2^a\, p_1 p_2 \cdots p_r,$$

where $a \geq 0$ and $p_1, \ldots, p_r$ are distinct Fermat primes. Equivalently, the regular n-gon is constructible iff $\varphi(n)$ is a power of 2.

Sketch. Necessity. Write $n = 2^a q_1^{e_1} \cdots q_s^{e_s}$ with odd primes q_j. Then $\varphi(n) = 2^{a-1} \prod_j q_j^{e_j - 1}(q_j - 1)$ (with the 2^{a-1} omitted if $a = 0$). For $\varphi(n)$ to be a power of 2 – forced by Lemma 13.8.6 – each odd prime must occur with exponent $e_j = 1$ (else $q_j \mid \varphi(n)$) and each $q_j - 1$ must be a power of 2, i.e. each q_j is a Fermat prime (Corollary 13.8.7). This is exactly the stated form of n.

Sufficiency. If n has this form then $\varphi(n)$ is a power of 2, so $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n) = 2^m$. The extension $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ is Galois with abelian Galois group $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \cong (\mathbb{Z}/n\mathbb{Z})^\times$ of order 2^m; a finite abelian 2-group has a chain of subgroups $1 = H_0 \lhd H_1 \lhd \cdots \lhd H_m = (\mathbb{Z}/n\mathbb{Z})^\times$ with each successive index 2. By the Galois correspondence the fixed fields give a tower $\mathbb{Q} = L_0 \subseteq L_1 \subseteq \cdots \subseteq L_m = \mathbb{Q}(\zeta_n)$ with every $[L_{i+1} : L_i] = 2$. Intersecting with $\mathbb{R}$ yields a real 2-tower up to $\mathbb{Q}(\beta) = \mathbb{Q}(\zeta_n) \cap \mathbb{R}$, so $\cos\frac{2\pi}{n}$ lies in a real quadratic tower and is constructible by Theorem 13.8.10. Hence the point ζ_n, and the regular n-gon, is constructible. □

Worked Example 13.8.12 (The pentagon (5-gon) is constructible)**.** Exhibit $\cos\frac{2\pi}{5}$ explicitly and confirm the pentagon is constructible.

Recognition. $5 = F_1$ is a Fermat prime, so Gauss-Wantzel predicts yes; verify with an exact quadratic value.

Solution. $\varphi(5) = 4 = 2^2$, so the real degree is $4/2 = 2$ – a single quadratic step. Concretely, $\beta = 2\cos\frac{2\pi}{5}$ is a root of $x^2 + x - 1 = 0$ (the real factor of $\frac{x^5-1}{x-1}$ after the substitution $x + x^{-1}$), giving

$$\cos\tfrac{2\pi}{5} = \frac{-1 + \sqrt{5}}{4}.$$

Since $\sqrt{5}$ is constructible (Theorem 13.8.10), so is $\cos\frac{2\pi}{5}$, hence the pentagon. *Check.* $[\mathbb{Q}(\cos\frac{2\pi}{5}) : \mathbb{Q}] = 2$, a power of 2, with the value visibly a single square root over $\mathbb{Q}$.

Worked Example 13.8.13 (The 17-gon: an explicit quadratic tower)**.** Show the regular 17-gon is constructible and display the tower of quadratic fields realizing $\cos\frac{2\pi}{17}$.

Recognition. $17 = F_2 = 2^{2^2}+1$ is a Fermat prime; $\varphi(17) = 16 = 2^4$, so the real subfield, of degree $8 = 2^3$, is reached by a chain of three quadratic steps.

Solution. $[\mathbb{Q}(\zeta_{17}):\mathbb{Q}] = 16$ and $\mathrm{Gal}(\mathbb{Q}(\zeta_{17})/\mathbb{Q}) \cong (\mathbb{Z}/17\mathbb{Z})^\times$ is cyclic of order 16, generated by $\sigma : \zeta \mapsto \zeta^3$ (3 is a primitive root mod 17). Its subgroup chain of indices 2 gives fixed fields

$$\mathbb{Q} \subset \mathbb{Q}(\sqrt{17}) \subset L_2 \subset L_3 = \mathbb{Q}(\beta), \qquad \beta = 2\cos\tfrac{2\pi}{17},$$

each step degree 2. Splitting the 16 powers ζ^{3^j} into Gaussian periods, set

$$\eta_1 = \sum_{j \text{ even}} \zeta^{3^j}, \quad \eta_2 = \sum_{j \text{ odd}} \zeta^{3^j};$$

then $\eta_1+\eta_2 = -1$ and $\eta_1\eta_2 = -4$, so η_1, η_2 are roots of $x^2+x-4=0$, i.e. $\eta_1 = \frac{-1+\sqrt{17}}{2} \in \mathbb{Q}(\sqrt{17})$. Splitting each η into two periods of length 4 gives the next quadratics over $\mathbb{Q}(\sqrt{17})$, then length 2 periods give $L_3 = \mathbb{Q}(\beta)$, where β satisfies a final quadratic. Every coefficient at every stage is constructible, so $\cos\frac{2\pi}{17}$ is a nested chain of square roots over $\mathbb{Q}$ and the 17-gon is constructible (Gauss, 1796). *Check.* The displayed real tower has length 3 ($2^3 = 8 = \varphi(17)/2$), and the last step $\mathbb{Q}(\beta) \subset \mathbb{Q}(\zeta_{17})$ gives $2^4 = 16 = \varphi(17)$, matching Theorem 13.8.11; the first floor $\mathbb{Q}(\sqrt{17})$ is already visible in η_1.

The quadratic tower for $\mathbb{Q}(\zeta_{17})$ is the spine of Gauss's construction.

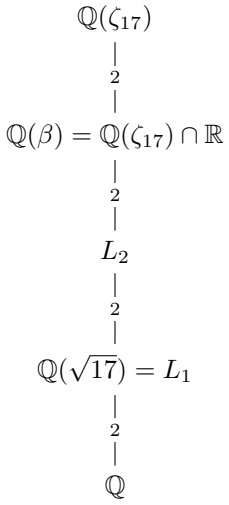

Diagram explanation. Objects: Five fields, all subfields of $\mathbb{C}$, arranged top to bottom in decreasing size. At the top: $\mathbb{Q}(\zeta_{17})$, the full 17th cyclotomic field, a degree-16 extension of $\mathbb{Q}$. Directly below it: $\mathbb{Q}(\beta) = \mathbb{Q}(\zeta_{17}) \cap \mathbb{R}$, the maximal real subfield, where $\beta = 2\cos\frac{2\pi}{17}$, of degree 8 over $\mathbb{Q}$. Then L_2, the first intermediate quadratic step inside the real subfield, of degree 4 over $\mathbb{Q}$. Then $\mathbb{Q}(\sqrt{17}) = L_1$, the ground-floor quadratic extension of $\mathbb{Q}$ generated by $\sqrt{17}$, of degree 2 over $\mathbb{Q}$. At the bottom: $\mathbb{Q}$ itself.

Arrows: Each vertical dash is an *inclusion* of subfields, labeled "2" to record the relative degree $[F_{\text{top}} : F_{\text{bottom}}] = 2$. The edges carry no arrowheads; each dash means "the upper field contains the lower field, with relative degree 2". No map has a formula; the edges are inclusions, not homomorphisms with data to chase.

What commutes: This is a *chain*, not a square, so there is no commutativity condition in the usual sense. The key multiplicativity statement is: $[\mathbb{Q}(\zeta_{17}):\mathbb{Q}] = 2\cdot 2\cdot 2\cdot 2 = 16 = \varphi(17)$, verified by reading the four "2" labels from top to bottom and multiplying (the tower law for degrees).

Why it commutes: By the tower law, $[F:K] = [F:E][E:K]$ for any tower $K \subseteq E \subseteq F$. Each consecutive pair has degree 2 because each step corresponds, via the Galois correspondence, to an index-2 inclusion in the unique chain of subgroups of $(\mathbb{Z}/17\mathbb{Z})^\times \cong \mathbb{Z}/16\mathbb{Z}$, $\{1\} \subset \langle\sigma^8\rangle \subset \langle\sigma^4\rangle \subset \langle\sigma^2\rangle \subset (\mathbb{Z}/17\mathbb{Z})^\times$ (where $\sigma : \zeta \mapsto \zeta^3$),

whose five members have exactly these five fixed fields. The field $\mathbb{Q}(\zeta_{17})$ has degree 2 over its real subfield $\mathbb{Q}(\beta)$ because $\zeta_{17} \notin \mathbb{R}$ satisfies the non-real quadratic $\zeta^2 - \beta\zeta + 1 = 0$ over $\mathbb{Q}(\beta)$.

Why this matters here: This diagram is the geometric spine of the sufficiency half of the Gauss-Wantzel theorem for $n = 17$. It makes explicit that $\cos\frac{2\pi}{17}$ lies at the top of a *real* quadratic tower $\mathbb{Q} \subset \mathbb{Q}(\sqrt{17}) \subset L_2 \subset \mathbb{Q}(\beta)$ of length 3 over $\mathbb{Q}$, so every element in the tower – including $\cos\frac{2\pi}{17}$ – is constructible by Theorem 13.8.10. Without this tower the abstract degree count ($\varphi(17) = 16 = 2^4$) would not by itself give a ruler-and-compass construction.

Concrete example: The bottom two floors are explicit: $\mathbb{Q} \subset \mathbb{Q}(\sqrt{17})$ is the familiar quadratic step, and the Gaussian period $\eta_1 = \frac{-1+\sqrt{17}}{2}$ lives exactly in $\mathbb{Q}(\sqrt{17}) = L_1$, witnessed by the computation $\eta_1 + \eta_2 = -1$, $\eta_1\eta_2 = -4$, so η_1, η_2 satisfy $x^2 + x - 4 = 0 \in \mathbb{Q}[x]$, a polynomial with $\mathbb{Q}(\sqrt{17})$-coefficients.

Common pitfall: Students sometimes read the four "2" labels and conclude that $[\mathbb{Q}(\zeta_{17}) : \mathbb{Q}] = 8$ (adding rather than multiplying the degrees). The tower law multiplies degrees along a chain: $2^4 = 16$, not $2 + 2 + 2 + 2 = 8$. A related error is to conflate the real subfield $\mathbb{Q}(\beta)$ with the full cyclotomic field $\mathbb{Q}(\zeta_{17})$; they are genuinely different – $\zeta_{17} \notin \mathbb{R}$, so the top step is essential.

Takeaway: The point of this diagram is that the abstract Galois-group computation ($(\mathbb{Z}/17\mathbb{Z})^\times$ is cyclic of 2-power order, hence has a full flag of index-2 subgroups) translates directly into a concrete four-step quadratic tower that witnesses the constructibility of $\cos\frac{2\pi}{17}$.

Remark 13.8.2. The pattern of the proof is uniform: for any constructible n the field $\mathbb{Q}(\zeta_n)$ has 2-power degree, its Galois group $(\mathbb{Z}/n\mathbb{Z})^\times$ is an abelian 2-group, and abelian 2-groups always admit a full flag of index-2 subgroups. The Galois correspondence turns that flag into the geometric tower of square-root steps. The Fermat-prime condition is just the arithmetic fingerprint of "$\varphi(n)$ is a power of 2".

13.9 Function Fields and Riemann Surfaces

Function fields and their Riemann surfaces

Artin's third class of field extensions sits between number theory and geometry. Fix the field of rational functions $F = \mathbb{C}(t)$, whose elements are fractions $p(t)/q(t)$ of complex polynomials with $q \neq 0$. A *function field* is a finite extension K/F. The novelty is that such a K is not just an abstract algebraic object: it carries a *geometric shadow*, a surface spread out over the complex t-line, and the algebra of K is faithfully recorded by the topology of that surface.

Definition 13.9.1 (Function field and its defining polynomial)**.** A *function field* is a finite extension K of $F = \mathbb{C}(t)$. Choosing a primitive element α with $K = F(\alpha)$ of degree n, let f be the irreducible polynomial of α over F. Clearing denominators makes f a primitive polynomial in two variables,

$$f(t, x) = a_n(t)\, x^n + \cdots + a_1(t)\, x + a_0(t) \in \mathbb{C}[t, x],$$

with the $a_i(t) \in \mathbb{C}[t]$ having greatest common divisor 1, and $a_n(t)$ monic. Thus $K \cong F[x]/(f)$, with α the residue of x.

Definition 13.9.2 (Riemann surface, branched covering)**.** The *Riemann surface* of f is the zero locus

$$X = \{\, (t, x) \in \mathbb{C}^2 \mid f(t, x) = 0 \,\}.$$

Projection $\pi : X \to T$, $(t, x) \mapsto t$, onto the complex t-plane T exhibits X as an *n-sheeted branched covering*: over a generic t_0 the fiber $\pi^{-1}(t_0)$ consists of the n distinct roots of the one-variable polynomial $f(t_0, x)$. The *branch points* are the finitely many t_0 where $f(t_0, x)$ has fewer than n roots, i.e. where it has a multiple root or where $a_n(t_0) = 0$.

Remark 13.9.1. Following Artin we write X' for X with an unspecified finite set deleted, and say a statement holds *on* X' when it holds off a finite set. A covering $\pi : X \to T$ is *path connected* when X' is: removing any finite $A \subset X$ leaves $X - A$ path connected. The branch points are exactly where the geometry knots the sheets together.

The central correspondence promotes "isomorphic field extensions" and "isomorphic coverings" to two descriptions of the same data.

Theorem 13.9.3 (Riemann Existence Theorem)**.** *There is a bijective correspondence*

$$\left\{\begin{array}{c}\text{isomorphism}\\ \text{classes of}\\ \text{degree-}n\text{ function}\\ \text{fields over } F\end{array}\right\} \longleftrightarrow \left\{\begin{array}{c}\text{isomorphism classes}\\ \text{of connected,}\\ n\text{-sheeted branched}\\ \text{coverings of } T\end{array}\right\},$$

under which the class of the extension $K = F[x]/(f)$ defined by an irreducible $f(t,x)$ corresponds to the class of its Riemann surface $X = \{\, f = 0 \,\}$.

Remark 13.9.2. The full proof is long, but it yields a usable diagnostic: *isomorphic function fields have coverings with matching branch behavior.* So two polynomials of the same x-degree can be tested for defining isomorphic extensions by comparing branch points and monodromy. What the theorem does *not* give is a recipe to produce a polynomial realizing a prescribed covering – existence is guaranteed, construction is left to guesswork.

One half of the bijection is elementary and worth seeing, because it explains why an F-isomorphism of fields must drag one surface onto the other.

Proposition 13.9.4 (Field isomorphism forces covering isomorphism)**.** *Let $f(t,x), g(t,y)$ be irreducible, with extensions $K = F[x]/(f)$, $L = F[y]/(g)$ and Riemann surfaces $X = \{\, f = 0 \,\}$, $Y = \{\, g = 0 \,\}$. If $K/F \cong L/F$ as extensions, then X and Y are isomorphic branched coverings of T.*

Proof. Let β be the residue of y in L, a root of g. An F-isomorphism $\varphi : K \to L$ produces a root of g inside K, namely $\gamma = \varphi^{-1}(\beta)$, so $g(t,\gamma) = 0$ in K. As an element of $K = F[x]/(f)$, γ is represented by some $u(t,x) \in F[x]$. Define $\eta : X \to Y$ by $\eta(t,x) = (t,\, u(t,x))$. Since $g(t,\gamma) = 0$ in K, the element $g(t,u)$ lies in the ideal (f): there is $h \in F[x]$ with $g(t,u) = f \cdot h$. Hence if $(t,x) \in X$, so $f(t,x) = 0$, then $g(t,u(t,x)) = 0$, i.e. $(t,u(t,x)) \in Y$. Because u, h have coefficients that are rational functions in t, η may be undefined on a finite set, which is exactly why we work on X'. Interchanging K and L gives the inverse. So η is a covering isomorphism over T. □

Cut and paste: branching as permutations

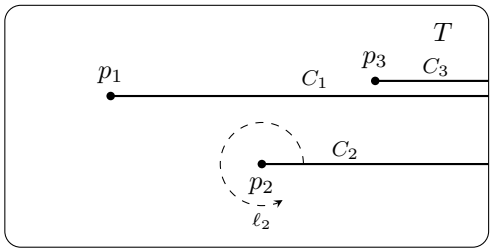
The geometric content of the theorem is that an n-sheeted covering is completely encoded by a tuple of permutations – the *monodromy.* Artin's construction makes this concrete.

Method (Reconstruct a covering from branching data)**.** Let $\{p_1, \dots, p_k\}$ be the branch points in T. Choose nonintersecting half-lines C_ν running from p_ν to infinity, and cut T open along them; the cut plane is simply connected. Cut X open over the C_ν. Then:

(1) (Lemma 15.9.7) The cut surface decomposes into n *sheets* $S_1, \dots, S_n$, each projecting bijectively to the cut plane.

(2) Stack n copies $S_1, \dots, S_n$ of the cut plane over T. To each cut C_ν assign a permutation $\sigma_\nu \in \mathrm{Sym}_n$.

(3) (Gluing rule) If $\sigma_\nu(i) = j$, glue side A_i of sheet S_i to side B_j of sheet S_j along C_ν.



When all cuts are glued, the union of sheets is the covering.

Theorem 13.9.5 (Permutation invariants of a covering)**.** *Every n-sheeted branched covering $X \to T$ is isomorphic to one built by cut and paste. Two such coverings X, Y over the same p_ν, C_ν, with gluing data (σ_ν) and (τ_ν), are isomorphic if and only if there is a single permutation $\rho \in \mathrm{Sym}_n$ with $\tau_\nu = \rho^{-1}\sigma_\nu\rho$ for every ν. Moreover X is path connected if and only if the subgroup $H = \langle \sigma_1, \dots, \sigma_k \rangle \le \mathrm{Sym}_n$ acts transitively on $\{1, \dots, n\}$.*

Sketch, following Artin. The numbering of sheets is arbitrary; relabeling by ρ replaces each σ_ν by its conjugate $\rho^{-1}\sigma_\nu\rho$, which is the only freedom in the data, giving the conjugacy criterion. For connectivity: each sheet S_i is path connected, and if $\sigma_\nu(i) = j$ the sheets S_i, S_j are glued along C_ν, so a short path crosses from S_i to S_j. Hence X' is path connected exactly when, for every pair i, j, some composite of the σ_ν carries i to j – that is, when H is transitive. □

Remark 13.9.3. If σ_ν is the identity, each sheet is glued to itself over C_ν: the cut is unnecessary and p_ν is not a *true* branch point. There is no intrinsic "top sheet": x becomes a single-valued function of t only after cutting, and wandering around X moves you from sheet to sheet. This multivaluedness is the entire point of the Riemann surface.

A schematic of the cut plane with three branch points and their slits:

A counterclockwise loop ℓ_ν around p_ν crosses C_ν and permutes the sheets by σ_ν; the side met before crossing is "A", after crossing is "B". The *local problem* of computing σ_ν is solved by comparison with the model surface of $y^k = t$.

Lemma 13.9.6 (Local monodromy is a k-cycle)**.** *Let t_0 be a branch point of $X = \{ f = 0 \}$ and $D(x) = f(t_0, x)$. If x_0 is a k-fold root of D and the partial derivative $\partial f/\partial t$ does not vanish at (t_0, x_0), then the permutation of the sheets obtained by looping around t_0 contains a k-cycle on the k sheets meeting at x_0.*

Sketch. Translate (t_0, x_0) to the origin, so $D(x) = f(0, x) = x^k m(x)$ with $m(0) \neq 0$, and write $f(t, x) = x^k m(x) - t\, v(t, x)$ with $v(0, 0) \neq 0$ (this is $-\partial f/\partial t$ at the origin). Near the origin $f = 0$ reads $x^k\, m/v = t$; after rescaling t so $m/v \to 1$, set $y = xw$ where w is the kth root of m/v near 1. Then locally $f = 0$ becomes $y^k = t$. The k sheets through the origin are thus permuted exactly as the sheets of the model $y^k = t$, which a loop around 0 cycles, $\zeta \mapsto \zeta \cdot e^{2\pi i/k}$. □

Worked Example 13.9.7 (The k-sheeted cyclic cover and $y^k = t$)**.** Classify the path-connected k-sheeted coverings of T branched at a single point, and name the field extension.

Recognition. One branch point gives one permutation σ; path-connectedness forces $\langle\sigma\rangle$ transitive, and the transitive permutations on k letters that are single cycles are the k-cycles.

Solution. With one branch point (the origin), the data is a single σ. By the transitivity criterion $\langle\sigma\rangle$ acts transitively on k letters; a permutation generating a transitive cyclic group on all k indices is a k-cycle, so after renumbering $\sigma = (1\,2\,\cdots\,k)$. Thus there is, up to isomorphism, exactly one such covering, and by Theorem 13.9.3 exactly one field. It is $K = F(y)$ with $y^k = t$, i.e. $y = \sqrt[k]{t}$: the surface of $y^k - t$ has k sheets and branches only at 0 since every $t \neq 0$ has k distinct kth roots. *Check.* $\deg_y(y^k - t) = k$ matches k sheets, and $y^k - t$ is Eisenstein at the prime t in $\mathbb{C}[t]$, hence irreducible – a genuine degree-k extension.

Worked Example 13.9.8 (A hyperelliptic surface $x^2 = t^3 - t$)**.** Describe the Riemann surface of $f(t, x) = x^2 - (t^3 - t)$ and its branching.

Recognition. Two sheets, so every nontrivial σ_ν is the transposition $(1\,2)$; branch points are where $f(t_0, x)$ has a double root, found from $f = \partial f/\partial x = 0$, with the lemma applying wherever $\partial f/\partial t \neq 0$.

Solution. Here $\partial f/\partial x = 2x$ and $\partial f/\partial t = -3t^2 + 1$. A double root needs $x = 0$, so $t^3 - t = 0$, giving branch points $t = 0$, $t = 1$, $t = -1$. At each, $\partial f/\partial t = -3t^2 + 1$ equals $1, -2, -2$ respectively, all nonzero, so the lemma gives a 2-cycle. With two sheets each $\sigma_\nu = (1\,2)$, and numbering is irrelevant. The subgroup $\langle(1\,2)\rangle$ is transitive on $\{1, 2\}$, so X is path connected. *Check.* Each of the three simple roots of $t^3 - t$ contributes $(1\,2)$; since $(1\,2)^3 = (1\,2) \neq \mathrm{id}$, a large circle also swaps the sheets, so the point at infinity is a fourth branch point of the square-root surface $x = \sqrt{t^3 - t}$ (the product of all local monodromies, infinity included, is the identity).

Worked Example 13.9.9 (Realizing two transpositions: $x^3 - 3x + t$)**.** Find a polynomial whose surface is a path-connected 3-sheeted cover branched at two points, with each local monodromy a transposition, and read off the branching of $f(t, x) = x^3 - 3x + t$.

Recognition. No general recipe exists; guess a simple cubic in x, then locate branch points via $\partial f/\partial x = 0$ and apply the lemma. With three sheets and σ_1 a transposition, transitivity (path-connectedness) forces σ_2 to be a different transposition.

Solution. Take $f = x^3 - 3x + t$. Then $\partial f/\partial x = 3x^2 - 3$ vanishes at $x = \pm 1$, and $\partial f/\partial t = 1 \neq 0$ everywhere, so the lemma applies. Substituting $x = \pm 1$ into $f = 0$ gives branch points $t = \pm 2$ (as $f(t, \pm 1) = t \mp 2$); at $p_1 = (2, 1)$ and $p_2 = (-2, -1)$ each $f(t_0, x)$ has a double root ($f(2, x) = (x-1)^2(x+2)$, $f(-2, x) = (x+1)^2(x-2)$), so each σ_ν is a transposition. Label so $\sigma_1 = (1\,2)$. By the transitivity criterion σ_2 must move sheet 3, so it is $(2\,3)$ or $(1\,3)$; switching sheets $1, 2$ fixes σ_1 and swaps these, so after renumbering $\sigma_1 = (1\,2)$, $\sigma_2 = (2\,3)$. *Check.* $\langle (1\,2), (2\,3) \rangle = \mathrm{Sym}_3$ acts transitively, confirming connectivity; up to branch-point location this is the unique such covering, realized by $F[x]/(x^3 - 3x + t)$.

Worked Example 13.9.10 (Using infinity: $x^3 = t^3 - t^2$)**.** For $f(t, x) = x^3 - t^3 + t^2$ the surface is a 3-sheeted cover branched at $t = 0$ and $t = 1$, where f has triple roots. The point $t = 1$ gives a 3-cycle $\sigma_1 = (1\,2\,3)$; determine σ_0 at $t = 0$.

Recognition. When path-connectedness alone does not pin down the monodromy (a single 3-cycle is already transitive), compute the permutation along a large circle, which equals the product $\sigma_0\sigma_1$, then use the substitution $t = u^{-1}$ to move the large circle to a small loop at $u = 0$.

Solution. Substituting $t = u^{-1}$ and clearing denominators, then setting $y = ux$, transforms f into $g(u, y) = y^3 - 1 + u$. The surface $Y = \{\, g = 0 \,\}$ is *unbranched* at $u = 0$ (there $y^3 = 1$ has three distinct roots), so a loop about $u = 0$ is the trivial permutation. A counterclockwise walk around the large circle in T corresponds to a clockwise walk about $u = 0$, hence is also trivial: $\sigma_0\sigma_1 = \mathrm{id}$. Since $\sigma_1 = (1\,2\,3)$, we get $\sigma_0 = \sigma_1^{-1} = (3\,2\,1)$. *Check.* The product of all local monodromies around the full set of branch points (including infinity) is trivial, the standard relation in Sym_3, and $\langle \sigma_0, \sigma_1 \rangle$ is transitive as required for a connected cover.

Caution. Branch points alone do not determine the covering, and conjugate permutation tuples give isomorphic surfaces – so when comparing two polynomials, match the *monodromy up to simultaneous conjugacy*, not merely the location of branch points. Also: looping around the point at infinity counts. The product of all local monodromies (finite branch points and infinity) is the identity, which is the bookkeeping that lets the last example resolve σ_0.

13.10 The Fundamental Theorem of Algebra via Winding Number

The fundamental theorem of algebra via winding number

A field F is *algebraically closed* if every polynomial of positive degree with coefficients in F has a root in F. The Fundamental Theorem of Algebra asserts that $\mathbb{C}$ is such a field. Among the many proofs, the one below is the most geometric: it watches the image of a circle and counts how many times that image wraps around the origin.

Definition 13.10.1. Let $\gamma\colon [0, 2\pi] \to \mathbb{C} \setminus \{0\}$ be a closed curve missing the origin. Its *winding number* about 0 is the net number of counterclockwise turns the argument of $\gamma(\theta)$ makes as θ runs from 0 to 2π. It is an integer, and – the only fact we need – it varies *continuously*, hence is *constant*, as γ is deformed continuously through curves that never touch 0.

Theorem 13.10.2 (Fundamental Theorem of Algebra)**.** *Every nonconstant polynomial with complex coefficients has a complex root. Equivalently, $\mathbb{C}$ is algebraically closed.*

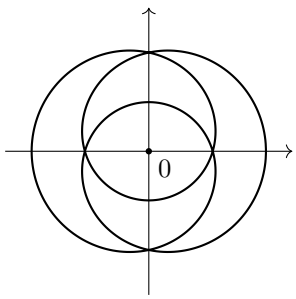
We may assume the polynomial is monic and reduce to

$$f(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0, \qquad n \geq 1,\ a_i \in \mathbb{C}. \tag{$*$}$$

If $a_0 = 0$ then 0 is a root and we are done, so assume $a_0 \neq 0$. For each radius $r > 0$ let C_r be the circle $x = re^{i\theta}$, $0 \leq \theta < 2\pi$, and inspect the image curve $f(C_r)$ in the y-plane.

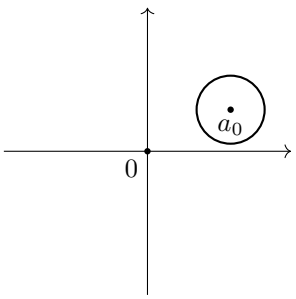
Proof (Artin's winding-number argument). **Warm-up: the pure power x^n.** As θ runs from 0 to 2π, the point $x = re^{i\theta}$ travels once around C_r, while $x^n = r^n e^{in\theta}$ has argument running from 0 to $2\pi n$. So the image of C_r under $x \mapsto x^n$ is the circle of radius r^n traversed n times: its winding number about 0 is n, for *every* r.

Large r: the leading term dominates, so $f(C_r)$ winds n times. Let $M = \max\{1, |a_0|, \dots, |a_{n-1}|\}$ (the 1 makes $M \geq 1$, so the condition $r \geq 10\,n\,M$ below forces $r \geq 1$, which the estimate needs). The lower terms are controlled by a single estimate: if $|x| = r \geq 10\,n\,M$, then



$$\big|f(x) - x^n\big| = \big|a_{n-1}x^{n-1} + \cdots + a_1 x + a_0\big| \leq n\,M\,|x|^{\,n-1} = \frac{nM}{r}\,r^n \leq \tfrac{1}{10}\,r^n.$$

Thus on C_r the value $f(x)$ never strays from x^n by more than a tenth of the radius r^n of the circle x^n traces. Picture the *dog on a leash*: a person walks x^n exactly n times around a circular path of radius r^n, and $f(x)$ is a dog on a leash of length $\leq \frac{1}{10}r^n$. Because the leash is shorter than the radius, the dog cannot get between the person and the flagpole at the origin: it must encircle the origin the same number of times. Formally, the deformation $g_t(\theta) = x^n + t\big(f(x) - x^n\big)$, $0 \leq t \leq 1$, from x^n to f never reaches 0 (its size is at least $r^n - \frac{1}{10}r^n > 0$), so the winding number is unchanged: $f(C_r)$ winds n times for all large r.



Small r: f is near $f(0) = a_0 \neq 0$, so $f(C_r)$ winds 0 times. As $r \to 0$ the circle C_r shrinks to the origin and, by continuity of f, the image $f(C_r)$ shrinks to the single point $f(0) = a_0$. For r small enough $f(C_r)$ lies inside a small disc about a_0 that excludes 0 (since $a_0 \neq 0$); a curve confined to a disc missing the origin makes 0 net turns. So $f(C_r)$ winds 0 times for all small r.

Continuity forces a root. As r varies continuously from small to large, $f(C_r)$ varies continuously. Its winding number about 0 would be a continuous integer-valued function of r – hence constant – *provided* no $f(C_r)$ ever passes through 0. But the winding number is 0 for small r and $n > 0$ for large r, a contradiction. The only escape is that for some intermediate radius r' the curve $f(C_{r'})$ passes through the origin: there is a point α on $C_{r'}$ with $f(\alpha) = 0$. That α is a root. □

Remark 13.10.1. The proof is honestly analytic: it uses that $\mathbb{C}$ (equivalently $\mathbb{R}$) is complete, packaged as the intermediate-value behaviour of the winding number. Some input beyond algebra is unavoidable, since the analogous statement fails for $\mathbb{Q}(i)$ (for instance $x^2 - 2$ has no root there); but little is needed: the Galois-theoretic proofs (D&F 14.6) use only that real polynomials of odd degree have real roots, by the intermediate value theorem, and that complex numbers have complex square roots. The single inequality $|f(x) - x^n| \leq \frac{1}{10}r^n$ does all the work; everything else is the geometry of "the leash is shorter than the radius."

large r: winds $n = 3$

small r: winds 0

The left curve $f(C_r)$, traced for large r, loops the origin $n = 3$ times; the right curve, for small r, is a tiny loop near $f(0) = a_0$ that never encloses 0. As r decreases the left picture must morph into the right, and the only way to lose the windings is to cross the origin.

Worked Example 13.10.3 (Counting windings for a quadratic at fixed radius)**.** For $f(x) = x^2 + 1$, describe $f(C_r)$ for very large r and for $r = \frac{1}{2}$, and locate where the winding number drops.

Recognition. Apply the dictionary: large r gives winding $n = \deg f = 2$; small r gives winding 0 about the origin (the curve stays near $f(0)$); a root sits at the radius where it changes.

Solution. For large r, x^2 dominates and $f(C_r)$ winds 2 times about 0. For $r = \frac{1}{2}$, $|x^2| = \frac{1}{4}$ while $f(0) = 1$, so $f(C_{1/2})$ stays in the disc $|y - 1| \leq \frac{1}{4}$, missing 0: winding 0. The transition happens at $r = 1$, where

$x = \pm i \in C_1$ satisfy $f(\pm i) = 0$. Sanity check: the genuine roots are $\pm i$, both of modulus 1, exactly the radius where the winding number falls from 2 to 0.

Worked Example 13.10.4 (Verifying the dominance estimate)**.** Take $f(x) = x^3 - 4x + 5$, so $n = 3$ and $M = \max\{1, 4, 5\} = 5$. Find an explicit radius beyond which $f(C_r)$ is guaranteed to wind 3 times, using Artin's bound.

Recognition. Use $|x| = r \geq 10\,nM$ to force $|f(x) - x^3| \leq \frac{1}{10}r^3$, so the "leash" is shorter than the "radius" and the winding equals $\deg f$.

Solution. Artin's threshold is $r \geq 10\,nM = 10 \cdot 3 \cdot 5 = 150$. For such r,

$$|f(x) - x^3| = |-4x + 5| \leq 4r + 5 \leq 5r \leq nM\,r^2/r \cdot \tfrac{r}{nM} \;\Rightarrow\; |f(x) - x^3| \leq \tfrac{1}{10}r^3,$$

the last step holding since $5r \leq \frac{1}{10}r^3$ once $r^2 \geq 50$, certainly true at $r \geq 150$. Hence $f(C_r)$ winds 3 times for $r \geq 150$. Sanity check: the bound is crude – by inspection $5r \leq \frac{1}{10}r^3$ already at $r \geq \sqrt{50} \approx 7.1$, but $r = 150$ is a safe, formula-driven radius and that is all the proof needs.

Worked Example 13.10.5 (Total curvature interpretation (Artin, Exercise 15.10.3))**.** Artin notes a companion "total curvature" picture: for large r the curve $f(C_r)$ makes n loops with total curvature $2\pi n$, while for small r (assuming $a_1 \neq 0$) the linear term $a_1 x + a_0$ dominates and $f(C_r)$ makes a single loop around a_0 with total curvature 2π. Explain what becomes of the extra loops.

Recognition. Total curvature divided by 2π is the *turning number* of the curve (the winding number of its tangent vector about 0), not its winding number about 0; as r varies it can change only when the tangent vector vanishes, i.e. when the curve develops a cusp.

Solution. The tangent vector of $\theta \mapsto f(re^{i\theta})$ is $ire^{i\theta}f'(re^{i\theta})$, so by the argument principle the total curvature of $f(C_r)$ is $2\pi(1 + N_r)$, where N_r is the number of roots of f' inside C_r (with multiplicity; none on C_r). For small r, $f(re^{i\theta}) \approx a_0 + a_1 re^{i\theta}$ traces a near-circle once around a_0 and $N_r = 0$ (as $f'(0) = a_1 \neq 0$): one loop, total curvature 2π, winding 1 about a_0 but 0 about the origin. For large r, $N_r = n - 1$: n loops, total curvature $2\pi n$, winding n about 0. As r increases the curve acquires the missing $n - 1$ loops at the moduli $|\beta_k|$ of the critical points β_k (the roots of f'): when C_r passes through β_k the curve $f(C_r)$ has a cusp at $f(\beta_k)$, which opens into a new small loop as r grows. Crossing the origin is a different event: it happens at the moduli $|\alpha_j|$ of the roots of f and raises the winding number about 0, not the number of loops. Sanity check: for $f(x) = x^2 + x + 1$ the second loop appears at $r = \frac{1}{2}$ (the critical point is $-\frac{1}{2}$), while $f(C_r)$ first meets 0 at $r = 1$ (both roots have modulus 1); the winding number about 0 climbs from 0 to n (one step per root), the number of loops from 1 to n (one step per critical point).

Corollary 13.10.6. *$\mathbb{C}$ is algebraically closed: every $f \in \mathbb{C}[x]$ of degree $n \geq 1$ factors as $f(x) = c\prod_{j=1}^{n}(x - \alpha_j)$ with $c, \alpha_j \in \mathbb{C}$.*

Proof. The theorem gives one root α_1; divide by $x - \alpha_1$ and induct on degree. The quotient is a complex polynomial of degree $n - 1$, which again has a root, and so on until the degree is 0. □

Remark 13.10.2. The same picture explains why $\mathbb{R}$ is *not* algebraically closed: restricting x to a real circle is meaningless, and a real polynomial such as $x^2 + 1$ has no real root precisely because its image cannot be made to wind around 0 without leaving the real line. Passing to $\mathbb{C}$ supplies the extra dimension in which the winding can happen.

Fraleigh 39.11 Classify $\alpha = \sqrt{\pi}$ over $F = \mathbb{Q}$ as algebraic or transcendental; if algebraic give $\deg(\alpha, F)$.

Fraleigh 39.12 Classify $\alpha = \sqrt{\pi}$ over $F = \mathbb{R}$ as algebraic or transcendental; if algebraic give $\deg(\alpha, F)$.

Fraleigh 39.13 Classify $\alpha = \sqrt{\pi}$ over $F = \mathbb{Q}(\pi)$ as algebraic or transcendental; if algebraic give $\deg(\alpha, F)$.

Fraleigh 39.14 Classify $\alpha = \pi^2$ over $F = \mathbb{Q}$ as algebraic or transcendental; if algebraic give $\deg(\alpha, F)$.

Fraleigh 39.15 Classify $\alpha = \pi^2$ over $F = \mathbb{Q}(\pi)$ as algebraic or transcendental; if algebraic give $\deg(\alpha, F)$.

Fraleigh 39.16 Classify $\alpha = \pi^2$ over $F = \mathbb{Q}(\pi^3)$ as algebraic or transcendental; if algebraic give $\deg(\alpha, F)$.

Fraleigh 40.1 Find the degree and a basis for $\mathbb{Q}(\sqrt{2})$ over $\mathbb{Q}$.

Fraleigh 40.2 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt{3})$ over $\mathbb{Q}$.

Fraleigh 40.3 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{18})$ over $\mathbb{Q}$.

Fraleigh 40.4 Find the degree and a basis for $\mathbb{Q}(\sqrt[3]{2}, \sqrt{3})$ over $\mathbb{Q}$.

Fraleigh 40.5 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2})$ over $\mathbb{Q}$.

Fraleigh 40.6 Find the degree and a basis for $\mathbb{Q}(\sqrt{2} + \sqrt{3})$ over $\mathbb{Q}$.

Fraleigh 40.7 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}\,\sqrt{3})$ over $\mathbb{Q}$.

Fraleigh 40.8 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt[3]{5})$ over $\mathbb{Q}$.

Fraleigh 40.9 Find the degree and a basis for $\mathbb{Q}(\sqrt[3]{2}, \sqrt[3]{6}, \sqrt[3]{24})$ over $\mathbb{Q}$.

Fraleigh 40.10 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt{6})$ over $\mathbb{Q}(\sqrt{3})$.

Fraleigh 40.11 Find the degree and a basis for $\mathbb{Q}(\sqrt{2} + \sqrt{3})$ over $\mathbb{Q}(\sqrt{3})$.

Fraleigh 40.12 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt{3})$ over $\mathbb{Q}(\sqrt{2} + \sqrt{3})$.

Fraleigh 41.1 Prove the identity $\cos 3\theta = 4\cos^3\theta - 3\cos\theta$ from $e^{i\theta} = \cos\theta + i\sin\theta$.

Fraleigh 41.4 Show algebraically that it is possible to construct an angle of $30°$.

Fraleigh 42.1 Determine whether there exists a finite field with 4096 elements.

Fraleigh 42.2 Determine whether there exists a finite field with 3127 elements.

Fraleigh 42.3 Determine whether there exists a finite field with 68,921 elements.

Fraleigh 42.4 Find the number of primitive 8th roots of unity in GF(9).

Fraleigh 42.5 Find the number of primitive 18th roots of unity in GF(19).

Fraleigh 42.6 Find the number of primitive 15th roots of unity in GF(31).

Fraleigh 42.7 Find the number of primitive 10th roots of unity in GF(23).

Medium

DF 13.1.2 Show $x^3 - 2x - 2$ is irreducible over $\mathbb{Q}$; for a root θ compute $(1+\theta)(1+\theta+\theta^2)$ and $\dfrac{1+\theta}{1+\theta+\theta^2}$ in $\mathbb{Q}(\theta)$.

DF 13.1.6 If α is a root of $a_n x^n + \cdots + a_0$, prove $a_n\alpha$ is a root of the displayed monic polynomial $x^n + a_{n-1}x^{n-1} + a_n a_{n-2}x^{n-2} + \cdots + a_n^{n-1}a_0$.

DF 13.1.7 Prove that $x^3 - nx + 2$ is irreducible for $n \neq -1, 3, 5$.

DF 13.2.2 Obtain fields of $4, 8, 9, 27$ elements by adjoining a root of $g(x) = x^2 + x - 1$ or $h(x) = x^3 - x + 1$ to $\mathbb{F}_2$ or $\mathbb{F}_3$; write the multiplication tables for the fields of 4 and 9 elements and show the nonzero elements are cyclic.

DF 13.2.6 Prove directly from the definitions that $F(\alpha_1, \ldots, \alpha_n)$ is the composite of $F(\alpha_1), \ldots, F(\alpha_n)$.

DF 13.2.7 Prove $\mathbb{Q}(\sqrt{2} + \sqrt{3}) = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, conclude $[\mathbb{Q}(\sqrt{2} + \sqrt{3}) : \mathbb{Q}] = 4$, and find an irreducible polynomial satisfied by $\sqrt{2} + \sqrt{3}$.

DF 13.2.11 Determine the degree of $\mathbb{Q}(\sqrt{3 + 2\sqrt{2}})$ over $\mathbb{Q}$.

DF 13.2.13 Suppose $F = \mathbb{Q}(\alpha_1, \ldots, \alpha_n)$ with each $\alpha_i^2 \in \mathbb{Q}$. Prove that $\sqrt[3]{2} \notin F$.

DF 13.2.15 Prove that if $[F(\alpha) : F]$ is odd then $F(\alpha) = F(\alpha^2)$.

DF 13.2.19 If K/F has degree n, prove that for $\alpha \in K$ left multiplication by α is an F-linear transformation of K, and that K embeds in the ring of $n \times n$ matrices over F.

DF 13.2.20 Show the matrix A of "multiplication by α" has α as a root of its characteristic polynomial; use this to find the monic cubic satisfied by $\sqrt[3]{2}$ and by $1+\sqrt[3]{2}+\sqrt[3]{4}$.

DF 13.2.21 For $K=\mathbb{Q}(\sqrt{D})$, D squarefree, and $\alpha=a+b\sqrt{D}$, show in the basis $1,\sqrt{D}$ that "multiplication by α" has matrix $\left(\begin{smallmatrix} a & bD \\ b & a\end{smallmatrix}\right)$ and that $a+b\sqrt{D}\mapsto\left(\begin{smallmatrix} a & bD \\ b & a\end{smallmatrix}\right)$ is an isomorphism onto a subfield of $\mathrm{M}_2(\mathbb{Q})$.

DF 13.3.4 Use the fact that $\alpha=2\cos(2\pi/7)$ satisfies $x^3+x^2-2x-1=0$ to prove the regular 7-gon is not constructible by straightedge and compass.

DF 13.3.5 Use the fact that $\alpha=2\cos(2\pi/5)$ satisfies $x^2+x-1=0$ to conclude the regular 5-gon is constructible by straightedge and compass.

DF 13.5.2 Find all irreducible polynomials of degrees $1,2,4$ over $\mathbb{F}_2$ and prove their product is $x^{16}-x$.

DF 13.5.3 Prove $d\mid n$ if and only if x^d-1 divides x^n-1.

DF 13.5.4 For an integer $a>1$, prove $d\mid n$ iff $a^d-1\mid a^n-1$; conclude $\mathbb{F}_{p^d}\subseteq\mathbb{F}_{p^n}$ iff $d\mid n$.

DF 13.5.6 Prove $x^{p^n-1}-1=\prod_{0\neq\alpha\in\mathbb{F}_{p^n}}(x-\alpha)$; conclude the product of the nonzero elements of $\mathbb{F}_{p^n}$ is $+1$ if $p=2$ and -1 if p odd, and derive Wilson's Theorem $(p-1)!\equiv -1 \pmod p$.

DF 13.5.9 Show $\binom{pn}{pi}$ is the coefficient of x^{pi} in $(1+x)^{pn}$; working over $\mathbb{F}_p$, show it is the coefficient of $(x^p)^i$ in $(1+x^p)^n$, and conclude $\binom{pn}{pi}\equiv\binom{n}{i} \pmod p$.

DF 13.6.1 If m,n are coprime, ζ_m a primitive mth root and ζ_n a primitive nth root of unity, prove $\zeta_m\zeta_n$ is a primitive mnth root of unity.

DF 13.6.2 If ζ_n is a primitive nth root of unity and $d\mid n$, prove ζ_n^d is a primitive (n/d)th root of unity.

DF 13.6.3 Prove that if a field contains the nth roots of unity for n odd then it also contains the $2n$th roots of unity.

DF 13.6.4 If $n=p^km$ with p prime and $p\nmid m$, prove there are exactly m distinct nth roots of unity over a field of characteristic p.

DF 13.6.5 Prove there are only finitely many roots of unity in any finite extension K of $\mathbb{Q}$.

DF 13.6.6 Prove that for n odd, $n>1$, $\Phi_{2n}(x)=\Phi_n(-x)$.

DF 13.6.9 If A is an $n\times n$ complex matrix with $A^k=I$, show A is diagonalizable; show $\left(\begin{smallmatrix} 1 & \alpha \\ 0 & 1\end{smallmatrix}\right)$ over a field of characteristic p satisfies $A^p=I$ but is not diagonalizable for $\alpha\neq 0$.

DF 13.6.10 Prove the Frobenius map $\varphi: x\mapsto x^p$ is an automorphism of $\mathbb{F}_{p^n}$, that $\varphi^n=\mathrm{id}$, and that no lower power of φ is the identity.

Artin 1.1 Let R be an integral domain containing a field F as a subring and finite-dimensional as an F-vector space. Prove R is a field.

Artin 1.2 For $x^2+bx+c=0$ over F (char $\neq 2$), prove that if $\delta^2=b^2-4c$ then $x=(-b+\delta)/2$ solves it, and that if b^2-4c is not a square the polynomial has no root in F.

Artin 2.2 For an irreducible $f(x)=x^n+a_{n-1}x^{n-1}+\cdots+a_0$ over F with root α, determine α^{-1} explicitly in terms of α and the coefficients a_i.

Artin 3.1 Let α generate a degree-5 extension of F. Prove α^2 generates the same extension.

Artin 3.6 Let a be a positive rational that is not a square in $\mathbb{Q}$. Prove $\sqrt[4]{a}$ has degree 4 over $\mathbb{Q}$.

Artin 3.7 (a) Is $i\in\mathbb{Q}(\sqrt[4]{2})$? (b) Is $\sqrt{2}\in\mathbb{Q}(\sqrt[4]{2})$?

Artin 3.8 If $\alpha+\beta$ and $\alpha\beta$ are algebraic numbers, prove α and β are also algebraic.

Artin 4.2 Determine the irreducible polynomial for $\alpha=\sqrt{2}+\sqrt{3}$ over (a) $\mathbb{Q}$, (b) $\mathbb{Q}(\sqrt{5})$, (c) $\mathbb{Q}(\sqrt{6})$, (d) $\mathbb{Q}(\sqrt{15})$.

Artin 6.1 Let F have characteristic zero and let g be an irreducible common divisor of a polynomial f and its derivative f'. Prove g^2 divides f.

Artin 6.2 (a) For F of characteristic zero, determine all square roots of elements of F that a quadratic extension $F(\sqrt{t})$ contains. (b) Classify the quadratic extensions of $\mathbb{Q}$.

Artin 7.2 Determine the irreducible polynomial over $\mathbb{F}_2$ of each element of $\mathbb{F}_8$ in the list 15.7.8.

Artin 7.4 Determine the number of irreducible polynomials of degree 3 over $\mathbb{F}_3$ and over $\mathbb{F}_5$.

Artin 7.6 Factor $x^{16} - x$ over the fields $\mathbb{F}_4$ and $\mathbb{F}_8$.

Artin 7.7 Let K be a finite field. Prove that the product of the nonzero elements of K is -1.

Artin 7.8 The polynomials $x^3 + x + 1$ and $x^3 + x^2 + 1$ are irreducible over $\mathbb{F}_2$; describe an explicit isomorphism between the two cubic extensions and count how many such isomorphisms there are.

Artin 7.14 Find a formula in terms of the Euler ϕ function for the number of irreducible polynomials of degree n over $\mathbb{F}_p$.

Artin 8.1 Prove that every finite extension of a finite field has a primitive element.

Artin 8.2 Determine all primitive elements for the extension $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ of $\mathbb{Q}$.

Artin M.1 Let $K = F(\alpha)$ be generated by a transcendental α, and let $\beta \in K \setminus F$. Prove α is algebraic over $F(\beta)$.

Fraleigh 39.17 In $\mathbb{Z}_2(\alpha)$ with $\alpha^2 = \alpha + 1$, factor $x^2 + x + 1$ into linear factors.

Fraleigh 39.18 (a) Show $x^2 + 1$ is irreducible in $\mathbb{Z}_3[x]$; (b) for a root α give the addition and multiplication tables of the nine elements of $\mathbb{Z}_3(\alpha)$.

Fraleigh 39.24 (a) Find a subfield $F \leq \mathbb{R}$ with π algebraic of degree 3 over F; (b) find a subfield $E \leq \mathbb{R}$ with e^2 algebraic of degree 5 over E.

Fraleigh 40.13 Find the degree and a basis for $\mathbb{Q}(\sqrt{2}, \sqrt{6} + \sqrt{10})$ over $\mathbb{Q}(\sqrt{3} + \sqrt{5})$.

Fraleigh 42.9 In $\overline{\mathbb{Z}_2}$, let α, β be roots of $x^3 + x^2 + 1$ and $x^3 + x + 1$; show $\mathbb{Z}_2(\alpha) = \mathbb{Z}_2(\beta)$.

Fraleigh 42.10 Show that every irreducible polynomial in $\mathbb{Z}_p[x]$ divides $x^{p^n} - x$ for some n.

Fraleigh 42.11 If F has p^n elements with prime subfield $\mathbb{Z}_p$ and α generates $F^\times$, show $\deg(\alpha, \mathbb{Z}_p) = n$.

Fraleigh 42.15 For $p(x), q(x) \in F[x]$ prove the derivative rules $D(p + q) = Dp + Dq$, $D(ap) = aD(p)$, $D(pq) = pD(q) + D(p)q$, and that $(x - a)^2 \mid p(x)$ iff a is a zero of both p and Dp.

Hard

DF 13.1.8 Prove $x^5 - ax - 1$ is irreducible over $\mathbb{Z}$ unless $a = 0, 2, -1$ (with the stated factorizations in the exceptional cases).

DF 13.2.8 For F of characteristic $\neq 2$ and $D_1, D_2 \in F$ nonsquares, prove $F(\sqrt{D_1}, \sqrt{D_2})$ has degree 4 over F if $D_1 D_2$ is not a square and degree 2 otherwise (a biquadratic extension).

DF 13.2.9 For F of characteristic $\neq 2$ and b a nonsquare, prove $\sqrt{a + \sqrt{b}} = \sqrt{m} + \sqrt{n}$ has a solution in F iff $a^2 - b$ is a square in F; deduce when $\mathbb{Q}(\sqrt{a + \sqrt{b}})$ is biquadratic over $\mathbb{Q}$.

DF 13.2.10 Determine the degree of $\mathbb{Q}(\sqrt{3 + 4i} + \sqrt{3 - 4i})$ over $\mathbb{Q}$ (first quadrant / fourth quadrant roots), and of $\mathbb{Q}(\sqrt{1 + \sqrt{-3}} + \sqrt{1 - \sqrt{-3}})$ over $\mathbb{Q}$.

DF 13.2.12 If $[K : F] = p$ is prime, show any subfield E with $F \subseteq E \subseteq K$ equals F or K.

DF 13.2.14 If F is formally real, $f \in F[x]$ irreducible of odd degree with root α, prove $F(\alpha)$ is also formally real.

DF 13.2.16 If K/F is algebraic and R is a ring with $F \subseteq R \subseteq K$, show R is a subfield of K containing F.

DF 13.2.17 For f irreducible of degree n over F and any $g \in F[x]$, prove every irreducible factor of $f(g(x))$ has degree divisible by n.

DF 13.2.18 For $t = P(x)/Q(x) \in k(x)$ with P, Q coprime, show $P(X) - tQ(X)$ is irreducible over $k(t)$ with root x, has degree $\max(\deg P, \deg Q)$ in X, and conclude $[k(x) : k(t)] = \max(\deg P, \deg Q)$.

DF 13.2.22 Prove $K_1 \otimes_F K_2$ is a field if and only if $[K_1K_2 : F] = [K_1 : F][K_2 : F]$, for finite extensions K_1, K_2 of F inside K.

DF 13.3.1 Prove that it is impossible to construct the regular 9-gon.

DF 13.3.2 Prove that Archimedes' construction actually trisects the angle θ.

DF 13.3.3 Prove that Conway's construction actually constructs $2k^{1/3}$ and $2k^{2/3}$.

DF 13.4.5 Prove K (finite over F) is a splitting field over F iff every irreducible polynomial in $F[x]$ with a root in K splits completely in $K[x]$.

DF 13.4.6 For K_1, K_2 splitting fields over F inside K, prove (a) the composite K_1K_2 and (b) the intersection $K_1 \cap K_2$ are splitting fields over F.

DF 13.5.5 For prime p and nonzero $a \in \mathbb{F}_p$, prove $x^p - x + a$ is irreducible and separable over $\mathbb{F}_p$.

DF 13.5.7 If K has characteristic p and $K \neq K^p$, prove there exist irreducible inseparable polynomials over K, hence inseparable finite extensions.

DF 13.5.10 For $f(x_1, \ldots, x_n) \in \mathbb{Z}[x_1, \ldots, x_n]$ and any prime p, prove $f(x_1, \ldots, x_n)^p - f(x_1^p, \ldots, x_n^p)$ has all coefficients divisible by p.

DF 13.5.11 If F is perfect, $K \supseteq F$, and $f \in F[x]$ has no repeated irreducible factors in $F[x]$, prove f has no repeated irreducible factors in $K[x]$.

DF 13.6.7 Use Mobius inversion to prove $\Phi_m(x) = \prod_{d|m}(x^d - 1)^{\mu(m/d)}$.

DF 13.6.8 For primes ℓ and p, determine the factorization of $\Phi_\ell(x)$ modulo p: $(x-1)^{\ell-1}$ if $p = \ell$, and for $p \neq \ell$ a product of $(\ell - 1)/f$ distinct irreducible factors of degree $f = \mathrm{ord}_\ell(p)$; in particular factor $\Phi_7(x)$ in $\mathbb{F}_2[x]$ and for $p \bmod 7$.

DF 13.6.11 Determine the rational canonical form over $\mathbb{F}_p$ of the Frobenius map $\varphi : x \mapsto x^p$ on the n-dimensional $\mathbb{F}_p$-space $\mathbb{F}_{p^n}$.

DF 13.6.12 Determine the Jordan canonical form (over a field containing all eigenvalues) of the Frobenius map φ on $\mathbb{F}_{p^n}$.

DF 13.6.13 (Wedderburn) Prove that a finite division ring D is a field, following Witt's class-equation / cyclotomic argument.

DF 13.6.14 For monic $P(x) \in \mathbb{Z}[x]$ of degree ≥ 1, show there are infinitely many distinct prime divisors of the values $P(1), P(2), P(3), \ldots$.

DF 13.6.15 For an odd prime $p \nmid m$ with $\Phi_m(a) \equiv 0 \pmod{p}$, prove $\gcd(a, p) = 1$ and that the order of a in $(\mathbb{Z}/p\mathbb{Z})^\times$ is exactly m.

DF 13.6.16 If p is an odd prime dividing $\Phi_m(a)$ for $a \in \mathbb{Z}$, prove $p \mid m$ or $p \equiv 1 \pmod{m}$.

DF 13.6.17 Prove there are infinitely many primes p with $p \equiv 1 \pmod{m}$.

Artin 2.3 Let $\beta = \omega\sqrt[3]{2}$ with $\omega = e^{2\pi i/3}$ and $K = \mathbb{Q}(\beta)$. Prove $x_1^2 + \cdots + x_n^2 = -1$ has no solution with $x_i \in K$.

Artin 3.3 Let $\zeta_n = e^{2\pi i/n}$. Prove that $\zeta_5 \notin \mathbb{Q}(\zeta_7)$.

Artin 3.4 Let $\zeta_n = e^{2\pi i/n}$. Determine the irreducible polynomial over $\mathbb{Q}$ and over $\mathbb{Q}(\zeta_3)$ of $\zeta_4, \zeta_6, \zeta_8, \zeta_9, \zeta_{10}, \zeta_{12}$.

Artin 3.5 Determine the values of n such that ζ_n has degree at most 3 over $\mathbb{Q}$.

Artin 3.9 For α, β complex roots of irreducibles $f, g \in \mathbb{Q}[x]$ with $K = \mathbb{Q}(\alpha)$, $L = \mathbb{Q}(\beta)$, prove f is irreducible in $L[x]$ iff g is irreducible in $K[x]$.

Artin 3.10 If K/F and L/K are algebraic extensions, prove L/F is algebraic.

Artin 5.3 Decide whether the regular 9-gon is constructible by ruler and compass.

Artin 5.4 Is it possible to construct a square whose area equals that of a given triangle?

Artin 6.3 Determine the quadratic number fields $\mathbb{Q}(\sqrt{d})$ that contain a primitive nth root of unity for some integer n.

Artin 7.9 Without using Theorem 15.7.3: count the monic irreducible quadratics over $F = \mathbb{F}_p$, show $F[x]/(f)$ has order p^2 for irreducible quadratic f, that every degree-2 polynomial has a root there, and that all such fields are isomorphic.

Artin 7.10 Let F be a finite field and f a nonconstant polynomial whose derivative is zero. Prove f is not irreducible over F.

Artin 7.12 For $q = p^r$, $q' = p^k$, determine for which r, k the polynomial $x^q - x$ divides $x^{q'} - x$ in $\mathbb{Z}[x]$.

Artin 7.13 Prove that a finite subgroup of the multiplicative group of any field is cyclic.

Artin M.3 For f irreducible of degree 6 over F and K a quadratic extension of F, determine the possible degrees of the irreducible factors of f in $K[x]$.

Artin M.4 For an odd prime p: prove exactly half of $\mathbb{F}_p^\times$ are squares and a product of two nonsquares is a square; extend to any finite field of odd order; show every element of a finite field of even order is a square; and prove the irreducible polynomial for $\sqrt{2} + \sqrt{3}$ over $\mathbb{Q}$ is reducible mod every prime p.

Artin M.5 Prove that any element of $\mathrm{GL}_2(\mathbb{Z})$ of finite order has order $1, 2, 3, 4$, or 6.

Fraleigh 41.3 Using the proof of Theorem 41.11, show the regular 9-gon is not constructible.

Fraleigh 42.12 Show a finite field of p^n elements has exactly one subfield of p^m elements for each divisor m of n.

Fraleigh 42.13 Show $x^{p^n} - x$ is the product of all monic irreducible polynomials in $\mathbb{Z}_p[x]$ of degree d dividing n.

Fraleigh 42.14 Let p be an odd prime. (a) For $a \not\equiv 0 \pmod{p}$ show $x^2 \equiv a \pmod{p}$ is solvable iff $a^{(p-1)/2} \equiv 1 \pmod{p}$; (b) decide whether $x^2 - 6$ is irreducible in $\mathbb{Z}_{17}[x]$.

Chapter 14

Galois Theory

14.1 Basic Definitions

Field automorphisms and the group $\mathrm{Aut}(K/F)$

Let K be a field. An *automorphism* of K is a ring isomorphism $\sigma : K \to K$; automatically $\sigma(1) = 1$, σ is a bijection respecting $+$ and $\times$, and $\sigma(\alpha^{-1}) = \sigma(\alpha)^{-1}$ for $\alpha \neq 0$. The set of all automorphisms of K forms a group under composition, written $\mathrm{Aut}(K)$. Galois theory studies not all of $\mathrm{Aut}(K)$ but the automorphisms that respect a chosen base field.

Definition 14.1.1. Let K/F be a field extension. An automorphism σ of K is said to *fix* F (or fix F pointwise) if $\sigma(a) = a$ for every $a \in F$. The collection of such automorphisms is

$$\mathrm{Aut}(K/F) = \{\, \sigma \in \mathrm{Aut}(K) : \sigma(a) = a \text{ for all } a \in F \,\},$$

a subgroup of $\mathrm{Aut}(K)$. We call σ an *F-automorphism* of K.

Two structural facts make the group manageable. First, an F-automorphism is *F-linear*: it fixes F and respects addition and scalar multiplication, so $\sigma \in \mathrm{Aut}(K/F)$ is a linear transformation of the F-vector space K. Second, every field K contains a unique smallest subfield, its *prime field* P ($\cong \mathbb{Q}$ if $\mathrm{char}\, K = 0$, $\cong \mathbb{F}_p$ if $\mathrm{char}\, K = p$), and *every* automorphism fixes P pointwise. Hence $\mathrm{Aut}(K) = \mathrm{Aut}(K/P)$: the unqualified automorphism group is automorphisms over the prime field.

Lemma 14.1.2 (an F-automorphism is determined by its values on generators)**.** *If $K = F(\alpha_1, \dots, \alpha_n)$ and $\sigma, \tau \in \mathrm{Aut}(K/F)$ satisfy $\sigma(\alpha_i) = \tau(\alpha_i)$ for all i, then $\sigma = \tau$. In particular $\sigma = \mathrm{id}$ iff σ fixes a generating set.*

Idea. Every element of $K = F(\alpha_1, \dots, \alpha_n)$ is built from the α_i and elements of F by the four field operations. Since σ fixes F and commutes with all four operations, its value on such an expression is forced once the values $\sigma(\alpha_i)$ are fixed. Thus agreeing on the α_i (and on F) forces agreement everywhere. □

Worked Example 14.1.3 (Reading an automorphism off a single generator)**.** Show that any $\sigma \in \mathrm{Aut}(\mathbb{Q}(\sqrt{2})/\mathbb{Q})$ is determined by the single value $\sigma(\sqrt{2})$, and list the only possible values.

Recognition. By the lemma, σ is determined by its action on the generator $\sqrt{2}$ of $\mathbb{Q}(\sqrt{2})$ over $\mathbb{Q}$; the value must itself be a root of the minimal polynomial of $\sqrt{2}$ (next subsection).

Solution. A general element is $a + b\sqrt{2}$ with $a, b \in \mathbb{Q}$, and $\sigma(a + b\sqrt{2}) = a + b\,\sigma(\sqrt{2})$ because σ fixes $\mathbb{Q}$. So σ is pinned down by $\sigma(\sqrt{2})$. Applying σ to $(\sqrt{2})^2 = 2$ gives $\sigma(\sqrt{2})^2 = \sigma(2) = 2$, so $\sigma(\sqrt{2}) = \pm\sqrt{2}$. Thus there are at most two automorphisms. Sanity check: both candidates are realizable – $\sigma(\sqrt{2}) = \sqrt{2}$ gives the identity, and $\sigma(\sqrt{2}) = -\sqrt{2}$ gives a well-defined ring map since $\mathbb{Q}(\sqrt{2}) \cong \mathbb{Q}[x]/(x^2 - 2)$ and $-\sqrt{2}$ is also a root of $x^2 - 2$.

Worked Example 14.1.4 (Complex conjugation as an automorphism)**.** Verify that $\tau : \mathbb{C} \to \mathbb{C}$, $\tau(a + bi) = a - bi$, is an element of $\mathrm{Aut}(\mathbb{C}/\mathbb{R})$, and find its order.

Recognition. An $\mathbb{R}$-automorphism is a bijective ring map fixing $\mathbb{R}$; conjugation visibly fixes $\mathbb{R}$ ($b = 0$) and is its own inverse.

Solution. For $z = a + bi$, $w = c + di$: $\tau(z + w) = (a + c) - (b + d)i = \tau(z) + \tau(w)$, and $\tau(zw) = \tau((ac - bd) + (ad + bc)i) = (ac - bd) - (ad + bc)i = (a - bi)(c - di) = \tau(z)\tau(w)$. Also $\tau(1) = 1$ and τ fixes every real number, so $\tau \in \mathrm{Aut}(\mathbb{C}/\mathbb{R})$. Finally $\tau^2(a + bi) = \tau(a - bi) = a + bi$, so $\tau^2 = \mathrm{id}$ and $\tau \neq \mathrm{id}$, giving $|\tau| = 2$. Sanity check: $[\mathbb{C} : \mathbb{R}] = 2$, and $\mathrm{Aut}(\mathbb{C}/\mathbb{R}) = \{\, \mathrm{id}, \tau \,\} \cong \mathbb{Z}/2\mathbb{Z}$ has order equal to the degree – exactly what the bound below predicts for this (Galois) extension.

Automorphisms permute roots

The single most useful fact in the section is that F-automorphisms cannot move a root of an F-polynomial to a non-root. This is what makes $\mathrm{Aut}(K/F)$ *finite* and computable when K/F is a finite extension: it embeds into a permutation group of finitely many roots.

Proposition 14.1.5 (σ permutes the roots of an F-polynomial)**.** *Let $\sigma \in \mathrm{Aut}(K/F)$ and let $p(x) \in F[x]$. If $\alpha \in K$ is a root of p, then $\sigma(\alpha)$ is also a root of p. Consequently σ permutes the set of roots of p lying in K, and if p is irreducible over F then σ sends each root of p to another root of p.*

Idea. Write $p(x) = \sum_i c_i x^i$ with $c_i \in F$. Applying σ to the equation $\sum_i c_i \alpha^i = 0$ and using $\sigma(c_i) = c_i$ (since $c_i \in F$) and the multiplicativity/additivity of σ gives $\sum_i c_i\, \sigma(\alpha)^i = 0$, i.e. $p(\sigma(\alpha)) = 0$. So σ maps roots to roots; being injective on the finite root set of p in K, it permutes them. □

Method (To compute $\mathrm{Aut}(K/F)$ for $K = F(\alpha_1, \ldots, \alpha_n)$: take each generator α_i, find its minimal polynomial $m_i(x)$ over F, and record which roots of m_i also lie in K. Any σ must send α_i to one of those in-K roots, and conversely each consistent choice that respects all algebraic relations among the α_i gives one automorphism. The number of automorphisms is the number of *consistent* root assignments.)**.**

Remark 14.1.1. The proposition explains the asymmetry between abstract and embedded roots. An automorphism may only send α to a conjugate that *actually lies in K*. If K contains some but not all roots of the minimal polynomial of α, the missing roots are simply unavailable as targets, and $\mathrm{Aut}(K/F)$ is smaller than the degree. This is precisely the failure of normality, seen below for $\mathbb{Q}(\sqrt[3]{2})$.

Worked Example 14.1.6 (The only roots available may be the obvious ones)**.** For $K = \mathbb{Q}(\sqrt[4]{2})$, show that an automorphism over $\mathbb{Q}$ can send $\sqrt[4]{2}$ only to $\pm\sqrt[4]{2}$, not to the complex roots $\pm i\sqrt[4]{2}$.

Recognition. $\sqrt[4]{2}$ has minimal polynomial $x^4 - 2$ over $\mathbb{Q}$ (Eisenstein at 2); by the proposition $\sigma(\sqrt[4]{2})$ is a root of $x^4 - 2$ *lying in K*.

Solution. The four roots of $x^4 - 2$ are $\pm\sqrt[4]{2}$, $\pm i\sqrt[4]{2}$. But $K = \mathbb{Q}(\sqrt[4]{2}) \subset \mathbb{R}$, so the non-real roots $\pm i\sqrt[4]{2}$ do not lie in K. Hence $\sigma(\sqrt[4]{2}) \in \{\, \sqrt[4]{2}, -\sqrt[4]{2} \,\}$, giving at most two automorphisms. Both occur: $\sqrt[4]{2} \mapsto -\sqrt[4]{2}$ extends $\sqrt{2} \mapsto \sqrt{2}$ (since $(-\sqrt[4]{2})^2 = \sqrt{2}$), so $\mathrm{Aut}(\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z}$. Sanity check: $[\mathbb{Q}(\sqrt[4]{2}) : \mathbb{Q}] = 4$ but only 2 automorphisms appear, so this real extension is *not* Galois – two of the four conjugates escaped the field.

Worked Example 14.1.7 (Automorphisms of $\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}(\sqrt{2})$)**.** Determine $\mathrm{Aut}(\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}(\sqrt{2}))$ explicitly.

Recognition. Now $\sqrt{2}$ is fixed, so $\sigma(\sqrt[4]{2})$ must be a root of the minimal polynomial of $\sqrt[4]{2}$ over the larger base $\mathbb{Q}(\sqrt{2})$, namely $x^2 - \sqrt{2}$.

Solution. Over $\mathbb{Q}(\sqrt{2})$ the element $\beta = \sqrt[4]{2}$ satisfies $\beta^2 = \sqrt{2}$, and $x^2 - \sqrt{2}$ is its minimal polynomial (degree $2 = [\mathbb{Q}(\sqrt[4]{2}) : \mathbb{Q}(\sqrt{2})]$). Its roots are $\pm\sqrt[4]{2}$, both in K. So $\sigma(\sqrt[4]{2}) = \pm\sqrt[4]{2}$, giving $\mathrm{Aut}(\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}(\sqrt{2})) = \{\, \mathrm{id},\ \sqrt[4]{2} \mapsto -\sqrt[4]{2} \,\} \cong \mathbb{Z}/2\mathbb{Z}$. Sanity check: $[\mathbb{Q}(\sqrt[4]{2}) : \mathbb{Q}(\sqrt{2})] = 2$ and we found 2 automorphisms, so this degree-2 step *is* Galois (both roots of the quadratic live in K).

Fixed fields and the bound $|\mathrm{Aut}(K/F)| \leq [K : F]$

The construction dual to "automorphisms over a base field" is "the field fixed by a set of automorphisms."

Definition 14.1.8. Let $H \subseteq \mathrm{Aut}(K)$ be any subset (most often a subgroup). The *fixed field* of H is

$$\mathrm{Fix}(H) = \{\, \alpha \in K : \sigma(\alpha) = \alpha \text{ for all } \sigma \in H \,\},$$

a subfield of K. If $H = \mathrm{Aut}(K/F)$ then $F \subseteq \mathrm{Fix}(H)$, since every $\sigma \in H$ fixes F by definition.

That $\mathrm{Fix}(H)$ is a field is immediate: if σ fixes α and β it fixes $\alpha \pm \beta$, $\alpha\beta$, α^{-1}. The inclusion $F \subseteq \mathrm{Fix}(\mathrm{Aut}(K/F))$ can be *strict* – this is exactly when the extension is not Galois – and the central goal of the chapter is to characterize equality.

Theorem 14.1.9 (the degree bound and the linear independence of characters)**.** *Let K/F be a finite extension. Then*

$$|\mathrm{Aut}(K/F)| \;\leq\; [K:F].$$

More generally, distinct automorphisms $\sigma_1, \ldots, \sigma_m$ of K are linearly independent over K as functions $K^\times \to K$ (Dedekind's lemma), and if $G \leq \mathrm{Aut}(K)$ is a finite subgroup of order m with $\mathrm{Fix}(G) = F$, then $[K:F] = m$.

Idea. Dedekind's lemma: a minimal-length nontrivial K-linear relation $\sum_i a_i\sigma_i(x) = 0$ (all x) is impossible – pick y with $\sigma_1(y) \neq \sigma_2(y)$, substitute xy, and subtract $\sigma_1(y)$ times the original to get a shorter relation, a contradiction. For the bound: if $[K:F] = n$, with F-basis $\omega_1, \ldots, \omega_n$, and there were $n+1$ distinct F-automorphisms $\sigma_1, \ldots, \sigma_{n+1}$, the homogeneous K-linear system $\sum_j \sigma_j(\omega_i)x_j = 0$ $(i = 1, \ldots, n)$ of n equations in $n+1$ unknowns would have a nonzero solution $x \in K^{n+1}$; by F-linearity $\sum_j x_j\sigma_j$ then vanishes on all of K, a nontrivial K-dependence among the σ_j, contradicting independence. The equality $[K : \mathrm{Fix}(G)] = |G|$ is the quantitative converse, proved by the same independence input (Artin's theorem). □

Corollary 14.1.10 (splitting field of a separable polynomial: equality)**.** *If K is the splitting field over F of a* separable *polynomial $f(x) \in F[x]$ (one with distinct roots), then*

$$|\mathrm{Aut}(K/F)| = [K:F].$$

Idea. Build automorphisms by the isomorphism-extension theorem. An F-isomorphism of subfields $F(\alpha) \to F(\alpha')$ sending a root α of an irreducible factor to another root α' extends, over a splitting field, to an automorphism; separability guarantees each irreducible factor encountered has *distinct* roots, so the number of extensions at each stage is exactly the degree of that factor. Multiplying these local counts up the tower of root adjunctions yields exactly $[K:F]$ automorphisms, meeting the bound. □

Worked Example 14.1.11 (Counting embeddings to realize all $[K:F]$ automorphisms)**.** For the splitting field K of $f(x) = (x^2-2)(x^2-3)$ over $\mathbb{Q}$, count $\mathrm{Aut}(K/\mathbb{Q})$ by extending one root choice at a time.

Recognition. f is separable (four distinct roots $\pm\sqrt{2}, \pm\sqrt{3}$), so by the corollary $|\mathrm{Aut}(K/\mathbb{Q})| = [K:\mathbb{Q}]$; count by isomorphism-extension across the tower $\mathbb{Q} \subset \mathbb{Q}(\sqrt{2}) \subset \mathbb{Q}(\sqrt{2},\sqrt{3})$.

Solution. Adjoin $\sqrt{2}$: the irreducible x^2-2 has 2 roots in K, so an embedding of $\mathbb{Q}(\sqrt{2})$ extends in 2 ways ($\sqrt{2} \mapsto \pm\sqrt{2}$). Over $\mathbb{Q}(\sqrt{2})$, $\sqrt{3}$ still has minimal polynomial x^2-3 (degree 2, $\sqrt{3} \notin \mathbb{Q}(\sqrt{2})$), with 2 roots $\pm\sqrt{3}$ in K, doubling each choice. Total $2 \cdot 2 = 4$ automorphisms, and $[K:\mathbb{Q}] = 2 \cdot 2 = 4$. Sanity check: the four maps are the independent sign choices $(\sqrt{2},\sqrt{3}) \mapsto (\pm\sqrt{2},\pm\sqrt{3})$; they meet the degree bound exactly, confirming separability gives equality.

Worked Example 14.1.12 (When the bound is strict: a tell-tale gap)**.** Without listing automorphisms, predict whether $|\mathrm{Aut}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q})|$ equals $[\mathbb{Q}(\sqrt[3]{2}):\mathbb{Q}] = 3$.

Recognition. Equality requires K to contain *all* roots of the minimal polynomials of its generators (normality) and those polynomials to be separable; check whether all roots of x^3-2 lie in $\mathbb{Q}(\sqrt[3]{2})$.

Solution. The roots of x^3-2 are $\sqrt[3]{2}$, $\zeta_3\sqrt[3]{2}$, $\zeta_3^2\sqrt[3]{2}$ with $\zeta_3 = e^{2\pi i/3}$ non-real. But $\mathbb{Q}(\sqrt[3]{2}) \subset \mathbb{R}$, so two of the three roots are absent. Any σ must send $\sqrt[3]{2}$ to a root *in* K, leaving only $\sigma(\sqrt[3]{2}) = \sqrt[3]{2}$, the identity. So $|\mathrm{Aut}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q})| = 1 < 3$: the bound is strict. Sanity check: this matches the degree bound (a number ≤ 3) and confirms a strict gap exactly where roots escape, anticipating the detailed count in the next subsection.

Galois extensions and the Galois group

Definition 14.1.13. A finite extension K/F is *Galois* if $|\mathrm{Aut}(K/F)| = [K:F]$, equivalently (by the theorem above) if $\mathrm{Fix}(\mathrm{Aut}(K/F)) = F$. When K/F is Galois we write

$$\mathrm{Gal}(K/F) = \mathrm{Aut}(K/F),$$

the *Galois group* of the extension. By the corollary and its converse (proved in Section 14.2), K/F is Galois precisely when K is the splitting field over F of some separable polynomial; equivalently K/F is *normal and separable*.

The two phrasings of "Galois" — a *counting* condition $|\mathrm{Aut}(K/F)| = [K : F]$ and a *fixed-field* condition $\mathrm{Fix}(\mathrm{Aut}(K/F)) = F$ — are the two hooks the Fundamental Theorem (Section 14.2) hangs on. For non-Galois extensions $\mathrm{Fix}(\mathrm{Aut}(K/F))$ is strictly larger than F, and the group sees only the Galois subextension.

Caution. Degree $[K : F]$ many automorphisms require BOTH normality (all conjugates of each generator lie in K) and separability (those conjugates are distinct). Degree alone is no guarantee: $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ has degree 3 but only the identity automorphism, since the field is real while two of the three cube roots of 2 are complex. It fails *normality*: $x^3 - 2$ does not split in $\mathbb{Q}(\sqrt[3]{2})$. (In characteristic p one can instead fail *separability*, e.g. $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$, where $x^p - t = (x - t^{1/p})^p$ has a single repeated root.)

Worked Example 14.1.14 ($\mathrm{Aut}(\mathbb{Q}(\sqrt{2})/\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z}$ is Galois)**.** Show $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ is Galois with group $\mathbb{Z}/2\mathbb{Z}$, and verify the fixed field is $\mathbb{Q}$.

Recognition. $\mathbb{Q}(\sqrt{2})$ is the splitting field of the separable $x^2 - 2$ over $\mathbb{Q}$, so by the corollary it is Galois of degree 2.

Solution. The two automorphisms are id and $\sigma : \sqrt{2} \mapsto -\sqrt{2}$ (from the first worked example), and $|\sigma| = 2$, so $\mathrm{Gal}(\mathbb{Q}(\sqrt{2})/\mathbb{Q}) = \{\,\mathrm{id}, \sigma\,\} \cong \mathbb{Z}/2\mathbb{Z}$, matching $[\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2$. The fixed field: $\sigma(a + b\sqrt{2}) = a - b\sqrt{2}$ equals $a + b\sqrt{2}$ iff $b = 0$, so $\mathrm{Fix}(\langle\sigma\rangle) = \mathbb{Q}$. Sanity check: $|\mathrm{Gal}| = 2 = [K : F]$ and $\mathrm{Fix}(\mathrm{Gal}) = \mathbb{Q} = F$, the two equivalent Galois criteria both hold.

Worked Example 14.1.15 ($\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ is NOT Galois)**.** Confirm explicitly that $\mathrm{Aut}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}) = \{\,\mathrm{id}\,\}$ and identify the fixed field, so the extension is not Galois despite having prime degree 3.

Recognition. By the root-permutation proposition, $\sigma(\sqrt[3]{2})$ is a root of $x^3 - 2$ in $K = \mathbb{Q}(\sqrt[3]{2}) \subset \mathbb{R}$; the other two roots are non-real.

Solution. The roots of $x^3 - 2$ are $\sqrt[3]{2},\ \zeta_3\sqrt[3]{2},\ \zeta_3^2\sqrt[3]{2}$; only $\sqrt[3]{2}$ is real, hence the only root in K. So $\sigma(\sqrt[3]{2}) = \sqrt[3]{2}$, forcing $\sigma = \mathrm{id}$ by the generator lemma. Thus $\mathrm{Aut}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}) = \{\,\mathrm{id}\,\}$, $|\mathrm{Aut}| = 1 < 3 = [K : \mathbb{Q}]$, and $\mathrm{Fix}(\{\,\mathrm{id}\,\}) = K = \mathbb{Q}(\sqrt[3]{2}) \supsetneq \mathbb{Q}$. Sanity check: both Galois criteria fail in agreement – the order is $1 \neq 3$, and the fixed field is all of K rather than $\mathbb{Q}$. The extension is separable (char 0) but not normal.

Worked Example 14.1.16 (The splitting field $\mathbb{Q}(\sqrt[3]{2}, \zeta_3)/\mathbb{Q}$ is Galois with group S_3)**.** Show the splitting field of $x^3 - 2$ over $\mathbb{Q}$ is Galois of degree 6 with $\mathrm{Gal} \cong S_3$.

Recognition. $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ is the splitting field of the separable $x^3 - 2$, hence Galois with $|\mathrm{Gal}| = [K : \mathbb{Q}]$; the group acts faithfully by permuting the 3 roots, so embeds in S_3.

Solution. Degree: $[\mathbb{Q}(\sqrt[3]{2}) : \mathbb{Q}] = 3$ and $[\mathbb{Q}(\sqrt[3]{2}, \zeta_3) : \mathbb{Q}(\sqrt[3]{2})] = 2$ (since ζ_3 satisfies $x^2 + x + 1$, irreducible over the real field $\mathbb{Q}(\sqrt[3]{2})$), so $[K : \mathbb{Q}] = 6$. Thus $|\mathrm{Gal}(K/\mathbb{Q})| = 6$. Every automorphism permutes the three roots $\sqrt[3]{2}, \zeta_3\sqrt[3]{2}, \zeta_3^2\sqrt[3]{2}$, giving an injection $\mathrm{Gal}(K/\mathbb{Q}) \hookrightarrow S_3$; as both have order 6 it is an isomorphism, $\mathrm{Gal}(K/\mathbb{Q}) \cong S_3$. Sanity check: $|S_3| = 6 = [K : \mathbb{Q}]$, and the extension is normal (all roots of $x^3 - 2$ are now present) and separable, so it is genuinely Galois – contrast the non-Galois subextension $\mathbb{Q}(\sqrt[3]{2})$. Concretely $\sigma : \sqrt[3]{2} \mapsto \zeta_3\sqrt[3]{2},\ \zeta_3 \mapsto \zeta_3$ has order 3 and $\tau : \zeta_3 \mapsto \zeta_3^2$ (complex conjugation) has order 2, with $\tau\sigma\tau^{-1} = \sigma^{-1}$, the defining S_3 relation.

Worked Example 14.1.17 ($\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$ is Galois with the Klein four-group)**.** Determine $\mathrm{Gal}(\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q})$.

Recognition. Splitting field of the separable $(x^2 - 2)(x^2 - 3)$, so Galois of degree 4; automorphisms are the independent sign choices on $\sqrt{2}, \sqrt{3}$.

Solution. The four automorphisms send $(\sqrt{2}, \sqrt{3})$ to $(\pm\sqrt{2}, \pm\sqrt{3})$; call them id, $\sigma : (-\sqrt{2}, \sqrt{3})$, $\tau : (\sqrt{2}, -\sqrt{3})$, $\sigma\tau : (-\sqrt{2}, -\sqrt{3})$. Each non-identity element has order 2 (σ^2 sends $\sqrt{2} \mapsto \sqrt{2}$, etc.), and $\sigma\tau = \tau\sigma$, so the group is $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, the Klein four-group V_4. Sanity check: $|V_4| = 4 = [\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}]$; the three order-2 subgroups fix the three quadratic subfields $\mathbb{Q}(\sqrt{3}), \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{6})$ respectively, and $\mathrm{Fix}(V_4) = \mathbb{Q}$,

confirming the Galois condition. The lattice anti-correspondence:

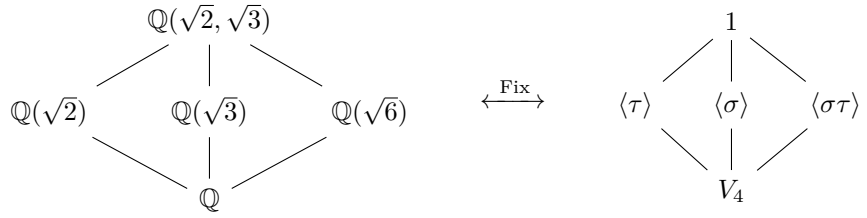

Diagram explanation. Objects: The left lattice has five field objects: the top node $\mathbb{Q}(\sqrt{2},\sqrt{3})$ is the degree-4 Galois extension K; the three middle nodes $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{3})$, $\mathbb{Q}(\sqrt{6})$ are the three degree-2 intermediate fields; the bottom node $\mathbb{Q}$ is the base field F. The right lattice has five subgroup objects: the top node 1 is the trivial subgroup of $V_4 = \mathrm{Gal}(K/\mathbb{Q})$; the three middle nodes $\langle\tau\rangle$, $\langle\sigma\rangle$, $\langle\sigma\tau\rangle$ are the three order-2 subgroups; the bottom node V_4 is the full Galois group.

Arrows: Every dash in both lattices is an inclusion. In the field lattice each dash from $\mathbb{Q}$ to a middle field is a degree-2 inclusion of fields; each dash from a middle field to K is another degree-2 inclusion. In the subgroup lattice each dash from 1 to a middle subgroup is subgroup inclusion, and each dash from a middle subgroup down to V_4 records the same. The horizontal $\xleftrightarrow{\text{Fix}}$ arrow is the Galois correspondence: a subgroup $H \leq V_4$ maps to its fixed field $\mathrm{Fix}(H) = \{\alpha \in K : \sigma(\alpha) = \alpha \text{ for all } \sigma \in H\}$, and an intermediate field E maps to $\mathrm{Gal}(K/E) \leq V_4$.

What commutes: The diagram records an *order-reversing* bijection, not path-commutativity. The key equalities are $\mathrm{Fix}(1) = K$, $\mathrm{Fix}(V_4) = \mathbb{Q}$, $\mathrm{Fix}(\langle\sigma\rangle) = \mathbb{Q}(\sqrt{3})$, $\mathrm{Fix}(\langle\tau\rangle) = \mathbb{Q}(\sqrt{2})$, $\mathrm{Fix}(\langle\sigma\tau\rangle) = \mathbb{Q}(\sqrt{6})$. Containment reverses: $\langle\sigma\rangle \leq V_4$ on the right corresponds to $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{3})$ on the left, so a larger subgroup fixes a smaller field.

Why it commutes: Chase $\langle\sigma\rangle$ explicitly. Since σ sends $\sqrt{2} \mapsto -\sqrt{2}$ and $\sqrt{3} \mapsto \sqrt{3}$, a general element $a + b\sqrt{2} + c\sqrt{3} + d\sqrt{6} \in K$ is fixed by σ iff $b = 0$ and $d = 0$, leaving $a + c\sqrt{3} \in \mathbb{Q}(\sqrt{3})$. So $\mathrm{Fix}(\langle\sigma\rangle) = \mathbb{Q}(\sqrt{3})$. Similarly $\tau(\sqrt{3} \mapsto -\sqrt{3},\ \sqrt{2} \mapsto \sqrt{2})$ fixes only $\mathbb{Q}(\sqrt{2})$, and $\sigma\tau(\sqrt{6} = \sqrt{2}\cdot\sqrt{3} \mapsto (-\sqrt{2})(-\sqrt{3}) = \sqrt{6})$ fixes only $\mathbb{Q}(\sqrt{6})$. These are genuine fixed-field computations, not just index counting.

Why this matters here: The worked example has just established $\mathrm{Gal}(\mathbb{Q}(\sqrt{2},\sqrt{3})/\mathbb{Q}) \cong V_4$ and verified the Galois condition $|\mathrm{Gal}| = [K : F] = 4$. The diagram is an explicit preview of the Fundamental Theorem of Galois Theory (Section 14.2): it shows the promised anti-isomorphism between the lattice of intermediate fields and the lattice of subgroups, making abstract theory concrete and checkable for this small but complete example.

Concrete example: The index $[\langle\sigma\rangle : 1] = 2$ in the right lattice corresponds to the degree $[K : \mathbb{Q}(\sqrt{3})] = 2$ in the left lattice. The subgroup $\langle\sigma\rangle$ has index 2 in V_4, so its fixed field $\mathbb{Q}(\sqrt{3})$ has degree 2 over $\mathbb{Q}$, exactly matching. Every index-to-degree correspondence in the diagram works out this cleanly, which is characteristic of a Galois extension where the theorem applies with full strength.

Common pitfall: Students often read the lattices as going in the same direction and conclude that $\mathbb{Q}$ (at the bottom left) corresponds to 1 (at the top right). The anti-isomorphism goes the other way: $\mathbb{Q}$ at the bottom of the field lattice corresponds to V_4 at the bottom of the subgroup lattice (a larger subgroup fixes a smaller field). Separately, because all three intermediate subgroups have the same order 2, you cannot identify which subgroup corresponds to which intermediate field by order alone; the explicit fixed-field calculation above is necessary.

Takeaway: The point of this diagram is that for a Galois extension with Galois group V_4, the lattice of intermediate fields and the lattice of subgroups are in perfect order-reversing bijection via the fixed-field map Fix, so the two diamond-shaped lattices are mirror images of each other.

Worked Example 14.1.18 (The cyclotomic extension $\mathbb{Q}(\zeta_5)/\mathbb{Q}$)**.** Identify $\mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q})$ where $\zeta_5 = e^{2\pi i/5}$.

Recognition. $\mathbb{Q}(\zeta_5)$ is the splitting field of the separable $x^5 - 1$ (roots the distinct 5th roots of unity), hence Galois; ζ_5 has minimal polynomial the cyclotomic $\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$.

Solution. Φ_5 is irreducible over $\mathbb{Q}$ (Eisenstein at 5 after $x \mapsto x + 1$), so $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = 4$ and $|\mathrm{Gal}| = 4$. An automorphism σ sends ζ_5 to another *primitive* 5th root, ζ_5^a with $a \in \{1, 2, 3, 4\}$; the rule $\sigma_a : \zeta_5 \mapsto \zeta_5^a$ gives

$\sigma_a\sigma_b = \sigma_{ab \bmod 5}$, so $\mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q}) \cong (\mathbb{Z}/5\mathbb{Z})^\times = (\mathbb{Z}/5\mathbb{Z})^\times$, cyclic of order 4. Sanity check: $(\mathbb{Z}/5\mathbb{Z})^\times = \langle 2\rangle$ since $2^1, 2^2, 2^3, 2^4 = 2, 4, 3, 1 \pmod 5$ runs through all units, so the group is $\mathbb{Z}/4\mathbb{Z}$, and $|(\mathbb{Z}/5\mathbb{Z})^\times| = \varphi(5) = 4 = [\mathbb{Q}(\zeta_5) : \mathbb{Q}]$, meeting the bound.

Worked Example 14.1.19 (The fixed field of complex conjugation on $\mathbb{C}$)**.** Determine $\mathrm{Fix}(\langle\tau\rangle)$ for τ complex conjugation, and relate it to $\mathrm{Aut}(\mathbb{C}/\mathbb{R})$.

Recognition. $\mathrm{Fix}(H)$ collects the elements moved by no element of H; for $\tau : a + bi \mapsto a - bi$ this is the equation $a + bi = a - bi$.

Solution. $\tau(a + bi) = a + bi$ iff $-bi = bi$ iff $b = 0$ iff $a + bi \in \mathbb{R}$. So $\mathrm{Fix}(\langle\tau\rangle) = \mathbb{R}$. Since $\langle\tau\rangle = \{\mathrm{id}, \tau\}$ has order $2 = [\mathbb{C} : \mathbb{R}]$ and fixes exactly $\mathbb{R}$, the extension $\mathbb{C}/\mathbb{R}$ is Galois with $\mathrm{Gal}(\mathbb{C}/\mathbb{R}) = \{\mathrm{id}, \tau\} \cong \mathbb{Z}/2\mathbb{Z}$. Sanity check: $[\mathbb{C} : \mathbb{R}] = 2$ equals $|\langle\tau\rangle|$, and the fixed field equals the base field $\mathbb{R}$ – both Galois criteria confirmed.

Worked Example 14.1.20 (Distinguishing $\mathbb{Q}(\sqrt{2})$ from $\mathbb{Q}(\sqrt{3})$ via automorphisms)**.** Show $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{3})$ are not isomorphic as fields.

Recognition. An isomorphism of fields preserves which elements are squares; the existence of $\sqrt{2}$ as a square is an isomorphism invariant.

Solution. Any field isomorphism $\varphi : \mathbb{Q}(\sqrt{2}) \to \mathbb{Q}(\sqrt{3})$ fixes $\mathbb{Q}$ (it fixes 1, hence $\mathbb{Z}$, hence $\mathbb{Q}$). Then $\varphi(\sqrt{2})^2 = \varphi(2) = 2$, so $\mathbb{Q}(\sqrt{3})$ would contain an element squaring to 2. But elements of $\mathbb{Q}(\sqrt{3})$ are $a + b\sqrt{3}$ with $(a + b\sqrt{3})^2 = a^2 + 3b^2 + 2ab\sqrt{3} = 2$ forcing $ab = 0$ and $a^2 + 3b^2 = 2$, which has no rational solution ($a^2 = 2$ or $3b^2 = 2$, neither solvable in $\mathbb{Q}$). So no such φ exists. Sanity check: equivalently 2 is a square in $\mathbb{Q}(\sqrt{2})$ but not in $\mathbb{Q}(\sqrt{3})$, an isomorphism-invariant property, so the fields differ – consistent with their distinct (though both order-2) automorphism groups acting on different generators.

Isomorphism-extension and the counting of embeddings

The bound and its sharpening rest on counting field *embeddings*, the engine behind every automorphism count above. We isolate the mechanism.

Theorem 14.1.21 (isomorphism-extension counts embeddings)**.** *Let $\varphi : F \to F'$ be a field isomorphism, K/F finite, and L a field containing $\varphi(F) = F'$. The number of embeddings $\sigma : K \hookrightarrow L$ extending φ is at most $[K : F]$, with equality when L contains a splitting field over F' of the (image under φ of the) minimal polynomials of a generating set and every such minimal polynomial is separable. Taking $F' = F$, $\varphi = \mathrm{id}$, and $L = K$ a splitting field recovers $|\mathrm{Aut}(K/F)| \le [K : F]$ with equality in the separable normal case.*

Idea. Induct on $[K : F]$. Write $K = F(\alpha)(\dots)$ and let m_α be the minimal polynomial of α, of degree $d = [F(\alpha) : F]$. An extension of φ to $F(\alpha)$ is determined by sending α to a root in L of $\varphi(m_\alpha)$; there are at most d such roots, exactly d distinct ones when $\varphi(m_\alpha)$ is separable and splits in L. Each choice fixes a new base isomorphism $F(\alpha) \to F(\alpha')$, and the inductive hypothesis multiplies in the remaining $[K : F(\alpha)]$ extensions. Multiplying degree by degree up the tower gives the bound and the equality criterion. □

Worked Example 14.1.22 (Embedding count up a tower for $\mathbb{Q}(\sqrt[3]{2}, \zeta_3)$)**.** Recount $|\mathrm{Aut}(\mathbb{Q}(\sqrt[3]{2}, \zeta_3)/\mathbb{Q})|$ purely as a product of per-step embedding counts.

Recognition. Embeddings multiply along a tower: (number of roots of each minimal polynomial available in K) at each adjunction; separability and normality make every factor maximal.

Solution. Step 1, adjoin $\sqrt[3]{2}$ with minimal polynomial $x^3 - 2$: in $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ all 3 roots $\sqrt[3]{2}, \zeta_3\sqrt[3]{2}, \zeta_3^2\sqrt[3]{2}$ are present, so 3 extensions. Step 2, adjoin ζ_3 with minimal polynomial $x^2 + x + 1$ over $\mathbb{Q}(\sqrt[3]{2})$: both roots ζ_3, ζ_3^2 lie in K, so 2 extensions each. Total $3 \cdot 2 = 6 = [K : \mathbb{Q}]$. Sanity check: this product equals the group order $|S_3| = 6$ found earlier; had a root been missing (as in $\mathbb{Q}(\sqrt[3]{2})$ alone) a factor would have dropped below the degree and the bound would be strict.

Worked Example 14.1.23 (Finite-field cross-reference: Frobenius realizes the bound)**.** For $K = \mathbb{F}_{p^n}$ over $F = \mathbb{F}_p$, identify the automorphism that achieves $|\mathrm{Aut}(K/F)| = [K : F] = n$, and point to where the lattice is worked out.

Recognition. $\mathbb{F}_{p^n}/\mathbb{F}_p$ is the splitting field of the separable $x^{p^n} - x$, so by the corollary it is Galois of degree n; the group is generated by Frobenius (Section 14.3).

Solution. The map $\mathrm{Frob}_p : \alpha \mapsto \alpha^p$ is an $\mathbb{F}_p$-automorphism (it fixes $\mathbb{F}_p$ by Fermat: $a^p = a$), and $\langle \mathrm{Frob}_p \rangle = \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) \cong \mathbb{Z}/n\mathbb{Z}$ has order $n = [\mathbb{F}_{p^n} : \mathbb{F}_p]$, meeting the bound. The full subfield/subgroup correspondence – subfields $\mathbb{F}_{p^d}$ for $d \mid n$ matched with $\langle \mathrm{Frob}_p^d \rangle$ – is developed in Section 14.3. Sanity check: $\mathrm{Frob}_p^n(\alpha) = \alpha^{p^n} = \alpha$ for all $\alpha \in \mathbb{F}_{p^n}$, while for $0 < k < n$ the polynomial $x^{p^k} - x$ has at most $p^k < p^n$ roots, so $\mathrm{Frob}_p^k \neq \mathrm{id}$; hence $|\,\mathrm{Frob}_p\,| = n$, and the extension is normal (a splitting field) and separable, hence genuinely Galois, exactly the equality case of the bound.

Worked Example 14.1.24 (Strictness from inseparability in characteristic p)**.** Show $K = \mathbb{F}_p(t^{1/p})$ over $F = \mathbb{F}_p(t)$ has degree p but only the trivial automorphism group, so equality fails for the separability reason.

Recognition. Here normality holds but separability fails: the minimal polynomial of $t^{1/p}$ is $x^p - t = (x - t^{1/p})^p$, a single root of multiplicity p.

Solution. $x^p - t$ is irreducible over $F = \mathbb{F}_p(t)$ (Eisenstein at the prime t in $\mathbb{F}_p[t]$), so $[K : F] = p$. Over K it factors as $(x - t^{1/p})^p$, so $t^{1/p}$ is the *only* root. Any $\sigma \in \mathrm{Aut}(K/F)$ must fix t and send $t^{1/p}$ to a root of $x^p - t$ in K, i.e. to $t^{1/p}$ itself; hence $\sigma = \mathrm{id}$ and $|\mathrm{Aut}(K/F)| = 1 < p$. Sanity check: the bound $|\mathrm{Aut}| \leq [K : F] = p$ holds, but is strict; the failure here is inseparability ($x^p - t$ has a repeated root), complementing the normality failure of $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$. Both reasons must be excluded for an extension to be Galois.

Exercises (from the text).

1. (a) Show that if the field K is generated over F by the elements $\alpha_1, \ldots, \alpha_n$ then an automorphism σ of K fixing F is uniquely determined by $\sigma(\alpha_1), \ldots, \sigma(\alpha_n)$. In particular show that an automorphism fixes K if and only if it fixes a set of generators for K.
   (b) Let $G \leq \mathrm{Gal}(K/F)$ be a subgroup of the Galois group of the extension K/F and suppose $\sigma_1, \ldots, \sigma_k$ are generators for G. Show that the subfield E/F is fixed by G if and only if it is fixed by the generators $\sigma_1, \ldots, \sigma_k$.
2. Let τ be the map $\tau : \mathbb{C} \to \mathbb{C}$ defined by $\tau(a + bi) = a - bi$ (*complex conjugation*). Prove that τ is an automorphism of $\mathbb{C}$.
3. Determine the fixed field of complex conjugation on $\mathbb{C}$.
4. Prove that $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{3})$ are not isomorphic.
5. Determine the automorphisms of the extension $\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}(\sqrt{2})$ explicitly.
6. Let k be a field.
   (a) Show that the mapping $\varphi : k[t] \to k[t]$ defined by $\varphi(f(t)) = f(at + b)$ for fixed $a, b \in k$, $a \neq 0$ is an automorphism of $k[t]$ which is the identity on k.
   (b) Conversely, let φ be an automorphism of $k[t]$ which is the identity on k. Prove that there exist $a, b \in k$ with $a \neq 0$ such that $\varphi(f(t)) = f(at + b)$ as in (a).
7. This exercise determines $\mathrm{Aut}(\mathbb{R}/\mathbb{Q})$.
   (a) Prove that any $\sigma \in \mathrm{Aut}(\mathbb{R}/\mathbb{Q})$ takes squares to squares and takes positive reals to positive reals. Conclude that $a < b$ implies $\sigma a < \sigma b$ for every $a, b \in \mathbb{R}$.
   (b) Prove that $-\dfrac{1}{m} < a - b < \dfrac{1}{m}$ implies $-\dfrac{1}{m} < \sigma a - \sigma b < \dfrac{1}{m}$ for every positive integer m. Conclude that σ is a continuous map on $\mathbb{R}$.
   (c) Prove that any continuous map on $\mathbb{R}$ which is the identity on $\mathbb{Q}$ is the identity map, hence $\mathrm{Aut}(\mathbb{R}/\mathbb{Q}) = 1$.
8. Prove that the automorphisms of the rational function field $k(t)$ which fix k are precisely the *fractional linear transformations* determined by $t \mapsto \dfrac{at + b}{ct + d}$ for $a, b, c, d \in k$, $ad - bc \neq 0$ (so $f(t) \in k(t)$ maps to $f\left(\dfrac{at + b}{ct + d}\right)$) (cf. Exercise 18 of Section 13.2).

9. Determine the fixed field of the automorphism $t \mapsto t+1$ of $k(t)$.

10. Let K be an extension of the field F. Let $\varphi : K \to K'$ be an isomorphism of K with a field K' which maps F to the subfield F' of K'. Prove that the map $\sigma \mapsto \varphi\sigma\varphi^{-1}$ defines a group isomorphism $\mathrm{Aut}(K/F) \xrightarrow{\sim} \mathrm{Aut}(K'/F')$.

Practice problems.

1. Let $K = \mathbb{Q}(\sqrt{5})$. Compute $\mathrm{Aut}(K/\mathbb{Q})$ explicitly by determining the possible values of $\sigma(\sqrt{5})$, exhibit the fixed field $\mathrm{Fix}(\mathrm{Aut}(K/\mathbb{Q}))$, and decide whether $K/\mathbb{Q}$ is Galois.

2. Let $K = \mathbb{Q}(\sqrt[3]{7})$ and $L = \mathbb{Q}(\sqrt[3]{7}, \zeta_3)$ where $\zeta_3 = e^{2\pi i/3}$. Compute $|\mathrm{Aut}(K/\mathbb{Q})|$ and $|\mathrm{Aut}(L/\mathbb{Q})|$, and in each case compare with the degree $[K:\mathbb{Q}]$, $[L:\mathbb{Q}]$ to say which extension is Galois.

3. Let $K = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$. Show $[K:\mathbb{Q}] = 8$, prove $K/\mathbb{Q}$ is Galois, and describe $\mathrm{Gal}(K/\mathbb{Q})$ as an abstract group by giving its action on the three generators.

4. For each of the following automorphisms of the rational function field $\mathbb{Q}(t)$, verify it lies in $\mathrm{Aut}(\mathbb{Q}(t)/\mathbb{Q})$ and compute its order: (a) $\sigma : t \mapsto -t$; (b) $\tau : t \mapsto 1 - t$; (c) $\rho : t \mapsto 1/t$.

5. Let $\zeta_7 = e^{2\pi i/7}$ and $K = \mathbb{Q}(\zeta_7)$. Show $K/\mathbb{Q}$ is Galois of degree 6, prove $\mathrm{Gal}(K/\mathbb{Q}) \cong (\mathbb{Z}/7\mathbb{Z})^\times$ is cyclic, and exhibit a generator $\sigma_a : \zeta_7 \mapsto \zeta_7^a$ by finding a primitive root a modulo 7.

6. Let $G = \{\,\mathrm{id}, \sigma\,\}$ where $\sigma \in \mathrm{Aut}(\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q})$ is the map $\sqrt{2} \mapsto -\sqrt{2}$, $\sqrt{3} \mapsto \sqrt{3}$. Compute $\mathrm{Fix}(G)$ directly from the action on a $\mathbb{Q}$-basis of $\mathbb{Q}(\sqrt{2}, \sqrt{3})$, and verify $[\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathrm{Fix}(G)] = |G|$.

7. Let K/F be a finite extension and let $\alpha \in K$ have minimal polynomial $m_{\alpha,F}(x)$ of degree d. Suppose K contains exactly r of the d roots of $m_{\alpha,F}$. Prove that $|\{\,\sigma(\alpha) : \sigma \in \mathrm{Aut}(K/F)\,\}| \le r$, and exhibit an explicit α and K for which this bound is strict (fewer images than available roots).

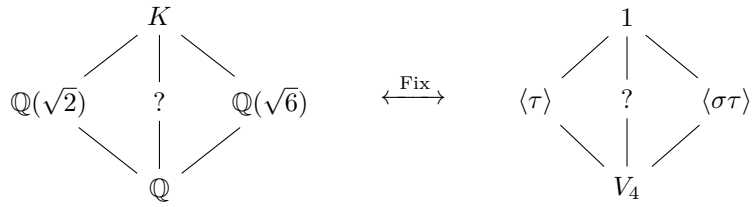
8. Let $F = \mathbb{Z}/p\mathbb{Z}(t)$ be the rational function field over $\mathbb{Z}/p\mathbb{Z}$ and $K = \mathbb{Z}/p\mathbb{Z}(t^{1/p})$. Show $[K:F] = p$ but $\mathrm{Aut}(K/F) = \{\,\mathrm{id}\,\}$, and explain in one sentence which of the two Galois conditions (normality or separability) fails here.

Additional exercises.

1. Let K/F be a finite extension and $G = \mathrm{Aut}(K/F)$. Prove that $F \subseteq \mathrm{Fix}(G)$ always holds, and that K/F is Galois if and only if $\mathrm{Fix}(G) = F$. Then give an explicit non-Galois extension $K/\mathbb{Q}$ for which $\mathrm{Fix}(\mathrm{Aut}(K/\mathbb{Q}))$ is strictly larger than $\mathbb{Q}$, and identify that fixed field.

2. Let $\sigma_1, \dots, \sigma_m$ be distinct automorphisms of a field K. Use Dedekind's lemma (linear independence of characters) to prove that no nontrivial relation $\sum_{i=1}^{m} a_i\,\sigma_i(x) = 0$ (for all $x \in K^\times$) with $a_i \in K$ can hold. Then deduce the bound $|\mathrm{Aut}(K/F)| \le [K:F]$ for K/F finite, sketching how independence forces it.

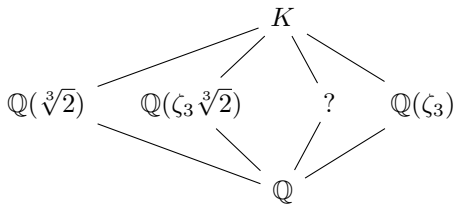
3. Let $\alpha = \sqrt{2+\sqrt{2}}$. Show $[\mathbb{Q}(\alpha):\mathbb{Q}] = 4$, that $\mathbb{Q}(\alpha)/\mathbb{Q}$ is Galois, and that $\mathrm{Gal}(\mathbb{Q}(\alpha)/\mathbb{Q}) \cong \mathbb{Z}/4\mathbb{Z}$ is cyclic (not V_4); produce a generator by computing its action on α. (Hint: relate $\alpha^2 - 2$ to $\sqrt{2}$ and find the conjugate $\sqrt{2-\sqrt{2}}$ inside $\mathbb{Q}(\alpha)$.)



4. Let K be the splitting field of $f(x) = x^4 - 2$ over $\mathbb{Q}$. Show $[K:\mathbb{Q}] = 8$, prove $K/\mathbb{Q}$ is Galois, and prove $\mathrm{Gal}(K/\mathbb{Q}) \cong D_8$ (the dihedral group of order 8) by exhibiting an order-4 element and an order-2 element with the dihedral relation.

5. Let K/F be finite and let $H \le \mathrm{Aut}(K/F)$ be a finite subgroup. Prove Artin's equality $[K : \mathrm{Fix}(H)] = |H|$ in the special case $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, $H = \langle\sigma\rangle$ for the order-2 map $\sigma : (\sqrt{2}, \sqrt{3}) \mapsto (-\sqrt{2}, -\sqrt{3})$, by computing $\mathrm{Fix}(H)$ and its degree explicitly, and confirm $\mathrm{Fix}(H) = \mathbb{Q}(\sqrt{6})$.

Commutative-diagram exercises.



1. Let $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ with $\mathrm{Gal}(K/\mathbb{Q}) = V_4 = \{\,\mathrm{id}, \sigma, \tau, \sigma\tau\,\}$ where $\sigma : (\sqrt{2}, \sqrt{3}) \mapsto (-\sqrt{2}, \sqrt{3})$ and $\tau : (\sqrt{2}, \sqrt{3}) \mapsto (\sqrt{2}, -\sqrt{3})$. Complete the subfield lattice on the left and the subgroup lattice on the right,

and prove the two are matched by Fix (each intermediate field is the fixed field of the indicated subgroup):

Fill in both "?" nodes, and for each of the three middle fields verify directly that it equals Fix of the subgroup placed opposite it.

2. Let $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ be the splitting field of $x^3 - 2$ over $\mathbb{Q}$, with $\mathrm{Gal}(K/\mathbb{Q}) \cong S_3$. Draw the full lattice of subgroups of S_3 and, opposite it, the lattice of intermediate fields between $\mathbb{Q}$ and K; complete the skeleton below and prove that the order-3 subgroup corresponds to $\mathbb{Q}(\zeta_3)$ while the three order-2 subgroups correspond to the three fields $\mathbb{Q}(\sqrt[3]{2})$, $\mathbb{Q}(\zeta_3\sqrt[3]{2})$, $\mathbb{Q}(\zeta_3^2\sqrt[3]{2})$:

State, for each intermediate field, whether it is Galois over $\mathbb{Q}$, and prove your claim using normality of the corresponding subgroup in S_3.

3. Let $\varphi : K \to K'$ be a field isomorphism carrying the subfield $F \subseteq K$ onto $F' \subseteq K'$. Prove that conjugation $\sigma \mapsto \varphi\,\sigma\,\varphi^{-1}$ is a group isomorphism $\mathrm{Aut}(K/F) \cong \mathrm{Aut}(K'/F')$ by showing the square

$$\begin{array}{ccc} K & \xrightarrow{\ \sigma\ } & K \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\varphi} \\ K' & \xrightarrow[\varphi\sigma\varphi^{-1}]{} & K' \end{array}$$

commutes for every $\sigma \in \mathrm{Aut}(K/F)$. Verify that $\varphi\sigma\varphi^{-1}$ does fix F' pointwise, and that the assignment respects composition.

4. Let K/F be finite with $G = \mathrm{Aut}(K/F)$, and let $E = \mathrm{Fix}(G)$. Construct the diagram of inclusions

$$F \xhookrightarrow{\ \iota\ } E \xhookrightarrow{\ j\ } K$$

and prove that K/E is Galois with $\mathrm{Gal}(K/E) = G$, while E/F carries only the trivial automorphism group "visible from G." Conclude that K/F is Galois if and only if the middle node collapses, i.e. $E = F$, and illustrate with $K = \mathbb{Q}(\sqrt[3]{2})$, $F = \mathbb{Q}$ by identifying E explicitly.

14.2 The Fundamental Theorem of Galois Theory

Linear independence of characters

The engine that drives the whole section is a deceptively simple fact about automorphisms: distinct field embeddings are linearly independent as functions. This is what makes counting automorphisms equivalent to counting degrees, and it is the technical heart of Artin's theorem below.

Definition 14.2.1. A *character* of a group G with values in a field L is a group homomorphism $\chi\colon G \to L^{\times}$. Characters $\chi_1, \dots, \chi_n$ are *linearly independent over L* if no relation $a_1\chi_1 + \cdots + a_n\chi_n = 0$ holds with $a_i \in L$ not all zero, where equality means $\sum_i a_i\chi_i(g) = 0$ for every $g \in G$.

Theorem 14.2.2 (linear independence of characters (Dedekind–Artin)). *If $\chi_1, \dots, \chi_n$ are distinct characters of a group G with values in a field L, then they are linearly independent over L. In particular, distinct field embeddings $\sigma_1, \dots, \sigma_n \colon K \to L$ are linearly independent as L-valued functions on $K^\times$.*

Idea. Suppose not, and take a dependence relation $\sum_{i=1}^{m} a_i \chi_i = 0$ with the fewest nonzero coefficients; clearly $m \geq 2$ and all $a_i \neq 0$. Since $\chi_1 \neq \chi_m$ there is $g_0 \in G$ with $\chi_1(g_0) \neq \chi_m(g_0)$. Evaluate the relation at $g_0 g$ and use $\chi_i(g_0 g) = \chi_i(g_0)\chi_i(g)$ to get a second relation $\sum_i a_i \chi_i(g_0)\chi_i = 0$. Subtract $\chi_m(g_0)$ times the original from this: the χ_m term cancels, leaving a shorter nontrivial relation (its χ_1 coefficient $a_1(\chi_1(g_0) - \chi_m(g_0))$ is nonzero), contradicting minimality. □

The single most important consequence: an automorphism group cannot collapse the dimension count. If $G = \{ \sigma_1, \dots, \sigma_n \}$ is a finite set of distinct automorphisms of K, the linear system over K that would force K^G to have small codimension is incompatible with independence. We extract two corollaries.

Corollary 14.2.3 (nonzero trace). *If K/F is a finite Galois extension with $G = \mathrm{Gal}(K/F)$, then the trace map $\mathrm{Tr}_{K/F}(\alpha) = \sum_{\sigma \in G} \sigma(\alpha)$ is not identically zero; some $\alpha \in K$ has $\mathrm{Tr}_{K/F}(\alpha) \neq 0$.*

Idea. $\mathrm{Tr}_{K/F} = \sum_{\sigma \in G} \sigma$ is exactly an F-linear combination (all coefficients 1) of the distinct embeddings σ. If it were the zero function, that would be a nontrivial linear dependence among distinct characters $K^\times \to K^\times$, contradicting the theorem. □

Worked Example 14.2.4 (Three embeddings of a number field are independent). Let $K = \mathbb{Q}(\theta)$ with $\theta = 2^{1/3}$ embedded in $\mathbb{C}$, and let $\sigma_1, \sigma_2, \sigma_3 \colon K \to \mathbb{C}$ send θ to θ, $\omega\theta$, $\omega^2\theta$ ($\omega = e^{2\pi i/3}$). Show no $a_i \in \mathbb{C}$ with $\sum a_i \sigma_i = 0$ exist unless all $a_i = 0$.

Recognition. These are three distinct embeddings of a field into $\mathbb{C}$, so the theorem on independence of characters applies directly.

Solution. Evaluate $\sum_i a_i \sigma_i$ at $1, \theta, \theta^2$. Since each σ_j fixes $\mathbb{Q}$, at 1 we get $a_1 + a_2 + a_3 = 0$. At θ we get $a_1\theta + a_2\omega\theta + a_3\omega^2\theta = 0$, i.e. $a_1 + a_2\omega + a_3\omega^2 = 0$. At θ^2 we get $a_1 + a_2\omega^2 + a_3\omega^4 = a_1 + a_2\omega^2 + a_3\omega = 0$. The coefficient matrix is the Vandermonde matrix on $1, \omega, \omega^2$, which is invertible (distinct entries), forcing $a_1 = a_2 = a_3 = 0$. Sanity check: the Vandermonde determinant is $\prod_{i<j}(\omega^j - \omega^i) \neq 0$ precisely because $1, \omega, \omega^2$ are distinct, which is the same nonvanishing that drives the general proof.

Artin's theorem and the four characterizations

We now state the structural result that converts a finite group of automorphisms into a Galois extension. It is the converse to the easy direction (a Galois group has order at most the degree).

Theorem 14.2.5 (Artin). *Let G be a finite group of automorphisms of a field K, and let $F = K^G = \mathrm{Fix}(G) = \{ \alpha \in K : \sigma(\alpha) = \alpha \text{ for all } \sigma \in G \}$ be its fixed field. Then K/F is a finite extension with*

$$[K : F] = |G|,$$

and K/F is Galois with $\mathrm{Gal}(K/F) = G$.

Idea. Write $G = \{ \sigma_1 = \mathrm{id}, \dots, \sigma_n \}$, $n = |G|$. First $[K : F] \leq n$: if $\alpha_1, \dots, \alpha_{n+1} \in K$ were F-linearly independent, the $n \times (n+1)$ system $\sum_j x_j \sigma_i(\alpha_j) = 0$ has a nonzero solution $x \in K^{n+1}$; choosing one with fewest nonzero entries and averaging over G produces (via independence of characters) a nontrivial F-relation among the α_j, a contradiction. Conversely $[K : F] \geq n$: the n distinct automorphisms σ_i are F-linear maps $K \to K$, and by independence of characters they are linearly independent in the F-vector space $\mathrm{Hom}_F(K, K)$, which has dimension $[K : F]^2$ over F, but more sharply they restrict to distinct embeddings, forcing $[K : F] \geq n$. Hence $[K : F] = n$. Since $G \subseteq \mathrm{Aut}(K/F)$ and $|\mathrm{Aut}(K/F)| \leq [K : F] = n = |G|$ always, we get $\mathrm{Aut}(K/F) = G$ of order $[K : F]$, which makes K/F Galois with $\mathrm{Gal}(K/F) = G$. □

Artin's theorem gives the cleanest definition of Galois: K/F is Galois exactly when F is the fixed field of $\mathrm{Aut}(K/F)$. The remaining theorem of the section collects all the equivalent ways to recognize this.

Theorem 14.2.6 (four characterizations of a finite Galois extension). *For a finite extension K/F the following are equivalent:*

(1) *K/F is normal and separable;*

(2) *K is the splitting field over F of some separable polynomial in $F[x]$;*

(3) *$|\mathrm{Aut}(K/F)| = [K : F]$;*

(4) *$F = \mathrm{Fix}(\mathrm{Aut}(K/F))$, i.e. F is exactly the fixed field of the full automorphism group.*

When these hold we call K/F Galois *and write* $\mathrm{Gal}(K/F) = \mathrm{Aut}(K/F)$.

Idea. (1) $\Rightarrow$ (2): a normal separable extension is the splitting field of the product of the (separable) minimal polynomials of a set of generators. (2) $\Rightarrow$ (3): counting embeddings of a splitting field, separability makes every root simple so all $[K : F]$ extensions of the identity exist as automorphisms. (3) $\Rightarrow$ (4): if $F_0 = \mathrm{Fix}(\mathrm{Aut}(K/F)) \supseteq F$, then by Artin $[K : F_0] = |\mathrm{Aut}(K/F)| = [K : F]$, forcing $F_0 = F$. (4) $\Rightarrow$ (1): by Artin K/F is Galois with $\mathrm{Gal} = \mathrm{Aut}(K/F)$, and a Galois extension is normal (the orbit of any root under the group gives all conjugates inside K) and separable (distinct conjugates, no repeated roots). □

Method (To decide whether a given finite extension K/F is Galois, pick the cheapest characterization for the situation. If you already have a polynomial whose splitting field is K, check it is separable (use (2)). If you can list $\mathrm{Aut}(K/F)$, compare $|\mathrm{Aut}(K/F)|$ with $[K : F]$ (use (3)). For a tower or a fixed-field problem, compute Fix and compare with F (use (4)). In characteristic 0 or over a finite field, separability is automatic, so Galois reduces to *normal* = splitting field.)**.**

Caution. Normality and separability are independent conditions and *both* are needed. $\mathbb{Q}(2^{1/3})/\mathbb{Q}$ is separable (characteristic 0) but not normal – it omits the complex roots $\omega 2^{1/3}, \omega^2 2^{1/3}$ – so $|\mathrm{Aut}(\mathbb{Q}(2^{1/3})/\mathbb{Q})| = 1 < 3 = [\mathbb{Q}(2^{1/3}) : \mathbb{Q}]$ and the extension is not Galois. Over $\mathbb{F}_p(t)$ the extension $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$ is normal (it is the splitting field of $x^p - t = (x - t^{1/p})^p$) but inseparable, again failing (3).

Worked Example 14.2.7 ($\mathbb{Q}(2^{1/3})/\mathbb{Q}$ is not Galois)**.** Show $|\mathrm{Aut}(\mathbb{Q}(2^{1/3})/\mathbb{Q})| = 1$ and conclude the extension is not Galois.

Recognition. Use characterization (3): an automorphism must send $2^{1/3}$ to another root of its minimal polynomial $x^3 - 2$ *lying in the field.*

Solution. The minimal polynomial of $\theta = 2^{1/3}$ over $\mathbb{Q}$ is $x^3 - 2$, with roots $\theta, \omega\theta, \omega^2\theta$. But $\mathbb{Q}(\theta) \subset \mathbb{R}$, while $\omega\theta, \omega^2\theta \notin \mathbb{R}$, so the only root inside $\mathbb{Q}(\theta)$ is θ itself. Any $\sigma \in \mathrm{Aut}(\mathbb{Q}(\theta)/\mathbb{Q})$ is determined by $\sigma(\theta)$, which must be a root of $x^3 - 2$ in $\mathbb{Q}(\theta)$, hence $\sigma(\theta) = \theta$ and $\sigma = \mathrm{id}$. So $|\mathrm{Aut}| = 1 \neq 3 = [\mathbb{Q}(\theta) : \mathbb{Q}]$. Sanity check: characterization (4) agrees – $\mathrm{Fix}(\mathrm{Aut}) = \mathrm{Fix}(\{\,\mathrm{id}\,\}) = \mathbb{Q}(\theta) \neq \mathbb{Q}$, so K/F fails the fixed-field test as well.

Worked Example 14.2.8 ($\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$ is Galois by all four tests)**.** Verify the four characterizations for $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ over $\mathbb{Q}$.

Recognition. K is the splitting field of $(x^2 - 2)(x^2 - 3)$, a separable polynomial in characteristic 0; this is characterization (2).

Solution. The polynomial $(x^2 - 2)(x^2 - 3)$ has roots $\pm\sqrt{2}, \pm\sqrt{3}$, all distinct, and $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ contains all of them, so K is its splitting field: (2) holds, hence (1) normal+separable. The four automorphisms send $\sqrt{2} \mapsto \pm\sqrt{2}$ and $\sqrt{3} \mapsto \pm\sqrt{3}$ independently, so $|\mathrm{Aut}(K/\mathbb{Q})| = 4 = [K : \mathbb{Q}]$: (3) holds. Finally any element fixed by all four sign-changes lies in $\mathbb{Q}$, giving $\mathrm{Fix}(\mathrm{Aut}) = \mathbb{Q}$: (4) holds. Sanity check: $[K : \mathbb{Q}] = [K : \mathbb{Q}(\sqrt{2})] \cdot [\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2 \cdot 2 = 4$, matching $|\mathrm{Aut}(K/\mathbb{Q})| = 4$.

Worked Example 14.2.9 (Recovering the base field as a fixed field)**.** With $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ and $\sigma\colon \sqrt{2} \mapsto -\sqrt{2}, \sqrt{3} \mapsto \sqrt{3}$, identify $\mathrm{Fix}(\langle\sigma\rangle)$.

Recognition. By Artin, $[K : \mathrm{Fix}(\langle\sigma\rangle)] = |\langle\sigma\rangle| = 2$, so $\mathrm{Fix}(\langle\sigma\rangle)$ is a degree-2 subfield – one of the quadratic subfields.

Solution. σ fixes $\sqrt{3}$ and negates $\sqrt{2}$, so it fixes $\mathbb{Q}(\sqrt{3})$ pointwise; since $[K : \mathbb{Q}(\sqrt{3})] = 2 = |\langle\sigma\rangle|$, Artin forces $\mathrm{Fix}(\langle\sigma\rangle) = \mathbb{Q}(\sqrt{3})$. Sanity check: $\sigma(\sqrt{6}) = \sigma(\sqrt{2})\sigma(\sqrt{3}) = -\sqrt{2} \cdot \sqrt{3} = -\sqrt{6}$, so $\sqrt{6} \notin \mathrm{Fix}(\langle\sigma\rangle)$, consistent with $\mathrm{Fix}(\langle\sigma\rangle) = \mathbb{Q}(\sqrt{3})$ not containing $\sqrt{6}$.

The fundamental theorem of Galois theory

We can now state the central result. For a Galois extension it makes the lattice of intermediate fields and the lattice of subgroups of the Galois group two views of one object, related by an order-reversing bijection.

Theorem 14.2.10 (the Fundamental Theorem of Galois Theory)**.** *Let K/F be a finite Galois extension with $G = \mathrm{Gal}(K/F)$. The maps*

$$H \longmapsto \mathrm{Fix}(H) = K^H, \qquad E \longmapsto \mathrm{Gal}(K/E)$$

*are mutually inverse, inclusion-*reversing *bijections between the set of subgroups $H \leq G$ and the set of intermediate fields $F \subseteq E \subseteq K$. Moreover:*

(1) *(Degrees.) If $E = \mathrm{Fix}(H)$ then $[K : E] = |H|$ and $[E : F] = [G : H]$.*

(2) *(Conjugacy.) For $\sigma \in G$, $\mathrm{Fix}(\sigma H \sigma^{-1}) = \sigma(\mathrm{Fix}(H))$; conjugate subgroups correspond to conjugate (i.e. F-isomorphic) intermediate fields.*

(3) *(Normality.) E/F is Galois $\iff$ $H = \mathrm{Gal}(K/E)$ is normal in G, and then restriction induces an isomorphism*

$$\mathrm{Gal}(E/F) \;\cong\; G/H.$$

Idea. That the maps are inverse bijections is Artin run in both directions: for any subgroup H, $K/\mathrm{Fix}(H)$ is Galois with group exactly H (so $\mathrm{Gal}(K/\mathrm{Fix}(H)) = H$), and for any intermediate E, K/E is Galois (it is a splitting field of the same separable polynomial), so $\mathrm{Fix}(\mathrm{Gal}(K/E)) = E$. Inclusion reversal is immediate: a bigger group fixes fewer elements. (1) is the degree formula $[K : F] = [K : E][E : F]$ combined with $|G| = [K : F]$, $|H| = [K : E]$. For (2), $\tau \in \sigma H \sigma^{-1}$ fixes $\sigma(\alpha)$ iff $\sigma^{-1}\tau\sigma \in H$ fixes α, giving $\mathrm{Fix}(\sigma H \sigma^{-1}) = \sigma\,\mathrm{Fix}(H)$. For (3), $E = \mathrm{Fix}(H)$ is stable under all of G (i.e. $\sigma(E) = E$ for all σ, equivalently E/F normal) iff $\sigma H \sigma^{-1} = H$ for all σ by (2), i.e. $H \trianglelefteq G$; the restriction map $G \to \mathrm{Gal}(E/F)$ is then onto with kernel exactly H, so $\mathrm{Gal}(E/F) \cong G/H$. □

Method (To find all intermediate fields of a Galois extension K/F: (i) compute $G = \mathrm{Gal}(K/F)$ and $|G| = [K : F]$; (ii) list *all* subgroups $H \leq G$ – the lattice of subgroups is the lattice of intermediate fields turned upside down; (iii) for each H, the corresponding field is $\mathrm{Fix}(H)$, of degree $[G : H]$ over F; (iv) mark which H are normal – exactly those $\mathrm{Fix}(H)$ are Galois over F. Identify a generator's image to compute each $\mathrm{Fix}(H)$ concretely.)**.**

Worked Example 14.2.11 (Degrees from the index, both directions)**.** In a Galois extension with $G = D_8$ (order 8), what are $[K : E]$ and $[E : F]$ for $E = \mathrm{Fix}(H)$ with $|H| = 2$?

Recognition. Apply part (1): $[K : E] = |H|$ and $[E : F] = [G : H] = |G|/|H|$.

Solution. $[K : E] = |H| = 2$ and $[E : F] = 8/2 = 4$. Sanity check: $[K : E] \cdot [E : F] = 2 \cdot 4 = 8 = |G| = [K : F]$, the tower law holds.

Showcase I: the Klein four extension $\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$

This is the smallest extension where the full paired lattice is interesting. The group is the Klein four-group $V_4 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, which has exactly three proper nontrivial subgroups, all of order 2, matching the three quadratic subfields.

Proposition 14.2.12 (the V_4 correspondence)**.** *Let $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, $G = \mathrm{Gal}(K/\mathbb{Q}) = \{\,\mathrm{id}, \sigma, \tau, \sigma\tau\,\}$ where*

$$\sigma\colon \sqrt{2} \mapsto -\sqrt{2},\ \sqrt{3} \mapsto \sqrt{3}, \qquad \tau\colon \sqrt{2} \mapsto \sqrt{2},\ \sqrt{3} \mapsto -\sqrt{3}.$$

Then $G \cong V_4$, and its three order-2 subgroups $\langle\tau\rangle, \langle\sigma\rangle, \langle\sigma\tau\rangle$ correspond to the three quadratic subfields $\mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{3}), \mathbb{Q}(\sqrt{6})$ respectively. Every subgroup is normal, so every intermediate field is Galois over $\mathbb{Q}$.

Idea. $\sigma^2 = \tau^2 = \mathrm{id}$ and $\sigma\tau = \tau\sigma$, so $G \cong V_4$. The element $\sigma\tau$ negates both $\sqrt{2}$ and $\sqrt{3}$, hence fixes their product $\sqrt{6}$; thus $\mathrm{Fix}(\langle\sigma\tau\rangle) \supseteq \mathbb{Q}(\sqrt{6})$, and by Artin equality holds (degree 2 each). Similarly $\langle\tau\rangle$ fixes $\sqrt{2}$ and $\langle\sigma\rangle$ fixes $\sqrt{3}$. Since G is abelian every subgroup is normal, so by part (3) every intermediate field is Galois over $\mathbb{Q}$ (each is a quadratic, automatically normal). □

The paired lattice (subgroups on the left, subfields on the right), joined by the order-reversing Fix:

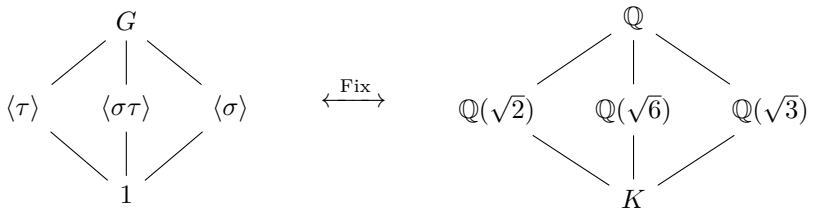


Diagram explanation. Objects: Left Hasse diagram: five groups – the full Galois group $G = V_4$ (top node), the three order-2 subgroups $\langle\tau\rangle, \langle\sigma\tau\rangle, \langle\sigma\rangle$ (middle row), and the trivial group 1 (bottom node). Right Hasse diagram: five fields – $\mathbb{Q}$ (top node), the three quadratic intermediate fields $\mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{6}), \mathbb{Q}(\sqrt{3})$ (middle row), and the top field $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ (bottom node). All edges are inclusion lines (dashes), not arrows with direction.

Arrows: The two Hasse diagrams are linked by the correspondence arrow $\overset{\text{Fix}}{\longleftrightarrow}$ between them. Within each diagram, the edges record containment: on the left, $1 \subset \langle\cdot\rangle \subset G$; on the right, $\mathbb{Q} \subset \mathbb{Q}(\sqrt{d}) \subset K$. The Fix arrow itself is the Galois correspondence map $H \mapsto K^H$, and its inverse is $E \mapsto \mathrm{Gal}(K/E)$.

What commutes: This is not a commutative square but a bijection of posets. The key content is the order-reversal: $H_1 \subset H_2$ in the left diagram if and only if $\mathrm{Fix}(H_2) \subset \mathrm{Fix}(H_1)$ in the right. Concretely: $1 \subset \langle\tau\rangle \subset G$ on the left maps to $K \supset \mathbb{Q}(\sqrt{2}) \supset \mathbb{Q}$ on the right; similarly for the other two chains.

Why it commutes: Artin's theorem guarantees $K/\mathrm{Fix}(H)$ is Galois with group exactly H, and $\mathrm{Fix}(\mathrm{Gal}(K/E)) = E$ for every intermediate E. Inclusion reversal holds because a larger group fixes fewer elements: if $H_1 \subset H_2$ then every element fixed by H_2 is also fixed by H_1, giving $\mathrm{Fix}(H_2) \subset \mathrm{Fix}(H_1)$.

Why this matters here: This is the first visual summary of the Fundamental Theorem applied to the V_4 example. It shows concretely that the three subgroups and three intermediate fields are in bijection via Fix, and the upside-down relationship between the two lattices encodes the inclusion-reversing nature of the Galois correspondence.

Concrete example: $\langle\sigma\tau\rangle$ consists of id and the automorphism c: $\sqrt{2} \mapsto -\sqrt{2}, \sqrt{3} \mapsto -\sqrt{3}$. Then $\mathrm{Fix}(\langle\sigma\tau\rangle) = \{r \in K : c(r) = r\}$. Since $c(\sqrt{6}) = (-\sqrt{2})(-\sqrt{3}) = \sqrt{6}$, we get $\mathbb{Q}(\sqrt{6}) \subseteq \mathrm{Fix}(\langle\sigma\tau\rangle)$; degree count gives equality. This matches the middle entry of the right diagram paired with the middle subgroup.

Common pitfall: Students often read the Hasse diagrams as having the same orientation and are surprised that the bigger group G at the top of the left diagram pairs with the smaller field $\mathbb{Q}$ at the top of the right diagram. The lattices are mirror images vertically: "top" in the group lattice (big group) pairs with "top" in the field lattice (small field), because more symmetry means fewer fixed elements.

Takeaway: The point of this diagram is that the Galois correspondence turns the subgroup lattice of V_4 upside-down to produce the intermediate-field lattice of $\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$, with each subgroup paired to its fixed field; since the field lattice is drawn inverted, each pair sits at the same height.

Note that the field diagram is drawn upside down (larger fields lower), so the two diagrams have the same shape: the top group G matches the top field $\mathbb{Q}$, the bottom group 1 matches the bottom field K, and each order-2 subgroup in the middle row sits opposite the quadratic field it fixes.

Writing $V_4 = \mathrm{Gal}(K/\mathbb{Q}) = \{1, a, b, c\}$ with a: $\sqrt{2} \mapsto -\sqrt{2}$, $\sqrt{3} \mapsto \sqrt{3}$; b: $\sqrt{2} \mapsto \sqrt{2}$, $\sqrt{3} \mapsto -\sqrt{3}$; and $c = ab$: $\sqrt{2} \mapsto -\sqrt{2}$, $\sqrt{3} \mapsto -\sqrt{3}$, the paired Hasse diagram makes the inclusion-reversing bijection fully explicit. On the left the subgroup lattice of V_4 grows *up* from 1; on the right the subfield lattice of K is drawn *inverted*, growing *down* from $\mathbb{Q}$, so a subgroup H and its fixed field $\mathrm{Fix}(H)$ sit at equal height and are joined by a faint tie-line.

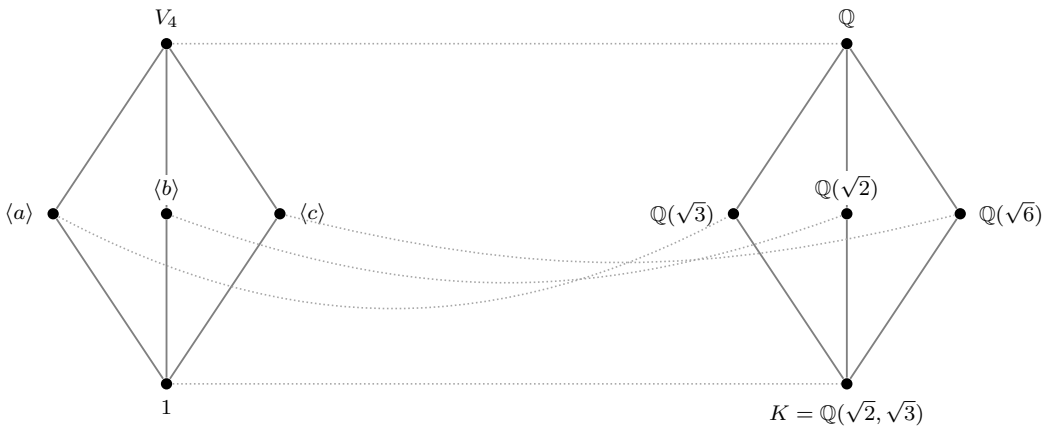

Diagram explanation. Objects: Left side: the subgroup lattice of $V_4 = \{1, a, b, c\}$ drawn growing upward, with nodes at three levels – trivial group 1 (bottom), the three order-2 subgroups $\langle a\rangle, \langle b\rangle, \langle c\rangle$ (middle), and V_4 (top). Right side: the subfield lattice of $K/\mathbb{Q}$ drawn inverted (growing downward), with nodes – $\mathbb{Q}$ (top), $\mathbb{Q}(\sqrt{3}), \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{6})$ (middle), and $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ (bottom). The dotted curved ties between the two lattices are the correspondence lines, not field or group morphisms.

Arrows: The solid edges within each lattice are inclusion relations. The dotted curved ties encode the bijection $H \leftrightarrow \mathrm{Fix}(H)$: each tie connects a subgroup on the left to its fixed field on the right at the same height. Specifically: $V_4 \leftrightarrow \mathbb{Q}$ (top tie), $1 \leftrightarrow K$ (bottom tie), $\langle a\rangle \leftrightarrow \mathbb{Q}(\sqrt{3})$ (since a negates $\sqrt{2}$ but fixes $\sqrt{3}$), $\langle b\rangle \leftrightarrow \mathbb{Q}(\sqrt{2})$ (since b fixes $\sqrt{2}$), $\langle c\rangle \leftrightarrow \mathbb{Q}(\sqrt{6})$ (since c negates both radicals so fixes their product).

What commutes: Equal-height pairing: $|H| = [K : \mathrm{Fix}(H)]$ and $[V_4 : H] = [\mathrm{Fix}(H) : \mathbb{Q}]$ for every subgroup H. So height from 1 on the left (which encodes $|H|$) equals height from K on the right (which encodes $[K : \mathrm{Fix}(H)]$).

Why it commutes: Artin's theorem applied to each H: $K/\mathrm{Fix}(H)$ is Galois with $\mathrm{Gal}(K/\mathrm{Fix}(H)) = H$, so $|H| = [K : \mathrm{Fix}(H)]$. The subgroup-lattice grows up (by inclusion) while the field lattice is drawn inverted (inclusion goes down), so equal height encodes equal index – the picture is literally the visual proof of inclusion-reversal.

Why this matters here: This is the fully explicit version of the paired lattice: it names every node and every tie-line, verifying the bijection concretely for V_4. It is placed here to show that the abstract theorem gives computable, checkable outputs for this specific 4-element group.

Concrete example: Take $H = \langle c\rangle$ where c: $\sqrt{2} \mapsto -\sqrt{2}, \sqrt{3} \mapsto -\sqrt{3}$. Then $\mathrm{Fix}(\langle c\rangle) = \{r \in K : c(r) = r\}$. We have $c(\sqrt{6}) = \sqrt{6}$, so $\mathbb{Q}(\sqrt{6}) \subseteq \mathrm{Fix}(\langle c\rangle)$; since $[K : \mathrm{Fix}(\langle c\rangle)] = |\langle c\rangle| = 2$ by Artin and $[K : \mathbb{Q}(\sqrt{6})] = 2$, equality holds. This is the tie joining $\langle c\rangle$ to $\mathbb{Q}(\sqrt{6})$ (the shallowest of the three curved middle ties).

Common pitfall: Students sometimes read the tie-lines as indicating field maps or ring homomorphisms. They are not: a tie H—$\mathrm{Fix}(H)$ records the bijection $H \leftrightarrow K^H$, which is a set-theoretic correspondence, not an algebraic map from the group to the field. The Galois correspondence is a bijection of posets, not a functor in the naive sense.

Takeaway: The point of this diagram is that placing the two lattices side-by-side at inverted heights makes the inclusion-reversal of the Galois correspondence geometrically obvious: going up on the left (bigger group) corresponds exactly to going up on the right (smaller field).

The dotted ties realize the Galois correspondence $H \leftrightarrow \mathrm{Fix}(H)$ as an inclusion-*reversing* bijection: $1 \leftrightarrow K$, $\langle a\rangle \leftrightarrow \mathbb{Q}(\sqrt{3})$ (since a fixes $\sqrt{3}$), $\langle b\rangle \leftrightarrow \mathbb{Q}(\sqrt{2})$ (since b fixes $\sqrt{2}$), $\langle c\rangle \leftrightarrow \mathbb{Q}(\sqrt{6})$ (since $c(\sqrt{6}) = (-\sqrt{2})(-\sqrt{3}) = \sqrt{6}$), and $V_4 \leftrightarrow \mathbb{Q}$. Heights match the index data: for every subgroup H one has $|H| = [K : \mathrm{Fix}(H)]$ and $[V_4 : H] = [\mathrm{Fix}(H) : \mathbb{Q}]$, so the bottom-to-top distance on the left equals the top-to-bottom distance on the right.

Worked Example 14.2.13 (Computing $\mathrm{Fix}(\langle\sigma\tau\rangle) = \mathbb{Q}(\sqrt{6})$)**.** Verify that the diagonal subgroup $\langle\sigma\tau\rangle$ fixes $\mathbb{Q}(\sqrt{6})$ and nothing larger.

Recognition. By Artin $[K : \mathrm{Fix}(\langle\sigma\tau\rangle)] = |\langle\sigma\tau\rangle| = 2$, so the fixed field is quadratic; find an explicit fixed element.

Solution. $\sigma\tau$ sends $\sqrt{2} \mapsto -\sqrt{2}$ and $\sqrt{3} \mapsto -\sqrt{3}$, hence $\sqrt{6} = \sqrt{2}\sqrt{3} \mapsto (-\sqrt{2})(-\sqrt{3}) = \sqrt{6}$. So $\mathbb{Q}(\sqrt{6}) \subseteq \mathrm{Fix}(\langle\sigma\tau\rangle)$; both have degree 2 over $\mathbb{Q}$ (the latter by Artin), so they are equal. Sanity check: $\sigma\tau(\sqrt{2}) = -\sqrt{2} \neq \sqrt{2}$, so $\sqrt{2} \notin \mathrm{Fix}(\langle\sigma\tau\rangle)$, confirming the fixed field is $\mathbb{Q}(\sqrt{6})$ and not all of K.

Worked Example 14.2.14 (All subfields of the splitting field of $(x^2-2)(x^2-3)(x^2-5)$)**.** Find $\mathrm{Gal}(K/\mathbb{Q})$ and count the intermediate fields for $K = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$.

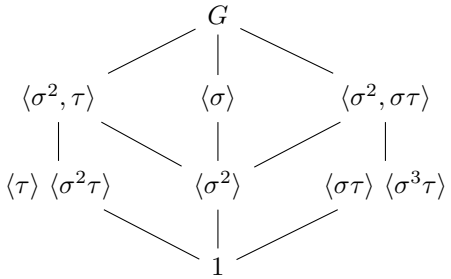
Recognition. Independent square roots give $G \cong V_4 \times \mathbb{Z}/2\mathbb{Z} \cong (\mathbb{Z}/2\mathbb{Z})^3$ by the biquadratic principle; subfields correspond to subgroups of $(\mathbb{Z}/2\mathbb{Z})^3$.

Solution. Each generator independently sends $\sqrt{2}, \sqrt{3}, \sqrt{5}$ to $\pm$ themselves, so $|G| = 8$ and $G \cong (\mathbb{Z}/2\mathbb{Z})^3$, with $[K : \mathbb{Q}] = 8$. The number of subgroups of $(\mathbb{Z}/2\mathbb{Z})^3$ by order: one trivial, 7 of order 2 (one per nonzero vector), 7 of order 4 (one per 2-dimensional subspace, equivalently per nonzero linear functional), one of order 8, total 16. Hence 16 intermediate fields: $\mathbb{Q}$ itself, 7 quadratic fields $\mathbb{Q}(\sqrt{d})$ for $d \in \{2, 3, 5, 6, 10, 15, 30\}$, 7 biquadratic fields of degree 4, and K. Sanity check: the 7 quadratics correspond to the 7 subgroups of *index* 2 (order 4), and the 7 degree-4 fields to the 7 subgroups of order 2 – the order-reversal swaps the two counts, both equal to $2^3 - 1 = 7$.

Showcase II: the splitting field of $x^4 - 2$, group D_8

This is the canonical worked example of the Fundamental Theorem: a nonabelian group, normal and non-normal subgroups, and a vivid distinction between intermediate fields that are Galois over $\mathbb{Q}$ and those that are not.

Proposition 14.2.15 ($\mathrm{Gal}(\mathbb{Q}(2^{1/4}, i)/\mathbb{Q}) \cong D_8$)**.** *Let $\theta = 2^{1/4}$ (real positive) and $K = \mathbb{Q}(\theta, i)$, the splitting field of $x^4 - 2$ over $\mathbb{Q}$. Then $[K : \mathbb{Q}] = 8$ and $G = \mathrm{Gal}(K/\mathbb{Q}) \cong D_8$, generated by*



$$\sigma\colon \theta \mapsto i\theta,\ i \mapsto i, \qquad \tau\colon \theta \mapsto \theta,\ i \mapsto -i \ (\textit{complex conjugation}),$$

with relations $\sigma^4 = \tau^2 = \mathrm{id}$ and $\tau\sigma\tau^{-1} = \sigma^{-1}$.

Idea. The four roots of $x^4 - 2$ are $\theta, i\theta, -\theta, -i\theta = i^k\theta$, so $K = \mathbb{Q}(\theta, i)$. Now $[\mathbb{Q}(\theta) : \mathbb{Q}] = 4$ (Eisenstein at 2) and $\theta \in \mathbb{R}$ while $i \notin \mathbb{R}$, so $[K : \mathbb{Q}(\theta)] = 2$, giving $[K : \mathbb{Q}] = 8$. The extension is Galois (splitting field of a separable polynomial), so $|G| = 8$. The map σ permutes the roots cyclically and fixes i; computing $\sigma^2(\theta) = i^2\theta = -\theta$, $\sigma^4 = \mathrm{id}$, so $|\sigma| = 4$. Complex conjugation τ fixes θ and inverts i, $|\tau| = 2$. Finally $\tau\sigma\tau^{-1}(\theta) = \tau\sigma(\theta) = \tau(i\theta) = -i\theta = \sigma^3(\theta) = \sigma^{-1}(\theta)$ and both fix i, so $\tau\sigma\tau^{-1} = \sigma^{-1}$: these are the dihedral relations, $G \cong D_8$. □

The eight elements are $\{\mathrm{id}, \sigma, \sigma^2, \sigma^3, \tau, \sigma\tau, \sigma^2\tau, \sigma^3\tau\}$. The subgroup lattice of D_8 has ten subgroups: 1; the subgroups of order 2, *central or otherwise* – precisely $\langle\sigma^2\rangle$ (central), $\langle\tau\rangle, \langle\sigma^2\tau\rangle$ (reflections) and $\langle\sigma\tau\rangle, \langle\sigma^3\tau\rangle$ (the other reflections), so five of order 2 in all; three of order 4 namely $\langle\sigma\rangle \cong \mathbb{Z}/4\mathbb{Z}$ and the two Klein fours $\langle\sigma^2, \tau\rangle, \langle\sigma^2, \sigma\tau\rangle$; and G. The three subgroups of order 4 have index 2, hence are *normal*; $\langle\sigma^2\rangle$ is the center, also normal; the four reflection subgroups of order 2 are *not* normal.

The subgroup lattice (top = G):

(The labels $\langle\tau\rangle$ $\langle\sigma^2\tau\rangle$ and $\langle\sigma\tau\rangle$ $\langle\sigma^3\tau\rangle$ each denote two distinct order-2 subgroups sitting in that position, both contained in the order-4 group above them and containing 1.)

Diagram explanation. Objects: Nodes are the ten subgroups of $G = D_8$, arranged by order. Top: G itself (order 8). Second row: three order-4 subgroups – $\langle\sigma^2, \tau\rangle \cong V_4$, $\langle\sigma\rangle \cong \mathbb{Z}/4\mathbb{Z}$, $\langle\sigma^2, \sigma\tau\rangle \cong V_4$. Third row: five order-2 subgroups – the central $\langle\sigma^2\rangle$ in the middle, and two pairs of reflection subgroups $\langle\tau\rangle, \langle\sigma^2\tau\rangle$ (left) and $\langle\sigma\tau\rangle, \langle\sigma^3\tau\rangle$ (right). Bottom: the trivial group 1.

Arrows: Every edge is a containment: $H_1 - H_2$ means $H_1 \subset H_2$. Edges go from each subgroup upward to every subgroup that contains it with no intermediate subgroup in between (Hasse diagram convention). No edge is a group homomorphism; the diagram is purely a poset diagram.

What commutes: The Hasse diagram records which subgroups contain which. The critical normality data: $\langle\sigma\rangle, \langle\sigma^2, \tau\rangle, \langle\sigma^2, \sigma\tau\rangle$ all have index 2, so they are normal in G; $\langle\sigma^2\rangle$ is the center, also normal; the four reflection subgroups of order 2 have two distinct G-conjugates each (i.e. $\langle\tau\rangle$ and $\langle\sigma^2\tau\rangle$ are conjugate, and $\langle\sigma\tau\rangle$ and $\langle\sigma^3\tau\rangle$ are conjugate), hence none are normal.

Why it commutes: Containment is checked by direct computation: e.g. $\langle\sigma^2\rangle = \{1, \sigma^2\} \subset \langle\sigma\rangle = \{1, \sigma, \sigma^2, \sigma^3\}$, and $\langle\sigma^2\rangle \subset \langle\sigma^2, \tau\rangle = \{1, \sigma^2, \tau, \sigma^2\tau\}$. The two top-row containments on each wing hold because a Klein-four subgroup contains each of its three involutions.

Why this matters here: This diagram is the complete subgroup atlas of D_8 needed to read off the intermediate field lattice via the Galois correspondence. By the Fundamental Theorem, normality in this diagram (index-2 subgroups and the center) exactly predicts which intermediate fields will be Galois over $\mathbb{Q}$, making this the lookup table for the analysis that follows.

Concrete example: The edge $\langle\sigma^2, \tau\rangle - G$ records $\langle\sigma^2, \tau\rangle \subset G$ with index 2, so $\langle\sigma^2, \tau\rangle \trianglelefteq G$, and its fixed field $\mathrm{Fix}(\langle\sigma^2, \tau\rangle) = \mathbb{Q}(\sqrt{2})$ is Galois over $\mathbb{Q}$ with group $G/\langle\sigma^2, \tau\rangle \cong \mathbb{Z}/2\mathbb{Z}$. By contrast, the absence of a direct edge from $\langle\tau\rangle$ to G (it passes through $\langle\sigma^2, \tau\rangle$) reflects only that $\langle\tau\rangle$ is not maximal (it has index 4); its non-normality is a separate fact ($\sigma\langle\tau\rangle\sigma^{-1} = \langle\sigma^2\tau\rangle$): $\langle\sigma^2\rangle$ also has no direct edge to G, yet it is normal.

Common pitfall: Students see five order-2 subgroups and expect five lines at the third row, but the diagram clusters $\langle\tau\rangle, \langle\sigma^2\tau\rangle$ together (they share a common order-4 parent $\langle\sigma^2, \tau\rangle$) and similarly $\langle\sigma\tau\rangle, \langle\sigma^3\tau\rangle$ (they share $\langle\sigma^2, \sigma\tau\rangle$). This clustering does not mean these pairs are equal – each pair consists of two genuinely distinct subgroups, and only the central $\langle\sigma^2\rangle$ connects to both wings.

Takeaway: The point of this diagram is that the subgroup lattice of D_8 organizes all ten subgroups by containment and implicitly marks which are normal (index-2 or central), giving the template for reading the Galois correspondence in the next diagram.

The corresponding subfield lattice, by $E = \mathrm{Fix}(H)$ with $[E : \mathbb{Q}] = [G : H]$ (drawn upside down, with $\mathbb{Q}$ on top, so that each $\mathrm{Fix}(H)$ sits where H sits in the lattice above):

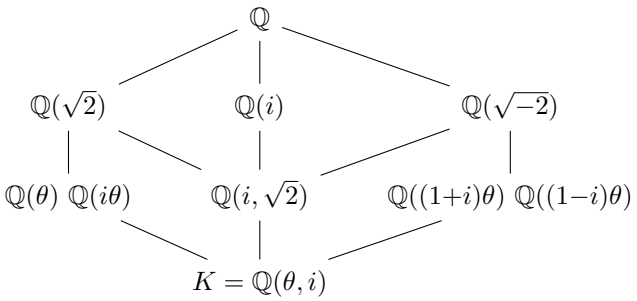


Diagram explanation. Objects: Nodes are the ten intermediate fields of $K = \mathbb{Q}(\theta, i)/\mathbb{Q}$ (with $\theta = 2^{1/4}$), arranged by inclusion. Top: $\mathbb{Q}$. Second row: the three quadratic subfields $\mathbb{Q}(\sqrt{2}), \mathbb{Q}(i), \mathbb{Q}(\sqrt{-2})$, each of degree 2 over $\mathbb{Q}$. Third row: the five degree-4 subfields – the Galois biquadratic $\mathbb{Q}(i, \sqrt{2})$ in the center, and four non-Galois fields $\mathbb{Q}(\theta), \mathbb{Q}(i\theta)$ (left) and $\mathbb{Q}((1+i)\theta), \mathbb{Q}((1-i)\theta)$ (right). Bottom: $K = \mathbb{Q}(\theta, i)$ of degree 8.

Arrows: Every edge is a field inclusion, pointing downward (toward the larger field). As in the subgroup lattice, edges are Hasse: $E_1 - E_2$ means $E_1 \subset E_2$ with no intermediate field between them. No edge is a field homomorphism beyond inclusion.

What commutes: Since the field lattice is drawn upside down (larger fields lower), this picture has exactly the shape of the subgroup lattice. Each field E sits at the same position in this lattice as $\mathrm{Gal}(K/E)$ sits in the

subgroup lattice (at height $[E:\mathbb{Q}]$ from the top here, versus height $|\mathrm{Gal}(K/E)|$ from the bottom there). The fields in the second row correspond to normal subgroups of index 2, so they are Galois over $\mathbb{Q}$. The central $\mathbb{Q}(i,\sqrt{2})$ corresponds to the center $\langle\sigma^2\rangle \trianglelefteq G$, so it is Galois over $\mathbb{Q}$.

Why it commutes: By the Fundamental Theorem, $\mathrm{Fix}(H) \subset \mathrm{Fix}(H')$ iff $H' \subset H$, so larger groups give smaller fields. Each row swap from the subgroup lattice comes from this reversal: the order-4 subgroups sit in row 2 of the subgroup lattice, their fixed fields (degree 2 over $\mathbb{Q}$) sit in row 2 of this lattice. Likewise order-2 subgroups give degree-4 fields occupying row 3 here.

Why this matters here: This is the complete field-theoretic output of the Galois correspondence for D_8. It distinguishes the six Galois intermediate fields ($\mathbb{Q}$, the three quadratics, $\mathbb{Q}(i,\sqrt{2})$ and K itself) from the four non-Galois ones (the four degree-4 fields fixed by non-normal reflections), demonstrating concretely why normality of a subgroup is the deciding criterion.

Concrete example: Compare $\mathbb{Q}(i)$ (second row, center) with $\mathbb{Q}(\theta)$ (third row, left). The field $\mathbb{Q}(i) = \mathrm{Fix}(\langle\sigma\rangle)$ where $\langle\sigma\rangle \trianglelefteq G$ (index 2), so $\mathbb{Q}(i)/\mathbb{Q}$ is Galois with group $G/\langle\sigma\rangle \cong \mathbb{Z}/2\mathbb{Z}$. The field $\mathbb{Q}(\theta) = \mathrm{Fix}(\langle\tau\rangle)$ where $\langle\tau\rangle$ is not normal, so $\mathbb{Q}(\theta)/\mathbb{Q}$ is not Galois: it contains only the two real roots $\pm\theta$ of x^4-2 and misses $i\theta$ and $-i\theta$.

Common pitfall: Students read the position of $\mathbb{Q}(\theta)$ in row 3 (far from $\mathbb{Q}$ in the diagram) and assume it is a "complicated" extension, then try to prove it is Galois by listing its automorphisms. The diagram shows it has degree 4 and corresponds to a non-normal subgroup; the correct conclusion is immediately that $\mathbb{Q}(\theta)/\mathbb{Q}$ is not Galois, with $|\mathrm{Aut}(\mathbb{Q}(\theta)/\mathbb{Q})| = 2 < 4 = [\mathbb{Q}(\theta):\mathbb{Q}]$.

Takeaway: The point of this diagram is that the subfield lattice of $\mathbb{Q}(2^{1/4},i)/\mathbb{Q}$ is the subgroup lattice of D_8 turned upside down, and normality of a subgroup can be read directly off this picture as the condition that its fixed field is itself Galois over $\mathbb{Q}$.

Here is the key reading of normality. The three index-2 subgroups $\langle\sigma\rangle, \langle\sigma^2,\tau\rangle, \langle\sigma^2,\sigma\tau\rangle$ are normal, so their fixed fields $\mathbb{Q}(i), \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{-2})$ are the three quadratic subfields and are Galois over $\mathbb{Q}$. The center $\langle\sigma^2\rangle$ is normal, so $\mathrm{Fix}(\langle\sigma^2\rangle) = \mathbb{Q}(i,\sqrt{2})$ is a degree-4 field Galois over $\mathbb{Q}$ (its group is $G/\langle\sigma^2\rangle \cong V_4$). By contrast the four non-normal reflection subgroups $\langle\tau\rangle, \langle\sigma^2\tau\rangle, \langle\sigma\tau\rangle, \langle\sigma^3\tau\rangle$ have fixed fields $\mathbb{Q}(\theta), \mathbb{Q}(i\theta), \mathbb{Q}((1+i)\theta), \mathbb{Q}((1-i)\theta)$ – the four degree-4 fields that are *not* Galois over $\mathbb{Q}$.

Worked Example 14.2.16 ($\mathrm{Fix}(\langle\tau\rangle) = \mathbb{Q}(\theta)$ is not Galois over $\mathbb{Q}$)**.** Identify the fixed field of complex conjugation τ and explain why it is not normal over $\mathbb{Q}$.

Recognition. τ fixes $\theta = 2^{1/4} \in \mathbb{R}$; by Artin $[K:\mathrm{Fix}(\langle\tau\rangle)] = 2$, so $\mathrm{Fix}(\langle\tau\rangle)$ is a degree-4 field. Non-normality of $\langle\tau\rangle$ in G predicts the field is not Galois over $\mathbb{Q}$.

Solution. τ fixes θ and $\mathbb{Q}$, so $\mathbb{Q}(\theta) \subseteq \mathrm{Fix}(\langle\tau\rangle)$; since $[\mathbb{Q}(\theta):\mathbb{Q}] = 4 = [G:\langle\tau\rangle]$, equality holds, $\mathrm{Fix}(\langle\tau\rangle) = \mathbb{Q}(\theta)$. Now $\langle\tau\rangle$ is not normal: $\sigma\tau\sigma^{-1}$ sends $\theta \mapsto \sigma\tau(-i\theta) = \sigma(i\theta) = -\theta$ and $i \mapsto -i$, so $\sigma\tau\sigma^{-1} = \sigma^2\tau$ and $\sigma\langle\tau\rangle\sigma^{-1} = \langle\sigma\tau\sigma^{-1}\rangle = \langle\sigma^2\tau\rangle \neq \langle\tau\rangle$. Correspondingly $\mathbb{Q}(\theta)$ contains only the real roots $\pm\theta$ of x^4-2, not the conjugates $i\theta, -i\theta$, so it is not a splitting field and not normal over $\mathbb{Q}$. Sanity check: $|\mathrm{Aut}(\mathbb{Q}(\theta)/\mathbb{Q})| = 2$ (only $\theta \mapsto \pm\theta$ stay in the real field $\mathbb{Q}(\theta)$) while $[\mathbb{Q}(\theta):\mathbb{Q}] = 4$, so by characterization (3) it is indeed not Galois.

Worked Example 14.2.17 ($\mathrm{Fix}(\langle\sigma^2\rangle) = \mathbb{Q}(i,\sqrt{2})$ is Galois over $\mathbb{Q}$)**.** Find the fixed field of the center $\langle\sigma^2\rangle$ and identify Gal of that field over $\mathbb{Q}$.

Recognition. $\langle\sigma^2\rangle$ is the center of D_8, hence normal; its fixed field is degree $[G:\langle\sigma^2\rangle] = 4$ and Galois over $\mathbb{Q}$ with group $G/\langle\sigma^2\rangle$.

Solution. σ^2 sends $\theta \mapsto -\theta$ and fixes i, so it fixes $\theta^2 = \sqrt{2}$ and i; thus $\mathbb{Q}(i,\sqrt{2}) \subseteq \mathrm{Fix}(\langle\sigma^2\rangle)$, and both are degree 4 over $\mathbb{Q}$, so equal. Since $\langle\sigma^2\rangle \trianglelefteq G$, the field $\mathbb{Q}(i,\sqrt{2})$ is Galois over $\mathbb{Q}$ with Gal $\cong G/\langle\sigma^2\rangle$. As $D_8/Z(D_8) \cong V_4$, we get $\mathrm{Gal}(\mathbb{Q}(i,\sqrt{2})/\mathbb{Q}) \cong V_4$. Sanity check: $\mathbb{Q}(i,\sqrt{2})$ is itself a biquadratic field $\mathbb{Q}(\sqrt{-1},\sqrt{2})$ whose group is visibly V_4 (independent sign changes on $i, \sqrt{2}$), agreeing with $D_8/Z \cong V_4$.

Worked Example 14.2.18 (The three quadratic subfields and which subgroups give them)**.** Determine the three quadratic subfields of $K = \mathbb{Q}(\theta,i)$ and the subgroups they correspond to.

Recognition. Quadratic subfields $\leftrightarrow$ index-2 (order-4) subgroups of G; there are exactly three subgroups of order 4 in D_8.

Solution. The order-4 subgroups are $\langle\sigma\rangle$ (cyclic), $\langle\sigma^2,\tau\rangle$, and $\langle\sigma^2,\sigma\tau\rangle$. Their fixed fields: $\mathrm{Fix}(\langle\sigma\rangle) = \mathbb{Q}(i)$ (since σ fixes i and moves θ); $\mathrm{Fix}(\langle\sigma^2,\tau\rangle) = \mathbb{Q}(\sqrt{2})$ (both fix $\theta^2 = \sqrt{2}$, and τ moves i); $\mathrm{Fix}(\langle\sigma^2,\sigma\tau\rangle) = \mathbb{Q}(\sqrt{-2})$

(one checks $\sigma\tau$ fixes $i\theta^2 = i\sqrt{2}$, and σ^2 fixes it too, with $(i\sqrt{2})^2 = -2$). All three are normal, so all three quadratics are Galois over $\mathbb{Q}$. Sanity check: the three quadratic subfields of any field containing $\mathbb{Q}(\sqrt{2}, i)$ that are $\mathbb{Q}(\sqrt{d})$ must have $d \in \{2, -1, -2\}$ up to squares, and indeed $2 \cdot (-1) = -2$, so $\{\mathbb{Q}(\sqrt{2}), \mathbb{Q}(i), \mathbb{Q}(\sqrt{-2})\}$ is exactly the V_4 family of quadratics inside $\mathbb{Q}(i, \sqrt{2})$.

Worked Example 14.2.19 (A non-normal reflection subgroup and its conjugate field)**.** Show $\langle\tau\rangle$ and $\langle\sigma^2\tau\rangle$ are conjugate in D_8 and that their fixed fields $\mathbb{Q}(\theta), \mathbb{Q}(i\theta)$ are $\mathbb{Q}$-isomorphic but distinct.

Recognition. Part (2) of the Fundamental Theorem: conjugate subgroups have conjugate (hence F-isomorphic) fixed fields, and a non-normal subgroup gives a non-Galois, hence properly conjugated, field.

Solution. Compute $\sigma\langle\tau\rangle\sigma^{-1} = \langle\sigma\tau\sigma^{-1}\rangle$. Since $\sigma\tau\sigma^{-1} = \sigma^2\tau$ (from $\tau\sigma = \sigma^{-1}\tau$, so $\sigma\tau = \tau\sigma^{-1}$ and $\sigma\tau\sigma^{-1} = \tau\sigma^{-2} = \tau\sigma^2 = \sigma^2\tau$ using $\tau\sigma^2 = \sigma^{-2}\tau = \sigma^2\tau$), we get $\sigma\langle\tau\rangle\sigma^{-1} = \langle\sigma^2\tau\rangle$. Hence by (2), $\sigma(\mathrm{Fix}(\langle\tau\rangle)) = \mathrm{Fix}(\langle\sigma^2\tau\rangle)$, i.e. $\sigma(\mathbb{Q}(\theta)) = \mathbb{Q}(\sigma\theta) = \mathbb{Q}(i\theta)$. The two fields $\mathbb{Q}(\theta)$ and $\mathbb{Q}(i\theta)$ are distinct (one is real, the other is not) but σ is a $\mathbb{Q}$-isomorphism between them. Sanity check: both are roots-of-$x^4 - 2$ adjunctions, $[\mathbb{Q}(\theta) : \mathbb{Q}] = [\mathbb{Q}(i\theta) : \mathbb{Q}] = 4$, and neither is normal over $\mathbb{Q}$ (each contains only one root pair of $x^4 - 2$), exactly as predicted for fixed fields of non-normal subgroups.

Showcase III: cyclotomic fields $\mathbb{Q}(\zeta_p)/\mathbb{Q}$

The cyclotomic extensions $\mathbb{Q}(\zeta_p)/\mathbb{Q}$, p prime, give the simplest abelian family: because the Galois group is cyclic, the Fundamental Theorem produces exactly one subfield of each degree dividing $p - 1$ (a chain of subfields only when $p - 1$ is a prime power).

Theorem 14.2.20 ($\mathbb{Q}(\zeta_p)/\mathbb{Q}$ is cyclic of order $p - 1$)**.** *Let p be an odd prime and $\zeta_p = e^{2\pi i/p}$ a primitive p-th root of unity. Then $\mathbb{Q}(\zeta_p)/\mathbb{Q}$ is Galois with*

$$\mathrm{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q}) \;\cong\; (\mathbb{Z}/p\mathbb{Z})^\times \;\cong\; \mathbb{Z}/(p-1)\mathbb{Z},$$

cyclic of order $p - 1$. The automorphism σ_a is given by $\sigma_a(\zeta_p) = \zeta_p^a$ for $a \in (\mathbb{Z}/p\mathbb{Z})^\times$. For each divisor $d \mid p - 1$ there is a unique *intermediate field of degree d over $\mathbb{Q}$, namely* Fix *of the unique subgroup of index d.*

Idea. The minimal polynomial of ζ_p over $\mathbb{Q}$ is the p-th cyclotomic polynomial $\Phi_p(x) = x^{p-1} + \cdots + x + 1$, irreducible (Eisenstein after $x \mapsto x + 1$), so $[\mathbb{Q}(\zeta_p) : \mathbb{Q}] = p - 1$. The extension is the splitting field of $x^p - 1$ (separable, since $p \neq 0$ in $\mathbb{Q}$), hence Galois. An automorphism must send ζ_p to another primitive root ζ_p^a with $a \in \{1, \ldots, p - 1\}$, and $\sigma_a\sigma_b = \sigma_{ab}$, giving $\mathrm{Gal} \cong (\mathbb{Z}/p\mathbb{Z})^\times$, which is cyclic of order $p - 1$ because $(\mathbb{Z}/p\mathbb{Z})^\times$ is cyclic for p prime. Subgroups of a cyclic group are unique of each order, so intermediate fields are unique of each degree. □

The subgroup/subfield correspondence for $\mathbb{Q}(\zeta_p)$ is an order anti-isomorphism between the (totally ordered, when $p - 1$ is a prime power, otherwise a divisor lattice) subgroup lattice of $\mathbb{Z}/(p-1)\mathbb{Z}$ and the subfield lattice. We illustrate with $p = 13$, where $p - 1 = 12$ reproduces the divisor lattice of 12 from the finite-fields section.

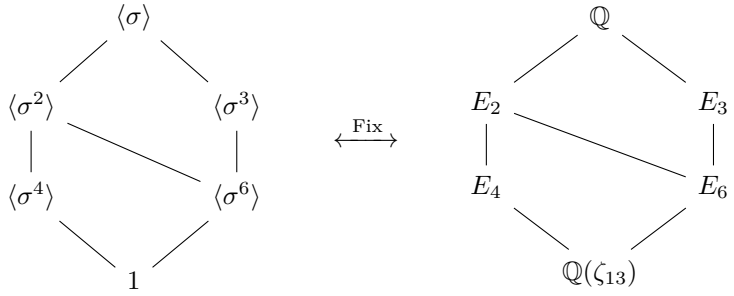

Diagram explanation. Objects: Left diagram: the subgroup lattice of $\mathrm{Gal}(\mathbb{Q}(\zeta_{13})/\mathbb{Q}) \cong \mathbb{Z}/12\mathbb{Z}$, a cyclic group of order 12. Nodes are the six subgroups of $\mathbb{Z}/12\mathbb{Z}$: the full group $\langle\sigma\rangle$ (order 12, top), then $\langle\sigma^2\rangle$ (order 6), $\langle\sigma^3\rangle$ (order 4), $\langle\sigma^4\rangle$ (order 3), $\langle\sigma^6\rangle$ (order 2), and 1 (order 1, bottom). Right diagram: the corresponding

subfield lattice of $\mathbb{Q}(\zeta_{13})/\mathbb{Q}$. Nodes are $\mathbb{Q}$ (top), E_2 (degree 2), E_3 (degree 3), E_4 (degree 4), E_6 (degree 6), and $\mathbb{Q}(\zeta_{13})$ (degree 12, bottom).

Arrows: The edges in both diagrams encode inclusion (of subgroups on the left, of fields on the right). The $\overset{\text{Fix}}{\longleftrightarrow}$ link between the two diagrams records the Galois correspondence $\langle\sigma^m\rangle \mapsto E_{12/\mathrm{ord}(\langle\sigma^m\rangle)}$: a subgroup of order k corresponds to a subfield of degree $12/k$ over $\mathbb{Q}$.

What commutes: The order anti-isomorphism: $\langle\sigma^a\rangle \subset \langle\sigma^b\rangle$ iff $E_{12/\mathrm{ord}(\langle\sigma^b\rangle)} \subset E_{12/\mathrm{ord}(\langle\sigma^a\rangle)}$. In the displayed case, $\langle\sigma^4\rangle$ (order 3) $\subset \langle\sigma^2\rangle$ (order 6) corresponds to $E_4 \supset E_2$. Every subgroup is normal (the group is cyclic, hence abelian), so every E_d is Galois over $\mathbb{Q}$.

Why it commutes: Because $\mathbb{Z}/12\mathbb{Z}$ is cyclic, its subgroups are exactly the cyclic subgroups $\langle\sigma^d\rangle$ for $d \mid 12$, one of each order $12/d$, and the unique subgroup of each given order means there is exactly one intermediate field of each degree dividing 12. The correspondence maps $\langle\sigma^d\rangle \mapsto \mathrm{Fix}(\langle\sigma^d\rangle)$, a subfield of degree $[\mathbb{Z}/12\mathbb{Z} : \langle\sigma^d\rangle] = d$ over $\mathbb{Q}$.

Why this matters here: This paired diagram specializes the Fundamental Theorem to the cyclotomic case $p = 13$, showing visually that the divisor lattice of 12 governs both sides. The unique-subfield property (one per divisor of $p-1$) and the abelian/normal property (every subfield is Galois over $\mathbb{Q}$) are both immediately visible from the diagram.

Concrete example: The subgroup $\langle\sigma^6\rangle \cong \mathbb{Z}/2\mathbb{Z}$ (order 2, generated by complex conjugation $\sigma_{-1}\colon \zeta_{13} \mapsto \zeta_{13}^{-1}$) corresponds to $E_6 = \mathrm{Fix}(\langle\sigma^6\rangle)$, the maximal real subfield $\mathbb{Q}(\zeta_{13} + \zeta_{13}^{-1}) = \mathbb{Q}(\cos\frac{2\pi}{13})$, of degree 6 over $\mathbb{Q}$. This sits in row E_6 of the right diagram, paired with $\langle\sigma^6\rangle$ at the same level on the left.

Common pitfall: Students sometimes confuse the degree of E_d with the order of the corresponding subgroup. The correspondence swaps these: the subfield E_d has degree d over $\mathbb{Q}$, but the corresponding subgroup $\langle\sigma^d\rangle$ has order $12/d$, not d. The formula is $[E_d : \mathbb{Q}] = [\mathbb{Z}/12\mathbb{Z} : \text{subgroup}] = 12/(\text{subgroup order})$.

Takeaway: The point of this diagram is that the divisor lattice of $p - 1 = 12$ simultaneously organizes the subgroups of the cyclic Galois group and the intermediate subfields of $\mathbb{Q}(\zeta_{13})/\mathbb{Q}$, with the correspondence reversing the order so that a larger subgroup gives a smaller fixed field.

Here $E_d = \mathrm{Fix}$ of the subgroup of order $12/d$ is the unique subfield with $[E_d : \mathbb{Q}] = d$; the subgroup $\langle\sigma^m\rangle$ has order $12/\gcd(12, m)$. Since $\langle\sigma\rangle \cong \mathbb{Z}/12\mathbb{Z}$ is abelian, every subgroup is normal, so *every* subfield E_d is Galois over $\mathbb{Q}$ (cyclic, in fact).

Worked Example 14.2.21 (The unique quadratic subfield of $\mathbb{Q}(\zeta_p)$)**.** Show $\mathbb{Q}(\zeta_p)$ contains a unique quadratic subfield, and identify it as $\mathbb{Q}(\sqrt{p^*})$ with $p^* = (-1)^{(p-1)/2}p$.

Recognition. Cyclic group of order $p-1$ (even) has a unique subgroup of index 2, hence a unique degree-2 subfield; the quadratic Gauss sum pins it down.

Solution. $\mathrm{Gal} \cong \mathbb{Z}/(p-1)\mathbb{Z}$ has a unique subgroup of index 2 (the squares in $(\mathbb{Z}/p\mathbb{Z})^\times$), so by the Fundamental Theorem a unique quadratic subfield $E_2 = \mathrm{Fix}(\text{squares})$. The quadratic Gauss sum $g = \sum_{a=1}^{p-1}\left(\frac{a}{p}\right)\zeta_p^a$ satisfies $g^2 = p^* = (-1)^{(p-1)/2}p$ and lies in $\mathbb{Q}(\zeta_p)$, so $E_2 = \mathbb{Q}(g) = \mathbb{Q}(\sqrt{p^*})$. Sanity check: for $p = 5$, $p^* = (-1)^2 \cdot 5 = 5$, and indeed $\mathbb{Q}(\zeta_5) \supset \mathbb{Q}(\sqrt{5})$ (the real subfield $\mathbb{Q}(\cos 72^\circ) = \mathbb{Q}(\frac{-1+\sqrt{5}}{4})$); for $p = 3$, $p^* = (-1)^1 \cdot 3 = -3$ and $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$, matching $\zeta_3 = \frac{-1+\sqrt{-3}}{2}$.

Worked Example 14.2.22 (Subfields of $\mathbb{Q}(\zeta_7)$)**.** List all subfields of $\mathbb{Q}(\zeta_7)$ and their degrees over $\mathbb{Q}$.

Recognition. $\mathrm{Gal}(\mathbb{Q}(\zeta_7)/\mathbb{Q}) \cong \mathbb{Z}/6\mathbb{Z}$, cyclic; subfields correspond to divisors of 6, one per divisor.

Solution. Divisors of 6 are $1, 2, 3, 6$, so there are subfields of degrees $1, 2, 3, 6$: $\mathbb{Q}$; the unique quadratic $\mathbb{Q}(\sqrt{-7})$ (since $7^* = (-1)^3 \cdot 7 = -7$); the unique cubic $E_3 = \mathrm{Fix}(\text{the order-2 subgroup})$, which is the real subfield $\mathbb{Q}(\zeta_7 + \zeta_7^{-1}) = \mathbb{Q}(\cos\frac{2\pi}{7})$; and $\mathbb{Q}(\zeta_7)$ itself. Sanity check: 4 divisors of 6 give 4 subfields; the cubic $\mathbb{Q}(\cos\frac{2\pi}{7})$ is real of degree 3 (it is Fix of complex conjugation $\zeta \mapsto \zeta^{-1}$, the unique order-2 subgroup), and $[\mathbb{Q}(\zeta_7) : \mathbb{Q}(\cos\frac{2\pi}{7})] = 2$ as it adjoins back the non-real ζ_7.

Worked Example 14.2.23 (The fixed field of complex conjugation in $\mathbb{Q}(\zeta_p)$)**.** Identify $\mathrm{Fix}(\langle c\rangle)$ where $c\colon \zeta_p \mapsto \zeta_p^{-1}$ is complex conjugation.

Recognition. $c = \sigma_{-1}$ has order 2 in the cyclic group Gal; its fixed field has degree $(p-1)/2$ and is the maximal real subfield.

Solution. Complex conjugation fixes $\eta = \zeta_p + \zeta_p^{-1} = 2\cos\frac{2\pi}{p} \in \mathbb{R}$, and $\mathbb{Q}(\eta)$ is real of degree $(p-1)/2$ over $\mathbb{Q}$. Since $\langle c\rangle$ has order 2, Artin gives $[\mathbb{Q}(\zeta_p) : \mathrm{Fix}(\langle c\rangle)] = 2$, so $[\mathrm{Fix}(\langle c\rangle) : \mathbb{Q}] = (p-1)/2 = [\mathbb{Q}(\eta) : \mathbb{Q}]$, forcing $\mathrm{Fix}(\langle c\rangle) = \mathbb{Q}(\eta) = \mathbb{Q}(\zeta_p) \cap \mathbb{R}$. Sanity check: $\langle c\rangle$ is normal (the group is abelian), so $\mathbb{Q}(\eta)$ is Galois over $\mathbb{Q}$ of degree $(p-1)/2$ with group $\mathrm{Gal}/\langle c\rangle \cong \mathbb{Z}/((p-1)/2)\mathbb{Z}$, cyclic – the maximal totally real subfield, as expected.

Worked Example 14.2.24 (Galois over an intermediate field that is not Galois over the base)**.** In $K = \mathbb{Q}(\theta, i)$ with $\theta = 2^{1/4}$, show $K/\mathbb{Q}(\theta)$ is Galois even though $\mathbb{Q}(\theta)/\mathbb{Q}$ is not.

Recognition. "Galois" is relative: K/E is always Galois for any intermediate E (it is the splitting field of the same separable polynomial over E), but E/F is Galois only when $\mathrm{Gal}(K/E) \trianglelefteq \mathrm{Gal}(K/F)$.

Solution. Over $E = \mathbb{Q}(\theta)$, the polynomial $x^4 - 2 = (x-\theta)(x+\theta)(x^2+\theta^2)$ has $K = E(i)$ as splitting field, separable, so K/E is Galois with $\mathrm{Gal}(K/E) = \langle\tau\rangle$ of order 2. But $\langle\tau\rangle$ is not normal in D_8, so $E/\mathbb{Q}$ is not Galois – consistent with $\mathbb{Q}(\theta)$ containing only the two real roots $\pm\theta$ of x^4-2. Sanity check: $[K : E] = 2 = |\langle\tau\rangle|$ confirms K/E Galois by (3); and the failure of normality of $\langle\tau\rangle$ in G is exactly the obstruction (3) of the Fundamental Theorem to $E/\mathbb{Q}$ being Galois.

Remark 14.2.1. The relativity in the last example is the most common source of confusion. Being Galois is a property of a *pair* of fields, never of a single field. In a tower $F \subseteq E \subseteq K$ with K/F Galois, K/E is automatically Galois, but E/F is Galois precisely when the corresponding subgroup is normal. The Fundamental Theorem is what converts the field-theoretic question (is E/F normal?) into a finite group-theoretic one (is $\mathrm{Gal}(K/E) \trianglelefteq \mathrm{Gal}(K/F)$?).

Exercises (from the text).

1. Determine the minimal polynomial over $\mathbb{Q}$ for the element $\sqrt{2} + \sqrt{5}$.
2. Determine the minimal polynomial over $\mathbb{Q}$ for the element $1 + \sqrt[3]{2} + \sqrt[3]{4}$.
3. Determine the Galois group of $(x^2-2)(x^2-3)(x^2-5)$. Determine *all* the subfields of the splitting field of this polynomial.
4. Let p be a prime. Determine the elements of the Galois group of $x^p - 2$.
5. Prove that the Galois group of $x^p - 2$ for p a prime is isomorphic to the group of matrices $\begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix}$ where $a, b \in \mathbb{F}_p$, $a \neq 0$.
6. Let $K = \mathbb{Q}(\sqrt[8]{2}, i)$ and let $F_1 = \mathbb{Q}(i)$, $F_2 = \mathbb{Q}(\sqrt{2})$, $F_3 = \mathbb{Q}(\sqrt{-2})$. Prove that $\mathrm{Gal}(K/F_1) \cong Z_8$, $\mathrm{Gal}(K/F_2) \cong D_8$, $\mathrm{Gal}(K/F_3) \cong Q_8$.
7. Determine all the subfields of the splitting field of $x^8 - 2$ which are Galois over $\mathbb{Q}$.
8. Suppose K is a Galois extension of F of degree p^n for some prime p and some $n \geq 1$. Show there are Galois extensions of F contained in K of degrees p and p^{n-1}.
9. Give an example of fields F_1, F_2, F_3 with $\mathbb{Q} \subseteq F_1 \subseteq F_2 \subseteq F_3$, $[F_3 : \mathbb{Q}] = 8$ and each field is Galois over all its subfields with the exception that F_2 is not Galois over $\mathbb{Q}$.
10. Determine the Galois group of the splitting field over $\mathbb{Q}$ of $x^8 - 3$.
11. Suppose $f(x) \in \mathbb{Z}[x]$ is an irreducible quartic whose splitting field has Galois group S_4 over $\mathbb{Q}$ (there are many such quartics, cf. Section 6). Let θ be a root of $f(x)$ and set $K = \mathbb{Q}(\theta)$. Prove that K is an extension of $\mathbb{Q}$ of degree 4 which has no proper subfields. Are there any Galois extensions of $\mathbb{Q}$ of degree 4 with no proper subfields?
12. Determine the Galois group of the splitting field over $\mathbb{Q}$ of $x^4 - 14x^2 + 9$.
13. Prove that if the Galois group of the splitting field of a cubic over $\mathbb{Q}$ is the cyclic group of order 3 then all the roots of the cubic are real.
14. Prove that $\mathbb{Q}(\sqrt{2+\sqrt{2}})$ is a cyclic quartic field, i.e., is a Galois extension of degree 4 with cyclic Galois group.

15. (*Biquadratic Extensions*) Let F be a field of characteristic $\neq 2$.

    (a) If $K = F(\sqrt{D_1}, \sqrt{D_2})$ where $D_1, D_2 \in F$ have the property that none of D_1, D_2 or D_1D_2 is a square in F, prove that K/F is a Galois extension with $\mathrm{Gal}(K/F)$ isomorphic to the Klein 4-group.

    (b) Conversely, suppose K/F is a Galois extension with $\mathrm{Gal}(K/F)$ isomorphic to the Klein 4-group. Prove that $K = F(\sqrt{D_1}, \sqrt{D_2})$ where $D_1, D_2 \in F$ have the property that none of D_1, D_2 or D_1D_2 is a square in F.

16.

    (a) Prove that $x^4 - 2x^2 - 2$ is irreducible over $\mathbb{Q}$.

    (b) Show the roots of this quartic are

$$\alpha_1 = \sqrt{1+\sqrt{3}} \quad \alpha_3 = -\sqrt{1+\sqrt{3}}$$
$$\alpha_2 = \sqrt{1-\sqrt{3}} \quad \alpha_4 = -\sqrt{1-\sqrt{3}}.$$

    (c) Let $K_1 = \mathbb{Q}(\alpha_1)$ and $K_2 = \mathbb{Q}(\alpha_2)$. Show that $K_1 \neq K_2$, and $K_1 \cap K_2 = \mathbb{Q}(\sqrt{3}) = F$.

    (d) Prove that K_1, K_2 and K_1K_2 are Galois over F with $\mathrm{Gal}(K_1K_2/F)$ the Klein 4-group. Determine all the subgroups of the Galois group and give their corresponding fixed subfields of K_1K_2 containing F.

    (e) Prove that the splitting field of $x^4 - 2x^2 - 2$ over $\mathbb{Q}$ is of degree 8 with dihedral Galois group.

17. Let K/F be any finite separable extension and let $\alpha \in K$. Let L be a Galois extension of F containing K and let $H \leq \mathrm{Gal}(L/F)$ be the subgroup corresponding to K. Define the *norm* of α from K to F to be

$$N_{K/F}(\alpha) = \prod_{\sigma} \sigma(\alpha),$$

    where the product is taken over all the embeddings of K into an algebraic closure of F (so over a set of coset representatives for H in $\mathrm{Gal}(L/F)$ by the Fundamental Theorem of Galois Theory). This is a product of Galois conjugates of α. In particular, if K/F is Galois this is $\prod_{\sigma \in \mathrm{Gal}(K/F)} \sigma(\alpha)$.

    (a) Prove that $N_{K/F}(\alpha) \in F$.

    (b) Prove that $N_{K/F}(\alpha\beta) = N_{K/F}(\alpha)N_{K/F}(\beta)$, so that the norm is a multiplicative map from K to F.

    (c) Let $K = F(\sqrt{D})$ be a quadratic extension of F. Show that $N_{K/F}(a + b\sqrt{D}) = a^2 - Db^2$.

    (d) Let $m_\alpha(x) = x^d + a_{d-1}x^{d-1} + \cdots + a_1x + a_0 \in F[x]$ be the minimal polynomial for $\alpha \in K$ over F. Let $n = [K : F]$. Prove that d divides n, that there are d distinct Galois conjugates of α which are all repeated n/d times in the product above and conclude that $N_{K/F}(\alpha) = (-1)^n a_0^{n/d}$.

18. With notation as in the previous problem, define the *trace* of α from K to F to be

$$\mathrm{Tr}_{K/F}(\alpha) = \sum_{\sigma} \sigma(\alpha),$$

    a sum of Galois conjugates of α.

    (a) Prove that $\mathrm{Tr}_{K/F}(\alpha) \in F$.

    (b) Prove that $\mathrm{Tr}_{K/F}(\alpha + \beta) = \mathrm{Tr}_{K/F}(\alpha) + \mathrm{Tr}_{K/F}(\beta)$, so that the trace is an additive map from K to F.

    (c) Let $K = F(\sqrt{D})$ be a quadratic extension of F. Show that $\mathrm{Tr}_{K/F}(a + b\sqrt{D}) = 2a$.

    (d) Let $m_\alpha(x)$ be as in the previous problem. Prove that $\mathrm{Tr}_{K/F}(\alpha) = -\frac{n}{d}a_{d-1}$.

19. With notation as in the previous problems show that $N_{K/F}(a\alpha) = a^n N_{K/F}(\alpha)$ and $\mathrm{Tr}_{K/F}(a\alpha) = a\,\mathrm{Tr}_{K/F}(\alpha)$ for all a in the base field F. In particular show that $N_{K/F}(a) = a^n$ and $\mathrm{Tr}_{K/F}(a) = na$ for all $a \in F$.

20. With notation as in the previous problems show more generally that $\prod_\sigma (x - \sigma(\alpha)) = (m_\alpha(x))^{n/d}$.

21. Use the linear independence of characters to show that for any Galois extension K of F there is an element $\alpha \in K$ with $\mathrm{Tr}_{K/F}(\alpha) \neq 0$.

22. Suppose K/F is a Galois extension and let σ be an element of the Galois group.

    (a) Suppose $\alpha \in K$ is of the form $\alpha = \dfrac{\beta}{\sigma\beta}$ for some nonzero $\beta \in K$. Prove that $N_{K/F}(\alpha) = 1$.

    (b) Suppose $\alpha \in K$ is of the form $\alpha = \beta - \sigma\beta$ for some $\beta \in K$. Prove that $\mathrm{Tr}_{K/F}(\alpha) = 0$.

23. (*Hilbert's Theorem 90*) Let K be a Galois extension of F with cyclic Galois group of order n generated by σ. Suppose $\alpha \in K$ has $N_{K/F}(\alpha) = 1$. Prove that α is of the form $\alpha = \dfrac{\beta}{\sigma\beta}$ for some nonzero $\beta \in K$. [By the linear independence of characters show there exists some $\theta \in K$ such that

$$\beta = \theta + \alpha\sigma(\theta) + (\alpha\,\sigma\alpha)\sigma^2(\theta) + \cdots + (\alpha\,\sigma\alpha\cdots\sigma^{n-2}\alpha)\sigma^{n-1}(\theta)$$

    is nonzero. Compute $\dfrac{\beta}{\sigma\beta}$ using the fact that α has norm 1 to F.]

24. Prove that the rational solutions $a, b \in \mathbb{Q}$ of Pythagoras' equation $a^2 + b^2 = 1$ are of the form $a = \dfrac{s^2 - t^2}{s^2 + t^2}$ and $b = \dfrac{2st}{s^2 + t^2}$ for some $s, t \in \mathbb{Q}$ and hence show that any right triangle with integer sides has sides of lengths $((m^2 - n^2)d, 2mnd, (m^2 + n^2)d)$ for some integers m, n, d. [Note that $a^2 + b^2 = 1$ is equivalent to $N_{\mathbb{Q}(i)/\mathbb{Q}}(a + ib) = 1$, then use Hilbert's Theorem 90 above with $\beta = s + it$.]

25. Generalize the previous problem to determine all the rational solutions of the equation $a^2 + Db^2 = 1$ for $D \in \mathbb{Z}$, $D > 0$, D not a perfect square in $\mathbb{Z}$.

26. (*Additive Hilbert's Theorem 90*) Let K be a Galois extension of F with cyclic Galois group of order n generated by σ. Suppose $\alpha \in K$ has $\mathrm{Tr}_{K/F}(\alpha) = 0$. Prove that α is of the form $\alpha = \beta - \sigma\beta$ for some $\beta \in K$. [Let $\theta \in K$ be an element with $\mathrm{Tr}_{K/F}(\theta) \neq 0$ by a previous exercise, let

$$\beta = \frac{1}{\mathrm{Tr}_{K/F}(\theta)}[\alpha\sigma(\theta) + (\alpha + \sigma\alpha)\sigma^2(\theta) + \cdots + (\alpha + \sigma\alpha + \cdots + \sigma^{n-2}\alpha)\sigma^{n-1}(\theta)]$$

    and compute $\beta - \sigma\beta$.]

27. Let $\alpha = \sqrt{(2 + \sqrt{2})(3 + \sqrt{3})}$ (positive real square roots) and consider the extension $E = \mathbb{Q}(\alpha)$.

    (a) Show that $a = (2 + \sqrt{2})(3 + \sqrt{3})$ is not a square in $F = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. [If $a = c^2$, $c \in F$, then also $a\varphi(a) = (2 + \sqrt{2})^2 \cdot 6 = (c\varphi c)^2$ for the automorphism $\varphi \in \mathrm{Gal}(F/\mathbb{Q})$ fixing $\mathbb{Q}(\sqrt{2})$. Since $c\varphi c = N_{F/\mathbb{Q}(\sqrt{2})}(c) \in \mathbb{Q}(\sqrt{2})$ conclude that this implies $\sqrt{6} \in \mathbb{Q}(\sqrt{2})$, a contradiction.]

    (b) Conclude from (a) that $[E : \mathbb{Q}] = 8$. Prove that the roots of the minimal polynomial over $\mathbb{Q}$ for α are the 8 elements $\pm\sqrt{(2 \pm \sqrt{2})(3 \pm \sqrt{3})}$.

    (c) Let $\beta = \sqrt{(2 - \sqrt{2})(3 + \sqrt{3})}$. Show that $\alpha\beta = \sqrt{2}(3 + \sqrt{3}) \in F$ so that $\beta \in E$. Show similarly that the other roots are also elements of E so that E is a Galois extension of $\mathbb{Q}$. Show that the elements of the Galois group are precisely the maps determined by mapping α to one of the eight elements in (b).

    (d) Let $\sigma \in \mathrm{Gal}(E/\mathbb{Q})$ be the automorphism which maps α to β. Show that since $\sigma(\alpha^2) = \beta^2$ that $\sigma(\sqrt{2}) = -\sqrt{2}$ and $\sigma(\sqrt{3}) = \sqrt{3}$. From $\alpha\beta = \sqrt{2}(3 + \sqrt{3})$ conclude that $\sigma(\alpha\beta) = -\alpha\beta$ and hence $\sigma(\beta) = -\alpha$. Show that σ is an element of order 4 in $\mathrm{Gal}(E/\mathbb{Q})$.

    (e) Show similarly that the map τ defined by $\tau(\alpha) = \sqrt{(2 + \sqrt{2})(3 - \sqrt{3})}$ is an element of order 4 in $\mathrm{Gal}(E/\mathbb{Q})$. Prove that σ and τ generate the Galois group, $\sigma^4 = \tau^4 = 1$, $\sigma^2 = \tau^2$ and that $\sigma\tau = \tau\sigma^3$.

(f) Conclude that $\mathrm{Gal}(E/\mathbb{Q}) \cong Q_8$, the quaternion group of order 8.

28. Let $f(x) \in F[x]$ be an irreducible polynomial of degree n over the field F, let L be the splitting field of $f(x)$ over F and let α be a root of $f(x)$ in L. If K is any Galois extension of F contained in L, show that the polynomial $f(x)$ splits into a product of m irreducible polynomials each of degree d over K, where $m = [F(\alpha) \cap K : F]$ and $d = [K(\alpha) : K]$ (cf. also the generalization in Exercise 4 of Section 4). [If H is the subgroup of the Galois group of L over F corresponding to K then the irreducible factors of $f(x)$ over K correspond to the orbits of H on the roots of $f(x)$. Use then Exercise 9 of Section 4.1.]

29. Let k be a field and let $k(t)$ be the field of rational functions in the variable t. Define the maps σ and τ of $k(t)$ to itself by $\sigma f(t) = f\left(\dfrac{1}{1-t}\right)$ and $\tau f(t) = f\left(\dfrac{1}{t}\right)$ for $f(t) \in k(t)$.

    (a) Prove that σ and τ are automorphisms of $k(t)$ (cf. Exercise 8 of Section 1) and that the group $G = \langle \sigma, \tau \rangle$ generated by them is isomorphic to S_3.

    (b) Prove that the element $I = \dfrac{(t^2 - t + 1)^3}{t^2(t-1)^2}$ is fixed by all the elements of G.

    (c) Prove that $k(I)$ is precisely the fixed field of G in $k(t)$ [compute the degree of the extension].

30. Prove that the fixed field of the subgroup of automorphisms generated by τ in the previous problem is $k(t + \dfrac{1}{t})$. Prove that the fixed field of the subgroup generated by the automorphism $\tau\sigma^2$ (which maps t to $1 - t$) is $k(t(1-t))$. Determine the fixed field of the subgroup generated by $\tau\sigma$ and the fixed field of the subgroup generated by σ.

31. Let K be a finite extension of F of degree n. Let α be an element of K.

    (a) Prove that α acting by left multiplication on K is an F-linear transformation T_α of K.

    (b) Prove that the minimal polynomial for α over F is the same as the minimal polynomial for the linear transformation T_α.

    (c) Prove that the trace $\mathrm{Tr}_{K/F}(\alpha)$ is the trace of the $n \times n$ matrix defined by T_α (which justifies these two uses of the same word "trace"). Prove that the norm $N_{K/F}(\alpha)$ is the determinant of T_α.

Practice problems.

1. Let $K = \mathbb{Q}(\sqrt{2}, \sqrt{7})$. Verify that $K/\mathbb{Q}$ is Galois with $G = \mathrm{Gal}(K/\mathbb{Q}) \cong V_4$, list the four automorphisms by their action on $\sqrt{2}, \sqrt{7}$, and identify all three intermediate fields $\mathbb{Q} < E < K$ together with the subgroup $H \leq G$ for which $E = \mathrm{Fix}(H)$.

2. Let $K = \mathbb{Q}(\zeta_5)$ with $\zeta_5 = e^{2\pi i/5}$. Show $\mathrm{Gal}(K/\mathbb{Q}) \cong (\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}/4\mathbb{Z}$, exhibit a generator σ as $\zeta_5 \mapsto \zeta_5^a$ for a suitable a, and use it to determine the unique quadratic subfield of K as $\mathrm{Fix}(\langle \sigma^2 \rangle)$, giving it in the form $\mathbb{Q}(\sqrt{d})$.

3. Let $G = \mathrm{Gal}(K/F)$ be cyclic of order 12. Using only the Fundamental Theorem, draw (or list) the complete lattice of intermediate fields of K/F, label each field by its degree over F and by the order of the subgroup it corresponds to, and state which intermediate fields are Galois over F.

4. Let K/F be a finite Galois extension and let E_1, E_2 be intermediate fields corresponding to subgroups $H_1, H_2 \leq \mathrm{Gal}(K/F)$. Prove that $\mathrm{Fix}(H_1 \cap H_2) = E_1E_2$ (the compositum) and $\mathrm{Fix}(\langle H_1, H_2 \rangle) = E_1 \cap E_2$, then specialize to $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ with $E_1 = \mathbb{Q}(\sqrt{2})$, $E_2 = \mathbb{Q}(\sqrt{3})$ to recover $E_1E_2 = K$ and $E_1 \cap E_2 = \mathbb{Q}$.

5. Let $K = \mathbb{Q}(\zeta_7 + \zeta_7^{-1}) = \mathbb{Q}(\cos \frac{2\pi}{7})$. Show K is the maximal real subfield of $\mathbb{Q}(\zeta_7)$, prove $[K : \mathbb{Q}] = 3$, decide whether $K/\mathbb{Q}$ is Galois, and if so name $\mathrm{Gal}(K/\mathbb{Q})$.

6. Let K/F be Galois with $\mathrm{Gal}(K/F) \cong S_3$. Determine the number of intermediate fields of each degree over F, state which of them are Galois over F, and explain using conjugacy of the order-2 subgroups why the three degree-3 subfields are pairwise F-isomorphic but distinct.

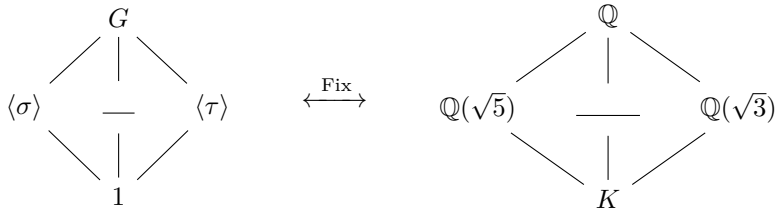
7. Let $K = \mathbb{F}_2[x]/(x^3+x+1)$, a field with 8 elements, viewed as an extension of $F = \mathbb{F}_2$. Show K/F is Galois, that $\mathrm{Gal}(K/F)$ is generated by the Frobenius $\mathrm{Frob}\colon \alpha \mapsto \alpha^2$, identify $\mathrm{Gal}(K/F)$ up to isomorphism, and explain why K/F has no proper intermediate fields.

8. Let $K = \mathbb{Q}(\sqrt{2})$ and consider the norm and trace from K to $\mathbb{Q}$ defined via $\mathrm{Gal}(K/\mathbb{Q}) = \{\,\mathrm{id}, \sigma\,\}$ with $\sigma(\sqrt{2}) = -\sqrt{2}$. Compute $\mathrm{N}_{K/\mathbb{Q}}(a+b\sqrt{2})$ and $\mathrm{Tr}_{K/\mathbb{Q}}(a+b\sqrt{2})$ for $a, b \in \mathbb{Q}$, and verify directly that both land in $\mathbb{Q}$ and that the norm is multiplicative on the two elements $1+\sqrt{2}$ and $3-\sqrt{2}$.

Additional exercises.

1. Let K be the splitting field of $x^3 - 5$ over $\mathbb{Q}$, so $K = \mathbb{Q}(\sqrt[3]{5}, \zeta_3)$. Prove $[K:\mathbb{Q}] = 6$ and $\mathrm{Gal}(K/\mathbb{Q}) \cong S_3$, then use the Fundamental Theorem to list every intermediate field, give each as an explicit generated subfield, and determine precisely which are Galois over $\mathbb{Q}$.

2. Let K/F be a finite Galois extension with $G = \mathrm{Gal}(K/F)$, and let $E = \mathrm{Fix}(H)$ for $H \le G$. Prove that the number of distinct fields of the form $\sigma(E)$, $\sigma \in G$, equals the index $[G : N_G(H)]$ of the normalizer of H, and that E/F is Galois exactly when this number is 1. Illustrate with the four non-Galois quartic fields $\mathbb{Q}(2^{1/4}), \mathbb{Q}(i\,2^{1/4}), \mathbb{Q}((1+i)2^{1/4}), \mathbb{Q}((1-i)2^{1/4})$ inside $\mathbb{Q}(2^{1/4}, i)$, which fall into two conjugacy classes of two fields each (here $[G : N_G(H)] = 2$).



3. Let K/F be Galois with $G = \mathrm{Gal}(K/F)$ abelian. Prove that every intermediate field E is Galois over F and that $\mathrm{Gal}(E/F) \cong G/\mathrm{Gal}(K/E)$ is again abelian. Conversely, give a Galois extension K/F in which some intermediate field E has E/F *not* Galois, and pinpoint the non-normal subgroup responsible.

4. Let K/F be a finite Galois extension of degree p^2 for a prime p, with $G = \mathrm{Gal}(K/F)$ abelian. Show that the number of intermediate fields E with $[E:F] = p$ is either 1 (when $G \cong \mathbb{Z}/p^2\mathbb{Z}$) or $p+1$ (when $G \cong \mathbb{Z}/p\mathbb{Z} \times \mathbb{Z}/p\mathbb{Z}$), and that all such E are Galois over F. Deduce that $\mathbb{Q}(\zeta_{p^2})$ for an odd prime p has a unique subfield of degree p over $\mathbb{Q}$.

5. Let $K = \mathbb{Q}(\sqrt[4]{3}, i)$, the splitting field of $x^4 - 3$ over $\mathbb{Q}$. Prove $\mathrm{Gal}(K/\mathbb{Q}) \cong D_8$, and partition the ten subgroups of D_8 into normal and non-normal; for each normal subgroup name the corresponding intermediate field as a Galois extension of $\mathbb{Q}$ and give its Galois group, and for each non-normal subgroup exhibit the (non-Galois) fixed field and a conjugate of it.

Commutative-diagram exercises.

1. For $K = \mathbb{Q}(\sqrt{3}, \sqrt{5})$ with $G = \mathrm{Gal}(K/\mathbb{Q}) \cong V_4$, complete both lattices below so that the right-hand diagram is the Fix-image of the left-hand one, filling each blank with the correct subgroup on the left and the correct subfield $\mathbb{Q}(\sqrt{d})$ on the right. Prove the correspondence is inclusion-reversing and that all three intermediate fields are Galois over $\mathbb{Q}$.

   Here $\sigma\colon \sqrt{3} \mapsto -\sqrt{3}, \sqrt{5} \mapsto \sqrt{5}$ and $\tau\colon \sqrt{3} \mapsto \sqrt{3}, \sqrt{5} \mapsto -\sqrt{5}$.

2. Let K/F be Galois with $G = \mathrm{Gal}(K/F)$ and let $H \trianglelefteq G$, so that $E = \mathrm{Fix}(H)$ is Galois over F. Show that restriction to E gives a surjective homomorphism with kernel H, and that the square

$$\begin{array}{ccc} G & \xrightarrow{\ \mathrm{res}\ } & \mathrm{Gal}(E/F) \\ \| & & \downarrow \cong \\ G & \xrightarrow[\ \pi\ ]{} & G/H \end{array}$$

   commutes, where π is the canonical projection. Identify the right-hand vertical isomorphism explicitly and explain why res fails to be defined as an automorphism of E when H is not normal.

3. Draw the full subgroup lattice of S_3 and, beside it, the corresponding intermediate-field lattice for a Galois extension K/F with $\mathrm{Gal}(K/F) \cong S_3$, joined by the order-reversing Fix as in

filling in all three order-2 subgroups and the corresponding three degree-3 subfields. Prove that $\langle(1\,2\,3)\rangle$ is the unique normal proper nontrivial subgroup, hence $E_2 = \mathrm{Fix}(\langle(1\,2\,3)\rangle)$ is the unique intermediate field E with $F \subsetneq E \subsetneq K$ that is Galois over F, with $\mathrm{Gal}(E_2/F) \cong \mathbb{Z}/2\mathbb{Z}$.

4. Let $F \subseteq E \subseteq K$ be a tower with K/F Galois, $H = \mathrm{Gal}(K/E) \leq G = \mathrm{Gal}(K/F)$. Complete the diagram of inclusions and Galois groups

by labeling $[K : E] = |H|$ and $[E : F] = [G : H]$, and prove the tower law $|G| = |H| \cdot [G : H]$ corresponds exactly to $[K : F] = [K : E]\,[E : F]$. Then show by a Lagrange-style argument that there is an intermediate field of every degree dividing $[K : F]$ if and only if G has a subgroup of the corresponding order.

14.3 Finite Fields

Existence and uniqueness: $\mathbb{F}_{p^n}$ as a splitting field

Fix a prime p. The field $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z}$ is the prime field of every field of characteristic p. We study its finite extensions. The starting observation is that a finite field cannot have an arbitrary number of elements: if F is finite of characteristic p, then F is a vector space over its prime field $\mathbb{F}_p$, say of dimension $n = [F : \mathbb{F}_p]$, so $|F| = p^n$. Thus the cardinality of a finite field is always a prime power.

The next theorem pins down such a field completely. The key is that every nonzero element of a field F with $|F| = p^n$ satisfies $\alpha^{p^n-1} = 1$ (Lagrange in the group $F^\times$ of order $p^n - 1$), so every element of F – including 0 – is a root of $x^{p^n} - x$. Since this polynomial has degree p^n and F supplies p^n distinct roots, F *is* exactly the set of roots of $x^{p^n} - x$.

Theorem 14.3.1 (existence and uniqueness of $\mathbb{F}_{p^n}$)**.** *Let p be a prime and $n \geq 1$. Then:*

(1) *There exists a field with exactly p^n elements, namely the splitting field of $f(x) = x^{p^n} - x$ over $\mathbb{F}_p$.*

(2) *Any two fields of order p^n are isomorphic. We write $\mathbb{F}_{p^n}$ for the field with p^n elements; it is the set of roots of $x^{p^n} - x$ in a fixed algebraic closure $\overline{\mathbb{F}_p}$.*

Idea. Let K be the splitting field of $f(x) = x^{p^n} - x$ over $\mathbb{F}_p$. Its formal derivative is $f'(x) = p^n x^{p^n-1} - 1 = -1$ (since $p = 0$ in K), which is a nonzero constant, hence $\gcd(f, f') = 1$ and f is *separable*: it has p^n distinct roots. The set E of roots is closed under addition, subtraction, multiplication, and inversion – this is exactly the Freshman's-dream identity $(\alpha \pm \beta)^{p^n} = \alpha^{p^n} \pm \beta^{p^n}$ together with $(\alpha\beta)^{p^n} = \alpha^{p^n}\beta^{p^n}$ – so E is a subfield of K with $|E| = p^n$. Since E already contains all roots of f, $K = E$ and $|K| = p^n$. Uniqueness: any field of order p^n is a splitting field of the same separable polynomial $x^{p^n} - x$ over $\mathbb{F}_p$, and splitting fields are unique up to isomorphism. □

Remark 14.3.1. The map $x \mapsto x^p$ is a ring homomorphism in characteristic p because of the Freshman's dream $(a + b)^p = a^p + b^p$ (all middle binomial coefficients $\binom{p}{k}$ with $0 < k < p$ are divisible by p). Iterating it n times gives $x \mapsto x^{p^n}$, the operator whose fixed points cut out $\mathbb{F}_{p^n}$ inside $\overline{\mathbb{F}_p}$. This single map is the protagonist of the whole section.

Worked Example 14.3.2 (Constructing $\mathbb{F}_4$ explicitly)**.** Build $\mathbb{F}_4$ as $\mathbb{F}_2[x]/(x^2+x+1)$ and verify every element is a root of $x^4 - x$.

Recognition. By the theorem $\mathbb{F}_4$ is the splitting field of $x^4 - x$ over $\mathbb{F}_2$; concretely we realize it by adjoining a root of an irreducible quadratic over $\mathbb{F}_2$.

Solution. Over $\mathbb{F}_2$ the polynomial x^2+x+1 has no root ($0, 1$ both give 1), so it is irreducible and $K = \mathbb{F}_2[x]/(x^2+x+1)$ is a field with $2^2 = 4$ elements. Writing α for the image of x, so $\alpha^2 = \alpha+1$, the elements are $\{0, 1, \alpha, \alpha+1\}$. Check the defining identity $x^4 - x = x(x-1)(x^2+x+1)$ over $\mathbb{F}_2$: its roots are $0, 1$ and the two roots $\alpha, \alpha+1$ of x^2+x+1. Sanity check on α: $\alpha^2 = \alpha+1$, so $\alpha^4 = (\alpha^2)^2 = (\alpha+1)^2 = \alpha^2+1 = (\alpha+1)+1 = \alpha$, i.e. $\alpha^4 = \alpha$. Good – every one of the four elements satisfies $x^4 = x$.

Worked Example 14.3.3 (Constructing $\mathbb{F}_8$ and $\mathbb{F}_9$)**.** Exhibit $\mathbb{F}_8$ and $\mathbb{F}_9$ by an explicit irreducible polynomial, and state the degree of the extension over the prime field.

Recognition. $\mathbb{F}_{p^n} = \mathbb{F}_p(\alpha)$ for α a root of any irreducible polynomial of degree n over $\mathbb{F}_p$; such a polynomial exists because $\mathbb{F}_{p^n}/\mathbb{F}_p$ is simple (its multiplicative group is cyclic, see below).

Solution. For $\mathbb{F}_8 = \mathbb{F}_{2^3}$: $x^3 + x + 1$ is irreducible over $\mathbb{F}_2$ (degree 3, no root in $\mathbb{F}_2$ since $0, 1$ give 1), so $\mathbb{F}_8 = \mathbb{F}_2[x]/(x^3+x+1)$ with $[\mathbb{F}_8 : \mathbb{F}_2] = 3$. For $\mathbb{F}_9 = \mathbb{F}_{3^2}$: $x^2 + 1$ is irreducible over $\mathbb{F}_3$ (-1 is not a square mod 3, as squares are $0, 1$), so $\mathbb{F}_9 = \mathbb{F}_3[x]/(x^2+1) = \mathbb{F}_3(i)$ with $i^2 = -1$ and $[\mathbb{F}_9 : \mathbb{F}_3] = 2$. Sanity check: $|\mathbb{F}_8| = 2^3 = 8$ and $|\mathbb{F}_9| = 3^2 = 9$, and in $\mathbb{F}_9$, $i^8 = (i^2)^4 = (-1)^4 = 1$, consistent with $\mathbb{F}_9^\times$ having order 8.

Worked Example 14.3.4 (Why there is no field with 6 elements)**.** Show that no field has exactly 6 elements.

Recognition. A finite field has prime-power order p^n; $6 = 2 \cdot 3$ is not a prime power.

Solution. If $|F| = 6$ then $\operatorname{char} F = p$ for some prime p and $|F| = p^n$. But 6 has two distinct prime factors, so $6 \neq p^n$ for any prime p and $n \geq 1$. Hence no field of order 6 exists. Sanity check: the same argument rules out $10, 12, 14, 15, \ldots$; the admissible small orders are $2, 3, 4, 5, 7, 8, 9, 11, 13, 16, \ldots$, exactly the prime powers.

Worked Example 14.3.5 (The roots of $x^{p^n} - x$ form a field)**.** Verify directly that $E = \{\alpha \in \overline{\mathbb{F}_p} : \alpha^{p^n} = \alpha\}$ is closed under the field operations.

Recognition. Use that $\sigma(x) = x^{p^n}$ is a field homomorphism (iterated Frobenius), so its fixed set is a subfield.

Solution. If $\alpha^{p^n} = \alpha$ and $\beta^{p^n} = \beta$ then $(\alpha+\beta)^{p^n} = \alpha^{p^n} + \beta^{p^n} = \alpha + \beta$ and $(\alpha\beta)^{p^n} = \alpha^{p^n}\beta^{p^n} = \alpha\beta$, so E is closed under $+$ and $\times$. Also $0, 1 \in E$, and for $\alpha \neq 0$, $(\alpha^{-1})^{p^n} = (\alpha^{p^n})^{-1} = \alpha^{-1}$. Thus E is a subfield; since $x^{p^n} - x$ is separable it has p^n distinct roots, so $|E| = p^n$ and $E = \mathbb{F}_{p^n}$. Sanity check: the fixed set of a ring endomorphism is always a subring; here it is even a subfield because $\overline{\mathbb{F}_p}$ is a field and inverses are preserved.

The Frobenius and the Galois group

Definition 14.3.6. The *Frobenius endomorphism* of a field F of characteristic p is the map $\operatorname{Frob}_p : F \to F$, $\operatorname{Frob}_p(\alpha) = \alpha^p$. On a finite field it is an automorphism (an injective endomorphism of a finite set is bijective), and it fixes $\mathbb{F}_p$ pointwise since $a^p = a$ for all $a \in \mathbb{F}_p$ by Fermat's little theorem.

The extension $\mathbb{F}_{p^n}/\mathbb{F}_p$ is the splitting field of the *separable* polynomial $x^{p^n} - x$, hence it is Galois. The whole Galois group is generated by a single, completely explicit automorphism.

Theorem 14.3.7 ($\mathbb{F}_{p^n}/\mathbb{F}_p$ is cyclic Galois of order n)**.** *The extension $\mathbb{F}_{p^n}/\mathbb{F}_p$ is Galois of degree n, and*

$$\operatorname{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) = \langle \operatorname{Frob}_p \rangle \cong \mathbb{Z}/n\mathbb{Z}$$

is cyclic of order n, generated by the Frobenius $\sigma = \operatorname{Frob}_p : \alpha \mapsto \alpha^p$.

Idea. $\mathbb{F}_{p^n}/\mathbb{F}_p$ is a splitting field of a separable polynomial, so it is Galois with $|\operatorname{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)| = [\mathbb{F}_{p^n} : \mathbb{F}_p] = n$. The Frobenius $\sigma(\alpha) = \alpha^p$ is an $\mathbb{F}_p$-automorphism. Its order in the group is the least $k \geq 1$ with $\sigma^k = \mathrm{id}$, i.e. $\alpha^{p^k} = \alpha$ for *all* $\alpha \in \mathbb{F}_{p^n}$. That says every element of $\mathbb{F}_{p^n}$ is a root of $x^{p^k} - x$, which has only p^k roots; since $|\mathbb{F}_{p^n}| = p^n$ this forces $p^k \geq p^n$, i.e. $k \geq n$. And $k = n$ works because $\alpha^{p^n} = \alpha$ on $\mathbb{F}_{p^n}$. So $|\sigma| = n = |\operatorname{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)|$, and $\langle\sigma\rangle$ is the whole group. □

Remark 14.3.2. The fixed field of $\sigma = \mathrm{Frob}_p$ is $\mathrm{Fix}(\langle\sigma\rangle) = \{\,\alpha : \alpha^p = \alpha\,\} = \mathbb{F}_p$, consistent with the Fundamental Theorem: the full group fixes exactly the base field. More generally, for $d \mid n$, $\mathrm{Fix}(\langle\sigma^d\rangle) = \{\,\alpha : \alpha^{p^d} = \alpha\,\} = \mathbb{F}_{p^d}$ (for arbitrary $d \geq 1$ it is $\mathbb{F}_{p^{\gcd(d,n)}}$), which is the engine of the subfield correspondence below.

Worked Example 14.3.8 (The Galois group of $\mathbb{F}_8/\mathbb{F}_2$ and a Frobenius orbit)**.** Compute $\mathrm{Gal}(\mathbb{F}_8/\mathbb{F}_2)$ and trace the orbit of a generator under Frobenius.

Recognition. By the theorem $\mathrm{Gal}(\mathbb{F}_8/\mathbb{F}_2) = \langle\mathrm{Frob}_2\rangle \cong \mathbb{Z}/3\mathbb{Z}$, order 3; the conjugates (Galois orbit) of a root are obtained by repeatedly applying $\sigma : \alpha \mapsto \alpha^2$.

Solution. Realize $\mathbb{F}_8 = \mathbb{F}_2(\alpha)$ with $\alpha^3 + \alpha + 1 = 0$, so $\alpha^3 = \alpha + 1$. The group is $\{\,\mathrm{id}, \sigma, \sigma^2\,\}$ with $\sigma(\alpha) = \alpha^2$. The orbit of α is

$$\alpha \overset{\sigma}{\mapsto} \alpha^2 \overset{\sigma}{\mapsto} \alpha^4 = \alpha \cdot \alpha^3 = \alpha(\alpha+1) = \alpha^2 + \alpha \overset{\sigma}{\mapsto} \alpha^8 = \alpha.$$

So the three conjugates of α are $\alpha,\ \alpha^2,\ \alpha^2+\alpha$, and these are exactly the three roots of x^3+x+1. Sanity check: their product is $(-1)^3 \cdot (\text{constant term}) = 1$ and indeed $\alpha \cdot \alpha^2 = \alpha^3 = \alpha + 1$, times $(\alpha^2 + \alpha) = \alpha(\alpha+1)$ gives $(\alpha+1) \cdot \alpha(\alpha+1) = \alpha(\alpha+1)^2 = \alpha(\alpha^2+1) = \alpha^3 + \alpha = (\alpha+1) + \alpha = 1$, matching $-(\text{constant term}) = -1 = 1$ in $\mathbb{F}_2$. The sum of the conjugates is $\alpha + \alpha^2 + (\alpha^2 + \alpha) = 0$, matching the zero x^2-coefficient.

Worked Example 14.3.9 ($\mathrm{Gal}(\mathbb{F}_{16}/\mathbb{F}_2)$ as a cyclic group of order 4)**.** Determine $\mathrm{Gal}(\mathbb{F}_{16}/\mathbb{F}_2)$ and list its elements as powers of Frobenius.

Recognition. $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) = \langle\mathrm{Frob}_p\rangle \cong \mathbb{Z}/n\mathbb{Z}$; here $n = 4$.

Solution. $\mathrm{Gal}(\mathbb{F}_{16}/\mathbb{F}_2) = \langle\sigma\rangle$ with $\sigma(\alpha) = \alpha^2$, cyclic of order 4: $\{\,\mathrm{id},\ \sigma : \alpha \mapsto \alpha^2,\ \sigma^2 : \alpha \mapsto \alpha^4,\ \sigma^3 : \alpha \mapsto \alpha^8\,\}$. The unique subgroup of order 2 is $\langle\sigma^2\rangle$, whose fixed field is $\mathbb{F}_4$. Sanity check: $\sigma^4(\alpha) = \alpha^{16} = \alpha$ for all $\alpha \in \mathbb{F}_{16}$, so $\sigma^4 = \mathrm{id}$ and no smaller power is the identity (e.g. $\sigma^2(\alpha) = \alpha^4 \neq \alpha$ for $\alpha \in \mathbb{F}_{16} \setminus \mathbb{F}_4$). The subgroup lattice $\{\,1\,\} \leq \langle\sigma^2\rangle \leq \langle\sigma\rangle$ has 3 subgroups, matching the 3 divisors of 4.

Worked Example 14.3.10 (Galois orbits partition $\mathbb{F}_9$ into conjugacy classes)**.** With $\mathbb{F}_9 = \mathbb{F}_3(i)$, $i^2 = -1$, list the Frobenius orbits and read off minimal polynomials over $\mathbb{F}_3$.

Recognition. $\mathrm{Gal}(\mathbb{F}_9/\mathbb{F}_3) = \langle\sigma\rangle$, $\sigma(\alpha) = \alpha^3$, order 2; elements with $\sigma(\alpha) = \alpha$ are exactly $\mathbb{F}_3$, and the remaining elements pair up into orbits of size 2.

Solution. The fixed points of σ are $\{\,0, 1, 2\,\} = \mathbb{F}_3$, each with linear minimal polynomial. The other six elements pair into orbits $\{\,\alpha, \alpha^3\,\}$: e.g. $i \mapsto i^3 = -i$, so $\{\,i, -i\,\}$ has minimal polynomial $x^2 + 1$; $1 + i \mapsto (1+i)^3 = 1 + 3i + 3i^2 + i^3 = 1 - i \pmod 3$ (using $3 \equiv 0$), so $\{\,1+i, 1-i\,\}$ has minimal polynomial $(x-1)^2 + 1 = x^2 - 2x + 2 = x^2 + x + 2$; and $\{\,2+i, 2-i\,\}$ has minimal polynomial $x^2 - 4x + 5 = x^2 + 2x + 2$ over $\mathbb{F}_3$. Sanity check: 3 linear factors plus 3 irreducible quadratics account for $3 + 3 \cdot 2 = 9$ roots, and indeed $x^9 - x = \prod(\text{these})$ over $\mathbb{F}_3$.

Worked Example 14.3.11 (Frobenius vs. a non-Galois-looking generator)**.** Show that on $\mathbb{F}_{p^n}$, $\sigma^k = \mathrm{Frob}_{p^k}$ (the map $\alpha \mapsto \alpha^{p^k}$), and that $\sigma^k = \mathrm{id}$ iff $n \mid k$.

Recognition. $\sigma = \mathrm{Frob}_p$ and composition of $\alpha \mapsto \alpha^p$ with itself k times gives $\alpha \mapsto \alpha^{p^k}$; σ has order n in the cyclic group, so $\sigma^k = \mathrm{id}$ iff $n \mid k$.

Solution. $\sigma^k(\alpha) = (\cdots((\alpha^p)^p)\cdots)^p = \alpha^{p^k}$ by induction. Then $\sigma^k = \mathrm{id}$ means $\alpha^{p^k} = \alpha$ for all $\alpha \in \mathbb{F}_{p^n}$, i.e. $\mathbb{F}_{p^n} \subseteq \{\,\alpha \in \overline{\mathbb{F}_p} : \alpha^{p^k} = \alpha\,\} = \mathbb{F}_{p^k}$. More directly, since $|\sigma| = n$, the order of σ^k is $n/\gcd(n,k)$ and $\sigma^k = \mathrm{id} \iff n \mid k$. Sanity check ($n = 6$): σ^2 has order $6/\gcd(6,2) = 3$, fixing $\mathbb{F}_{p^2}$; σ^3 has order 2, fixing $\mathbb{F}_{p^3}$; matching divisors $2, 3$ of 6.

The lattice of subfields

The Fundamental Theorem of Galois Theory turns the subfield problem into a subgroup problem, and the subgroups of a cyclic group are completely understood: a cyclic group of order n has exactly one subgroup of each order $d \mid n$. Translating through the correspondence gives the cleanest possible description of the subfields of a finite field.

Theorem 14.3.12 (subfields of $\mathbb{F}_{p^n}$)**.** *The subfields of $\mathbb{F}_{p^n}$ are exactly the fields $\mathbb{F}_{p^d}$ for $d \mid n$, one for each divisor d of n, and*

$$\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^m} \quad \Longleftrightarrow \quad d \mid m.$$

Concretely $\mathbb{F}_{p^d} = \mathrm{Fix}\big(\langle \sigma^d \rangle\big) = \{\, \alpha \in \mathbb{F}_{p^n} : \alpha^{p^d} = \alpha \,\}$, where $\sigma = \mathrm{Frob}_p$.

Idea. By the Fundamental Theorem, subfields of $\mathbb{F}_{p^n}$ containing $\mathbb{F}_p$ correspond bijectively (inclusion-reversing) to subgroups of the cyclic group $G = \langle \sigma \rangle$ of order n. The subgroups of G are $\langle \sigma^{n/d} \rangle$ of order d, one for each $d \mid n$; the subgroup of order n/d is $\langle \sigma^d \rangle$, whose fixed field has degree d over $\mathbb{F}_p$, i.e. is $\mathbb{F}_{p^d}$. Inclusion of fields reverses inclusion of groups, which on the divisor side becomes the divisibility relation $d \mid m$. □

The Galois correspondence here is an *order anti-isomorphism* between the lattice of subfields of $\mathbb{F}_{p^n}$ and the lattice of subgroups of $\mathbb{Z}/n\mathbb{Z}$, and – because subgroups of $\mathbb{Z}/n\mathbb{Z}$ match divisors of n – it is an order *isomorphism* between the subfield lattice and the divisor lattice of n. The following diagram records this for $n = 12$.

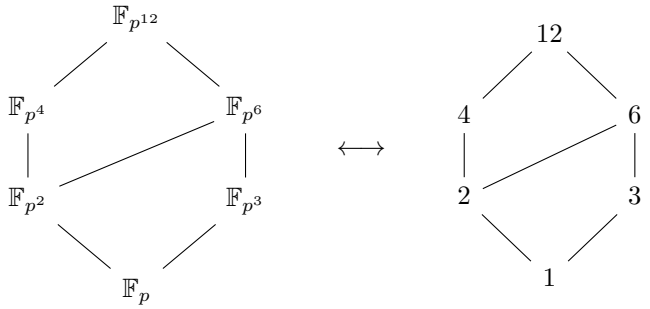


Diagram explanation. Objects: Left lattice: six fields $\mathbb{F}_p, \mathbb{F}_{p^2}, \mathbb{F}_{p^3}, \mathbb{F}_{p^4}, \mathbb{F}_{p^6}, \mathbb{F}_{p^{12}}$, each a finite extension of $\mathbb{F}_p$ inside a fixed algebraic closure $\overline{\mathbb{F}_p}$. Right lattice: the six positive divisors $1, 2, 3, 4, 6, 12$ of 12, viewed as a poset under divisibility. Both are drawn with larger objects higher up.

Arrows: The dashes (unlabelled edges) denote covering relations: an edge from $\mathbb{F}_{p^a}$ up to $\mathbb{F}_{p^b}$ (left) means $\mathbb{F}_{p^a} \subsetneq \mathbb{F}_{p^b}$ with no intermediate subfield, equivalently $a \mid b$ and b/a is prime. On the right the same covering relation is purely divisibility $a \mid b$, b/a prime. The double-headed arrow $\longleftrightarrow$ between the two lattices is the order-isomorphism $\mathbb{F}_{p^d} \leftrightarrow d$.

What commutes: There are no maps to compose here; the claim is an order-isomorphism: $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^m}$ if and only if $d \mid m$. The diagram makes that bijection visually explicit for every pair.

Why it commutes: By the subfield theorem, $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^m}$ iff $\mathbb{F}_{p^d}$ is a splitting field of $x^{p^d} - x$ whose roots all satisfy $x^{p^m} - x$ as well, which happens iff $d \mid m$. So the inclusion order on fields is *exactly* the divisibility order on exponents.

Why this matters here: This is the payoff of the Fundamental Theorem applied to the cyclic group $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) \cong \mathbb{Z}/n\mathbb{Z}$: the subgroup lattice of $\mathbb{Z}/n\mathbb{Z}$ is isomorphic to the divisor lattice of n (each divisor d gives the unique subgroup of order d), and the Galois correspondence turns that into the subfield lattice. The diagram makes the three-way identification concrete for $n = 12$.

Concrete example: For $p = 2, n = 4$: divisors $1, 2, 4$ give $\mathbb{F}_2 \subset \mathbb{F}_4 \subset \mathbb{F}_{16}$; no other subfields. Concretely $\mathbb{F}_4 = \mathbb{F}_2(\alpha)$, $\alpha^2 + \alpha + 1 = 0$, is a subfield of $\mathbb{F}_{16} = \mathbb{F}_2(\beta)$, $\beta^4 + \beta + 1 = 0$.

Common pitfall: Students sometimes read the lattice as indicating that $\mathbb{F}_{p^4}$ and $\mathbb{F}_{p^6}$ are comparable; they are not – there is no edge between them because $4 \nmid 6$ and $6 \nmid 4$. Incomparability in the divisor lattice is incomparability in the subfield lattice.

Takeaway: The point of this diagram is that the subfield lattice of $\mathbb{F}_{p^{12}}$ is an exact copy of the divisor lattice of 12, so all containment questions reduce to elementary number theory.

The order-isomorphism is the point: *containment of subfields is divisibility of exponents.*

Worked Example 14.3.13 (The subfield lattice of $\mathbb{F}_{p^{12}}$)**.** List all subfields of $\mathbb{F}_{p^{12}}$ and draw the inclusion lattice.

Recognition. Subfields $\leftrightarrow$ divisors $d \mid 12$; $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^m} \iff d \mid m$.

Solution. The divisors of 12 are $1, 2, 3, 4, 6, 12$, giving subfields $\mathbb{F}_p, \mathbb{F}_{p^2}, \mathbb{F}_{p^3}, \mathbb{F}_{p^4}, \mathbb{F}_{p^6}, \mathbb{F}_{p^{12}}$. The lattice (drawn with the divisor lattice alongside):

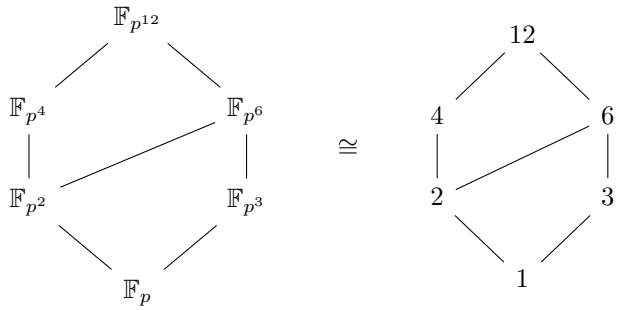

Diagram explanation. Objects: Left lattice: the six subfields of $\mathbb{F}_{p^{12}}$, namely $\mathbb{F}_{p^d}$ for $d \in \{1, 2, 3, 4, 6, 12\}$, arranged by inclusion with larger fields higher. Right lattice: the six divisors $1, 2, 3, 4, 6, 12$ arranged by divisibility. The $\cong$ symbol between them labels the order-isomorphism $\mathbb{F}_{p^d} \leftrightarrow d$.

Arrows: Each edge on the left is a field inclusion $\mathbb{F}_{p^a} \subsetneq \mathbb{F}_{p^b}$ at a covering step (b/a prime). On the right the same edge is the covering relation $a \mid b$ with b/a prime. The $\cong$ sign between the two sides is not a ring map – it is a poset isomorphism, asserting that the two Hasse diagrams are combinatorially identical.

What commutes: The defining equivalence: $\mathbb{F}_{p^a} \subseteq \mathbb{F}_{p^b} \iff a \mid b$, for all pairs of divisors a, b of 12. Every edge on the left corresponds to the same edge on the right under this rule.

Why it commutes: If $a \mid b$, say $b = ak$, then every $\alpha \in \mathbb{F}_{p^a}$ satisfies $\alpha^{p^b} = \alpha$ (apply $\alpha \mapsto \alpha^{p^a}$ k times), so $\mathbb{F}_{p^a} \subseteq \{\, \alpha : \alpha^{p^b} = \alpha \,\} = \mathbb{F}_{p^b}$. Conversely, if $\mathbb{F}_{p^a} \subseteq \mathbb{F}_{p^b}$, then $\mathbb{F}_{p^b}$ is a vector space over $\mathbb{F}_{p^a}$, so $p^b = (p^a)^k$ with $k = [\mathbb{F}_{p^b} : \mathbb{F}_{p^a}]$, i.e. $b = ak$ and $a \mid b$. (Comparing sizes alone is not enough: $p^2 < p^3$, yet $\mathbb{F}_{p^2} \not\subseteq \mathbb{F}_{p^3}$.) So divisibility is the exact algebraic condition for inclusion.

Why this matters here: This worked example makes the abstract theorem concrete for $n = 12$, a case with a genuinely non-chain subfield lattice (having both $\mathbb{F}_{p^4}$ and $\mathbb{F}_{p^6}$ as incomparable intermediate subfields; the smallest non-chain case is $n = 6$, where $\mathbb{F}_{p^2}$ and $\mathbb{F}_{p^3}$ are incomparable). Seeing the $\cong$ sign between the two diagrams is a sanity check: any inclusion question about subfields of $\mathbb{F}_{p^{12}}$ can be answered by pure arithmetic on divisors of 12.

Concrete example: $\mathbb{F}_{p^4} \not\subseteq \mathbb{F}_{p^6}$ because $4 \nmid 6$: confirmed by the absence of an edge from 4 to 6 on the right. Their compositum is $\mathbb{F}_{p^{12}}$ since $\operatorname{lcm}(4, 6) = 12$ (top node), and their intersection is $\mathbb{F}_{p^2}$ since $\gcd(4, 6) = 2$ (node 2).

Common pitfall: The $\cong$ label does not mean the fields are isomorphic to numbers; it means the two posets have the same shape. Students sometimes confuse a poset isomorphism with a field isomorphism.

Takeaway: The point of this diagram is that the inclusion structure of all subfields of $\mathbb{F}_{p^{12}}$ is completely determined by the single number 12, via divisibility.

Reading the cover relations: $\mathbb{F}_p \subset \mathbb{F}_{p^2} \subset \mathbb{F}_{p^4} \subset \mathbb{F}_{p^{12}}$ and $\mathbb{F}_p \subset \mathbb{F}_{p^3} \subset \mathbb{F}_{p^6} \subset \mathbb{F}_{p^{12}}$, with $\mathbb{F}_{p^2} \subset \mathbb{F}_{p^6}$ as well ($2 \mid 6$). Sanity check: there are 6 divisors of 12 and 6 subfields; and $\mathbb{F}_{p^4} \not\subseteq \mathbb{F}_{p^6}$ because $4 \nmid 6$, matching that $4, 6$ are incomparable in the divisor lattice.

Worked Example 14.3.14 (Subfields via the subgroup lattice of $\operatorname{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_p)$)**.** Express the correspondence of the previous example through subgroups of the cyclic group $G \cong \mathbb{Z}/12\mathbb{Z}$.

Recognition. The Fundamental Theorem gives an inclusion-reversing bijection $H \mapsto \operatorname{Fix}(H)$; subgroups of $\mathbb{Z}/12\mathbb{Z}$ are $\langle \sigma^{12/d} \rangle$ of order d.

Solution. With $\sigma = \operatorname{Frob}_p$, the subgroup of order d is $\langle \sigma^{12/d} \rangle$ and $\operatorname{Fix}\big(\langle \sigma^m \rangle\big) = \mathbb{F}_{p^m}$ where here $m = 12/d$ runs over divisors. Spelled out: $\langle \sigma^{12} \rangle = 1 \leftrightarrow \mathbb{F}_{p^{12}}$, $\langle \sigma^6 \rangle \leftrightarrow \mathbb{F}_{p^6}$, $\langle \sigma^4 \rangle \leftrightarrow \mathbb{F}_{p^4}$, $\langle \sigma^3 \rangle \leftrightarrow \mathbb{F}_{p^3}$, $\langle \sigma^2 \rangle \leftrightarrow \mathbb{F}_{p^2}$,

$\langle\sigma\rangle = G \leftrightarrow \mathbb{F}_p$. The anti-isomorphism is visible:

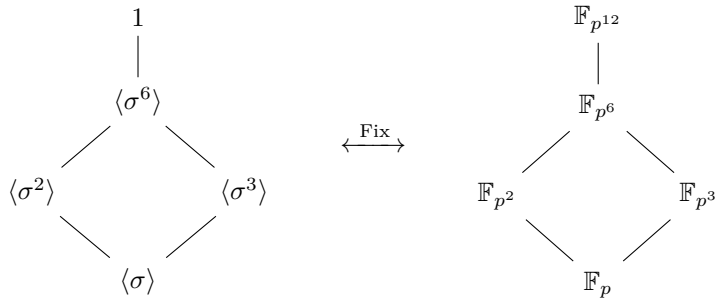

Diagram explanation. Objects: Left lattice: five subgroups of $G = \mathrm{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_p) \cong \mathbb{Z}/12\mathbb{Z}$, namely $\{1\}$, $\langle\sigma^6\rangle$ (order 2), $\langle\sigma^2\rangle$ (order 6), $\langle\sigma^3\rangle$ (order 4), and $G = \langle\sigma\rangle$ (order 12), arranged by subgroup inclusion with larger subgroups lower. Right lattice: the corresponding fixed fields $\mathbb{F}_{p^{12}}, \mathbb{F}_{p^6}, \mathbb{F}_{p^2}, \mathbb{F}_{p^3}, \mathbb{F}_p$, arranged by field inclusion with larger fields higher.

Arrows: Edges on the left are subgroup inclusions (going down = larger). Edges on the right are field inclusions (going up = larger). The horizontal $\overset{\text{Fix}}{\longleftrightarrow}$ arrow is the Galois correspondence $H \mapsto \mathrm{Fix}(H) = \{\alpha \in \mathbb{F}_{p^{12}} : \sigma^k(\alpha) = \alpha \text{ for all } \sigma^k \in H\}$; it is a bijection from subgroups of G to intermediate fields, reversing inclusion.

What commutes: The anti-isomorphism: $H_1 \subseteq H_2$ (as subgroups) if and only if $\mathrm{Fix}(H_1) \supseteq \mathrm{Fix}(H_2)$ (as fields). For instance, $\{1\} \subseteq \langle\sigma^6\rangle$ corresponds to $\mathbb{F}_{p^{12}} \supseteq \mathbb{F}_{p^6}$, and $\langle\sigma^6\rangle \subseteq G$ corresponds to $\mathbb{F}_{p^6} \supseteq \mathbb{F}_p$.

Why it commutes: A larger subgroup imposes more fixed-point conditions, so its fixed field is smaller. Formally: if $H_1 \subseteq H_2$ then $\mathrm{Fix}(H_2) \subseteq \mathrm{Fix}(H_1)$ because any α fixed by all of H_2 is also fixed by the subset H_1. The Fundamental Theorem guarantees this is a bijection (not just a map) for a finite Galois extension.

Why this matters here: This is the worked-example display of the Galois correspondence for $\mathbb{F}_{p^{12}}/\mathbb{F}_p$. Placing the subgroup and subfield lattices side by side, with Fix connecting them, makes the anti-isomorphism visually unmistakable: the diagram is upside-down on the left compared to the right. This is the conceptual heart of the example.

Concrete example: With $p = 2$, $n = 4$: $G = \mathbb{Z}/4\mathbb{Z}$, $\langle\sigma^2\rangle$ (order 2) corresponds to $\mathrm{Fix}(\langle\sigma^2\rangle) = \mathbb{F}_4$ (since $\sigma^2(\alpha) = \alpha$ iff $\alpha^4 = \alpha$ iff $\alpha \in \mathbb{F}_4$), and G corresponds to $\mathbb{F}_2$. Inclusion $\langle\sigma^2\rangle \subseteq G$ reverses to $\mathbb{F}_4 \supseteq \mathbb{F}_2$.

Common pitfall: The lattices are drawn with opposite orientations (subgroups grow downward, fields grow upward), so the order-reversal is built into the picture. Students who read both lattices in the same direction will miss the reversal and incorrectly conclude the correspondence preserves order.

Takeaway: The point of this diagram is that the Galois correspondence literally flips the subgroup lattice upside-down to produce the subfield lattice, making the inclusion-reversal a visual fact.

Sanity check: the largest subgroup $G = \langle\sigma\rangle$ (order 12) corresponds to the smallest field $\mathbb{F}_p$, and the trivial subgroup to the whole field $\mathbb{F}_{p^{12}}$ – the hallmark of an order-reversing correspondence. (The diagram above shows only five of the six subgroups: 1 and the four subgroups containing $\langle\sigma^6\rangle$. Adding the missing subgroup $\langle\sigma^4\rangle$ of order 3, which lies between 1 and $\langle\sigma^2\rangle$ and has fixed field $\mathbb{F}_{p^4}$ (between $\mathbb{F}_{p^2}$ and $\mathbb{F}_{p^{12}}$), fills it out to the full 6-element lattice of the previous example.)

Worked Example 14.3.15 ($\mathbb{F}_{p^6}$ and a non-containment)**.** Inside $\mathbb{F}_{p^6}$, which subfields occur, and is $\mathbb{F}_{p^4}$ a subfield of $\mathbb{F}_{p^6}$?

Recognition. Subfields of $\mathbb{F}_{p^6} \leftrightarrow$ divisors of 6; $\mathbb{F}_{p^4} \subseteq \mathbb{F}_{p^6} \iff 4 \mid 6$.

Solution. Divisors of 6 are $1, 2, 3, 6$, so the subfields are $\mathbb{F}_p, \mathbb{F}_{p^2}, \mathbb{F}_{p^3}, \mathbb{F}_{p^6}$. Since $4 \nmid 6$, $\mathbb{F}_{p^4}$ is *not* a subfield of $\mathbb{F}_{p^6}$. (The smallest field containing both $\mathbb{F}_{p^4}$ and $\mathbb{F}_{p^6}$ is $\mathbb{F}_{p^{\mathrm{lcm}(4,6)}} = \mathbb{F}_{p^{12}}$, and their intersection is $\mathbb{F}_{p^{\gcd(4,6)}} = \mathbb{F}_{p^2}$.) Sanity check: $\mathbb{F}_{p^2}$ and $\mathbb{F}_{p^3}$ are both in $\mathbb{F}_{p^6}$ since $2 \mid 6$ and $3 \mid 6$, and $\mathbb{F}_{p^2} \cap \mathbb{F}_{p^3} = \mathbb{F}_{p^{\gcd(2,3)}} = \mathbb{F}_p$.

Worked Example 14.3.16 (Compositum and intersection of finite subfields)**.** For subfields of a common $\overline{\mathbb{F}_p}$, prove $\mathbb{F}_{p^a} \cap \mathbb{F}_{p^b} = \mathbb{F}_{p^{\gcd(a,b)}}$ and $\mathbb{F}_{p^a}\mathbb{F}_{p^b} = \mathbb{F}_{p^{\mathrm{lcm}(a,b)}}$.

Recognition. Containment of finite fields is divisibility of exponents; intersection is the largest common subfield, compositum the smallest common overfield.

Solution. $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^a} \cap \mathbb{F}_{p^b} \iff d \mid a$ and $d \mid b \iff d \mid \gcd(a,b)$, so the intersection is $\mathbb{F}_{p^{\gcd(a,b)}}$. Dually $\mathbb{F}_{p^a}\mathbb{F}_{p^b} \subseteq \mathbb{F}_{p^m} \iff a \mid m$ and $b \mid m \iff \operatorname{lcm}(a,b) \mid m$, so the compositum is $\mathbb{F}_{p^{\operatorname{lcm}(a,b)}}$. Sanity check $(a,b) = (4,6)$: gcd $= 2$, lcm $= 12$, giving $\mathbb{F}_{p^4} \cap \mathbb{F}_{p^6} = \mathbb{F}_{p^2}$ and $\mathbb{F}_{p^4}\mathbb{F}_{p^6} = \mathbb{F}_{p^{12}}$, consistent with the lattice above.

Irreducible polynomials over $\mathbb{F}_p$

The factorization $x^{p^n} - x = \prod_{d|n}$(product of all monic irreducibles of degree d) is the polynomial shadow of the subfield lattice: an element $\alpha \in \overline{\mathbb{F}_p}$ lies in $\mathbb{F}_{p^n}$ iff its degree $d = [\mathbb{F}_p(\alpha) : \mathbb{F}_p]$ divides n, and $\mathbb{F}_p(\alpha) = \mathbb{F}_{p^d}$.

Theorem 14.3.17 (irreducibles and the factorization of $x^{p^n} - x$)**.** *Let p be prime and $n \geq 1$.*

(1) *For each $d \geq 1$ there exists an irreducible polynomial of degree d in $\mathbb{F}_p[x]$; a root generates $\mathbb{F}_{p^d}$.*

(2) *In $\mathbb{F}_p[x]$,*

$$x^{p^n} - x = \prod_{d|n} \prod_{\substack{g \text{ monic irreducible} \\ \deg g = d}} g(x),$$

i.e. $x^{p^n} - x$ is the product of all monic irreducible polynomials over $\mathbb{F}_p$ whose degree divides n, each occurring exactly once.

Idea. A monic irreducible g of degree d has its roots generating $\mathbb{F}_{p^d}$; those roots lie in $\mathbb{F}_{p^n}$ (hence divide $x^{p^n} - x$) exactly when $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^n}$, i.e. when $d \mid n$. Separability of $x^{p^n} - x$ forces each such g to occur to the first power. Counting degrees gives $p^n = \sum_{d|n} d \cdot N_p(d)$, where $N_p(d)$ is the number of monic irreducibles of degree d; Mobius inversion then yields $N_p(n) = \frac{1}{n}\sum_{d|n} \mu(d)\, p^{n/d} > 0$, proving existence. □

Worked Example 14.3.18 (Counting monic irreducibles of small degree over $\mathbb{F}_2$)**.** Compute $N_2(d)$, the number of monic irreducible polynomials of degree d over $\mathbb{F}_2$, for $d = 1, 2, 3, 4$.

Recognition. Use $2^n = \sum_{d|n} d\, N_2(d)$ (degree count in the factorization theorem), solved recursively, or directly $N_p(n) = \frac{1}{n}\sum_{d|n} \mu(d) p^{n/d}$.

Solution. Degree 1: $N_2(1) = 2$ (namely $x,\ x+1$). Degree 2: $2^2 = 1 \cdot N_2(1) + 2 \cdot N_2(2) \Rightarrow 4 = 2 + 2N_2(2) \Rightarrow N_2(2) = 1$ (namely $x^2 + x + 1$). Degree 3: $2^3 = 1 \cdot 2 + 3N_2(3) \Rightarrow 8 = 2 + 3N_2(3) \Rightarrow N_2(3) = 2$ (namely $x^3 + x + 1,\ x^3 + x^2 + 1$). Degree 4: $2^4 = 1 \cdot N_2(1) + 2 \cdot N_2(2) + 4 \cdot N_2(4) = 2 + 2 + 4N_2(4) \Rightarrow 16 = 4 + 4N_2(4) \Rightarrow N_2(4) = 3$. Sanity check via Mobius: $N_2(4) = \frac{1}{4}(\mu(1)2^4 + \mu(2)2^2 + \mu(4)2^1) = \frac{1}{4}(16 - 4 + 0) = 3$, agreeing.

Worked Example 14.3.19 (Factoring $x^8 - x$ over $\mathbb{F}_2$)**.** Write $x^8 - x$ as a product of monic irreducibles over $\mathbb{F}_2$ and confirm the degree pattern.

Recognition. $x^{2^3} - x$ is the product of all monic irreducibles over $\mathbb{F}_2$ of degree $d \mid 3$, i.e. $d \in \{1, 3\}$.

Solution. The divisors of 3 are $1, 3$. Degree 1 irreducibles: $x,\ x+1$. Degree 3 irreducibles: $x^3+x+1,\ x^3+x^2+1$. Hence

$$x^8 - x = x(x+1)(x^3 + x + 1)(x^3 + x^2 + 1).$$

Sanity check on degrees: $1 + 1 + 3 + 3 = 8 = \deg(x^8 - x)$; and there is no degree-2 factor because $2 \nmid 3$, so $\mathbb{F}_4 \not\subseteq \mathbb{F}_8$.

Worked Example 14.3.20 (Factoring $x^{16} - x$ over $\mathbb{F}_2$)**.** Factor $x^{16} - x$ over $\mathbb{F}_2$ into irreducibles.

Recognition. $x^{2^4} - x$ collects all monic irreducibles of degree $d \mid 4$, i.e. $d \in \{1, 2, 4\}$.

Solution. Degree 1: $x,\ x+1$. Degree 2: $x^2 + x + 1$. Degree 4: the $N_2(4) = 3$ irreducibles $x^4 + x + 1,\ x^4 + x^3 + 1,\ x^4 + x^3 + x^2 + x + 1$. So

$$x^{16} - x = x(x+1)(x^2 + x + 1)(x^4 + x + 1)(x^4 + x^3 + 1)(x^4 + x^3 + x^2 + x + 1).$$

Sanity check: degrees sum to $1 + 1 + 2 + 3 \cdot 4 = 16$; the degree-2 factor appears because $2 \mid 4$ (i.e. $\mathbb{F}_4 \subseteq \mathbb{F}_{16}$), but no degree-3 factor appears since $3 \nmid 4$.

Worked Example 14.3.21 (Number of irreducibles of degree 5 over $\mathbb{F}_3$)**.** Compute $N_3(5)$.

Recognition. For n prime, $N_p(n) = \frac{1}{n}(p^n - p)$ since the only divisors are $1, n$.

Solution. 5 is prime, so $N_3(5) = \frac{1}{5}(3^5 - 3) = \frac{1}{5}(243 - 3) = \frac{240}{5} = 48$. Sanity check via the degree equation $3^5 = 1 \cdot N_3(1) + 5 \cdot N_3(5) = 3 + 5 \cdot 48 = 3 + 240 = 243$. Correct.

Worked Example 14.3.22 (Reading off $\mathbb{F}_p(\alpha)$ from deg of the minimal polynomial)**.** If $\alpha \in \overline{\mathbb{F}_5}$ has minimal polynomial of degree 4 over $\mathbb{F}_5$, what is $\mathbb{F}_5(\alpha)$, and inside which $\mathbb{F}_{5^n}$ does α live?

Recognition. $\mathbb{F}_p(\alpha) = \mathbb{F}_{p^{\deg}}$, and $\alpha \in \mathbb{F}_{p^n} \iff \deg(\alpha) \mid n$.

Solution. $\mathbb{F}_5(\alpha) = \mathbb{F}_{5^4}$, a field of 625 elements. Then $\alpha \in \mathbb{F}_{5^n} \iff 4 \mid n$, so α lies in $\mathbb{F}_{5^4}, \mathbb{F}_{5^8}, \mathbb{F}_{5^{12}}, \ldots$ but not, e.g., in $\mathbb{F}_{5^2}$ or $\mathbb{F}_{5^6}$ (since $4 \nmid 2$, $4 \nmid 6$). Sanity check: $\mathbb{F}_{5^4} \subseteq \mathbb{F}_{5^{12}}$ because $4 \mid 12$, consistent with $\alpha \in \mathbb{F}_{5^{12}}$.

The multiplicative group $\mathbb{F}_{p^n}^\times$

The last structural fact makes everything above effective: it guarantees a single element generating all of $\mathbb{F}_{p^n}$ over $\mathbb{F}_p$, and explains why an irreducible of each degree exists.

Theorem 14.3.23 ($\mathbb{F}_{p^n}^\times$ is cyclic)**.** *The multiplicative group $\mathbb{F}_{p^n}^\times$ of nonzero elements of $\mathbb{F}_{p^n}$ is cyclic of order $p^n - 1$. A generator is called a* primitive element *(or primitive root) of $\mathbb{F}_{p^n}$; there are $\varphi(p^n - 1)$ of them.*

Idea. This is the general fact that every finite subgroup of the multiplicative group of a field is cyclic. If $G = \mathbb{F}_{p^n}^\times$ had two distinct subgroups of some order m, it would contain more than m solutions of $x^m = 1$, impossible over a field where $x^m - 1$ has at most m roots. Hence G has at most one subgroup of each order, which forces G cyclic. □

Corollary 14.3.24 (primitive element)**.** *Every finite extension $\mathbb{F}_{p^n}/\mathbb{F}_p$ (indeed $\mathbb{F}_{p^n}/\mathbb{F}_{p^d}$ for $d \mid n$) is simple: $\mathbb{F}_{p^n} = \mathbb{F}_p(\gamma)$ for any generator γ of the cyclic group $\mathbb{F}_{p^n}^\times$, and the minimal polynomial of γ over $\mathbb{F}_p$ is an irreducible of degree n.*

Worked Example 14.3.25 (A primitive root of $\mathbb{F}_8^\times$)**.** With $\mathbb{F}_8 = \mathbb{F}_2(\alpha)$, $\alpha^3 = \alpha + 1$, show α generates $\mathbb{F}_8^\times$.

Recognition. $\mathbb{F}_8^\times$ is cyclic of order 7; since 7 is prime, every non-identity element is a generator.

Solution. $|\mathbb{F}_8^\times| = 7$, a prime, so any $\alpha \neq 1$ has order 7 and generates. Explicitly the powers of α are $\alpha^0 = 1, \alpha, \alpha^2, \alpha^3 = \alpha + 1, \alpha^4 = \alpha^2 + \alpha, \alpha^5 = \alpha^2 + \alpha + 1, \alpha^6 = \alpha^2 + 1$, then $\alpha^7 = 1$ – all seven nonzero elements appear. Sanity check: the order of α divides 7 and is not 1, hence is 7; and there are $\varphi(7) = 6$ generators, namely $\alpha, \ldots, \alpha^6$.

Worked Example 14.3.26 (A primitive root of $\mathbb{F}_9^\times$ and a non-example)**.** In $\mathbb{F}_9 = \mathbb{F}_3(i)$, $i^2 = -1$, determine the order of i and find a primitive root.

Recognition. $\mathbb{F}_9^\times$ is cyclic of order 8; an element is primitive iff its order is 8. Orders divide 8, so they are $1, 2, 4, 8$.

Solution. The element i has $i^2 = -1 \neq 1$, $i^4 = 1$, so $|i| = 4$ – *not* a generator. Try $\gamma = 1+i$: $\gamma^2 = 1+2i+i^2 = 2i$, $\gamma^4 = (2i)^2 = 4i^2 = 4 \cdot (-1) = -4 = -1 = 2 \pmod 3$, so $\gamma^4 = 2 \neq 1$, hence $|\gamma| \nmid 4$; since $|\gamma| \mid 8$, $|\gamma| = 8$ and $1 + i$ is primitive. Sanity check: $\gamma^8 = (\gamma^4)^2 = 2^2 = 4 = 1 \pmod 3$. There are $\varphi(8) = 4$ primitive roots.

Worked Example 14.3.27 (Discrete logarithm via a primitive root)**.** Using the primitive root α of $\mathbb{F}_8$ from above, solve $\alpha^x = \alpha^2 + 1$.

Recognition. In a cyclic group $\langle \alpha \rangle$ every element is a unique power α^x with $0 \leq x < |\alpha|$; we read x from the power table.

Solution. From the table $\alpha^6 = \alpha^2 + 1$, so $x \equiv 6 \pmod 7$. Sanity check: multiplying, $(\alpha^2 + 1) \cdot \alpha = \alpha^3 + \alpha = (\alpha + 1) + \alpha = 1 = \alpha^7 = \alpha^0$, confirming $\alpha^6 \cdot \alpha = \alpha^7 = 1$, i.e. $\alpha^2 + 1 = \alpha^{-1} = \alpha^6$.

Worked Example 14.3.28 (Counting primitive roots and elements of given order)**.** How many elements of $\mathbb{F}_{16}^\times$ have order exactly 5, and how many are primitive?

Recognition. In a cyclic group of order m, the number of elements of order d (for $d \mid m$) is $\varphi(d)$; primitive means order m.

Solution. $|\mathbb{F}_{16}^{\times}| = 15$. Elements of order 5: $\varphi(5) = 4$. Primitive elements (order 15): $\varphi(15) = \varphi(3)\varphi(5) = 2 \cdot 4 = 8$. Sanity check: summing $\varphi(d)$ over divisors $d \mid 15$ gives $\varphi(1)+\varphi(3)+\varphi(5)+\varphi(15) = 1+2+4+8 = 15 = |\mathbb{F}_{16}^{\times}|$, as it must.

Worked Example 14.3.29 (Simple extension and minimal polynomial of a primitive root)**.** Show $\mathbb{F}_{16} = \mathbb{F}_2(\gamma)$ for γ a primitive root, and identify deg of its minimal polynomial over $\mathbb{F}_2$.

Recognition. By the primitive-element corollary $\mathbb{F}_{p^n} = \mathbb{F}_p(\gamma)$ for any generator γ of $\mathbb{F}_{p^n}^{\times}$; the minimal polynomial then has degree $n = [\mathbb{F}_{p^n} : \mathbb{F}_p]$.

Solution. Let γ generate $\mathbb{F}_{16}^{\times}$ (order 15). Then $\mathbb{F}_2(\gamma)$ is a subfield of $\mathbb{F}_{16}$ containing the cyclic group $\langle\gamma\rangle = \mathbb{F}_{16}^{\times}$, so $\mathbb{F}_2(\gamma) = \mathbb{F}_{16}$. Hence the minimal polynomial of γ over $\mathbb{F}_2$ has degree $[\mathbb{F}_{16} : \mathbb{F}_2] = 4$. Sanity check: γ has order 15, which does not divide $2^d - 1$ for $d = 1, 2, 3$ ($2^1 - 1 = 1,\ 2^2 - 1 = 3,\ 2^3 - 1 = 7$), so $\gamma \notin \mathbb{F}_{2^d}$ for $d < 4$, confirming $\deg \gamma = 4$.

Frobenius as a structure map: a summary diagram

The three theorems of the section fit into one picture. The Frobenius $\sigma = \mathrm{Frob}_p$ generates the Galois group; its powers σ^d have fixed fields $\mathbb{F}_{p^d}$; and the divisor lattice of n indexes everything. The square below shows how a subfield inclusion is mediated by the corresponding Frobenius powers (here $d \mid m \mid n$), with vertical maps the inclusions and horizontal maps the relative Frobenius $\mathrm{Frob}_{p^d} = \sigma^d$ generating $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d})$.

$$\begin{array}{ccc} \mathbb{F}_{p^m} & \xrightarrow{\sigma^d = \mathrm{Frob}_{p^d}} & \mathbb{F}_{p^m} \\ \big\downarrow & & \big\downarrow \\ \mathbb{F}_{p^n} & \xrightarrow[\sigma^d = \mathrm{Frob}_{p^d}]{} & \mathbb{F}_{p^n} \end{array} \qquad \begin{array}{ccc} \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d}) & \xrightarrow{\cong} & \langle\sigma^d\rangle \cong \mathbb{Z}/(n/d)\mathbb{Z} \\ \big\downarrow{\scriptstyle \text{restrict}} & & \big\downarrow \\ \mathrm{Gal}(\mathbb{F}_{p^m}/\mathbb{F}_{p^d}) & \xrightarrow{\cong} & \langle\sigma^d|_{\mathbb{F}_{p^m}}\rangle \cong \mathbb{Z}/(m/d)\mathbb{Z} \end{array}$$

Diagram explanation. Objects: Left square: fields $\mathbb{F}_{p^m}$ (top) and $\mathbb{F}_{p^n}$ (bottom), each appearing twice (left and right columns), where $d \mid m \mid n$. Right square: Galois groups $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d})$ (top-left), $\mathrm{Gal}(\mathbb{F}_{p^m}/\mathbb{F}_{p^d})$ (bottom-left), and their cyclic presentations $\langle\sigma^d\rangle \cong \mathbb{Z}/(n/d)\mathbb{Z}$ (top-right) and $\langle\sigma^d|_{\mathbb{F}_{p^m}}\rangle \cong \mathbb{Z}/(m/d)\mathbb{Z}$ (bottom-right).

Arrows: Left square: horizontal arrows labelled $\sigma^d = \mathrm{Frob}_{p^d}$ are the relative Frobenius automorphism acting on $\mathbb{F}_{p^m}$ and $\mathbb{F}_{p^n}$ respectively; vertical hook arrows are field inclusions $\mathbb{F}_{p^m} \hookrightarrow \mathbb{F}_{p^n}$. Right square: horizontal arrows are the isomorphisms identifying each Galois group with a cyclic group generated by a Frobenius power; left vertical arrow is restriction of automorphisms from $\mathbb{F}_{p^n}$ to $\mathbb{F}_{p^m}$ (a surjective group homomorphism because $\mathbb{F}_{p^m}/\mathbb{F}_{p^d}$ is also Galois); right vertical arrow is the induced surjection $\mathbb{Z}/(n/d)\mathbb{Z} \twoheadrightarrow \mathbb{Z}/(m/d)\mathbb{Z}$.

What commutes: Left square: the inclusion $\mathbb{F}_{p^m} \hookrightarrow \mathbb{F}_{p^n}$ intertwines the two horizontal Frobenius actions – Frob_{p^d} on $\mathbb{F}_{p^m}$ is the same map as Frob_{p^d} on $\mathbb{F}_{p^n}$ restricted to $\mathbb{F}_{p^m}$. Right square: restrict-then-present equals present-then-quotient: both routes send σ^{dk} to k mod (m/d), i.e. the right vertical map is reduction modulo m/d.

Why it commutes: For the left square, $\mathrm{Frob}_{p^d}(\alpha) = \alpha^{p^d}$ is defined by the same formula on all of $\overline{\mathbb{F}_p}$, so restricting to the subfield $\mathbb{F}_{p^m}$ commutes with inclusion by definition. For the right square, the restriction map sends a generator σ^d of $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d})$ to $\sigma^d|_{\mathbb{F}_{p^m}}$, which generates $\mathrm{Gal}(\mathbb{F}_{p^m}/\mathbb{F}_{p^d})$ and has order m/d; this is exactly a generator of $\mathbb{Z}/(m/d)\mathbb{Z}$.

Why this matters here: This pair of squares is the structural summary of the entire section: it encodes in one picture (i) the explicit generator of the Galois group of any finite-field extension, (ii) the compatibility of Frobenius across the tower $\mathbb{F}_{p^d} \subseteq \mathbb{F}_{p^m} \subseteq \mathbb{F}_{p^n}$, and (iii) the surjection of cyclic groups corresponding to the restriction of automorphisms. The author places it here as a capstone before the worked examples on relative extensions.

Concrete example: Take $p = 2$, $d = 1$, $m = 2$, $n = 4$: the left square says Frob_2 acts on both $\mathbb{F}_4$ and $\mathbb{F}_{16}$, and $\mathbb{F}_4 \hookrightarrow \mathbb{F}_{16}$ intertwines them. The right square gives $\mathrm{Gal}(\mathbb{F}_{16}/\mathbb{F}_2) \cong \mathbb{Z}/4\mathbb{Z}$ restricting to $\mathrm{Gal}(\mathbb{F}_4/\mathbb{F}_2) \cong \mathbb{Z}/2\mathbb{Z}$, which is the quotient map $\mathbb{Z}/4\mathbb{Z} \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$.

Common pitfall: The left square is not a diagram of distinct objects: $\mathbb{F}_{p^m}$ appears twice (once in each column). Students sometimes think the horizontal arrows are isomorphisms between two different fields; they are endomorphisms (automorphisms) of the same field.

Takeaway: The point of this diagram is that the Frobenius automorphism is functorial across tower inclusions, and the restriction map on Galois groups corresponds to the natural surjection of cyclic groups.

Worked Example 14.3.30 (Relative extension $\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}$ and its Galois group)**.** Compute $\mathrm{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2})$, its order, and its subgroup/subfield lattice.

Recognition. For $d \mid n$, $\mathbb{F}_{p^n}/\mathbb{F}_{p^d}$ is Galois with group $\langle \mathrm{Frob}_{p^d} \rangle = \langle \sigma^d \rangle \cong \mathbb{Z}/(n/d)\mathbb{Z}$ of order n/d; subfields correspond to divisors of n/d.

Solution. Here $d = 2,\ n = 12$, so $\mathrm{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}) = \langle \sigma^2 \rangle$, cyclic of order $12/2 = 6$, generated by the relative Frobenius $\tau = \mathrm{Frob}_{p^2} : \alpha \mapsto \alpha^{p^2}$. Its subgroups correspond to divisors of 6, i.e. to the intermediate fields between $\mathbb{F}_{p^2}$ and $\mathbb{F}_{p^{12}}$:

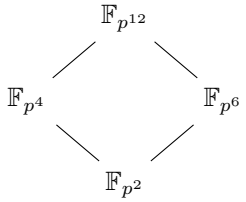

Diagram explanation. Objects: Four fields arranged in a diamond: $\mathbb{F}_{p^2}$ at the bottom (the base of the relative extension), $\mathbb{F}_{p^4}$ and $\mathbb{F}_{p^6}$ in the middle (incomparable intermediate fields), and $\mathbb{F}_{p^{12}}$ at the top (the total field). All four are subfields of a fixed $\overline{\mathbb{F}_p}$, and this is the lattice of intermediate fields for the extension $\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}$.

Arrows: Each edge is an upward field inclusion at a covering step. $\mathbb{F}_{p^2} \subset \mathbb{F}_{p^4}$ has degree 2 ($4/2 = 2$); $\mathbb{F}_{p^2} \subset \mathbb{F}_{p^6}$ has degree 3 ($6/2 = 3$); $\mathbb{F}_{p^4} \subset \mathbb{F}_{p^{12}}$ has degree 3; $\mathbb{F}_{p^6} \subset \mathbb{F}_{p^{12}}$ has degree 2. The absence of an edge between $\mathbb{F}_{p^4}$ and $\mathbb{F}_{p^6}$ records that $4 \nmid 6$ and $6 \nmid 4$.

What commutes: The covering relations: going up-left from $\mathbb{F}_{p^2}$ to $\mathbb{F}_{p^4}$ to $\mathbb{F}_{p^{12}}$ has the same endpoint as going up-right from $\mathbb{F}_{p^2}$ to $\mathbb{F}_{p^6}$ to $\mathbb{F}_{p^{12}}$; both paths end at the same object $\mathbb{F}_{p^{12}}$. Formally $\mathbb{F}_{p^4} \cdot \mathbb{F}_{p^6} = \mathbb{F}_{p^{\mathrm{lcm}(4,6)}} = \mathbb{F}_{p^{12}}$ and $\mathbb{F}_{p^4} \cap \mathbb{F}_{p^6} = \mathbb{F}_{p^{\gcd(4,6)}} = \mathbb{F}_{p^2}$.

Why it commutes: The intermediate fields of $\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}$ correspond to subgroups of $\mathrm{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}) \cong \mathbb{Z}/6\mathbb{Z}$. The divisors of 6 are $1, 2, 3, 6$, giving exponents $2 \cdot 1, 2 \cdot 2, 2 \cdot 3, 2 \cdot 6 = 2, 4, 6, 12$. The diamond shape is forced because 2 and 3 are the only proper divisors of 6, and $2, 3$ do not divide each other.

Why this matters here: This is the key output of the worked example: the subfield lattice of a *relative* extension $\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}$ is the divisor lattice of $6 = 12/2$. This shows that the entire theory (Galois correspondence, divisor lattice, Frobenius structure) applies to relative extensions $\mathbb{F}_{p^n}/\mathbb{F}_{p^d}$ with n/d in place of n.

Concrete example: For $p = 2$: $\mathbb{F}_4 \subset \mathbb{F}_{16}$ and $\mathbb{F}_4 \subset \mathbb{F}_{64}$ are the two length-1 upward steps from $\mathbb{F}_4$; their compositum is $\mathbb{F}_{4096} = \mathbb{F}_{2^{12}}$ (since $\mathrm{lcm}(4, 6) = 12$ in exponents, i.e. $\mathbb{F}_{2^4} \cdot \mathbb{F}_{2^6} = \mathbb{F}_{2^{12}}$) and intersection is $\mathbb{F}_4 = \mathbb{F}_{2^2}$ (the base), consistent with the diamond.

Common pitfall: Students sometimes expect $\mathbb{F}_{p^4}$ and $\mathbb{F}_{p^6}$ to have an inclusion relation since both sit between $\mathbb{F}_{p^2}$ and $\mathbb{F}_{p^{12}}$; the diagram makes explicit that they are incomparable – two middle nodes with no edge between them.

Takeaway: The point of this diagram is that the intermediate fields of $\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2}$ form a diamond determined by the divisors of $12/2 = 6$, with the top and bottom given by the compositum and intersection formulas.

The intermediate fields are $\mathbb{F}_{p^2} \subset \mathbb{F}_{p^4} \subset \mathbb{F}_{p^{12}}$ and $\mathbb{F}_{p^2} \subset \mathbb{F}_{p^6} \subset \mathbb{F}_{p^{12}}$ (the divisors $1, 2, 3, 6$ of 6 give exponents $2, 4, 6, 12$, the multiples of 2 dividing 12). Sanity check: $|\mathrm{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_{p^2})| = [\mathbb{F}_{p^{12}} : \mathbb{F}_{p^2}] = 12/2 = 6$, and $\mathbb{F}_{p^4}\mathbb{F}_{p^6} = \mathbb{F}_{p^{\mathrm{lcm}(4,6)}} = \mathbb{F}_{p^{12}}$, $\mathbb{F}_{p^4} \cap \mathbb{F}_{p^6} = \mathbb{F}_{p^{\gcd(4,6)}} = \mathbb{F}_{p^2}$, exactly the top and bottom of this sublattice.

Exercises (from the text).

1. Factor $x^8 - x$ into irreducibles in $\mathbb{Z}[x]$ and in $\mathbb{F}_2[x]$.
2. Write out the multiplication table for $\mathbb{F}_4$ and $\mathbb{F}_8$.
3. Prove that an algebraically closed field must be infinite.
4. Construct the finite field of 16 elements and find a generator for the multiplicative group. How many generators are there?

5. Exhibit an explicit isomorphism between the splitting fields of $x^3 - x + 1$ and $x^3 - x - 1$ over $\mathbb{F}_3$.

6. Suppose $K = \mathbb{Q}(\theta) = \mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})$ with $D_1, D_2 \in \mathbb{Z}$, is a biquadratic extension and that $\theta = a + b\sqrt{D_1} + c\sqrt{D_2} + d\sqrt{D_1 D_2}$ where $a, b, c, d \in \mathbb{Z}$ are integers. Prove that the minimal polynomial $m_\theta(x)$ for θ over $\mathbb{Q}$ is irreducible of degree 4 over $\mathbb{Q}$ but is reducible modulo every prime p. In particular show that the polynomial $x^4 - 10x^2 + 1$ is irreducible in $\mathbb{Z}[x]$ but is reducible modulo every prime. [Use the fact that there are no biquadratic extensions over finite fields.]

7. Prove that one of $2, 3$ or 6 is a square in $\mathbb{F}_p$ for every prime p. Conclude that the polynomial

$$x^6 - 11x^4 + 36x^2 - 36 = (x^2 - 2)(x^2 - 3)(x^2 - 6)$$

has a root modulo p for every prime p but has no root in $\mathbb{Z}$.

8. Determine the splitting field of the polynomial $x^p - x - a$ over $\mathbb{F}_p$ where $a \neq 0, a \in \mathbb{F}_p$. Show explicitly that the Galois group is cyclic. [Show $\alpha \mapsto \alpha + 1$ is an automorphism.] Such an extension is called an *Artin–Schreier extension* (cf. Exercise 9 of Section 7).

9. Let $q = p^m$ be a power of the prime p and let $\mathbb{F}_q = \mathbb{F}_{p^m}$ be the finite field with q elements. Let $\sigma_q = \sigma_p^m$ be the mth power of the Frobenius automorphism σ_p, called the q-Frobenius automorphism.

   (a) Prove that σ_q fixes $\mathbb{F}_q$.

   (b) Prove that every finite extension of $\mathbb{F}_q$ of degree n is the splitting field of $x^{q^n} - x$ over $\mathbb{F}_q$, hence is unique.

   (c) Prove that every finite extension of $\mathbb{F}_q$ of degree n is cyclic with σ_q as generator.

   (d) Prove that the subfields of the unique extension of $\mathbb{F}_q$ of degree n are in bijective correspondence with the divisors d of n.

10. Prove that n divides $\varphi(p^n - 1)$. [Observe that $\varphi(p^n - 1)$ is the order of the group of automorphisms of a cyclic group of order $p^n - 1$.]

11. Prove that $x^{p^n} - x + 1$ is irreducible over $\mathbb{F}_p$ only when $n = 1$ or $n = p = 2$. [Note that if α is a root then so is $\alpha + a$ for any $a \in \mathbb{F}_{p^n}$. Show that this implies $\mathbb{F}_p(\alpha)$ contains $\mathbb{F}_{p^n}$ and that $[\mathbb{F}_p(\alpha) : \mathbb{F}_{p^n}] = p$.]

12. *(Berlekamp's Factorization Algorithm)* Let $f(x) \in \mathbb{F}_p[x]$ be a monic polynomial of degree n and let $f(x) = p_1(x)p_2(x)\cdots p_k(x)$, where $p_1(x), p_2(x), \ldots, p_k(x)$ are powers of distinct monic irreducibles in $\mathbb{F}_p[x]$ (this notation is kept in the following exercises). Show that in order to write $f(x)$ as a product of irreducible polynomials in $\mathbb{F}_p[x]$ it suffices to determine the factors $p_1(x), \ldots, p_k(x)$. [If $p(x) = q(x)^N \in \mathbb{F}_p[x]$ with $q(x)$ monic and irreducible, show that $q(x)$ can be determined from $p(x)$ by checking for p^{th} powers and by computing greatest common divisors involving derivatives.]

13. Let $g(x) \in \mathbb{F}_p[x]$ be any polynomial of degree $< n$. Denote by $R(h(x))$ the remainder of $h(x)$ after division by $f(x)$. Prove the following are equivalent:

   (a) $R(g(x^p)) = g(x)$.

   (b) $f(x)$ divides $[g(x) - 0][g(x) - 1]\cdots[g(x) - (p-1)]$. [Use the fact that $g(x)^p = g(x^p)$ together with the factorization of $x^p - x$ in $\mathbb{F}_p[x]$.]

   (c) $p_i(x)$ divides the product in (b) for $i = 1, 2, \ldots, k$.

   (d) For each $i = 1, 2, \ldots, k$ there is an $s_i \in \mathbb{F}_p$ such that $p_i(x)$ divides $g(x) - s_i$, i.e., $g(x) \equiv s_i \pmod{p_i(x)}$.

14. Prove that the polynomials $g(x)$ of degree $< n$ satisfying the equivalent conditions of the previous exercise form a vector space V over $\mathbb{F}_p$ of dimension k. [Use the Chinese Remainder Theorem applied to the p^k possible choices for the s_i in 13(d)].

15. Let $g(x) = b_0 + b_1 x + \cdots + b_{n-1}x^{n-1}$ be any polynomial of degree $< n$ and for $j = 0, 1, \ldots, n-1$ let

$$R(x^{pj}) = a_{0,j} + a_{1,j}x + \cdots + a_{n-1,j}x^{n-1}$$

and let A be the $n \times n$ matrix

$$A = \begin{pmatrix} a_{0,0} & a_{0,1} & \cdots & a_{0,n-1} \\ a_{1,0} & a_{1,1} & \cdots & a_{1,n-1} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n-1,0} & a_{n-1,1} & \cdots & a_{n-1,n-1} \end{pmatrix}. \qquad (*)$$

Show that condition (a) of Exercise 13 for $g(x) \in V$ is equivalent to

$$(A - I)B = 0 \qquad (**)$$

where B is the column matrix with entries $b_0, b_1, \ldots, b_{n-1}$. Conclude that the rank of the matrix $A - I$ is $n - k$. Note that this already suffices to determine if $f(x)$ is irreducible, without actually determining the factors.

16. Let $g_1(x), g_2(x), \ldots, g_k(x)$ be a basis of solutions to $(**)$ (so a basis for V), where we may take $g_1(x) = 1$. Beginning with $u(x) = f(x)$, compute the greatest common divisor $(u(x), g_i(x) - s)$ for $i = 2, 3, \ldots, k$ and $s \in \mathbb{F}_p$ for every factor of $f(x)$ already computed. Note by Exercise 13(d) that every factor $p_i(x)$ of $f(x)$ divides such a g.c.d. The process terminates when k relatively prime factors have been determined. Prove that this procedure actually gives all the factors $p_1(x), p_2(x), \ldots, p_k(x)$ of $f(x)$, i.e., separate the individual factors $p_1(x), p_2(x), \ldots, p_k(x)$ by this procedure, as follows:

    If this were not the case, then for two of the factors, say $p_1(x)$ and $p_2(x)$, for each $i = 1, 2, \ldots, k$ there would exist $s_i \in \mathbb{F}_p$ such that $g_i(x) - s_i$ is divisible by both $p_1(x)$ and $p_2(x)$. Use the Chinese Remainder Theorem to show that there exist $c_i \in \mathbb{F}_p$ such that $g(x) = \sum_{i=1}^{k} c_i g_i(x)$ satisfies $g(x) \equiv 0 \pmod{p_1(x)}$ and $g(x) \equiv 1 \pmod{p_2(x)}$. Write $g(x) = \sum_{i=1}^{k} c_i g_i(x)$ in terms of the basis for V and let $s = \sum_{i=1}^{k} c_i s_i \in \mathbb{F}_p$. Show that $s \equiv 0 \pmod{p_1(x)}$ and $s \equiv 1 \pmod{p_2(x)}$ so that $s = 1$, a contradiction.

17. This exercise follows Berlekamp's Factorization Algorithm outlined in the previous exercises to determine the factorization of $f(x) = x^5 + x^2 + 4x + 6$ in $\mathbb{F}_7[x]$.

    (a) Show that $x^7 = x^2 + 3x^3 + 6x^4 \pmod{f(x)}$. Similarly compute x^{14}, x^{21}, and x^{28} modulo $f(x)$ (note that x^{14} can most easily be computed by squaring the result for x^7 and then reducing, etc.) to show that in this case the matrix A in Exercise 15 is

    $$\begin{pmatrix} 1 & 0 & 5 & 1 & 4 \\ 0 & 0 & 1 & 1 & 2 \\ 0 & 1 & 3 & 3 & 3 \\ 0 & 3 & 4 & 2 & 2 \\ 0 & 6 & 3 & 1 & 1 \end{pmatrix}.$$

    (b) Show that the reduced row echelon form for $A - I$ is the matrix

    $$\begin{pmatrix} 0 & 1 & 0 & 0 & 6 \\ 0 & 0 & 1 & 0 & 6 \\ 0 & 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

    Conclude that $k = 2$ (so $f(x)$ is the product of precisely two factors which are powers of irreducible polynomials) and that $g_1(x) = 1$ and $g_2(x) = x^4 + 5x^3 + x^2 + x$ give a basis for the solutions to $(**)$ in Exercise 15.

    (c) Following the procedure in Exercise 16, show that $(f(x), g_2(x) - 1) = x^2 + 3x + 5 = p_1(x)$, so that $f(x)/p_1(x) = x^3 + 4x^2 + 4x + 4 = p_2(x)$, giving the powers of the irreducible polynomials dividing $f(x)$ in $\mathbb{F}_7[x]$. Show that neither factor is a 7th power in $\mathbb{F}_7[x]$ and that each is relatively prime to its derivative to conclude that both factors are irreducible polynomials, giving the complete factorization of $f(x)$ into irreducible polynomials:

    $$f(x) = (x^2 + 3x + 5)(x^3 + 4x^2 + 4x + 4) \in \mathbb{F}_7[x].$$

Practice problems.

1. Show that x^2+1 is irreducible over $\mathbb{F}_3$, construct $\mathbb{F}_9 = \mathbb{F}_3[x]/(x^2+1) = \mathbb{F}_3(i)$ with $i^2=-1$, and verify directly that every element of $\mathbb{F}_9$ satisfies $\alpha^9 = \alpha$.

2. Construct $\mathbb{F}_{27}$ as $\mathbb{F}_3[x]/(x^3-x+1)$ after checking that x^3-x+1 is irreducible over $\mathbb{F}_3$. Let α be the image of x; compute the three conjugates $\alpha, \alpha^3, \alpha^9$ of α under the Frobenius $\sigma : \beta \mapsto \beta^3$, and confirm that they are the three roots of x^3-x+1.

3. List all the subfields of $\mathbb{F}_{2^{30}}$, organized by the divisors of 30, and for each pair determine the containment relation. Identify $\mathbb{F}_{2^a} \cap \mathbb{F}_{2^b}$ and the compositum $\mathbb{F}_{2^a}\mathbb{F}_{2^b}$ for $(a,b) = (6,10)$.

4. Compute the number $N_2(6)$ of monic irreducible polynomials of degree 6 over $\mathbb{F}_2$ using $N_p(n) = \frac{1}{n}\sum_{d\mid n}\mu(d)\,p^{n/d}$, and check your answer against the degree-counting identity $2^6 = \sum_{d\mid 6} d\,N_2(d)$ (you may use $N_2(1)=2, N_2(2)=1, N_2(3)=2$).

5. In $\mathbb{F}_{16} = \mathbb{F}_2(\alpha)$ with $\alpha^4 = \alpha+1$, determine $|\alpha|$ in $\mathbb{F}_{16}^\times$ and decide whether α is a primitive root. How many primitive roots does $\mathbb{F}_{16}$ have, and how many elements have order exactly 3?

6. Factor $x^{3^2} - x = x^9 - x$ into monic irreducibles over $\mathbb{F}_3$, confirm that the factor degrees are exactly the divisors of 2, and check that the degrees sum to 9.

7. Let $\alpha \in \overline{\mathbb{F}_7}$ have minimal polynomial of degree 6 over $\mathbb{F}_7$. Identify $\mathbb{F}_7(\alpha)$ as some $\mathbb{F}_{7^n}$, list which fields $\mathbb{F}_{7^m}$ contain α for $m \le 12$, and state $[\mathbb{F}_7(\alpha) : \mathbb{F}_7]$.

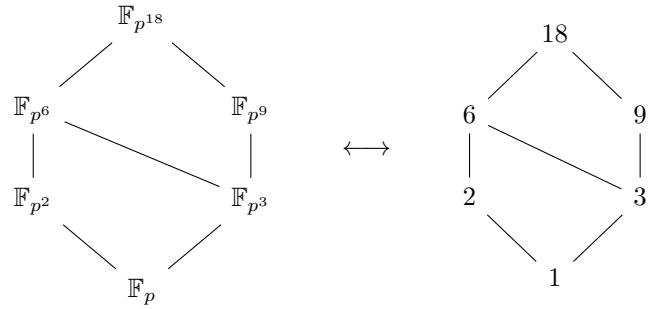
8. Let $\sigma = \mathrm{Frob}_p$ generate $\mathrm{Gal}(\mathbb{F}_{p^{20}}/\mathbb{F}_p) \cong \mathbb{Z}/20\mathbb{Z}$. Compute the order of σ^8, identify the fixed field $\mathrm{Fix}(\langle\sigma^8\rangle)$ as a power of p, and determine $[\mathbb{F}_{p^{20}} : \mathrm{Fix}(\langle\sigma^8\rangle)]$.

Additional exercises.

1. Prove that a finite field $\mathbb{F}_{p^n}$ has a unique subfield of order p^d for each $d \mid n$ and no others, by combining the Fundamental Theorem of Galois Theory with the fact that a cyclic group of order n has exactly one subgroup of each order dividing n. Deduce that the lattice of subfields of $\mathbb{F}_{p^n}$ is order-isomorphic to the divisor lattice of n.

2. Let $\alpha \in \mathbb{F}_{p^n}$ and put $d = [\mathbb{F}_p(\alpha) : \mathbb{F}_p]$. Prove that the minimal polynomial of α over $\mathbb{F}_p$ is $m_{\alpha,\mathbb{F}_p}(x) = \prod_{i=0}^{d-1}\left(x - \alpha^{p^i}\right)$, that d is the least positive integer with $\alpha^{p^d} = \alpha$, and that $d \mid n$. Conclude that the distinct conjugates of α over $\mathbb{F}_p$ are exactly its Frobenius orbit.

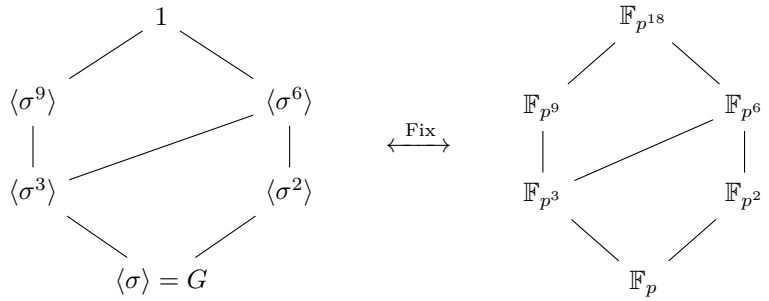
3. Show that the relative extension $\mathbb{F}_{p^n}/\mathbb{F}_{p^d}$ (for $d \mid n$) is Galois with $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d}) = \langle \mathrm{Frob}_{p^d}\rangle = \langle\sigma^d\rangle \cong \mathbb{Z}/(n/d)\mathbb{Z}$, where $\sigma = \mathrm{Frob}_p$. Use this to count the intermediate fields between $\mathbb{F}_{p^d}$ and $\mathbb{F}_{p^n}$ in terms of the divisors of n/d, and apply it to list all intermediate fields of $\mathbb{F}_{2^{12}}/\mathbb{F}_{2^2}$.



4. Prove that the number $N_p(n)$ of monic irreducible polynomials of degree n over $\mathbb{F}_p$ satisfies $N_p(n) = \frac{1}{n}\sum_{d\mid n}\mu(d)\,p^{n/d}$, by applying Mobius inversion to the degree-counting identity $p^n = \sum_{d\mid n} d\,N_p(d)$ that comes from the factorization of $x^{p^n} - x$. Conclude $N_p(n) > 0$ for all $n \ge 1$, hence an irreducible of every degree exists over $\mathbb{F}_p$.

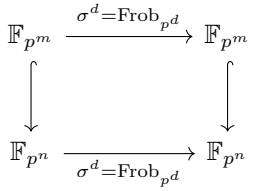
5. Let γ be a generator of $\mathbb{F}_{p^n}^\times$ (a primitive element). Prove $\mathbb{F}_{p^n} = \mathbb{F}_p(\gamma)$ and that the minimal polynomial of γ over $\mathbb{F}_p$ is irreducible of degree n. Then show that an element $\beta \in \mathbb{F}_{p^n}^\times$ is itself a generator if and only if $\mathbb{F}_p(\beta) = \mathbb{F}_{p^n}$ *and* $|\beta| = p^n - 1$, and give an explicit β with $\mathbb{F}_p(\beta) = \mathbb{F}_{p^n}$ that is *not* a primitive root (for a suitable p, n).

Commutative-diagram exercises.



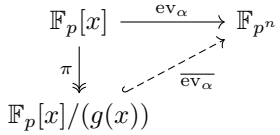
1. Draw the subfield lattice of $\mathbb{F}_{p^{18}}$ alongside the divisor lattice of 18, and prove the labelled correspondence is an order isomorphism (containment of fields matches divisibility of exponents). Complete the skeleton

below:



Label each edge with the relative degree and verify $[\mathbb{F}_{p^6} : \mathbb{F}_{p^2}] = 3$, $[\mathbb{F}_{p^{18}} : \mathbb{F}_{p^9}] = 2$.

2. Let $\sigma = \mathrm{Frob}_p$ and $G = \mathrm{Gal}(\mathbb{F}_{p^{18}}/\mathbb{F}_p) \cong \mathbb{Z}/18\mathbb{Z}$. Complete the subgroup lattice of G and exhibit the inclusion-reversing bijection $H \mapsto \mathrm{Fix}(H)$ with the subfield lattice of the previous problem; prove the correspondence reverses inclusions. Fill in the skeleton:



State the order of each subgroup and confirm $|\langle\sigma^d\rangle| = 18/d$ and $\mathrm{Fix}(\langle\sigma^d\rangle) = \mathbb{F}_{p^d}$.

3. For $d \mid m \mid n$, the relative Frobenius $\sigma^d = \mathrm{Frob}_{p^d}$ generates $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d})$ and commutes with the inclusions. Prove the square below commutes (the horizontal maps are $\beta \mapsto \beta^{p^d}$, the vertical maps the field inclusions), and conclude that Frob_{p^d} on $\mathbb{F}_{p^n}$ restricts to Frob_{p^d} on $\mathbb{F}_{p^m}$:

Then show the restriction map $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_{p^d}) \twoheadrightarrow \mathrm{Gal}(\mathbb{F}_{p^m}/\mathbb{F}_{p^d})$ is the surjection $\mathbb{Z}/(n/d)\mathbb{Z} \twoheadrightarrow \mathbb{Z}/(m/d)\mathbb{Z}$ and identify its kernel.

4. Let $K = \mathbb{F}_{p^n}$ and consider the splitting field $\mathbb{F}_{p^n}$ of $x^{p^n} - x$ over $\mathbb{F}_p$. Complete the diagram showing the evaluation/quotient factorization for a monic irreducible $g(x) \in \mathbb{F}_p[x]$ of degree $d \mid n$ with root $\alpha \in \mathbb{F}_{p^n}$, and prove the induced map is an isomorphism onto $\mathbb{F}_p(\alpha) = \mathbb{F}_{p^d}$:

Identify $\ker(\mathrm{ev}_\alpha)$, explain why the image is exactly $\mathbb{F}_{p^d}$, and use this to justify why $g(x) \mid x^{p^n} - x$ precisely when $d \mid n$.

14.4 Composite Extensions and Simple Extensions

The composite field KL

Inside a fixed field Ω containing both, the *composite* (or *compositum*) of two subfields K and L is the smallest subfield of Ω containing both. It is written KL.

Definition 14.4.1. Let K and L be subfields of a common field Ω. Their *composite* KL is the intersection of all subfields of Ω containing $K \cup L$; equivalently, KL is the subfield generated by K and L. If $K = F(\alpha_1, \dots, \alpha_r)$ and $L = F(\beta_1, \dots, \beta_s)$ over a common base F, then $KL = F(\alpha_1, \dots, \alpha_r, \beta_1, \dots, \beta_s)$.

The composite is not a direct product: $[KL : F]$ is generally smaller than $[K : F] \cdot [L : F]$, with equality only when K and L are "independent" over F. The whole point of the section is to measure the deficit precisely. The first bound is elementary and comes from extending a spanning set.

Proposition 14.4.2 (degree of a composite)**.** *Let K, L be finite extensions of F inside Ω. Then*

$$[KL : F] \le [K : F] \cdot [L : F],$$

and $[KL : L] \le [K : F]$. If $[K : F]$ and $[L : F]$ are coprime, then $[KL : F] = [K : F] \cdot [L : F]$.

Idea. If $\alpha_1, \dots, \alpha_m$ is an F-basis of K, then $K = F(\alpha_1, \dots, \alpha_m)$, so $KL = L(\alpha_1, \dots, \alpha_m)$ is spanned over L by the α_i (each α_i is algebraic over L of degree $\le m$, and products reduce via the relations over F). Hence $[KL : L] \le m = [K : F]$. Multiplying by $[L : F]$ via the tower $F \subseteq L \subseteq KL$ gives the first inequality. For the coprime case, $[K : F]$ and $[L : F]$ both divide $[KL : F]$ (each is the degree of a subextension), so their lcm $= [K : F][L : F]$ divides $[KL : F]$; combined with the upper bound, equality holds. □

Worked Example 14.4.3 (Composite of coprime-degree fields)**.** With $K = \mathbb{Q}(\sqrt[3]{2})$ and $L = \mathbb{Q}(\sqrt{2})$, compute $[KL : \mathbb{Q}]$.

Recognition. $[K : \mathbb{Q}] = 3$ and $[L : \mathbb{Q}] = 2$ are coprime, so the proposition forces the composite to have the full product degree.

Solution. $[K : \mathbb{Q}] = 3$ (minimal polynomial $x^3 - 2$) and $[L : \mathbb{Q}] = 2$ (minimal polynomial $x^2 - 2$). Since $\gcd(3, 2) = 1$, $[KL : \mathbb{Q}] = 3 \cdot 2 = 6$, and $KL = \mathbb{Q}(\sqrt[3]{2}, \sqrt{2})$. Sanity check: $3 \mid [KL : \mathbb{Q}]$ and $2 \mid [KL : \mathbb{Q}]$, so $6 \mid [KL : \mathbb{Q}]$; the upper bound $[KL : \mathbb{Q}] \le 6$ then pins it to exactly 6. Equivalently $x^3 - 2$ stays irreducible over $\mathbb{Q}(\sqrt{2})$ (a degree-3 polynomial with no root in the degree-2 field $\mathbb{Q}(\sqrt{2})$).

Worked Example 14.4.4 (When the product bound is not attained)**.** Take $K = \mathbb{Q}(\sqrt{2})$ and $L = \mathbb{Q}(\sqrt{2})$ (or $L = \mathbb{Q}(\sqrt{8})$). Compute $[KL : \mathbb{Q}]$ and compare to $[K : \mathbb{Q}][L : \mathbb{Q}]$.

Recognition. If $K \subseteq L$ then $KL = L$, so the degree of the composite collapses; the product bound is a strict overestimate.

Solution. Here $\sqrt{8} = 2\sqrt{2} \in \mathbb{Q}(\sqrt{2})$, so $L = \mathbb{Q}(\sqrt{8}) = \mathbb{Q}(\sqrt{2}) = K$ and $KL = K$, giving $[KL : \mathbb{Q}] = 2$. But $[K : \mathbb{Q}][L : \mathbb{Q}] = 2 \cdot 2 = 4$. Sanity check: the deficit is explained by $K \cap L = \mathbb{Q}(\sqrt{2})$ being as large as possible; the next theorem will show $[KL : L] = [K : K \cap L] = [K : K] = 1$, consistent with $KL = L$.

Galois over the bottom of a diamond

The central theorem of the section says that adjoining an arbitrary extension L to a Galois extension K/F is "free": the composite KL is Galois over L, and its Galois group is a faithful copy of part of $\mathrm{Gal}(K/F)$ – precisely the part that does not already live in L. The deficit measured above is governed entirely by $K \cap L$.

Theorem 14.4.5 (Galois group of a composite over the top extension)**.** *Let K/F be Galois and let L/F be any extension, both inside a common field Ω. Then KL/L is Galois, and restriction to K defines an isomorphism*

$$\mathrm{Gal}(KL/L) \xrightarrow{\ \cong\ } \mathrm{Gal}\big(K/(K \cap L)\big), \qquad \sigma \longmapsto \sigma|_K.$$

In particular

$$[KL : L] = \big[K : K \cap L\big].$$

Idea. Since K is the splitting field of a separable polynomial $f \in F[x]$ over F, KL is the splitting field of the same f over L, hence KL/L is Galois. Each $\sigma \in \mathrm{Gal}(KL/L)$ fixes $L \supseteq F$ and permutes the roots of f, so it maps K to K; restriction $\sigma \mapsto \sigma|_K$ is therefore a homomorphism $\mathrm{Gal}(KL/L) \to \mathrm{Gal}(K/F)$. It is *injective* because KL is generated by K and L, so an automorphism fixing L and fixing K pointwise is the identity. Its image is a subgroup $H \leq \mathrm{Gal}(K/F)$, and $\mathrm{Fix}(H)$ in K consists of the elements of K fixed by everything in $\mathrm{Gal}(KL/L)$, namely $K \cap L$ (anything in K fixed by all of $\mathrm{Gal}(KL/L)$ lies in $\mathrm{Fix}(\mathrm{Gal}(KL/L)) = L$, and conversely). By the Fundamental Theorem applied to K/F, $H = \mathrm{Gal}(K/(K \cap L))$, giving the isomorphism; counting orders yields $[KL : L] = |H| = [K : K \cap L]$. □

The picture to memorize is the *diamond*: KL on top, K and L on the two sides, $K \cap L$ at the bottom. The two slanted edges drawn with the *same* relative degree are the two "equal" sides of the parallelogram.

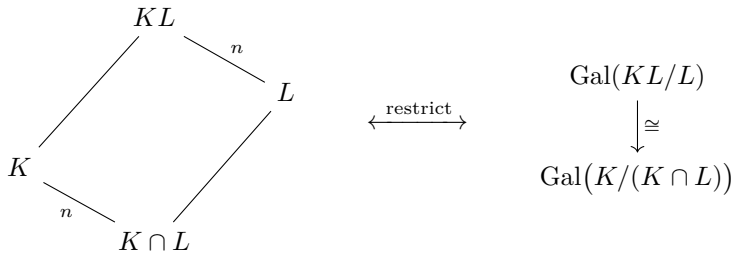


Diagram explanation. Objects: The left lattice has four field nodes: KL (composite, at the top), K (lower-left, a Galois extension of F), L (upper-right, an arbitrary extension of F), and $K \cap L$ (intersection field, at the bottom). The right diagram has two group nodes: $\mathrm{Gal}(KL/L)$ (the full automorphism group of the composite fixing L) and $\mathrm{Gal}(K/(K \cap L))$ (the subgroup of $\mathrm{Gal}(K/F)$ fixing the intersection $K \cap L$).

Arrows: In the lattice, each dash denotes a field extension (going upward by convention); the two short edges KL/L and $K/(K \cap L)$ carry the same label n, their common degree $n = [KL : L] = [K : K \cap L]$. The double-headed arrow $\xleftrightarrow{\text{restrict}}$ between the two diagrams signals that the correspondence is given by restriction. The downward arrow labeled $\cong$ is the restriction homomorphism $\sigma \mapsto \sigma|_K$, which the theorem asserts is a group isomorphism.

What commutes: The key equality is that the restriction map $\mathrm{Gal}(KL/L) \to \mathrm{Gal}(K/F)$, $\sigma \mapsto \sigma|_K$, lands inside $\mathrm{Gal}(K/(K \cap L))$ and is an isomorphism onto it: $\mathrm{im}(\text{restrict}) = \mathrm{Gal}(K/(K \cap L))$. Equivalently, the two "equal-length" sides of the diamond satisfy $[KL : L] = [K : K \cap L]$.

Why it commutes: Take any $\sigma \in \mathrm{Gal}(KL/L)$. Because K/F is normal, σ maps K into K, so $\sigma|_K \in \mathrm{Gal}(K/F)$. An element of K fixed by every such $\sigma|_K$ is also fixed by every element of $\mathrm{Gal}(KL/L)$, placing it in L; so it lies in $K \cap L$. Conversely, any element of $K \cap L$ is already fixed by $\mathrm{Gal}(KL/L)$ (which fixes L pointwise). Hence $\mathrm{Fix}(\mathrm{im}(\text{restrict})) = K \cap L$, and by the Fundamental Theorem of Galois Theory applied to K/F, the image equals $\mathrm{Gal}(K/(K \cap L))$. Injectivity: if $\sigma|_K = \mathrm{id}_K$ and $\sigma|_L = \mathrm{id}_L$, then $\sigma = \mathrm{id}_{KL}$ since K and L generate KL.

Why this matters here: This diagram is the geometric core of the theorem: it says the "missing" automorphisms of KL/L (compared to all of $\mathrm{Gal}(K/F)$) are exactly those in $\mathrm{Gal}(K/F)$ that already fix the overlap $K \cap L$. The restriction isomorphism converts a question about the composite into a question about an intermediate field of the Galois extension K/F, which we can read off from the Galois correspondence.

Concrete example: Take $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$ (Galois, group $(\mathbb{Z}/2\mathbb{Z})^2$) and $L = \mathbb{Q}(\sqrt{3})$. Then $KL = K$, $K \cap L = \mathbb{Q}(\sqrt{3})$, and $\mathrm{Gal}(KL/L) = \mathrm{Gal}(K/\mathbb{Q}(\sqrt{3})) \cong \mathbb{Z}/2\mathbb{Z}$, generated by $\sqrt{2} \mapsto -\sqrt{2}$. The restriction isomorphism matches this copy of $\mathbb{Z}/2\mathbb{Z}$ with $\mathrm{Gal}(K/\mathbb{Q}(\sqrt{3}))$, exactly the subgroup of $\mathrm{Gal}(K/\mathbb{Q})$ fixing $\sqrt{3}$.

Common pitfall: Students often confuse $\mathrm{Gal}(KL/L)$ with $\mathrm{Gal}(K/F)$. The restriction map is *injective*, not surjective in general: those automorphisms in $\mathrm{Gal}(K/F)$ that already fix everything in L – i.e., those in $\mathrm{Gal}(K/(K \cap L))$ – are the ones that extend to KL fixing L; the rest do not extend. Do not assume $\mathrm{Gal}(KL/L) \cong \mathrm{Gal}(K/F)$ unless $K \cap L = F$.

Takeaway: The point of this diagram is that restricting automorphisms of the composite KL/L to K is an isomorphism onto the Galois group of K over the overlap, so the "size" of the composite extension is governed entirely by how much K and L share at the bottom.

The two short edges KL/L and $K/(K\cap L)$ have equal degree; so do the two long edges KL/K and $L/(K\cap L)$ whenever L/F is also finite, with no Galois hypothesis on L/F: dividing the corollary below by $[K:F]$ gives $[KL:K]=[L:F]/[K\cap L:F]=[L:K\cap L]$.

Corollary 14.4.6 (degree of the composite, Galois case)**.** *If K/F is Galois of finite degree and L/F is finite, then*

$$[KL:F]=\frac{[K:F]\cdot[L:F]}{[K\cap L:F]}.$$

Idea. Use the tower $F\subseteq L\subseteq KL$: $[KL:F]=[KL:L]\,[L:F]=[K:K\cap L]\,[L:F]$ by the theorem. Then $[K:K\cap L]=[K:F]/[K\cap L:F]$ from the tower $F\subseteq K\cap L\subseteq K$. Substitute. □

Method (To compute $[KL:F]$ when K/F is Galois: find $K\cap L$ first, then $[KL:L]=[K:K\cap L]$, and lift through the tower $F\subseteq L\subseteq KL$.)**.** The intersection $K\cap L$ is an intermediate field of the Galois extension K/F, so it corresponds to a subgroup of $\mathrm{Gal}(K/F)$; its degree over F divides $[K:F]$. Pinning down $K\cap L$ usually means finding which subfields of K happen to lie in L – often via degree constraints (only fields of degree dividing $\gcd([K:F],[L:F])$ can occur).

Worked Example 14.4.7 ($\mathbb{Q}(\sqrt2,\sqrt3)$ over $\mathbb{Q}(\sqrt3)$ via the diamond)**.** With $K=\mathbb{Q}(\sqrt2,\sqrt3)$ Galois over $\mathbb{Q}$ and $L=\mathbb{Q}(\sqrt3)$, recompute $[KL:L]$ from the theorem.

Recognition. $K/\mathbb{Q}$ is Galois (splitting field of $(x^2-2)(x^2-3)$); apply $[KL:L]=[K:K\cap L]$ with $L=\mathbb{Q}(\sqrt3)\subseteq K$.

Solution. Here $L=\mathbb{Q}(\sqrt3)\subseteq K$, so $KL=K$ and $K\cap L=L=\mathbb{Q}(\sqrt3)$. The theorem gives $[KL:L]=[K:K\cap L]=[K:\mathbb{Q}(\sqrt3)]=4/2=2$, and $\mathrm{Gal}(KL/L)=\mathrm{Gal}(K/\mathbb{Q}(\sqrt3))\cong\mathbb{Z}/2\mathbb{Z}$, generated by $\sqrt2\mapsto-\sqrt2$ (fixing $\sqrt3$). Sanity check: $[KL:\mathbb{Q}]=[KL:L][L:\mathbb{Q}]=2\cdot2=4=[K:\mathbb{Q}]$, consistent with $KL=K$.

Worked Example 14.4.8 (A nontrivial intersection forces a degree drop)**.** Let $K=\mathbb{Q}(\sqrt2,\sqrt3)$ and $L=\mathbb{Q}(\sqrt6)$. Compute $K\cap L$, then $[KL:L]$ and $[KL:\mathbb{Q}]$.

Recognition. $K/\mathbb{Q}$ is Galois with group $(\mathbb{Z}/2\mathbb{Z})^2$; $\sqrt6=\sqrt2\sqrt3\in K$, so $L\subseteq K$ and $K\cap L=L$. Apply the corollary.

Solution. Since $\sqrt6=\sqrt2\cdot\sqrt3\in K$, we have $L=\mathbb{Q}(\sqrt6)\subseteq K$, so $K\cap L=\mathbb{Q}(\sqrt6)$, of degree 2 over $\mathbb{Q}$. Then $[KL:L]=[K:K\cap L]=4/2=2$ and $KL=K$, so $[KL:\mathbb{Q}]=4$. By the corollary, $[KL:\mathbb{Q}]=[K:\mathbb{Q}][L:\mathbb{Q}]/[K\cap L:\mathbb{Q}]=4\cdot2/2=4$, agreeing. Sanity check: the three quadratic subfields of K are $\mathbb{Q}(\sqrt2),\mathbb{Q}(\sqrt3),\mathbb{Q}(\sqrt6)$, matching the three index-2 subgroups of $(\mathbb{Z}/2\mathbb{Z})^2$; $\mathbb{Q}(\sqrt6)$ is one of them, so indeed $L\subseteq K$.

Worked Example 14.4.9 (Composite of two cyclotomic fields)**.** Let $K=\mathbb{Q}(\zeta_3)$ and $L=\mathbb{Q}(\zeta_4)=\mathbb{Q}(i)$. Compute $K\cap L$ and $[KL:\mathbb{Q}]$.

Recognition. Both are Galois over $\mathbb{Q}$ (abelian). $K=\mathbb{Q}(\zeta_3)$ has degree 2, $L=\mathbb{Q}(i)$ has degree 2; the intersection is a common quadratic subfield, if any.

Solution. $\mathbb{Q}(\zeta_3)=\mathbb{Q}(\sqrt{-3})$ and $\mathbb{Q}(i)=\mathbb{Q}(\sqrt{-1})$ are distinct quadratic fields, so $K\cap L$ is a field whose degree over $\mathbb{Q}$ divides $\gcd(2,2)=2$ and is contained in both. If $K\cap L$ had degree 2 it would equal both K and L, forcing $\sqrt{-3}\in\mathbb{Q}(i)$, false. Hence $K\cap L=\mathbb{Q}$. Therefore $[KL:L]=[K:\mathbb{Q}]=2$ and $[KL:\mathbb{Q}]=2\cdot2=4$; indeed $KL=\mathbb{Q}(\zeta_3,i)=\mathbb{Q}(\zeta_{12})$, of degree $\varphi(12)=4$. Sanity check: $\varphi(12)=\varphi(4)\varphi(3)=2\cdot2=4$, and the corollary gives $[K:\mathbb{Q}][L:\mathbb{Q}]/[K\cap L:\mathbb{Q}]=4/1=4$. Both routes agree.

Worked Example 14.4.10 (Reading the restriction isomorphism explicitly)**.** With $K=\mathbb{Q}(\sqrt2,\sqrt3)$ and $L=\mathbb{Q}(\sqrt5)$, identify $\mathrm{Gal}(KL/L)$ and how each element acts.

Recognition. $K\cap L=\mathbb{Q}$ here ($\sqrt5\notin K$ and no quadratic subfield of K equals $\mathbb{Q}(\sqrt5)$), so $\mathrm{Gal}(KL/L)\cong\mathrm{Gal}(K/\mathbb{Q})\cong(\mathbb{Z}/2\mathbb{Z})^2$ via restriction.

Solution. The quadratic subfields of K are $\mathbb{Q}(\sqrt2),\mathbb{Q}(\sqrt3),\mathbb{Q}(\sqrt6)$, none equal to $\mathbb{Q}(\sqrt5)$; so $K\cap L=\mathbb{Q}$ since no degree-2 subfield of K contains $\sqrt5$. Thus restriction gives $\mathrm{Gal}(KL/L)\cong\mathrm{Gal}(K/\mathbb{Q})=\{\,\mathrm{id},\ \sigma,\ \tau,\ \sigma\tau\,\}$ where $\sigma:\sqrt2\mapsto-\sqrt2,\sqrt3\mapsto\sqrt3$ and $\tau:\sqrt2\mapsto\sqrt2,\sqrt3\mapsto-\sqrt3$; over L every one of these additionally fixes $\sqrt5$. Sanity check: $[KL:L]=|(\mathbb{Z}/2\mathbb{Z})^2|=4$, so $[KL:\mathbb{Q}]=4\cdot2=8=[K:\mathbb{Q}][L:\mathbb{Q}]/[K\cap L:\mathbb{Q}]=4\cdot2/1$, consistent.

Composite of two Galois extensions

When *both* extensions are Galois the diamond becomes symmetric: the composite is Galois over the base, and its group embeds into the product of the two groups, cut out by the single compatibility condition of agreeing on the intersection.

Theorem 14.4.11 (Galois group of a composite of two Galois extensions)**.** *Let K/F and K'/F both be Galois (inside a common Ω). Then:*

(1) *KK'/F is Galois, and $K \cap K'/F$ is Galois.*

(2) *The map $\sigma \mapsto (\sigma|_K,\ \sigma|_{K'})$ is an injective homomorphism*

$$\mathrm{Gal}(KK'/F) \ \hookrightarrow\ \mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F),$$

with image

$$\{\,(s,t) :\ s|_{K\cap K'} = t|_{K\cap K'}\,\}.$$

(3) *This embedding is onto the full product if and only if $K \cap K' = F$. In that case* $\mathrm{Gal}(KK'/F) \cong \mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)$.

Idea. K and K' are splitting fields of separable $f, g \in F[x]$; their composite KK' is the splitting field over F of the separable polynomial $\mathrm{lcm}(f, g)$ (it has the same roots as fg, each simple), hence Galois. An automorphism σ of KK' over F maps $K \to K$ and $K' \to K'$ (each is normal over F), so $\sigma \mapsto (\sigma|_K, \sigma|_{K'})$ is a homomorphism into the product. It is injective because K and K' generate KK', so fixing both restrictions forces $\sigma = \mathrm{id}$. A pair (s, t) extends to KK' iff s and t are compatible where K and K' overlap, i.e. on $K \cap K'$; this is the agreement condition. Counting: the image has order $[K : F][K' : F]/[K \cap K' : F]$, matching $[KK' : F]$ from the previous corollary. Surjectivity onto the full product happens exactly when the agreement condition is vacuous, i.e. $\mathrm{Gal}(K \cap K'/F)$ is trivial, i.e. $K \cap K' = F$. □

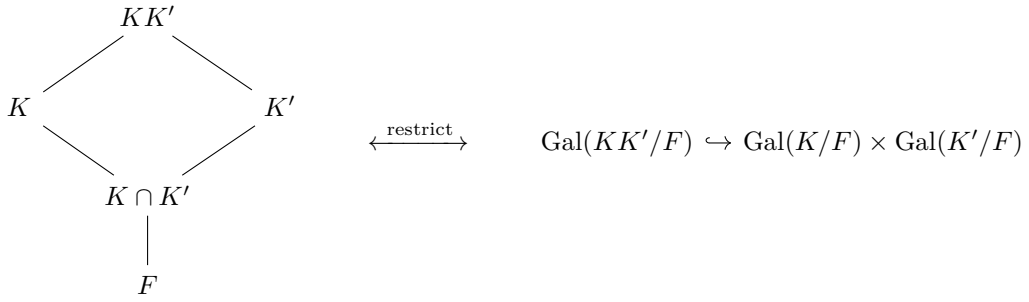

Diagram explanation. Objects: The left lattice has five field nodes: KK' (composite, top), K (upper-left, Galois over F), K' (upper-right, also Galois over F), $K \cap K'$ (intersection, middle, also Galois over F), and F (ground field, bottom). The right diagram has two group nodes: $\mathrm{Gal}(KK'/F)$ (the full Galois group of the composite) and $\mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)$ (the direct product of the two individual Galois groups).

Arrows: Each dash in the lattice is a field extension. The hook $\hookrightarrow$ in the right diagram is the injective group homomorphism $\sigma \mapsto (\sigma|_K,\ \sigma|_{K'})$; the theorem says it is injective but not surjective in general. Its image consists exactly of the pairs (s, t) with $s|_{K\cap K'} = t|_{K\cap K'}$.

What commutes: Surjectivity onto the full product is the key path-equality question: $\mathrm{Gal}(KK'/F) \xrightarrow{\cong} \mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)$ holds if and only if $K \cap K' = F$. In the general case, the image is $\{\,(s,t) : s|_{K\cap K'} = t|_{K\cap K'}\,\}$, and the subgroup has index $|\,\mathrm{Gal}(K \cap K'/F)| = [K \cap K' : F]$ in the full product.

Why it commutes: Take $\sigma \in \mathrm{Gal}(KK'/F)$. Since K/F is normal, $\sigma(K) = K$; similarly $\sigma(K') = K'$. So the map $\sigma \mapsto (\sigma|_K, \sigma|_{K'})$ lands in $\mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)$. It is injective: if $\sigma|_K = \mathrm{id}_K$ and $\sigma|_{K'} = \mathrm{id}_{K'}$, then σ fixes both generators of KK', so $\sigma = \mathrm{id}_{KK'}$. A pair (s, t) in the product extends to KK' iff s and t agree on the overlap $K \cap K'$, because an element of $K \cap K'$ is simultaneously in K (where s would act) and in K' (where t would act); unless $s|_{K\cap K'} = t|_{K\cap K'}$, the proposed extension is inconsistent on $K \cap K'$.

Why this matters here: This diagram is the conclusion of the theorem for the symmetric case (both extensions Galois). It encodes the structure theorem: $\mathrm{Gal}(KK'/F)$ is not the full product but a fiber product over $\mathrm{Gal}(K \cap K'/F)$. Knowing this sub-diamond determines both $[KK' : F]$ and the group structure of $\mathrm{Gal}(KK'/F)$ without computing the composite directly.

Concrete example: Let $K = \mathbb{Q}(\sqrt{2})$ and $K' = \mathbb{Q}(\sqrt{3})$, both Galois of degree 2 over $\mathbb{Q}$. Then $K \cap K' = \mathbb{Q}$, the agreement condition on $\mathrm{Gal}(\mathbb{Q}/\mathbb{Q}) = \{\,\mathrm{id}\,\}$ is vacuous, and the injection is onto: $\mathrm{Gal}(KK'/\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ with generators $\sqrt{2} \mapsto -\sqrt{2}$ and $\sqrt{3} \mapsto -\sqrt{3}$ acting independently. The lattice is the Klein-four diamond with $F = \mathbb{Q}$ at the bottom.

Common pitfall: The injection $\mathrm{Gal}(KK'/F) \hookrightarrow \mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)$ is *never* surjective when $K \cap K' \supsetneq F$, because a pair (s, t) with $s|_{K\cap K'} \neq t|_{K\cap K'}$ cannot extend to any automorphism of KK' at all. Students sometimes compute $|\,\mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)| = [K : F][K' : F]$ and conclude $[KK' : F] = [K : F][K' : F]$; this fails when $[K \cap K' : F] > 1$, and the correct count is $[K : F][K' : F]/[K \cap K' : F]$.

Takeaway: The point of this diagram is that when both K/F and K'/F are Galois, the Galois group of their composite is the fiber product of the two individual groups over the Galois group of the intersection, so the structure of $\mathrm{Gal}(KK'/F)$ is completely determined by how much the two extensions overlap at $K \cap K'$.

Corollary 14.4.12 (intersection is the base)**.** *If K/F and K'/F are Galois with $K \cap K' = F$, then*

$$[KK' : F] = [K : F] \cdot [K' : F], \qquad \mathrm{Gal}(KK'/F) \cong \mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F).$$

Worked Example 14.4.13 (An explicit (s, t)-agreement computation)**.** Let $K = \mathbb{Q}(\zeta_3, \sqrt[3]{2})$ (splitting field of $x^3 - 2$) and $K' = \mathbb{Q}(\zeta_3)$. Determine which pairs $(s, t) \in \mathrm{Gal}(K/\mathbb{Q}) \times \mathrm{Gal}(K'/\mathbb{Q})$ occur in $\mathrm{Gal}(KK'/\mathbb{Q})$.

Recognition. Both K, K' are Galois over $\mathbb{Q}$; the image of $\mathrm{Gal}(KK'/\mathbb{Q})$ in the product is the agreement set on $K \cap K'$. Since $K' = \mathbb{Q}(\zeta_3) \subseteq K$, the intersection is $\mathbb{Q}(\zeta_3)$, which is nontrivial.

Solution. Here $K \cap K' = \mathbb{Q}(\zeta_3) = K'$, so $KK' = K$. The condition "$s|_{K\cap K'} = t|_{K\cap K'}$" says $s|_{\mathbb{Q}(\zeta_3)} = t$ (since t is already an automorphism of all of $K' = \mathbb{Q}(\zeta_3)$). Thus a pair (s, t) occurs iff t equals the restriction of s to $\mathbb{Q}(\zeta_3)$ – i.e. t is *determined* by s. Writing $\mathrm{Gal}(K/\mathbb{Q}) \cong S_3$ with the quotient map $S_3 \to \mathrm{Gal}(\mathbb{Q}(\zeta_3)/\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z}$ (sending each automorphism to its effect $\zeta_3 \mapsto \zeta_3$ or $\zeta_3 \mapsto \zeta_3^2$), the allowed pairs are exactly $\{\,(s,\ \overline{s}) : s \in S_3\,\}$ where $\overline{s}$ is the image of s. Sanity check: the agreement set has order $|S_3| = 6 = [KK' : \mathbb{Q}] = [K : \mathbb{Q}]$, matching $KK' = K$; were we to demand the *full* product we would need order $6 \cdot 2 = 12$, impossible since $K \cap K' \neq \mathbb{Q}$.

Worked Example 14.4.14 (Full product when the intersection is $\mathbb{Q}$)**.** Let $K = \mathbb{Q}(\sqrt{2})$ and $K' = \mathbb{Q}(\sqrt{3})$. Show $\mathrm{Gal}(KK'/\mathbb{Q}) \cong \mathrm{Gal}(K/\mathbb{Q}) \times \mathrm{Gal}(K'/\mathbb{Q})$.

Recognition. Both Galois of degree 2; $K \cap K' = \mathbb{Q}$ (distinct quadratic fields), so the embedding is onto the full product.

Solution. $K \cap K'$ is a subfield of $\mathbb{Q}(\sqrt{2})$ and of $\mathbb{Q}(\sqrt{3})$; if it were larger than $\mathbb{Q}$ it would be all of K and of K', forcing $\sqrt{2} \in \mathbb{Q}(\sqrt{3})$, false. So $K \cap K' = \mathbb{Q}$ and by the corollary $\mathrm{Gal}(KK'/\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, with the four elements determined by independent sign choices on $\sqrt{2}$ and $\sqrt{3}$. Sanity check: $[KK' : \mathbb{Q}] = 2 \cdot 2 = 4$, and $KK' = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, the Klein-four Galois extension; the agreement condition is vacuous because $K \cap K' = \mathbb{Q}$ has trivial Galois group.

Worked Example 14.4.15 (Recovering $[KK' : F]$ from the intersection)**.** Let $K = \mathbb{Q}(\zeta_8)$ and $K' = \mathbb{Q}(\sqrt{2})$. Compute $K \cap K'$, $[KK' : \mathbb{Q}]$, and $\mathrm{Gal}(KK'/\mathbb{Q})$.

Recognition. $\mathbb{Q}(\zeta_8)$ is Galois of degree 4 and contains $\sqrt{2} = \zeta_8 + \zeta_8^{-1}$; so $K' = \mathbb{Q}(\sqrt{2}) \subseteq K$ and $K \cap K' = K'$.

Solution. Since $\zeta_8 = e^{2\pi i/8}$, $\zeta_8 + \zeta_8^{-1} = 2\cos(\pi/4) = \sqrt{2}$, so $\sqrt{2} \in \mathbb{Q}(\zeta_8)$ and $K' \subseteq K$. Then $K \cap K' = \mathbb{Q}(\sqrt{2})$, of degree 2, $KK' = K = \mathbb{Q}(\zeta_8)$, and $[KK' : \mathbb{Q}] = 4$. The corollary's formula gives $[K : \mathbb{Q}][K' : \mathbb{Q}]/[K \cap K' : \mathbb{Q}] = 4 \cdot 2/2 = 4$, agreeing. As $\mathrm{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8\mathbb{Z})^\times \cong (\mathbb{Z}/2\mathbb{Z})^2$, we get $\mathrm{Gal}(KK'/\mathbb{Q}) \cong (\mathbb{Z}/2\mathbb{Z})^2$. Sanity check: the embedding into $\mathrm{Gal}(K/\mathbb{Q}) \times \mathrm{Gal}(K'/\mathbb{Q})$ of orders 4 and 2 would give a product of order 8, but the agreement on $K \cap K' = \mathbb{Q}(\sqrt{2})$ (a degree-2 condition) cuts it to $8/2 = 4$, exactly $[KK' : \mathbb{Q}]$.

The primitive element theorem

A finite extension K/F is *simple* if $K = F(\gamma)$ for a single γ, called a *primitive element*. Adjoining one element is the cleanest possible description of an extension, and for separable extensions it is always available.

Theorem 14.4.16 (the primitive element theorem)**.** *If K/F is a finite* separable *extension, then $K = F(\gamma)$ for some $\gamma \in K$; that is, K/F is simple. In particular every finite extension of a field of characteristic* 0*, and every finite extension of a finite field, is simple.*

Idea. Two cases. *Finite base field:* then K is a finite field, and its multiplicative group $K^\times$ is cyclic; any generator γ of $K^\times$ satisfies $K = F(\gamma)$, since $F(\gamma) \supseteq \langle\gamma\rangle \cup \{0\} = K$. *Infinite base field:* it suffices to treat $K = F(\alpha, \beta)$ (then induct on the number of generators). Let M be a Galois closure of K/F; the intermediate fields of K/F correspond to subgroups of the finite group $\mathrm{Gal}(M/F)$, so there are only *finitely many* of them. For $c \in F$ consider $\gamma_c = \alpha + c\beta$. If $F(\gamma_c) = F(\gamma_{c'})$ for $c \neq c'$, then this field contains $\gamma_c - \gamma_{c'} = (c - c')\beta$, hence β, hence α, hence equals K. Since F is infinite and there are only finitely many subfields, two distinct values c, c' must give the same $F(\gamma_c)$; that common field is K, so $K = F(\alpha + c\beta)$ for that c. □

Remark 14.4.1. The classical Lagrange recipe makes the infinite-field argument constructive. Let $\alpha = \alpha_1, \ldots, \alpha_m$ and $\beta = \beta_1, \ldots, \beta_n$ be the distinct roots (in a splitting field) of the minimal polynomials of α and β, with β separable so the β_j are distinct. Choose $c \in F$ avoiding the finitely many "bad" values $c = (\alpha_i - \alpha)/(\beta - \beta_j)$ for $j \neq 1$. Then $\gamma = \alpha + c\beta$ has the property that the polynomials $m_{\beta,F}(x)$ and $m_{\alpha,F}(\gamma - cx)$, both in $F(\gamma)[x]$, share exactly the one common root $x = \beta$ in the splitting field (a simple root of $m_{\beta,F}$), so their gcd in $F(\gamma)[x]$ is $x - \beta$ and $\beta \in F(\gamma)$, hence $\alpha \in F(\gamma)$, and $F(\gamma) = F(\alpha, \beta)$.

Method (To produce a primitive element of $F(\alpha, \beta)$ over an infinite F: try $\gamma = \alpha + c\beta$ for small integers c, and verify $[F(\gamma) : F] = [F(\alpha, \beta) : F]$.)**.** Pick $c = 1$ first. Confirm success by computing $\deg(\gamma)$ over F (e.g. exhibit the minimal polynomial, or show $\alpha, \beta \in F(\gamma)$ separately). Only the finitely many c making two conjugate combinations collide are forbidden, so almost any choice works.

Worked Example 14.4.17 ($\mathbb{Q}(\sqrt{2}, \sqrt{3}) = \mathbb{Q}(\sqrt{2} + \sqrt{3})$ with minimal polynomial $x^4 - 10x^2 + 1$)**.** Show $\gamma = \sqrt{2} + \sqrt{3}$ is primitive for $\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$ and find its minimal polynomial.

Recognition. The extension is separable (characteristic 0), so a primitive element exists; try $\gamma = \sqrt{2} + \sqrt{3}$ and check $\deg_{\mathbb{Q}} \gamma = 4 = [\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}]$.

Solution. First show $\mathbb{Q}(\gamma) = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Clearly $\mathbb{Q}(\gamma) \subseteq \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Conversely, $\gamma^2 = 2 + 2\sqrt{6} + 3 = 5 + 2\sqrt{6}$, so $\sqrt{6} = (\gamma^2 - 5)/2 \in \mathbb{Q}(\gamma)$. Then $\gamma \cdot \sqrt{6} = (\sqrt{2} + \sqrt{3})\sqrt{6} = \sqrt{12} + \sqrt{18} = 2\sqrt{3} + 3\sqrt{2}$, and combined with $\gamma = \sqrt{2} + \sqrt{3}$ we solve the linear system $\sqrt{2} + \sqrt{3} = \gamma$, $3\sqrt{2} + 2\sqrt{3} = \gamma\sqrt{6}$ to get $\sqrt{2} = \gamma\sqrt{6} - 2\gamma \in \mathbb{Q}(\gamma)$ and $\sqrt{3} = 3\gamma - \gamma\sqrt{6} \in \mathbb{Q}(\gamma)$. Hence $\mathbb{Q}(\gamma) = \mathbb{Q}(\sqrt{2}, \sqrt{3})$, degree 4. Now the minimal polynomial: from $\gamma^2 = 5 + 2\sqrt{6}$ we get $\gamma^2 - 5 = 2\sqrt{6}$, square to get $(\gamma^2 - 5)^2 = 24$, i.e. $\gamma^4 - 10\gamma^2 + 25 = 24$, so

$$\gamma^4 - 10\gamma^2 + 1 = 0.$$

This monic quartic has γ as a root and degree $4 = \deg_{\mathbb{Q}} \gamma$, so it is the minimal polynomial (it is therefore irreducible over $\mathbb{Q}$). Sanity check: the four roots $\pm\sqrt{2} \pm \sqrt{3}$ are the conjugates of γ; their sum is 0 (matching the missing x^3 term) and their product is $(\sqrt{2} + \sqrt{3})(\sqrt{2} - \sqrt{3})(-\sqrt{2} + \sqrt{3})(-\sqrt{2} - \sqrt{3}) = (2 - 3)(2 - 3) = 1$ (matching the constant term $+1$). The sum of products of pairs is -10, matching the x^2 coefficient.

Worked Example 14.4.18 (A primitive element for $\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$)**.** Exhibit a single generator for $\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})/\mathbb{Q}$ and state its degree.

Recognition. Separable of degree 8; iterate the two-generator construction, or take $\gamma = \sqrt{2} + \sqrt{3} + \sqrt{5}$ and check $\deg_{\mathbb{Q}} \gamma = 8$.

Solution. Set $\gamma = \sqrt{2} + \sqrt{3} + \sqrt{5}$. The Galois group $(\mathbb{Z}/2\mathbb{Z})^3$ acts by independent sign changes on $\sqrt{2}, \sqrt{3}, \sqrt{5}$, producing 8 distinct images $\pm\sqrt{2} \pm \sqrt{3} \pm \sqrt{5}$ of γ (distinct because $\sqrt{2}, \sqrt{3}, \sqrt{5}, 1$ are linearly independent over $\mathbb{Q}$, so no two sign patterns give the same value). Since γ has 8 distinct conjugates, $\deg_{\mathbb{Q}} \gamma = 8 = [\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}]$, hence $\mathbb{Q}(\gamma) = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$. Sanity check: only an element moved nontrivially by every nonidentity automorphism can have 8 conjugates; γ qualifies since flipping any nonempty set of signs changes its value (by the linear independence above), so its stabilizer in $(\mathbb{Z}/2\mathbb{Z})^3$ is trivial and its orbit has full size 8.

Worked Example 14.4.19 (Primitive element of a finite field)**.** Show $\mathbb{F}_{16} = \mathbb{F}_2(\gamma)$ for a generator γ of $\mathbb{F}_{16}^\times$, and contrast with the infinite-field method.

Recognition. Finite base field: use the cyclic-multiplicative-group case of the theorem – a generator of $K^\times$ is automatically primitive.

Solution. $\mathbb{F}_{16}^\times$ is cyclic of order 15; let γ be a generator. Then $\mathbb{F}_2(\gamma)$ contains every power of γ, i.e. all of $\mathbb{F}_{16}^\times$, plus 0, so $\mathbb{F}_2(\gamma) = \mathbb{F}_{16}$ and the minimal polynomial of γ has degree 4. No "avoid bad c" step is needed; the finite-field case is purely group-theoretic. Sanity check: $\mathbb{F}_{16}/\mathbb{F}_2$ has only the intermediate field $\mathbb{F}_4$ (divisors of 4 are $1, 2, 4$), so the finitely-many-subfields heuristic also applies, but the cyclic-group argument is cleaner and gives an explicit γ of order 15.

Worked Example 14.4.20 (Choosing a good c by the Lagrange criterion)**.** For $\alpha = \sqrt{2}$ (conjugates $\pm\sqrt{2}$) and $\beta = \sqrt{3}$ (conjugates $\pm\sqrt{3}$) over $\mathbb{Q}$, list the "bad" constants c and confirm $c = 1$ is admissible.

Recognition. The bad c are $c = (\alpha_i - \alpha)/(\beta - \beta_j)$ over *all* conjugates α_i of α (including $\alpha_i = \alpha$, which gives $c = 0$) paired with $\beta_j \neq \beta$; any other c gives a primitive $\gamma = \alpha + c\beta$.

Solution. The conjugates of $\alpha = \sqrt{2}$ are $\pm\sqrt{2}$, and the only $\beta_j \neq \beta = \sqrt{3}$ is $-\sqrt{3}$. Taking $\alpha_i = \alpha$ gives the bad value $c = 0$ (indeed $\gamma = \sqrt{2}$ is not primitive); the only other bad value, from $\alpha_i = -\sqrt{2}$, is

$$c = \frac{\alpha_i - \alpha}{\beta - \beta_j} = \frac{-\sqrt{2} - \sqrt{2}}{\sqrt{3} - (-\sqrt{3})} = \frac{-2\sqrt{2}}{2\sqrt{3}} = -\sqrt{\tfrac{2}{3}} \notin \mathbb{Q}.$$

So the only rational bad value is $c = 0$, and in particular $c = 1$ works: $\gamma = \sqrt{2} + \sqrt{3}$ is primitive, recovering the previous example. Sanity check: the criterion's geometric meaning is that $\alpha + c\beta = \alpha_i + c\beta_j$ for some conjugate pair, which would let two conjugates of γ collide; here that requires $c = 0$ or an irrational c, so every nonzero $c \in \mathbb{Q}$ keeps all four conjugates $\pm\sqrt{2} \pm c\sqrt{3}$ distinct.

Separability is essential: a non-simple extension

The primitive element theorem fails without separability. The standard counterexample is the inseparable extension $\mathbb{F}_p(s, t)$ over $\mathbb{F}_p(s^p, t^p)$: it has degree p^2 but every element has degree $\leq p$, and it carries infinitely many intermediate fields, so it cannot be generated by one element.

Proposition 14.4.21 (an inseparable extension with infinitely many intermediate fields)**.** *Let p be prime, let $F = \mathbb{F}_p(u, v)$ be the rational function field in two indeterminates, and set $K = \mathbb{F}_p(s, t)$ where s, t are chosen with $s^p = u$, $t^p = v$; equivalently take $F = \mathbb{F}_p(s^p, t^p) \subset K = \mathbb{F}_p(s, t)$. Then $[K : F] = p^2$, every $\theta \in K$ satisfies $\theta^p \in F$ (so $[F(\theta) : F] \leq p$), and there are infinitely many intermediate fields $F \subsetneq F(s + ct) \subsetneq K$ as c ranges over F. Hence K/F is* not *simple.*

Idea. Since $s^p, t^p \in F$ but $s \notin F$ and $t \notin F(s) = \mathbb{F}_p(s, t^p)$ (as s, t are independent indeterminates), each of $F(s)/F$ and $F(s, t)/F(s)$ has degree p (minimal polynomials $x^p - s^p = (x - s)^p$ and $x^p - t^p = (x - t)^p$), so $[K : F] = p^2$. For any $\theta = \sum a_{ij} s^i t^j \in K$, the Freshman's dream gives $\theta^p = \sum a_{ij}^p s^{ip} t^{jp} \in \mathbb{F}_p(s^p, t^p) = F$, so θ satisfies $x^p - \theta^p = (x - \theta)^p$ and $[F(\theta) : F] \leq p < p^2 = [K : F]$; thus *no single* θ generates K. The fields $L_c = F(s + ct)$ for $c \in F$ are pairwise distinct: if $L_c = L_{c'}$ with $c \neq c'$ then it contains $(s + ct) - (s + c't) = (c - c')t$, hence t and then s, so $L_c = K$, contradicting $[L_c : F] = p < p^2$. Since F is infinite, there are infinitely many such intermediate fields. □

Caution. "Finite extensions are simple" is *false* in general – it requires separability. In characteristic p, an extension with too many p-th-root relations (like $\mathbb{F}_p(s, t)/\mathbb{F}_p(s^p, t^p)$) has every element of degree $\leq p$ yet total degree p^2, so a single generator cannot reach the whole field. Equivalently, having only finitely many intermediate fields is what powers the proof, and that finiteness can fail in the inseparable world. Always check separability before invoking the primitive element theorem.

Worked Example 14.4.22 (Infinitely many intermediate fields in $\mathbb{F}_p(s, t)/\mathbb{F}_p(s^p, t^p)$)**.** Verify directly that $F(s + ct)$ and $F(s + c't)$ are distinct for $c \neq c'$ in $F = \mathbb{F}_p(s^p, t^p)$, and conclude $K = \mathbb{F}_p(s, t)$ is not simple.

Recognition. Inseparable case: every element has degree $\leq p$ but $[K : F] = p^2$, ruling out a primitive element; the fields $F(s + ct)$ form an infinite distinct family.

Solution. Each $L_c = F(s+ct)$ has degree p over F, since $(s+ct)^p = s^p + c^p t^p \in F$ (Freshman's dream, $c^p \in F$ as $c \in F$) gives a degree-$\leq p$ minimal polynomial $x^p - (s^p + c^p t^p)$, while $s + ct \notin F$ forces degree exactly p. If $L_c = L_{c'}$ with $c \neq c'$, then $L_c \ni (c - c')t$, so $t \in L_c$ (as $c - c' \in F^\times$), whence $s = (s + ct) - ct \in L_c$ and $L_c = K$ of degree $p^2 \neq p$, a contradiction. So the L_c are pairwise distinct, giving infinitely many intermediate fields. A field with infinitely many intermediate fields cannot be simple (in a simple extension $F(\gamma)$, each intermediate field E is generated over F by the coefficients of $m_{\gamma,E}$, a monic divisor of $m_{\gamma,F}$ in $F(\gamma)[x]$, so $E \mapsto m_{\gamma,E}$ injects the intermediate fields into the finite set of such divisors). Sanity check: contrast with $\mathbb{Q}(\sqrt{2}, \sqrt{3})/\mathbb{Q}$, which is separable, has exactly 5 intermediate fields (lattice of $(\mathbb{Z}/2\mathbb{Z})^2$: itself, $\mathbb{Q}$, and three quadratics), and *is* simple via $\sqrt{2} + \sqrt{3}$ – the finiteness of the lattice is exactly what the inseparable example destroys.

Worked Example 14.4.23 (Degree-p ceiling on elements)**.** In $K = \mathbb{F}_p(s,t)$ over $F = \mathbb{F}_p(s^p, t^p)$, compute the degree over F of $\theta = s + t$ and of $\theta = st$, confirming each is at most p.

Recognition. Every $\theta \in K$ has $\theta^p \in F$, so θ is a root of $x^p - \theta^p = (x - \theta)^p$ and $[F(\theta) : F] \in \{1, p\}$.

Solution. For $\theta = s + t$: $\theta^p = s^p + t^p \in F$, and $\theta \notin F$, so $m_{\theta,F}(x) = x^p - (s^p + t^p)$ has degree p and $[F(s + t) : F] = p$. For $\theta = st$: $\theta^p = s^p t^p \in F$, and $st \notin F$, so likewise $[F(st) : F] = p$. Both are $< p^2 = [K : F]$, so neither generates K. Sanity check: $F(s + t) \neq F(st)$ in general (e.g. $(s + t)$ and st are algebraically independent shadows of s, t), yet both are degree-p intermediate fields, illustrating again that the intermediate-field set is large – here even two "natural" generators each fall a factor of p short of all of K.

Exercises (from the text).

1. Determine the Galois closure of the field $\mathbb{Q}(\sqrt{1 + \sqrt{2}})$ over $\mathbb{Q}$.
2. Find a primitive generator for $\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$ over $\mathbb{Q}$.
3. Let F be a field contained in the ring of $n \times n$ matrices over $\mathbb{Q}$. Prove that $[F : \mathbb{Q}] \leq n$. (Note that, by Exercise 19 of Section 13.2, the ring of $n \times n$ matrices over $\mathbb{Q}$ does contain fields of degree n over $\mathbb{Q}$.)
4. Let $f(x) \in F[x]$ be an irreducible polynomial of degree n over the field F, let L be the splitting field of $f(x)$ over F and let α be a root of $f(x)$ in L. If K is any Galois extension of F, show that the polynomial $f(x)$ splits into a product of m irreducible polynomials each of degree d over K, where $d = [K(\alpha) : K] = [(L \cap K)(\alpha) : L \cap K]$ and $m = n/d = [F(\alpha) \cap K : F]$. [Show first that the factorization of $f(x)$ over K is the same as its factorization over $L \cap K$. Then if H is the subgroup of the Galois group of L over F corresponding to $L \cap K$ the factors of $f(x)$ over $L \cap K$ correspond to the orbits of H on the roots of $f(x)$. Use Exercise 9 of Section 4.1.]
5. Let p be a prime and let F be a field. Let K be a Galois extension of F whose Galois group is a p-group (i.e., the degree $[K : F]$ is a power of p). Such an extension is called a *p-extension* (note that p-extensions are Galois by definition).
   (a) Let L be a p-extension of K. Prove that the Galois closure of L over F is a p-extension of F.
   (b) Give an example to show that (a) need not hold if $[K : F]$ is a power of p but K/F is not Galois.
6. Prove that $K = \mathbb{F}_p(x, y)/\mathbb{F}_p(x^p, y^p)$ is not a simple extension by explicitly exhibiting an infinite number of intermediate subfields.
7. Let $F \subseteq K \subseteq L$ and let $\theta \in L$ with $p(x) = m_{\theta,F}(x)$. Prove that $K \otimes_F F(\theta) \cong K[x]/(p(x))$ as K-algebras.
8. Let K_1 and K_2 be two algebraic extensions of a field F contained in the field L of characteristic zero. Prove that the F-algebra $K_1 \otimes_F K_2$ has no nonzero nilpotent elements. [Use the preceding exercise.]

Practice problems.

1. Let $K = \mathbb{Q}(\sqrt[4]{2})$ and $L = \mathbb{Q}(\sqrt{3})$. Compute $[K : \mathbb{Q}]$, $[L : \mathbb{Q}]$, $K \cap L$, and $[KL : \mathbb{Q}]$. Justify the value of $K \cap L$ by a degree argument, and state whether the product bound $[KL : \mathbb{Q}] \leq [K : \mathbb{Q}][L : \mathbb{Q}]$ is attained.
2. Let $K = \mathbb{Q}(\sqrt[3]{5})$ and $L = \mathbb{Q}(\zeta_3)$. Show $[K : \mathbb{Q}] = 3$ and $[L : \mathbb{Q}] = 2$ are coprime, conclude $[KL : \mathbb{Q}] = 6$, and identify KL as the splitting field of $x^3 - 5$ over $\mathbb{Q}$.

3. Let K/F be Galois with $[K:F]=12$ and let L/F satisfy $[L:F]=8$. Suppose $K\cap L$ has degree 4 over F. Using the corollary to the composite theorem, compute $[KL:F]$ and $[KL:L]$, and state which group $\mathrm{Gal}(KL/L)$ is isomorphic to a subgroup of.

4. Let $K=\mathbb{Q}(\zeta_5)$ and $K'=\mathbb{Q}(\zeta_7)$, both Galois over $\mathbb{Q}$. Show $K\cap K'=\mathbb{Q}$, and conclude $\mathrm{Gal}(KK'/\mathbb{Q})\cong(\mathbb{Z}/5\mathbb{Z})^\times\times(\mathbb{Z}/7\mathbb{Z})^\times$. Identify KK' as a single cyclotomic field $\mathbb{Q}(\zeta_n)$ and give n and $[KK':\mathbb{Q}]$.

5. Find a primitive element γ for $\mathbb{Q}(\sqrt{2},\sqrt[3]{2})$ over $\mathbb{Q}$, state $[\mathbb{Q}(\sqrt{2},\sqrt[3]{2}):\mathbb{Q}]$, and verify your γ generates the whole field by showing both $\sqrt{2}$ and $\sqrt[3]{2}$ lie in $\mathbb{Q}(\gamma)$.

6. Let $\gamma=\sqrt{2}+\sqrt{-1}$. Show $\mathbb{Q}(\gamma)=\mathbb{Q}(\sqrt{2},i)$, compute $[\mathbb{Q}(\gamma):\mathbb{Q}]$, and find the minimal polynomial $m_{\gamma,\mathbb{Q}}(x)$ by exhibiting its four conjugate roots $\pm\sqrt{2}\pm i$.

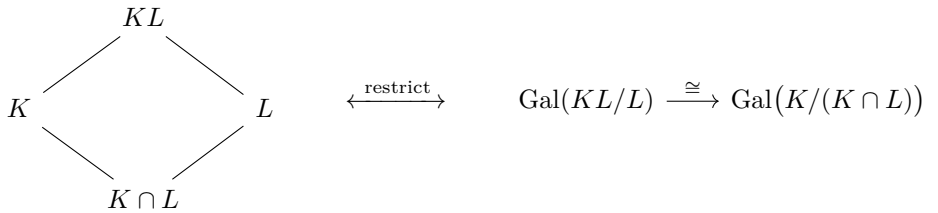
7. Let $F=\mathbb{F}_3$ and $K=\mathbb{F}_{3^4}$. Using the cyclic-multiplicative-group case of the primitive element theorem, explain why $K=F(\gamma)$ for a generator γ of $K^\times$, state the order of γ, and give the degree of $m_{\gamma,F}(x)$.

8. Let p be prime, $F=\mathbb{F}_p(s^p,t^p)\subset K=\mathbb{F}_p(s,t)$. Show that $\theta=s+t^2$ satisfies $\theta^p\in F$, conclude $[F(\theta):F]\le p$, and explain why this prevents θ from being a primitive element of K/F.

Additional exercises.

1. Let K/F be Galois and L/F arbitrary, inside a common Ω. Prove that if $[K:F]$ and $[L:F]$ are coprime then $K\cap L=F$ and $[KL:F]=[K:F][L:F]$. Then show by example with $K=\mathbb{Q}(\sqrt[3]{2},\zeta_3)$ and a suitable L that the conclusion $K\cap L=F$ can hold even when the degrees are *not* coprime.

2. Let $K=\mathbb{Q}(\zeta_8)$ and $K'=\mathbb{Q}(\zeta_{12})$, both abelian over $\mathbb{Q}$. Compute $K\cap K'$, $[KK':\mathbb{Q}]$, and $\mathrm{Gal}(KK'/\mathbb{Q})$, and verify the order of the agreement-set image inside $\mathrm{Gal}(K/\mathbb{Q})\times\mathrm{Gal}(K'/\mathbb{Q})$ matches $[KK':\mathbb{Q}]$.

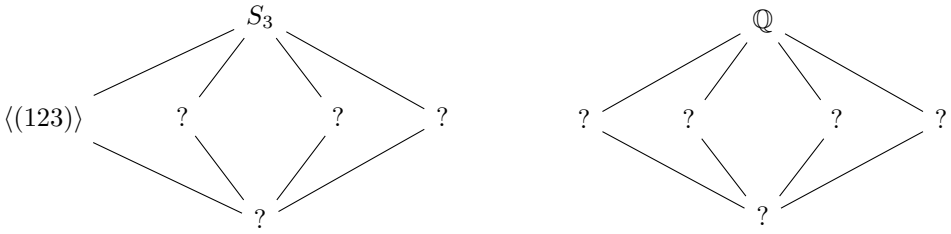


3. Let K/F and K'/F be Galois with $K\cap K'=F$, so $\mathrm{Gal}(KK'/F)\cong\mathrm{Gal}(K/F)\times\mathrm{Gal}(K'/F)$. Prove that under this isomorphism the intermediate fields of KK'/F of the form MM' with $F\subseteq M\subseteq K$ and $F\subseteq M'\subseteq K'$ correspond to product subgroups $H\times H'$, and give an example of an intermediate field of KK'/F that is *not* of the form MM'.

4. Let K/F be a finite separable extension of degree n with Galois closure M/F. Prove that $K=F(\gamma)$ for some γ whose set of distinct F-conjugates inside M has exactly n elements, and conversely that any $\gamma\in K$ with n distinct conjugates is primitive. Use this to recount the primitive element $\sqrt{2}+\sqrt{3}+\sqrt{5}$ for $\mathbb{Q}(\sqrt{2},\sqrt{3},\sqrt{5})$.

5. Let F be a field, K/F finite separable, and suppose K/F has exactly r intermediate fields. Prove K/F is simple, and prove conversely that a finite simple extension $F(\gamma)/F$ has only finitely many intermediate fields by relating them to the monic divisors of $m_{\gamma,F}(x)$ in $K[x]$.

Commutative-diagram exercises.

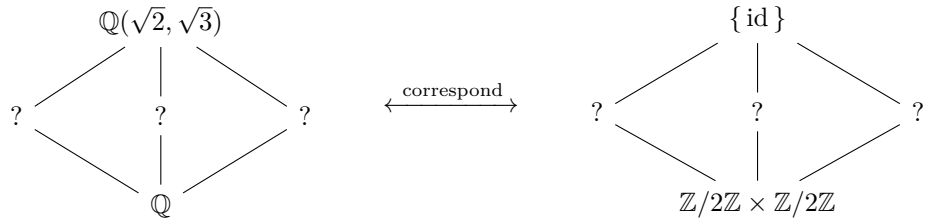


1. Let K/F be Galois and L/F any extension inside Ω. Complete the diamond and its Galois-correspondence partner below, label every edge with its degree (in terms of $[K:F]$, $[L:F]$, $[K\cap L:F]$), and prove the restriction map $\sigma\mapsto\sigma|_K$ is the indicated isomorphism:

   State why $\mathrm{Fix}\big(\mathrm{Gal}(KL/L)\big)\cap K=K\cap L$.

2. Take $K=\mathbb{Q}(\sqrt[3]{2},\zeta_3)$, the splitting field of x^3-2 over $\mathbb{Q}$, with $\mathrm{Gal}(K/\mathbb{Q})\cong S_3$. Draw the full subgroup lattice of S_3 and, beside it, the inverted lattice of intermediate fields of $K/\mathbb{Q}$, completing the tikz-cd

skeleton below so that each subgroup sits opposite its fixed field. Prove that the unique normal subgroup of order 3 corresponds to the unique Galois quadratic subfield $\mathbb{Q}(\zeta_3)$.



3. Let K/F and K'/F be Galois with $K \cap K' = F$. Complete the diagram exhibiting the injection $\mathrm{Gal}(KK'/F) \hookrightarrow \mathrm{Gal}(K/F) \times \mathrm{Gal}(K'/F)$ as an isomorphism, and prove the two projection triangles commute, where each π is restriction:

Explain precisely where the hypothesis $K \cap K' = F$ is used to upgrade the injection to a surjection.

4. For $K = \mathbb{Q}(\sqrt{2})$ and $K' = \mathbb{Q}(\sqrt{3})$ over $F = \mathbb{Q}$, draw the intermediate-field diamond of $KK' = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ and the matching subgroup lattice of $\mathrm{Gal}(KK'/\mathbb{Q}) \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, completing the skeleton below so that fixed fields and subgroups are correctly paired by the Fundamental Theorem. Prove that the three index-2 subgroups correspond exactly to the three quadratic subfields $\mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{3}), \mathbb{Q}(\sqrt{6})$.

14.5 Cyclotomic Extensions and Abelian Extensions over $\mathbb{Q}$

Roots of unity and cyclotomic polynomials

Fix $n \geq 1$ and work inside $\mathbb{C}$ (any algebraically closed field of characteristic 0 would do). The *nth roots of unity* are the roots of $x^n - 1$; since $\gcd(x^n - 1,\, nx^{n-1}) = 1$ in $\mathbb{Q}[x]$, this polynomial is separable and has exactly n distinct roots. They form a group under multiplication,

$$\mu_n = \{\ z \in \mathbb{C} : z^n = 1\ \} = \{\ e^{2\pi i k/n} : 0 \leq k < n\ \},$$

which is cyclic of order n (a finite subgroup of the multiplicative group of a field is cyclic). A generator of μ_n is a *primitive nth root of unity*; we fix the standard choice $\zeta_n = e^{2\pi i/n}$. The primitive roots are exactly the ζ_n^a with $\gcd(a, n) = 1$, so there are $\varphi(n)$ of them.

Definition 14.5.1. The *nth cyclotomic polynomial* is

$$\Phi_n(x) = \prod_{\substack{1 \leq a \leq n \\ \gcd(a,n)=1}} \left(x - \zeta_n^{\,a}\right) = \prod_{\substack{\zeta \in \mu_n \\ \zeta \text{ primitive}}} (x - \zeta),$$

the monic polynomial whose roots are precisely the primitive nth roots of unity. Its degree is $\deg \Phi_n = \varphi(n)$.

Every nth root of unity is a primitive dth root for exactly one $d \mid n$ (namely $d = |\zeta|$ in μ_n). Grouping the linear factors of $x^n - 1$ by the order of the root gives the fundamental factorization.

Proposition 14.5.2 (the product factorization)**.** *In $\mathbb{Z}[x]$,*

$$x^n - 1 = \prod_{d \mid n} \Phi_d(x).$$

Consequently each Φ_n is monic, has integer coefficients, and $\sum_{d \mid n} \varphi(d) = n$.

Idea. Every root of $x^n - 1$ has a well-defined order $d \mid n$ and is a primitive dth root, contributing to exactly one factor Φ_d; conversely every primitive dth root with $d \mid n$ is an nth root. So the two sides have the same (distinct, monic-linear) factors. That $\Phi_n \in \mathbb{Z}[x]$ follows by strong induction on n: dividing $x^n - 1$ by the monic integer polynomial $\prod_{d \mid n,\, d<n} \Phi_d$ leaves the monic quotient Φ_n, and division of a monic integer polynomial by a monic integer polynomial yields an integer quotient (Gauss). The degree identity is $\sum_{d \mid n} \deg \Phi_d = \sum_{d \mid n} \varphi(d) = \deg(x^n - 1) = n$. □

This recursion computes Φ_n from scratch: $\Phi_1 = x - 1$, and in general $\Phi_n(x) = \dfrac{x^n - 1}{\prod_{d \mid n,\, d<n} \Phi_d(x)}$. Two shortcuts streamline the work. For a prime p, $\Phi_p(x) = \dfrac{x^p - 1}{x - 1} = 1 + x + \cdots + x^{p-1}$. For a prime power, $\Phi_{p^k}(x) = \Phi_p\big(x^{p^{k-1}}\big)$. More generally, if $p \nmid m$ then $\Phi_{pm}(x) = \Phi_m(x^p)/\Phi_m(x)$, and $\Phi_{p^k m}(x) = \Phi_{pm}\big(x^{p^{k-1}}\big)$.

Method (To compute Φ_n: factor n, then either divide $x^n - 1$ by the lower Φ_d ($d \mid n$, $d < n$), or apply the prime-power / $\Phi_{pm}(x) = \Phi_m(x^p)/\Phi_m(x)$ shortcuts. Check $\deg = \varphi(n)$ and $\Phi_n(1)$ at the end.)**.**

Worked Example 14.5.3 (Compute Φ_5)**.** Find the fifth cyclotomic polynomial.

Recognition. 5 is prime, so $\Phi_5(x) = (x^5 - 1)/(x - 1)$, a degree $\varphi(5) = 4$ polynomial.

Solution. Dividing, $\Phi_5(x) = \dfrac{x^5 - 1}{x - 1} = x^4 + x^3 + x^2 + x + 1$. Sanity check: $\deg = 4 = \varphi(5)$; and $\Phi_5(1) = 1 + 1 + 1 + 1 + 1 = 5 = p$, matching the general fact $\Phi_p(1) = p$.

Worked Example 14.5.4 (Compute Φ_8)**.** Find the eighth cyclotomic polynomial.

Recognition. $8 = 2^3$ is a prime power, so $\Phi_8(x) = \Phi_2(x^4) = \big(x^4 + 1\big)$ via $\Phi_{p^k}(x) = \Phi_p(x^{p^{k-1}})$ with $p = 2,\ k = 3$.

Solution. $\Phi_2(x) = x + 1$, so $\Phi_8(x) = \Phi_2(x^4) = x^4 + 1$. Cross-check by division: $x^8 - 1 = (x^4 - 1)(x^4 + 1)$ and $x^4 - 1 = \Phi_1\Phi_2\Phi_4 = (x-1)(x+1)(x^2+1)$, leaving $\Phi_8 = x^4 + 1$. Sanity check: $\deg = 4 = \varphi(8) = 8 \cdot (1 - \frac{1}{2}) = 4$; and $\Phi_8(1) = 2 = p$ (for $n = p^k$, $\Phi_n(1) = p$), as expected. Its roots $e^{\pm \pi i/4}, e^{\pm 3\pi i/4}$ are the four primitive 8th roots, none of which is a lower root of unity.

Worked Example 14.5.5 (Compute Φ_{12})**.** Find the twelfth cyclotomic polynomial.

Recognition. $12 = 2^2 \cdot 3$. Use $\Phi_{12} = \Phi_{2 \cdot 6}$ but more cleanly $\Phi_{12}(x) = \Phi_6(x^2)$ since $12 = 2^2 \cdot 3$ gives $\Phi_{2^2 \cdot 3}(x) = \Phi_{2 \cdot 3}(x^2)$; and $\Phi_6(x) = x^2 - x + 1$.

Solution. First compute Φ_6 via the rule $\Phi_{2m}(x) = \Phi_m(-x)$ for odd $m > 1$, so $\Phi_6(x) = \Phi_3(-x) = (-x)^2 + (-x) + 1 = x^2 - x + 1$. Then $\Phi_{12}(x) = \Phi_6(x^2) = x^4 - x^2 + 1$. Cross-check by the product: $x^{12} - 1 = \prod_{d \mid 12} \Phi_d$ with divisors $1, 2, 3, 4, 6, 12$, degrees $\varphi = 1, 1, 2, 2, 2, 4$ summing to 12. Sanity check: $\deg \Phi_{12} = 4 = \varphi(12) = \varphi(4)\varphi(3) = 2 \cdot 2$; and $\Phi_{12}(1) = 1 - 1 + 1 = 1$, consistent with $\Phi_n(1) = 1$ whenever n has at least two distinct prime factors.

Irreducibility over $\mathbb{Q}$

The decisive theorem of the section is that Φ_n does not factor over $\mathbb{Q}$: all primitive nth roots of unity are conjugate. This is what makes $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ a degree-$\varphi(n)$ Galois extension with the cleanest possible group.

Theorem 14.5.6 (irreducibility of the cyclotomic polynomial)**.** *For every $n \geq 1$, the cyclotomic polynomial $\Phi_n(x)$ is irreducible over $\mathbb{Q}$. Hence Φ_n is the minimal polynomial over $\mathbb{Q}$ of every primitive nth root of unity, and*

$$[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \deg \Phi_n = \varphi(n).$$

Idea. Let $f(x)$ be the minimal polynomial of $\zeta = \zeta_n$ over $\mathbb{Q}$; since ζ is a root of $\Phi_n \in \mathbb{Z}[x]$ and Φ_n is monic, $f \in \mathbb{Z}[x]$ and $f \mid \Phi_n$ in $\mathbb{Z}[x]$. It suffices to show that whenever η is a root of f and $p \nmid n$ is prime, η^p is also a root of f; then, starting from ζ and applying this repeatedly, every ζ^a with $\gcd(a, n) = 1$ (writing a as a product of primes not dividing n) is a root of f, so $f = \Phi_n$. Suppose not: write $\Phi_n = f \cdot g$ in $\mathbb{Z}[x]$ with $g(\eta^p) = 0$, so η is a root of $g(x^p)$, hence $f(x) \mid g(x^p)$ in $\mathbb{Z}[x]$. Reduce mod p: in $\mathbb{F}_p[x]$, $g(x^p) = g(x)^p$ (Freshman's dream), so $\bar{f} \mid \bar{g}^p$, and any irreducible factor of $\bar{f}$ divides $\bar{g}$. Then $\bar{f}$ and $\bar{g}$ share a root, making $\bar{\Phi}_n = \bar{f}\bar{g}$ have a repeated root in $\overline{\mathbb{F}_p}$. But $\Phi_n \mid x^n - 1$ and $x^n - 1$ is separable mod p exactly when $p \nmid n$ (its derivative nx^{n-1} is then nonzero) – contradiction. So no such factorization exists, and Φ_n is irreducible. □

Remark 14.5.1. Irreducibility is special to $\mathbb{Q}$ (and to $\mathbb{Z}$): over a finite field $\mathbb{F}_p$ with $p \nmid n$ the polynomial Φ_n usually factors, into $\varphi(n)/d$ irreducibles each of degree $d = |p|$ in $(\mathbb{Z}/n\mathbb{Z})^\times$. The argument above genuinely uses that $\mathbb{Z}$ has residue fields $\mathbb{F}_p$ for every prime, the Freshman's dream in characteristic p, and separability of $x^n - 1$ away from $p \mid n$.

Caution. Do not assume Φ_n has coefficients in $\{0, \pm 1\}$. This holds for all $n < 105$, but Φ_{105} has a coefficient -2 (the smallest n with three distinct odd prime factors). The structural facts ($\Phi_n \in \mathbb{Z}[x]$, monic, degree $\varphi(n)$, irreducible over $\mathbb{Q}$) are what matter, not the spurious "coefficients are tiny" pattern.

Worked Example 14.5.7 (Verify Φ_p is irreducible directly)**.** Show $\Phi_p(x) = 1 + x + \cdots + x^{p-1}$ is irreducible over $\mathbb{Q}$ for p prime, without the general theorem.

Recognition. Eisenstein at p applies not to $\Phi_p(x)$ but to $\Phi_p(x+1)$; irreducibility is invariant under $x \mapsto x + 1$.

Solution. Compute $\Phi_p(x+1) = \dfrac{(x+1)^p - 1}{(x+1) - 1} = \dfrac{1}{x} \sum_{k=1}^{p} \binom{p}{k} x^k = \sum_{k=1}^{p} \binom{p}{k} x^{k-1} = x^{p-1} + \binom{p}{1} x^{p-2} + \cdots + \binom{p}{p-1}$. Every coefficient except the leading one is $\binom{p}{j}$ with $1 \leq j \leq p-1$, divisible by p; the constant term is $\binom{p}{p-1} = p$, not divisible by p^2. By Eisenstein at p, $\Phi_p(x+1)$ is irreducible over $\mathbb{Q}$, hence so is $\Phi_p(x)$. Sanity check ($p = 5$): $\Phi_5(x+1) = x^4 + 5x^3 + 10x^2 + 10x + 5$, with $5 \mid 5, 10, 10, 5$ and $25 \nmid 5$ – Eisenstein applies.

The Galois group $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) \cong (\mathbb{Z}/n\mathbb{Z})^\times$

Because $\mathbb{Q}(\zeta_n)$ is the splitting field of the separable polynomial $x^n - 1$ over $\mathbb{Q}$, the extension $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ is Galois of degree $\varphi(n)$. Any automorphism σ must send ζ_n to another primitive nth root, say ζ_n^a with $\gcd(a, n) = 1$, and σ is then completely determined (it fixes $\mathbb{Q}$ and ζ_n generates). This is the whole group.

Theorem 14.5.8 (the cyclotomic Galois group)**.** *The map*

$$(\mathbb{Z}/n\mathbb{Z})^\times \xrightarrow{\cong} \mathrm{Gal}\big(\mathbb{Q}(\zeta_n)/\mathbb{Q}\big), \qquad a \longmapsto \sigma_a, \quad \sigma_a(\zeta_n) = \zeta_n^a,$$

is a group isomorphism. In particular $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ *is abelian of order* $\varphi(n)$.

Idea. For $\gcd(a, n) = 1$ the primitive root ζ_n^a is a root of Φ_n, the minimal polynomial of ζ_n (irreducibility), so $\zeta_n \mapsto \zeta_n^a$ extends to a well-defined $\mathbb{Q}$-automorphism σ_a of $\mathbb{Q}(\zeta_n)$; the assignment $a \mapsto \sigma_a$ is injective because $\sigma_a = \sigma_b$ forces $\zeta_n^a = \zeta_n^b$, i.e. $a \equiv b \pmod{n}$. It is a homomorphism: $\sigma_a\sigma_b(\zeta_n) = \sigma_a(\zeta_n^b) = (\zeta_n^a)^b = \zeta_n^{ab} = \sigma_{ab}(\zeta_n)$, so $\sigma_a\sigma_b = \sigma_{ab}$. Both groups have order $\varphi(n)$ (using irreducibility for the right-hand side), so the injection is a bijection. □

Remark 14.5.2. The recipe $\sigma_a(\zeta_n) = \zeta_n^a$ extends to *every* nth root of unity: $\sigma_a(\zeta_n^k) = \zeta_n^{ak} = (\zeta_n^k)^a$. Two consequences. First, complex conjugation is σ_{-1}, since $\overline{\zeta_n} = \zeta_n^{-1}$; it generates the order-2 subgroup whose fixed field is the *maximal real subfield* $\mathbb{Q}(\zeta_n + \zeta_n^{-1})$. Second, by the Chinese Remainder Theorem $(\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_i (\mathbb{Z}/p_i^{a_i}\mathbb{Z})^\times$, which mirrors the compositum $\mathbb{Q}(\zeta_n) = \prod_i \mathbb{Q}(\zeta_{p_i^{a_i}})$.

Worked Example 14.5.9 ($\mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q})$ is cyclic of order 4)**.** Identify the Galois group of $\mathbb{Q}(\zeta_5)/\mathbb{Q}$ and a generator.

Recognition. $\mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q}) \cong (\mathbb{Z}/5\mathbb{Z})^\times$, which has order $\varphi(5) = 4$; $(\mathbb{Z}/5\mathbb{Z})^\times$ is cyclic because 5 is prime.

Solution. $(\mathbb{Z}/5\mathbb{Z})^\times = \{1, 2, 3, 4\}$ under multiplication mod 5. Take $a = 2$: $2^1 = 2,\ 2^2 = 4,\ 2^3 = 3,\ 2^4 = 1$, so 2 has order 4 and generates. Thus $\mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q}) = \langle\sigma_2\rangle \cong \mathbb{Z}/4\mathbb{Z}$, cyclic of order 4. Sanity check: the powers of σ_2 act on ζ_5 by $\zeta_5 \mapsto \zeta_5^2 \mapsto \zeta_5^4 \mapsto \zeta_5^3 \mapsto \zeta_5$, cycling through all four primitive roots, confirming order 4.

Worked Example 14.5.10 (The automorphisms of $\mathbb{Q}(\zeta_n)$ act on all roots of unity)**.** Show that σ_a satisfies $\sigma_a(\zeta) = \zeta^a$ for *every* $\zeta \in \mu_n$, not only the primitive ones.

Recognition. σ_a is a ring homomorphism fixing $\mathbb{Q}$, and every $\zeta \in \mu_n$ is a power of the chosen primitive root ζ_n.

Solution. Write $\zeta = \zeta_n^k$ for some k. Then $\sigma_a(\zeta) = \sigma_a(\zeta_n^k) = \sigma_a(\zeta_n)^k = (\zeta_n^a)^k = \zeta_n^{ak} = (\zeta_n^k)^a = \zeta^a$. Sanity check: applied to $\zeta = 1 = \zeta_n^0$ this gives $\sigma_a(1) = 1$ (correct, σ_a fixes $\mathbb{Q}$); applied to $\zeta = -1 = \zeta_n^{n/2}$ (when n even) it gives $\sigma_a(-1) = (-1)^a = -1$ since a is odd (coprime to even n).

The subfield–subgroup correspondence

The Fundamental Theorem makes intermediate fields of $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ correspond, inclusion-reversingly, to subgroups of $(\mathbb{Z}/n\mathbb{Z})^\times$. Since the group is abelian, every intermediate field is itself Galois over $\mathbb{Q}$, with group a quotient of $(\mathbb{Z}/n\mathbb{Z})^\times$. We illustrate with $n = 8$ (group Klein four) and $n = 7$ (group cyclic C_6), and then extract the unique quadratic subfield of $\mathbb{Q}(\zeta_p)$ in general.

Worked Example 14.5.11 ($\mathrm{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$ and its three quadratic subfields)**.** Determine the Galois group of $\mathbb{Q}(\zeta_8)/\mathbb{Q}$ and all intermediate fields, and draw the paired lattice.

Recognition. $\mathrm{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8\mathbb{Z})^\times = \{1, 3, 5, 7\}$; every nonidentity element squares to 1 (e.g. $3^2 = 9 \equiv 1$, $5^2 = 25 \equiv 1$, $7^2 = 49 \equiv 1 \pmod 8$), so the group is the Klein four-group V_4, with three subgroups of order 2.

Solution. Write $\zeta = \zeta_8 = e^{\pi i/4} = \frac{\sqrt{2}}{2}(1 + i)$, so $\zeta + \zeta^{-1} = 2\cos\frac{\pi}{4} = \sqrt{2}$ and $\zeta^2 = i$. The three involutions and their fixed fields:

$$\sigma_7 = \sigma_{-1} :\ \zeta \mapsto \zeta^{-1} \text{ (complex conjugation);}\ \text{fixes } \zeta + \zeta^{-1} = \sqrt{2},\ \text{so Fix} = \mathbb{Q}(\sqrt{2}).$$
$$\sigma_3 :\ \zeta \mapsto \zeta^3;\ \text{fixes } \zeta + \zeta^3 = \tfrac{\sqrt{2}}{2}(1 + i) + \tfrac{\sqrt{2}}{2}(-1 + i) = \sqrt{2}\, i = \sqrt{-2},\ \text{so Fix} = \mathbb{Q}(\sqrt{-2}).$$
$$\sigma_5 :\ \zeta \mapsto \zeta^5 = -\zeta;\ \text{fixes } \zeta^2 = i\ (\sigma_5(\zeta^2) = \zeta^{10} = \zeta^2),\ \text{so Fix} = \mathbb{Q}(i).$$

Thus the three quadratic subfields are $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{-2})$. The Galois correspondence (subgroups grow downward on the left, subfields grow upward on the right):

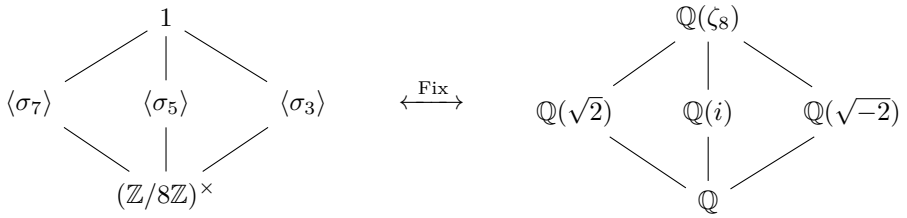


Diagram explanation. Objects: Left lattice: subgroups of $\mathrm{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8\mathbb{Z})^\times \cong V_4$. Top node 1 is the trivial subgroup; middle nodes $\langle\sigma_7\rangle$, $\langle\sigma_5\rangle$, $\langle\sigma_3\rangle$ are the three subgroups of order 2; bottom node $(\mathbb{Z}/8\mathbb{Z})^\times$ is the whole Galois group. Right lattice: intermediate fields of the degree-4 extension $\mathbb{Q}(\zeta_8)/\mathbb{Q}$. Top is $\mathbb{Q}(\zeta_8)$; the three middle nodes are the quadratic subfields $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{-2})$; bottom is $\mathbb{Q}$.

Arrows: All edges are drawn with `dash` (no arrowhead), denoting containment. In the subgroup lattice, higher position means smaller subgroup (the trivial group 1 sits at top). In the field lattice, higher position means larger field ($\mathbb{Q}(\zeta_8)$ sits at top). The central arrow $\overset{\text{Fix}}{\longleftrightarrow}$ is the Galois correspondence sending each subgroup H to its fixed field $\mathrm{Fix}(H)$.

What commutes: This is a correspondence diagram encoding inclusion-reversal: $H_1 \subseteq H_2$ as subgroups if and only if $\mathrm{Fix}(H_1) \supseteq \mathrm{Fix}(H_2)$ as fields. Concretely, each order-2 subgroup pairs with a degree-2 field; $(\mathbb{Z}/8\mathbb{Z})^\times$ pairs with $\mathbb{Q}$ (fixed by everything); the trivial group pairs with $\mathbb{Q}(\zeta_8)$ (fixed by nothing).

Why it commutes: Compute Fix of each involution. $\sigma_7(\zeta) = \zeta^{-1}$ (complex conjugation) fixes $\zeta + \zeta^{-1} = \sqrt{2}$, so $\mathrm{Fix}(\langle\sigma_7\rangle) = \mathbb{Q}(\sqrt{2})$. $\sigma_5(\zeta) = -\zeta$, so $\sigma_5(\zeta^2) = (-\zeta)^2 = \zeta^2 = i$, giving $\mathrm{Fix}(\langle\sigma_5\rangle) = \mathbb{Q}(i)$. $\sigma_3(\zeta) = \zeta^3$, and one checks $\sigma_3(\zeta + \zeta^3) = \zeta^3 + \zeta^9 = \zeta^3 + \zeta$ (since $\zeta^8 = 1$), so $\zeta + \zeta^3 = \sqrt{-2}$ is fixed, giving $\mathrm{Fix}(\langle\sigma_3\rangle) = \mathbb{Q}(\sqrt{-2})$. These three element-level verifications are what the arrows encode.

Why this matters here: The diagram is the visual punchline of the entire worked example: it records all intermediate fields of $\mathbb{Q}(\zeta_8)/\mathbb{Q}$ at once, making the Fundamental Theorem of Galois Theory concrete. It also shows the symmetry – all three involutions of V_4 play equal structural roles, and the three resulting quadratic fields are on an equal footing inside the biquadratic field $\mathbb{Q}(i, \sqrt{2})$.

Concrete example: In $\mathbb{Q}(\zeta_8)/\mathbb{Q}$, the subgroup $\langle\sigma_5\rangle$ has order 2 and index 2, so $\mathrm{Fix}(\langle\sigma_5\rangle)$ is quadratic over $\mathbb{Q}$. Since $\sigma_5(\zeta) = -\zeta$, we get $\sigma_5(\zeta^2) = \zeta^2$, so $i = \zeta^2 \in \mathrm{Fix}(\langle\sigma_5\rangle)$, yielding $\mathrm{Fix}(\langle\sigma_5\rangle) = \mathbb{Q}(i)$. The diagram then shows $\langle\sigma_5\rangle$ in the middle-center of the left lattice paired with $\mathbb{Q}(i)$ in the middle-center of the right lattice.

Common pitfall: A common error is reading both lattices with containment going in the same direction. The left lattice has the *whole group* $(\mathbb{Z}/8\mathbb{Z})^\times$ at the bottom ("smallest" in the sense of fixed field) and the *trivial group* at the top ("largest" fixed field). The Galois correspondence reverses inclusion, so larger subgroup corresponds to smaller field – exactly encoded by the diagrams being "upside down" relative to each other: top of left lattice (trivial group) pairs with top of right lattice (all of $\mathbb{Q}(\zeta_8)$), but containment in the two lattices runs in opposite directions.

Takeaway: The point of this diagram is that the Klein four-group structure of $(\mathbb{Z}/8\mathbb{Z})^\times$ forces exactly three quadratic subfields of $\mathbb{Q}(\zeta_8)$, one for each involution, and the paired lattice makes the inclusion-reversing Galois correspondence completely explicit.

Sanity check: $\mathbb{Q}(\zeta_8)$ has degree $\varphi(8) = 4$ over $\mathbb{Q}$, and indeed $\mathbb{Q}(\zeta_8) = \mathbb{Q}(i, \sqrt{2})$ is the biquadratic field with exactly three quadratic subfields, matching the three order-2 subgroups of V_4. Also $\mathbb{Q}(i) \cdot \mathbb{Q}(\sqrt{2}) = \mathbb{Q}(i, \sqrt{2})$ and $\sqrt{2} \cdot i = \sqrt{-2}$, so the third subfield $\mathbb{Q}(\sqrt{-2})$ is forced – consistent with the product $\sqrt{2} \cdot \sqrt{-2} = 2i$ lying in the top field.

Worked Example 14.5.12 ($\mathrm{Gal}(\mathbb{Q}(\zeta_7)/\mathbb{Q})$ is cyclic C_6 and its subfields)**.** Determine the Galois group of $\mathbb{Q}(\zeta_7)/\mathbb{Q}$ and its lattice of subfields.

Recognition. $\mathrm{Gal}(\mathbb{Q}(\zeta_7)/\mathbb{Q}) \cong (\mathbb{Z}/7\mathbb{Z})^\times$, cyclic of order $\varphi(7) = 6$; a cyclic group of order 6 has exactly one subgroup of each order $1, 2, 3, 6$, hence one intermediate field of each degree dividing 6.

Solution. $(\mathbb{Z}/7\mathbb{Z})^\times = \langle 3\rangle$ since $3^1 = 3, 3^2 = 2, 3^3 = 6, 3^4 = 4, 3^5 = 5, 3^6 = 1$, so σ_3 generates C_6. The proper subgroups are $\langle\sigma_3^2\rangle = \langle\sigma_2\rangle$ of order 3 (indices $\{1, 2, 4\}$, the quadratic residues mod 7) and $\langle\sigma_3^3\rangle = \langle\sigma_6\rangle = \langle\sigma_{-1}\rangle$ of order 2 (complex conjugation). Their fixed fields:

- $\mathrm{Fix}(\langle\sigma_{-1}\rangle) = \mathbb{Q}(\zeta_7 + \zeta_7^{-1}) = \mathbb{Q}(2\cos\frac{2\pi}{7})$, the real cubic subfield (degree $6/2 = 3$ over $\mathbb{Q}$).
- $\mathrm{Fix}(\langle\sigma_2\rangle)$ is the quadratic subfield (degree $6/3 = 2$); by the next theorem it is $\mathbb{Q}(\sqrt{p^*})$ with $p^* = (-1)^{(7-1)/2} \cdot 7 = -7$, i.e. $\mathbb{Q}(\sqrt{-7})$.

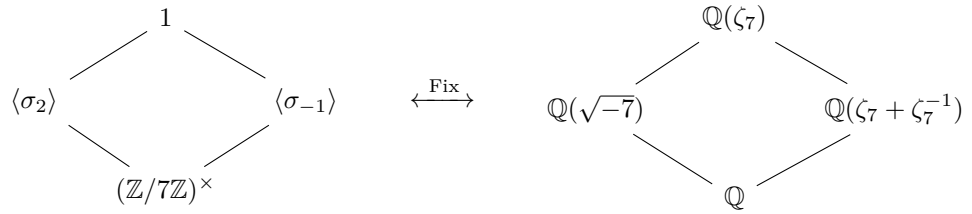

Diagram explanation. Objects: Left lattice: subgroups of $\mathrm{Gal}(\mathbb{Q}(\zeta_7)/\mathbb{Q}) \cong (\mathbb{Z}/7\mathbb{Z})^\times \cong C_6$. Top node 1 is the trivial subgroup; middle nodes are $\langle\sigma_2\rangle$ (cyclic of order 3, generated by the Frobenius-like σ_2) and $\langle\sigma_{-1}\rangle$ (cyclic of order 2, complex conjugation); bottom node is $(\mathbb{Z}/7\mathbb{Z})^\times$ (the whole group). Right lattice: intermediate fields of $\mathbb{Q}(\zeta_7)/\mathbb{Q}$, a degree-6 Galois extension. Top is $\mathbb{Q}(\zeta_7)$; middle nodes are $\mathbb{Q}(\sqrt{-7})$ (quadratic, degree 2) and $\mathbb{Q}(\zeta_7 + \zeta_7^{-1})$ (real cubic, degree 3); bottom is $\mathbb{Q}$.

Arrows: Plain (undirected) edges denote containment in each lattice (subgroup on the left, field on the right). The central arrow $\overset{\text{Fix}}{\longleftrightarrow}$ is the Galois correspondence, sending H to its fixed field $\text{Fix}(H)$: $\langle\sigma_2\rangle \leftrightarrow \mathbb{Q}(\sqrt{-7})$ and $\langle\sigma_{-1}\rangle \leftrightarrow \mathbb{Q}(\zeta_7+\zeta_7^{-1})$.

What commutes: The correspondence reverses inclusion: $H_1 \subseteq H_2$ implies $\text{Fix}(H_1) \supseteq \text{Fix}(H_2)$. Specifically, $\langle\sigma_{-1}\rangle \subseteq (\mathbb{Z}/7\mathbb{Z})^\times$ corresponds to $\mathbb{Q} \subseteq \mathbb{Q}(\zeta_7+\zeta_7^{-1})$; and $\langle\sigma_2\rangle \subseteq (\mathbb{Z}/7\mathbb{Z})^\times$ corresponds to $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{-7})$. The index-order relation reads: $[\mathbb{Q}(\zeta_7):\mathbb{Q}(\sqrt{-7})] = |\langle\sigma_2\rangle| = 3$ and $[\mathbb{Q}(\zeta_7):\mathbb{Q}(\zeta_7+\zeta_7^{-1})] = |\langle\sigma_{-1}\rangle| = 2$.

Why it commutes: Chase the fixed fields. $\sigma_{-1}(\zeta_7) = \zeta_7^{-1}$, so $\sigma_{-1}(\zeta_7+\zeta_7^{-1}) = \zeta_7^{-1}+\zeta_7$: fixed. Since $[\mathbb{Q}(\zeta_7):\mathbb{Q}(\zeta_7+\zeta_7^{-1})] = 2$, the fixed field of the order-2 subgroup $\langle\sigma_{-1}\rangle$ is exactly $\mathbb{Q}(\zeta_7+\zeta_7^{-1})$. For $\langle\sigma_2\rangle$ (order 3): the unique quadratic subfield of $\mathbb{Q}(\zeta_7)$ is $\mathbb{Q}(\sqrt{p^*})$ with $p^* = (-1)^{(7-1)/2}\cdot 7 = -7$, giving $\mathbb{Q}(\sqrt{-7})$; one verifies $\sigma_2(\sqrt{-7}) = \sqrt{-7}$ because σ_2 acts on the Gauss sum $g = \sqrt{-7}$ by the Legendre symbol $\left(\frac{2}{7}\right) = 1$, fixing it.

Why this matters here: This paired lattice is the concrete realization of the Fundamental Theorem of Galois Theory for $\mathbb{Q}(\zeta_7)/\mathbb{Q}$: a cyclic group of order 6 has exactly two proper nontrivial subgroups (one of each prime order 2 and 3), and correspondingly $\mathbb{Q}(\zeta_7)/\mathbb{Q}$ has exactly two proper intermediate fields. The diagram makes visible why the cubic and quadratic subfields are "dual" – they are the fixed fields of the two prime-order subgroups of C_6.

Concrete example: $\langle\sigma_{-1}\rangle$ has order 2 and index 3, so $\text{Fix}(\langle\sigma_{-1}\rangle)$ has degree $6/2 = 3$ over $\mathbb{Q}$. The real period $\zeta_7+\zeta_7^{-1} = 2\cos(2\pi/7)$ is a generator, and it satisfies a cubic over $\mathbb{Q}$ (computed from $\Phi_7(\zeta_7) = 0$ by substituting $\alpha = \zeta_7+\zeta_7^{-1}$, dividing by ζ_7^3 to get $\alpha^3+\alpha^2-2\alpha-1 = 0$). This degree-3 minimal polynomial confirms $[\mathbb{Q}(\zeta_7+\zeta_7^{-1}):\mathbb{Q}] = 3$.

Common pitfall: Students expect the larger subgroup to correspond to the larger field. But the larger subgroup $\langle\sigma_2\rangle$ (order 3) fixes *fewer* elements, giving the *smaller* field $\mathbb{Q}(\sqrt{-7})$ (degree 2), while the smaller subgroup $\langle\sigma_{-1}\rangle$ (order 2) fixes more elements, giving the *larger* field $\mathbb{Q}(\zeta_7+\zeta_7^{-1})$ (degree 3). The mnemonic is: each automorphism in the subgroup imposes one more condition on an element that is to be fixed, so a bigger subgroup has fewer fixed elements, i.e. a smaller fixed field (lower degree over $\mathbb{Q}$).

Takeaway: The point of this diagram is that the two nontrivial intermediate fields of $\mathbb{Q}(\zeta_7)/\mathbb{Q}$ are in exact bijection with the two nontrivial subgroups of C_6, with inclusion reversed: the order-3 subgroup fixes the quadratic subfield and the order-2 subgroup (complex conjugation) fixes the real cubic subfield.

The cubic real subfield $\mathbb{Q}(\zeta_7+\zeta_7^{-1})$ corresponds to $\langle\sigma_{-1}\rangle$ (order 2, index 3); the quadratic field $\mathbb{Q}(\sqrt{-7})$ corresponds to $\langle\sigma_2\rangle$ (order 3, index 2) – larger subgroup, smaller field. Sanity check: degrees multiply correctly, $[\mathbb{Q}(\zeta_7):\mathbb{Q}] = 6 = 3\cdot 2$, and $\mathbb{Q}(\sqrt{-7}) \cap \mathbb{Q}(\zeta_7+\zeta_7^{-1}) = \mathbb{Q}$ since their degrees $2, 3$ are coprime; their compositum is all of $\mathbb{Q}(\zeta_7)$ since $\text{lcm}(2,3) = 6$.

Theorem 14.5.13 (the unique quadratic subfield of $\mathbb{Q}(\zeta_p)$)**.** *Let p be an odd prime and $p^* = (-1)^{(p-1)/2}p$ (so $p^* = p$ if $p \equiv 1 \pmod 4$ and $p^* = -p$ if $p \equiv 3 \pmod 4$). Then $\mathbb{Q}(\zeta_p)$ contains a unique quadratic subfield, namely*

$$\mathbb{Q}\big(\sqrt{p^*}\big) \subseteq \mathbb{Q}(\zeta_p).$$

It is the fixed field of the unique index-2 subgroup of $(\mathbb{Z}/p\mathbb{Z})^\times$, i.e. of the squares (quadratic residues) mod p.

Idea. $(\mathbb{Z}/p\mathbb{Z})^\times$ is cyclic of order $p-1$, so it has a unique subgroup of index 2 – the squares – giving a unique quadratic subfield F. To name it, form the quadratic Gauss sum $g = \sum_{a=1}^{p-1}\left(\frac{a}{p}\right)\zeta_p^a$, where $\left(\frac{a}{p}\right)$ is the Legendre symbol. One computes $g^2 = (-1)^{(p-1)/2}p = p^*$ (the cross terms collect into a count of solutions of $a+b \equiv$ fixed, controlled by the Legendre symbol), and any σ_c sends $g \mapsto \left(\frac{c}{p}\right)g = \pm g$, so g is fixed exactly by the squares. Hence $g \in F$, $g \notin \mathbb{Q}$, and $F = \mathbb{Q}(g) = \mathbb{Q}(\sqrt{p^*})$. □

Worked Example 14.5.14 (The quadratic subfields for $p = 5, 7, 13$ via p^*)**.** Identify the quadratic subfield of $\mathbb{Q}(\zeta_p)$ for $p = 5, 7, 13$.

Recognition. The quadratic subfield is $\mathbb{Q}(\sqrt{p^*})$ with $p^* = (-1)^{(p-1)/2}p$: positive when $p \equiv 1 \pmod 4$, negative when $p \equiv 3 \pmod 4$.

Solution. $p = 5$: $5 \equiv 1 \pmod 4$, so $p^* = 5$ and the quadratic subfield is $\mathbb{Q}(\sqrt{5})$. $p = 7$: $7 \equiv 3 \pmod 4$, so $p^* = -7$ and it is $\mathbb{Q}(\sqrt{-7})$. $p = 13$: $13 \equiv 1 \pmod 4$, so $p^* = 13$ and it is $\mathbb{Q}(\sqrt{13})$. Sanity check: for $p = 5$, $\zeta_5+\zeta_5^{-1} = 2\cos\frac{2\pi}{5} = \frac{-1+\sqrt{5}}{2}$ lies in $\mathbb{Q}(\sqrt{5})$, confirming $\sqrt{5} \in \mathbb{Q}(\zeta_5)$; this real period is a root of $x^2+x-1 = 0$ whose discriminant is $5 > 0$, matching $p^* = 5$.

Worked Example 14.5.15 (The period $\zeta_5+\zeta_5^{-1}$ and the real subfield of $\mathbb{Q}(\zeta_5)$)**.** Find the quadratic over $\mathbb{Q}$ satisfied by $\alpha=\zeta_5+\zeta_5^{-1}$, and locate $\mathbb{Q}(\alpha)$ in the lattice.

Recognition. α is fixed by complex conjugation σ_{-1}, so it lies in the maximal real subfield $\mathbb{Q}(\zeta_5+\zeta_5^{-1})$; since $[\mathbb{Q}(\zeta_5):\mathbb{Q}]=4$ and $[\mathbb{Q}(\zeta_5):\mathbb{Q}(\alpha)]=2$, α has degree 2.

Solution. From $1+\zeta_5+\zeta_5^2+\zeta_5^3+\zeta_5^4=0$ (the relation $\Phi_5(\zeta_5)=0$), group the terms into real periods: $\alpha=\zeta_5+\zeta_5^4$ and $\beta=\zeta_5^2+\zeta_5^3$ satisfy $\alpha+\beta=-1$ and $\alpha\beta=(\zeta_5+\zeta_5^4)(\zeta_5^2+\zeta_5^3)=\zeta_5^3+\zeta_5^4+\zeta_5^6+\zeta_5^7=\zeta_5^3+\zeta_5^4+\zeta_5+\zeta_5^2=-1$. So α,β are the roots of $x^2-(\alpha+\beta)x+\alpha\beta=x^2+x-1=0$, giving $\alpha=\frac{-1+\sqrt{5}}{2}$ (the positive root, since $\alpha=2\cos 72^\circ>0$). Sanity check: for the real subfield to be quadratic we need the discriminant $1+4=5$ a non-square, and indeed $\mathbb{Q}(\alpha)=\mathbb{Q}(\sqrt{5})$ is the unique quadratic subfield found above; numerically $\frac{-1+\sqrt{5}}{2}\approx 0.618=2\cos 72^\circ$. Correct.

Worked Example 14.5.16 (Reading subfields of $\mathbb{Q}(\zeta_{13})$ off the divisors of 12)**.** List the intermediate fields of $\mathbb{Q}(\zeta_{13})/\mathbb{Q}$ and their degrees.

Recognition. $\mathrm{Gal}(\mathbb{Q}(\zeta_{13})/\mathbb{Q})\cong(\mathbb{Z}/13\mathbb{Z})^\times$ is cyclic of order $\varphi(13)=12$; subfields correspond one-to-one to divisors of 12 (a cyclic group has one subgroup per divisor of its order).

Solution. The divisors of 12 are $1,2,3,4,6,12$, so there are six intermediate fields, of degrees $1,2,3,4,6,12$ over $\mathbb{Q}$. The unique subgroup of order d has fixed field of degree $12/d$. Notably the degree-2 field is $\mathbb{Q}(\sqrt{13})$ (since $13\equiv 1 \pmod 4$, $p^*=13$), and the degree-6 field is the maximal real subfield $\mathbb{Q}(\zeta_{13}+\zeta_{13}^{-1})$ (fixed by complex conjugation, the unique order-2 subgroup). Sanity check: a cyclic group of order 12 has exactly $\tau(12)=6$ subgroups, matching six subfields; and the degrees pair as $(d,12/d)$: $(1,12),(2,6),(3,4)$ – the maximal real subfield (degree 6) sits below $\mathbb{Q}(\zeta_{13})$ at index 2, exactly the conjugation involution.

Abelian extensions of $\mathbb{Q}$ and constructible polygons

The cyclotomic fields are the abelian extensions of $\mathbb{Q}$ par excellence: $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ is abelian, hence so is every intermediate field's group over $\mathbb{Q}$. The deep converse is the crowning theorem of the subject.

Theorem 14.5.17 (Kronecker–Weber)**.** *Every finite abelian extension $K/\mathbb{Q}$ is contained in a cyclotomic field: there exists n with $K\subseteq\mathbb{Q}(\zeta_n)$. Equivalently, the maximal abelian extension of $\mathbb{Q}$ is the union $\bigcup_{n\geq 1}\mathbb{Q}(\zeta_n)$ of all cyclotomic fields.*

Remark 14.5.3. We do not prove Kronecker–Weber here (it belongs to class field theory), but its reach is immediate: every quadratic field $\mathbb{Q}(\sqrt{d})$ lies in some $\mathbb{Q}(\zeta_n)$ – indeed $\mathbb{Q}(\sqrt{d})\subseteq\mathbb{Q}(\zeta_{|D|})$ where D is the discriminant of $\mathbb{Q}(\sqrt{d})$ – and conversely a field like $\mathbb{Q}(\sqrt[3]{2})$, whose Galois closure has the *non-abelian* group S_3, can never sit inside any cyclotomic field. Abelianness over $\mathbb{Q}$ is precisely the obstruction.

A classical payoff is Gauss's determination of which regular polygons are constructible by straightedge and compass. A length is constructible iff it lies in a tower of quadratic extensions of $\mathbb{Q}$, so the regular n-gon (equivalently the point ζ_n, equivalently $\cos\frac{2\pi}{n}$) is constructible iff $[\mathbb{Q}(\zeta_n):\mathbb{Q}]=\varphi(n)$ is a power of 2.

Theorem 14.5.18 (Gauss: constructible regular polygons)**.** *The regular n-gon is constructible by straightedge and compass if and only if $\varphi(n)$ is a power of 2, equivalently if and only if*

$$n=2^k\,p_1p_2\cdots p_r,$$

a power of 2 times a product of distinct *Fermat primes $p_i=2^{2^{m_i}}+1$.*

Idea. $\mathbb{Q}(\zeta_n)/\mathbb{Q}$ is abelian, so all its subfields are Galois over $\mathbb{Q}$; a constructible point generates a field reached by a tower of degree-2 steps, which (in a Galois situation with abelian group) is possible iff the whole degree $\varphi(n)$ is a power of 2. Writing $n=2^{a_0}p_1^{a_1}\cdots p_r^{a_r}$, $\varphi(n)=\varphi(2^{a_0})\prod_i p_i^{a_i-1}(p_i-1)$ is a power of 2 iff each odd prime power has $a_i=1$ and p_i-1 a power of 2, i.e. $p_i=2^s+1$. Such a prime forces s itself a power of 2 (else 2^s+1 has a nontrivial factor), giving the Fermat primes $3,5,17,257,65537,\ldots$. □

Worked Example 14.5.19 (The regular 17-gon is constructible)**.** Decide whether the regular 17-gon is constructible, and describe the constructive tower.

Recognition. Constructibility of the n-gon $\iff$ $\varphi(n)$ is a power of 2; here 17 is prime, so $\varphi(17)=16=2^4$.

Solution. $\varphi(17) = 16 = 2^4$, a power of 2, so the regular 17-gon *is* constructible (Gauss, 1796). Concretely $\mathrm{Gal}(\mathbb{Q}(\zeta_{17})/\mathbb{Q}) \cong (\mathbb{Z}/17\mathbb{Z})^\times \cong \mathbb{Z}/16\mathbb{Z}$ is cyclic of order 16, with a chain of subgroups of orders $16, 8, 4, 2, 1$; the corresponding fixed fields form a tower

$$\mathbb{Q} = K_0 \subset K_1 \subset K_2 \subset K_3 \subset K_4 = \mathbb{Q}(\zeta_{17}), \qquad [K_{j+1} : K_j] = 2,$$

so ζ_{17} is built from $\mathbb{Q}$ by four successive square roots, and $\cos\frac{2\pi}{17}$, which lies in the real subfield K_3 of degree 8, already by three (the Gaussian periods $\eta_1, \eta_1', \eta_1''$ of the exercises realize these steps). Sanity check: $17 = 2^{2^2} + 1$ is a Fermat prime, fitting the form $n = 2^0 \cdot 17$, exactly the Gauss criterion; and $16 = 2^4$ predicts a depth-4 tower of quadratics, which is what the period construction produces.

Worked Example 14.5.20 (The regular 7-gon and 9-gon are not constructible)**.** Decide constructibility of the regular 7-gon and the regular 9-gon.

Recognition. Constructible $\iff$ $\varphi(n)$ is a power of 2. Compute $\varphi(7)$ and $\varphi(9)$.

Solution. $\varphi(7) = 6 = 2 \cdot 3$, which is *not* a power of 2, so the regular 7-gon is not constructible: $\mathbb{Q}(\zeta_7)$ contains the degree-3 real subfield $\mathbb{Q}(\zeta_7 + \zeta_7^{-1})$, and a cubic over $\mathbb{Q}$ cannot be reached by quadratic steps. Likewise $\varphi(9) = \varphi(3^2) = 3^2 - 3 = 6 = 2 \cdot 3$, not a power of 2, so the regular 9-gon (equivalently trisecting the 120° angle to get 40°) is not constructible. Sanity check: 7 is prime but not a Fermat prime, since $7 - 1 = 6$ is not a power of 2; and $9 = 3^2$ has a *repeated* odd prime, violating the "distinct Fermat primes, each to the first power" rule. Both fail for the same structural reason – a factor of 3 survives in $\varphi(n)$.

Worked Example 14.5.21 (Which $n \le 20$ give constructible n-gons)**.** List the n with $3 \le n \le 20$ for which the regular n-gon is constructible.

Recognition. Use $n = 2^k \prod p_i$ with distinct Fermat primes $p_i \in \{3, 5, 17, \dots\}$; equivalently test whether $\varphi(n)$ is a power of 2.

Solution. The Fermat primes available below 20 are $3, 5, 17$. Admissible n: powers of 2 times squarefree products of distinct Fermat primes. This gives $n = 3, 4, 5, 6, 8, 10, 12, 15, 16, 17, 20$ (e.g. $6 = 2 \cdot 3$, $10 = 2 \cdot 5$, $12 = 4 \cdot 3$, $15 = 3 \cdot 5$, $20 = 4 \cdot 5$). The non-constructible ones are $n = 7, 9, 11, 13, 14, 18, 19$ (each has an odd prime factor that is not Fermat, or a repeated prime 3^2). Sanity check by φ: $\varphi(15) = \varphi(3)\varphi(5) = 2 \cdot 4 = 8 = 2^3$ (constructible), while $\varphi(9) = 6$ and $\varphi(11) = 10 = 2 \cdot 5$ (not powers of 2, non-constructible); the list is consistent.

Exercises (from the text).

1. Determine the minimal polynomials satisfied by the primitive generators given in the text for the subfields of $\mathbb{Q}(\zeta_{13})$.

2. Determine the subfields of $\mathbb{Q}(\zeta_8)$ generated by the periods of ζ_8 and in particular show that not every subfield has such a period as primitive element.

3. Determine the quadratic equation satisfied by the period $\alpha = \zeta_5 + \zeta_5^{-1}$ of the 5th root of unity ζ_5. Determine the quadratic equation satisfied by ζ_5 over $\mathbb{Q}(\alpha)$ and use this to explicitly solve for the 5th root of unity.

4. Let $\sigma_a \in \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ denote the automorphism of the cyclotomic field of nth roots of unity which maps ζ_n to ζ_n^a where a is relatively prime to n and ζ_n is a primitive n^{th} root of unity. Show that $\sigma_a(\zeta) = \zeta^a$ for every n^{th} root of unity ζ.

5. Let p be a prime and let $\epsilon_1, \epsilon_2, \dots, \epsilon_{p-1}$ denote the primitive p^{th} roots of unity. Set $p_n = \epsilon_1^n + \epsilon_2^n + \cdots + \epsilon_{p-1}^n$, the sum of the nth powers of the ϵ_i. Prove that $p_n = -1$ if p does not divide n and that $p_n = p - 1$ if p does divide n. [One approach: $p_1 = -1$ from $\Phi_p(x)$; show that p_n is a Galois conjugate of p_1 for p not dividing n, hence it is also -1.]

6. Let ζ_n denote a primitive n^{th} root of unity and let $K = \mathbb{Q}(\zeta_n)$ be the associated cyclotomic field. Let a denote the trace of ζ_n from K to $\mathbb{Q}$ (cf. Exercise 18 of Section 2). Prove that $a = 1$ if $n = 1$, or 0 if n is divisible by the square of a prime, and $a = (-1)^r$ if n is the product of r distinct primes.

7. Show that complex conjugation restricts to the automorphism $\sigma_{-1} \in \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ of the cyclotomic field of nth roots of unity. Show that the field $K^+ = \mathbb{Q}(\zeta_n + \zeta_n^{-1})$ is the subfield of real elements in $K = \mathbb{Q}(\zeta_n)$, called the *maximal real subfield* of K.

8. Let $K_n = \mathbb{Q}(\zeta_{2^{n+2}})$ be the cyclotomic field of 2^{n+2}-th roots of unity, $n \geq 0$. Set $\alpha_n = \zeta_{2^{n+2}} + \zeta_{2^{n+2}}^{-1}$ and $K_n^+ = \mathbb{Q}(\alpha_n)$, the maximal real subfield of K_n.

   (a) Show that for all $n \geq 0$, $[K_n : \mathbb{Q}] = 2^{n+1}$, $[K_n : K_n^+] = 2$, $[K_n^+ : \mathbb{Q}] = 2^n$, and $[K_{n+1}^+ : K_n^+] = 2$.

   (b) Determine the quadratic equation satisfied by $\zeta_{2^{n+2}}$ over K_n^+.

   (c) Show that for $n \geq 0$, $\alpha_{n+1}^2 = 2 + \alpha_n$ and hence show that

$$\alpha_n = \sqrt{2 + \sqrt{2 + \sqrt{\cdots + \sqrt{2}}}} \qquad (n \text{ times}),$$

   giving an explicit formula for the (constructible) 2^{n+2}-th roots of unity.

9. Notation as in the previous exercise.

   (a) Prove that K_n^+ is a cyclic extension of $\mathbb{Q}$ of degree 2^n. [Use an explicit isomorphism $(\mathbb{Z}/2^{n+2}\mathbb{Z})^\times \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2^n\mathbb{Z}$ as abelian groups (i.e., $(\mathbb{Z}/2^{n+2}\mathbb{Z})^\times$ is isomorphic to the direct product of a cyclic group of order 2 and a cyclic group of order 2^n — cf. Exercises 22 and 23 of Section 2.3).]

   (b) Prove that K_n is a biquadratic extension of K_{n-1}^+ and that two of the three intermediate subfields are K_n^+ and K_{n-1}. Prove that the remaining field intermediate between K_{n-1}^+ and K_n is a cyclic extension of $\mathbb{Q}$ of degree 2^n.

10. Prove that $\mathbb{Q}(\sqrt[3]{2})$ is not a subfield of any cyclotomic field over $\mathbb{Q}$.

11. Prove that the primitive n^{th} roots of unity form a basis over $\mathbb{Q}$ for the cyclotomic field of nth roots of unity if and only if n is squarefree (i.e., n is not divisible by the square of any prime).

12. Let σ_p denote the Frobenius automorphism $x \mapsto x^p$ of the finite field $\mathbb{F}_q$ of $q = p^n$ elements. Viewing $\mathbb{F}_q$ as a vector space V of dimension n over $\mathbb{F}_p$ we can consider σ_p as a linear transformation of V. Determine the characteristic polynomial of σ_p and prove that the linear transformation σ_p is diagonalizable over $\mathbb{F}_p$ if and only if n divides $p-1$, and is diagonalizable over the algebraic closure of $\mathbb{F}_p$ if and only if $(n,p) = 1$.

13. Let $n = p_1^{a_1} p_2^{a_2} \cdots p_k^{a_k}$ be the prime factorization of n and let ζ_n be a primitive n^{th} root of unity. For each i let $\zeta_{p_i^{a_i}} = \zeta_n^{n/p_i^{a_i}}$, so that $\zeta_{p_i^{a_i}}$ is a particular primitive $p_i^{a_i}$-th root of unity. Let $\sigma_a \in \text{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ be the automorphism mapping ζ_n to ζ_n^a for a relatively prime to n.

   (a) Prove that for $i = 1, 2, \ldots, k$, σ_a maps $\zeta_{p_i^{a_i}}$ to $\zeta_{p_i^{a_i}}^a$ and gives an automorphism of $\mathbb{Q}(\zeta_{p_i^{a_i}})/\mathbb{Q}$ which depends only on $a \pmod{p_i^{a_i}}$, which we may denote $\sigma_{a \pmod{p_i^{a_i}}}$.

   (b) Prove that the map $\sigma_a \mapsto (\sigma_{a \pmod{p_1^{a_1}}}, \ldots, \sigma_{a \pmod{p_k^{a_k}}})$ is the isomorphism of Corollary 27 corresponding to the Chinese Remainder Theorem for $(\mathbb{Z}/n\mathbb{Z})^\times$.

14. Let $\zeta = \zeta_{17} = \cos\frac{2\pi}{17} + i\sin\frac{2\pi}{17}$ be a fixed primitive 17th root of unity in $\mathbb{C}$. Define the *periods* of ζ as follows:

$$\eta_1 = \zeta + \zeta^2 + \zeta^4 + \zeta^8 + \zeta^9 + \zeta^{13} + \zeta^{15} + \zeta^{16} \qquad \eta_3' = \zeta^6 + \zeta^7 + \zeta^{10} + \zeta^{11}$$
$$\eta_2 = \zeta^3 + \zeta^5 + \zeta^6 + \zeta^7 + \zeta^{10} + \zeta^{11} + \zeta^{12} + \zeta^{14} \qquad \eta_4' = \zeta^3 + \zeta^5 + \zeta^{12} + \zeta^{14}$$
$$\eta_1' = \zeta + \zeta^4 + \zeta^{13} + \zeta^{16} \qquad \eta_1'' = \zeta + \zeta^{16}$$
$$\eta_2' = \zeta^2 + \zeta^8 + \zeta^9 + \zeta^{15} \qquad \eta_2'' = \zeta^4 + \zeta^{13}.$$

   (a) Show that all of these periods are real numbers and that $\eta_1'' = 2\cos\frac{2\pi}{17}$. Show that as real numbers these are equal to approximately

$$\eta_1 \sim 1.562 \qquad \eta_1' \sim 2.049 \qquad \eta_3' \sim -2.906 \qquad \eta_1'' \sim 1.865$$
$$\eta_2 \sim -2.562 \qquad \eta_2' \sim -0.488 \qquad \eta_4' \sim 0.344 \qquad \eta_2'' \sim 0.185.$$

   (b) Prove that η_1 and η_2 are roots of the equation $x^2 + x - 4 = 0$.

(c) Prove that η_1' and η_2' are roots of the equation $x^2 - \eta_1 x - 1 = 0$ and that η_3' and η_4' are roots of the equation $x^2 - \eta_2 x - 1 = 0$.

(d) Prove that η_1'' and η_2'' are roots of the equation $x^2 - \eta_1' x + \eta_4' = 0$.

15. Prove that if $\tan 2\theta = a$ $(0 < 2\theta < \frac{\pi}{2})$ then $\tan\theta$ satisfies the equation $x^2 + \frac{2}{a}x - 1 = 0$.

16. Let C be the circle in $\mathbb{R}^2$ having the points (h,k) and $(0,1)$ as a diameter. Prove that this circle intersects the x-axis if and only if $h^2 - 4k \geq 0$ and in this case the two intercepts are the roots of the equation $x^2 - hx + k = 0$.

17. *(Construction of the Regular 17-gon)* Draw a circle of radius 2 centered at the origin $(0,0)$.

(a) Join the point $(4,0)$ to the point $(0,1)$ and construct the line ℓ_1 bisecting the angle between this line and the y-axis. Construct the line ℓ_2 perpendicular to ℓ_1 in Figure 2.

(b) Using the intersection of ℓ_1 and the x-axis as center and radius equal to the distance to $(0,1)$, construct the circle C_1 and let $A = (s,0)$ be the right-hand point of intersection of C_1 with the x-axis. Similarly, let $B = (t,0)$ denote the right-hand point of intersection of the x-axis and the circle C_2 whose center is the intersection of ℓ_2 and the x-axis and whose radius is equal to the distance to $(0,1)$ as in Figure 3.

(c) Construct a perpendicular to the x-axis at the point A and mark off the distance t from $(0,0)$ to B to construct the point (s,t). Construct the circle with (s,t) and $(0,1)$ as a diameter and let P denote the right-hand point of intersection of this circle with the x-axis. The perpendicular to the x-axis at P intersects the circle of radius 2 at the second vertex of a regular 17-gon whose first vertex is at $(2,0)$, hence constructs the regular 17-gon by straightedge and compass as in Figure 4.

18. Notation as in the previous exercises.

(a) Prove that ℓ_1 intersects the x-axis in the point $(\eta_1/2, 0)$ and that ℓ_2 intersects the x-axis in the point $(\eta_2/2, 0)$.

(b) Prove that C_1 is the circle having the points $(\eta_1, -1)$ and $(0,1)$ as diameter. Prove that $s = \eta_1'$. Similarly prove that C_2 is the circle having the points $(\eta_2, -1)$ and $(0,1)$ as diameter and that $t = \eta_4'$.

(c) Prove that P has coordinates $(\eta_1'', 0)$ and hence that the construction in the previous problem constructs the regular 17-gon by straightedge and compass.

Practice problems.

1. Compute the cyclotomic polynomials $\Phi_9(x)$, $\Phi_{15}(x)$, and $\Phi_{18}(x)$ using the prime-power and $\Phi_{pm}(x) = \Phi_m(x^p)/\Phi_m(x)$ shortcuts, and verify in each case that $\deg\Phi_n = \varphi(n)$ and that $\Phi_n(1)$ equals p when n is a prime power p^k and equals 1 when n has at least two distinct prime factors.

2. Determine the structure of $\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ as an abelian group for $n = 15,\ 16,\ 20,\ 24$. In each case give $[\mathbb{Q}(\zeta_n) : \mathbb{Q}] = \varphi(n)$, decide whether the group is cyclic, and if it is not, write it as a direct product of cyclic groups.

3. Inside $\mathbb{Q}(\zeta_{12})$, identify all three quadratic subfields explicitly as $\mathbb{Q}(\sqrt{d})$. Match each to the order-2 subgroup of $(\mathbb{Z}/12\mathbb{Z})^\times$ that fixes it, using $\zeta_{12} + \zeta_{12}^{-1}$, $\zeta_{12}^3 = i$, and $\zeta_{12}^2 = \zeta_6$ to name the fixed elements.

4. Let $\sigma_a \in \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ be the automorphism $\zeta_n \mapsto \zeta_n^a$. For $n = 15$, determine the order of σ_2 in $(\mathbb{Z}/15\mathbb{Z})^\times$ and the fixed field $\mathrm{Fix}(\langle\sigma_2\rangle)$ as an explicit subfield of $\mathbb{Q}(\zeta_{15})$, giving its degree over $\mathbb{Q}$.

5. Show directly that $\mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$ and that $\mathbb{Q}(\zeta_4) = \mathbb{Q}(i)$, then prove that $\mathbb{Q}(\zeta_3) \cap \mathbb{Q}(\zeta_4) = \mathbb{Q}$ and that the compositum $\mathbb{Q}(\zeta_3)\mathbb{Q}(\zeta_4) = \mathbb{Q}(\zeta_{12})$. Relate this to the isomorphism $(\mathbb{Z}/12\mathbb{Z})^\times \cong (\mathbb{Z}/3\mathbb{Z})^\times \times (\mathbb{Z}/4\mathbb{Z})^\times$.

6. Using $p^* = (-1)^{(p-1)/2}p$, name the unique quadratic subfield $\mathbb{Q}(\sqrt{p^*})$ of $\mathbb{Q}(\zeta_p)$ for $p = 11, 17, 19, 23$, and state for each the index in $(\mathbb{Z}/p\mathbb{Z})^\times$ of the subgroup of quadratic residues that fixes it.

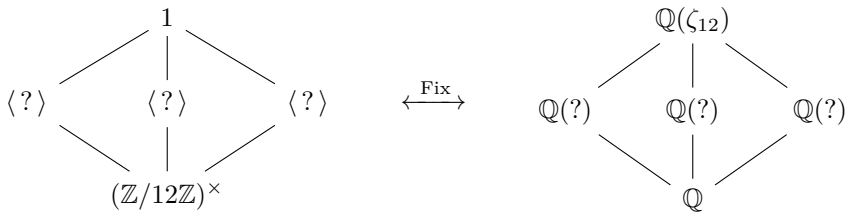
7. For each $n \in \{\,7, 9, 15, 17, 24, 40\,\}$ decide whether the regular n-gon is constructible by straightedge and compass, justifying via whether $\varphi(n)$ is a power of 2 and via the Fermat-prime form $n = 2^k p_1 \cdots p_r$.

8. Determine the degree $[\mathbb{Q}(\zeta_n+\zeta_n^{-1}):\mathbb{Q}]$ of the maximal real subfield of $\mathbb{Q}(\zeta_n)$ for $n=5,8,9,12$, and in each case decide whether $\zeta_n+\zeta_n^{-1}$ generates the full subfield fixed by complex conjugation.

Additional exercises.

1. Let $m,n\geq 1$ with $\gcd(m,n)=1$. Prove that $\mathbb{Q}(\zeta_m)\cap\mathbb{Q}(\zeta_n)=\mathbb{Q}$ and that $\mathbb{Q}(\zeta_m)\mathbb{Q}(\zeta_n)=\mathbb{Q}(\zeta_{mn})$, and deduce the isomorphism $\mathrm{Gal}(\mathbb{Q}(\zeta_{mn})/\mathbb{Q})\cong\mathrm{Gal}(\mathbb{Q}(\zeta_m)/\mathbb{Q})\times\mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$ as a manifestation of $(\mathbb{Z}/mn\mathbb{Z})^\times\cong(\mathbb{Z}/m\mathbb{Z})^\times\times(\mathbb{Z}/n\mathbb{Z})^\times$. Show by example that coprimality is essential by exhibiting m,n with $\mathbb{Q}(\zeta_m)\cap\mathbb{Q}(\zeta_n)\neq\mathbb{Q}$.

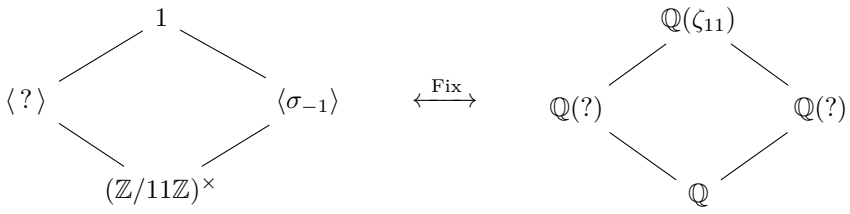
2. Fix an odd prime p. Prove that $\mathbb{Q}(\zeta_p)$ contains a subfield K with $[K:\mathbb{Q}]=d$ for exactly those d dividing $p-1$, that each such K is unique and is Galois over $\mathbb{Q}$ with cyclic group $\mathbb{Z}/d\mathbb{Z}$, and that $K\subseteq\mathbb{Q}(\zeta_p+\zeta_p^{-1})$ if and only if K is real, i.e. if and only if $d\mid(p-1)/2$.



3. Let p be a prime and $k\geq 1$. Prove that $\mathrm{Gal}(\mathbb{Q}(\zeta_{p^k})/\mathbb{Q})\cong(\mathbb{Z}/p^k\mathbb{Z})^\times$ is cyclic when p is odd, and that for $p=2$, $k\geq 3$ it is $\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/2^{k-2}\mathbb{Z}$ and hence not cyclic. Conclude that $\mathbb{Q}(\zeta_{2^k})$ for $k\geq 3$ has exactly three subfields of degree $[\mathbb{Q}(\zeta_{2^k}):\mathbb{Q}]/2$ over $\mathbb{Q}$, and identify them when $k=3$.

4. Let $K/\mathbb{Q}$ be a finite abelian extension. Define the *conductor* of K to be the least n with $K\subseteq\mathbb{Q}(\zeta_n)$ (such n exists by Kronecker–Weber). Compute the conductor of $\mathbb{Q}(\sqrt{2})$, of $\mathbb{Q}(i)$, of $\mathbb{Q}(\sqrt{-3})$, and of $\mathbb{Q}(\sqrt{5})$, and explain why no K with non-abelian Galois closure over $\mathbb{Q}$ can be embedded in any $\mathbb{Q}(\zeta_n)$; illustrate with $\mathbb{Q}(\sqrt[3]{2})$.

5. Let p be an odd prime and let $g=\sum_{a=1}^{p-1}\left(\frac{a}{p}\right)\zeta_p^a$ be the quadratic Gauss sum, where $\left(\frac{a}{p}\right)$ is the Legendre symbol. Prove that $\sigma_c(g)=\left(\frac{c}{p}\right)g$ for every c coprime to p, deduce that $g^2\in\mathbb{Q}$ is fixed by all of $\mathrm{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$, and use the value $g^2=p^*$ to conclude $\mathbb{Q}(g)=\mathbb{Q}(\sqrt{p^*})$ is the unique quadratic subfield of $\mathbb{Q}(\zeta_p)$.



Commutative-diagram exercises.

1. For $\mathbb{Q}(\zeta_{12})/\mathbb{Q}$, complete the paired Galois-correspondence lattice below: fill the three blank nodes of the left lattice with the three subgroups of order 2 of $(\mathbb{Z}/12\mathbb{Z})^\times\cong V_4$ and the right lattice with the matching subfields, then prove the correspondence is inclusion-reversing and that every intermediate field is Galois over $\mathbb{Q}$ (because $(\mathbb{Z}/12\mathbb{Z})^\times$ is abelian).

Identify which of the three quadratic subfields is the maximal real subfield $\mathbb{Q}(\zeta_{12}+\zeta_{12}^{-1})$.

2. Let p be an odd prime with $(\mathbb{Z}/p\mathbb{Z})^\times$ cyclic of order $p-1$. Draw the full subfield lattice of $\mathbb{Q}(\zeta_p)/\mathbb{Q}$ for $p=11$ (so $\varphi(11)=10$): place the subgroups of orders $1,2,5,10$ on the left and the fixed fields of degrees $10,5,2,1$ on the right, and prove that the degree-2 field is $\mathbb{Q}(\sqrt{-11})$ while the degree-5 field is the real subfield $\mathbb{Q}(\zeta_{11}+\zeta_{11}^{-1})$ fixed by $\langle\sigma_{-1}\rangle$. Use the skeleton

and label each edge with its degree.

3. Let m, n be coprime. Show that the Chinese-remainder isomorphism and the compositum decomposition fit into the commutative square

$$\begin{array}{ccc} \mathrm{Gal}(\mathbb{Q}(\zeta_{mn})/\mathbb{Q}) & \xrightarrow{\ \cong\ } & (\mathbb{Z}/mn\mathbb{Z})^\times \\ \Big\downarrow{\scriptstyle \mathrm{res}} & & \Big\downarrow{\scriptstyle \cong} \\ \mathrm{Gal}(\mathbb{Q}(\zeta_m)/\mathbb{Q}) \times \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q}) & \xrightarrow[\ \cong\ ]{} & (\mathbb{Z}/m\mathbb{Z})^\times \times (\mathbb{Z}/n\mathbb{Z})^\times \end{array}$$

where the left vertical map is restriction $\sigma \mapsto (\sigma|_{\mathbb{Q}(\zeta_m)}, \sigma|_{\mathbb{Q}(\zeta_n)})$ and the right vertical map is the CRT isomorphism. Prove the square commutes, that every map is an isomorphism, and explain why this forces $\mathbb{Q}(\zeta_m) \cap \mathbb{Q}(\zeta_n) = \mathbb{Q}$.

4. For the constructible regular 17-gon, exhibit the tower of fixed fields realizing $\mathrm{Gal}(\mathbb{Q}(\zeta_{17})/\mathbb{Q}) \cong \mathbb{Z}/16\mathbb{Z}$ as a chain of degree-2 steps. Complete the diagram by labelling each K_j with its degree over $\mathbb{Q}$ and each subgroup $H_j = \mathrm{Gal}(\mathbb{Q}(\zeta_{17})/K_j)$ with its order, and prove that $[K_{j+1} : K_j] = 2$ for every j from the cyclic subgroup structure:

$$\begin{array}{ccccccccc} \mathbb{Q} = K_0 & \text{——} & K_1 & \text{——} & K_2 & \text{——} & K_3 & \text{——} & K_4 = \mathbb{Q}(\zeta_{17}) \\ \text{Fix} & & \text{Fix} & & \text{Fix} & & \text{Fix} & & \text{Fix} \\ \langle\sigma\rangle = H_0 & & H_1 & & H_2 & & H_3 & & 1 = H_4 \end{array}$$

where σ is a generator of $(\mathbb{Z}/17\mathbb{Z})^\times$; specify $|H_j|$ and conclude that $\cos\frac{2\pi}{17}$ is constructible.

14.6 Galois Groups of Polynomials

The Galois group as a permutation group on the roots

Let $f(x) \in F[x]$ be a separable polynomial of degree n with distinct roots $\alpha_1, \dots, \alpha_n$ in a splitting field K. The *Galois group of f* means $\mathrm{Gal}(K/F)$. Its defining feature is that it acts on the set of roots: each $\sigma \in \mathrm{Gal}(K/F)$ permutes $\{\alpha_1, \dots, \alpha_n\}$, because σ fixes the coefficients of f, so $f(\sigma\alpha_i) = \sigma(f(\alpha_i)) = 0$ forces $\sigma\alpha_i$ to be another root. Since $K = F(\alpha_1, \dots, \alpha_n)$, an automorphism is completely determined by what it does to the roots. This gives an injection $\mathrm{Gal}(K/F) \hookrightarrow \mathrm{Sym}(\{\alpha_1, \dots, \alpha_n\}) \cong S_n$ once we number the roots.

Definition 14.6.1. The *Galois group of the separable polynomial f* over F is $\mathrm{Gal}(K/F)$, where K is a splitting field of f over F, realized as a subgroup of S_n via its faithful action permuting the n roots. A different numbering of the roots conjugates this subgroup inside S_n, so the Galois group is well defined up to conjugacy in S_n.

The single most useful structural fact links irreducibility of f to a group-theoretic property of the action.

Theorem 14.6.2 (transitivity criterion)**.** *Let $f \in F[x]$ be separable with splitting field K and Galois group $G \le S_n$ acting on the roots. Then f is irreducible over F if and only if G acts* transitively *on the roots.*

Idea. If f is irreducible and α_i, α_j are two roots, both have the same minimal polynomial f, so there is an F-isomorphism $F(\alpha_i) \to F(\alpha_j)$ sending $\alpha_i \mapsto \alpha_j$; since K/F is normal this extends to some $\sigma \in G$, giving $\sigma\alpha_i = \alpha_j$. Hence G is transitive. Conversely, if $f = gh$ factors nontrivially, the roots of g form a proper nonempty subset stable under G (automorphisms preserve g), so no element of G carries a root of g to a root of h, and the action is intransitive. □

Remark 14.6.1. A transitive subgroup of S_n has order divisible by n (orbit-stabilizer: the single orbit has size n, so $n \mid |G|$). This is the same statement as $n = \deg f = [F(\alpha) : F]$ divides $[K : F] = |G|$ when f is irreducible. The transitive subgroups of S_n are thus the only candidates for Galois groups of irreducible polynomials, which is exactly why the classification of transitive subgroups of S_3 and S_4 (below) is so useful.

Worked Example 14.6.3 (A reducible quadratic versus an irreducible one)**.** Compare the Galois groups of x^2-1 and x^2-2 over $\mathbb{Q}$.

Recognition. By the transitivity criterion the group is transitive on the two roots iff the quadratic is irreducible; over $\mathbb{Q}$ a quadratic is irreducible iff its discriminant is not a square.

Solution. For $x^2-1=(x-1)(x+1)$ the splitting field is $\mathbb{Q}$ itself, so Gal $=1$, the trivial (intransitive) subgroup of S_2. For x^2-2 the roots are $\pm\sqrt{2}$, splitting field $\mathbb{Q}(\sqrt{2})$ of degree 2, so Gal $\cong S_2=\mathbb{Z}/2\mathbb{Z}$, which swaps $\sqrt{2}\leftrightarrow-\sqrt{2}$ transitively. Sanity check: S_2 has order $2=[\mathbb{Q}(\sqrt{2}):\mathbb{Q}]$, and $2\mid|G|$ as transitivity requires; for x^2-1 the order is 1 and the action is intransitive, matching reducibility.

Worked Example 14.6.4 (Reading transitivity off a factorization)**.** Determine whether the Galois group of $(x^2-2)(x^2-3)$ over $\mathbb{Q}$ acts transitively on its four roots.

Recognition. Transitivity holds iff the degree-4 polynomial is irreducible; here it factors, so expect intransitivity, and the group should preserve the partition of roots into the two quadratic factors.

Solution. The splitting field is $\mathbb{Q}(\sqrt{2},\sqrt{3})$, with Gal $\cong V_4=\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}$ generated by $\sqrt{2}\mapsto-\sqrt{2}$ and $\sqrt{3}\mapsto-\sqrt{3}$. No automorphism sends $\sqrt{2}$ to $\sqrt{3}$, so the action on $\{\pm\sqrt{2},\pm\sqrt{3}\}$ has two orbits $\{\pm\sqrt{2}\}$ and $\{\pm\sqrt{3}\}$ – intransitive. Sanity check: $|V_4|=4=[\mathbb{Q}(\sqrt{2},\sqrt{3}):\mathbb{Q}]$, and as a subgroup of S_4 it is $\langle(12),(34)\rangle$, which indeed fixes the partition $\{1,2\}\cup\{3,4\}$, consistent with the reducible factorization.

Symmetric functions and the general polynomial

If we treat the roots as *independent indeterminates*, the symmetry between them is total, and the Galois group is as large as possible. Let $x_1,\dots,x_n$ be independent variables over a field F. The *elementary symmetric polynomials* are

$$s_1=\sum_i x_i,\quad s_2=\sum_{i<j}x_ix_j,\quad\dots,\quad s_n=x_1x_2\cdots x_n,$$

the coefficients (up to sign) of the polynomial $\prod_i(x-x_i)=x^n-s_1x^{n-1}+s_2x^{n-2}-\cdots+(-1)^ns_n$. The *general polynomial of degree n* is this last polynomial regarded over the field $F(s_1,\dots,s_n)$ of rational functions in the symmetric functions.

Theorem 14.6.5 (the fundamental theorem on symmetric functions)**.** *Every symmetric polynomial in $x_1,\dots,x_n$ over F is a polynomial in the elementary symmetric functions $s_1,\dots,s_n$, and this expression is unique. Equivalently, the fixed field of S_n acting on $F(x_1,\dots,x_n)$ by permuting the variables is exactly $F(s_1,\dots,s_n)$.*

Idea. For existence one runs a lexicographic-ordering algorithm: the leading monomial $x_1^{a_1}\cdots x_n^{a_n}$ of a symmetric polynomial must have $a_1\ge a_2\ge\cdots\ge a_n$, and subtracting the matching monomial $s_1^{a_1-a_2}s_2^{a_2-a_3}\cdots s_n^{a_n}$ cancels the leading term, strictly lowering the order; the process terminates. Uniqueness amounts to algebraic independence of $s_1,\dots,s_n$ over F. The field-theoretic statement follows because $F(x_1,\dots,x_n)$ is the splitting field of $\prod_i(x-x_i)$ over $F(s_1,\dots,s_n)$, of degree $n!$. □

Theorem 14.6.6 (Galois group of the general polynomial)**.** *Over $E=F(s_1,\dots,s_n)$, the general polynomial $\prod_i(x-x_i)$ is separable with splitting field $F(x_1,\dots,x_n)$, and*

$$\mathrm{Gal}\big(F(x_1,\dots,x_n)/F(s_1,\dots,s_n)\big)\cong S_n,$$

the full symmetric group, acting by permuting the indeterminate roots $x_1,\dots,x_n$.

Idea. S_n acts on $F(x_1,\dots,x_n)$ by permuting variables, fixing exactly $E=F(s_1,\dots,s_n)$ by the previous theorem. By Artin's theorem the extension $F(x_1,\dots,x_n)/E$ is Galois with group S_n, of degree $|S_n|=n!$. Since $[F(x_1,\dots,x_n):E]=n!$ is also the degree of the splitting field of the degree-n general polynomial, that polynomial *is* its defining polynomial, and its Galois group is all of S_n. □

Worked Example 14.6.7 (Newton's identity for the power sum p_2)**.** With $p_k=x_1^k+\cdots+x_n^k$, express p_2 in terms of the elementary symmetric functions.

Recognition. p_2 is symmetric, so by the fundamental theorem it is a polynomial in $s_1, \dots, s_n$; being homogeneous of degree 2 it involves only s_1^2 and s_2.

Solution. Expand $s_1^2 = \left(\sum_i x_i\right)^2 = \sum_i x_i^2 + 2\sum_{i<j} x_i x_j = p_2 + 2s_2$, hence $p_2 = s_1^2 - 2s_2$. Sanity check with $n = 2$, $x_1 = 2, x_2 = 3$: $s_1 = 5, s_2 = 6$, so $s_1^2 - 2s_2 = 25 - 12 = 13$, and directly $p_2 = 4 + 9 = 13$. Agreement.

Worked Example 14.6.8 (The discriminant of $x^2 + bx + c$ as a symmetric function)**.** Write $(x_1 - x_2)^2$ in terms of $s_1 = x_1 + x_2$ and $s_2 = x_1 x_2$, and relate it to $x^2 + bx + c$.

Recognition. $(x_1 - x_2)^2$ is symmetric (a square of the antisymmetric difference), so it is a polynomial in s_1, s_2; it is the discriminant of the quadratic with roots x_1, x_2.

Solution. $(x_1 - x_2)^2 = (x_1 + x_2)^2 - 4x_1 x_2 = s_1^2 - 4s_2$. For $x^2 + bx + c$ with roots x_1, x_2 we have $s_1 = -b$, $s_2 = c$, so the discriminant is $b^2 - 4c$. Sanity check: this is the classical discriminant of a quadratic, positive exactly when the two roots are distinct reals, and a perfect square in the base field exactly when the roots are rational – consistent with $x^2 - 1$ (disc 4, a square) versus $x^2 - 2$ (disc 8, not a square) above.

The discriminant and the alternating group

The Galois group of a separable f always sits inside S_n; whether it lands inside the alternating group A_n is governed by a single field element, the discriminant. Recall that A_n is the kernel of the sign homomorphism $S_n \to \{\pm 1\}$.

Definition 14.6.9. Let f have distinct roots $\alpha_1, \dots, \alpha_n$. Set

$$\Delta = \prod_{i<j} (\alpha_i - \alpha_j), \qquad D = \operatorname{disc}(f) = \Delta^2 = \prod_{i<j} (\alpha_i - \alpha_j)^2.$$

Then D is symmetric in the roots, hence lies in F; it is a polynomial in the coefficients of f. The square root Δ lies in K but generally not in F.

Theorem 14.6.10 (discriminant criterion)**.** *Let* $\operatorname{char} F \neq 2$ *and let* $f \in F[x]$ *be separable with Galois group* $G \leq S_n$ *and discriminant* D*. For* $\sigma \in G$, $\sigma(\Delta) = \operatorname{sgn}(\sigma)\,\Delta$*. Consequently*

$$G \leq A_n \iff \sigma(\Delta) = \Delta \text{ for all } \sigma \in G \iff \Delta \in F \iff D \text{ is a square in } F.$$

Idea. A transposition (ij) swaps the factor $(\alpha_i - \alpha_j)$ with $-(\alpha_i - \alpha_j)$ and permutes the remaining factors among themselves, so it negates Δ; a general σ multiplies Δ by $\operatorname{sgn}(\sigma)$. Hence σ fixes Δ iff $\operatorname{sgn}(\sigma) = 1$, i.e. $\sigma \in A_n$. Therefore $G \leq A_n$ iff every element fixes Δ, i.e. $\Delta \in \operatorname{Fix}(G) = F$; and $\Delta \in F$ iff its square D has a square root in F. (Characteristic 2 is excluded because there sgn is trivial and one needs the Berlekamp discriminant instead.) □

The field $F(\Delta) = F(\sqrt{D})$ is the fixed field of $G \cap A_n$, so it is the unique quadratic subextension detecting the sign of the permutation action – the Galois-theoretic meaning of "$\sqrt{D}$ lies in the splitting field."

Method (Discriminant as a first invariant. Given separable f of degree n over F (char $\neq 2$): (1) compute $D = \operatorname{disc}(f)$ from the coefficient formula; (2) decide whether D is a square in F. If yes, $G \leq A_n$; if no, $G \not\leq A_n$. Combine with the degree $[K : F] = |G|$ and transitivity to pin down G.)**.**

Worked Example 14.6.11 (Recovering the quadratic discriminant from Δ)**.** For $f = x^2 + bx + c$ verify $D = \Delta^2 = b^2 - 4c$ and interpret the criterion in S_2.

Recognition. $S_2 = \{e, (12)\}$ and $A_2 = \{e\}$; the criterion says $G \leq A_2$ (i.e. G trivial, f split) iff D is a square.

Solution. With roots α_1, α_2, $\Delta = \alpha_1 - \alpha_2$ and $D = (\alpha_1 - \alpha_2)^2 = (\alpha_1 + \alpha_2)^2 - 4\alpha_1\alpha_2 = b^2 - 4c$. If D is a square in F then $\Delta \in F$, the roots $\frac{-b \pm \sqrt{D}}{2}$ lie in F, and G is trivial; if not, $G = S_2 = \langle (12) \rangle$. Sanity check: $x^2 - 2$ has $D = 8$, not a square in $\mathbb{Q}$, so $G = S_2$; $x^2 - 1$ has $D = 4 = 2^2$, a square, so $G = A_2 = 1$ – exactly the warmups above.

Cubics

For a cubic, S_3 has only two transitive subgroups, S_3 itself and $A_3 = \langle (123) \rangle \cong \mathbb{Z}/3\mathbb{Z}$. The discriminant alone decides between them. We may assume the cubic is *depressed*, $x^3 + px + q$ (if $\operatorname{char} F \neq 3$, any cubic $x^3 + ax^2 + bx + c$ is brought to this form by $x \mapsto x - \frac{a}{3}$, which does not change the splitting field, the Galois group, or the discriminant).

Theorem 14.6.12 (discriminant of a depressed cubic)**.** *The discriminant of $f(x) = x^3 + px + q$ is*

$$D = -4p^3 - 27q^2.$$

Idea. By the resultant formula $D = (-1)^{3\cdot 2/2} R(f, f') = -R(f, f') = -\prod_i f'(\alpha_i)$ with $f'(x) = 3x^2 + p$. Using $\alpha_i^3 = -p\alpha_i - q$ to reduce $f'(\alpha_i) = 3\alpha_i^2 + p$ and multiplying over the three roots (or expanding $\prod_{i<j}(\alpha_i - \alpha_j)^2$ via Newton's identities) gives $-4p^3 - 27q^2$. □

Corollary 14.6.13 (Galois group of an irreducible cubic)**.** *Let $f = x^3 + px + q \in F[x]$ ($\operatorname{char} F \neq 2$) be irreducible and separable with discriminant $D = -4p^3 - 27q^2$. Then*

$$\operatorname{Gal}(f) = \begin{cases} A_3 \cong \mathbb{Z}/3\mathbb{Z}, & \text{if } D \text{ is a square in } F, \\ S_3, & \text{if } D \text{ is not a square in } F. \end{cases}$$

In the first case $[K : F] = 3$ and the splitting field is $F(\alpha)$ for any one root α; in the second $[K : F] = 6$ and $K = F(\alpha, \sqrt{D})$.

Idea. Irreducibility forces G transitive, so $3 \mid |G|$ and $G \in \{ A_3, S_3 \}$. The discriminant criterion sends G into A_3 exactly when D is a square. In the square case $|G| = 3$, so the splitting field already has degree 3 and equals $F(\alpha)$; otherwise $|G| = 6$ and adjoining $\sqrt{D}$ supplies the missing quadratic. □

Worked Example 14.6.14 ($x^3 - 2$ over $\mathbb{Q}$ has Galois group S_3)**.** Compute the Galois group and splitting field of $x^3 - 2$ over $\mathbb{Q}$.

Recognition. Eisenstein at 2 gives irreducibility; the discriminant criterion then chooses between A_3 and S_3. Here $p = 0$, $q = -2$.

Solution. $D = -4p^3 - 27q^2 = -27 \cdot 4 = -108$, which is negative, hence not a square in $\mathbb{Q}$, so $\operatorname{Gal} \cong S_3$ and $[K : \mathbb{Q}] = 6$. Concretely the roots are $\sqrt[3]{2}$, $\zeta_3\sqrt[3]{2}$, $\zeta_3^2\sqrt[3]{2}$, so $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ with $[K : \mathbb{Q}] = 3 \cdot 2 = 6$, matching $|S_3| = 6$. Sanity check: $\sqrt{D} = \sqrt{-108} = 6\sqrt{-3}$, and indeed $\mathbb{Q}(\sqrt{-3}) = \mathbb{Q}(\zeta_3)$ is the quadratic subfield $\operatorname{Fix}(A_3)$ inside K, exactly the $F(\sqrt{D})$ predicted by the theorem.

Worked Example 14.6.15 ($x^3 - 3x - 1$ has Galois group C_3 and is totally real)**.** Show $x^3 - 3x - 1$ is irreducible over $\mathbb{Q}$ with cyclic Galois group of order 3, and that all its roots are real.

Recognition. Rational-root test gives irreducibility (a cubic with no rational root is irreducible over $\mathbb{Q}$); then the discriminant decides. Here $p = -3$, $q = -1$.

Solution. The only candidate rational roots are ± 1, and $f(1) = -3$, $f(-1) = 1$, both nonzero, so f is irreducible. Discriminant $D = -4p^3 - 27q^2 = -4(-27) - 27(1) = 108 - 27 = 81 = 9^2$, a square in $\mathbb{Q}$. Hence $\operatorname{Gal} \cong A_3 = C_3$, $[K : \mathbb{Q}] = 3$, and $K = \mathbb{Q}(\theta)$ for any root θ. Since $D = 81 > 0$ all three roots are real, so $\mathbb{Q}(\theta) \subset \mathbb{R}$ is a totally real cyclic cubic field. Sanity check: $D > 0$ means the cubic has three distinct real roots, consistent with the field being real; and a cubic field generated by one root that already contains all conjugates must be Galois of degree 3, forcing the cyclic group C_3, as found.

Worked Example 14.6.16 (A cubic with a quadratic-subfield discriminant: $x^3 - x - 1$)**.** Determine the Galois group of $x^3 - x - 1$ over $\mathbb{Q}$.

Recognition. No rational root (test ± 1) gives irreducibility; compute D with $p = -1$, $q = -1$.

Solution. $f(1) = 1 - 1 - 1 = -1$ and $f(-1) = -1 + 1 - 1 = -1$, both nonzero, so f is irreducible. $D = -4(-1)^3 - 27(-1)^2 = 4 - 27 = -23$, not a square in $\mathbb{Q}$ (it is negative), so $\operatorname{Gal} \cong S_3$ with $[K : \mathbb{Q}] = 6$ and $K = \mathbb{Q}(\alpha, \sqrt{-23})$. Sanity check: $D = -23 < 0$ signals exactly one real root and a complex-conjugate pair, so complex conjugation is a transposition in G, which an order-3 group A_3 cannot contain – it must be S_3, agreeing with the discriminant test.

Worked Example 14.6.17 (Forcing A_3 by engineering a square discriminant)**.** For which integers q does $x^3 - 3q^2x - q^3$ have a square discriminant pattern, and what does that say (when irreducible)?

Recognition. Substitute into $D = -4p^3 - 27q^2$ with $p = -3q^2$ and the constant term $-q^3$; a perfect-square D forces A_3 when the cubic is irreducible.

Solution. With $p = -3q^2$ and constant term $c = -q^3$, the discriminant of $x^3 + px + c$ is $D = -4(-3q^2)^3 - 27(-q^3)^2 = -4(-27q^6) - 27q^6 = 108q^6 - 27q^6 = 81q^6 = (9q^3)^2$, always a perfect square. So whenever this cubic is irreducible over $\mathbb{Q}$, its group is $A_3 = C_3$. Sanity check: at $q = 1$ this is $x^3 - 3x - 1$ from the totally real example, where indeed $D = 81 = (9)^2$ and the group was C_3; the formula $81q^6$ specializes correctly.

Quartics and the resolvent cubic

A quartic is harder: S_4 has *five* transitive subgroups up to conjugacy. Order them as

$$S_4\ (24), \quad A_4\ (12), \quad D_8\ (8), \quad C_4\ (4), \quad V_4\ (4),$$

where $V_4 = \{\, e, (12)(34), (13)(24), (14)(23) \,\}$ is the normal Klein four-group, the D_8's are the Sylow 2-subgroups (each containing that V_4), and the transitive C_4's are generated by a 4-cycle. We assume $f = x^4 + px^2 + qx + r$ depressed (kill the cube term by $x \mapsto x - \frac{a}{4}$).

Definition 14.6.18. Let $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ be the roots of the depressed quartic $f = x^4 + px^2 + qx + r$. The three quantities

$$\beta_1 = \alpha_1\alpha_2 + \alpha_3\alpha_4, \quad \beta_2 = \alpha_1\alpha_3 + \alpha_2\alpha_4, \quad \beta_3 = \alpha_1\alpha_4 + \alpha_2\alpha_3$$

are permuted among themselves by S_4. Their monic cubic, the *resolvent cubic*, is

$$g(x) = (x - \beta_1)(x - \beta_2)(x - \beta_3) = x^3 - px^2 - 4rx + (4pr - q^2) \ \in F[x].$$

The point is that the action of $G \le S_4$ on $\{\, \beta_1, \beta_2, \beta_3 \,\}$ factors through the quotient $S_4/V_4 \cong S_3$: the stabilizer of the partition $\{\, \{\, 1, 2 \,\}, \{\, 3, 4 \,\} \,\}$ giving β_1 is precisely the D_8 containing V_4, and V_4 fixes all three β_i. So the splitting field of g is the fixed field of $G \cap V_4$, and the factorization type of g over F reads off how G meets V_4 and A_4.

Theorem 14.6.19 (quartic decision via the resolvent cubic)**.** *Let f be an irreducible separable quartic over F (*$\operatorname{char} F \neq 2$*) with discriminant D and resolvent cubic g. The discriminant of g equals D. Then* $\mathrm{Gal}(f)$ *is determined by the factorization of g over F together with whether D is a square:*

g irreducible over F	*D not a square*	$G = S_4$
g irreducible over F	*D a square*	$G = A_4$
g splits completely over F	*(D a square automatically)*	$G = V_4$
g has exactly one root in F	*D not a square*	$G = D_8$ *or* C_4

In the last line $G = C_4$ if and only if f becomes reducible over $F(\sqrt{D})$ (equivalently f factors into two quadratics over $F(\sqrt{D})$ that are not defined over F); if instead f remains irreducible over $F(\sqrt{D})$ then $G = D_8$.

Idea. $\operatorname{disc}(g) = \operatorname{disc}(f)$ because $\beta_1 - \beta_2 = (\alpha_1 - \alpha_4)(\alpha_2 - \alpha_3)$ and the like, so $\prod_{i<j}(\beta_i - \beta_j)^2$ rearranges into $\prod_{i<j}(\alpha_i - \alpha_j)^2$. The image of G in $S_4/V_4 \cong S_3$ is exactly $\mathrm{Gal}(g)$ as a permutation group on the β_i, so: g irreducible $\iff$ that image is transitive, i.e. A_3 or S_3 $\iff$ $3 \mid |G|$ $\iff$ $G \in \{\, S_4, A_4 \,\}$ (distinguished by D; note A_4 maps onto $A_4/V_4 \cong A_3$, not onto S_3); g totally split $\iff$ trivial image $\iff$ $G \le V_4$, which for an irreducible (hence transitive) quartic forces $G = V_4$; g with one root in F $\iff$ image of order 2 $\iff$ $|G| = 8$ or 4, i.e. D_8 or C_4, separated by the behaviour of f over $F(\sqrt{D})$. □

Method (Quartic decision procedure. For irreducible depressed $f = x^4 + px^2 + qx + r$ over F (char $\neq 2$): (1) form $g(x) = x^3 - px^2 - 4rx + (4pr - q^2)$; (2) factor g over F and compute $D = \operatorname{disc}(f) = \operatorname{disc}(g)$; (3) read the table: g irreducible $\Rightarrow$ S_4 (D nonsquare) or A_4 (D square); g totally split $\Rightarrow$ V_4; g with one rational root $\Rightarrow$ D_8 or C_4, deciding C_4 iff f becomes reducible over $F(\sqrt{D})$ (and D_8 iff f stays irreducible there).)**.**

Worked Example 14.6.20 (x^4+1 over $\mathbb{Q}$ has Galois group V_4)**.** Determine the Galois group and splitting field of x^4+1 over $\mathbb{Q}$.

Recognition. $x^4+1=\Phi_8$ is irreducible (Eisenstein after $x\mapsto x+1$), splitting field $\mathbb{Q}(\zeta_8)$; abelian Galois group $(\mathbb{Z}/8\mathbb{Z})^\times\cong V_4$. Cross-check with the resolvent cubic, here $p=0,q=0,r=1$.

Solution. The roots are the primitive 8th roots of unity, so $K=\mathbb{Q}(\zeta_8)$ and $\mathrm{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q})\cong(\mathbb{Z}/8\mathbb{Z})^\times=\{1,3,5,7\}\cong\mathbb{Z}/2\mathbb{Z}\times\mathbb{Z}/2\mathbb{Z}=V_4$. Resolvent cubic: $g(x)=x^3-0\cdot x^2-4x+(0-0)=x^3-4x=x(x-2)(x+2)$, which splits completely over $\mathbb{Q}$, so the table gives $G=V_4$. Sanity check: using the roots $0,2,-2$ of g, $D=\mathrm{disc}(g)=\big[(0-2)(0+2)(2-(-2))\big]^2=[(-2)(2)(4)]^2=(-16)^2=256=16^2$, a square – consistent with $V_4\le A_4$. Also $\zeta_8=\frac{\sqrt{2}}{2}(1+i)$, so $K=\mathbb{Q}(i,\sqrt{2})$, a biquadratic field of degree 4, matching $|V_4|=4$.

Worked Example 14.6.21 (x^4-2 over $\mathbb{Q}$ has Galois group D_8)**.** Determine the Galois group of x^4-2 over $\mathbb{Q}$ (cf. Section 14.2).

Recognition. Eisenstein at 2 gives irreducibility; the splitting field $\mathbb{Q}(\sqrt[4]{2},i)$ has degree 8 (computed in 14.2), so $|G|=8$ and $G=D_8$. Confirm via the resolvent cubic with $p=0,q=0,r=-2$.

Solution. The roots are $\pm\sqrt[4]{2},\pm i\sqrt[4]{2}$; $K=\mathbb{Q}(\sqrt[4]{2},i)$ with $[K:\mathbb{Q}]=8$, so G is a transitive order-8 subgroup of S_4, i.e. a D_8. Resolvent cubic: $g(x)=x^3-0\cdot x^2-4(-2)x+(0-0)=x^3+8x=x(x^2+8)$, which has exactly one rational root ($x=0$) since x^2+8 is irreducible over $\mathbb{Q}$. The table then gives D_8 or C_4; to separate, $D=\mathrm{disc}(f)$ for x^4-2 is $-2048<0$, not a square, and $f=x^4-2$ stays irreducible over $\mathbb{Q}(\sqrt{D})=\mathbb{Q}(\sqrt{-2})$ (adjoining the root $\sqrt[4]{2}$ to $\mathbb{Q}(\sqrt{-2})$ gives a field containing $\sqrt{2}$ and $\sqrt{-2}$, hence i, so it is all of K and has degree $8/2=4$ over $\mathbb{Q}(\sqrt{-2})$), giving D_8. Sanity check: $|D_8|=8=[K:\mathbb{Q}]$, and D_8 is the Sylow 2-subgroup of S_4; the geometric picture $\langle r,s\mid r^4=s^2=1,\ srs=r^{-1}\rangle$ matches $r:\sqrt[4]{2}\mapsto i\sqrt[4]{2}$ (order 4) and $s=$ complex conjugation (order 2).

Worked Example 14.6.22 (Computing and factoring a resolvent cubic: $x^4+8x+12$)**.** Form the resolvent cubic of $x^4+8x+12$ over $\mathbb{Q}$ and read off the Galois group.

Recognition. This f is irreducible over $\mathbb{Q}$ (no rational roots and no factorization into rational quadratics). Apply the method with $p=0$, $q=8$, $r=12$.

Solution. Resolvent: $g(x)=x^3-px^2-4rx+(4pr-q^2)=x^3-48x-64$. Test rational roots (divisors of 64): $g(-4)=-64+192-64=64\neq0$; $g(8)=512-384-64=64\neq0$; $g(-2)=-8+96-64=24\neq0$; in fact g has no rational root, so it is irreducible over $\mathbb{Q}$. Hence $G\in\{S_4,A_4\}$, decided by $D=\mathrm{disc}(g)=\mathrm{disc}(f)$. Compute $D=-4p^3-27\cdot(\text{const of }g)^2$ for $g=x^3-48x-64$: $D=-4(-48)^3-27(-64)^2=-4(-110592)-27(4096)=442368-110592=331776=576^2$, a perfect square. So $G=A_4$. Sanity check: $576^2=331776$ indeed, and A_4 is the unique transitive subgroup of S_4 of order 12; D a square places $G\le A_4$, while irreducibility of g rules out the order-4 and order-8 groups, leaving exactly A_4.

Worked Example 14.6.23 (Distinguishing D_8 from C_4: x^4+1 revisited as a biquadratic V_4 versus a C_4 example)**.** Use the resolvent-cubic table to separate the V_4, D_8, C_4 outcomes for biquadratics x^4+px^2+r.

Recognition. For $q=0$ the resolvent cubic is $g(x)=x^3-px^2-4rx+4pr=(x-p)(x^2-4r)$, which always has the rational root $x=p$. So a biquadratic never gives S_4 or A_4; the group is among V_4,C_4,D_8, decided by squareness of r and of $r(p^2-4r)$.

Solution. Since g factors as $(x-p)(x^2-4r)$, the quadratic factor x^2-4r splits over $\mathbb{Q}$ iff r is a square (then g splits completely, $G=V_4$); if r is not a square, g has the single rational root p, so $G=D_8$ or C_4. The standard refinement: $G=V_4\iff r$ is a square; $G=C_4\iff r(p^2-4r)$ is a square (but r is not); $G=D_8$ otherwise. For x^4+1 ($p=0,r=1$): $r=1$ is a square, so V_4 – matching the earlier computation. For $x^4-x^2+1=\Phi_{12}$ ($p=-1,r=1$): again $r=1$ a square, V_4 (indeed $\mathbb{Q}(\zeta_{12})$ has group $(\mathbb{Z}/12\mathbb{Z})^\times\cong V_4$). For a genuine C_4 take x^4+5x^2+5 ($p=5,r=5$): here $r=5$ is not a square but $r(p^2-4r)=5(25-20)=25=5^2$ is a square, so $G=C_4$. Sanity check: x^4+x^2-1 ($p=1,r=-1$) has $r=-1$ (not a square) and $r(p^2-4r)=(-1)(1+4)=-5$ (not a square), giving D_8; x^4-x^2+1 giving V_4 and x^4+5x^2+5 giving C_4 exhibit all three biquadratic outcomes, so the criterion is internally consistent.

Worked Example 14.6.24 (A full S_4 example: x^4+x+1 over $\mathbb{Q}$)**.** Determine the Galois group of x^4+x+1 over $\mathbb{Q}$.

Recognition. Irreducible over $\mathbb{Q}$ (no rational roots; the only quadratic-times-quadratic factorization over $\mathbb{Z}$ would need integer coefficients that fail to match). Apply the method with $p=0,q=1,r=1$.

Solution. Resolvent: $g(x) = x^3 - 0 \cdot x^2 - 4x + (0 - 1) = x^3 - 4x - 1$. Rational-root test ± 1: $g(1) = -4$, $g(-1) = 2$, both nonzero, so g is irreducible over $\mathbb{Q}$. Hence $G \in \{ S_4, A_4 \}$. Discriminant of $g = x^3 - 4x - 1$: $D = -4(-4)^3 - 27(-1)^2 = -4(-64) - 27 = 256 - 27 = 229$, which is prime, hence not a perfect square. So $G = S_4$. Sanity check: $\operatorname{disc}(f) = \operatorname{disc}(g) = 229$ is not a square, placing $G \not\leq A_4$; combined with g irreducible (transitive image in S_3) this forces the full S_4, the generic case for a quartic. (Complex conjugation gives no extra evidence here: $D = 229 > 0$ means the number of complex-conjugate pairs of roots is even, and in fact $x^4 + x + 1 > 0$ on $\mathbb{R}$, so the roots form two conjugate pairs and complex conjugation is a double transposition, which lies in A_4; it is the non-square discriminant that excludes A_4.)

Caution. When applying the discriminant criterion, "D is a square" always means a square *in the base field* F, not merely a positive integer. For example $\operatorname{disc}(x^3 - x - 1) = -23$ is negative, so it cannot be a square in $\mathbb{Q}$ regardless of magnitude, forcing S_3. Conversely D can be a large positive non-square (like 229 above): always factor or test for squareness in F, never judge by size or sign alone. And the resolvent-cubic table requires f to be *irreducible* first – a reducible quartic has an intransitive group not on the list.

The correspondence between the two lattices, for S_4

The five transitive subgroups of S_4 each produce a different shape of subfield lattice for the splitting field, and the resolvent cubic is precisely the device that measures the projection $S_4 \twoheadrightarrow S_4/V_4 \cong S_3$. The diagram below records this quotient and the corresponding tower of fixed fields when $G = S_4$: the normal subgroup V_4 corresponds to the splitting field of the resolvent cubic, and A_4 to $F(\sqrt{D})$.

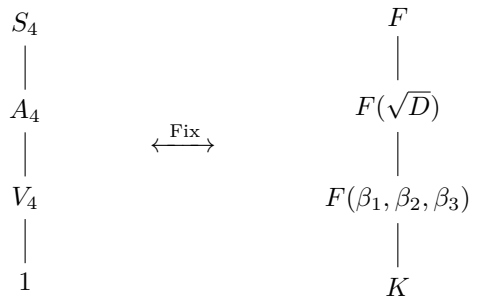


Diagram explanation. Objects: Left lattice: four groups, each a node – S_4 (the full Galois group, order 24), A_4 (the alternating subgroup, order 12, kernel of the sign map), V_4 (the normal Klein four-group $\{e, (12)(34), (13)(24), (14)(23)\}$, order 4, the subgroup fixing each of the three pairings of the roots into two pairs), and 1 (the trivial subgroup). Right lattice: four fields – F (the base field), $F(\sqrt{D})$ (the quadratic resolvent, degree 2 over F), $F(\beta_1, \beta_2, \beta_3)$ (the splitting field of the resolvent cubic g, degree 6 over F when $G = S_4$), and K (the full splitting field of f, degree 24 over F). All four groups are subgroups of S_4, connected by the chain of normal inclusions $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$.

Arrows: The dashes in each lattice denote containment (upward = larger group, downward = larger field). The double-headed horizontal arrow labeled Fix is the Galois correspondence: it sends a subgroup $H \leq S_4$ to its fixed field $\operatorname{Fix}(H) = \{x \in K : \sigma(x) = x \ \forall \sigma \in H\}$, and in reverse sends an intermediate field L to $\operatorname{Gal}(K/L)$. This is an order-reversing bijection: $H_1 \leq H_2$ corresponds to $\operatorname{Fix}(H_1) \supseteq \operatorname{Fix}(H_2)$.

What commutes: Inclusion-reversal at each level: $1 \leq V_4$ corresponds to $K \supseteq F(\beta_1, \beta_2, \beta_3)$; $V_4 \leq A_4$ corresponds to $F(\beta_1, \beta_2, \beta_3) \supseteq F(\sqrt{D})$; $A_4 \leq S_4$ corresponds to $F(\sqrt{D}) \supseteq F$. Precisely: $\operatorname{Fix}(1) = K$, $\operatorname{Fix}(V_4) = F(\beta_1, \beta_2, \beta_3)$, $\operatorname{Fix}(A_4) = F(\sqrt{D})$, $\operatorname{Fix}(S_4) = F$.

Why it commutes: Chase the group V_4: an element $\sigma \in V_4$ is a product of two disjoint transpositions, so $\sigma(\beta_i) = \beta_i$ for each resolvent root β_i (since V_4 stabilizes every pairing $\{\alpha_i\alpha_j + \alpha_k\alpha_l\}$ set-wise while fixing each individual value). Hence every element of $F(\beta_1, \beta_2, \beta_3)$ is fixed by V_4, giving $\operatorname{Fix}(V_4) \supseteq F(\beta_1, \beta_2, \beta_3)$; since $[K : F(\beta_1, \beta_2, \beta_3)] = |V_4| = 4$, equality holds. Similarly a transposition $\sigma \in S_4 \setminus A_4$ satisfies $\sigma(\Delta) = -\Delta$, so $\Delta \notin F$ when $G \not\leq A_4$, giving $\operatorname{Fix}(A_4) = F(\Delta) = F(\sqrt{D})$ by the discriminant criterion.

Why this matters here: This diagram is the structural payoff for the entire resolvent-cubic method: it shows that the three auxiliary quantities $\sqrt{D}$ and $\beta_1, \beta_2, \beta_3$ are *not ad hoc tools* but the fixed fields of the natural

normal subgroups in the solvability series $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$. Reading the diagram left-to-right translates the purely algebraic question (which subgroup is G?) into the arithmetic question (which fields $F(\sqrt{D})$ and $F(\beta_i)$ are actually defined over F?), which is what the resolvent-cubic table answers.

Concrete example: For $f = x^4 + x + 1$ over $\mathbb{Q}$ (previous worked example, $G = S_4$, $D = 229$): $\mathrm{Fix}(A_4) = \mathbb{Q}(\sqrt{229})$ (a real quadratic field, degree 2); $\mathrm{Fix}(V_4) = \mathbb{Q}(\beta_1, \beta_2, \beta_3)$ is the splitting field of the irreducible resolvent cubic $g = x^3 - 4x - 1$ (degree 6); and K is the full splitting field of f (degree 24). The chain $\mathbb{Q} \subset \mathbb{Q}(\sqrt{229}) \subset \mathbb{Q}(\beta_1, \beta_2, \beta_3) \subset K$ has degree steps $2, 3, 4$, and $2 \cdot 3 \cdot 4 = 24 = |S_4|$.

Common pitfall: Students read the diagram and confuse the direction of containment: $V_4 \leq A_4$ in the left lattice means $\mathrm{Fix}(V_4) \supseteq \mathrm{Fix}(A_4)$ in the right – the *larger* subgroup has the *smaller* fixed field. It is tempting to think "A_4 is bigger, so $\mathrm{Fix}(A_4)$ is bigger," but the correspondence is order-reversing: more symmetry (larger subgroup) means fewer fixed elements (smaller field).

Takeaway: The point of this diagram is that the normal subgroup chain $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$ translates, term by term via the Galois correspondence, into the tower $K \supset F(\beta_1, \beta_2, \beta_3) \supset F(\sqrt{D}) \supset F$, so the resolvent cubic and discriminant are not tricks but the canonical intermediate fields forced by the structure of S_4.

Here $F(\sqrt{D}) = \mathrm{Fix}(A_4)$ is the quadratic resolvent, $F(\beta_1, \beta_2, \beta_3) = \mathrm{Fix}(V_4)$ is the splitting field of the resolvent cubic (degree 6 over F when $G = S_4$, since $S_4/V_4 \cong S_3$), and $K = \mathrm{Fix}(1)$ is the full splitting field of f (degree 24). The chain of normal subgroups $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$ with abelian quotients V_4, $\mathbb{Z}/3\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z}$ is exactly the solvability of S_4 that makes the quartic solvable by radicals. For the smaller groups the picture truncates: $G = A_4$ drops the top quadratic ($F = F(\sqrt{D})$); $G = D_8$ has $G \cap V_4 = V_4$ and G/V_4 of order 2, so the resolvent cubic contributes only a quadratic; $G = V_4$ makes the resolvent cubic split entirely (no new field); and $G = C_4$ meets V_4 in a group of order 2.

Worked Example 14.6.25 (Subfield tower for the S_4 quartic $x^4 + x + 1$)**.** Describe the distinguished subfields of the splitting field K of $x^4 + x + 1$ predicted by the S_4 correspondence.

Recognition. With $G = S_4$ (previous example, $D = 229$, resolvent $g = x^3 - 4x - 1$ irreducible), the normal series $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$ gives a canonical tower $F \subset F(\sqrt{D}) \subset \mathrm{Fix}(V_4) \subset K$.

Solution. Here $[K : \mathbb{Q}] = |S_4| = 24$. The quadratic resolvent is $\mathbb{Q}(\sqrt{D}) = \mathbb{Q}(\sqrt{229})$ (degree 2, $= \mathrm{Fix}(A_4)$). The splitting field of the resolvent cubic $g = x^3 - 4x - 1$ is $\mathrm{Fix}(V_4)$, of degree $[S_4 : V_4] = 6$ over $\mathbb{Q}$ and containing $\mathbb{Q}(\sqrt{229})$ (since $\mathrm{disc}\, g = 229$ is a non-square, $\mathrm{Gal}(g) = S_3$). Finally K itself has degree 24. Sanity check: the degrees multiply correctly along the tower, $2 \cdot 3 \cdot 4 = 24$, matching $|V_4| = 4$, $[A_4 : V_4] = 3$, $[S_4 : A_4] = 2$; and $\mathbb{Q}(\sqrt{229}) \subset \mathrm{Fix}(V_4)$ because $A_4 \supset V_4$ forces $\mathrm{Fix}(A_4) \subset \mathrm{Fix}(V_4)$, exactly the inclusion-reversal of the Galois correspondence.

Worked Example 14.6.26 (Why $x^4 - 25$ is reducible and falls off the transitive list)**.** Determine the Galois group of $x^4 - 25$ over $\mathbb{Q}$ and explain why the resolvent-cubic table does not apply directly.

Recognition. $x^4 - 25 = (x^2 - 5)(x^2 + 5)$ is reducible, so its group is intransitive and not among the five transitive subgroups; analyze it as a compositum instead.

Solution. The roots are $\pm\sqrt{5}, \pm i\sqrt{5}$, so $K = \mathbb{Q}(\sqrt{5}, i\sqrt{5}) = \mathbb{Q}(\sqrt{5}, i)$, a biquadratic field of degree 4 with $\mathrm{Gal} \cong V_4 = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ generated by $\sqrt{5} \mapsto -\sqrt{5}$ and $i \mapsto -i$. As a subgroup of S_4 acting on $\{\sqrt{5}, -\sqrt{5}, i\sqrt{5}, -i\sqrt{5}\}$ it is intransitive: $\{\pm\sqrt{5}\}$ and $\{\pm i\sqrt{5}\}$ are separate orbits. Sanity check: although $|G| = 4$ matches a transitive V_4, the action here is the *intransitive* $\langle (12), (34) \rangle$, not the transitive $\langle (12)(34), (13)(24) \rangle$; this is why the table – which presupposes an irreducible quartic – cannot be applied, and we read the group off the compositum $\mathbb{Q}(\sqrt{5}) \cdot \mathbb{Q}(i)$ directly.

Worked Example 14.6.27 (Locating complex conjugation as a permutation: $x^4 - 2$)**.** Identify complex conjugation as an explicit permutation of the roots of $x^4 - 2$ and confirm it lies in $D_8 \setminus A_4$.

Recognition. Complex conjugation restricts to an automorphism of the splitting field $\mathbb{Q}(\sqrt[4]{2}, i)$; it fixes the real roots and swaps each complex root with its conjugate, so it is a product of transpositions.

Solution. Number the roots $\alpha_1 = \sqrt[4]{2}$, $\alpha_2 = -\sqrt[4]{2}$, $\alpha_3 = i\sqrt[4]{2}$, $\alpha_4 = -i\sqrt[4]{2}$. Conjugation fixes α_1, α_2 (real) and swaps $\alpha_3 \leftrightarrow \alpha_4$, so it is the transposition (34), an odd permutation. Since $D_8 = \langle r, s \rangle$ with $r = (1324)$ (a 4-cycle sending $\sqrt[4]{2} \mapsto i\sqrt[4]{2}$) and $s = (34)$, conjugation is the reflection $s \in D_8$. Sanity check: (34) is odd, so it is *not* in A_4; this is consistent with $D = \mathrm{disc}(x^4 - 2) = -2048$ being a non-square (placing $G \not\leq A_4$), and the presence of a transposition-type element confirms G is not the all-even A_4 or V_4.

Worked Example 14.6.28 (The general quartic has group S_4)**.** Explain why the general quartic $x^4 - s_1x^3 + s_2x^2 - s_3x + s_4$ over $\mathbb{Q}(s_1, s_2, s_3, s_4)$ has Galois group S_4.

Recognition. This is the $n = 4$ case of the general-polynomial theorem: over the field of symmetric functions the Galois group of $\prod_i (x - x_i)$ is the full S_n.

Solution. Take x_1, x_2, x_3, x_4 independent, $E = \mathbb{Q}(s_1, s_2, s_3, s_4)$ with the s_i the elementary symmetric functions. Then $\mathbb{Q}(x_1, \ldots, x_4)/E$ is Galois with group S_4 permuting the x_i, of degree $4! = 24$. The Galois group S_4 permutes the roots $\beta_1, \beta_2, \beta_3$ of the resolvent cubic g transitively and contains odd permutations, so g is irreducible over E and $D = \operatorname{disc}(f)$ is not a square in E, landing in the top row of the table: S_4. Sanity check: $[\mathbb{Q}(x_1, \ldots, x_4) : E] = 24 = |S_4|$, and the normal tower $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$ exhibits the classical resolvent fields $E(\sqrt{D}) \subset E(\beta_1, \beta_2, \beta_3)$, the abstract template every specific S_4-quartic (like $x^4 + x + 1$) specializes.

Exercises (from the text).

1. Show that a cubic in $\mathbb{Q}[x]$ with a multiple root has a linear factor. Is the same true for quartics?
2. Determine the Galois groups over $\mathbb{Q}$ of the following polynomials:
   (a) $x^3 - x^2 - 4$
   (b) $x^3 - 2x + 4$
   (c) $x^3 - x + 1$
   (d) $x^3 + x^2 - 2x - 1$.
3. Prove for any $a, b \in \mathbb{F}_p$, that if $x^3 + ax + b$ is irreducible then $-4a^3 - 27b^2$ is a square in $\mathbb{F}_p$.
4. Determine the Galois group over $\mathbb{Q}$ of $x^4 - 25$.
5. Determine the Galois group over $\mathbb{Q}$ of $x^4 + 4$.
6. Determine the Galois group over $\mathbb{Q}$ of $x^4 + 3x^3 - 3x - 2$.
7. Determine the Galois group over $\mathbb{Q}$ of $x^4 + 2x^2 + x + 3$.
8. Determine the Galois group over $\mathbb{Q}$ of $x^4 + 8x + 12$.
9. Determine the Galois group over $\mathbb{Q}$ of $x^4 + 4x - 1$ (cf. Exercise 19).
10. Determine the Galois group over $\mathbb{Q}$ of $x^5 + x - 1$.
11. Let F be an extension of $\mathbb{Q}$ of degree 4 that is not Galois over $\mathbb{Q}$. Prove that the Galois closure of F has Galois group either S_4, A_4 or the dihedral group D_8 of order 8. Prove that the Galois group is dihedral if and only if F contains a quadratic extension of $\mathbb{Q}$.
12. Prove that an extension F of $\mathbb{Q}$ of degree 4 can be generated by the root of an irreducible biquadratic $x^4 + ax^2 + b$ over $\mathbb{Q}$ if and only if F contains a quadratic extension of $\mathbb{Q}$.
13. (a) Let $\pm\alpha$, $\pm\beta$ denote the roots of the polynomial $f(x) = x^4 + ax^2 + b \in \mathbb{Z}[x]$. Prove that $f(x)$ is irreducible if and only if α^2, $\alpha \pm \beta$ are not elements of $\mathbb{Q}$.
    (b) Suppose $f(x)$ is irreducible and let G be the Galois group of $f(x)$. Prove that
        (i) $G \cong V$, the Klein 4-group, if and only if b is a square in $\mathbb{Q}$ if and only if $\alpha\beta$ is rational.
        (ii) $G \cong C$, the cyclic group of order 4, if and only if $b(a^2 - 4b)$ is a square in $\mathbb{Q}$ if and only if $\mathbb{Q}(\alpha\beta) = \mathbb{Q}(\alpha^2)$.
        (iii) $G \cong D_8$, the dihedral group of order 8, if and only if b and $b(a^2 - 4b)$ are not squares in $\mathbb{Q}$ if and only if $\alpha\beta \notin \mathbb{Q}(\alpha^2\beta)$.
14. Prove the polynomial $x^4 - px^2 + q$ is irreducible for any distinct odd primes p and q and has as Galois group the dihedral group of order 8.
15. Prove the polynomial $x^4 + px + p$ is irreducible for every prime p and for $p \neq 3, 5$ has Galois group S_4. Prove the Galois group for $p = 3$ is dihedral of order 8 and for $p = 5$ is cyclic of order 4.

16. Determine the Galois group over $\mathbb{Q}$ of the polynomial $x^4 + 8x^2 + 8x + 4$. Determine which of the subfields of this field are Galois over $\mathbb{Q}$ and for each subfield which are Galois determine a polynomial in $\mathbb{Q}[x]$ for which they are the splitting field over $\mathbb{Q}$.

17. Find the Galois group of $x^4 - 7$ over $\mathbb{Q}$ explicitly as a permutation group on the roots.

18. Let θ be a root of $x^3 - 3x + 1$. Prove that the splitting field of this polynomial is $\mathbb{Q}(\theta)$ and that the Galois group is cyclic of order 3. In particular the other roots of this polynomial can be written in the form $a + b\theta + c\theta^2$ for some $a, b, c \in \mathbb{Q}$. Determine the other roots explicitly in terms of θ.

19. Let $f(x)$ be an irreducible polynomial of degree 4 in $\mathbb{Q}[x]$ with discriminant D. Let K denote the splitting field of $f(x)$, viewed as a subfield of the complex numbers $\mathbb{C}$.

    (a) Prove that $\mathbb{Q}(\sqrt{D}) \subset K$.

    (b) Let τ denote complex conjugation and let τ_K denote the restriction of complex conjugation to K. Prove that τ_K is an element of $\mathrm{Gal}(K/\mathbb{Q})$ of order 1 or 2 depending on whether every element of K is real or not.

    (c) Prove that if $D < 0$ then K cannot be cyclic of degree 4 over $\mathbb{Q}$ (i.e., $\mathrm{Gal}(K/\mathbb{Q})$ cannot be a cyclic group of order 4).

    (d) Prove generally that $\mathbb{Q}(\sqrt{D})$ for squarefree $D < 0$ is not a subfield of a cyclic quartic field (cf. also Exercise 19 of Section 7).

20. Determine the Galois group of $(x^3 - 2)(x^3 - 3)$ over $\mathbb{Q}$. Determine all the subfields which contain $\mathbb{Q}(\rho)$ where ρ is a primitive 3rd root of unity.

21. Let $G \leq S_n$ be a subgroup of the symmetric group and suppose $\sigma_1, \ldots, \sigma_k$ are generators for G. If the polynomial $f(x_1, x_2, \ldots, x_n)$ is fixed by the generators σ_i show it is fixed by G.

22. (*Newton's Formulas*) Let $f(x)$ be a monic polynomial of degree n with roots $\alpha_1, \ldots, \alpha_n$. Let s_i be the elementary symmetric function of degree i in the roots and define $s_i = 0$ for $i > n$. Let $p_i = \alpha_1^i + \cdots + \alpha_n^i$ be the sum of the ith powers of the roots of $f(x)$. Prove *Newton's Formulas*:

$$\begin{aligned} p_1 - s_1 &= 0 \\ p_2 - s_1 p_1 + 2s_2 &= 0 \\ p_3 - s_1 p_2 + s_2 p_1 - 3s_3 &= 0 \\ &\vdots \\ p_i - s_1 p_{i-1} + s_2 p_{i-2} - \cdots + (-1)^{i-1} s_{i-1} p_1 + (-1)^i i s_i &= 0. \end{aligned}$$

23. (a) If $x + y + z = 1$, $x^2 + y^2 + z^2 = 2$ and $x^3 + y^3 + z^3 = 3$, determine $x^4 + y^4 + z^4$.

    (b) Prove generally that x, y, z are not rational but that $x^n + y^n + z^n$ is rational for every positive integer n.

24. Prove that an $n \times n$ matrix A over a field of characteristic 0 is nilpotent if and only if the trace of A^k is 0 for all $k \geq 1$.

25. Prove that two $n \times n$ matrices A and B over a field of characteristic 0 have the same characteristic polynomial if and only if the trace of A^k equals the trace of B^k for all $k \geq 0$.

26. Use the fact that the trace of AB is the same as the trace of BA for any two $n \times n$ matrices A and B to show that AB and BA have the same characteristic polynomial over a field of characteristic 0 (the same result is true over a field of arbitrary characteristic).

27. Let $f(x)$ be a monic polynomial of degree n with roots $\alpha_1, \alpha_2, \ldots, \alpha_n$.

(a) Show that the discriminant D of $f(x)$ is the square of the Vandermonde determinant

$$\begin{vmatrix} 1 & \alpha_1 & \alpha_1^2 & \cdots & \alpha_1^{n-1} \\ 1 & \alpha_2 & \alpha_2^2 & \cdots & \alpha_2^{n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \alpha_n & \alpha_n^2 & \cdots & \alpha_n^{n-1} \end{vmatrix} = \prod_{i>j} (\alpha_i - \alpha_j).$$

(b) Taking the Vandermonde matrix above, multiplying on the left by its transpose and taking the determinant show that one obtains

$$D = \begin{vmatrix} p_0 & p_1 & p_2 & \cdots & p_{n-1} \\ p_1 & p_2 & p_3 & \cdots & p_n \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ p_{n-1} & p_n & p_{n+1} & \cdots & p_{2n-2} \end{vmatrix}$$

where $p_i = \alpha_1^i + \cdots + \alpha_n^i$ is the sum of the ith powers of the roots of $f(x)$, which can be computed in terms of the coefficients of $f(x)$ using Newton's formulas above. This gives an efficient procedure for calculating the discriminant of a polynomial.

28. Let α be a root of the irreducible polynomial $f(x) \in F[x]$ and let $K = F(\alpha)$. Let D be the discriminant of $f(x)$. Prove that $D = (-1)^{n(n-1)/2} N_{K/F}(f'(\alpha))$, where $f'(x) = D_x f(x)$ is the derivative of $f(x)$. The following exercises describe the *resultant* of two polynomials and in particular provide another efficient method for calculating the discriminant of a polynomial.

29. Let F be a field and let $f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0$ and $g(x) = b_m x^m + b_{m-1} x^{m-1} + \cdots + b_1 x + b_0$ be two polynomials in $F[x]$.

(a) Prove that a necessary and sufficient condition for $f(x)$ and $g(x)$ to have a common root (or equivalently, a nonconstant common divisor in $F[x]$) is the existence of a nonzero polynomial $a(x) \in F[x]$ of degree at most $m-1$ and a nonzero polynomial $b(x) \in F[x]$ of degree at most $n-1$ with $a(x)f(x) = b(x)g(x)$.

(b) Writing $a(x)$ and $b(x)$ explicitly as polynomials show that equating coefficients in the equation $a(x)f(x) = b(x)g(x)$ gives a system of $n+m$ linear equations for the coefficients of $a(x)$ and $b(x)$. Prove that this system has a nontrivial solution (hence $f(x)$ and $g(x)$ have a common zero) if and only if the determinant

$$R(f,g) = \begin{vmatrix} a_n & a_{n-1} & \cdots & & a_0 & & & \\ & a_n & a_{n-1} & \cdots & & a_0 & & \\ & & a_n & a_{n-1} & \cdots & & a_0 & \\ & & & \ddots & & & & \\ & & & & a_n & a_{n-1} & \cdots & a_0 \\ b_m & b_{m-1} & \cdots & & b_0 & & & \\ & b_m & b_{m-1} & \cdots & & b_0 & & \\ & & b_m & b_{m-1} & \cdots & & b_0 & \\ & & & \ddots & & & & \\ & & & & b_m & b_{m-1} & \cdots & b_0 \end{vmatrix}$$

is zero. Here $R(f,g)$, called the *resultant* of the two polynomials, is the determinant of an $(n+m) \times (n+m)$ matrix R with m rows involving the coefficients of $f(x)$ and n rows involving the coefficients of $g(x)$.

30. (a) With notations as in the previous problem, show that we have the matrix equation

$$R\begin{pmatrix} x^{n+m-1} \\ x^{n+m-2} \\ \vdots \\ x \\ 1 \end{pmatrix} = \begin{pmatrix} x^{m-1}f(x) \\ x^{m-2}f(x) \\ \vdots \\ f(x) \\ x^{n-1}g(x) \\ x^{n-2}g(x) \\ \vdots \\ g(x) \end{pmatrix}.$$

(b) Let R' denote the matrix of cofactors of R as in Theorem 30 of Section 11.4, so $R'R = R(f,g)I$, where I is the identity matrix. Multiply both sides of the matrix equation above by R' and equate the bottom entry of the resulting column matrices to prove there are polynomials $r(x), s(x) \in F[x]$ such that $R(f,g)$ is equal to $r(x)f(x) + s(x)g(x)$, i.e., the resultant of two polynomials is a linear combination (in $F[x]$) of the polynomials.

31. Consider $f(x)$ and $g(x)$ as general polynomials and suppose the roots of $f(x)$ are $x_1, \ldots, x_n$ and the roots of $g(x)$ are $y_1, \ldots, y_m$. The coefficients of $f(x)$ are powers of a_n times the elementary symmetric functions in $x_1, x_2, \ldots, x_n$ and the coefficients of $g(x)$ are powers of b_m times the elementary symmetric functions in $y_1, y_2, \ldots, y_m$.

(a) By expanding the determinant show that $R(f,g)$ is homogeneous of degree m in the coefficients a_i and homogeneous of degree n in the coefficients b_j.

(b) Show that $R(f,g)$ is $a_n^m b_m^n$ times a symmetric function in $x_1, \ldots, x_n$ and $y_1, \ldots, y_m$.

(c) Since $R(f,g)$ is 0 if any polynomials $f(x)$ and $g(x)$ have a common root, show that $R(f,g)$ is divisible by $x_i - y_j$ for $i = 1, 2, \ldots, n$, $j = 1, 2, \ldots, m$. Conclude by degree considerations that

$$R = a_n^m b_m^n \prod_{i=1}^{n} \prod_{j=1}^{m} (x_i - y_j).$$

(d) Show that the product in (c) can be also written

$$R(f,g) = a_n^m \prod_{i=1}^{n} g(x_i) = (-1)^{nm} b_m^n \prod_{j=1}^{m} f(y_j).$$

This gives an interesting *reciprocity* between the product of g evaluated at the roots of f and the product of f evaluated at the roots of g.

32. Consider now the special case where $g(x) = f'(x)$ is the derivative of the polynomial $f(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ and suppose the roots of $f(x)$ are $\alpha_1, \alpha_2, \ldots, \alpha_n$. Using the formula

$$R(f,f') = \prod_{i=1}^{n} f'(\alpha_i)$$

of the previous exercise, prove that

$$D = (-1)^{n(n-1)/2} R(f,f')$$

where D is the discriminant of $f(x)$.

33. (a) Prove that the discriminant of the cyclotomic polynomial $\Phi_p(x)$ for the pth roots of unity for an odd prime p is $(-1)^{(p-1)/2} p^{p-2}$. [One approach: use Exercise 5 of the previous section together with the determinant form for the discriminant in terms of the power sums p_i.]

(b) Prove that $\mathbb{Q}(\sqrt{(-1)^{(p-1)/2}p}) \subset \mathbb{Q}(\zeta_p)$ for p an odd prime. (Cf. also Exercise 11 of Section 7.)

34. Use the previous exercise to prove that every quadratic extension of $\mathbb{Q}$ is contained in a cyclotomic extension (a special case of the Kronecker–Weber Theorem).

35. Prove that the discriminant D of the polynomial $x^n + px + q$ is given by the formula $(-1)^{n(n-1)/2}n^n q^{n-1} + (-1)^{(n-1)(n-2)/2}(n-1)^{n-1}p^n$.

36. Prove that the discriminant of $x^n + nx^{n-1} + n(n-1)x^{n-2} + \cdots + n(n-1)\cdots(3)(2)x + n!$ is $(-1)^{n(n-1)/2}(n!)^n$.

The following exercises 37 to 43 outline two procedures for writing a symmetric function as a polynomial in the elementary symmetric functions. Let $f(x_1, \ldots, x_n)$ be a polynomial which is symmetric in $x_1, \ldots, x_n$. Recall that the degree (sometimes called the *weight*) of the monomial $Ax_1^{a_1}x_2^{a_2}\cdots x_n^{a_n}$ $(a_i \geq 0)$ is $a_1 + a_2 + \cdots + a_n$ and that a polynomial is *homogeneous* (*of degree* m) if every monomial has the same degree (m).

37. (a) Show that every polynomial $f(x_1, \ldots, x_n)$ can be written as a sum of homogeneous polynomials. Show that if $f(x_1, \ldots, x_n)$ is symmetric then each of these homogeneous polynomials is also symmetric.

    (b) Show that the monomial $Bs_1^{b_1}s_2^{b_2}\cdots s_n^{b_n}$ in the elementary symmetric functions is a homogeneous polynomial in $x_1, x_2, \ldots, x_n$ of degree $b_1 + 2b_2 + \cdots + nb_n$.

    In writing $f(x_1, \ldots, x_n)$ as a polynomial in the symmetric functions it therefore suffices to assume that $f(x_1, \ldots, x_n)$ is homogeneous.

38. (a) Order monomials lexicographically with $x_1 > x_2 > \cdots > x_n$ and let $Ax_1^{a_1}x_2^{a_2}\cdots x_n^{a_n}$ be the lexicographically largest term of the symmetric polynomial $f(x_1, \ldots, x_n)$, so that $a_1 \geq a_2 \geq \cdots \geq a_n \geq 0$. Show that the monomial $As_1^{a_1-a_2}s_2^{a_2-a_3}\cdots s_n^{a_n}$ in the elementary symmetric functions has the same lexicographic initial term as $f(x_1, \ldots, x_n)$.

    (b) Show that subtracting $As_1^{a_1-a_2}s_2^{a_2-a_3}\cdots s_n^{a_n}$ from $f(x)$ yields either 0 or a symmetric polynomial of the same degree whose terms are lexicographically smaller than the initial term of $f(x_1, \ldots, x_n)$.

    (c) Show that the iteration of this procedure (lexicographic ordering, choosing the lexicographically largest term, subtracting the associated monomial in the elementary symmetric functions) terminates, expressing $f(x_1, \ldots, x_n)$ as a polynomial in the elementary symmetric functions.

39. Use the algorithm described in Exercise 38 to prove that a polynomial $f(x_1, \ldots, x_n)$ that is symmetric in $x_1, \ldots, x_n$ can be expressed as a polynomial in the elementary symmetric functions.

40. Use the procedure in Exercise 38 to express each of the following symmetric functions as a polynomial in the elementary symmetric functions:

    (a) $(x_1 - x_2)^2$

    (b) $x_1^3 + x_2^3 + x_3^3$

    (c) $x_1^2x_2^2 + x_1^2x_3^2 + x_2^2x_3^2$.

41. Use the procedure in Exercise 38 to express $\sum_{i \neq j} x_i^2 x_j$ as a polynomial in the elementary symmetric functions. We now know that a symmetric polynomial $f(x_1, \ldots, x_n)$ can be written uniquely as a polynomial in the elementary symmetric functions. Knowing this existence and uniqueness we can describe an algorithm and computationally useful method for determining the coefficients of the elementary symmetric functions in this polynomial. As in Exercise 37 we may assume that $f(x_1, \ldots, x_n)$ is homogeneous of degree M. Let N be the maximum degree of any of the variables $x_1, \ldots, x_n$ in $f(x_1, \ldots, x_n)$.

    (a) Determine all of the possible monomials $A_i s_1^{a_1}s_2^{a_2}\cdots s_n^{a_n}$ appearing in $f(x_1, \ldots, x_n)$ from the constraints

$$a_1 + 2a_2 + \cdots + na_n = M$$
$$a_1 + a_2 + \cdots + a_n \leq N.$$

    (b) Since $f(x_1, \ldots, x_n) = \sum A_i s_1^{a_1}s_2^{a_2}\cdots s_n^{a_n}$ is a polynomial *identity*, it is valid for any substitution of values for $x_1, \ldots, x_n$. Each substitution gives a linear relation on the coefficients A_i and so a sufficient number of substitutions will determine the A_i.

42. Show that the function $(x_1+x_2-x_3-x_4)(x_1+x_3-x_2-x_4)(x_1+x_4-x_2-x_3)$ is symmetric in x_1, x_2, x_3, x_4 and use the preceding procedure to prove it can be expressed as a polynomial in the elementary symmetric functions. Show that this polynomial is $s_1^3 - 4s_1s_2 + 8s_3$.

43. Express each of the following in terms of the elementary symmetric functions:

    (a) $\sum_{i\neq j} x_i^2 x_j$

    (b) $\sum_{i,j,k \text{ distinct}} x_i^2 x_j x_k$

    (c) $\sum_{i,j,k \text{ distinct}} x_i^2 x_j^2 x_k^2$.

44. Let $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ be the roots of a quartic polynomial $f(x)$ over $\mathbb{Q}$. Show that the quantities $\alpha_1\alpha_2 + \alpha_3\alpha_4$, $\alpha_1\alpha_3 + \alpha_2\alpha_4$, and $\alpha_1\alpha_4 + \alpha_2\alpha_3$ are permuted by the Galois group of $f(x)$. Conclude that these elements are the roots of a cubic polynomial with coefficients in $\mathbb{Q}$ (also sometimes referred to as the *resolvent cubic* of $f(x)$).

45. If $f(x) = x^3 + px + q \in \mathbb{Z}[x]$ is irreducible, prove that its discriminant $D = -4p^3 - 27q^2$ is an integer not equal to 0, ± 1.

46. Prove that every finite group occurs as the Galois group of a field extension of the form $F(x_1, \ldots, x_n)/E$.

47. Let F be a field of characteristic 0 in which every cubic polynomial has a root. Let $f(x)$ be an irreducible quartic polynomial over F whose discriminant is a square in F. Determine the Galois group of $f(x)$.

48. Determine the splitting field K for the polynomial $f(x) = x^6 - 2x^3 - 2$ over $\mathbb{Q}$ (cf. also Exercise 2 of Section 8).

    (a) Prove that $f(x)$ is irreducible over $\mathbb{Q}$ with roots the three cube roots of $1 \pm \sqrt{3}$.

    (b) Prove that K contains the field $\mathbb{Q}(\sqrt{-3})$ of 3rd roots of unity and contains $\mathbb{Q}(\sqrt{3})$, hence contains the biquadratic field $F = \mathbb{Q}(i, \sqrt{3})$. Take the product of two of the roots in (a) to prove that K contains $\sqrt[3]{2}$ and conclude that K is an extension of the field $L = \mathbb{Q}(\sqrt[3]{2}, i, \sqrt{3})$.

    (c) Prove that $[L : \mathbb{Q}] = 12$ and that K is obtained from L by adjoining the cube root of an element in L, so that $[K : \mathbb{Q}] = 12$ or 36.

    (d) Prove that if $[K : \mathbb{Q}] = 12$ then $K = \mathbb{Q}(\sqrt[3]{2}, i, \sqrt{3})$ and that $\text{Gal}(K/\mathbb{Q})$ is isomorphic to the direct product of the cyclic group of order 2 and S_3. Prove that if $[K : \mathbb{Q}] = 12$ then there is a unique real cubic subfield in K, namely $\mathbb{Q}(\sqrt[3]{2})$.

    (e) Take the quotient of the two real roots in (a) to show that $\sqrt[3]{2+\sqrt{3}}$ and $\sqrt[3]{2-\sqrt{3}}$ (real roots) are both elements of K. Show that $\alpha = \sqrt[3]{2+\sqrt{3}} + \sqrt[3]{2-\sqrt{3}}$ is a real root of the irreducible cubic equation $x^3 - 3x - 4$ whose discriminant is $-2^2 3^4$. Conclude that the Galois closure of the cubic field $\mathbb{Q}(\alpha)$ contains $\mathbb{Q}(i)$ so in particular $\mathbb{Q}(\alpha) \neq \mathbb{Q}(\sqrt[3]{2})$.

    (f) Conclude from (e) that $G = \text{Gal}(K/\mathbb{Q})$ is of order 36. Determine all the elements of G explicitly and in particular show that G is isomorphic to $S_3 \times S_3$.

49. Prove that the Galois group of $x^6 - 4x^3 + 1$ is isomorphic to the dihedral group of order 12. [Observe that the real roots are inverses of each other.]

50. (*Criterion for the Galois Group of an Irreducible Cubic over an Arbitrary Field*) Suppose K is a field and $f(x) = x^3 + ax^2 + bx + c \in K[x]$ is irreducible, so the Galois group of $f(x)$ is either S_3 or A_3.

    (a) Show that the Galois group of $f(x)$ is A_3 if and only if the resultant quadratic polynomial $g(x) = x^2 + (ab - 3c)x + (b^3 + a^3c - 6abc + 9c^2)$ has a root in K. [If α, β, γ are the roots of $f(x)$ show that the Galois group is A_3 if and only if the element $\theta = \alpha\beta^2 + \beta\gamma^2 + \gamma\alpha^2$ is an element of K and that θ is a root of $g(x)$.] Show that the discriminant of $g(x)$ is the same as the discriminant of $f(x)$.

    (b) ($\text{ch}(K) \neq 2$) If K has characteristic different from 2 show either from (a) or directly from the definition of the discriminant that the Galois group of $f(x)$ is A_3 if and only if the discriminant of $f(x)$ is a square in K.

(c) ($\mathrm{ch}(K) = 2$) If K has characteristic 2 show that the discriminant of $f(x)$ is always a square. Show that $f(x)$ can be taken to be of the form $x^3 + px + q$ and that the Galois group of $f(x)$ is A_3 if and only if the quadratic $x^2 + qx + (p^3 + q^2)$ has a root in K (equivalently, if $(p^3 + q^2)/q^2 \in K$ is in the image of the *Artin–Schreier map* $x \mapsto x^2 - x$ mapping K to K).

(d) If $K = \mathbb{F}_2(t)$ where t is transcendental over $\mathbb{F}_2$. Prove that the polynomials $x^3 + t^2x + t^3$, $x^3 + (t^2 + t + 1)x + (t^2 + t + 1)$, and $x^3 + (t^2 + t + 1)x + (t^3 + t^2 + t)$ have A_3 as Galois group while $x^3 + t^2x + t^2$ and $x^3 + x + t$ have S_3 as Galois group.

51. This exercise proves *Sturm's Theorem* determining the number of real roots of a polynomial $f(x) \in \mathbb{R}[x]$ inside an interval $[a, b]$. The multiple roots of $f(x)$ are zeros of the g.c.d. of $f(x)$ and its derivative $f'(x)$, and it follows that to determine the real roots of $f(x)$ in $[a, b]$ we may assume that the roots of $f(x)$ are *simple*. Apply the (negative of the) Euclidean algorithm to $f_0(x) = f(x)$ and its derivative $f_1(x) = f'(x)$ to find a sequence of polynomials $f(x)$, $f'(x)$, $f_2(x)$, ..., $f_n(x)$ with

$$f_{i-1}(x) = q_i(x)f_i(x) - f_{i+1}(x) \qquad i = 0, 1, \ldots, n-1$$

where $f_n(x) \in \mathbb{R}$ is a nonzero constant.

(a) Prove that consecutive polynomials $f_i(x)$, $f_{i+1}(x)$ for $i = 0, 1, \ldots, n-1$ have no common zeros. [Show that otherwise $f_{i+2}(c) = f_{i+3}(c) = \cdots = 0$, and derive a contradiction.]

(b) Prove that if $f_i(c) = 0$ for some $i = 1, 2, \ldots, n-1$, then $f_{i-1}(c)$, $f_{i+1}(c)$ are nonzero and of opposite signs. For any real number α, let $V(\alpha)$ denote the number of sign changes in the *Sturm sequence* of real numbers

$$f(\alpha), f'(\alpha), f_2(\alpha), \ldots, f_n(\alpha),$$

ignoring any 0's that appear (for example $-1, -2, 0, +3, -4$ has signs $--+-$ disregarding the 0, so there are 2 sign changes, the first from -2 to $+3$, the second from $+3$ to -4).

(c) Suppose $\alpha < \beta$ and that all the elements in the Sturm sequences for α and for β are nonzero. Prove that unless $f_i(c) = 0$ for some $\alpha < c < \beta$ and some $i = 0, 1, \ldots, n$, then the signs of all the elements in the Sturm sequence are the same, so in particular $V(\alpha) = V(\beta)$.

(d) If $f_i(c) = 0$ prove there is a sufficiently small interval (α, β) containing c so that $f_i(x)$ has no zero other than c for $\alpha < x < \beta$.

(e) If $j \geq 1$ in (d), prove that the number of sign changes in $f_{j-1}(\alpha)$, $f_j(\alpha)$, $f_{j+1}(\alpha)$ and in $f_{j-1}(\beta)$, $f_j(\beta)$, $f_{j+1}(\beta)$ are the same. [Observe that $f_{j-1}(c)$ and $f_{j+1}(c)$ have opposite signs (use (b)) and that $f_{j-1}(x)$ and $f_{j+1}(x)$ do not change sign in (α, β).]

(f) If $j = 0$ in (d) show that the number of sign changes in $f_0(\alpha)$, $f'(\alpha)$ is one more than the number of sign changes in $f_0(\beta)$, $f'(\beta)$. [If $f'(c) > 0$ then $f(x)$ is increasing at c, so that $f(\alpha) < 0$, $f(\beta) > 0$, and $f'(x)$ does not change sign in (α, β), so the signs change from $-+$ to $++$. Similarly if $f'(c) < 0$.]

(g) Prove *Sturm's Theorem*: if $f(x)$ is a polynomial with real coefficients all of whose real roots are simple then the number of real zeros of $f(x)$ in an interval $[a, b]$ where $f(a)$ and $f(b)$ are both nonzero is given by $V(a) - V(b)$. [Use (c), (e) and (f) to see that as α runs from a to b the number $V(\alpha)$ of sign changes is constant unless α passes through a root of $f(x)$, in which case it decreases by 1.]

(h) Suppose $f(x) = x^5 + px + q \in \mathbb{R}[x]$ with $p \neq 0$ has simple roots. Show that the sequence of polynomials above is given by $f(x)$, $5x^4 + p$, $-(4p/5)x - q$, and $-D/(256p^4)$ where $D = 256p^5 + 3125q^4$ is the discriminant of $f(x)$. Conclude for $p > 0$ that $f(x)$ has precisely one real root and for $p < 0$ that $f(x)$ has precisely 1 or 3 real roots depending on whether $D > 0$ or $D < 0$, respectively. [E.g., if $p < 0$ and $D < 0$ then at $-\infty$ the signs are $-+-+$ with 3 sign changes and at $+\infty$ the signs are $++++$ with no sign changes.]

Practice problems.

1. Let $f(x) = x^3 - 7x + 7 \in \mathbb{Q}[x]$. Show f is irreducible over $\mathbb{Q}$, compute its discriminant $D = -4p^3 - 27q^2$, and determine whether $\mathrm{Gal}(f) \cong A_3 \cong \mathbb{Z}/3\mathbb{Z}$ or S_3. State $[K : \mathbb{Q}]$ for the splitting field K and describe the quadratic subfield $\mathbb{Q}(\sqrt{D})$ in the S_3 case.

2. For the depressed cubic $f(x) = x^3 + px + q$ with distinct roots $\alpha_1, \alpha_2, \alpha_3$, verify directly from $\Delta = \prod_{i<j}(\alpha_i - \alpha_j)$ that the 3-cycle $\sigma = (123)$ satisfies $\sigma(\Delta) = \Delta$ while the transposition $\tau = (12)$ satisfies $\tau(\Delta) = -\Delta$. Conclude the discriminant criterion $\mathrm{Gal}(f) \leq A_3 \iff \sqrt{D} \in \mathbb{Q}$ without invoking the general theorem.

3. Use the power-sum / Newton's-identity computation to express $p_3 = x_1^3 + x_2^3 + x_3^3$ as a polynomial in the elementary symmetric functions s_1, s_2, s_3, and check your formula on $x_1 = 1$, $x_2 = 2$, $x_3 = 3$.

4. Let $f(x) = x^4 - 10x^2 + 1 \in \mathbb{Q}[x]$. Show f is irreducible over $\mathbb{Q}$, form its resolvent cubic $g(x) = x^3 - px^2 - 4rx + (4pr - q^2)$, factor g over $\mathbb{Q}$, and determine $\mathrm{Gal}(f)$. (Hint: this is a biquadratic, so g always has the rational root $x = p$; decide V_4 vs. C_4 vs. D_8 using squareness of r and of $r(p^2 - 4r)$.)

5. Determine the Galois group of $f(x) = x^4 + 2x^2 + 4$ over $\mathbb{Q}$. Compute the resolvent cubic, identify its rational root, test squareness of r and of $r(p^2 - 4r)$, and conclude which of V_4, C_4, D_8 occurs. Then state $[K : \mathbb{Q}]$.

6. Let $f(x) = x^4 - 2x^2 - 2 \in \mathbb{Q}[x]$ (Eisenstein at 2). Show f is irreducible, compute the resolvent cubic and its factorization, decide whether $\mathrm{Gal}(f)$ is D_8 or C_4 by testing whether f stays irreducible over $\mathbb{Q}(\sqrt{D})$, and name the group.

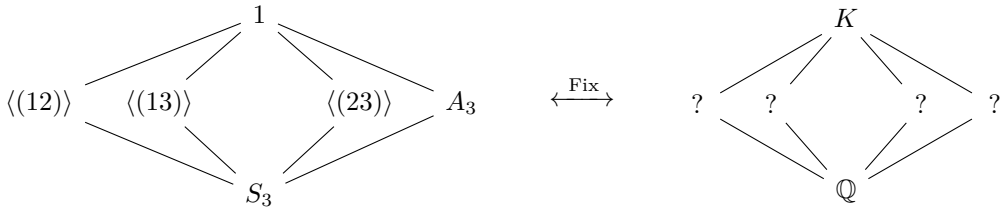
7. Let $g(x) = x^3 - px^2 - 4rx + (4pr - q^2)$ be the resolvent cubic of the depressed quartic $f = x^4 + px^2 + qx + r$ with roots $\alpha_1, \ldots, \alpha_4$. Using $\beta_1 = \alpha_1\alpha_2 + \alpha_3\alpha_4$ and its companions, verify that $\beta_1 + \beta_2 + \beta_3 = p$, that $\beta_1\beta_2 + \beta_1\beta_3 + \beta_2\beta_3 = -4r$ (use $s_1 = 0$), and hence that g has the stated coefficients.

8. Let $f(x) = x^3 + x^2 - 2x - 1 \in \mathbb{Q}[x]$. Show f is irreducible over $\mathbb{Q}$, reduce it to depressed form by $x \mapsto x - \frac{1}{3}$ (or compute D via the resultant directly), show D is a perfect square in $\mathbb{Q}$, and conclude $\mathrm{Gal}(f) \cong \mathbb{Z}/3\mathbb{Z}$ with all roots real. Verify $K = \mathbb{Q}(\theta)$ for any root θ, so $K/\mathbb{Q}$ is cyclic of degree 3.

Additional exercises.

1. Let $f(x) = (x^2 - 2)(x^2 - 3)(x^2 - 6) \in \mathbb{Q}[x]$. Determine the splitting field K, show $[K : \mathbb{Q}] = 4$ (not 8), and prove $\mathrm{Gal}(K/\mathbb{Q}) \cong V_4 = \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$. Realize the group as a subgroup of S_6 on the six roots and describe its orbits, explaining why the action is intransitive (consistent with reducibility of f).

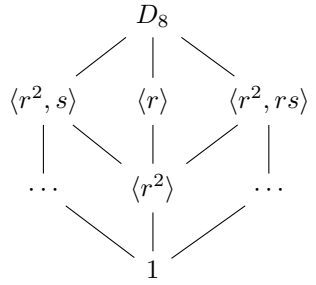
2. Let K be the splitting field over $\mathbb{Q}$ of $f(x) = x^4 + x + 1$, with $\mathrm{Gal}(K/\mathbb{Q}) \cong S_4$ (the worked S_4 example, $D = 229$). Using the normal series $1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$, list the degrees over $\mathbb{Q}$ of $\mathbb{Q}(\sqrt{229}) = \mathrm{Fix}(A_4)$, of $\mathrm{Fix}(V_4)$ (the splitting field of the resolvent cubic $x^3 - 4x - 1$), and of K, and verify $2 \cdot 3 \cdot 4 = 24$. Show $\mathbb{Q}(\sqrt{229}) \subseteq \mathrm{Fix}(V_4)$ as an instance of inclusion-reversal.



3. Prove that there is no quartic polynomial in $\mathbb{Q}[x]$ whose Galois group is the cyclic group C_4 and which has exactly two real roots. (Hint: complex conjugation would then act on the roots as a transposition; relate $D = \mathrm{disc}(f)$ to the number of real roots, and recall a transitive C_4 in S_4 is generated by a 4-cycle, so it contains no transposition. Totally real C_4-quartics do exist, e.g. $x^4 - 4x^2 + 2$, with roots $\pm\sqrt{2 \pm \sqrt{2}}$. Compare with Exercise 19(c)–(d) of the text.)

4. Let p be an odd prime and let $f(x) = x^3 + px + p \in \mathbb{Q}[x]$. Prove f is irreducible (Eisenstein at p), compute $D = -4p^3 - 27p^2 = -p^2(4p + 27)$, and determine for which primes p the Galois group is A_3 versus S_3 in terms of whether $-(4p + 27)$ is a square in $\mathbb{Q}$. Conclude that $\mathrm{Gal}(f) \cong S_3$ for every odd prime p, and identify the quadratic subfield $\mathbb{Q}(\sqrt{D}) = \mathbb{Q}(\sqrt{-(4p + 27)})$.

5. Let F be a field of characteristic $\neq 2$ and let $f \in F[x]$ be a separable quartic with resolvent cubic g. Suppose f is *reducible* over F, factoring as a product of two irreducible quadratics. Prove that, numbering the roots of the two factors $1, 2$ and $3, 4$, $\mathrm{Gal}(f)$ is a nontrivial subgroup of $\langle (12), (34) \rangle \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ (acting intransitively on the four roots; this is not the normal Klein group V_4), and show by examples over $\mathbb{Q}$ that both $\mathbb{Z}/2\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$ can occur. Explain why such an f never appears in the resolvent-cubic table for irreducible quartics.



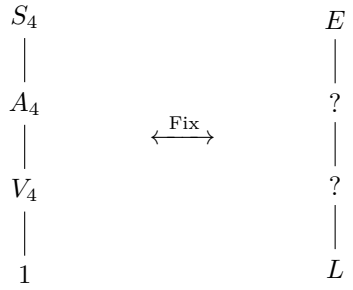
Commutative-diagram exercises.

1. Let $f(x) = x^3 - 2 \in \mathbb{Q}[x]$, with splitting field $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ and $\mathrm{Gal}(K/\mathbb{Q}) \cong S_3$. Complete the Galois-correspondence lattice below by labelling each node on the right with the fixed field $\mathrm{Fix}(H)$ of the indicated subgroup $H \le S_3$, give $[\mathrm{Fix}(H) : \mathbb{Q}]$ for each, and mark which subgroups are normal (hence which fixed fields are Galois over $\mathbb{Q}$):

Prove that $\mathrm{Fix}(A_3) = \mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$ is the unique quadratic subfield and is Galois over $\mathbb{Q}$, while the three order-2 subgroups give three conjugate cubic fields that are *not* Galois over $\mathbb{Q}$.

2. Let $f(x) = x^4 - 2 \in \mathbb{Q}[x]$ with splitting field $K = \mathbb{Q}(\sqrt[4]{2}, i)$ and $\mathrm{Gal}(K/\mathbb{Q}) \cong D_8 = \langle r, s \mid r^4 = s^2 = 1,\ srs = r^{-1} \rangle$, where $r : \sqrt[4]{2} \mapsto i\sqrt[4]{2}$ fixing i, and s is complex conjugation. Draw the full subgroup lattice of D_8 (order 8, with its three subgroups of order 4 and five of order 2) and the corresponding inverted lattice of subfields of K, completing the skeleton:

Identify $\mathrm{Fix}(\langle r \rangle)$, $\mathrm{Fix}(\langle r^2 \rangle)$, and $\mathrm{Fix}(\langle s \rangle)$ explicitly (e.g. $\mathrm{Fix}(\langle r^2 \rangle) = \mathbb{Q}(\sqrt{2}, i)$), prove $\langle r^2 \rangle$ is the centre and is normal so its fixed field is Galois of degree 4 over $\mathbb{Q}$, and exhibit a subgroup of order 2 that is *not* normal together with the non-Galois subfield it fixes.



3. Let $g(x) = g_f(x)$ be the resolvent cubic of an irreducible quartic $f \in F[x]$ ($\mathrm{char}\, F \neq 2$), and recall the surjection $S_4 \twoheadrightarrow S_4/V_4 \cong S_3$. Complete and prove the commutativity of the diagram relating the Galois action on the roots $\{\, \alpha_i \,\}$ of f to the action on the roots $\{\, \beta_j \,\}$ of g:

$$\begin{array}{ccc} \mathrm{Gal}(f) & \hookrightarrow & S_4 \\ {\scriptstyle \pi}\big\downarrow & & \big\downarrow{\scriptstyle S_4/V_4} \\ \mathrm{Gal}(g) & \hookrightarrow & S_3 \end{array}$$

Show $\ker \pi = \mathrm{Gal}(f) \cap V_4 = \mathrm{Gal}(K_f/K_g)$ where K_f, K_g are the splitting fields, conclude $K_g = \mathrm{Fix}(\mathrm{Gal}(f) \cap V_4)$, and use the diagram to explain why "g irreducible over F" is equivalent to "the image of $\mathrm{Gal}(f)$ in S_3 is transitive (all of S_3, or A_3)", i.e. $\mathrm{Gal}(f) \in \{\, S_4, A_4 \,\}$.

4. Let $E = \mathbb{Q}(s_1, s_2, s_3, s_4)$ be the field of symmetric functions and $L = \mathbb{Q}(x_1, x_2, x_3, x_4)$ with $\mathrm{Gal}(L/E) \cong S_4$. Let $D = \mathrm{disc}$ and let $\Delta = \prod_{i<j}(x_i - x_j)$. Draw the Galois-correspondence square for the chain

$1 \trianglelefteq V_4 \trianglelefteq A_4 \trianglelefteq S_4$ and complete it:

Prove $\mathrm{Fix}(A_4) = E(\Delta) = E(\sqrt{D})$, identify $\mathrm{Fix}(V_4)$ as the splitting field over E of the resolvent cubic, and verify the tower degrees $[E(\sqrt{D}) : E] = 2$, $[\mathrm{Fix}(V_4) : E(\sqrt{D})] = 3$, $[L : \mathrm{Fix}(V_4)] = 4$ multiply to $|S_4| = 24$.

14.7 Solvable and Radical Extensions: Insolvability of the Quintic

Radical extensions and solvability by radicals

The classical problem behind this section is the one that animated algebra for three centuries: can the roots of a polynomial be written using only the coefficients, the field operations $+, -, \times, \div$, and the extraction of nth roots? The quadratic, cubic, and quartic all admit such formulas. The quintic, in general, does not – and Galois theory explains exactly why. The bridge from the formula problem to group theory is the notion of a radical extension.

Definition 14.7.1. An extension K/F is a *radical extension* if there is a tower

$$F = K_0 \subseteq K_1 \subseteq \cdots \subseteq K_m = K, \qquad K_{i+1} = K_i(\alpha_{i+1}), \quad \alpha_{i+1}^{n_{i+1}} \in K_i$$

for some integers $n_i \geq 1$. Equivalently, each step adjoins an n_ith root of an element already present. A polynomial $f(x) \in F[x]$ is *solvable by radicals* if its splitting field is contained in some radical extension of F.

So "solvable by radicals" means: every root of f can be reached from F by a finite sequence of root extractions (and field operations). The point is *not* that the splitting field is itself a radical tower, only that it sits inside one. This flexibility – allowing extra radicals (e.g. roots of unity) that do not lie in the splitting field – is what makes the theory clean.

Remark 14.7.1. Throughout this section, to keep the cyclic theory uniform we usually work over a field F of characteristic 0 (or characteristic not dividing the n in question), and we freely adjoin roots of unity. Adjoining ζ_n is itself a radical step (a root of $x^n - 1$), and $F(\zeta_n)/F$ is abelian, hence harmless for solvability. The genuinely new content is the structure of the individual cyclic steps, to which we turn next.

Worked Example 14.7.2 ($\mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ is a radical extension)**.** Exhibit a radical tower realizing the splitting field of $x^3 - 2$ over $\mathbb{Q}$.

Recognition. A radical tower adjoins one root at a time; the splitting field of $x^3 - 2$ is $\mathbb{Q}(\sqrt[3]{2}, \zeta_3)$, and both generators are radicals (ζ_3 a cube root of 1, $\sqrt[3]{2}$ a cube root of 2).

Solution. Take $K_0 = \mathbb{Q}$, $K_1 = \mathbb{Q}(\zeta_3) = \mathbb{Q}(\sqrt{-3})$ (adjoin a square root of -3, since $\zeta_3 = \frac{-1+\sqrt{-3}}{2}$), and $K_2 = K_1(\sqrt[3]{2})$. Then $\zeta_3^3 = 1 \in K_0$ and $(\sqrt[3]{2})^3 = 2 \in K_1$, so the tower is radical, and $K_2 = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ is the splitting field of $x^3 - 2$. Sanity check: $[K_2 : \mathbb{Q}] = [K_2 : K_1] \cdot [K_1 : \mathbb{Q}] = 3 \cdot 2 = 6 = |S_3|$, matching $\mathrm{Gal}(x^3 - 2/\mathbb{Q}) \cong S_3$.

Cyclic extensions: Kummer theory and Hilbert 90

The atoms of a radical tower are the single steps $K_i(\sqrt[n]{a})$. To understand them as Galois extensions we first record the prototype, and the structural input is Hilbert's Theorem 90.

Theorem 14.7.3 (Hilbert's Theorem 90, norm form)**.** *Let K/F be a cyclic extension of degree n with $\mathrm{Gal}(K/F) = \langle\sigma\rangle$, and let $\mathrm{N}_{K/F}$ denote the norm. Then an element $\beta \in K$ has $\mathrm{N}_{K/F}(\beta) = 1$ if and only if*

$$\beta = \frac{\alpha}{\sigma(\alpha)} \qquad \text{for some } \alpha \in K^{\times}.$$

Idea. If $\beta = \alpha/\sigma(\alpha)$ then $\mathrm{N}_{K/F}(\beta) = \prod_{i=0}^{n-1} \sigma^i(\beta) = \prod_i \sigma^i(\alpha)/\sigma^{i+1}(\alpha)$, a telescoping product equal to 1. Conversely, suppose $\mathrm{N}_{K/F}(\beta) = 1$. By Dedekind's lemma the distinct automorphisms $\mathrm{id}, \sigma, \dots, \sigma^{n-1}$ are linearly independent over K, so the "twisted" operator

$$\theta \;\longmapsto\; \theta + \beta\,\sigma(\theta) + \beta\,\sigma(\beta)\,\sigma^2(\theta) + \cdots + \beta\,\sigma(\beta)\cdots\sigma^{n-2}(\beta)\,\sigma^{n-1}(\theta)$$

is not identically zero. Pick θ giving a nonzero value α; the norm-one hypothesis makes the coefficients satisfy $\sigma(\alpha) = \beta^{-1}\alpha$, i.e. $\beta = \alpha/\sigma(\alpha)$. □

Now suppose F contains a primitive nth root of unity ζ (so $\mathrm{char}\, F \nmid n$). Then the cyclic degree-n extensions of F are *exactly* the simple radical extensions $F(\sqrt[n]{a})$ of degree n. This is the heart of Kummer theory.

Theorem 14.7.4 (cyclic extensions are radical when roots of unity are present)**.** *Let F contain a primitive nth root of unity. Then:*

(1) *For any $a \in F^{\times}$, the extension $F(\sqrt[n]{a})/F$ is cyclic of degree d, where $d \mid n$ is the order of a in $F^{\times}/(F^{\times})^n$; in particular $x^n - a$ has cyclic Galois group.*

(2) *Conversely, if K/F is cyclic of degree n, then $K = F(\sqrt[n]{a})$ for some $a \in F^{\times}$, i.e. K is the splitting field of $x^n - a$.*

Idea. (1) If $\alpha = \sqrt[n]{a}$, the other roots of $x^n - a$ are $\zeta^i\alpha$, all in $F(\alpha)$ since $\zeta \in F$; so $F(\alpha)/F$ is Galois. Each $\sigma \in \mathrm{Gal}(F(\alpha)/F)$ sends $\alpha \mapsto \zeta^{c(\sigma)}\alpha$, and $\sigma \mapsto \zeta^{c(\sigma)}$ is an injective homomorphism into the cyclic group $\langle\zeta\rangle$, so the Galois group is cyclic.

(2) Let $\mathrm{Gal}(K/F) = \langle\sigma\rangle$ of order n. Then $\mathrm{N}_{K/F}(\zeta^{-1}) = (\zeta^{-1})^n = 1$ (as $\zeta \in F$), so by Hilbert 90 there is $\alpha \in K^{\times}$ with $\zeta^{-1} = \alpha/\sigma(\alpha)$, i.e. $\sigma(\alpha) = \zeta\alpha$. Then $\sigma(\alpha^n) = (\zeta\alpha)^n = \alpha^n$, so $a := \alpha^n \in F$. The conjugates $\sigma^i(\alpha) = \zeta^i\alpha$ are distinct, so α has n conjugates and $[F(\alpha) : F] = n = [K : F]$, giving $K = F(\alpha) = F(\sqrt[n]{a})$. □

Remark 14.7.2. The element α with $\sigma(\alpha) = \zeta\alpha$ in part (2) is precisely a *Lagrange resolvent*, formed with the primitive root ζ^{-1} in place of ζ: in the notation below, $\alpha = (\alpha/n, \zeta^{-1})$. For any $\theta \in K$ the resolvent is

$$(\theta, \zeta) \;=\; \sum_{i=0}^{n-1} \zeta^i\,\sigma^i(\theta) \;=\; \theta + \zeta\,\sigma(\theta) + \zeta^2\sigma^2(\theta) + \cdots + \zeta^{n-1}\sigma^{n-1}(\theta),$$

and a direct computation gives $\sigma\big((\theta,\zeta)\big) = \zeta^{-1}(\theta,\zeta)$; thus $(\theta,\zeta)^n$ is fixed by σ, hence lies in F. Resolvents are the explicit machine that turns a cyclic extension into a radical one – and, run in reverse, they are exactly what produces Cardano's formula.

In characteristic p the polynomial $x^p - a$ degenerates ($x^p - a = (x - \sqrt[p]{a})^p$ is inseparable), so degree-p cyclic extensions are governed by a different model.

Theorem 14.7.5 (Artin–Schreier, degree p in characteristic p)**.** *Let F have characteristic p. Every cyclic extension K/F of degree p has the form $K = F(\alpha)$ where α is a root of an* Artin–Schreier polynomial

$$x^p - x - a, \qquad a \in F,$$

and conversely such a polynomial is either split over F or irreducible with cyclic Galois group of order p.

Idea. The additive analogue of Hilbert 90 (the trace form: $\mathrm{Tr}_{K/F}(\beta) = 0 \iff \beta = \gamma - \sigma(\gamma)$) applies. Since $\mathrm{char}\, F = p$, $\mathrm{Tr}_{K/F}(-1) = p \cdot (-1) = 0$, so $-1 = \alpha - \sigma(\alpha)$ for some α, i.e. $\sigma(\alpha) = \alpha + 1$. Then $\sigma(\alpha^p - \alpha) = (\alpha+1)^p - (\alpha+1) = \alpha^p + 1 - \alpha - 1 = \alpha^p - \alpha$, so $a := \alpha^p - \alpha \in F$, and the conjugates $\alpha, \alpha+1, \dots, \alpha+(p-1)$ are distinct, forcing $[F(\alpha) : F] = p$. □

Worked Example 14.7.6 (The Galois group of $x^n - a$ over $\mathbb{Q}(\zeta_n)$)**.** With $F = \mathbb{Q}(\zeta_5)$ and $a = 2$, identify $\mathrm{Gal}(F(\sqrt[5]{2})/F)$.

Recognition. F contains ζ_5, so by the Kummer theorem $F(\sqrt[5]{2})/F$ is cyclic; its degree is the order of 2 in $F^\times/(F^\times)^5$.

Solution. $x^5 - 2$ is irreducible over $\mathbb{Q}$ (Eisenstein at 2), so $[\mathbb{Q}(\sqrt[5]{2}) : \mathbb{Q}] = 5$; since $[F : \mathbb{Q}] = \varphi(5) = 4$ is coprime to 5, the degree $[F(\sqrt[5]{2}) : F]$ stays 5, hence 2 has order 5 in $F^\times/(F^\times)^5$ and $\mathrm{Gal}(F(\sqrt[5]{2})/F) \cong \mathbb{Z}/5\mathbb{Z}$. The generator sends $\sqrt[5]{2} \mapsto \zeta_5\sqrt[5]{2}$. Sanity check: 5 is prime, so the only possible degrees are 1 or 5; degree 1 would mean 2 is a 5th power in F, impossible since $\sqrt[5]{2}$ already generates a degree-5 extension of $\mathbb{Q}$.

Worked Example 14.7.7 (A Lagrange resolvent computation in a C_3 extension)**.** Let K/F be cyclic of degree 3 with $\mathrm{Gal}(K/F) = \langle\sigma\rangle$ and $\zeta = \zeta_3 \in F$. For $\theta \in K$ form $r = (\theta, \zeta) = \theta + \zeta\sigma\theta + \zeta^2\sigma^2\theta$ and verify $r^3 \in F$.

Recognition. $\sigma(\theta, \zeta) = \zeta^{-1}(\theta, \zeta)$ for any resolvent, so r is an eigenvector of σ with eigenvalue ζ^{-1} and r^3 is σ-fixed.

Solution. Apply σ: $\sigma(r) = \sigma\theta + \zeta\sigma^2\theta + \zeta^2\sigma^3\theta = \sigma\theta + \zeta\sigma^2\theta + \zeta^2\theta$ (since $\sigma^3 = \mathrm{id}$). Factor out $\zeta^{-1} = \zeta^2$: $\zeta^2 r = \zeta^2\theta + \sigma\theta + \zeta\sigma^2\theta$, which equals $\sigma(r)$. So $\sigma(r) = \zeta^{-1}r$, hence $\sigma(r^3) = \zeta^{-3}r^3 = r^3$, so $r^3 \in \mathrm{Fix}(\langle\sigma\rangle) = F$. Sanity check: σ has order 3 and $r \neq 0$ generically, so r cannot be σ-fixed (that would put $r \in F$); indeed its eigenvalue $\zeta^{-1} \neq 1$ confirms $r \notin F$ while $r^3 \in F$ – exactly a radical generator.

Cardano's cubic via Lagrange resolvents

We now use resolvents to derive Cardano's formula, which is the cleanest illustration of how the cyclic theory produces an explicit radical solution. Take a depressed cubic

$$f(x) = x^3 + px + q \in F[x], \qquad \mathrm{char}\, F \neq 2, 3, \quad \zeta = \zeta_3 \in F.$$

Let $\alpha_1, \alpha_2, \alpha_3$ be its roots, so $\alpha_1 + \alpha_2 + \alpha_3 = 0$. Let σ be the 3-cycle $(\alpha_1\,\alpha_2\,\alpha_3)$ in the Galois group.

Worked Example 14.7.8 (Cardano's formula from the two resolvents)**.** Derive $\alpha = \sqrt[3]{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} + \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}}$.

Recognition. The two Lagrange resolvents $r_1 = (\alpha_1, \zeta)$ and $r_2 = (\alpha_1, \zeta^2)$ diagonalize the 3-cycle, and r_1^3, r_2^3 live in the resolvent field; solving the resulting quadratic recovers them as radicals.

Solution. Set $r_1 = \alpha_1 + \zeta\alpha_2 + \zeta^2\alpha_3$ and $r_2 = \alpha_1 + \zeta^2\alpha_2 + \zeta\alpha_3$. With $\alpha_1 + \alpha_2 + \alpha_3 = 0$, the three equations invert to

$$\alpha_1 = \tfrac{1}{3}(r_1 + r_2), \quad \alpha_2 = \tfrac{1}{3}(\zeta^2 r_1 + \zeta r_2), \quad \alpha_3 = \tfrac{1}{3}(\zeta r_1 + \zeta^2 r_2).$$

By the resolvent identity r_1^3 and r_2^3 are symmetric under the 3-cycle, so they are roots of a quadratic over F (the "resolvent quadratic"). Direct expansion using the elementary symmetric relations $\sum \alpha_i = 0$, $\sum_{i<j} \alpha_i\alpha_j = p$, $\alpha_1\alpha_2\alpha_3 = -q$ gives

$$r_1^3 + r_2^3 = -27q, \qquad r_1 r_2 = -3p \;\Rightarrow\; r_1^3 r_2^3 = -27p^3.$$

Hence r_1^3, r_2^3 are the roots of $t^2 + 27q\,t - 27p^3 = 0$, namely $t = -\frac{27q}{2} \pm \frac{27}{2}\sqrt{q^2 + \frac{4p^3}{27}}$. Taking cube roots and dividing by 3 (i.e. $\alpha_1 = \frac{1}{3}(r_1 + r_2)$) yields

$$\alpha_1 = \sqrt[3]{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} + \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}},$$

with the cube roots chosen so their product is $-p/3$ (i.e. $r_1 r_2 = -3p$). Sanity check: the discriminant under the square root is $\frac{q^2}{4} + \frac{p^3}{27} = -\frac{1}{108}\,\mathrm{disc}(f)$, where $\mathrm{disc}(f) = -4p^3 - 27q^2$; so, as $\sqrt{-3} \in F$ (because $\zeta_3 \in F$), the formula's square root lies in F exactly when $\mathrm{disc}(f)$ is a square in F, which is precisely the condition $\mathrm{Gal}(f) \subseteq A_3 = C_3$ rather than S_3. (Over $\mathbb{Q}$, where $\sqrt{-3} \notin \mathbb{Q}$, a nonzero square $\mathrm{disc}(f)$ makes this square root imaginary instead, as in the next example.)

Worked Example 14.7.9 (Worked cubic: solve $x^3 - 3x - 1 = 0$)**.** Apply the formula to $p = -3, q = -1$ and identify the splitting field's Galois group.

Recognition. Cardano with $p = -3, q = -1$; the sign and shape of $\operatorname{disc}(f)$ decides whether the group is C_3 or S_3.

Solution. Here $\frac{q^2}{4} + \frac{p^3}{27} = \frac{1}{4} + \frac{-27}{27} = \frac{1}{4} - 1 = -\frac{3}{4}$, so the inner square root is $\sqrt{-3/4} = \frac{\sqrt{-3}}{2}$. Then $(r_1/3)^3 = -\frac{q}{2} + \frac{\sqrt{-3}}{2} = \frac{1}{2} + \frac{\sqrt{-3}}{2} = e^{i\pi/3}$, a primitive 6th root of unity; its cube root $e^{i\pi/9}$ and the cube root $e^{-i\pi/9}$ of $\frac{1}{2} - \frac{\sqrt{-3}}{2}$ have product $1 = -p/3$, so the formula gives the real root $\alpha_1 = e^{i\pi/9} + e^{-i\pi/9} = 2\cos(\pi/9)$, numerically ≈ 1.879. The discriminant is $\operatorname{disc}(f) = -4(-3)^3 - 27(-1)^2 = 108 - 27 = 81 = 9^2$, a perfect square, so $\operatorname{Gal}(f/\mathbb{Q}) \cong A_3 = C_3$ and $\mathbb{Q}(\alpha_1)/\mathbb{Q}$ is already the (cyclic, degree 3) splitting field. Sanity check: f is irreducible over $\mathbb{Q}$ (a rational root would be ± 1, but $f(1) = -3 \neq 0$ and $f(-1) = 1 \neq 0$), so the group is transitive of order divisible by 3; with square discriminant it lies in A_3, forcing exactly C_3 – consistent with all three roots being real, $2\cos(\pi/9), 2\cos(7\pi/9), 2\cos(13\pi/9)$.

The splitting-field picture for a cubic is the smallest interesting Galois correspondence. When $\operatorname{disc}(f)$ is not a square the group is the full S_3, and the lattice is:

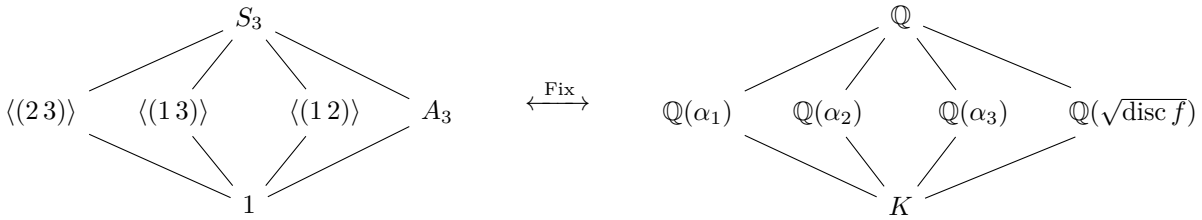


Diagram explanation. Objects: The left lattice contains six groups: the full symmetric group S_3 at the top, three order-2 subgroups $\langle(2\,3)\rangle$, $\langle(1\,3)\rangle$, $\langle(1\,2)\rangle$ in the middle row, the alternating subgroup $A_3 \cong C_3$ also in the middle row, and the trivial group 1 at the bottom. The right lattice mirrors these with six fields: $\mathbb{Q}$ at the top, the three cubic subfields $\mathbb{Q}(\alpha_1), \mathbb{Q}(\alpha_2), \mathbb{Q}(\alpha_3)$ (each generated by one root), the quadratic subfield $\mathbb{Q}(\sqrt{\operatorname{disc} f})$, and the splitting field K at the bottom. Both lattices are drawn with inclusions reversed: larger subgroup higher on the left, smaller subfield higher on the right.

Arrows: Every edge is a plain inclusion dash, drawn with `[dash]` to suppress arrowheads. On the group side an edge from H to H' below it means $H' \leq H$; on the field side it means the lower field contains the upper one as a subfield. The double-headed arrow $\xleftrightarrow{\text{Fix}}$ in the middle names the Galois correspondence: each subgroup $H \leq S_3$ maps to the fixed field $\operatorname{Fix}(H) = K^H$, and each intermediate field E maps to $\operatorname{Gal}(K/E)$.

What commutes: This is a correspondence diagram, not a commutative square, so the relevant equality is the order-reversing bijection $H \leftrightarrow K^H$: $[S_3 : H] = [K^H : \mathbb{Q}]$ and $|H| = [K : K^H]$. Concretely: $[S_3 : \langle(i\,j)\rangle] = 3$ matches $[\mathbb{Q}(\alpha_k) : \mathbb{Q}] = 3$, and $[S_3 : A_3] = 2$ matches $[\mathbb{Q}(\sqrt{\operatorname{disc} f}) : \mathbb{Q}] = 2$.

Why it commutes: By the fundamental theorem of Galois theory, $K/\mathbb{Q}$ is Galois with group S_3, so $H \mapsto K^H$ and $E \mapsto \operatorname{Gal}(K/E)$ are mutually inverse bijections reversing inclusion. The transposition $(i\,j)$ fixes α_k (the root not moved) and swaps the other two, so $K^{\langle(i\,j)\rangle} = \mathbb{Q}(\alpha_k)$. The 3-cycle $(1\,2\,3)$ generates A_3 and fixes $\sqrt{\operatorname{disc} f}$ (since the discriminant is a symmetric function of the roots and A_3 consists of even permutations), giving $K^{A_3} = \mathbb{Q}(\sqrt{\operatorname{disc} f})$.

Why this matters here: This diagram appears immediately after the worked cubic $x^3 - 3x - 1$, whose group is C_3 (its discriminant 81 is a square); it shows the case in which $\operatorname{disc} f$ is not a square. It makes the Galois correspondence concrete for the generic cubic: the six intermediate fields (including $\mathbb{Q}$ and K) are read directly from the six subgroups of S_3, organizing what would otherwise be a list of assertions about index and degree into a single visual structure.

Concrete example: For $f(x) = x^3 - 3x - 1$ the discriminant is $81 = 9^2$, a perfect square, so that cubic actually has group $C_3 \cong A_3$, not S_3. The present diagram applies to, say, $x^3 - 2$ over $\mathbb{Q}$, where $\operatorname{disc}(x^3 - 2) = -108$, not a square, so $\operatorname{Gal} \cong S_3$. The three roots $\sqrt[3]{2}, \zeta_3\sqrt[3]{2}, \zeta_3^2\sqrt[3]{2}$ give the three cubic subfields, and $\mathbb{Q}(\sqrt{-108}) = \mathbb{Q}(\sqrt{-3})$ is the quadratic one.

Common pitfall: Students often read the lattice arrows as pointing toward *larger* objects on both sides. Remember: subgroups and subfields are reversed – a subgroup high on the left corresponds to a subfield

high on the right (i.e., a small subfield), not a large one. Concretely, A_3 is a large subgroup (index 2) and corresponds to the small quadratic extension $\mathbb{Q}(\sqrt{\operatorname{disc} f})$ of degree 2, not to the whole splitting field K.

Takeaway: The point of this diagram is that the entire intermediate-field structure of the splitting field of a cubic with Galois group S_3 is completely and visually encoded by the subgroup lattice of S_3 via the order-reversing Galois correspondence.

The index-2 subgroup A_3 corresponds to the unique quadratic subfield $\mathbb{Q}(\sqrt{\operatorname{disc} f})$; the three index-3 subgroups $\langle (i\,j) \rangle$ correspond to the three cubic fields $\mathbb{Q}(\alpha_k)$.

Solvable groups and Galois's criterion

The group-theoretic notion matching "solvable by radicals" is solvability.

Definition 14.7.10. A group G is *solvable* if it has a subnormal series

$$1 = G_0 \lhd G_1 \lhd \cdots \lhd G_s = G$$

with every quotient G_{i+1}/G_i abelian.

Proposition 14.7.11 (closure properties of solvable groups)**.** *Subgroups and quotients of solvable groups are solvable; and if $N \trianglelefteq G$ with N and G/N both solvable, then G is solvable. Consequently a finite group is solvable iff its composition factors are all cyclic of prime order.*

Idea. Intersect a solvable series of G with a subgroup H (giving a series of H with quotients embedding into the abelian G_{i+1}/G_i); push it forward along $G \twoheadrightarrow G/N$ (quotients are images of abelian groups). For the extension statement, splice a solvable series of N onto the pullback of a solvable series of G/N. The composition-factor characterization follows because abelian-by-abelian-by-$\cdots$ refines to prime-cyclic factors. □

The fundamental theorem of the section ties the two threads together.

Theorem 14.7.12 (Galois's solvability criterion)**.** *Let F have characteristic 0 and let $f(x) \in F[x]$ with splitting field K. Then f is solvable by radicals if and only if the Galois group $\operatorname{Gal}(K/F)$ is a solvable group.*

Idea. ($\Leftarrow$) If $G = \operatorname{Gal}(K/F)$ is solvable, refine its series to one with prime-cyclic quotients $G_{i+1}/G_i \cong \mathbb{Z}/p_i\mathbb{Z}$. Adjoin enough roots of unity at the start (an abelian, radical step). By the Galois correspondence the series gives a tower of fields each cyclic of prime degree over the previous; by Kummer theory each such cyclic step is $F_i(\sqrt[p_i]{a_i})$, a radical step. So K sits in a radical tower.

($\Rightarrow$) If K lies in a radical extension, enlarge it to a radical extension L/F that is Galois (adjoin conjugates and roots of unity; the result is still radical). Each radical step, after adjoining roots of unity, is cyclic by Kummer theory, so $\operatorname{Gal}(L/F)$ has a subnormal series with abelian (even cyclic) quotients, i.e. is solvable. Then $\operatorname{Gal}(K/F)$ is a quotient of $\operatorname{Gal}(L/F)$, hence solvable. □

Worked Example 14.7.13 (Every quartic is solvable by radicals)**.** Explain why $\operatorname{Gal}(f/\mathbb{Q}) \subseteq S_4$ is always solvable, so every degree ≤ 4 polynomial has a radical formula.

Recognition. Galois's criterion reduces "radical formula exists" to "the group is solvable"; for $n \leq 4$ the group sits in S_n, and S_2, S_3, S_4 are all solvable.

Solution. S_4 has the subnormal series $1 \lhd V_4 \lhd A_4 \lhd S_4$ with quotients $V_4 \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, $A_4/V_4 \cong \mathbb{Z}/3\mathbb{Z}$, $S_4/A_4 \cong \mathbb{Z}/2\mathbb{Z}$ – all abelian. So S_4 is solvable, and every subgroup (every possible quartic Galois group: $1, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \mathbb{Z}/4\mathbb{Z}, V_4, S_3, D_8, A_4, S_4$) is solvable by the closure proposition. By Galois's criterion every quartic is solvable by radicals. Sanity check: the Klein four-group V_4 inside A_4 is exactly the kernel of the action giving the "resolvent cubic," the classical device for solving quartics – the group series mirrors the algebraic reduction quartic → cubic → quadratics.

S_n is not solvable for $n \geq 5$, and the insolvable quintic

The obstruction to a quintic formula is a single group-theoretic fact.

Theorem 14.7.14 (A_n simple, S_n insolvable for $n \geq 5$)**.** *For $n \geq 5$ the alternating group A_n is simple and nonabelian. Consequently S_n is not solvable for $n \geq 5$.*

Idea. Simplicity of A_n ($n \geq 5$) is proved by showing A_n is generated by 3-cycles and that any nontrivial normal subgroup must contain a 3-cycle, hence all of them. A nonabelian simple group cannot be solvable: its only normal subgroups are 1 and itself, so its only possible subnormal series is $1 \lhd A_n$, whose quotient A_n is nonabelian. Since $A_n \trianglelefteq S_n$ is non-solvable, the subgroup-closure of solvability forces S_n non-solvable. □

Method (Proving a specific quintic $f \in \mathbb{Q}[x]$ is not solvable by radicals.)**.** The goal is to show $\mathrm{Gal}(f/\mathbb{Q}) = S_5$ (which is non-solvable), via three checks:

(1) **Irreducible.** Show f is irreducible over $\mathbb{Q}$ (e.g. Eisenstein, or reduction mod a prime). Then the group acts *transitively* on the 5 roots, so $5 \mid |\mathrm{Gal}(f)|$; by Cauchy the group contains an element of order 5, i.e. a 5-*cycle*.

(2) **Exactly two non-real roots.** Use calculus (count real roots via sign changes / critical points) to show f has exactly 3 real and 2 complex roots. Complex conjugation is then an element of $\mathrm{Gal}(f)$ fixing the 3 real roots and swapping the conjugate pair: a *transposition*.

(3) **Generate S_5.** A 5-cycle and a transposition in S_5 generate all of S_5 (when the prime $p = 5$ and a transposition are both present, this always holds). Hence $\mathrm{Gal}(f) = S_5$, which is not solvable, so f is not solvable by radicals.

Caution. Step (3) needs $p = \deg f$ prime. A p-cycle plus a transposition generate S_p because some power of the p-cycle (again a p-cycle, since p is prime) carries one point of the transposition to the other; for composite n an n-cycle and a transposition need not generate S_n ($(1\,2\,3\,4)$ and $(1\,3)$ generate only $D_8 \leq S_4$), and a transposition together with a 4-cycle in S_5, say, need not generate S_5. Also, "two non-real roots" must be exactly two: if there were 4 non-real roots, complex conjugation would be a product of two transpositions (an even permutation in A_5), and the argument collapses.

Worked Example 14.7.15 ($x^5 - 6x + 3$ has Galois group S_5)**.** Show in full detail that $f(x) = x^5 - 6x + 3$ over $\mathbb{Q}$ has $\mathrm{Gal}(f/\mathbb{Q}) = S_5$ and is not solvable by radicals.

Recognition. Run the method: Eisenstein for irreducibility (hence a 5-cycle), calculus for exactly two non-real roots (hence a transposition), then $\langle 5\text{-cycle}, \text{transposition} \rangle = S_5$.

Solution. Irreducible: $f = x^5 - 6x + 3$ is Eisenstein at $p = 3$ ($3 \mid 6, 3 \mid 3$, $3^2 = 9 \nmid 3$), so f is irreducible over $\mathbb{Q}$. Thus $\mathrm{Gal}(f)$ acts transitively on 5 roots and $5 \mid |\mathrm{Gal}(f)|$; by Cauchy it contains a 5-cycle.

Exactly two non-real roots: $f'(x) = 5x^4 - 6$ has the two real critical points $x = \pm(6/5)^{1/4} \approx \pm 1.046$. Evaluate: at the local max $x_- = -(6/5)^{1/4}$, $f(x_-) > 0$ (since $f(-2) = -32 + 12 + 3 = -17 < 0$ and $f(-1) = -1 + 6 + 3 = 8 > 0$, the value at the local max near -1.05 is positive); at the local min $x_+ = (6/5)^{1/4}$, $f(x_+) < 0$ (since $f(1) = 1 - 6 + 3 = -2 < 0$ and $f(2) = 32 - 12 + 3 = 23 > 0$). A quintic with positive local max and negative local min, in that order along the real axis, crosses the axis exactly 3 times – so f has exactly 3 real roots and 2 complex (conjugate) roots.

Conjugation is a transposition: complex conjugation restricts to an automorphism of the splitting field; it fixes the 3 real roots and swaps the conjugate pair, hence acts as a single transposition $\tau \in \mathrm{Gal}(f)$.

Generate S_5: $\mathrm{Gal}(f) \leq S_5$ contains a 5-cycle ρ and a transposition τ. Relabelling so $\tau = (1\,2)$, some power of ρ is a 5-cycle sending $1 \mapsto 2$; a transposition of adjacent points together with a 5-cycle through them generates S_5. Hence $\mathrm{Gal}(f) = S_5$. Since S_5 is not solvable, f is not solvable by radicals. Sanity check: $|\mathrm{Gal}(f)| = [K : \mathbb{Q}]$ divides $5! = 120$ and is divisible by 5 (transitive) and by 2 (the transposition); having both a 5-cycle and a transposition forces the full 120, and $120 = 5!$ is the maximum possible for a degree-5 polynomial, internally consistent.

Worked Example 14.7.16 (A solvable quintic: $x^5 - 2$ over $\mathbb{Q}$)**.** Show $x^5 - 2$ is irreducible with a solvable Galois group of order 20, so it *is* solvable by radicals – contrasting the previous example.

Recognition. The splitting field is $\mathbb{Q}(\sqrt[5]{2}, \zeta_5)$; its group is a semidirect product (Frobenius group F_{20}), which is solvable, and Kummer theory makes the radical solution explicit.

Solution. $x^5 - 2$ is Eisenstein at 2, hence irreducible, so $[\mathbb{Q}(\sqrt[5]{2}) : \mathbb{Q}] = 5$. The splitting field is $K = \mathbb{Q}(\sqrt[5]{2}, \zeta_5)$ with $[\mathbb{Q}(\zeta_5) : \mathbb{Q}] = 4$; since $\gcd(4, 5) = 1$, $[K : \mathbb{Q}] = 20$. An automorphism is determined by $\sqrt[5]{2} \mapsto \zeta_5^i \sqrt[5]{2}$ ($i \in \mathbb{Z}/5\mathbb{Z}$) and $\zeta_5 \mapsto \zeta_5^j$ ($j \in (\mathbb{Z}/5\mathbb{Z})^\times$), so

$$\mathrm{Gal}(K/\mathbb{Q}) \cong \mathbb{Z}/5\mathbb{Z} \rtimes (\mathbb{Z}/5\mathbb{Z})^\times \cong F_{20},$$

the Frobenius group of order 20 (the normalizer of a Sylow 5-subgroup in S_5). It is solvable: $1 \lhd \mathbb{Z}/5\mathbb{Z} \lhd F_{20}$ with quotients $\mathbb{Z}/5\mathbb{Z}$ and $(\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}/4\mathbb{Z}$, both abelian. By Galois's criterion $x^5 - 2$ is solvable by radicals – indeed visibly so, since $\sqrt[5]{2}$ and ζ_5 are radicals. Sanity check: $F_{20} \leq S_5$ has order $20 \mid 120$ and contains a 5-cycle (from $\mathbb{Z}/5\mathbb{Z}$) but its point-stabilizer is $\mathbb{Z}/4\mathbb{Z}$, generated by a 4-cycle on the non-fixed points – *no transposition*, so it cannot be all of S_5, consistent with solvability. The lattice of the two key subgroups:

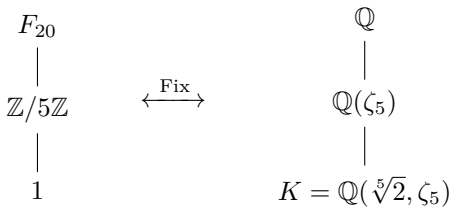

Diagram explanation. Objects: The left chain shows three groups: the Frobenius group $F_{20} = \mathbb{Z}/5\mathbb{Z} \rtimes (\mathbb{Z}/5\mathbb{Z})^\times$ of order 20 at the top, its normal subgroup $\mathbb{Z}/5\mathbb{Z}$ (order 5, generated by $\sqrt[5]{2} \mapsto \zeta_5 \sqrt[5]{2}$) in the middle, and the trivial group 1 at the bottom. The right chain shows three fields: $\mathbb{Q}$ at the top, the cyclotomic subfield $\mathbb{Q}(\zeta_5)$ in the middle (a degree-4 extension of $\mathbb{Q}$), and the splitting field $K = \mathbb{Q}(\sqrt[5]{2}, \zeta_5)$ of degree 20 over $\mathbb{Q}$ at the bottom. Each lattice has only two edges, reflecting the linear (chain) structure of the subgroup/subfield tower.

Arrows: Each vertical dash on the left is an inclusion of subgroups ($1 \leq \mathbb{Z}/5\mathbb{Z} \leq F_{20}$); each vertical dash on the right is a subfield inclusion ($\mathbb{Q} \subseteq \mathbb{Q}(\zeta_5) \subseteq K$). The central $\overset{\text{Fix}}{\longleftrightarrow}$ is again the Galois correspondence $H \mapsto K^H$: F_{20} fixes only $\mathbb{Q}$, $\mathbb{Z}/5\mathbb{Z}$ fixes $\mathbb{Q}(\zeta_5)$, and 1 fixes all of K.

What commutes: The key index–degree equalities are: $[F_{20} : \mathbb{Z}/5\mathbb{Z}] = 4 = [\mathbb{Q}(\zeta_5) : \mathbb{Q}]$ and $[F_{20} : 1] = 20 = [K : \mathbb{Q}]$. The normal containment $\mathbb{Z}/5\mathbb{Z} \trianglelefteq F_{20}$ corresponds to the fact that $\mathbb{Q}(\zeta_5)/\mathbb{Q}$ is Galois (as a fixed field of a normal subgroup), with quotient group $F_{20}/\mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \cong \mathrm{Gal}(\mathbb{Q}(\zeta_5)/\mathbb{Q})$.

Why it commutes: The element $\sqrt[5]{2}$ is not fixed by any nontrivial element of $\mathbb{Z}/5\mathbb{Z}$ (the generator sends $\sqrt[5]{2} \mapsto \zeta_5 \sqrt[5]{2} \neq \sqrt[5]{2}$), so $K^{\mathbb{Z}/5\mathbb{Z}}$ contains no $\sqrt[5]{2}$. But $\zeta_5 \in \mathbb{Q}(\zeta_5)$ is fixed by every element of $\mathbb{Z}/5\mathbb{Z}$ (which only moves $\sqrt[5]{2}$, not ζ_5), giving $K^{\mathbb{Z}/5\mathbb{Z}} = \mathbb{Q}(\zeta_5)$. Since $\mathbb{Z}/5\mathbb{Z} \trianglelefteq F_{20}$, the quotient $F_{20}/\mathbb{Z}/5\mathbb{Z}$ acts faithfully on $\mathbb{Q}(\zeta_5)/\mathbb{Q}$, and $|F_{20}/\mathbb{Z}/5\mathbb{Z}| = 4 = [\mathbb{Q}(\zeta_5) : \mathbb{Q}]$ confirms this quotient is the full Galois group.

Why this matters here: This diagram appears at the end of the example proving $x^5 - 2$ is solvable by radicals. It makes the solvable series $1 \lhd \mathbb{Z}/5\mathbb{Z} \lhd F_{20}$ visually concrete as a tower of fields, connecting the abstract group-theoretic criterion (solvability) to the explicit radical tower $\mathbb{Q} \subset \mathbb{Q}(\zeta_5) \subset K$. Each abelian quotient in the series ($\mathbb{Z}/5\mathbb{Z}$ and $(\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}/4\mathbb{Z}$) corresponds to a cyclic radical step, as guaranteed by Kummer theory.

Concrete example: The step $\mathbb{Q} \subset \mathbb{Q}(\zeta_5)$ is the adjunction of a 5th root of unity, a radical step ($\zeta_5^5 = 1 \in \mathbb{Q}$) with cyclic Galois group $(\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}/4\mathbb{Z}$. The step $\mathbb{Q}(\zeta_5) \subset K$ adjoins $\sqrt[5]{2}$, a radical step with cyclic Galois group $\mathbb{Z}/5\mathbb{Z}$ (the generator sends $\sqrt[5]{2} \mapsto \zeta_5 \sqrt[5]{2}$, as Kummer theory predicts since $\zeta_5 \in \mathbb{Q}(\zeta_5)$). Both quotients are abelian, realizing the solvable series as an explicit radical tower.

Common pitfall: Students sometimes confuse the roles of $\mathbb{Z}/5\mathbb{Z}$ and $(\mathbb{Z}/5\mathbb{Z})^\times$ in F_{20}. The subgroup $\mathbb{Z}/5\mathbb{Z} \leq F_{20}$ in the left lattice is the group of automorphisms moving $\sqrt[5]{2}$ (it fixes ζ_5), so it corresponds to $\mathbb{Q}(\zeta_5)$ (the field where $\sqrt[5]{2}$ is *not* yet present). The factor $(\mathbb{Z}/5\mathbb{Z})^\times \cong \mathbb{Z}/4\mathbb{Z}$ describes automorphisms of ζ_5 and is the Galois group of the $\mathbb{Q}(\zeta_5)/\mathbb{Q}$ step, not the $K/\mathbb{Q}(\zeta_5)$ step.

Takeaway: The point of this diagram is that the solvable series $1 \lhd \mathbb{Z}/5\mathbb{Z} \lhd F_{20}$ is precisely the group-theoretic shadow of the radical tower $\mathbb{Q} \subset \mathbb{Q}(\zeta_5) \subset K$, showing that Galois's criterion is not abstract – it directly names the field steps that produce the radical solution.

The normal subgroup $\mathbb{Z}/5\mathbb{Z} \trianglelefteq F_{20}$ corresponds to the subfield $\mathbb{Q}(\zeta_5)$, which is Galois over $\mathbb{Q}$ with group $F_{20}/\mathbb{Z}/5\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z}$.

Worked Example 14.7.17 ($x^5 - 4x + 2$ is not solvable by radicals)**.** Confirm $f(x) = x^5 - 4x + 2$ has Galois group S_5.

Recognition. Same method: Eisenstein at 2 for irreducibility, then count real roots via f'.

Solution. f is Eisenstein at 2, hence irreducible, giving a 5-cycle. $f'(x) = 5x^4 - 4$ has real critical points $x = \pm(4/5)^{1/4} \approx \pm 0.946$. Values: $f(-2) = -32 + 8 + 2 = -22 < 0$, $f(-1) = -1 + 4 + 2 = 5 > 0$, $f(1) = 1 - 4 + 2 = -1 < 0$, $f(2) = 32 - 8 + 2 = 26 > 0$, so f changes sign on $(-2, -1)$, on $(-1, 1)$ and on $(1, 2)$; since f' has only two real zeros, f has a local max near $x \approx -0.946$ (positive) and local min near $x \approx 0.946$ (negative), giving exactly 3 real roots and 2 complex ones. Complex conjugation is a transposition; with the 5-cycle it generates S_5. Sanity check: the pattern of signs $f(-2) < 0 < f(-1)$, $f(-1) > 0 > f(1)$, $f(1) < 0 < f(2)$ gives three sign changes hence three real roots, leaving exactly two non-real – the transposition criterion is met, so $\mathrm{Gal}(f) = S_5$ and f is not solvable by radicals.

Worked Example 14.7.18 (Insolvability is not just "degree 5": a solvable vs. insolvable contrast)**.** Contrast $x^5 - 2$ (solvable, group F_{20}) with $x^5 - 6x + 3$ (insolvable, group S_5) and locate the dividing line.

Recognition. Both quintics are irreducible, so both groups are transitive subgroups of S_5 containing a 5-cycle; the difference is whether a transposition is present (forcing S_5) or not.

Solution. For $x^5 - 2$ all that enters is one 5-cycle plus the $\mathbb{Z}/4\mathbb{Z}$ acting on ζ_5; the group F_{20} has no transposition and is solvable, so the equation has a radical solution $\sqrt[5]{2}, \zeta_5\sqrt[5]{2}, \ldots$. For $x^5 - 6x + 3$, the extra structure "exactly two non-real roots" injects a transposition, and $\langle 5\text{-cycle}, \text{transposition}\rangle = S_5$ is non-solvable, killing any radical formula. So degree 5 alone is not the obstruction; the obstruction is the appearance of the simple group A_5 as a composition factor. Sanity check: up to conjugacy the transitive subgroups of S_5 are $\mathbb{Z}/5\mathbb{Z} \subset D_{10} \subset F_{20}$ (a chain of orders $5 \mid 10 \mid 20$) together with $A_5 \subset S_5$ (orders $60 \mid 120$); note F_{20} and A_5 are incomparable, since F_{20} contains a 4-cycle (an odd permutation) and so is *not* inside A_5. The first three are solvable and the last two are not (both contain A_5), so an irreducible quintic is solvable by radicals iff its group lies in F_{20} – exactly the criterion of the text's exercises.

Worked Example 14.7.19 (Why no general quintic formula can exist)**.** Deduce that there is no formula in radicals for the roots of the "generic" quintic.

Recognition. The generic polynomial $x^5 - t_1x^4 + \cdots \pm t_5$ over the field $\mathbb{Q}(t_1, \ldots, t_5)$ of its coefficients has Galois group exactly S_5; insolvability of S_5 then applies.

Solution. Over $F = \mathbb{Q}(t_1, \ldots, t_5)$ with the t_i the elementary symmetric functions of independent transcendentals $x_1, \ldots, x_5$, the splitting field is $\mathbb{Q}(x_1, \ldots, x_5)$ and $\mathrm{Gal} = S_5$ (it permutes the x_i and fixes the symmetric functions t_i). Since S_5 is not solvable, Galois's criterion says the generic quintic is not solvable by radicals: there is no universal radical formula in the coefficients. The explicit $x^5 - 6x + 3$ shows this already fails over $\mathbb{Q}$, not merely generically. Sanity check: the same argument gives $\mathrm{Gal} = S_n$ for the generic degree-n polynomial, solvable iff $n \leq 4$ – recovering the classical existence of quadratic/cubic/quartic formulas and the nonexistence for all $n \geq 5$.

Exercises (from the text).

1. Use Cardano's Formulas to solve the equation $x^3 + x^2 - 2 = 0$. In particular show that the equation has the real root
$$\frac{1}{3}\big(\sqrt[3]{26 + 15\sqrt{3}} + \sqrt[3]{26 - 15\sqrt{3}} - 1\big).$$
Show directly that the roots of this cubic are 1, $-1 \pm i$. Explain this by proving that
$$\sqrt[3]{26 + 15\sqrt{3}} = 2 + \sqrt{3} \qquad \sqrt[3]{26 - 15\sqrt{3}} = 2 - \sqrt{3}$$
so that
$$\sqrt[3]{26 + 15\sqrt{3}} + \sqrt[3]{26 - 15\sqrt{3}} = 4.$$

2. Let ζ_7 be a primitive 7th root of unity and let $\alpha = \zeta_7 + \zeta_7^{-1}$.
   (a) Show that ζ_7 is a root of the quadratic $z^2 - \alpha z + 1$ over $\mathbb{Q}(\alpha)$.
   (b) Show using the minimal polynomial for ζ_7 that α is a root of the cubic $x^3 + x^2 - 2x - 1$.
   (c) Use (a) and (b) together with the explicit solution of the cubic in (b) in the text to express ζ_7 in terms of radicals similar to the expressions given earlier for the other roots of unity of small order. (The complicated nature of the expression explains why we did not include ζ_7 earlier in our list of explicit roots of unity.)

3. Let F be a field of characteristic $\neq 2$. State and prove a necessary and sufficient condition on $a, b \in F$ so that $F(\sqrt{a}) = F(\sqrt{b})$. Use this to determine whether $\mathbb{Q}(\sqrt{1-\sqrt{2}}) = \mathbb{Q}(i, \sqrt{2})$.

4. Let $K = \mathbb{Q}(\sqrt[n]{a})$, where $a \in \mathbb{Q}$, $a > 0$ and suppose $[K : \mathbb{Q}] = n$ (i.e., $x^n - a$ is irreducible). Let E be any subfield of K and let $[E : \mathbb{Q}] = d$. Prove that $E = \mathbb{Q}(\sqrt[d]{a})$. [Consider $N_{K/E}(\sqrt[n]{a}) \in E$.]

5. Let K be as in the previous exercise. Prove that if n is odd then K has no nontrivial subfields which are Galois over $\mathbb{Q}$ and if n is even then the only nontrivial subfield of K which is Galois over $\mathbb{Q}$ is $\mathbb{Q}(\sqrt{a})$.

6. Let L be the Galois closure of K in the previous two exercises (i.e., the splitting field of $x^n - a$). Prove that $[L : \mathbb{Q}] = n\varphi(n)$ or $\frac{1}{2}n\varphi(n)$. [Note that $\mathbb{Q}(\zeta_n) \cap K$ is a Galois extension of $\mathbb{Q}$.]

7. *(Kummer Generators for Cyclic Extensions)* Let F be a field of characteristic not dividing n containing the nth roots of unity and let K be a cyclic extension of degree d dividing n. Then $K = F(\sqrt[d]{a})$ for some nonzero $a \in F$ as follows. Let σ be a generator for the cyclic extension $\text{Gal}(K/F)$.
   (a) Show that $\sigma(\sqrt[d]{a}) = \zeta \sqrt[d]{a}$ for some primitive d^{th} root of unity ζ.
   (b) Suppose $K = F(\sqrt[d]{a}) = F(\sqrt[d]{b})$. Use (a) to show that $\dfrac{\sigma(\sqrt[d]{a})}{\sqrt[d]{a}} = \left(\dfrac{\sigma(\sqrt[d]{b})}{\sqrt[d]{b}}\right)^i$ for some integer i relatively prime to d. Conclude that σ fixes the element $\dfrac{\sqrt[d]{a}}{(\sqrt[d]{b})^i}$ so this is an element of F.
   (c) Prove that $K = F(\sqrt[d]{a}) = F(\sqrt[d]{b})$ if and only if $a = b^i c^d$ and $b = a^j e^d$ for some $c, e \in F$ and integers i, j, i.e., if and only if a and b generate the same subgroup of $F^\times$ modulo d^{th} powers.

8. Let p, q and r be primes in $\mathbb{Z}$ with $q \neq r$. Let $\sqrt[p]{q}$ denote any root of $x^p - q$ and let $\sqrt[p]{r}$ denote any root of $x^p - r$. Prove that $\mathbb{Q}(\sqrt[p]{q}) \neq \mathbb{Q}(\sqrt[p]{r})$.

9. *(Artin-Schreier Extensions)* Let F be a field of characteristic p and let K be a cyclic extension of F of degree p. Prove that $K = F(\alpha)$ where α is a root of the polynomial $x^p - x - a$ for some $a \in F$. [Note that $\text{Tr}_{K/F}(-1) = 0$ since K is of characteristic p, so that $-1 = \alpha - \sigma\alpha$ for some $\alpha \in K$ where σ is a generator of $\text{Gal}(K/F)$ by Exercise 26 of Section 2. Show that $a = \alpha^p - \alpha$ is an element of F.] Note that this completes the description of all cyclic extensions of prime degree p over fields containing the pth roots of unity in all characteristics.

10. Let $K = \mathbb{Q}(\zeta_p)$ be the cyclotomic field of pth roots of unity for the prime p and let $G = \text{Gal}(K/\mathbb{Q})$. Let ζ denote any p^{th} root of unity. Prove that $\sum_{\sigma \in G} \sigma(\zeta)$ (the trace from K to $\mathbb{Q}$ of ζ) is -1 or $p-1$ depending on whether ζ is or is not a primitive p^{th} root of unity.

11. *(The Classical Gauss Sum)* Let $K = \mathbb{Q}(\zeta_p)$ be the cyclotomic field of pth roots of unity for the odd prime p, viewed as a subfield of $\mathbb{C}$, and let $G = \text{Gal}(K/\mathbb{Q})$. Let H denote the subgroup of index 2 in the cyclic group G. Define $\eta_0 = \sum_{\tau \in H} \tau(\zeta_p)$, $\eta_1 = \sum_{\tau \in \sigma H} \tau(\zeta_p)$, where σ is a generator of $\text{Gal}(K/\mathbb{Q})$ (the two *periods* of ζ_p with respect to H, i.e., the sum of the conjugates of ζ_p with respect to the two cosets of H in G, cf. Section 5).
   (a) Prove that $\sigma(\eta_0) = \eta_1$, $\sigma(\eta_1) = \eta_0$ and that
   $$\eta_0 = \sum_{a=\text{square}} \zeta_p^a, \qquad \eta_1 = \sum_{b=\text{nonsquare}} \zeta_p^b,$$
   where the sums are over the squares and nonsquares (respectively) in $(\mathbb{Z}/p\mathbb{Z})^\times$. [Observe that H is the subgroup of squares in $(\mathbb{Z}/p\mathbb{Z})^\times$.]

(b) Prove that $\eta_0 + \eta_1 = (\zeta_p, 1) = -1$ and that $\eta_0 - \eta_1 = (\zeta_p, -1)$ where $(\zeta_p, 1)$ and $(\zeta_p, -1)$ are two of the Lagrange resolvents of ζ_p.

(c) Let $g = \sum_{i=0}^{p-1} \zeta_p^{i^2}$ (the classical Gauss sum). Prove that

$$g = (\zeta_p, -1) = \sum_{i=0}^{p-2} (-1)^i \, \sigma^i(\zeta_p).$$

(d) Prove that $\tau g = g$ if $\tau \in H$ and $\tau g = -g$ if $\tau \notin H$. Conclude that $[\mathbb{Q}(g) : \mathbb{Q}] = 2$. Recall that complex conjugation is the automorphism σ_{-1} on K (cf. Exercise 7 of Section 5). Conclude that $\bar{g} = g$ if $p \equiv 1 \pmod 4$ and $\bar{g} = -g$ if $p \equiv 3 \pmod 4$; with $g\bar{g} = p$ from (e) this makes g a square root of p (i.e., $g^2 = p$) if $p \equiv 1 \pmod 4$ and a square root of $-p$ (i.e., $g^2 = -p$) if $p \equiv 3 \pmod 4$, where $\bar{g}$ denotes the complex conjugate of g.

(e) Prove that $g^2 = \pm p$. [The complex conjugate of a root of unity is its reciprocal. $\bar{g} = \sum_{i=0}^{p-2} (-1)^i (\sigma^i(\zeta_p))^{-1}$ gives

$$g\bar{g} = \sum_{i,j=0}^{p-2} (-1)^i (-1)^j \frac{\sigma^i(\zeta_p)}{\sigma^j(\zeta_p)} = \sum_{i,j=0}^{p-2} (-1)^{i-j} \sigma^j\Big(\frac{\sigma^{i-j}(\zeta_p)}{\zeta_p}\Big)$$

$$= \sum_{k=0}^{p-2} (-1)^k \sum_{j=0}^{p-2} \sigma^j \frac{\sigma^k(\zeta_p)}{\zeta_p}$$

where $k = i - j$. If $k = 0$ the element $\frac{\sigma^k(\zeta_p)}{\zeta_p}$ is 1, and if $k \neq 0$ then this is a primitive p^{th} root of unity. Use the previous exercise to conclude that the inner sum is $p - 1$ when $k = 0$ and is -1 otherwise.]

(f) Conclude that $g^2 = (-1)^{(p-1)/2} p$ and that $\mathbb{Q}(\sqrt{(-1)^{(p-1)/2} p})$ is the unique quadratic subfield of $\mathbb{Q}(\zeta_p)$. (Cf. also Exercise 33 of Section 6.)

12. Let L be the Galois closure of the finite extension $\mathbb{Q}(\alpha)$ of $\mathbb{Q}$. For any prime p dividing the order of $\mathrm{Gal}(L/\mathbb{Q})$ prove there is a subfield F of L with $[L : F] = p$ and $L = F(\alpha)$.

13. Let F be a subfield of the real numbers $\mathbb{R}$. Let a be an element of F and let $K = F(\sqrt[n]{a})$ where $\sqrt[n]{a}$ denotes any real n^{th} root of a. Prove that if L is any Galois extension of F contained in K then $[L : F] \leq 2$.

14. This exercise shows that in general it is necessary to use complex numbers when expressing real roots in terms of radicals and generalizes the *Casus irreducibilis* of cubic equations. Let $f(x) \in \mathbb{Q}[x]$ be an irreducible polynomial all of whose roots are real. Suppose further that one of the roots, α, of $f(x)$ can be expressed in terms of real radicals (i.e., there is a root extension of real fields $\mathbb{Q} = K_0 \subset K_1 \subset \cdots \subset K_m$ with $K_{i+1} = K_i(\sqrt[n_i]{a_i})$, $i = 1, 2, \ldots, m-1$, for some integers n_i and some $a_i \in K_i$ and $\alpha \in K_m$). Prove that the Galois group of $f(x)$ is a 2-group. Conclude in particular that the degree of $f(x)$ is a power of 2 and that the real roots of such a polynomial can be expressed entirely in terms of real radicals if and only if these roots can be constructed by straightedge and compass. [The argument is similar to the case of cubics. Let $L \subseteq \mathbb{R}$ be the Galois closure of $\mathbb{Q}(\alpha)$ and suppose the order of $\mathrm{Gal}(L/\mathbb{Q})$ is divisible by some odd prime p. Let F be a subfield of L with $[L : F] = p$ and $L = F(\alpha)$ by Exercise 12 and consider the composite fields $K_i' = FK_i$, $i = 0, 1, \ldots, m$. These are again real radical extensions and by the argument in the text for the *Casus irreducibilis*, we may assume each $[K_{i+1}' : K_i']$ is a prime. Since $\alpha \notin F = FK_0$, there is an integer s with $\alpha \notin K_s'$, $\alpha \in K_{s+1}'$. Since the extensions are of prime degree, we have $K_{s+1}' = K_s'(\alpha)$. Since $L = F(\alpha)$ is a Galois extension of degree p, K_{s+1}' is a Galois extension of K_s' of degree p, contradicting the previous exercise.]

15. *('Cardano's Formulas' for a Cubic in Characteristic 2)* Suppose $f(x) = x^3 + px + q$ is an irreducible cubic over a field of characteristic 2. Let ρ be a primitive 3rd root of unity and let θ, θ' be the roots of the quadratic $x^2 + qx + (p^3 + q^2)$, cf. Exercise 50 of Section 6. Let θ_1 and θ_2 be cube roots of $\rho q + \theta$ and $\rho q + \theta'$, respectively, where the cube roots are chosen so that $\theta_1 \theta_2 = p$. Show that the roots of $f(x)$ are given by $\alpha = \theta_1 + \theta_2$, $\beta = \rho\alpha + \theta_1$, and $\gamma = \rho\alpha + \theta_2 = \alpha + \beta$.

16. Let a be a nonzero rational number.

    (a) Determine when the extension $\mathbb{Q}(\sqrt{ai})$ ($i^2 = -1$) is of degree 4 over $\mathbb{Q}$.

    (b) When $K = \mathbb{Q}(\sqrt{ai})$ is of degree 4 over $\mathbb{Q}$ show that K is Galois over $\mathbb{Q}$ with the Klein 4-group as Galois group. In this case determine the quadratic extensions of $\mathbb{Q}$ contained in K.

17. Let D be a squarefree integer and let $a \in \mathbb{Q}$ be a nonzero rational number. Show that $\mathbb{Q}(\sqrt{a\sqrt{D}})$ cannot be a cyclic extension of degree 4 over $\mathbb{Q}$.

18. Let $D \neq 1$ be a squarefree integer and let $a \in \mathbb{Q}$ be a nonzero rational number. Prove that if $\mathbb{Q}(\sqrt{a\sqrt{D}})$ is Galois over $\mathbb{Q}$ then $D = -1$.

19. Let $D \in \mathbb{Z}$ be a squarefree integer and let $K = \mathbb{Q}(\sqrt{D})$.

    (a) Prove that if $D = s^2 + t^2$ is the sum of two rational squares then there exists an extension $L/\mathbb{Q}$ containing K which is Galois over $\mathbb{Q}$ with a cyclic Galois group of order 4. [Consider the extension $\mathbb{Q}(\sqrt{D + s\sqrt{D}})$.] (Note also that D is the sum of two rational squares if and only if D is also the sum of two integer squares, so one may assume s and t are integral without loss.)

    (b) Prove conversely that if K can be embedded in a cyclic extension L of degree 4 as in (a) then D is the sum of two squares. [One approach: (i) observe first that L is quadratic over K, so $L = K(\sqrt{a + b\sqrt{D}})$ for some $a, b \in \mathbb{Q}$. (ii) show that L contains the quadratic subfield $\mathbb{Q}(\sqrt{a^2 - b^2 D})$, which must be $\mathbb{Q}(\sqrt{D})$ if $L/\mathbb{Q}$ is cyclic, see Exercise 7.]

    (c) Conclude in particular that $\mathbb{Q}(\sqrt{3})$ is not a subfield of any cyclic extension of degree 4 over $\mathbb{Q}$. Similarly conclude that the fields $\mathbb{Q}(\sqrt{D})$ for squarefree integers $D < 0$ are never contained in cyclic extensions of degree 4 over $\mathbb{Q}$ (this gives an alternate proof for Exercise 19, Section 6).

20. Let p be a prime. Show that any solvable subgroup of S_p of order divisible by p is contained in the normalizer of a Sylow p-subgroup of S_p (a Frobenius group of order $p(p-1)$). Conclude that an irreducible polynomial $f(x) \in \mathbb{Q}[x]$ of degree p is solvable by radicals if and only if its Galois group is contained in the Frobenius group of order $p(p-1)$. [Let $G \leq S_p$ be a solvable subgroup of order divisible by p. Then G contains a p-cycle, hence a transitive on $\{1, 2, \ldots, p\}$. Let $H < G$ be the stabilizer of the element 1, so H has index p in G. Show that H contains no nontrivial normal subgroups of G (note the conjugates of H are the stabilizers of the other points). Let $G^{(n-1)}$ be the last nontrivial subgroup in the derived series for G. Show that $H \cap G^{(n-1)} = 1$ and conclude that $|G^{(n-1)}| = p$, so that the Sylow p-subgroup of G (which is also a Sylow p-subgroup in S_p) is normal in G.]

21. *(Criterion for the Solvability of a Quintic)* By the previous exercise, an irreducible quintic $f(x) \in \mathbb{Q}[x]$ of degree 5 is solvable by radicals if and only if its Galois group (considered as a subgroup of S_5) is contained in the Frobenius group of order 20. It is known that this is the case if and only if an associated polynomial $g(x)$ of degree 6 has a rational root (cf. Dummit, *Solving Solvable Quintics*, Math. Comp., 57(1991), pp. 387–401). If the quintic is in the general form (where a translation is performed so that the coefficient of x^4 is zero)

$$f(x) = x^5 + px^3 + qx^2 + rx + s, \qquad p, q, r, s \in \mathbb{Q}$$

then the associated polynomial of degree 6 is

$$\begin{aligned} g(x) = x^6 &+ 8rx^5 + (2pq^2 - 6p^2r + 40r^2 - 50qs)x^4 \\ &+ (-2q^4 + 21pq^2r - 40p^2r^2 + 160r^3 - 15p^2qs - 400qrs + 125ps^2)x^3 \\ &+ (p^2q^4 - 8q^4r + 9p^4r^2 - 136p^2r^3 + 625q^2s^2 + 400r^4 - 6p^3q^2r \\ &\quad + 76pq^2r^2 - 50pq^3s - 1400qr^2s + 500prs^2 + 90p^2qrs)x^2 \\ &+ (-108p^5s^2 + 32p^4r^3 - 256p^2r^4 - 3125s^4 + 512r^5 - 2pq^6 + 3q^4r^2 \\ &\quad - 58q^5s + 2750q^2rs^2 - 31p^3q^3s - 500pr^2s^2 + 19p^2q^4r \\ &\quad - 51p^3q^2r^2 + 76pq^2r^3 - 2400qr^3s - 325p^2q^2s^2 + 525p^3rs^2 \\ &\quad + 625pqs^3 + 117p^4qrs + 105pq^3rs + 260p^2qr^2s)x \\ &+ (q^8 + 256r^6 + 17q^4r^3 - 27p^7s^2 - 4p^6r^3 + 48p^4r^4 - 192p^2r^5 \\ &\quad + 3125p^2s^4 - 9375rs^4 - 1600qr^4s - 99p^5rs^2 - 125pq^4s^2 \\ &\quad - 124q^5rs + 3250q^2r^2s^2 - 2000pr^3s^2 - 13pq^6r + p^5q^2r^2 \\ &\quad + 65p^2q^4r^2 - 128p^3q^2r^3 - 16pq^2r^4 - 4p^5q^3s - 12p^2q^5s \\ &\quad - 150p^4q^2s^2 + 1200p^3r^2s^2 + 18p^6qrs + 12p^3q^3rs + 196p^4qr^2s \\ &\quad + 590pq^3r^2s - 160p^2qr^3s - 725p^2q^2rs^2 - 1250pqrs^3). \end{aligned}$$

In the particular case where $f(x) = x^5 + Ax + B$ this polynomial is simply

$$g(x) = x^6 + 8Ax^5 + 40A^2x^4 + 160A^3x^3 + 400A^4x^2 + (512A^5 - 3125B^4)x - 9375AB^4 + 256A^6.$$

(a) Use this criterion to prove that the Galois group of $\mathbb{Q}$ of the polynomial $x^5 - 5x + 12$ is the dihedral group of order 10. [Use the associated sixth degree polynomial $g(x) = x^6 - 40x^5 + 1000x^4 - 20000x^3 + 250000x^2 - 66400000x + 976000000$ and has $x = 40$ as a rational root. Cf. also Exercise 35 in Section 6.]

(b) Use this criterion to prove that $x^5 - x - 1$ is not solvable by radicals.

Practice problems.

1. Exhibit an explicit radical tower $\mathbb{Q} = K_0 \subseteq K_1 \subseteq \cdots \subseteq K_m = K$ realizing the splitting field K of $x^4 - 2$ over $\mathbb{Q}$, giving each generator α_{i+1} and the element $\alpha_{i+1}^{n_{i+1}} \in K_i$ of which it is a root. Compute $[K : \mathbb{Q}]$ and identify $\mathrm{Gal}(K/\mathbb{Q})$.

2. Let $F = \mathbb{Q}(\zeta_7)$ and $a = 3$. Determine $[F(\sqrt[7]{3}) : F]$, prove that $F(\sqrt[7]{3})/F$ is cyclic, and find the order of 3 in the group $F^\times/(F^\times)^7$. Describe a generator σ of $\mathrm{Gal}(F(\sqrt[7]{3})/F)$ by its effect on $\sqrt[7]{3}$.

3. Let K/F be cyclic of degree 4 with $\mathrm{Gal}(K/F) = \langle\sigma\rangle$, and suppose $\zeta = \zeta_4 = i \in F$. For $\theta \in K$ form the Lagrange resolvent $(\theta, \zeta) = \theta + \zeta\,\sigma(\theta) + \zeta^2\sigma^2(\theta) + \zeta^3\sigma^3(\theta)$. Prove that $\sigma\big((\theta,\zeta)\big) = \zeta^{-1}(\theta,\zeta)$ and deduce that $(\theta,\zeta)^4 \in F$.

4. Decide, with full justification, whether each of the following is solvable by radicals over $\mathbb{Q}$: (a) $x^4 - 10x^2 + 1$; (b) $x^5 - 1$; (c) $x^6 + 3$; (d) $x^3 - 3x - 1$. For each, name the Galois group (up to isomorphism) and explain why it is or is not solvable.

5. Determine which of the symmetric groups S_2, S_3, S_4, S_5, S_6 are solvable, exhibiting a subnormal series with abelian quotients in each solvable case and naming the nonabelian simple composition factor in each non-solvable case.

6. Show that $f(x) = x^5 - 4x^4 + 2$ is irreducible over $\mathbb{Q}$, has exactly three real roots, and conclude that $\mathrm{Gal}(f/\mathbb{Q}) \cong S_5$, so f is not solvable by radicals. (Use f' to count real roots.)

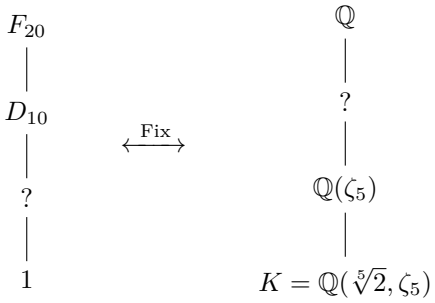
7. Let F have characteristic 5 and consider the Artin–Schreier polynomial $g(x) = x^5 - x - a$ for $a \in F$. Prove that g is either split over F or irreducible over F, that in the irreducible case $F(\alpha)/F$ is cyclic of degree 5 for any root α, and describe a generator of $\mathrm{Gal}(F(\alpha)/F)$ by its effect on α.

8. Let $a \in \mathbb{Q}^\times$ and let K be the splitting field of $x^p - a$ over $\mathbb{Q}$, where p is an odd prime and $x^p - a$ is irreducible. Show that $\mathrm{Gal}(K/\mathbb{Q})$ is isomorphic to the group of affine maps $x \mapsto ux + v$ on $\mathbb{Z}/p\mathbb{Z}$ with $u \in (\mathbb{Z}/p\mathbb{Z})^\times$, $v \in \mathbb{Z}/p\mathbb{Z}$, and prove directly from this description that $\mathrm{Gal}(K/\mathbb{Q})$ is solvable.

Additional exercises.

1. Let F contain a primitive nth root of unity, and let $a, b \in F^\times$. Prove that $F(\sqrt[n]{a}) = F(\sqrt[n]{b})$ if and only if a and b generate the same cyclic subgroup of $F^\times/(F^\times)^n$. Use this to count the distinct fields among $F(\sqrt[5]{a})$ as a ranges over a system of representatives when $|F^\times/(F^\times)^5|$ has order 5.

2. Let $f(x) \in \mathbb{Q}[x]$ be irreducible of prime degree p. Prove that f is solvable by radicals if and only if its splitting field is generated over $\mathbb{Q}$ by any two of its roots. (One direction: use that a transitive solvable subgroup of S_p lies in the affine group $\mathrm{AGL}_1(\mathbb{Z}/p\mathbb{Z})$ of order $p(p-1)$, in which a point stabilizer acts freely on the remaining points.)

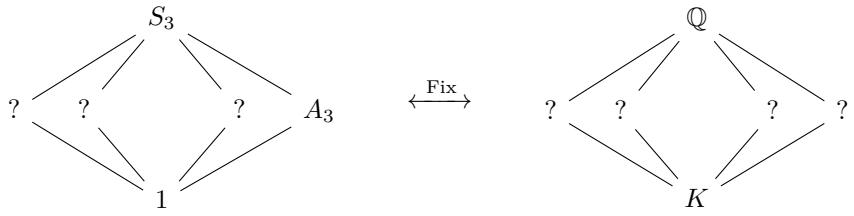


3. Let K/F be a radical Galois extension in characteristic 0. Prove that $\mathrm{Gal}(K/F)$ is solvable *without* invoking the full solvability criterion, by induction on $[K : F]$: adjoin a suitable root of unity, peel off the bottom cyclic step via Kummer theory, and apply the closure properties of solvable groups to the quotient.

4. Construct an irreducible quintic $f(x) \in \mathbb{Q}[x]$ whose Galois group is the dihedral group D_{10} of order 10 (so f *is* solvable by radicals), and prove that your f has exactly one real root. Explain why the number of real roots is consistent with $\mathrm{Gal}(f) \le F_{20}$, and why exactly three real roots would be incompatible with $\mathrm{Gal}(f) \le F_{20}$. (One real root does not rule out S_5: $x^5 - x - 1$ has one real root and group S_5.)

5. Let p be a prime and let F have characteristic 0 and contain a primitive pth root of unity. Suppose K/F is Galois with $\mathrm{Gal}(K/F)$ a nonabelian group of order p^3. Prove that K/F is a radical extension, and exhibit a chain of subfields corresponding to a composition series of $\mathrm{Gal}(K/F)$ in which every successive step is a degree-p Kummer extension $F_i(\sqrt[p]{a_i})$.

Commutative-diagram exercises.

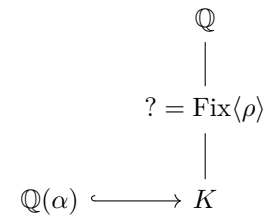


1. Let K be the splitting field of $x^5 - 2$ over $\mathbb{Q}$, so $\mathrm{Gal}(K/\mathbb{Q}) \cong F_{20} = \mathbb{Z}/5\mathbb{Z} \rtimes (\mathbb{Z}/5\mathbb{Z})^\times$. The subgroup lattice and its Fix-image are partially drawn below. Complete both diagrams by inserting the missing group $\mathbb{Z}/5\mathbb{Z}$ on the left (the index-2 subgroup D_{10} is $\mathbb{Z}/5\mathbb{Z} \rtimes \mathbb{Z}/2\mathbb{Z}$; F_{20} has no element of order 10, so no $\mathbb{Z}/10\mathbb{Z}$ occurs) and the missing fixed field on the right, then prove that the correspondence is inclusion-reversing and matches normal subgroups with Galois subextensions of $\mathbb{Q}$:

   Identify which of the subfields are Galois over $\mathbb{Q}$ and give the corresponding quotient group.

2. Let $K = \mathbb{Q}(\sqrt[3]{2}, \zeta_3)$ be the splitting field of $x^3 - 2$, with $\mathrm{Gal}(K/\mathbb{Q}) \cong S_3$. Draw the full subgroup lattice of S_3 and the corresponding lattice of intermediate fields, in the skeleton below, then prove that the unique normal proper nontrivial subgroup $A_3 = \langle \sigma \rangle$ corresponds to the unique Galois quadratic subfield, and

identify that subfield explicitly:



3. Let K/F be Galois in characteristic 0 with $G = \mathrm{Gal}(K/F)$ solvable, and fix a composition series $1 = G_0 \lhd G_1 \lhd \cdots \lhd G_s = G$ with each $G_{i+1}/G_i \cong \mathbb{Z}/p_i\mathbb{Z}$. After adjoining the needed roots of unity, the Galois correspondence yields a tower of fixed fields. Complete the diagram identifying the fixed field $L_i = \mathrm{Fix}(G_i)$ at each level and the dashed Kummer generator of each step, and prove that each square commutes (inclusion on the left, the cyclic Kummer extension across):

$$\begin{array}{ccccccc} F = L_s & \hookrightarrow & L_{s-1} & \hookrightarrow & \cdots & \hookrightarrow & L_0 = K \\ \| & & \| & & & & \\ \mathrm{Fix}(G_s) & \xrightarrow{\sqrt[p_{s-1}]{a_{s-1}}} & ? & & & & \end{array}$$

   State precisely why each $L_i \subseteq L_{i-1}$ is cyclic of degree p_{i-1} and how Kummer theory supplies the radical generator.

4. Let σ denote complex conjugation restricted to the splitting field $K \subseteq \mathbb{C}$ of an irreducible quintic $f \in \mathbb{Q}[x]$ with exactly three real roots, and let $\rho \in \mathrm{Gal}(K/\mathbb{Q})$ be a 5-cycle (from transitivity). Draw the diagram of inclusions $\mathbb{Q} \hookrightarrow \mathbb{Q}(\alpha) \hookrightarrow K$ for a real root α, mark where σ and ρ act, and prove that $\langle \sigma, \rho \rangle = S_5$ so that the diagram below has $\mathrm{Gal}(K/\mathbb{Q}) = S_5$ at the top:

   Explain why σ being a transposition forces non-solvability, and identify the order of $\mathrm{Gal}(K/\mathbb{Q})$.

14.8 Computation of Galois Groups over $\mathbb{Q}$

Reduction mod p and Dedekind's theorem

Let $f(x) \in \mathbb{Z}[x]$ be monic, separable, of degree n, with splitting field K over $\mathbb{Q}$ and Galois group $G = \mathrm{Gal}(K/\mathbb{Q})$. Labelling the n distinct roots $\alpha_1, \ldots, \alpha_n$ identifies G with a subgroup of S_n (every automorphism permutes the roots, and is determined by that permutation). The central computational problem of the section is to locate this subgroup of S_n exactly. The single most powerful tool is to reduce f modulo a prime and read the resulting factorization as a permutation.

Write $\overline{f} \in \mathbb{F}_p[x]$ for the reduction of f mod p, and recall $\mathrm{disc}(f) \in \mathbb{Z}$, the discriminant. A prime p is *unramified* for f when $p \nmid \mathrm{disc}(f)$; then $\overline{f}$ is still separable (its discriminant $\overline{\mathrm{disc}(f)} \neq 0$ in $\mathbb{F}_p$), so $\overline{f}$ factors into *distinct* irreducibles over $\mathbb{F}_p$.

Theorem 14.8.1 (Dedekind's theorem)**.** *Let $f \in \mathbb{Z}[x]$ be monic and separable, and let p be a prime with $p \nmid \mathrm{disc}(f)$. Suppose*

$$\overline{f} = \overline{g_1}\,\overline{g_2} \cdots \overline{g_k} \quad \text{in } \mathbb{F}_p[x],$$

a product of distinct *monic irreducibles with $\deg \overline{g_i} = d_i$. Then $\mathrm{Gal}(f/\mathbb{Q})$, viewed in S_n, contains a permutation whose cycle type is $(d_1, d_2, \ldots, d_k)$.*

Idea. Each prime $\mathfrak{p}$ of the splitting-field ring lying over p has a Frobenius automorphism $\mathrm{Frob}_{\mathfrak{p}} \in G$, characterized by $\mathrm{Frob}_{\mathfrak{p}}(x) \equiv x^p \pmod{\mathfrak{p}}$. Because p is unramified, reduction mod $\mathfrak{p}$ is a bijection between the roots of f in characteristic 0 and the roots of $\overline{f}$ in $\overline{\mathbb{F}_p}$. Frobenius acts on the latter as $\alpha \mapsto \alpha^p$, and on the roots of a single irreducible factor $\overline{g_i}$ of degree d_i it acts as a single d_i-cycle (the roots of an irreducible over $\mathbb{F}_p$ form one Frobenius orbit, of size equal to the degree). Pulling this back through the bijection, $\mathrm{Frob}_{\mathfrak{p}}$ is an element of G with cycle type $(d_1, \ldots, d_k)$. □

Remark 14.8.1. Dedekind's theorem only ever produces *lower* bounds: each prime hands us one cycle type known to occur in G. It never certifies that a cycle type is *absent*. So the method is to collect cycle types from several primes and ask which transitive subgroup of S_n is forced to contain all of them. The discriminant test and resolvents supply the complementary upper bounds.

Worked Example 14.8.2 (A 4-cycle and a transposition from two primes)**.** For $f(x) = x^4 - x - 1$, find primes exhibiting a 4-cycle and a transposition in $\mathrm{Gal}(f/\mathbb{Q})$.

Recognition. By Dedekind's theorem an irreducible reduction $\overline{f}$ of degree 4 gives a 4-cycle, and a factorization of type $2+1+1$ gives a transposition; we just factor mod small primes.

Solution. Mod 2: $x^4 - x - 1 \equiv x^4 + x + 1$, which is irreducible over $\mathbb{F}_2$ (no root since $0, 1$ both give 1; and the only way a rootless quartic could factor is as a product of two irreducible quadratics, but the unique irreducible quadratic over $\mathbb{F}_2$ is $x^2 + x + 1$, whose square $(x^2 + x + 1)^2 = x^4 + x^2 + 1 \neq x^4 + x + 1$). Hence $\overline{f}$ is irreducible mod 2, giving both transitivity (so f is irreducible over $\mathbb{Q}$) and a **4-cycle**. So G is a transitive subgroup of S_4 containing a 4-cycle: $G \in \{\, C_4, D_8, S_4 \,\}$. The discriminant is $\mathrm{disc}(f) = -283$, which is negative and hence not a perfect square, so $G \not\subseteq A_4$ (this is automatic here, since a 4-cycle is already odd). Mod 17: $x^4 - x - 1$ factors as a product of two linear factors and one irreducible quadratic (cycle type $2+1+1$), giving a **transposition** in G. This alone does not force S_4: D_8 also contains transpositions (e.g. $\langle (1\,2\,3\,4), (1\,3) \rangle = D_8$). Mod 7: $\overline{f} = (x+4)(x^3 + 3x^2 + 2x + 5)$ with the cubic irreducible (cycle type $3+1$), giving a **3-cycle**; then $3 \mid |G|$, which rules out C_4 and D_8, so $G = S_4$. Sanity check: $-283 < 0$ is certainly not a square, consistent with the odd 4-cycle (and the transposition) lying in G; and $|G|$ is divisible by 4 and by 3 while G contains odd permutations, so $G \neq A_4$ and $|G| = 24$.

The strategy: transitivity, discriminant, known subgroups

Three facts convert raw cycle types into a group identification.

Proposition 14.8.3 (transitivity from irreducibility)**.** *$f \in \mathbb{Q}[x]$ is irreducible if and only if $G = \mathrm{Gal}(f/\mathbb{Q})$ acts transitively on the roots. In particular an irreducible f of degree n has $n \mid |G|$.*

Idea. G is transitive iff there is a single orbit of roots iff the roots form one irreducible factor's worth, i.e. f is irreducible over $\mathbb{Q}$. The orbit-stabilizer count gives $n = [G : G_\alpha] \mid |G|$. □

Theorem 14.8.4 (the discriminant test)**.** *Let $f \in \mathbb{Q}[x]$ be separable of degree n with roots α_i and $\mathrm{disc}(f) = \prod_{i<j}(\alpha_i - \alpha_j)^2$. Then $\sqrt{\mathrm{disc}(f)} \in \mathbb{Q}$ if and only if $G \subseteq A_n$. Equivalently, for monic $f \in \mathbb{Z}[x]$ with squarefree-checked discriminant, $G \subseteq A_n \iff \mathrm{disc}(f)$ is a perfect square in $\mathbb{Q}$.*

Idea. The element $\delta = \prod_{i<j}(\alpha_i - \alpha_j)$ satisfies $\delta^2 = \mathrm{disc}(f) \in \mathbb{Q}$, and any $\sigma \in G$ sends $\delta \mapsto \mathrm{sgn}(\sigma)\,\delta$. Thus δ is fixed by all of G (hence $\delta \in \mathbb{Q}$ and $\mathrm{disc}\, f$ is a square) exactly when every $\sigma \in G$ is even, i.e. $G \subseteq A_n$. □

Method (Pinning down $\mathrm{Gal}(f/\mathbb{Q})$ for irreducible $f \in \mathbb{Z}[x]$ of degree n.)**.** (1) Confirm f is irreducible over $\mathbb{Q}$, so G is a transitive subgroup of S_n. (2) Compute $\mathrm{disc}(f)$; decide whether it is a perfect square. If yes, $G \subseteq A_n$; if no, $G \not\subseteq A_n$. (3) Factor $\overline{f}$ for several primes $p \nmid \mathrm{disc}(f)$, recording cycle types via Dedekind. (4) Intersect the constraints with the (short) list of transitive subgroups of S_n. A single cycle type often eliminates all but one candidate. (5) If two candidates survive, one inside the other, cycle types can never rule out the larger one (e.g. $C_4 \leq D_8$ when no transposition has appeared, or the solvable groups $C_5 \leq D_{10} \leq F_{20}$ in S_5); separate them with a resolvent polynomial.

Caution. Reduction mod p never *proves* a cycle type is missing from G, so you cannot conclude $G \neq S_n$ just because you have not seen a transposition. Likewise a square discriminant only says $G \subseteq A_n$; it does not by itself distinguish, say, V_4 from A_4 inside S_4, nor A_n from a proper transitive subgroup of A_n. Always pair cycle-type evidence with the discriminant and, when needed, a resolvent.

Worked Example 14.8.5 (Discriminant forces S_3 vs. A_3 for a cubic)**.** Show $f(x) = x^3 - x - 1$ has Galois group S_3.

Recognition. For an irreducible cubic, G is transitive in S_3, so $G \in \{ A_3, S_3 \}$; the discriminant test decides which, since disc $= -4a^3 - 27b^2$ for $x^3 + ax + b$.

Solution. f is irreducible over $\mathbb{Q}$ (no rational root: ± 1 give $-1, -1$). Here $a = -1, b = -1$, so $\mathrm{disc}(f) = -4(-1)^3 - 27(-1)^2 = 4 - 27 = -23$. Since -23 is negative it is not a perfect square in $\mathbb{Q}$, so $G \not\subseteq A_3$, forcing $G = S_3$. Sanity check: mod 2, $\overline{f} = x^3 + x + 1$ is irreducible, giving a 3-cycle; mod 5, $f(2) = 8 - 2 - 1 = 5 \equiv 0$, so $x \equiv 2$ is a root and $\overline{f} = (x - 2)(x^2 + 2x - 2)$ splits as (linear)(irreducible quadratic), a transposition. A 3-cycle and a transposition generate S_3, confirming $G = S_3$.

Worked Example 14.8.6 (An S_4 quartic via discriminant and a 4-cycle)**.** Prove $f(x) = x^4 + x + 1$ has Galois group S_4.

Recognition. Irreducible quartic gives transitive $G \leq S_4$; a non-square discriminant rules out A_4 and V_4 (the transitive subgroups inside A_4), and a mod-p 4-cycle plus a 3-cycle pin S_4.

Solution. Irreducibility over $\mathbb{Q}$: no rational roots (± 1 give $3, 1$), and $x^4 + x + 1$ is not a product of two rational quadratics (matching coefficients $x^4 + x + 1 = (x^2 + bx + c)(x^2 - bx + d)$ forces $c + d - b^2 = 0,\ b(d - c) = 1,\ cd = 1$, which has no rational solution). So G is transitive in S_4. Discriminant of $x^4 + px + q$ is $-27p^4 + 256q^3$; with $p = q = 1$ this is $-27 + 256 = 229$, which is prime, hence not a perfect square: $G \not\subseteq A_4$. Mod 2: $x^4 + x + 1$ is irreducible over $\mathbb{F}_2$, giving a 4-cycle. The transitive subgroups of S_4 are C_4, V_4, D_8, A_4, S_4; those containing a 4-cycle are C_4, D_8, S_4. Of these, only S_4 contains an element of order 3 ($|C_4| = 4$ and $|D_8| = 8$ are not divisible by 3), so a 3-cycle will pin down S_4. Mod 5: testing residues, $f(0) = 1, f(1) = 3, f(2) = 16 + 2 + 1 = 19 \equiv 4, f(3) = 81 + 3 + 1 = 85 \equiv 0$, so $x \equiv 3$ is a root mod 5 and $\overline{f} = (x - 3) \cdot (\text{cubic})$; that cubic is irreducible mod 5 (it has no root among the remaining residues), giving cycle type $3 + 1$, a 3-cycle. A 4-cycle and a 3-cycle generate S_4, so $G = S_4$. Sanity check: $|S_4| = 24$ is divisible by 4 (transitivity) and by 3 (the 3-cycle); and 229 not a square is consistent with the odd permutation (the 4-cycle) lying in G.

The resolvent cubic and the quartic playbook

When $\mathrm{disc}(f)$ *is* a square the discriminant test only narrows G to a subgroup of A_n, and for $n = 4$ several such subgroups can share cycle types. The resolvent cubic resolves them. For a quartic

$$f(x) = x^4 + px^2 + qx + r \quad \text{(depressed; remove the cubic term first)},$$

with roots $\alpha_1, \alpha_2, \alpha_3, \alpha_4$, the three quantities

$$\beta_1 = \alpha_1\alpha_2 + \alpha_3\alpha_4, \quad \beta_2 = \alpha_1\alpha_3 + \alpha_2\alpha_4, \quad \beta_3 = \alpha_1\alpha_4 + \alpha_2\alpha_3$$

are permuted by S_4 through the quotient $S_4/V_4 \cong S_3$. Their elementary symmetric functions are polynomials in p, q, r, giving the *resolvent cubic*

$$g(x) = x^3 - p\,x^2 - 4r\,x + (4pr - q^2).$$

Theorem 14.8.7 (quartic Galois groups via the resolvent)**.** *Let $f \in \mathbb{Q}[x]$ be an irreducible quartic with resolvent cubic g, and let $G = \mathrm{Gal}(f/\mathbb{Q}) \leq S_4$. Then, writing $D = \mathrm{disc}(f) = \mathrm{disc}(g)$:*

$G \cong S_4$	$\iff$	*g is irreducible and D is not a square*;
$G \cong A_4$	$\iff$	*g is irreducible and D is a square*;
$G \cong V_4$	$\iff$	*g splits completely over $\mathbb{Q}$*;
$G \cong C_4$ *or* D_8	$\iff$	*g has exactly one rational root.*

In the last case C_4 and D_8 are separated by whether f remains irreducible over $\mathbb{Q}(\sqrt{D})$: C_4 if f becomes reducible there, D_8 if it stays irreducible.

Idea. The roots β_i of g are fixed exactly by $V_4 = \{\, e, (12)(34), (13)(24), (14)(23) \,\} \trianglelefteq S_4$, so $\mathrm{Gal}(g/\mathbb{Q}) \cong G/(G \cap V_4) \leq S_4/V_4 \cong S_3$. The number of rational β_i records how many of the three V_4-cosets G collapses: all three rational $\iff G \leq V_4$; exactly one rational $\iff G$ stabilizes one pairing, i.e. $G \leq C_4$ or D_8; none rational (g irreducible) $\iff$ the image of G in S_3 is transitive (A_3 or S_3), forcing $G \in \{\, A_4, S_4 \,\}$, which the discriminant then separates. □

Worked Example 14.8.8 (A V_4 quartic: square discriminant, split resolvent)**.** Determine $\mathrm{Gal}(f/\mathbb{Q})$ for $f(x) = x^4 + 1$.

Recognition. Irreducible quartic; compute disc and the resolvent cubic. A completely split resolvent signals V_4.

Solution. $x^4 + 1 = \Phi_8(x)$ is irreducible over $\mathbb{Q}$ (the 8th cyclotomic polynomial). It is already depressed with $p = 0, q = 0, r = 1$. Resolvent: $g(x) = x^3 - 0 \cdot x^2 - 4x + 0 = x^3 - 4x = x(x-2)(x+2)$, which splits completely over $\mathbb{Q}$. By the theorem $G \cong V_4$. Sanity check: $\mathbb{Q}(\zeta_8)$ has degree $\varphi(8) = 4$ over $\mathbb{Q}$ with abelian Galois group $(\mathbb{Z}/8\mathbb{Z})^\times \cong \mathbb{Z}/2 \times \mathbb{Z}/2 \cong V_4$, matching exactly; and $\mathrm{disc}(x^4 + 1) = 256 = 16^2$ is a perfect square, consistent with $V_4 \subseteq A_4$.

Worked Example 14.8.9 (A_4 vs. V_4 when the discriminant is a square)**.** Show $f(x) = x^4 + 8x + 12$ has Galois group A_4.

Recognition. Square discriminant puts $G \leq A_4$, so $G \in \{\, V_4, A_4 \,\}$; the resolvent cubic being irreducible (not split) selects A_4.

Solution. f is irreducible over $\mathbb{Q}$ (no rational roots by the rational-root test on divisors of 12, and no rational quadratic factorization). It is depressed: $p = 0, q = 8, r = 12$. Discriminant of $x^4 + qx + r$ is $-27q^4 + 256r^3 = -27 \cdot 4096 + 256 \cdot 1728 = -110592 + 442368 = 331776 = 576^2$, a perfect square, so $G \leq A_4$. Resolvent cubic: $g(x) = x^3 - 0 \cdot x^2 - 4(12)x + (0 - 64) = x^3 - 48x - 64$. This is irreducible over $\mathbb{Q}$: a rational root would be an integer dividing 64; for $|x| \geq 16$ we have $|x^3 - 48x| = |x|\,(x^2 - 48) > 64$, and testing $\pm 1, \pm 2, \pm 4, \pm 8$ gives no zero (e.g. $g(8) = 512 - 384 - 64 = 64 \neq 0$, $g(-4) = -64 + 192 - 64 = 64 \neq 0$). Since g is irreducible and D is a square, $G \cong A_4$. Sanity check: $\sqrt{D} = 576 \in \mathbb{Q}$ matches $G \subseteq A_4$; an irreducible resolvent means $\mathrm{Gal}(g/\mathbb{Q}) = S_3$ or $A_3 = C_3$, and $\mathrm{disc}(g) = \mathrm{disc}(f)$ is a square so $\mathrm{Gal}(g/\mathbb{Q}) = C_3$, hence $G/(G \cap V_4) \cong C_3$, giving $|G| = 12$, i.e. A_4.

Worked Example 14.8.10 (C_4 vs. D_8: one rational resolvent root)**.** Identify $\mathrm{Gal}(f/\mathbb{Q})$ for $f(x) = x^4 + 5x^2 + 5$.

Recognition. One rational resolvent root signals C_4 or D_8; the tiebreak is whether f stays irreducible over $\mathbb{Q}(\sqrt{D})$.

Solution. By the rational root test and Eisenstein at 5, $f = x^4 + 5x^2 + 5$ is irreducible over $\mathbb{Q}$. Depressed with $p = 5, q = 0, r = 5$. Resolvent: $g(x) = x^3 - 5x^2 - 20x + (4 \cdot 25 - 0) = x^3 - 5x^2 - 20x + 100 = (x - 5)(x^2 - 20)$. So g has exactly one rational root $x = 5$ (since $x^2 - 20$ is irreducible over $\mathbb{Q}$), placing $G \in \{\, C_4, D_8 \,\}$. Discriminant: f is biquadratic, $x^2 = \frac{-5 \pm \sqrt{5}}{2}$, so the splitting field is $\mathbb{Q}\big(\sqrt{\frac{-5+\sqrt{5}}{2}}\big)$, which contains $\sqrt{5}$; one computes $D = \mathrm{disc}(f) = 2000 = 400 \cdot 5$, so $\sqrt{D} = 20\sqrt{5}$ and $\mathbb{Q}(\sqrt{D}) = \mathbb{Q}(\sqrt{5})$. Over $\mathbb{Q}(\sqrt{5})$ the quartic factors as $\big(x^2 - \frac{-5+\sqrt{5}}{2}\big)\big(x^2 - \frac{-5-\sqrt{5}}{2}\big)$, i.e. f becomes reducible, so $G \cong C_4$. Sanity check: a biquadratic $x^4 + px^2 + r$ with $\sqrt{r} = \sqrt{5}$ irrational but $\sqrt{p^2 - 4r} = \sqrt{25 - 20} = \sqrt{5}$ relating the two radicals is the classic C_4 pattern (Galois group cyclic of order 4), and indeed $|\mathbb{Q}(\zeta) : \mathbb{Q}|$-type cyclic structure gives $|G| = 4$ with a single 4-cycle generator.

Worked Example 14.8.11 (Reading the resolvent backwards)**.** Given that an irreducible quartic f has resolvent cubic g with $\mathrm{disc}(g)$ a non-square and g irreducible, name G.

Recognition. g irreducible means $\mathrm{Gal}(g/\mathbb{Q})$ is transitive in S_3; a non-square $\mathrm{disc}(g) = \mathrm{disc}(f)$ means $G \not\subseteq A_4$.

Solution. Irreducible g with non-square discriminant has $\mathrm{Gal}(g/\mathbb{Q}) = S_3$, so $G/(G \cap V_4) \cong S_3$ has order 6; since G is transitive, $4 \mid |G| = 6\,|G \cap V_4|$, so $12 \mid |G|$; and $G \neq A_4$, because the image of A_4 in $S_4/V_4 \cong S_3$ is only A_3. Hence $|G| = 24$, giving $G \cong S_4$. Sanity check: this is exactly the first row of the table (g irreducible, D not a square $\Rightarrow S_4$), and $|S_4| = 24 = 6 \cdot 4$ matches $|S_3| \cdot |V_4|$.

Resolvents in general: separating same-cycle-type subgroups

The resolvent cubic is one instance of a general device. Given f of degree n and a polynomial expression $\theta(\alpha_1, \ldots, \alpha_n)$ whose S_n-orbit has size m, the *resolvent*

$$R(x) = \prod_{\sigma \in S_n / \operatorname{Stab}(\theta)} \big(x - \sigma \cdot \theta\big) \in \mathbb{Q}[x]$$

has degree m and rational coefficients (symmetric in the α_i). The factorization pattern of R over $\mathbb{Q}$ reflects the orbits of G on the cosets $S_n/\operatorname{Stab}(\theta)$: when R has distinct roots, a rational root of R corresponds to a G-fixed coset $\tau \operatorname{Stab}(\theta)$, i.e. to $G \le \tau \operatorname{Stab}(\theta)\tau^{-1}$. This separates transitive subgroups that Dedekind cannot, since cycle types only exhibit elements of G and can never show that G lies in a smaller group.

Remark 14.8.2. The canonical pair Dedekind cannot tell apart in S_5 is the cyclic C_5, the dihedral D_{10}, the Frobenius group F_{20}, and A_5, S_5: the transitive subgroups of S_5 are exactly $C_5 < D_{10} < F_{20} < S_5$ together with A_5. Each of C_5, D_{10}, F_{20} contains 5-cycles, and cycle types alone (constrained also by the discriminant, which is a square iff $G \le A_5$) leave genuine ambiguity. A degree-6 *sextic resolvent* is built from a polynomial expression θ in the roots whose stabilizer in S_5 is exactly F_{20} (order 20, index 6), so that S_5 permutes the six conjugates of θ through S_5/F_{20}; this resolvent has a rational root precisely when G fixes one of the six cosets, i.e. when G is conjugate into F_{20}, separating the solvable groups C_5, D_{10}, F_{20} from A_5, S_5.

Method (The low-degree playbook.)**.** Cubics ($n = 3$): irreducible $\Rightarrow G \in \{ A_3, S_3 \}$; disc a square $\iff A_3 = C_3$, else S_3. Quartics ($n = 4$): transitive subgroups C_4, V_4, D_8, A_4, S_4; use the resolvent cubic table above. Quintics ($n = 5$): transitive subgroups $C_5, D_{10}, F_{20}, A_5, S_5$. First, disc a square $\iff G \le A_5$, separating $\{ C_5, D_{10}, A_5 \}$ (square) from $\{ F_{20}, S_5 \}$ (non-square). Then a transposition (cycle type $2+1+1+1$) or a single 2-cycle from Dedekind forces $G = S_5$; a 5-cycle is automatic from transitivity; an element of cycle type $2+2+1$ lies in A_5 and (with the discriminant) helps separate C_5, D_{10}, A_5. The sextic resolvent separates the solvable trio $\{ C_5, D_{10}, F_{20} \}$ (rational root) from $\{ A_5, S_5 \}$ (no rational root).

Worked Example 14.8.12 ($x^5 - x - 1$ has Galois group S_5)**.** Prove the irreducible quintic $f(x) = x^5 - x - 1$ has $\operatorname{Gal}(f/\mathbb{Q}) = S_5$.

Recognition. Irreducible quintic is transitive in S_5; by the playbook, exhibiting a 5-cycle, an element of order 6 (type $2+3$), and a transposition forces S_5, since S_5 is the only transitive subgroup of S_5 containing a transposition.

Solution. Irreducibility over $\mathbb{Q}$: mod 3, $f(x) = x^5 - x - 1 \equiv x^5 + 2x + 2$. Testing $0, 1, 2$: $f(0) = 2, f(1) = 1 + 2 + 2 = 5 \equiv 2, f(2) = 32 - 2 - 1 = 29 \equiv 2 \pmod 3$, no linear factor; one checks it has no quadratic factor either, so $\overline{f}$ is irreducible over $\mathbb{F}_3$ (a known irreducible quintic mod 3). Hence f is irreducible over $\mathbb{Q}$ and $\overline{f}$ irreducible mod 3 gives a **5-cycle**. Mod 2: $x^5 - x - 1 \equiv x^5 + x + 1 = (x^2 + x + 1)(x^3 + x^2 + 1)$ over $\mathbb{F}_2$ (both factors irreducible: the quadratic is the unique irreducible one, and the cubic has no root in $\mathbb{F}_2$). This gives cycle type $\mathbf{2 + 3}$, an element of order $\operatorname{lcm}(2, 3) = 6$. Its cube, $((2\text{-cycle})(3\text{-cycle}))^3$, equals the 2-cycle (the 3-cycle cubes to identity), so G contains a **transposition**. The only transitive subgroup of S_5 that contains a transposition is S_5 itself (a transitive subgroup generated by transpositions and acting transitively is all of S_5; more directly, a transposition together with a 5-cycle generates S_5). Hence $G = S_5$. Sanity check: $\operatorname{disc}(x^5 - x - 1) = 2869 = 19 \cdot 151$, which is not a perfect square, so $G \not\subseteq A_5$, fully consistent with the odd transposition lying in G; and a 5-cycle plus a transposition is the textbook generating set for S_5.

Worked Example 14.8.13 ($x^5 + 20x + 16$ lands in A_5)**.** Show $f(x) = x^5 + 20x + 16$ has Galois group A_5 (not S_5).

Recognition. Square discriminant forces $G \le A_5$; combined with transitivity (a 5-cycle) and a 3-cycle (an even element of order 3), which rules out the solvable groups C_5, D_{10}, we get $G = A_5$.

Solution. f is irreducible over $\mathbb{Q}$ (Eisenstein fails at 2 since $4 \mid 16$; instead reduce mod 3: $x^5 + 20x + 16 \equiv x^5 + 2x + 1$, irreducible over $\mathbb{F}_3$, so f is irreducible over $\mathbb{Q}$). The mod-3 irreducibility gives a **5-cycle**. Discriminant: for $x^5 + ax + b$, $\operatorname{disc} = 4^4a^5 + 5^5b^4 = 256a^5 + 3125b^4$; with $a = 20, b = 16$ this is $256 \cdot 20^5 + 3125 \cdot 16^4$. Now $20^5 = 3.2 \times 10^6 = 3200000$, so $256 \cdot 3200000 = 819200000$; and $16^4 = 65536$, so $3125 \cdot 65536 = 204800000$; sum $= 1024000000 = 32000^2$, a perfect square. So $G \le A_5$, i.e. $G \in \{ C_5, D_{10}, A_5 \}$. Mod 7: $x^5 + 20x + 16 \equiv (x + 2)(x + 3)(x^3 + 2x^2 - 2x - 2)$ over $\mathbb{F}_7$, cycle type $\mathbf{3 + 1 + 1}$, a 3-cycle (an

even permutation), forcing $3 \mid |G|$. Since $3 \nmid |C_5| = 5$ and $3 \nmid |D_{10}| = 10$, neither C_5 nor D_{10} can contain a 3-cycle, so the only remaining even transitive group is A_5 ($|A_5| = 60$). Hence $G = A_5$. Sanity check: $1024000000 = (32000)^2$ is a clean square, matching $G \subseteq A_5$; and $|A_5| = 60$ is divisible by 5 (transitivity) and by 3 (the 3-cycle), exactly the primes our cycle types demanded, while $|C_5| = 5, |D_{10}| = 10$ both fail the divisibility-by-3 test. (One can also confirm an even $2 + 2 + 1$ element appears, e.g. mod 23, consistent with $G \subseteq A_5$.)

Worked Example 14.8.14 (Two primes already forcing S_n)**.** Explain why for $f(x) = x^6 + 24x - 20$ a transposition plus a reduction of type $5 + 1$ would force S_6, and contrast with the actual answer A_6.

Recognition. If Dedekind ever delivers a transposition and (via another prime) a p-cycle on $n-1$ or all n points appropriately, transitivity plus a transposition can force S_n; a square discriminant blocks any transposition, redirecting to A_n.

Solution. For a transitive $G \leq S_n$, possessing a transposition and an $(n-1)$-cycle (with the fixed point disjoint) generates S_n; even just a transposition together with an n-cycle when n is prime generates S_n. So, once f is known to be irreducible, two well-chosen primes – one giving cycle type $(n-1)+1$ (an $(n-1)$-cycle; when n is prime an irreducible $\overline{f}$, i.e. an n-cycle, also works) and one giving cycle type $2+1+\cdots+1$ (a transposition) – already force $G = S_n$. (For composite n an n-cycle does not suffice: $\langle (1\,2\,3\,4\,5\,6), (1\,4) \rangle$ is transitive of order only 24.) For $f = x^6 + 24x - 20$, however, $\mathrm{disc}(f)$ turns out to be a perfect square, so $G \subseteq A_6$ and *no* prime can ever produce a transposition (a single 2-cycle is odd). Thus the transposition route is unavailable; instead one collects even cycle types (e.g. a 5-cycle from an irreducible-quintic-times-linear reduction, type $5 + 1$, which is even; and a 3-cycle, type $3 + 1 + 1 + 1$) and shows the only transitive even subgroup of S_6 generated by them is A_6. Sanity check: $5 + 1$ and $3 + 1 + 1 + 1$ are both even permutations (a 5-cycle and a 3-cycle), consistent with $G \subseteq A_6$; and a 5-cycle together with a 3-cycle inside a transitive group on 6 points generates a large group, with A_6 the smallest containing both while respecting the square-discriminant constraint.

The Galois correspondence as the backdrop

Every identification above is, through the Fundamental Theorem, a statement about the subfield lattice of the splitting field K. Once G is named as a subgroup of S_n, its subgroups read off all intermediate fields, and the cycle-type data has a clean field-theoretic meaning: the degrees d_i of the irreducible factors of $\overline{f}$ are the residue degrees of the primes above p in the root field $\mathbb{Q}(\alpha_1)$, while every prime of K above p has residue degree $\mathrm{lcm}(d_1, \ldots, d_k)$, the order of the Frobenius. The picture for the S_4 case (Worked Example with $x^4 + x + 1$) pairs the 30-element subgroup lattice of S_4 with the subfield lattice of K; we record only the principal layers.

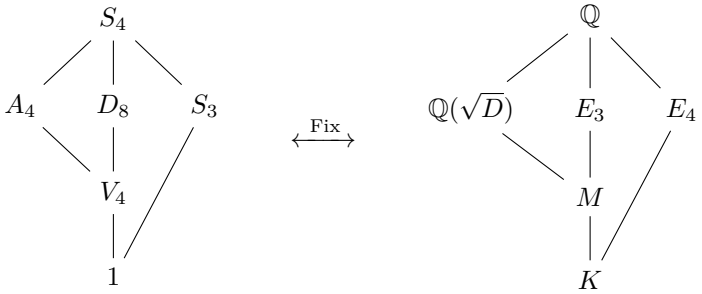


Diagram explanation. Objects: The left lattice contains six nodes that are subgroups of S_4: the full group S_4 (order 24) at the top; the alternating group A_4 (order 12, index 2), the dihedral group D_8 (order 8, index 3), and the point-stabilizer S_3 (order 6, index 4) in the middle layer; the Klein four-group V_4 (order 4, index 6) one step lower; and the trivial group 1 (order 1, index 24) at the bottom. The right lattice contains six nodes that are intermediate fields of the Galois extension $K/\mathbb{Q}$ ($[K : \mathbb{Q}] = 24$): the base field $\mathbb{Q}$ at the top; the quadratic field $\mathbb{Q}(\sqrt{D})$, the cubic field $E_3 = \mathrm{Fix}(D_8)$, and the quartic field $E_4 = \mathrm{Fix}(S_3)$ in the middle layer; the degree-6 field $M = \mathrm{Fix}(V_4)$ below; and the splitting field K at the bottom.

Arrows: Every edge in each lattice is an inclusion: on the left, $H_1 \leq H_2$ when H_1 is below H_2; on the right, $F_1 \subseteq F_2$ when F_2 is below F_1 (the smallest field $\mathbb{Q}$ is at the top). The double-headed horizontal arrow $\overset{\text{Fix}}{\longleftrightarrow}$

between the two lattices denotes the order-reversing Galois correspondence $H \mapsto K^H = \mathrm{Fix}(H)$ (left to right) and $F \mapsto \mathrm{Gal}(K/F)$ (right to left); it is a bijection between the lattice of subgroups of $G = S_4$ and the lattice of intermediate fields of $K/\mathbb{Q}$.

What commutes: The correspondence is order-reversing: $H_1 \leq H_2$ if and only if $\mathrm{Fix}(H_1) \supseteq \mathrm{Fix}(H_2)$. Concretely: $A_4 \leq S_4$ corresponds to $\mathbb{Q} \subseteq \mathbb{Q}(\sqrt{D})$; $V_4 \leq A_4$ and $V_4 \leq D_8$ correspond to $\mathbb{Q}(\sqrt{D}) \subseteq M$ and $E_3 \subseteq M$; $1 \leq V_4$ corresponds to $M \subseteq K$. Index equals degree: $[S_4 : H] = [Fix(H) : \mathbb{Q}]$, so $[S_4 : A_4] = 2$ matches $[\mathbb{Q}(\sqrt{D}) : \mathbb{Q}] = 2$, and $[S_4 : V_4] = 6$ matches $[M : \mathbb{Q}] = 6$.

Why it commutes: The Fundamental Theorem of Galois Theory guarantees the bijection. For a concrete element chase: take $\sigma \in A_4 \leq S_4$; because σ is even, the sign character $S_4 \to \{\pm 1\}$ sends $\sigma \mapsto 1$, which equals $\sigma(\sqrt{D}) = \sqrt{D}$ (since σ permutes roots via sign), so $\sqrt{D} \in \mathrm{Fix}(A_4) = \mathbb{Q}(\sqrt{D})$. Similarly, V_4 fixes all three quantities β_i (the resolvent roots), so $\beta_i \in \mathrm{Fix}(V_4) = M$, making M the splitting field of the resolvent cubic.

Why this matters here: This diagram is the payoff of the entire section. After identifying $G = S_4$ by Dedekind's theorem plus the discriminant, the diagram decodes every intermediate field at once: the resolvent cubic's splitting field M corresponds to V_4; the quadratic field $\mathbb{Q}(\sqrt{D})$ corresponds to A_4; and a single root field $E_4 = \mathbb{Q}(\alpha)$ corresponds to a point-stabilizer $S_3 \leq S_4$. The diagram makes visible why the resolvent cubic test works: factoring g over $\mathbb{Q}$ measures how G meets V_4, which by the correspondence determines the subfields of M.

Concrete example: For $f(x) = x^4 - x - 1$ with $G = S_4$ and splitting field K: the discriminant $\mathrm{disc}(f) = -283$ is not a square, so $\mathbb{Q}(\sqrt{-283})$ is the quadratic subfield corresponding to A_4; the resolvent cubic $x^3 + 4x - 1$ (here $p = 0$, $q = -1$, $r = -1$) is irreducible over $\mathbb{Q}$ (no rational root), so its splitting field M is a degree-6 extension corresponding to V_4; and $\mathbb{Q}(\alpha_1)$ for a root α_1 of f is a degree-4 subfield corresponding to the stabilizer S_3 of index 4.

Common pitfall: Students often read the left lattice top-down as "bigger group on top" and forget that on the right lattice the smaller field ($\mathbb{Q}$) is at the top. The correspondence *reverses* inclusion: S_4 (largest group) corresponds to $\mathbb{Q}$ (smallest field), while 1 (smallest group) corresponds to K (largest field). Also, $V_4 \leq S_3$ fails (since $4 \nmid 6$), and correspondingly $M \not\supseteq E_4$ on the field side – a beginner who overlooks this will draw an incorrect field lattice by forcing a nonexistent inclusion.

Takeaway: The point of this diagram is that knowing $G = S_4$ completely determines the intermediate-field lattice of the splitting field via the order-reversing Galois correspondence, and the key subgroups A_4, V_4, S_3, D_8 map directly to the computationally accessible fields cut out by the discriminant, the resolvent cubic, and the root fields.

Here $\mathbb{Q}(\sqrt{D}) = \mathrm{Fix}(A_4)$ (index 2) is the quadratic subfield cut out by the discriminant; $E_3 = \mathrm{Fix}(D_8)$ (index 3) is a cubic field, a root field of the resolvent cubic; $E_4 = \mathrm{Fix}(S_3)$ (index 4, with S_3 a point stabilizer) is the quartic field $\mathbb{Q}(\alpha)$ generated by a single root of f; and $M = \mathrm{Fix}(V_4)$ is the degree-6 field whose Galois group over $\mathbb{Q}$ is $S_4/V_4 \cong S_3$ – the splitting field of the resolvent cubic. Note $V_4 \leq A_4$ and $V_4 \leq D_8$ but $V_4 \not\leq S_3$ (since $4 \nmid 6$), so on the field side $M \supseteq E_3$ but M does not contain the point-stabilizer field E_4; correspondingly E_4 sits above K on its own branch. The order-reversing nature is visible: the largest group S_4 sits over the base $\mathbb{Q}$, the trivial group over the top field K.

Worked Example 14.8.15 (Subfields forced by the A_4 identification)**.** For an irreducible quartic with $G \cong A_4$, list the degrees of the intermediate fields and the unique proper subfield that is normal over $\mathbb{Q}$ of small degree.

Recognition. Intermediate fields correspond to subgroups of A_4; degrees over $\mathbb{Q}$ equal indices $[A_4 : H]$. The only normal subgroup giving a small abelian quotient is $V_4 \trianglelefteq A_4$.

Solution. $|A_4| = 12$, so $[K : \mathbb{Q}] = 12$. Subgroups of A_4: the trivial group, three subgroups of order 2 (each $\langle (ab)(cd) \rangle$), one V_4 of order 4, four C_3's of order 3, and A_4. The corresponding subfield degrees $[\cdot : \mathbb{Q}] = [A_4 : H]$ are 12 (top K), 6 (from the order-2 subgroups), 3 (from V_4), 4 (from the C_3's), and 1 (base). The normal subgroup $V_4 \trianglelefteq A_4$ has quotient $A_4/V_4 \cong C_3$, so $\mathrm{Fix}(V_4)$ is a *cyclic* cubic field normal over $\mathbb{Q}$ – the splitting field of the (irreducible, square-discriminant) resolvent cubic. Sanity check: A_4 has no subgroup of order 6 (a classical fact), so there is *no* intermediate field of degree 2 over $\mathbb{Q}$; consistent with the resolvent test for A_4 requiring g irreducible (no rational/quadratic resolvent root), hence no quadratic subfield other than $\mathbb{Q}$ itself – indeed disc being a square means $\mathbb{Q}(\sqrt{D}) = \mathbb{Q}$.

Worked Example 14.8.16 (Residue degrees as cycle lengths)**.** With $f = x^4 + x + 1$ ($G = S_4$) and $p = 5$, interpret the factorization $\overline{f} = (x-3)$(irreducible cubic) in terms of primes of K above 5.

Recognition. The degrees of the irreducible factors of $\overline{f}$ over $\mathbb{F}_p$ are the residue degrees $f(\mathfrak{p} \mid p)$ of the primes $\mathfrak{p}$ of (the ring of integers of) the root field $\mathbb{Q}(\alpha)$ lying over p, and they form the cycle type of a Frobenius element; every prime of K over p has residue degree equal to the order of that Frobenius.

Solution. Mod 5, $\overline{f} = (x-3)(x^3 + \cdots)$ has factor degrees 1 and 3, so the Frobenius at 5 has cycle type $(1,3)$ – a 3-cycle fixing one root. Correspondingly, in the field $\mathbb{Q}(\alpha) = \mathbb{Q}[x]/(f)$ the prime 5 splits as $\mathfrak{p}_1\mathfrak{p}_2$ with residue degrees 1 and 3 (and ramification 1, since $5 \nmid \operatorname{disc} f = 229$). In the full splitting field K the prime 5 is unramified with Frobenius conjugacy class equal to that of a $(1,3)$-element of S_4. Sanity check: the residue degrees sum to $1 + 3 = 4 = \deg f = [\mathbb{Q}(\alpha) : \mathbb{Q}]$, as required for an unramified prime; and a 3-cycle is an even permutation, while the existence (at other primes) of odd permutations is what makes $G = S_4 \not\subseteq A_4$.

Exercises (from the text).

1. Let p be a prime. Prove that the polynomial $x^4 + 1$ splits mod p either into two irreducible quadratics or into 4 linear factors using Corollary 41 together with the knowledge that the Galois group of this polynomial is the Klein 4-group.
2. (Cf. Exercise 48 of Section 6.)
   (a) Let K be the splitting field of $x^6 - 2x^3 - 2$. Prove that if $[K : \mathbb{Q}] = 12$ then $K = \mathbb{Q}(\sqrt[3]{2} \cdot i, \sqrt{3})$ and K is generated over the biquadratic field $F = \mathbb{Q}(i, \sqrt{3})$ by $\alpha = \sqrt[3]{1 + \sqrt{3}}$ and $\beta = \sqrt[3]{1 - \sqrt{3}}$. Conclude that any element of $\mathrm{Gal}(K/\mathbb{Q})$ of order 3 maps α to another cube root of $1 + \sqrt{3}$ and β to another cube root of $1 - \sqrt{3}$, and if it is the identity on α or β then it is the identity on all of K.
   (b) Show that the factorization of $f(x)$ into irreducibles over $\mathbb{F}_{13}$ is $(x-7)(x-8)(x-11)(x^3+3)$ and use Corollary 41 to show that $[K : \mathbb{Q}] = 36$.
   (c) Knowing that $G = \mathrm{Gal}(K/\mathbb{Q})$ is of order 36 determine all the elements of G explicitly when the group G is isomorphic to $S_3 \times S_3$.
3. Prove that the Galois group of $x^5 + 20x + 16$ is A_5.
4. Prove that the Galois group of $x^5 + x^4 - 4x^3 - 3x^2 + 3x + 1$ is cyclic of order 5. [Show this is the minimal polynomial of $\zeta_{11} + \zeta_{11}^{-1}$.]
5. Prove that the Galois group of $x^5 + 11x + 44$ is the dihedral group D_{10} (cf. Exercise 21 of Section 7).
6. Prove that the Galois group of $x^5 + 15x + 12$ is F_{20}, the Frobenius group of order 20 (cf. Exercise 21 of Section 7).
7. Prove that the Galois group of $x^6 + 24x - 20$ is A_6.
8. Prove that the Galois group of $x^7 + 7x^4 + 14x + 3$ is A_7.
9. Determine a polynomial of degree 7 whose Galois group is cyclic of order 7.
10. Determine the probable Galois group of $x^7 - 7x + 3$.

Practice problems.

1. Let $f(x) = x^3 + x^2 - 2x - 1 \in \mathbb{Q}[x]$. Show f is irreducible over $\mathbb{Q}$, compute $\operatorname{disc}(f)$, and use the discriminant test to prove $\mathrm{Gal}(f/\mathbb{Q}) \cong \mathbb{Z}/3\mathbb{Z}$ (the cyclic group A_3). [This is the minimal polynomial of $\zeta_7 + \zeta_7^{-1}$.]
2. Use Dedekind's theorem to determine $\mathrm{Gal}(f/\mathbb{Q})$ for $f(x) = x^3 - 2$. Reduce mod a prime giving an irreducible cubic and a prime giving cycle type $2 + 1$, and confirm the result against $\operatorname{disc}(x^3 + b) = -27b^2$.
3. For $f(x) = x^4 - 2x^2 - 2$ (Eisenstein at 2), form the resolvent cubic $g(x) = x^3 - px^2 - 4rx + (4pr - q^2)$, factor g over $\mathbb{Q}$, and identify $\mathrm{Gal}(f/\mathbb{Q})$ among $\{ C_4, V_4, D_8, A_4, S_4 \}$. If you land in the C_4-vs-D_8 case, carry out the tiebreak using irreducibility of f over $\mathbb{Q}(\sqrt{\operatorname{disc} f})$.

4. Let $f(x) = x^4 + 3x + 3$. Verify f is irreducible over $\mathbb{Q}$, compute $\mathrm{disc}(x^4 + qx + r) = -27q^4 + 256r^3$ for this f, and decide whether $\mathrm{Gal}(f/\mathbb{Q}) \subseteq A_4$. Then factor $\overline{f}$ modulo two unramified primes to find a 4-cycle and a transposition in G, and pin down G with the resolvent cubic (cycle types alone can never rule out S_4).

5. Let $f \in \mathbb{Z}[x]$ be monic, separable, of degree 7, with $\overline{f}$ irreducible mod 11 and $\overline{f}$ of cycle type $2 + 5$ mod 13 (both primes unramified). Prove that $\mathrm{Gal}(f/\mathbb{Q}) = S_7$. State precisely which two group-theoretic facts about transitive subgroups of S_7 you are using.

6. Suppose $f \in \mathbb{Z}[x]$ is monic separable of degree 5 and that, over several unramified primes, the cycle types 5, $2 + 2 + 1$, and 5 all occur, while $\mathrm{disc}(f)$ is a perfect square. Show these data force $G \in \{ D_{10}, A_5 \}$ (the element of type $2 + 2 + 1$ already rules out C_5) but cannot by themselves distinguish these two, and describe what additional computation (a resolvent of which degree) would separate the solvable case D_{10} from A_5.

7. Let ζ_{13} be a primitive 13th root of unity and $f(x)$ the minimal polynomial of $\alpha = \zeta_{13} + \zeta_{13}^{-1}$ over $\mathbb{Q}$. Determine $\deg f$, prove $\mathrm{Gal}(f/\mathbb{Q})$ is cyclic, and give its order. [Use $\mathrm{Gal}(\mathbb{Q}(\zeta_{13})/\mathbb{Q}) \cong (\mathbb{Z}/13\mathbb{Z})^\times$ and the order-2 subgroup $\{ \pm 1 \}$ (of index 6).]

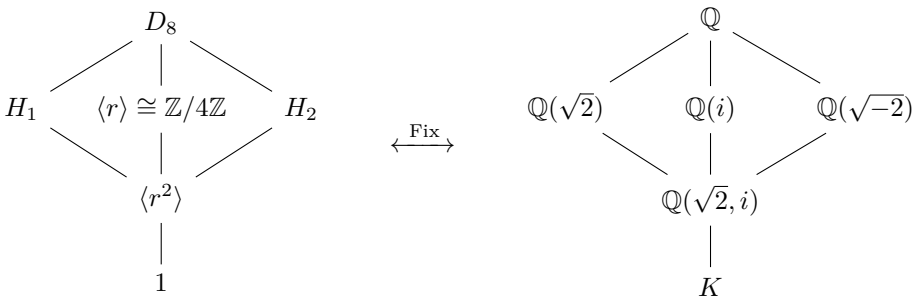
8. Let $f(x) = x^4 + 1$ and let p be an odd prime. Using the fact that $\mathrm{Gal}(f/\mathbb{Q}) \cong V_4$, show via Dedekind's theorem that $\overline{f}$ can never have an irreducible quartic factor mod p, and conclude that $\overline{f}$ factors mod every odd p as a product of linear and/or quadratic factors. Relate the three possible factorization patterns to the three index-2 subgroups of V_4.

Additional exercises.

1. Let $f(x) = x^5 - 5x + 12$. It is known that $\mathrm{disc}(f)$ is a perfect square. Assuming f is irreducible over $\mathbb{Q}$, find unramified primes exhibiting cycle types that, together with the square discriminant, rule out C_5 and leave only D_{10} or A_5; explain why no cycle-type data can rule out A_5 (every cycle type of D_{10} occurs in A_5), and use the sextic resolvent (which has the rational root 40 here) to conclude $\mathrm{Gal}(f/\mathbb{Q}) \cong D_{10}$. Explain why a $2+2+1$ element together with a 5-cycle is compatible with D_{10} but a 3-cycle would not be.

2. Construct a monic irreducible $f \in \mathbb{Z}[x]$ of degree 6 with $\mathrm{Gal}(f/\mathbb{Q})$ cyclic of order 6, by taking f to be the minimal polynomial of $\zeta_7 + \zeta_7^{-1}$ pulled up appropriately, or more directly the minimal polynomial of a real generator of the degree-6 subfield of $\mathbb{Q}(\zeta_n)$ for a suitable n. Identify your n, justify $\mathrm{Gal} \cong \mathbb{Z}/6\mathbb{Z}$, and explain why no real subfield of a cyclotomic field can have Galois group S_n for $n \geq 3$.

3. Let $f \in \mathbb{Z}[x]$ be monic separable of degree n and let p be an odd prime with $p \nmid \mathrm{disc}(f)$. Prove carefully that the product of the cycle lengths' parities equals the Legendre symbol $\left(\frac{\mathrm{disc}(f)}{p}\right)$; i.e. the Frobenius at p is an even permutation if and only if $\mathrm{disc}(f)$ is a square mod p. Deduce that if $\mathrm{disc}(f)$ is a perfect square in $\mathbb{Z}$ then every Frobenius is even, recovering $G \subseteq A_n$.



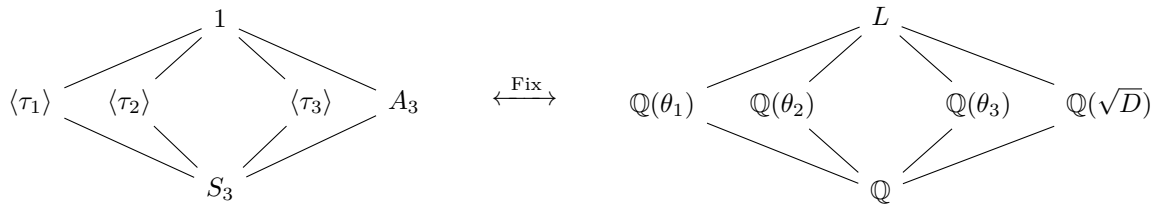
4. Show that the cycle-type data from Dedekind's theorem alone can never prove that $G \cong C_4$ rather than D_8: list the cycle types achievable in each, observe that every cycle type of C_4 also occurs in D_8 (only D_8 contains transpositions, so a factorization of type $2 + 1 + 1$ does rule out C_4), and explain in terms of the resolvent cubic why an extra invariant (a quadratic subfield computation) is genuinely required. Give explicit irreducible quartics realizing each of C_4 and D_8.

5. Let $K/\mathbb{Q}$ be the splitting field of an irreducible quartic f with $\mathrm{Gal}(f/\mathbb{Q}) \cong S_4$. Using the Galois correspondence, count the intermediate fields of each degree $2, 3, 4, 6, 8, 12$ over $\mathbb{Q}$, by counting subgroups of S_4 of the corresponding index. Identify which of these intermediate fields are normal over $\mathbb{Q}$ and match them to the normal subgroups V_4 and A_4.

Commutative-diagram exercises.

1. Let $f(x) = x^4 - 2$ with splitting field $K = \mathbb{Q}(\sqrt[4]{2}, i)$, so $G = \mathrm{Gal}(K/\mathbb{Q}) \cong D_8$ (the dihedral group of order 8, realized as a transitive subgroup of S_4). Complete the subgroup lattice of D_8 on the left and the corresponding subfield lattice on the right, labelling each field with its degree over $\mathbb{Q}$ and proving the

indicated correspondence is order-reversing:



Here H_1, H_2 are the two Klein-four subgroups of D_8. Identify H_1, H_2 as concrete subgroups of S_4, verify $\mathrm{Fix}(\langle r^2\rangle) = \mathbb{Q}(\sqrt{2}, i)$, and explain why $\langle r\rangle$ corresponds to the quadratic field $\mathbb{Q}(i)$, while the field $\mathbb{Q}(\sqrt{\operatorname{disc} f}) = \mathbb{Q}(\sqrt{-2})$ cut out by the discriminant ($\operatorname{disc} f = -2^{11}$) corresponds to $H_2 = D_8 \cap A_4$.

2. Let f be an irreducible quartic with $G = \mathrm{Gal}(f/\mathbb{Q}) \cong A_4$ and splitting field K. The resolvent cubic g is irreducible with square discriminant, so its splitting field $M = \mathrm{Fix}(V_4)$ is a cyclic cubic over $\mathbb{Q}$. Draw the diagram exhibiting M as the fixed field of $V_4 \trianglelefteq A_4$ and prove $\mathrm{Gal}(M/\mathbb{Q}) \cong A_4/V_4 \cong \mathbb{Z}/3\mathbb{Z}$ by completing the quotient square:

$$\begin{array}{ccc} A_4 & \xrightarrow{\ q\ } & A_4/V_4 \\ \| & & \downarrow\cong \\ \mathrm{Gal}(K/\mathbb{Q}) & \xrightarrow[\mathrm{res}]{} & \mathrm{Gal}(M/\mathbb{Q}) \end{array}$$

State why A_4 has no subgroup of index 2, and conclude that K has no quadratic subfield over $\mathbb{Q}$ (so the only proper normal subextension of small degree is the cyclic cubic M).

3. Let $L/\mathbb{Q}$ be Galois with $\mathrm{Gal}(L/\mathbb{Q}) \cong S_3$, arising as the splitting field of an irreducible cubic h with non-square discriminant D. Complete the lattice below, where $\mathbb{Q}(\sqrt{D}) = \mathrm{Fix}(A_3)$ is the unique quadratic subfield and $\mathbb{Q}(\theta_i) = \mathrm{Fix}(\langle\tau_i\rangle)$ are the three conjugate non-normal cubic root fields, and prove that exactly one of the four proper intermediate fields is normal over $\mathbb{Q}$:

Show $[\mathbb{Q}(\theta_i) : \mathbb{Q}] = 3$ and $[\mathbb{Q}(\sqrt{D}) : \mathbb{Q}] = 2$, and explain via the Galois correspondence why the cubic fields are not normal over $\mathbb{Q}$ while $\mathbb{Q}(\sqrt{D})$ is.

4. Let K be the splitting field of a monic separable $f \in \mathbb{Z}[x]$ and let $p \nmid \operatorname{disc}(f)$ with Frobenius $\mathrm{Frob}_p \in \mathrm{Gal}(K/\mathbb{Q})$ acting on the roots with cycle type $(d_1, \dots, d_k)$. For each fixed-point-free arrangement, draw the diagram relating the decomposition group $D_{\mathfrak{p}} = \langle \mathrm{Frob}_p\rangle$ at a prime $\mathfrak{p} \mid p$ of K to the factorization of p in the root field $\mathbb{Q}(\alpha) = \mathrm{Fix}(G_\alpha)$:

$$\begin{array}{ccc} D_{\mathfrak{p}} = \langle \mathrm{Frob}_p\rangle & \xrightarrow{\mathrm{Fix}} & K^{D_{\mathfrak{p}}} \\ | & & | \\ G & \xrightarrow{\mathrm{Fix}} & \mathbb{Q} \end{array}$$

Prove that the residue degrees of the primes of $\mathbb{Q}(\alpha)$ above p equal the lengths d_i of the orbits of $\langle \mathrm{Frob}_p\rangle$ on the cosets G/G_α, and confirm $\sum_i d_i = \deg f$.

14.9 Transcendental Extensions, Inseparable Extensions, Infinite Galois Groups

Algebraic independence and transcendence degree

Up to now every extension has been algebraic: each new element satisfied a polynomial over the base. We now make room for elements that satisfy *no* polynomial relation. Fix a field F and an extension K/F.

Definition 14.9.1. A subset $S = \{ t_1, \dots, t_n \} \subseteq K$ is *algebraically independent* over F if there is no nonzero polynomial $g \in F[x_1, \dots, x_n]$ with $g(t_1, \dots, t_n) = 0$; equivalently, the evaluation map $F[x_1, \dots, x_n] \to K$ is injective. A maximal algebraically independent subset of K is a *transcendence basis* of K/F, and its cardinality is the *transcendence degree* $\operatorname{trdeg}_F K$. The extension is *purely transcendental* if $K = F(S)$ for some algebraically independent S, so that K is F-isomorphic to a rational function field $F(x_1, \dots, x_n)$.

A single element t is algebraically independent over F precisely when it is transcendental over F in the old sense (no $g(t) = 0$ for $g \neq 0$ in one variable). The leap is that algebraic independence is exactly the field-theoretic analogue of linear independence: it satisfies an exchange property, so all maximal independent sets have the same size, just as for a vector-space basis.

Theorem 14.9.2 (the exchange lemma and well-definedness of transcendence degree)**.** *Algebraic dependence is a* matroid *(it satisfies the Steinitz exchange axiom). Consequently any two transcendence bases of K/F have the same cardinality, so* $\operatorname{trdeg}_F K$ *is well defined. Moreover* trdeg *is additive in towers: for $F \subseteq L \subseteq K$,*

$$\operatorname{trdeg}_F K = \operatorname{trdeg}_F L + \operatorname{trdeg}_L K.$$

Idea. Call α *dependent* on a set T if α is algebraic over $F(T)$. The Steinitz exchange axiom says: if α is dependent on $T \cup \{ \beta \}$ but not on T, then β is dependent on $T \cup \{ \alpha \}$ – this follows by clearing denominators in the polynomial relation witnessing the dependence and solving for β, which now appears to positive degree. Exchange forces all maximal independent sets to be equinumerous by the usual replacement argument (replace the elements of one basis one at a time by elements of another). Additivity in towers: concatenate a transcendence basis S of L/F with a transcendence basis T of K/L. The union is algebraically independent over F: a relation $g(S, T) = 0$ with g over F, read as a polynomial in the elements of T with coefficients in $F[S] \subseteq L$, has all these coefficients equal to 0 because T is independent over L, and then each coefficient is the zero polynomial because S is independent over F. Maximality follows from transitivity of "algebraic over": K is algebraic over $L(T)$, which is algebraic over $F(S \cup T)$ because L is algebraic over $F(S)$. □

Method (To find a transcendence basis and compute the transcendence degree, greedily select elements that are transcendental over the field generated by those already chosen; stop when every remaining generator is algebraic over the selection. The size of the selection is the transcendence degree, and K is then algebraic over the purely transcendental field F(selection).)**.**

Worked Example 14.9.3 (Transcendence degree of a rational function field)**.** Show $\operatorname{trdeg}_F F(x, y) = 2$, where x, y are independent transcendentals.

Recognition. By definition x, y independent means no nonzero $g \in F[X, Y]$ has $g(x, y) = 0$; this is exactly the statement that $\{ x, y \}$ is algebraically independent, and it is maximal because $F(x, y)$ is algebraic over itself.

Solution. The set $\{ x, y \}$ is algebraically independent over F by hypothesis, so $\operatorname{trdeg}_F F(x, y) \geq 2$. It is maximal: any third element $z \in F(x, y)$ is a rational function $z = p(x, y)/q(x, y)$, hence satisfies $q(x, y)\, z - p(x, y) = 0$, a nonzero polynomial relation among x, y, z over F. So $\{ x, y \}$ is a transcendence basis and $\operatorname{trdeg}_F F(x, y) = 2$. Sanity check: additivity gives $\operatorname{trdeg}_F F(x, y) = \operatorname{trdeg}_F F(x) + \operatorname{trdeg}_{F(x)} F(x)(y) = 1 + 1 = 2$, since y is transcendental over $F(x)$.

Worked Example 14.9.4 (A dependent set and a transcendence basis inside $F(x)$)**.** Show $\{ x^2, x^3 \}$ is *not* algebraically independent over F, while $\{ x \}$ is a transcendence basis of $F(x)/F$.

Recognition. Algebraic independence of $\{ a, b \}$ fails as soon as one nonzero $g \in F[X, Y]$ kills (a, b); here a single relation between x^2 and x^3 is visible.

Solution. Put $a = x^2,\ b = x^3$. Then $a^3 = x^6 = b^2$, so $g(X,Y) = X^3 - Y^2$ is a nonzero polynomial with $g(a,b) = 0$. Hence $\{ x^2, x^3 \}$ is algebraically *dependent*; its transcendence degree is only 1 (both lie in $F(x)$, which has transcendence degree 1). On the other hand $\{ x \}$ is algebraically independent (a single transcendental) and maximal, because every element of $F(x)$ is algebraic – indeed rational – over $F(x)$. So $\operatorname{trdeg}_F F(x) = 1$. Sanity check: $F(x^2, x^3) = F(x)$ since $x = x^3/x^2$, so adjoining the dependent pair recovers the whole field, confirming both generate a transcendence-degree-1 extension, not 2.

Worked Example 14.9.5 (Transcendence degree is insensitive to algebraic extensions)**.** Let $K = F(x,y)$ and let $L = K(\sqrt{x}) = F(\sqrt{x}, y)$. Compute $\operatorname{trdeg}_F L$.

Recognition. Adjoining an algebraic element changes the algebraic part of an extension but not its transcendence degree, by additivity in the tower $F \subseteq K \subseteq L$ with $\operatorname{trdeg}_K L = 0$.

Solution. Let $u = \sqrt{x}$, so $u^2 = x$ and u is algebraic over K. Then $L = K(u)$ is algebraic over K, giving $\operatorname{trdeg}_K L = 0$. By additivity $\operatorname{trdeg}_F L = \operatorname{trdeg}_F K + \operatorname{trdeg}_K L = 2 + 0 = 2$. A transcendence basis is $\{ u, y \}$: indeed $x = u^2 \in F(u,y)$ and $L = F(u,y)$ is purely transcendental of degree 2 in u, y. Sanity check: $\{ x, y \}$ and $\{ u, y \}$ are both transcendence bases of L, each of size 2, consistent with well-definedness; the only change is that $L/F(u,y)$ is trivial whereas $L/F(x,y)$ is algebraic of degree 2.

Worked Example 14.9.6 (An elliptic relation: a non-purely-transcendental extension)**.** Show $\mathbb{Q}\big(k, \sqrt{k^3 - k}\big)$ has transcendence degree 1 over $\mathbb{Q}$ but is not purely transcendental.

Recognition. Transcendence degree is computed by a greedy basis; pure transcendentality is a finer property that can fail even at degree 1, detected by an irreducible relation of the wrong shape (an elliptic curve has genus 1, not 0).

Solution. Let $y = \sqrt{k^3 - k}$, so $y^2 = k^3 - k$ with k transcendental over $\mathbb{Q}$. Then $\{ k \}$ is a transcendence basis: y is algebraic of degree 2 over $\mathbb{Q}(k)$, so $\operatorname{trdeg}_{\mathbb{Q}} \mathbb{Q}(k,y) = 1$. It is not purely transcendental: a purely transcendental degree-1 field is $\mathbb{Q}(z)$, a rational function field, whose associated curve has genus 0, whereas $y^2 = k^3 - k$ defines a smooth cubic (an elliptic curve) of genus 1; a field of genus 1 cannot equal one of genus 0. Concretely, no rational parametrization $k = \phi(z),\ y = \psi(z)$ with ϕ nonconstant exists: it would identify $\mathbb{Q}(k,y)$ with a subfield of $\mathbb{Q}(z)$ strictly containing $\mathbb{Q}$, and by Lüroth's theorem every such subfield is again a rational function field $\mathbb{Q}(w)$, of genus 0. The obstruction is the genus, not a lack of rational points: the curve contains $(0,0)$, $(\pm 1, 0)$ and the rational point $[0:1:0]$ at infinity. Sanity check: contrast with $y^2 = k^2 - k$, which factors via $y = k\sqrt{1 - 1/k}$ – a conic, genus 0, which *is* rational; the cubic's nonzero discriminant $\operatorname{disc}(k^3 - k) = -4(-1)^3 = 4 \neq 0$ confirms $y^2 = k^3 - k$ is genuinely elliptic, not a degenerate conic.

Separating transcendence bases

In characteristic p a purely transcendental field can still hide inseparability one layer up. The right notion is a transcendence basis over which the remaining extension is separable.

Definition 14.9.7. A transcendence basis S of K/F is a *separating transcendence basis* if K is a (finite) separable algebraic extension of $F(S)$. When such a basis exists, K/F is called *separably generated*.

Over a perfect field every finitely generated extension has a separating transcendence basis, but over an imperfect field this can fail spectacularly.

Worked Example 14.9.8 (A separating transcendence basis exists)**.** Let $K = \mathbb{F}_p(t)(\alpha)$ where $\alpha^2 - \alpha - t = 0$ and p is odd. Exhibit a separating transcendence basis.

Recognition. An Artin–Schreier-type relation $\alpha^2 - \alpha - t = 0$ is separable when its derivative in α is nonzero; we look for a transcendental base leaving a separable residual extension.

Solution. Here $\{ t \}$ is a transcendence basis and α is algebraic over $\mathbb{F}_p(t)$ with minimal polynomial $f(x) = x^2 - x - t$. Its derivative $f'(x) = 2x - 1$ is nonzero (p odd), and $\gcd(f, f') = 1$, so f is separable and $K/\mathbb{F}_p(t)$ is separable. Thus $\{ t \}$ is a separating transcendence basis. Sanity check: alternatively take $\{ \alpha \}$ as the basis – then $t = \alpha^2 - \alpha \in \mathbb{F}_p(\alpha)$ so $K = \mathbb{F}_p(\alpha)$ is purely transcendental in α, hence trivially separable over $\mathbb{F}_p(\alpha)$; either basis separates.

Worked Example 14.9.9 (No separating transcendence base: infinitely many p-power roots)**.** Let $K = \bigcup_{k\ge 0} \mathbb{F}_p\big(t^{1/p^k}\big)$, the field obtained from $\mathbb{F}_p(t)$ by adjoining all p-power roots of t. Show $\operatorname{trdeg}_{\mathbb{F}_p} K = 1$ but $K/\overline{\mathbb{F}}_p$ has no separating transcendence base.

Recognition. Transcendence degree counts independent transcendentals; a separating base would make K separable over a rational function field, but every element here has a p-th root in K, an obstruction to separability.

Solution. Each t^{1/p^k} is transcendental over $\mathbb{F}_p$, and any two of them are algebraically dependent ($t^{1/p^k} = (t^{1/p^{k+1}})^p$), so $\operatorname{trdeg}_{\mathbb{F}_p} K = 1$; e.g. $\{\, t \,\}$ is a transcendence basis. Suppose $\{\, u \,\}$ were a separating transcendence base, so $K/\mathbb{F}_p(u)$ is separable algebraic. Every element of K is a p-th power in K: if $a = r(t^{1/p^k})$ with $r \in \mathbb{F}_p(X)$, then $a = \big(r(t^{1/p^{k+1}})\big)^p$, since the Frobenius fixes the coefficients of r. In particular $v = u^{1/p} \in K$. But v is a root of $x^p - u = (x - v)^p$, which is irreducible over $\mathbb{F}_p(u)$ because the transcendental u is not a p-th power in $\mathbb{F}_p(u)$; so v is inseparable over $\mathbb{F}_p(u)$, a contradiction. Hence no separating base exists. Sanity check: K being closed under p-th roots means $K = K^{1/p}$, the exact failure of separable generation; this matches that K is not finitely generated over $\mathbb{F}_p$, the hypothesis under which separating bases are guaranteed over perfect fields.

Separable and inseparable degree

We now isolate, for a finite extension K/F, the two competing contributions to its degree: how many distinct embeddings it admits, and the unavoidable repetition forced by characteristic p.

Definition 14.9.10. Let K/F be finite and fix an algebraic closure $\overline{F} \supseteq K$. The *separable degree* $[K : F]_s$ is the number of F-embeddings $K \hookrightarrow \overline{F}$. The *inseparable degree* is the quotient $[K : F]_i = [K : F]/[K : F]_s$.

Theorem 14.9.11 (multiplicativity and the degree factorization)**.** *For finite extensions $F \subseteq L \subseteq K$:*

$$[K : F]_s = [K : L]_s\,[L : F]_s, \qquad [K : F] = [K : F]_s\,[K : F]_i,$$

and $[K : F]_i$ is always a power of $p = \operatorname{char} F$ (and $= 1$ in characteristic 0). The extension K/F is separable *iff $[K : F]_s = [K : F]$, equivalently $[K : F]_i = 1$.*

Idea. For a simple extension $F(\alpha)/F$ with minimal polynomial m_α, the F-embeddings into $\overline{F}$ are in bijection with the *distinct* roots of m_α, so $[F(\alpha) : F]_s$ counts distinct roots while $[F(\alpha) : F] = \deg m_\alpha$ counts roots with multiplicity. In characteristic p, $m_\alpha(x) = g(x^{p^e})$ for a separable g, and every root has the same multiplicity p^e, so $[F(\alpha) : F]_i = p^e$. Multiplicativity of $[\cdot : \cdot]_s$ comes from extending embeddings step by step through a tower (each of the $[L : F]_s$ embeddings of L extends in exactly $[K : L]_s$ ways to K). Dividing the multiplicative relation for ordinary degree by that for separable degree gives multiplicativity of the inseparable degree, hence $[K : F]_i$ is a product of prime-power local inseparable degrees, a power of p. □

Worked Example 14.9.12 (Separable degree equals degree for a separable extension)**.** Compute $[\mathbb{Q}(\sqrt[3]{2}, \omega) : \mathbb{Q}]_s$, where $\omega = e^{2\pi i/3}$.

Recognition. In characteristic 0 every extension is separable, so $[K : F]_s = [K : F]$ and $[K : F]_i = 1$; we only need the ordinary degree.

Solution. $K = \mathbb{Q}(\sqrt[3]{2}, \omega)$ is the splitting field of $x^3 - 2$, with $[K : \mathbb{Q}] = 6$. Since $\operatorname{char} \mathbb{Q} = 0$, $K/\mathbb{Q}$ is separable, so $[K : \mathbb{Q}]_s = 6$ and $[K : \mathbb{Q}]_i = 1$. Sanity check: $K/\mathbb{Q}$ is Galois with $\operatorname{Gal}(K/\mathbb{Q}) \cong S_3$ of order 6, and the number of $\mathbb{Q}$-embeddings of a Galois extension into $\overline{\mathbb{Q}}$ equals $|\operatorname{Gal}(K/\mathbb{Q})| = 6 = [K : \mathbb{Q}]_s$, exactly as the separable degree should.

Worked Example 14.9.13 (A mixed example: computing $[K : F]_s$ and $[K : F]_i$)**.** Let p be a prime, $F = \mathbb{F}_p(s, t)$ with s, t independent transcendentals, and $K = F(\alpha, \beta)$ where $\alpha^p = s$ and $\beta^2 - \beta - t = 0$ (take p odd). Find $[K : F]$, $[K : F]_s$, $[K : F]_i$.

Recognition. Factor through the tower $F \subseteq F(\alpha) \subseteq K$. The first step $x^p - s$ is purely inseparable (one repeated root), contributing to $[\cdot : \cdot]_i$; the second step $x^2 - x - t$ is separable, contributing to $[\cdot : \cdot]_s$.

Solution. Step one: $x^p - s$ is irreducible over F (Eisenstein at the prime s in $\mathbb{F}_p[s][t]$-localized, or since s is not a p-th power in F) and equals $(x - \alpha)^p$ over $\overline{F}$, so $[F(\alpha) : F] = p$ with a single root: $[F(\alpha) : F]_s = 1$,

$[F(\alpha):F]_i = p$. Step two: $x^2 - x - t$ has derivative $2x - 1 \neq 0$, hence is separable of degree 2 over $F(\alpha)$: $[K:F(\alpha)] = [K:F(\alpha)]_s = 2$, $[K:F(\alpha)]_i = 1$. Multiplying: $[K:F] = p \cdot 2 = 2p$, $[K:F]_s = 1 \cdot 2 = 2$, $[K:F]_i = p \cdot 1 = p$. Sanity check: $[K:F]_s \cdot [K:F]_i = 2 \cdot p = 2p = [K:F]$, and $[K:F]_i = p$ is a power of p, both as required.

Worked Example 14.9.14 (Separable and inseparable degree each equal p)**.** Let $K = \mathbb{F}_p(x, y)$ with x, y independent transcendentals and $F = \mathbb{F}_p(x^p - x,\ y^p - x)$. Show $[K:F] = p^2$ with $[K:F]_s = [K:F]_i = p$.

Recognition. Write $s = x^p - x$ and $t = y^p - x$. Then x is a root of a separable polynomial over F, while y is a p-th root, the inseparable layer; build the tower so each layer's type is visible.

Solution. Over $F = \mathbb{F}_p(s, t)$, the element x satisfies $x^p - x - s = 0$, an Artin–Schreier polynomial: separable (derivative $px^{p-1} - 1 = -1 \neq 0$) and irreducible of degree p, so $[F(x):F] = [F(x):F]_s = p$ with $[F(x):F]_i = 1$. Now over $F(x)$ we have $y^p = t + x$, i.e. y is a root of $z^p - (t + x) = (z - y)^p$: purely inseparable of degree p, so $[K:F(x)] = [K:F(x)]_i = p$, $[K:F(x)]_s = 1$. Hence $[K:F] = p \cdot p = p^2$, $[K:F]_s = p \cdot 1 = p$, $[K:F]_i = 1 \cdot p = p$. Sanity check: $[K:F]_s\,[K:F]_i = p \cdot p = p^2 = [K:F]$; and $s - t = (x^p - x) - (y^p - x) = x^p - y^p = (x - y)^p \in F$, so $E = F(x - y)$ is a p-th root extension realizing the purely inseparable degree-p piece, consistent with $[K:F]_i = p$.

Purely inseparable extensions and perfect fields

The extreme opposite of separable is the case where K admits only one embedding – the inclusion itself.

Definition 14.9.15. An algebraic extension K/F of characteristic p is *purely inseparable* if every $\alpha \in K$ has $\alpha^{p^k} \in F$ for some $k \geq 0$; equivalently the minimal polynomial of each α over F has the form $x^{p^k} - a$. Then $[K:F]_s = 1$, so K/F admits only the identity embedding and $\mathrm{Aut}(K/F) = 1$.

Proposition 14.9.16 (purely inseparable means trivial separable degree)**.** *A finite extension K/F is purely inseparable iff $[K:F]_s = 1$, iff $[K:F] = [K:F]_i$. In that case $[K:F]$ is a power of p and $\mathrm{Aut}(K/F) = \{\,\mathrm{id}\,\}$.*

Idea. If $\alpha^{p^k} = a \in F$ then $m_\alpha \mid x^{p^k} - a = (x - \alpha)^{p^k}$, so α is the only root: one embedding. Conversely if $[K:F]_s = 1$ each generator has a single root in $\overline{F}$, forcing minimal polynomials of the shape $(x - \alpha)^{p^k}$, i.e. $x^{p^k} - \alpha^{p^k}$ with $\alpha^{p^k} \in F$. Finally, every $\sigma \in \mathrm{Aut}(K/F)$, followed by the inclusion $K \subseteq \overline{F}$, is an F-embedding $K \hookrightarrow \overline{F}$; the inclusion is the only one, so $\sigma = \mathrm{id}$ and $\mathrm{Aut}(K/F) = 1$. □

Definition 14.9.17. A field F is *perfect* if every algebraic extension of F is separable. Characteristic 0 fields are perfect; a characteristic p field F is perfect iff the Frobenius $x \mapsto x^p$ is surjective, i.e. $F = F^p$. Finite fields and algebraically closed fields are perfect.

Worked Example 14.9.18 (The purely inseparable extension $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$ of degree p)**.** Show $K = \mathbb{F}_p(t^{1/p})$ is purely inseparable of degree p over $F = \mathbb{F}_p(t)$ with $\mathrm{Aut}(K/F) = 1$, even though K/F is normal.

Recognition. t is not a p-th power in $F = \mathbb{F}_p(t)$, so $x^p - t$ is irreducible; in characteristic p it factors as $(x - t^{1/p})^p$, the signature of pure inseparability.

Solution. Let $\theta = t^{1/p}$, so $\theta^p = t$. Over F, $x^p - t = (x - \theta)^p$ has θ as its only root, with multiplicity p. The polynomial is irreducible (Eisenstein at t in $\mathbb{F}_p[t]$), so $[K:F] = p$, $[K:F]_s = 1$, $[K:F]_i = p$: purely inseparable. Any $\sigma \in \mathrm{Aut}(K/F)$ must send θ to a root of $x^p - t$, but θ is the only root, so $\sigma(\theta) = \theta$ and $\sigma = \mathrm{id}$. Thus $\mathrm{Aut}(K/F) = 1$. Yet K/F *is* normal: K is the splitting field of $x^p - t$ (it splits completely, as $(x - \theta)^p$). Sanity check: $|\mathrm{Aut}(K/F)| = 1 \neq p = [K:F]$, so the would-be "Galois group" is too small – this is precisely why normal + inseparable is *not* Galois; the count $|\mathrm{Aut}(K/F)| = [K:F]$ holds only when K/F is also separable.

Caution. "Normal" does not imply "Galois." The extension $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$ is normal (it is a splitting field) but $|\mathrm{Aut}(K/F)| = 1 < p = [K:F]$. Galois requires normal *and separable*; equivalently $|\mathrm{Aut}(K/F)| = [K:F]$, which forces $[K:F]_s = [K:F]$. Whenever an extension has nontrivial inseparable degree, its automorphism group is strictly too small to "see" the whole extension.

Worked Example 14.9.19 (A perfect field: $F = F^p$ for finite fields)**.** Verify that $\mathbb{F}_q$ ($q = p^n$) is perfect by checking Frobenius is surjective.

Recognition. A characteristic-p field is perfect iff $x \mapsto x^p$ is onto; on a finite field an injective endomorphism is automatically onto.

Solution. Frobenius $\phi : \mathbb{F}_q \to \mathbb{F}_q$, $\phi(a) = a^p$, is a field homomorphism, hence injective (its kernel is 0). An injective map from a finite set to itself is surjective, so ϕ is onto: $\mathbb{F}_q = \mathbb{F}_q^p$. Therefore $\mathbb{F}_q$ is perfect and every algebraic extension of $\mathbb{F}_q$ is separable. Sanity check: concretely in $\mathbb{F}_p$, $a^p = a$ for all a (Fermat), so $\phi = \mathrm{id}$ is trivially surjective; and there are no purely inseparable extensions of a finite field, consistent with $\overline{\mathbb{F}_p}/\mathbb{F}_p$ being separable.

Worked Example 14.9.20 (An imperfect field and its separable closure)**.** Show $F = \mathbb{F}_p(t)$ is not perfect, and describe the separable closure of F inside a purely inseparable extension.

Recognition. F imperfect means $F \neq F^p$: some element is not a p-th power. The separable closure F^{sep} of F in $\overline{F}$ collects all elements separable over F; purely inseparable elements lie outside it.

Solution. In $F = \mathbb{F}_p(t)$, the element t is not a p-th power: if $t = g(t)^p$ for $g \in F$, comparing degrees forces $1 = p \deg g$, impossible. So $F \neq F^p$ and F is imperfect. Inside $\overline{F}$, $F^{\mathrm{sep}} = \{\, \alpha \in \overline{F} : \alpha \text{ separable over } F \,\}$ is a field (the separable elements form a subfield), and $\overline{F}/F^{\mathrm{sep}}$ is purely inseparable. The element $t^{1/p}$ is *not* in F^{sep}: its minimal polynomial $x^p - t = (x - t^{1/p})^p$ is inseparable. Sanity check: $[F^{\mathrm{sep}} : F] = [\overline{F} : F]_s$ and $[\overline{F} : F^{\mathrm{sep}}] = [\overline{F} : F]_i$, factoring the closure into its separable-then-purely-inseparable layers; over the perfect field $\mathbb{F}_p$ this inseparable layer is trivial, matching the previous example.

Worked Example 14.9.21 (Every purely inseparable extension is normal)**.** Prove that a purely inseparable extension K/F is normal.

Recognition. Normal means every irreducible polynomial over F with a root in K splits in K. For purely inseparable K/F the minimal polynomials have the single-root form $(x - \alpha)^{p^k}$, which trivially splits once it has one root.

Solution. Let $\alpha \in K$ with minimal polynomial $m_\alpha \in F[x]$. By pure inseparability $\alpha^{p^k} = a \in F$ for some k, so $m_\alpha \mid x^{p^k} - a = (x - \alpha)^{p^k}$; being irreducible and monic, $m_\alpha = (x - \alpha)^{p^j}$ for some $j \leq k$. This polynomial splits completely in K (all roots equal $\alpha \in K$). Since every such m_α splits in K, the extension K/F is normal. Sanity check: this matches the example $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$, which we already saw is a splitting field (of $x^p - t$), hence normal – normality holds despite the trivial automorphism group.

The Krull topology and profinite Galois groups

For an *infinite* Galois extension K/F (algebraic, normal, separable) the naive Fundamental Theorem fails: there are more subgroups of $\mathrm{Gal}(K/F)$ than intermediate fields. The repair is topological. We topologize the group so that the correspondence sees only the *closed* subgroups.

Definition 14.9.22. Let K/F be Galois, possibly infinite. The *Krull topology* on $G = \mathrm{Gal}(K/F)$ has, as a base of open neighborhoods of id, the subgroups $\mathrm{Gal}(K/E)$ where E/F ranges over the finite Galois subextensions $F \subseteq E \subseteq K$. These subgroups are normal of finite index, and G becomes a Hausdorff, compact, totally disconnected topological group.

Theorem 14.9.23 ($\mathrm{Gal}(K/F)$ is profinite)**.** *For K/F Galois, $\mathrm{Gal}(K/F)$ is the inverse limit of the finite Galois groups of its finite subextensions:*

$$\mathrm{Gal}(K/F) \;\cong\; \varprojlim_{E} \mathrm{Gal}(E/F),$$

the limit taken over finite Galois E/F inside K, with transition maps the restriction homomorphisms $\mathrm{Gal}(E'/F) \twoheadrightarrow \mathrm{Gal}(E/F)$ for $E \subseteq E'$. The Krull topology coincides with the inverse-limit (subspace of product) topology, making G a profinite group*: compact, Hausdorff, totally disconnected.*

Idea. An automorphism $\sigma \in \mathrm{Gal}(K/F)$ is determined by its restrictions $\sigma|_E$ to all finite Galois E/F, and these restrictions are compatible: $(\sigma|_{E'})|_E = \sigma|_E$ for $E \subseteq E'$. This is exactly the data of an element of the

inverse limit, giving an injective homomorphism $\sigma \mapsto (\sigma|_E)_E$. It is surjective because a compatible system glues to a well-defined automorphism of $K = \bigcup_E E$. The product $\prod_E \mathrm{Gal}(E/F)$ of finite (discrete) groups is compact by Tychonoff; the inverse limit is a closed subset, hence compact, and the subspace topology is the Krull topology. □

Method (To analyze an infinite Galois group, do *not* list elements – write it as an inverse limit of the manageable finite quotients $\mathrm{Gal}(E/F)$ and read off its structure (and its closed subgroups) from the finite layers.)**.**

Theorem 14.9.24 (Fundamental Theorem for infinite Galois extensions)**.** *Let K/F be Galois with group $G = \mathrm{Gal}(K/F)$ carrying the Krull topology. Then*

$$\{\ \textit{closed subgroups } H \le G\ \} \ \xleftrightarrow{\ \mathrm{Fix}\ }\ \{\ \textit{intermediate fields } F \le E \le K\ \}$$

is an inclusion-reversing bijection, $H \mapsto \mathrm{Fix}(H)$ and $E \mapsto \mathrm{Gal}(K/E)$. Under it:

(1) open *subgroups correspond to* finite-degree *subextensions E/F;*

(2) closed normal *subgroups correspond to Galois subextensions E/F, with* $\mathrm{Gal}(E/F) \cong G/\mathrm{Gal}(K/E)$.

Every open subgroup is closed of finite index, but not every (abstract) finite-index subgroup is open; the correspondence sees only closed subgroups.

Idea. The finite case applies to each finite Galois layer E/F; passing to the limit, $\mathrm{Gal}(K/E)$ is closed (the intersection, over all $\alpha \in E$, of the open subgroups $\mathrm{Gal}(K/F(\alpha))$; E/F need not be finitely generated). Closedness of H is exactly the condition $H = \mathrm{Gal}(K/\mathrm{Fix}(H))$, i.e. that no extra automorphisms "approximate" H in the Krull topology. For closed H: open $\iff$ finite index $\iff$ contains some $\mathrm{Gal}(K/E)$ with E/F finite, which translates to $\mathrm{Fix}(H)/F$ finite. Normality and the quotient identification descend from the finite layers. □

Worked Example 14.9.25 (The absolute Galois group of a finite field is $\widehat{\mathbb{Z}}$)**.** Identify $\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$ as a profinite group and locate the Frobenius.

Recognition. $\overline{\mathbb{F}_p} = \bigcup_n \mathbb{F}_{p^n}$ with each $\mathbb{F}_{p^n}/\mathbb{F}_p$ finite Galois cyclic of order n; the absolute group is the inverse limit of these $\mathbb{Z}/n\mathbb{Z}$ under restriction, which is $\widehat{\mathbb{Z}} = \varprojlim \mathbb{Z}/n\mathbb{Z}$.

Solution. The finite Galois subextensions of $\overline{\mathbb{F}_p}/\mathbb{F}_p$ are the $\mathbb{F}_{p^n}$, with $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) \cong \mathbb{Z}/n\mathbb{Z}$ generated by the Frobenius $\mathrm{Frob}_p : x \mapsto x^p$. For $n \mid m$, restriction $\mathrm{Gal}(\mathbb{F}_{p^m}/\mathbb{F}_p) \to \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)$ is the natural surjection $\mathbb{Z}/m\mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ sending Frobenius to Frobenius. Hence

$$\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p) \ \cong\ \varprojlim_n \mathbb{Z}/n\mathbb{Z} \ =\ \widehat{\mathbb{Z}},$$

topologically generated by $\mathrm{Frob}_p = (\,1 \bmod n\,)_n$: the closure of $\langle \mathrm{Frob}_p \rangle$ is all of $\widehat{\mathbb{Z}}$. The inverse system of restriction maps is:

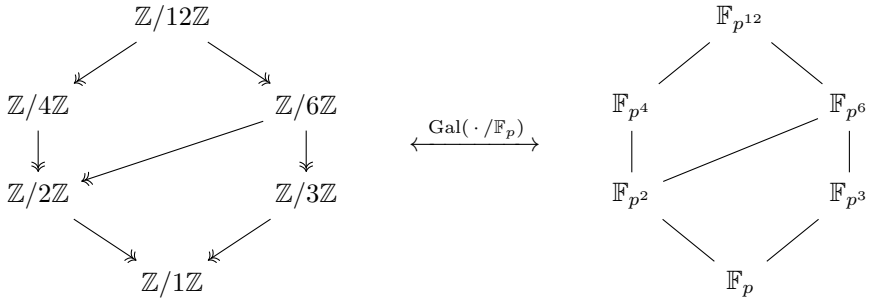


Diagram explanation. Objects: The left diagram contains finite cyclic groups $\mathbb{Z}/n\mathbb{Z}$ for various n (here $n \in \{1, 2, 3, 4, 6, 12\}$), each of which is the Galois group $\mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)$ of a finite subextension; each node is a finite group, a quotient of $\widehat{\mathbb{Z}}$. The right diagram contains finite fields $\mathbb{F}_{p^n}$ arranged by inclusion; each node is a finite field extension of $\mathbb{F}_p$ of degree n. The two lattices are placed in bijective correspondence by the Galois pairing: groups on the left, fields on the right.

Arrows: Left side: every arrow $\mathbb{Z}/m\mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ (when $n \mid m$) is the restriction homomorphism $\mathrm{Gal}(\mathbb{F}_{p^m}/\mathbb{F}_p) \to \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)$, concretely the reduction map sending $[k \bmod m] \mapsto [k \bmod n]$; it is surjective (indicated by the double-headed arrow). Right side: each dash-arrow $\mathbb{F}_{p^n} \to \mathbb{F}_{p^m}$ (when $n \mid m$) is the unique field inclusion $\mathbb{F}_{p^n} \hookrightarrow \mathbb{F}_{p^m}$; these are the transition maps going in the opposite direction from the group maps. The horizontal double-arrow $\xleftrightarrow{\mathrm{Gal}(\,\cdot\,/\mathbb{F}_p)}$ records that the two lattices are matched node by node by $\mathbb{F}_{p^n} \mapsto \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) \cong \widehat{\mathbb{Z}}/n\widehat{\mathbb{Z}}$. This is not the Galois correspondence itself: $H \mapsto \mathrm{Fix}(H)$, $E \mapsto \mathrm{Gal}(\overline{\mathbb{F}_p}/E)$ pairs $\mathbb{F}_{p^n}$ with the closed subgroup $n\widehat{\mathbb{Z}} = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_{p^n})$, the kernel of $\widehat{\mathbb{Z}} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$.

What commutes: The diagram encodes compatibility of restrictions: for $n \mid m \mid r$, the composite restriction $\mathbb{Z}/r\mathbb{Z} \twoheadrightarrow \mathbb{Z}/m\mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ equals the direct restriction $\mathbb{Z}/r\mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$, i.e. reduction mod r then mod m then mod n equals reduction mod r then mod n directly, because $n \mid m \mid r$ makes $k \bmod n = (k \bmod m) \bmod n$. This is the inverse-system compatibility condition whose limit defines $\widehat{\mathbb{Z}}$.

Why it commutes: Chase a generator: the Frobenius Frob_p corresponds to 1 in each $\mathbb{Z}/n\mathbb{Z}$. Along the path $\mathbb{Z}/12\mathbb{Z} \twoheadrightarrow \mathbb{Z}/4\mathbb{Z} \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$, the element $1 \in \mathbb{Z}/12\mathbb{Z}$ maps to $1 \in \mathbb{Z}/4\mathbb{Z}$ then to $1 \in \mathbb{Z}/2\mathbb{Z}$. Along the direct path $\mathbb{Z}/12\mathbb{Z} \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$, 1 maps to $1 \in \mathbb{Z}/2\mathbb{Z}$ immediately. Both give $1 \in \mathbb{Z}/2\mathbb{Z}$ because $1 \bmod 4 = 1$ and $1 \bmod 2 = 1$; reduction is transitive. The right-hand inclusion lattice commutes for the dual reason: $\mathbb{F}_{p^2} \subseteq \mathbb{F}_{p^4} \subseteq \mathbb{F}_{p^{12}}$ and $\mathbb{F}_{p^2} \subseteq \mathbb{F}_{p^{12}}$ are the same inclusion.

Why this matters here: This diagram is the key visual for why $\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p) \cong \widehat{\mathbb{Z}}$: it shows that the entire absolute Galois group is completely controlled by the finite pieces $\mathbb{Z}/n\mathbb{Z}$ and their compatible restriction maps. An element of $\widehat{\mathbb{Z}}$ is precisely a compatible system of residues $(a_n \in \mathbb{Z}/n\mathbb{Z})_n$ with $a_n \equiv a_m \pmod{n}$ for $n \mid m$, which is exactly what Frobenius gives: $a_n = 1 \bmod n$ for all n. The paired lattice also makes the Fundamental Theorem for $\overline{\mathbb{F}_p}/\mathbb{F}_p$ visible in one picture: larger quotients $\mathbb{Z}/n\mathbb{Z}$ on the left sit beside larger fields $\mathbb{F}_{p^n}$ on the right, while the closed subgroups $n\widehat{\mathbb{Z}}$ fixing these fields get smaller (fewer automorphisms fix more elements).

Concrete example: Take $n = 2$, $m = 6$: $\mathbb{Z}/6\mathbb{Z} \twoheadrightarrow \mathbb{Z}/2\mathbb{Z}$ sends $[1] \mapsto [1]$, $[2] \mapsto [0]$, $[3] \mapsto [1]$, etc. (reduce mod 2), and the corresponding field inclusion is $\mathbb{F}_{p^2} \hookrightarrow \mathbb{F}_{p^6}$. The Frobenius $\mathrm{Frob}_p \in \mathrm{Gal}(\mathbb{F}_{p^6}/\mathbb{F}_p) \cong \mathbb{Z}/6\mathbb{Z}$ restricts to $\mathrm{Frob}_p \in \mathrm{Gal}(\mathbb{F}_{p^2}/\mathbb{F}_p) \cong \mathbb{Z}/2\mathbb{Z}$: the p-th power map on $\mathbb{F}_{p^6}$ restricts to the p-th power map on the subfield $\mathbb{F}_{p^2}$, and $[1 \bmod 6]$ maps to $[1 \bmod 2]$, consistently.

Common pitfall: Students often read the arrows as going in the same direction on both sides. They do not: group restriction maps $\mathbb{Z}/m\mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ go from larger group to smaller (decreasing $m \to n$ with $n \mid m$), while field inclusions go from smaller field to larger ($\mathbb{F}_{p^n} \hookrightarrow \mathbb{F}_{p^m}$). This reversal is the inclusion-reversing nature of the Galois correspondence; missing it leads to thinking $\mathbb{F}_{p^{12}}$ is "killed" by the largest group, when in fact $\mathbb{F}_{p^{12}}$ is *fixed* by the smallest group $\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_{p^{12}})$. Also: $\widehat{\mathbb{Z}}$ itself does not appear as a node in the left lattice – the lattice only shows the finite quotients; $\widehat{\mathbb{Z}}$ is the limit of the whole diagram, not a single term.

Takeaway: The point of this diagram is that the infinite profinite group $\widehat{\mathbb{Z}} = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$ is completely and faithfully encoded by the finite data on the left – the lattice of cyclic groups $\mathbb{Z}/n\mathbb{Z}$ connected by surjective reduction maps – which is paired arrow-by-arrow with the lattice of finite fields on the right by $\mathbb{F}_{p^n} \mapsto \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p)$.

On the left the maps $\mathbb{Z}/m\mathbb{Z} \twoheadrightarrow \mathbb{Z}/n\mathbb{Z}$ (for $n \mid m$) are reduction-of-residues; the limit over *all* n is $\widehat{\mathbb{Z}} \cong \prod_\ell \mathbb{Z}_\ell$. On the right, larger fields sit higher: $\mathbb{F}_{p^n} = \mathrm{Fix}\big(\overline{\langle \mathrm{Frob}_p^{\,n} \rangle}\big)$, the closed subgroup $n\widehat{\mathbb{Z}}$. Sanity check: $\widehat{\mathbb{Z}}$ is uncountable and compact, whereas $\langle \mathrm{Frob}_p \rangle \cong \mathbb{Z}$ is countable – so Frobenius generates $\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$ only *topologically* (its closure is everything), never as an abstract group; this is exactly the gap between abstract and closed subgroups that the Krull topology fixes.

Worked Example 14.9.26 (An open subgroup and its finite subextension)**.** In $G = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p) = \widehat{\mathbb{Z}}$, identify the open subgroup corresponding to $\mathbb{F}_{p^n}$ and its index.

Recognition. Open subgroups $\leftrightarrow$ finite-degree subextensions; the subgroup fixing $\mathbb{F}_{p^n}$ is $\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_{p^n})$, the closed (and open) subgroup $n\widehat{\mathbb{Z}} \leq \widehat{\mathbb{Z}}$.

Solution. The intermediate field $\mathbb{F}_{p^n}$ has $[\mathbb{F}_{p^n} : \mathbb{F}_p] = n < \infty$, so it corresponds to an open subgroup $H = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_{p^n})$. As a subgroup of $\widehat{\mathbb{Z}}$ this is $n\widehat{\mathbb{Z}} = \overline{\langle \mathrm{Frob}_p^n \rangle}$, with $[\widehat{\mathbb{Z}} : n\widehat{\mathbb{Z}}] = n$. Indeed $H \cong \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_{p^n}) \cong \widehat{\mathbb{Z}}$ again (generated by $\mathrm{Frob}_{p^n} = \mathrm{Frob}_p^n$), since $\overline{\mathbb{F}_p}/\mathbb{F}_{p^n}$ has the same shape. Sanity check: the index n equals $[\mathbb{F}_{p^n} : \mathbb{F}_p] = |G/H|$, matching that $G/H \cong \mathrm{Gal}(\mathbb{F}_{p^n}/\mathbb{F}_p) \cong \mathbb{Z}/n\mathbb{Z}$ – the open subgroup has finite index exactly equal to the finite degree it fixes.

Worked Example 14.9.27 (A closed-but-not-open subgroup)**.** Exhibit in $\widehat{\mathbb{Z}} = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$ a closed subgroup of infinite index, and name its fixed field.

Recognition. Closed subgroups $\leftrightarrow$ all intermediate fields; an infinite-index closed subgroup fixes an *infinite*-degree subextension. The ℓ-part of $\widehat{\mathbb{Z}}$ gives one.

Solution. Fix a prime ℓ and let $H = \prod_{q \neq \ell} \mathbb{Z}_q \leq \widehat{\mathbb{Z}} = \prod_q \mathbb{Z}_q$ (drop the ℓ-component). Then H is closed (a product of closed factors), and $[\widehat{\mathbb{Z}} : H]$ is infinite (the quotient is $\mathbb{Z}_\ell$, infinite). Its fixed field $\mathrm{Fix}(H) = \bigcup_k \mathbb{F}_{p^{\ell^k}}$ is the union of all $\mathbb{F}_{p^{\ell^k}}$, an infinite algebraic extension of $\mathbb{F}_p$ with $\mathrm{Gal} \cong \mathbb{Z}_\ell$. This H is *not* open: open subgroups have finite index. Sanity check: $\mathrm{Fix}(H)/\mathbb{F}_p$ being infinite matches H being closed but not open (item (1) of the Fundamental Theorem); and $\widehat{\mathbb{Z}}/H \cong \mathbb{Z}_\ell$ is itself profinite, consistent with $\mathrm{Fix}(H)/\mathbb{F}_p$ being Galois with group $\mathbb{Z}_\ell$.

Worked Example 14.9.28 (The motivating open problem: $\mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$)**.** Frame the absolute Galois group of $\mathbb{Q}$ as an inverse limit and state why it is hard.

Recognition. Every finite Galois $E/\mathbb{Q}$ gives a finite quotient $\mathrm{Gal}(E/\mathbb{Q})$; the absolute group is their inverse limit, but unlike the finite-field case the finite quotients are not all cyclic and are far from understood.

Solution. Set $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) = \varprojlim_E \mathrm{Gal}(E/\mathbb{Q})$ over finite Galois $E/\mathbb{Q}$, a profinite group under the Krull topology. By the Fundamental Theorem, closed subgroups of $G_{\mathbb{Q}}$ correspond to subfields of $\overline{\mathbb{Q}}$, and open subgroups to number fields (finite-degree $E/\mathbb{Q}$). Unlike $\widehat{\mathbb{Z}} = G_{\mathbb{F}_p}$, which is abelian and topologically cyclic, $G_{\mathbb{Q}}$ is highly nonabelian, and *which* finite groups arise as quotients $\mathrm{Gal}(E/\mathbb{Q})$ is the unsolved Inverse Galois Problem. Sanity check: the abelianization $G_{\mathbb{Q}}^{\mathrm{ab}} = \mathrm{Gal}(\mathbb{Q}^{\mathrm{ab}}/\mathbb{Q}) \cong \widehat{\mathbb{Z}}^\times$ is known (Kronecker–Weber: $\mathbb{Q}^{\mathrm{ab}} = \mathbb{Q}(\mu_\infty)$ is generated by all roots of unity), so even the *abelian* part already requires the full profinite machinery of this section – the nonabelian part remains open.

Exercises (from the text).

1. Prove that every purely inseparable extension is normal.
2. Let p be a prime and let $K = \mathbb{F}_p(x, y)$ with x and y independent transcendentals over $\mathbb{F}_p$. Let $F = \mathbb{F}_p(x^p - x, y^p - x)$.
   (a) Prove that $[K : F] = p^2$ and the separable degree and inseparable degree of K/F are each p.
   (b) Prove that there is a subfield E of K containing F which is purely inseparable over F of degree p (so then K is a separable extension of E of degree p). [Let $s = x^p - x$ and $t = y^p - x$ and consider $s - t$.]
3. Let p be an odd prime, let s and t be independent transcendentals over $\mathbb{F}_p$, and let F be the field $\mathbb{F}_p(s, t)$. Let β be a root of $x^2 - sx + t = 0$ and let α be a root of $x^p - \beta = 0$ (in some algebraic closure of F). Set $E = F(\beta)$ and $K = F(\alpha)$.
   (a) Prove that E is a Galois extension of F of degree 2 and that K is a purely inseparable extension of E of degree p.
   (b) Prove that K is not a normal extension of F. [If it were, conjugate β over F to show that K would contain a pth root of s and then also a pth root of t, so that $[K : F] \geq p^2$, a contradiction.]
   (c) Prove that there is no field K_0 such that $F \subseteq K_0 \subseteq K$ with K_0/F purely inseparable and K/K_0 separable. [If there were such a field, use Exercise 1 and the fact that the composite of two normal extensions is again normal to show that K would be a normal extension of F.]

4. Under the notation of the previous exercise prove that α, s is a separating transcendence base for K over $\mathbb{F}_p$.

5. Let p be a prime, let t be transcendental over $\mathbb{F}_p$ and let K be obtained by adjoining to $\mathbb{F}_p(t)$ all p-power roots of t. Prove that K has transcendence degree 1 over $\mathbb{F}_p$ and has no separating transcendence base.

6. Show that if k is transcendental over $\mathbb{Q}$ then $\mathbb{Q}(k, \sqrt{k^3 - k})$ is not a purely transcendental extension of $\mathbb{Q}$. (This is an example of what is called an *elliptic* function field.)

7. Let k be the field with 4 elements, t transcendental over k, $F = k(t^4 + t)$ and $K = k(t)$.

   (a) Show that $[K : F] = 4$.

   (b) Show that K is separable over F.

   (c) Show that K is Galois over F.

   (d) Describe the lattice of subgroups of the Galois group and the corresponding lattice of subfields of K, giving each subfield in the form $k(r)$, for some rational function r.

8. Let p be an odd prime, let k be an algebraically closed field of characteristic p and let t be transcendental over k. Suppose F is a degree 2 field extension of $k(t)$. Show that F can be written in the form $k(t, y)$, for some $y \in F$ with $y^2 \in k(t)$ and y transcendental over k. If $y^2 = 4t^3 - t - 1$, find $[F : k(y)]$ and determine if $k(t) \cap k(y)$ is the field k.

9. Let t be transcendental over $\mathbb{F}_3$, let $K = \mathbb{F}_3(t)$, let $G = \mathrm{Aut}(K/\mathbb{F}_3)$ and let F be the fixed field of G.

   (a) Prove $G \cong S_4$ and deduce that there is a unique field E with $F \subseteq E \subseteq K$ and $[E : F] = 2$. [Recall that $G \cong PGL_2(\mathbb{F}_3)$; show that $GL_2(\mathbb{F}_3)$ permutes the 4 lines in a 2-dimensional vector space over $\mathbb{F}_3$ and the kernel of this permutation representation is the scalar matrices.]

   (b) Complete the description of the lattice of subfields of K containing E:

   Give each subfield in the form $E(r)$ for some rational function r. (The lattice of subgroups of A_4 appears in Section 3.5).

10. Prove that a purely transcendental proper extension of a field is never algebraically closed.

11. Let S be a set of independent transcendentals over a field F and let Ω be an algebraic closure of $F(S)$. Prove that any permutation on S extends to an element of $\mathrm{Aut}(F(S)/F)$. Prove that any such automorphism of $F(S)$ extends to an automorphism of Ω. Deduce that $\mathbb{C}$ has infinitely many automorphisms.

12. Let K be a subfield of $\mathbb{C}$ maximal with respect to the property "$\sqrt{2} \notin K$."

   (a) Show such a field K exists.

(b) Show that $\mathbb{C}$ is algebraic over K.

(c) Prove that every finite extension of K in $\mathbb{C}$ is Galois with Galois group a cyclic 2-group.

(d) Deduce that $[\mathbb{C} : K]$ is countable (and not finite).

13. Let K be the fixed field in $\mathbb{C}$ of an automorphism of $\mathbb{C}$. Prove that every finite extension of K in $\mathbb{C}$ is cyclic.

14. Let K_n be the splitting field of $(x^2 - p_1)(x^2 - p_2)\cdots(x^2 - p_n)$ over $\mathbb{Q}$, where $p_1, \ldots, p_n$ are the first n primes. Prove that the Galois group of $K_n/\mathbb{Q}$ is an elementary abelian 2-group of order 2^n.

15. Let $K_0 = \mathbb{Q}$ and for $n \geq 0$ define the field K_{n+1} as the extension of K_n obtained by adjoining to K_n all roots of all cubic polynomials over K_n. Let K be the union of the subfields K_n, $n \geq 0$. Prove that K is a Galois extension of $\mathbb{Q}$. Prove that every cubic polynomial over K splits completely over K. Prove that there are nontrivial abelian extensions of K.

16. Let F be the composite of all the splitting fields of irreducible cubics over $\mathbb{Q}$. Prove that F does contain all quadratic extensions of $\mathbb{Q}$. [One way is to consider the polynomials $x^3 + 3ax + 2a$ for $a \in \mathbb{Z}^+$.]

17. Let $K_0 = \mathbb{Q}$ and for $n \geq 0$ define the field K_{n+1} as the extension of K_n obtained by adjoining to K_n all radicals of elements in K_n. Let K be the union of the subfields K_n, $n \geq 0$. Prove that K is a Galois extension of $\mathbb{Q}$. Prove that there are no nontrivial solvable Galois extensions of K. Prove that there are nontrivial Galois extensions of K.

18. Let $F_0 = \mathbb{Q}$ and for $n \geq 0$ define the field F_{n+1} as the extension of F_n obtained by adjoining to F_n all real radicals of elements in F_n. Let F be the union of the subfields F_n, $n \geq 0$. Let K^+ be the fixed field of complex conjugation restricted to the field K in the previous exercise (the maximal real subfield of K). Prove that $F \neq K^+$.

19. This exercise proves that if K/F is a Galois extension of fields, then $\mathrm{Gal}(K/F)$ is isomorphic to $\varprojlim \mathrm{Gal}(L/F)$, where the inverse limit is taken over all the finite Galois extensions L of F contained in K.

(a) Show that K is the union of the fields L.

(b) Prove that the map $\varphi : \mathrm{Gal}(K/F) \to \varprojlim \mathrm{Gal}(L/F)$ defined by mapping σ in $\mathrm{Gal}(K/F)$ to $(\ldots, \sigma|_L, \ldots)$, where $\sigma|_L$ is the restriction of σ to L, is a homomorphism.

(c) Prove that φ is injective.

(d) If $(\ldots, \sigma_L, \ldots) \in \varprojlim \mathrm{Gal}(L/F)$, define $\sigma \in \mathrm{Gal}(K/F)$ by $\sigma(\alpha) = \sigma_L(\alpha)$ if $\alpha \in L$. Prove that σ is a well defined automorphism and deduce that φ is surjective.

Practice problems.

1. Let x, y, z be independent transcendentals over a field F. For each of the following subsets of $F(x, y, z)$, decide whether it is algebraically independent over F and compute the transcendence degree of the subfield it generates: (a) $\{ x + y,\ x - y \}$; (b) $\{ x^2,\ xy,\ y^2 \}$; (c) $\{ x,\ y,\ xy + z \}$.

2. Let $K = F(x, y)$ with x, y independent transcendentals and let $L = F(x) \subseteq K$. Using additivity of transcendence degree in the tower $F \subseteq L \subseteq K$, compute $\mathrm{trdeg}_F K$, $\mathrm{trdeg}_F L$, and $\mathrm{trdeg}_L K$, and exhibit a transcendence basis of K/F that contains a transcendence basis of L/F.

3. Let p be a prime, $F = \mathbb{F}_p(t)$, and $K = F(\alpha)$ where $\alpha^p = t$. Compute $[K : F]$, $[K : F]_s$, and $[K : F]_i$, and write down the minimal polynomial of α over F together with its factorization in $\overline{F}[x]$.

4. Let p be an odd prime, $F = \mathbb{F}_p(s, t)$ with s, t independent transcendentals, and $K = F(\alpha, \beta)$ where $\alpha^p = s$ and $\beta^p = t$. Show $[K : F] = p^2$ and determine $[K : F]_s$ and $[K : F]_i$. Prove that K/F is purely inseparable and that $\mathrm{Aut}(K/F) = 1$.

5. Decide whether each extension is separable, purely inseparable, or neither, with justification: (a) $\mathbb{F}_p(t^{1/p})/\mathbb{F}_p(t)$; (b) $\mathbb{F}_p(t)(\alpha)/\mathbb{F}_p(t)$ where $\alpha^2 - \alpha - t = 0$ and p is odd; (c) $K = \mathbb{F}_p(t^{1/p}, u)$ over $F = \mathbb{F}_p(t, u)$, where u is a further transcendental, independent of t.

6. Show that the Frobenius endomorphism $\varphi\colon a \mapsto a^p$ of $F = \mathbb{F}_p(t)$ is injective but not surjective, exhibit an element of F not in the image F^p, and conclude that F is not a perfect field.

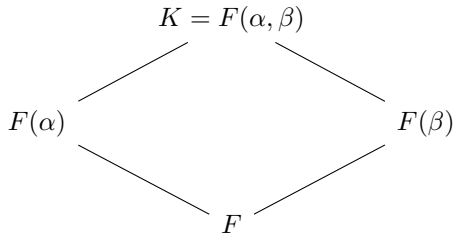
7. Let $G = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p) \cong \widehat{\mathbb{Z}}$ with topological generator the Frobenius $\mathrm{Frob}_p\colon x \mapsto x^p$. For $n = 12$, list all intermediate fields $\mathbb{F}_p \subseteq E \subseteq \mathbb{F}_{p^{12}}$, and for each give the corresponding subgroup of $\mathrm{Gal}(\mathbb{F}_{p^{12}}/\mathbb{F}_p) \cong \mathbb{Z}/12\mathbb{Z}$ as the subgroup generated by a power of Frob_p, so that E is its Fix. State which of these E are Galois over $\mathbb{F}_p$.

8. In $G = \widehat{\mathbb{Z}} = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$, decide for each subgroup whether it is open, closed-but-not-open, or neither, and name its fixed field when it is closed: (a) $n\widehat{\mathbb{Z}}$ for a fixed integer $n \geq 1$; (b) $\prod_{q \neq \ell} \mathbb{Z}_q$ for a fixed prime ℓ; (c) the abstract subgroup $\langle \mathrm{Frob}_p \rangle \cong \mathbb{Z}$ generated by Frobenius.

Additional exercises.

1. Let p be a prime, $F = \mathbb{F}_p(s,t)$, and let $K = F(x,y)$ where $x^p - x = s$ (Artin–Schreier) and $y^p = t + x$. Compute $[K:F]$, $[K:F]_s$, and $[K:F]_i$ by passing through the tower $F \subseteq F(x) \subseteq K$, identifying which step is separable and which is purely inseparable. Then exhibit an element $w \in K$ with $w^p \in F$ but $w \notin F$, and describe the maximal purely inseparable subextension of K/F.

2. Prove the multiplicativity of separable degree in a tower: for finite extensions $F \subseteq L \subseteq K$, show $[K:F]_s = [K:L]_s\,[L:F]_s$ by counting extensions of F-embeddings $L \hookrightarrow \overline{F}$ to F-embeddings $K \hookrightarrow \overline{F}$. Deduce that $[K:F]_i$ is multiplicative as well, and hence is always a power of $\mathrm{char}\, F$ when positive.

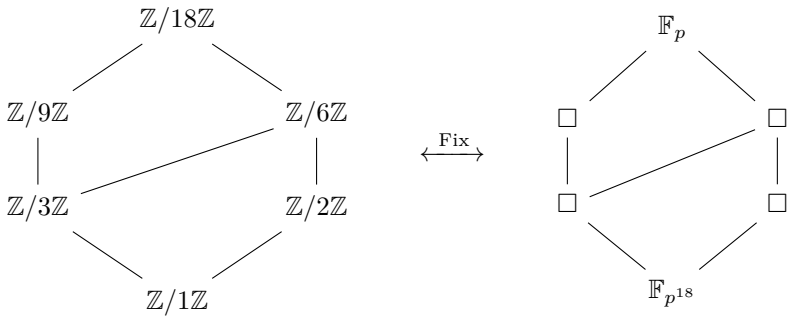


3. Let K/F be a finite extension in characteristic p. Let K_{sep} be the separable closure of F in K (the set of elements of K separable over F). Prove K_{sep} is a field with $F \subseteq K_{\mathrm{sep}} \subseteq K$, that $[K_{\mathrm{sep}} : F] = [K:F]_s$, and that K/K_{sep} is purely inseparable with $[K : K_{\mathrm{sep}}] = [K:F]_i$. Illustrate with $F = \mathbb{F}_p(s,t)$, $K = F(\alpha,\beta)$ where $\alpha^p - \alpha = s$ and $\beta^p = t$, by naming K_{sep} explicitly.

4. Let K/F be a (possibly infinite) Galois extension with $G = \mathrm{Gal}(K/F)$ under the Krull topology. Prove that for every intermediate field E with $F \subseteq E \subseteq K$ the subgroup $\mathrm{Gal}(K/E)$ is closed, and that $\mathrm{Fix}(\mathrm{Gal}(K/E)) = E$. Then exhibit, for $K = \overline{\mathbb{F}_p}$ over $F = \mathbb{F}_p$, an abstract subgroup of G that is *not* closed, and identify the closed subgroup it determines via $H \mapsto \mathrm{Gal}(K/\mathrm{Fix}(H))$.

5. Prove that $\widehat{\mathbb{Z}} \cong \prod_\ell \mathbb{Z}_\ell$, the product over all primes ℓ, by combining the Chinese Remainder isomorphisms $\mathbb{Z}/n\mathbb{Z} \cong \prod_\ell \mathbb{Z}/\ell^{v_\ell(n)}\mathbb{Z}$ in the inverse limit $\widehat{\mathbb{Z}} = \varprojlim_n \mathbb{Z}/n\mathbb{Z}$. Using this, show $\mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$ has, for each prime ℓ, a unique closed subgroup with quotient $\mathbb{Z}_\ell$, and name its fixed field as a union of finite fields.

Commutative-diagram exercises.



1. Let p be an odd prime, $F = \mathbb{F}_p(s,t)$, and $K = F(\alpha,\beta)$ where $\alpha^p = s$ (purely inseparable, degree p) and $\beta^2 - \beta - t = 0$ (separable, degree 2). Complete the Galois/degree lattice below, labelling each edge with its degree and marking each as separable (s) or purely inseparable (i):

   Identify which intermediate field is K_{sep}, prove $F(\beta)/F$ is Galois, and show K/F is neither separable nor purely inseparable by computing $[K:F]_s$ and $[K:F]_i$.

2. For $G = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p) \cong \widehat{\mathbb{Z}}$, complete the two mutually corresponding lattices below for the layer $\mathbb{F}_{p^{18}}/\mathbb{F}_p$ (so $n = 18$): on the left the subgroups of $\mathbb{Z}/18\mathbb{Z}$, on the right the intermediate fields. Fill in every node on the right, write each subgroup on the left as $\langle \mathrm{Frob}_p^{18/m} \rangle$ (the node $\mathbb{Z}/m\mathbb{Z}$ stands for the unique subgroup

of order m, and each edge is an inclusion of subgroups), then state the Fix correspondence between them.

Prove that the correspondence is inclusion-reversing and that every subextension here is Galois over $\mathbb{F}_p$ with cyclic Galois group, identifying $\mathrm{Gal}(\mathbb{F}_{p^d}/\mathbb{F}_p)$ for each divisor d of 18.

3. Let K/F be Galois with $G = \mathrm{Gal}(K/F)$ profinite, and let $F \subseteq E \subseteq K$ be a finite Galois subextension. Show that restriction fits into the commutative diagram of profinite groups

$$\begin{array}{ccc} G = \mathrm{Gal}(K/F) & \xrightarrow{\ \rho\ } & G/\mathrm{Gal}(K/E) \\ & \searrow^{\mathrm{res}_E} & \downarrow \cong \\ & & \mathrm{Gal}(E/F) \end{array}$$

where ρ is the quotient map and res_E is restriction to E. Prove $\mathrm{Gal}(K/E)$ is open and normal in G, that the vertical map is the canonical isomorphism, and that res_E is a continuous open surjection.

4. In $G = \widehat{\mathbb{Z}} = \mathrm{Gal}(\overline{\mathbb{F}_p}/\mathbb{F}_p)$, fix a prime ℓ and let $H = \prod_{q \neq \ell} \mathbb{Z}_q$. Complete and justify the diagram exhibiting $\mathrm{Fix}(H) = \bigcup_{k \geq 0} \mathbb{F}_{p^{\ell^k}}$ as an infinite Galois extension of $\mathbb{F}_p$ with group $\widehat{\mathbb{Z}}/H \cong \mathbb{Z}_\ell$:

$$\begin{array}{ccc} \widehat{\mathbb{Z}} & \longleftarrow & H \\ \mathrm{Fix} & & \mathrm{Fix} \\ \mathbb{F}_p & \longhookrightarrow & \mathrm{Fix}(H) \end{array}$$

Show H is closed but not open, that $[\widehat{\mathbb{Z}} : H]$ is infinite, and conclude that $\mathrm{Fix}(H)/\mathbb{F}_p$ is an infinite-degree subextension corresponding (by item (1) of the infinite Fundamental Theorem) to a closed non-open subgroup.

14.10 Symmetric Functions and the Discriminant

Symmetric functions and the elementary symmetric polynomials

A permutation σ of the indices $\{1, \ldots, n\}$ acts on the polynomial ring $R[u] = R[u_1, \ldots, u_n]$ by permuting the variables: for $f = f(u_1, \ldots, u_n)$ we set $(\sigma f)(u_1, \ldots, u_n) = f(u_{\sigma 1}, \ldots, u_{\sigma n})$. Since σ fixes the constants, it is an R-algebra automorphism, and the symmetric group Sym_n acts on $R[u]$ by R-automorphisms. A polynomial is *symmetric* if it is fixed by every permutation.

Definition 14.10.1 (Symmetric polynomial)**.** $g \in R[u_1, \ldots, u_n]$ is *symmetric* if $\sigma g = g$ for all $\sigma \in \mathrm{Sym}_n$, i.e. $g(u_{\sigma 1}, \ldots, u_{\sigma n}) = g(u_1, \ldots, u_n)$. The symmetric polynomials form a subring of $R[u]$. Equivalently, g is symmetric iff any two monomials in the same Sym_n-orbit (e.g. $u_1^2 u_2$ and $u_2 u_3^2$) occur with the same coefficient; the sum of the monomials in one orbit is an *orbit sum*, and the orbit sums form an R-basis of the symmetric polynomials.

Definition 14.10.2 (Elementary symmetric polynomials)**.** The *elementary symmetric polynomials* $e_1, \dots, e_n$ in $u_1, \dots, u_n$ are the orbit sums of the squarefree monomials:

$$e_1 = \sum_i u_i, \qquad e_2 = \sum_{i<j} u_i u_j, \qquad e_3 = \sum_{i<j<k} u_i u_j u_k, \qquad \dots, \qquad e_n = u_1 u_2 \cdots u_n.$$

Thus e_k is the orbit sum of $u_1 u_2 \cdots u_k$; it is the sum of all $\binom{n}{k}$ squarefree degree-k monomials. (Artin writes these $s_1, \dots, s_n$; we use e_k here.)

The e_k arise as the coefficients of the polynomial with roots $u_1, \dots, u_n$. Expanding $P(x) = (x-u_1)\cdots(x-u_n)$ and collecting by degree gives Vieta's formulas with alternating signs:

$$P(x) = (x-u_1)(x-u_2)\cdots(x-u_n) = x^n - e_1 x^{n-1} + e_2 x^{n-2} - \cdots + (-1)^n e_n.$$

For $n=2$ this is $x^2 - (u_1+u_2)x + u_1u_2$; for $n=3$ it is $x^3 - (u_1+u_2+u_3)x^2 + (u_1u_2+u_1u_3+u_2u_3)x - u_1u_2u_3$. Following Artin, we therefore label undetermined coefficients of a monic degree-n polynomial in the matching alternating form

$$f(x) = x^n - a_1 x^{n-1} + a_2 x^{n-2} - \cdots + (-1)^n a_n.$$

Lemma 14.10.3 (coefficients are the elementary symmetric functions of the roots)**.** *If $f(x) = x^n - a_1 x^{n-1} + \cdots + (-1)^n a_n$ splits as $f(x) = (x-\alpha_1)\cdots(x-\alpha_n)$ in a field K, then $a_k = e_k(\alpha_1, \dots, \alpha_n)$ for each k. That is, the coefficients are obtained by evaluating the elementary symmetric functions at the roots.*

Proof. Substitute $u_i = \alpha_i$ into the expansion of $P(x) = \prod_i (x - u_i)$ above and compare coefficients with $f(x) = \prod_i (x - \alpha_i)$. The coefficient of x^{n-k} in $\prod_i (x-\alpha_i)$ is exactly $(-1)^k$ times the sum of all products of k distinct roots, namely $(-1)^k e_k(\alpha)$; matching against $(-1)^k a_k$ gives $a_k = e_k(\alpha)$. □

The fundamental theorem of symmetric functions

The central theorem says the e_i are not merely examples of symmetric polynomials – they generate all of them, freely.

Theorem 14.10.4 (Fundamental (Symmetric Functions) Theorem)**.** *Let R be any commutative ring. Every symmetric polynomial $g(u_1, \dots, u_n) \in R[u]$ can be written as a polynomial in the elementary symmetric functions, and in exactly one way: there is a* unique *polynomial $G(z_1, \dots, z_n) \in R[z_1, \dots, z_n]$ in new variables such that*

$$g(u_1, \dots, u_n) = G\big(e_1, \dots, e_n\big).$$

Equivalently, $R[e_1, \dots, e_n]$ is the full ring of symmetric polynomials, and $e_1, \dots, e_n$ are algebraically independent over R.

Existence, by induction (Artin's reduction). Induct on n; the case $n = 1$ is trivial since $u_1 = e_1$. Assume the theorem for $n-1$ variables. Given a symmetric g in $u_1, \dots, u_n$, substitute $u_n = 0$ to get $g^0(u_1, \dots, u_{n-1}) = g(u_1, \dots, u_{n-1}, 0)$, which is symmetric in $u_1, \dots, u_{n-1}$. Under $u_n = 0$ the elementary symmetric functions specialize to $e_1^0, \dots, e_{n-1}^0$ (those in $u_1, \dots, u_{n-1}$) while $e_n \mapsto 0$. By the induction hypothesis $g^0 = Q(e_1^0, \dots, e_{n-1}^0)$ for some polynomial Q.

Now set $p = g - Q(e_1, \dots, e_{n-1})$, a difference of symmetric polynomials, hence symmetric. Setting $u_n = 0$ gives $p|_{u_n=0} = g^0 - Q(e_1^0, \dots, e_{n-1}^0) = 0$, so $u_n \mid p$. Because p is symmetric, every u_i divides p, and therefore the product $e_n = u_1 \cdots u_n$ divides p. Write $p = e_n\, h$ with h symmetric; comparing degrees, $\deg h = \deg p - n < \deg g$. A second induction, on the degree, expresses h as a polynomial in the e_i, hence so is p, hence so is

$$g = Q(e_1, \dots, e_{n-1}) + e_n\, h.$$

Uniqueness (algebraic independence of the e_i) is checked by tracking the lexicographically leading term in the algorithm below: distinct monomials $e_1^{b_1} \cdots e_n^{b_n}$ have distinct leading monomials $u_1^{b_1+\cdots+b_n} u_2^{b_2+\cdots+b_n} \cdots u_n^{b_n}$, each with coefficient 1; so if $G \neq 0$, the largest leading monomial among the e-monomials occurring in G appears in $G(e)$ with the nonzero coefficient it has in G, and $G \mapsto G(e)$ is injective. □

Method (Lexicographic leading-term algorithm: reduce a symmetric g to a polynomial in the e_i.)**.** Order monomials lexicographically by exponent ($u_1 > u_2 > \cdots > u_n$). Let the leading monomial of g be $c\,u_1^{a_1}u_2^{a_2}\cdots u_n^{a_n}$; symmetry forces $a_1 \geq a_2 \geq \cdots \geq a_n$. Subtract

$$c\,e_1^{a_1-a_2}\,e_2^{a_2-a_3}\cdots e_{n-1}^{a_{n-1}-a_n}\,e_n^{a_n},$$

whose own leading monomial is exactly $c\,u_1^{a_1}\cdots u_n^{a_n}$ (since e_k leads with $u_1\cdots u_k$). The difference is symmetric with a strictly smaller leading monomial. Repeat; the process terminates because the leading exponent vector decreases in a well-ordering. The accumulated subtractions reassemble g as a polynomial $G(e_1,\ldots,e_n)$.

Worked Example 14.10.5 (The power sum $\sum u_i^2$ in the e_i)**.** Express the symmetric polynomial $p_2 = u_1^2 + u_2^2 + \cdots + u_n^2$ as a polynomial in $e_1,\ldots,e_n$.

Recognition. p_2 is symmetric of degree 2, so it is a linear combination of the degree-2 products e_1^2 and e_2 (the only weight-2 monomials in the e_i). Find the coefficients by undetermined coefficients, evaluating at special values (Artin's method) or by direct expansion.

Solution. Write $p_2 = c_1e_1^2 + c_2e_2$. Evaluate at $u = (1,0,\ldots,0)$: then $e_1 = 1$, $e_2 = 0$, $p_2 = 1$, giving $c_1 = 1$. Evaluate at $u = (1,-1,0,\ldots,0)$: then $e_1 = 0$, $e_2 = -1$, $p_2 = 2$, giving $-c_2 = 2$, so $c_2 = -2$. Hence

$$u_1^2 + \cdots + u_n^2 = e_1^2 - 2e_2.$$

Check. Directly, $e_1^2 = (\sum_i u_i)^2 = \sum_i u_i^2 + 2\sum_{i<j} u_iu_j = p_2 + 2e_2$, so $p_2 = e_1^2 - 2e_2$, matching.

Worked Example 14.10.6 (The power sum $\sum u_i^3$ in the e_i)**.** Express $p_3 = u_1^3 + u_2^3 + \cdots + u_n^3$ in terms of e_1, e_2, e_3.

Recognition. p_3 is symmetric of degree 3, hence a combination of the weight-3 monomials $e_1^3,\ e_1e_2,\ e_3$. Pin the three coefficients by special substitutions, or apply Newton's identity below.

Solution. Write $p_3 = c_1e_1^3 + c_2e_1e_2 + c_3e_3$. At $u = (1,0,\ldots)$: $e_1 = 1$, $e_2 = e_3 = 0$, $p_3 = 1 \Rightarrow c_1 = 1$. At $u = (1,1,0,\ldots)$: $e_1 = 2$, $e_2 = 1$, $e_3 = 0$, $p_3 = 2$, so $8c_1 + 2c_2 = 2$, i.e. $8 + 2c_2 = 2 \Rightarrow c_2 = -3$. At $u = (1,1,1,0,\ldots)$: $e_1 = 3$, $e_2 = 3$, $e_3 = 1$, $p_3 = 3$, so $27c_1 + 9c_2 + c_3 = 3$, i.e. $27 - 27 + c_3 = 3 \Rightarrow c_3 = 3$. Hence

$$u_1^3 + \cdots + u_n^3 = e_1^3 - 3e_1e_2 + 3e_3.$$

Check. For $n = 2$ (so $e_3 = 0$) this reads $p_3 = e_1^3 - 3e_1e_2 = (u_1+u_2)^3 - 3(u_1+u_2)u_1u_2$, which expands to $u_1^3 + u_2^3$ – correct.

Power sums and Newton's identities

The polynomials $p_k = u_1^k + \cdots + u_n^k$ are the *power sums*. They are symmetric, so by the Fundamental Theorem each is a polynomial in the e_i; the recursive bridge is Newton's identities.

Proposition 14.10.7 (Newton's identities)**.** *With $e_0 = 1$ and $e_k = 0$ for $k > n$, the power sums and elementary symmetric functions satisfy, for every $k \geq 1$,*

$$p_k - e_1p_{k-1} + e_2p_{k-2} - \cdots + (-1)^{k-1}e_{k-1}p_1 + (-1)^k k\,e_k = 0.$$

In particular $p_1 = e_1$, $p_2 = e_1p_1 - 2e_2 = e_1^2 - 2e_2$, and $p_3 = e_1p_2 - e_2p_1 + 3e_3 = e_1^3 - 3e_1e_2 + 3e_3$.

Sketch. Form the generating identity $\prod_i(1-u_it) = \sum_{k\geq 0}(-1)^k e_kt^k$. Take the logarithmic derivative in t:

$$\frac{d}{dt}\log\prod_i(1-u_it) = \sum_i \frac{-u_i}{1-u_it} = -\sum_i\sum_{k\geq 1} u_i^kt^{k-1} = -\sum_{k\geq 1} p_k\,t^{k-1}.$$

Writing $E(t) = \sum_k(-1)^k e_kt^k$, the left side equals $E'(t)/E(t)$, so $-\big(\sum_{k\geq 1} p_kt^{k-1}\big)E(t) = E'(t)$. Multiplying out and equating the coefficient of t^{k-1} on both sides yields exactly the stated identity for each k. □

Worked Example 14.10.8 (Algorithmic reduction of a degree-three symmetric polynomial)**.** Reduce the orbit sum

$$g = u_1^2u_2 + u_1^2u_3 + u_2^2u_1 + u_2^2u_3 + u_3^2u_1 + u_3^2u_2$$

in three variables (the orbit of $u_1^2u_2$) to a polynomial in e_1, e_2, e_3, following Artin's set-$u_3 = 0$ reduction.

Recognition. g is symmetric of degree 3. Use the inductive reduction: set $u_3 = 0$, solve in two variables, then correct by a multiple of e_3 to repair the three-variable case (Lemma in the proof of the Fundamental Theorem).

Solution. Step 1. Set $u_3 = 0$. Then $g^0 = u_1^2u_2 + u_2^2u_1 = u_1u_2(u_1 + u_2) = e_2^0\, e_1^0$, where $e_1^0 = u_1 + u_2$, $e_2^0 = u_1u_2$ are the two-variable elementary symmetric functions. So the two-variable answer is $e_1^0e_2^0$.

Step 2. Compare g with the three-variable $e_1e_2 = (u_1 + u_2 + u_3)(u_1u_2 + u_1u_3 + u_2u_3)$. This product has nine terms; six of them are exactly the orbit sum g (each $u_i^2u_j$ appears once), and the remaining three terms are each $u_1u_2u_3 = e_3$. Thus $e_1e_2 = g + 3e_3$, giving

$$g = e_1e_2 - 3e_3.$$

This matches the leading-term algorithm too: g leads with $u_1^2u_2$ (exponents $(2, 1, 0)$), and the prescribed subtraction is $e_1^{2-1}e_2^{1-0}e_3^0 = e_1e_2$, leaving $-3e_3$. *Check.* At $u = (1, 1, 1)$, $g = 6$ while $e_1e_2 - 3e_3 = 3\cdot3 - 3\cdot1 = 6$; at $u = (1, 1, 0)$, $g = 2$ while $e_1e_2 - 3e_3 = 2 \cdot 1 - 0 = 2$. Both agree.

Corollary 14.10.9 (symmetric functions of roots stay in the base field)**.** *Let $f(x) = x^n - a_1x^{n-1} + \cdots + (-1)^na_n \in F[x]$ split completely in an extension K/F with roots $\alpha_1, \ldots, \alpha_n$. If $g(u_1, \ldots, u_n)$ is any symmetric polynomial with coefficients in F, then $g(\alpha_1, \ldots, \alpha_n) \in F$.*

Proof. By Theorem 14.10.4, $g = G(e_1, \ldots, e_n)$ with G having coefficients in F. Evaluating at $u_i = \alpha_i$ and using Lemma 14.10.3, $e_k(\alpha) = a_k \in F$. Hence $g(\alpha) = G(a_1, \ldots, a_n)$ is a polynomial expression in the $a_k \in F$ with coefficients in F, so it lies in F. For instance $\alpha_1^k + \cdots + \alpha_n^k \in F$ for every k, even when no individual root lies in F. □

Remark 14.10.1. Corollary 14.10.9 is the bridge to Galois theory: the coefficients a_k *are* the elementary symmetric functions of the roots, so any quantity invariant under permuting the roots is already expressible in the a_k and therefore rational over F. The Galois group acts on the roots by permutations, and the symmetric (fully invariant) functions are precisely the ones fixed by the whole symmetric group – the bottom of the fixed-field correspondence.

The chain of subrings underlying the theorem is best seen as a tower: the full polynomial ring sits above its symmetric subring, which is freely generated by the e_i, and specializing the variables to the roots $u_i \mapsto \alpha_i$ sends those generators to the coefficients of f.

$$\begin{array}{ccc} R[u_1, \ldots, u_n] & & \\ \Big| & & \\ R[e_1, \ldots, e_n] = R[u]^{\mathrm{Sym}_n} & \xrightarrow{u_i \mapsto \alpha_i} & F[a_1, \ldots, a_n] \\ \Big| & & \\ R & = & R \end{array}$$

Diagram explanation. Objects: Five nodes arranged as a lopsided tower. Upper-left: $R[u_1, \ldots, u_n]$, the full polynomial ring in n indeterminates over a commutative ring R. Middle-left: $R[e_1, \ldots, e_n] = R[u]^{\mathrm{Sym}_n}$, the subring of symmetric polynomials; by the Fundamental Theorem it equals the polynomial ring in the elementary symmetric functions $e_1, \ldots, e_n$, which are algebraically independent over R. Bottom-left: R, the base ring (constant polynomials). Middle-right: $F[a_1, \ldots, a_n]$, the polynomial ring (actually a subring of F) generated by the coefficients a_k of f; since the $a_k \in F$, this is just F itself in the splitting situation, but writing it this way highlights the parallelism with the left column. Bottom-right: R again (identifying the two copies by the "equal" sign).

Arrows: Four arrows. (1) Upper vertical edge: inclusion $R[u]^{\mathrm{Sym}_n} \hookrightarrow R[u_1, \ldots, u_n]$, inserting the symmetric subring into the full ring. (2) Lower vertical edge: inclusion $R \hookrightarrow R[u]^{\mathrm{Sym}_n}$, viewing R as constant symmetric polynomials. (3) Horizontal middle: the evaluation/specialization map $\mathrm{ev}_\alpha \colon R[u]^{\mathrm{Sym}_n} \to F[a_1, \ldots, a_n]$ defined by $u_i \mapsto \alpha_i$; since $e_k(\alpha_1, \ldots, \alpha_n) = a_k$ by Vieta (Lemma 14.10.3), this carries $e_k \mapsto a_k$ and is a ring homomorphism. (4) Bottom horizontal: the identity/equality $R \xrightarrow{=} R$. Well-definedness of ev_α: a polynomial map $u_i \mapsto \alpha_i$ is always a ring homomorphism and needs no coset check; the point is merely that symmetric polynomials evaluated at the roots stay in F (proved in Corollary 14.10.9).

What commutes: The square formed by arrows (2), (3), (4), and the inclusion $R \hookrightarrow F[a_1, \ldots, a_n]$ commutes: going right-then-up ($R \to R \to F[a_1, \ldots, a_n]$: arrow (4), then the inclusion) and going up-then-right ($R \to R[u]^{\mathrm{Sym}_n} \to F[a_1, \ldots, a_n]$: arrows (2) and (3)) both land a constant $r \in R$ at $r \in F[a_1, \ldots, a_n]$. The upper-left triangle is not a commuting square but an inclusion chain: $R \subseteq R[u]^{\mathrm{Sym}_n} \subseteq R[u_1, \ldots, u_n]$.

Why it commutes: Take a constant $r \in R$. Along the up-then-right path: r is already in $R[u]^{\mathrm{Sym}_n}$ (constant polynomial), and $\mathrm{ev}_\alpha(r) = r \in F$. Along the right-then-up path: $r \mapsto r$ by the equality arrow, then $r \mapsto r$ by the inclusion. These agree because evaluating a constant polynomial at any point returns that constant; no u_i are substituted. The key nontrivial commutativity is $\mathrm{ev}_\alpha(e_k) = a_k$, which is exactly Vieta's theorem: the coefficient of x^{n-k} in $\prod_i (x - \alpha_i)$ is $(-1)^k e_k(\alpha) = (-1)^k a_k$.

Why this matters here: This diagram is the geometric summary of Corollary 14.10.9 and the Fundamental Theorem together. It shows that the specialization $u_i \mapsto \alpha_i$ does not leave the base field: any symmetric polynomial (left column) maps to a polynomial in the a_k (right column), which lie in F. The author places it here to make visible why "symmetric functions of roots are rational": the horizontal evaluation map is the concrete realization of the abstract isomorphism $R[u]^{\mathrm{Sym}_n} \cong R[e_1, \ldots, e_n]$, and it lands in F because $a_k \in F$.

Concrete example: Take $R = F = \mathbb{Q}$, $n = 2$, $f(x) = x^2 - 3x + 1$ (roots $\alpha_1, \alpha_2 = \frac{3 \pm \sqrt{5}}{2}$, which are irrational). $e_1(\alpha_1, \alpha_2) = \alpha_1 + \alpha_2 = 3 = a_1 \in \mathbb{Q}$. $e_2(\alpha_1, \alpha_2) = \alpha_1 \alpha_2 = 1 = a_2 \in \mathbb{Q}$. The power sum $p_2 = \alpha_1^2 + \alpha_2^2 = e_1^2 - 2e_2 = 9 - 2 = 7 \in \mathbb{Q}$, even though $\alpha_i \notin \mathbb{Q}$. The horizontal arrow in the diagram sends $e_1 \mapsto 3$, $e_2 \mapsto 1$, entirely within $\mathbb{Q}$.

Common pitfall: Students read the horizontal arrow as an isomorphism $R[u]^{\mathrm{Sym}_n} \cong F[a_1, \ldots, a_n]$ and conclude the two rings are the same. They are *not* in general isomorphic as abstract rings; the arrow is an evaluation homomorphism, not an isomorphism: in the basic case $R = F$ it is onto $F[a_1, \ldots, a_n] = F$, and its kernel is the maximal ideal $(e_1 - a_1, \ldots, e_n - a_n)$ of the polynomial ring $F[e_1, \ldots, e_n]$ – never zero, and consisting exactly of the relations forced by f. What matters is the *image*: every symmetric combination of the roots is a polynomial in the a_k, hence in F.

Takeaway: The point of this diagram is that the Fundamental Theorem converts the abstract statement "symmetric functions of roots are rational" into a concrete factorization: every such function factors through the elementary symmetric functions e_k, which are sent to the coefficients $a_k \in F$ by Vieta, so the result lands in F automatically.

The left edges are the inclusions $R \subseteq R[u]^{\mathrm{Sym}_n} \subseteq R[u]$, with $R[u]^{\mathrm{Sym}_n}$ free on $e_1, \ldots, e_n$; the horizontal map is evaluation at the roots, carrying $e_k \mapsto a_k$.

Caution. The theorem expresses symmetric polynomials in the e_i *with coefficients in* R only; it does not let you divide. Newton's identity $p_k + \cdots + (-1)^k k\, e_k = 0$ solves for p_k in terms of lower data without dividing, but solving for e_k in terms of the p_j introduces the factor $\frac{1}{k}$. Hence the change of generators from e's to power sums p's is valid only when $1, 2, \ldots, n$ are invertible in R (e.g. over a field of characteristic 0, or any characteristic exceeding n), and can fail in small positive characteristic.

The discriminant

Let $f(x) = x^n - s_1 x^{n-1} + s_2 x^{n-2} - \cdots \pm s_n$ have roots $\alpha_1, \ldots, \alpha_n$ in a splitting field. The single most useful symmetric function of the roots, aside from the elementary symmetric functions s_i themselves, measures how far the roots are from colliding.

Definition 14.10.10 (discriminant)**.** The *discriminant* of f is

$$\mathrm{disc}(f) = \prod_{i<j} (\alpha_i - \alpha_j)^2 = (\alpha_1 - \alpha_2)^2 (\alpha_1 - \alpha_3)^2 \cdots (\alpha_{n-1} - \alpha_n)^2.$$

Two features stand out, and they are forced by the very shape of the product. First, $\operatorname{disc}(f) = 0$ if and only if two roots coincide – that is, $\operatorname{disc}(f) \neq 0$ exactly when f has n distinct roots (is separable). Second, the discriminant is a *symmetric* function of the roots.

Proposition 14.10.11 (the discriminant is a polynomial in the coefficients)**.** $\operatorname{disc}(f)$ *is a symmetric polynomial in* $\alpha_1, \dots, \alpha_n$ *with integer coefficients. Consequently, by the Symmetric Functions Theorem, it is an integer polynomial in the elementary symmetric functions* $s_1, \dots, s_n$*; writing* $A(z_1, \dots, z_n)$ *for that polynomial,*

$$\operatorname{disc}(f) = A(s_1, \dots, s_n) \in F$$

whenever $f \in F[x]$*. In particular the discriminant of* f *lies in the base field* F*, even though it is defined through the roots.*

Proof. A permutation $\tau \in \mathrm{Sym}_n$ of the variables sends each factor $(\alpha_i - \alpha_j)^2$ to another factor $(\alpha_{\tau(i)} - \alpha_{\tau(j)})^2$ of the same product: since $(\alpha_j - \alpha_i)^2 = (\alpha_i - \alpha_j)^2$, the squaring kills the sign that the transposition would otherwise introduce, so τ merely permutes the $\binom{n}{2}$ factors among themselves and fixes their product. Thus $\operatorname{disc}(f)$ is symmetric. The Symmetric Functions Theorem then writes any symmetric integer polynomial uniquely as an integer polynomial $A(s_1, \dots, s_n)$ in the elementary symmetric functions. When the α_i are the roots of $f \in F[x]$, the s_i are (up to sign) the coefficients of f, hence lie in F, so $\operatorname{disc}(f) = A(s_1, \dots, s_n) \in F$. □

Remark 14.10.2. For $n = 2$, $f(x) = x^2 - s_1 x + s_2$ has $\operatorname{disc}(f) = (\alpha_1 - \alpha_2)^2 = (\alpha_1 + \alpha_2)^2 - 4\alpha_1\alpha_2 = s_1^2 - 4s_2$ – the familiar $b^2 - 4ac$ for $x^2 - s_1 x + s_2$. The point that this is literally the *square* of the difference of the roots is exactly what generalizes.

The discriminant of a cubic

For $n = 3$ the polynomial A already resists memorization, but a Tschirnhausen substitution $x = y + s_1/3$ (legal when $\operatorname{char} F \neq 3$) kills the quadratic term and reduces every cubic to a *depressed* cubic $y^3 + py + q$. There the formula is clean.

Theorem 14.10.12 (discriminant of a depressed cubic)**.** *Over a field of characteristic* $\neq 2, 3$*,*

$$\operatorname{disc}(x^3 + px + q) = -4p^3 - 27q^2.$$

Sketch. Let $\alpha_1, \alpha_2, \alpha_3$ be the roots of $g(x) = x^3 + px + q$, so $g'(x) = 3x^2 + p$. From $g(x) = \prod_i (x - \alpha_i)$ one gets $g'(\alpha_i) = \prod_{j \neq i} (\alpha_i - \alpha_j)$, and multiplying over i yields the resultant identity

$$\prod_i g'(\alpha_i) = \prod_{i \neq j} (\alpha_i - \alpha_j) = (-1)^{\binom{3}{2}} \prod_{i<j} (\alpha_i - \alpha_j)^2 = -\operatorname{disc}(g).$$

Now evaluate $\prod_i g'(\alpha_i) = \prod_i (3\alpha_i^2 + p)$ using $\alpha_i^3 = -p\alpha_i - q$. Expanding the symmetric product $\prod_i (3\alpha_i^2 + p)$ and rewriting in the elementary symmetric functions $s_1 = 0,\ s_2 = p,\ s_3 = -q$ of the depressed cubic gives $\prod_i g'(\alpha_i) = 4p^3 + 27q^2$. Hence $\operatorname{disc}(g) = -(4p^3 + 27q^2) = -4p^3 - 27q^2$. □

Method (To take the discriminant of any cubic $x^3 + ax^2 + bx + c$: substitute $x = y - a/3$ to reach a depressed cubic $y^3 + py + q$ (Tschirnhausen), then read off $\operatorname{disc} = -4p^3 - 27q^2$. The substitution leaves the discriminant unchanged, since it only translates all roots by the same amount.)**.**

Worked Example 14.10.13 (Discriminant of $x^3 + 3x + 1$)**.** Compute $\operatorname{disc}(x^3 + 3x + 1)$.

Recognition. Already depressed ($p = 3,\ q = 1$); apply Theorem 14.10.12 directly.

Solution. $\operatorname{disc} = -4(3)^3 - 27(1)^2 = -4 \cdot 27 - 27 = -108 - 27 = -135 = -5 \cdot 3^3$. *Check.* $-135 < 0$, and for a real cubic a negative discriminant signals one real and two complex-conjugate roots; here $x^3 + 3x + 1$ is strictly increasing ($g'(x) = 3x^2 + 3 > 0$), so it has exactly one real root, consistent with $\operatorname{disc} < 0$.

Worked Example 14.10.14 (Discriminant of $x^3 - 3x + 1$)**.** Compute $\operatorname{disc}(x^3 - 3x + 1)$.

Recognition. Depressed with $p = -3,\ q = 1$; use $\operatorname{disc} = -4p^3 - 27q^2$.

Solution. $\operatorname{disc} = -4(-3)^3 - 27(1)^2 = -4(-27) - 27 = 108 - 27 = 81 = 3^4$. *Check.* $81 = 9^2$ is a perfect square in $\mathbb{Q}$. Also $81 > 0$, predicting three distinct real roots; indeed $g(x) = x^3 - 3x + 1 = 2\cos 3\theta$-type behavior gives $g(-2) < 0 < g(-1)$, $g(0) > 0 > g(1)$, $g(1) < 0 < g(2)$, three real roots. Both checks agree.

Worked Example 14.10.15 (Reduce a non-depressed cubic first)**.** Compute $\operatorname{disc}(x^3 - 3x^2 + 1)$.

Recognition. Not depressed; substitute $x = y + 1$ (i.e. $x = y - a/3$ with $a = -3$) to remove the x^2 term, then apply the formula.

Solution. $x = y + 1$: $(y+1)^3 - 3(y+1)^2 + 1 = y^3 + 3y^2 + 3y + 1 - 3y^2 - 6y - 3 + 1 = y^3 - 3y - 1$, so $p = -3,\ q = -1$. Then $\operatorname{disc} = -4(-3)^3 - 27(-1)^2 = 108 - 27 = 81 = 3^4$. *Check.* Translation by 1 does not move root differences, so the answer must match a depressed cubic with the same differences; $y^3 - 3y - 1$ has the same discriminant 81 as $y^3 - 3y + 1$ since disc depends on q only through q^2.

The discriminant and the Galois group

The discriminant is a perfect square as a function of the roots:

$$\delta := \prod_{i<j} (\alpha_i - \alpha_j), \qquad \operatorname{disc}(f) = \delta^2.$$

The element δ lies in the splitting field K, is nonzero when the roots are distinct, and a permutation σ of the roots multiplies it by the sign:

$$\sigma(\delta) = \operatorname{sgn}(\sigma)\, \delta.$$

This single transformation rule is the bridge between the discriminant and the Galois group.

Theorem 14.10.16 (discriminant criterion)**.** *Let $f \in F[x]$ be separable with splitting field K, $\operatorname{char} F \neq 2$, and view $G = \operatorname{Gal}(K/F)$ as a subgroup of Sym_n via its action on the roots. Then*

$$\operatorname{disc}(f) \text{ is a square in } F \iff G \leq \mathrm{A}_n.$$

Proof. Since $\operatorname{disc}(f) = \delta^2 \in F$, we have $\delta \in F$ if and only if $\operatorname{disc}(f)$ is a square in F. Now $\delta \in F$ iff δ is fixed by every $\sigma \in G$ (Galois). But $\sigma(\delta) = \operatorname{sgn}(\sigma)\, \delta$ and $\delta \neq 0$, so $\sigma(\delta) = \delta$ iff $\operatorname{sgn}(\sigma) = 1$, i.e. iff $\sigma \in \mathrm{A}_n$. Hence $\delta \in F$ iff every element of G is even, i.e. iff $G \leq \mathrm{A}_n$. (Characteristic $\neq 2$ guarantees $\operatorname{sgn}(\sigma) = -1$ is genuinely distinct from $+1$.) □

Specializing to $n = 3$ recovers Artin's complete classification: the only transitive subgroups of Sym_3 are A_3 (cyclic of order 3) and Sym_3 itself.

Corollary 14.10.17 (Galois theory for a cubic)**.** *Let f be an irreducible cubic over F ($\operatorname{char} F \neq 2, 3$) with splitting field K and $G = \operatorname{Gal}(K/F)$, and let $D = \operatorname{disc}(f)$.*

- *If D is a square in F, then $G = \mathrm{A}_3$ and $[K : F] = 3$.*
- *If D is not a square in F, then $G = \operatorname{Sym}_3$ and $[K : F] = 6$.*

Proof. Because f is irreducible of degree 3, G is a transitive subgroup of Sym_3, hence $G = \mathrm{A}_3$ or $G = \operatorname{Sym}_3$. By Theorem 14.10.16, $G \leq \mathrm{A}_3$ exactly when D is a square in F; the only transitive subgroup of Sym_3 contained in A_3 is A_3 itself. So D square gives $G = \mathrm{A}_3$ with $[K : F] = |\mathrm{A}_3| = 3$, and D non-square gives $G = \operatorname{Sym}_3$ with $[K : F] = 6$. □

When $G = \operatorname{Sym}_3$ the proper intermediate fields are exactly the four predicted by the four nontrivial proper subgroups of Sym_3: the three fields $F(\alpha_1), F(\alpha_2), F(\alpha_3)$ (each fixed by a transposition) and the quadratic field $F(\delta)$ fixed by A_3.

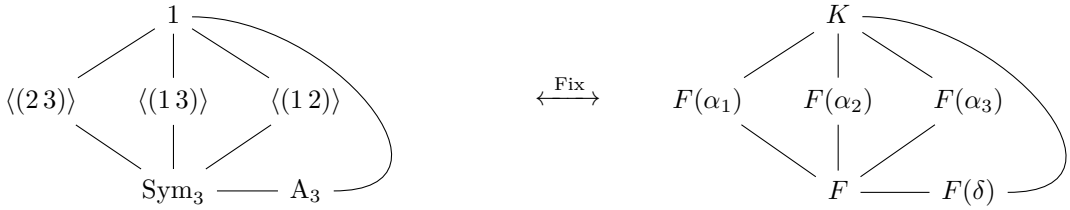


Diagram explanation. Objects: Left lattice: subgroups of Sym_3 under inclusion – the trivial group 1 at the top, the three order-2 cyclic subgroups $\langle(2\,3)\rangle$, $\langle(1\,3)\rangle$, $\langle(1\,2)\rangle$ in the middle, and at the bottom Sym_3 itself alongside A_3 (the unique index-2 normal subgroup, order 3). Right lattice: intermediate fields of the splitting extension K/F – the full splitting field K at the top, the three cubic subfields $F(\alpha_1)$, $F(\alpha_2)$, $F(\alpha_3)$ in the middle, and at the bottom F alongside the quadratic subfield $F(\delta) = F(\sqrt{D})$. Both lattices are ordered by inclusion (subgroups) and by containment (fields); the dash edges record these inclusions.

Arrows: The double-headed arrow $\xleftrightarrow{\text{Fix}}$ between the two lattices is the Galois correspondence: to each subgroup $H \leq \mathrm{Sym}_3$ it assigns the fixed field $\mathrm{Fix}(H) = \{x \in K : \sigma(x) = x \text{ for all } \sigma \in H\}$; to each intermediate field L it assigns $\mathrm{Gal}(K/L)$. Every dash edge in both diagrams is an inclusion; no edge carries an explicit formula because the correspondence is the conceptual content, not element-level maps.

What commutes: The correspondence reverses inclusion: if $H_1 \leq H_2$ then $\mathrm{Fix}(H_2) \subseteq \mathrm{Fix}(H_1)$. Concretely, $1 \leq \langle(i\,j)\rangle \leq \mathrm{Sym}_3$ maps to $K \supseteq F(\alpha_k) \supseteq F$, and $1 \leq \mathrm{A}_3 \leq \mathrm{Sym}_3$ maps to $K \supseteq F(\delta) \supseteq F$. Every containment on the left reverses to a containment on the right: this order-reversal is the defining "commuting" property of the Galois correspondence.

Why it commutes: Suppose $H_1 \subseteq H_2$ and $x \in \mathrm{Fix}(H_2)$. Every $\sigma \in H_1$ lies in H_2 and therefore fixes x, so $x \in \mathrm{Fix}(H_1)$; that is, $\mathrm{Fix}(H_2) \subseteq \mathrm{Fix}(H_1)$. The inclusion flips because a larger group imposes more conditions $\sigma(x) = x$, so fewer elements satisfy all of them – a direct consequence of the definition of fixed field, no element-chasing beyond this.

Why this matters here: This diagram is the payoff of Corollary 14.10.17: once we know $G = \mathrm{Sym}_3$, it displays all proper intermediate fields in one picture, including the distinguished quadratic field $F(\delta)$ fixed by A_3. The position of A_3 in the left lattice (index 2 in Sym_3, containing none of the index-3 subgroups $\langle(i\,j)\rangle$) explains why $F(\delta)$ is a degree-2 extension of F and is contained in none of the cubic fields $F(\alpha_k)$ (a degree-2 subfield cannot lie in a degree-3 extension of F).

Concrete example: Take $f(x) = x^3 - 3x + 1$ over $\mathbb{Q}$, where disc $= 81 = 9^2$ and $G = \mathrm{A}_3$. In that case the left lattice collapses: only $1 \leq \mathrm{A}_3$ survive as subgroups, and the right lattice collapses to $K \supseteq \mathbb{Q}$ with $F(\delta) = \mathbb{Q}(9) = \mathbb{Q}$. Contrast with $f(x) = x^3 + 3x + 1$ (disc $= -135$, $G = \mathrm{Sym}_3$): the full diagram applies, $F(\delta) = \mathbb{Q}(\sqrt{-135})$ is genuinely quadratic, and each $\mathbb{Q}(\alpha_i)$ is a distinct cubic subfield of the degree-6 splitting field.

Common pitfall: A_3 is drawn in the same row as Sym_3 only to keep the picture compact; the two are comparable, $\mathrm{A}_3 \subsetneq \mathrm{Sym}_3$ (the horizontal edge), and correspondingly $F \subsetneq F(\delta)$, with $F = \mathrm{Fix}(\mathrm{Sym}_3)$ the fixed field of the full Galois group. What A_3 is incomparable with are the three order-2 subgroups (it contains none of them and lies in none of them), which is why $F(\delta)$ neither contains nor is contained in any $F(\alpha_k)$.

Takeaway: The point of this diagram is that the Galois correspondence turns the subgroup lattice of Sym_3 upside-down into the field lattice of K/F, making the distinguished quadratic subfield $F(\sqrt{D})$ visible as the fixed field of the unique index-2 subgroup A_3, so reading off all intermediate fields reduces to reading off all subgroups of the Galois group.

The larger subgroup A_3 (order 3, index 2) corresponds to the smaller field $F(\delta) = F(\sqrt{D})$, a quadratic over F; the small subgroups $\langle(i\,j)\rangle$ (order 2, index 3) correspond to the larger cubic fields $F(\alpha_k)$.

Worked Example 14.10.18 (Read off the group of $x^3 + 3x + 1$ over $\mathbb{Q}$)**.** Determine $\mathrm{Gal}(K/\mathbb{Q})$ for the splitting field of $x^3 + 3x + 1$.

Recognition. $x^3 + 3x + 1$ is irreducible over $\mathbb{Q}$ (no rational root: ± 1 fail), so use Corollary 14.10.17 with the discriminant computed above.

Solution. disc $= -135$, and -135 is not a square in $\mathbb{Q}$ (it is negative). Hence $G = \mathrm{Sym}_3$ and $[K : \mathbb{Q}] = 6$. *Check.* A single real root and a complex-conjugate pair means complex conjugation acts as a transposition of the two non-real roots, an *odd* permutation living in G – so $G \not\leq \mathrm{A}_3$, confirming $G = \mathrm{Sym}_3$.

Worked Example 14.10.19 (Read off the group of $x^3 - 3x + 1$ over $\mathbb{Q}$)**.** Determine $\mathrm{Gal}(K/\mathbb{Q})$ for the splitting field of $x^3 - 3x + 1$.

Recognition. Irreducible over $\mathbb{Q}$ (± 1 are not roots); apply Corollary 14.10.17.

Solution. disc $= 81 = 9^2$ is a square in $\mathbb{Q}$, so $G = \mathrm{A}_3$ and $[K : \mathbb{Q}] = 3$. *Check.* All three roots are real (we saw disc > 0), and $\delta = \sqrt{81} = 9 \in \mathbb{Q}$ is genuinely rational, so every automorphism fixes δ and is therefore even –

exactly $G = \mathrm{A}_3$. Since 3 is prime there are no proper intermediate fields, matching A_3 having no nontrivial proper subgroups.

Caution. "Square in F" is essential – the discriminant is computed in F, but whether it is a *square* depends on F. Over $\mathbb{Q}$, $\mathrm{disc}(x^3 - 3x + 1) = 81$ is a square and the group is A_3; but -135 being negative is automatically a non-square in $\mathbb{Q}$, while over $\mathbb{C}$ *every* element is a square, so this criterion is only informative over fields with genuine non-squares. Also remember $D = \delta^2$ is the square; the field-theoretic content lives in $\delta = \sqrt{D}$, not in D.

14.11 Cubic Equations and the Lagrange Resolvent

Cubic equations: Galois group, Lagrange resolvent, Cardano

Let $f(x) = x^3 - c_1x^2 + c_2x - c_3$ be an irreducible cubic over a field F (characteristic $\neq 2, 3$), and let K be a splitting field of f over F, with roots $\alpha_1, \alpha_2, \alpha_3 \in K$, so

$$f(x) = (x - \alpha_1)(x - \alpha_2)(x - \alpha_3) \in K[x].$$

Because $c_1 = \alpha_1 + \alpha_2 + \alpha_3 \in F$, the third root lies in the field generated by the first two: $F(\alpha_1, \alpha_2) = F(\alpha_1, \alpha_2, \alpha_3) = K$. Setting $L = F(\alpha_1)$, irreducibility gives $[L : F] = 3$, and over L the cubic factors as $f(x) = (x - \alpha_1)q(x)$ with q the quadratic whose roots are α_2, α_3. Thus K is obtained from L by adjoining a root of a quadratic, and there are exactly two cases:

$$[K : F] = \begin{cases} 6, & q \text{ irreducible over } L \ \ (\text{then } [K : L] = 2), \\ 3, & q \text{ splits over } L \ \ (\text{then } K = L). \end{cases}$$

Remark 14.11.1. Acting on the three roots, $\mathrm{Gal}(K/F)$ embeds as a *transitive* subgroup of S_3. The only transitive subgroups of S_3 are S_3 itself and $A_3 = \langle (1\,2\,3) \rangle$, the cyclic group of order 3. So G is one of these two, matched to the two degree cases above: $[K : F] = 3 \iff G = A_3$ and $[K : F] = 6 \iff G = S_3$.

The discriminant decides the group

To tell the two cases apart without working in the awkward field L, use the square root of the discriminant, which can be read off in F itself. With $\delta = (\alpha_1 - \alpha_2)(\alpha_1 - \alpha_3)(\alpha_2 - \alpha_3)$ and $D = \delta^2$ the discriminant, three facts drive everything: $\delta \in K$; $\delta \neq 0$ (the roots are distinct, as f is separable); and a permutation of the roots multiplies δ by its sign. The last point is the whole idea: an *odd* permutation negates δ, an *even* one fixes it.

Theorem 14.11.1 (Galois theory for a cubic, after Artin 16.8.5)**.** *Let K be the splitting field of an irreducible cubic f over F, let $D = \mathrm{disc}(f)$, and let $G = \mathrm{Gal}(K/F)$.*

- *If D is a square in F, then $[K : F] = 3$ and $G \cong A_3$.*
- *If D is* not *a square in F, then $[K : F] = 6$ and $G \cong S_3$.*

Proof. We have $\delta^2 = D$, so D is a square in F exactly when $\delta \in F$. A permutation of the roots multiplies δ by its sign, so δ is fixed by every *even* element of G and negated by every *odd* one. If $\delta \in F$ then δ is fixed by all of G; hence G contains no odd permutation, forcing $G \leq A_3$. As G is transitive this gives $G = A_3$ and $[K : F] = 3$. If $\delta \notin F$ then δ is moved by some element of G, so G contains an odd permutation; a transitive subgroup of S_3 with an odd permutation must be all of S_3, so $G = S_3$ and $[K : F] = 6$. □

For a depressed cubic $x^3 + px + q$ (the x^2 term cleared by $x \mapsto x + c_1/3$), the discriminant simplifies to

$$D = -4p^3 - 27q^2.$$

The subfield lattice mirrors the subgroup lattice of G. When $G = A_3$ there are no proper intermediate fields (degree 3 is prime); when $G = S_3$ the four nontrivial proper subgroups give four proper intermediate fields, $F(\alpha_1), F(\alpha_2), F(\alpha_3)$ and $F(\delta) = F(\sqrt{D})$.

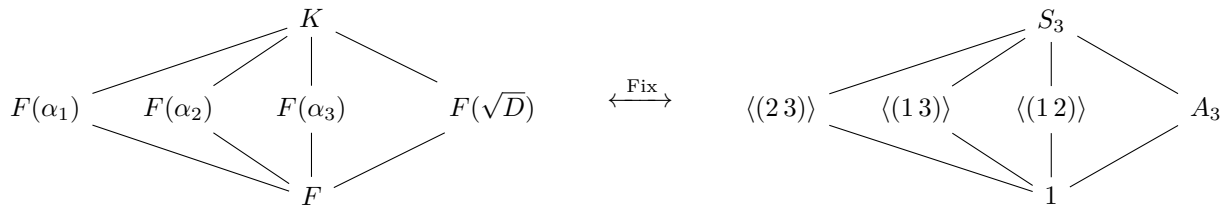

Diagram explanation. Objects: Left diagram: six nodes arranged as a lattice of *subfields* of the splitting field K over F. Top node is K (the full splitting field, degree 6 over F when $G = S_3$). The four middle nodes are $F(\alpha_1)$, $F(\alpha_2)$, $F(\alpha_3)$ (each of degree 3 over F, generated by one root) and $F(\sqrt{D})$ (degree 2 over F, the fixed field of A_3). Bottom node is F (the base field). Right diagram: six nodes arranged as the *subgroup lattice* of S_3. Top is S_3 itself, the four middle nodes are $\langle(2\,3)\rangle$, $\langle(1\,3)\rangle$, $\langle(1\,2)\rangle$ (order-2 transpositions), and A_3 (index-2 normal subgroup of order 3), and the bottom node is the trivial subgroup 1.

Arrows: All edges are drawn as unlabelled dashes, indicating *containment* (field inclusions on the left; subgroup inclusions on the right). The horizontal double arrow $\overset{\text{Fix}}{\longleftrightarrow}$ between the two diagrams is the Galois correspondence: it sends each subgroup $H \leq S_3$ to its fixed field $\text{Fix}(H) = \{x \in K : \sigma(x) = x \text{ for all } \sigma \in H\}$, and in the other direction sends each intermediate field E to $\text{Gal}(K/E)$. The correspondence *reverses* inclusion: larger subgroups correspond to smaller (lower) subfields.

What commutes: There is no loop to chase here; instead the key equalities are the index–degree pairings. For each pair (E, H) matched by Fix: $[K : E] = |H|$ and $[E : F] = [S_3 : H]$. Concretely: $\text{Fix}(\langle(2\,3)\rangle) = F(\alpha_1)$ because $(2\,3)$ swaps α_2 and α_3 while fixing α_1; $\text{Fix}(A_3) = F(\sqrt{D})$ because the even permutations fix $\delta = \sqrt{D}$; $\text{Fix}(1) = K$ and $\text{Fix}(S_3) = F$.

Why it commutes: The Fundamental Theorem of Galois Theory guarantees the correspondence is an *inclusion-reversing bijection* between the lattice of intermediate fields $F \subseteq E \subseteq K$ and the lattice of subgroups $H \leq G = S_3$, because K/F is a finite Galois extension (K is a splitting field of a separable polynomial). The sign-of-permutation argument from the proof shows δ is fixed exactly by even permutations, placing $F(\sqrt{D})$ opposite A_3; and α_i is fixed by the unique transposition that fixes index i, placing $F(\alpha_i)$ opposite $\langle(\text{the other two})\rangle$.

Why this matters here: This diagram is the payoff of Theorem 14.11.1. It makes visible, simultaneously, (a) the degree formula $[K : F] = |G| = 6$, (b) why $F(\sqrt{D})$ is the *unique* degree-2 intermediate field (corresponding to the unique index-2 subgroup A_3), and (c) why the three fields $F(\alpha_i)$ are conjugate (corresponding to the three conjugate order-2 subgroups). A student who only sees the algebraic statement gains this geometric picture of the full intermediate-field structure at a glance.

Concrete example: Take $F = \mathbb{Q}$ and $f(x) = x^3 + 3x + 1$ (Worked Example above, $D = -135$, not a square, $G = S_3$, $[K : \mathbb{Q}] = 6$). The four proper intermediate fields are $\mathbb{Q}(\alpha_1)$, $\mathbb{Q}(\alpha_2)$, $\mathbb{Q}(\alpha_3)$ (each of degree 3 and generated by a single root: one of them by the real root, the other two by the two non-real, complex-conjugate roots) and $\mathbb{Q}(\sqrt{-135}) = \mathbb{Q}(\sqrt{-15})$ (degree 2). Matching to the right diagram: $\text{Gal}(K/\mathbb{Q}(\alpha_i)) = \langle(\text{transposition fixing } i)\rangle$ and $\text{Gal}(K/\mathbb{Q}(\sqrt{-15})) = A_3$.

Common pitfall: Students often read the correspondence as *order-preserving*, thinking a *larger* subgroup corresponds to a *larger* subfield. It is order-*reversing*: the biggest proper subgroup A_3 (order 3) corresponds to the *smallest* proper intermediate field $F(\sqrt{D})$ (degree 2 over F, degree 3 below K). Also, the diagram applies only to the $G = S_3$ case (D not a square); when $G = A_3$ the lattices collapse to two-node chains ($F \subset K$ and $1 < A_3$) with no proper intermediate fields.

Takeaway: The point of this diagram is that the Galois correspondence turns the abstract group-theoretic structure of S_3 (four nontrivial proper subgroups in two conjugacy classes) into a concrete map of all intermediate fields between F and its cubic splitting field, with the discriminant field $F(\sqrt{D})$ sitting at the unique degree-2 level.

Worked Example 14.11.2 ($x^3 + 3x + 1$ has Galois group S_3)**.** Show $f(x) = x^3 + 3x + 1$ is irreducible over $\mathbb{Q}$ and determine $\text{Gal}(K/\mathbb{Q})$ and $[K : \mathbb{Q}]$.

Recognition. The cubic is already depressed ($p = 3, q = 1$); use the rational root test for irreducibility, then Theorem 14.11.1 via $D = -4p^3 - 27q^2$.

Solution. A cubic is reducible over $\mathbb{Q}$ iff it has a rational root; the only candidates are ± 1, and $f(1) = 5 \neq 0$, $f(-1) = -3 \neq 0$, so f is irreducible. The discriminant is

$$D = -4(3)^3 - 27(1)^2 = -108 - 27 = -135 = -5 \cdot 3^3.$$

This is negative, hence not a square in $\mathbb{Q}$, so by Theorem 14.11.1 we get $G = S_3$ and $[K : \mathbb{Q}] = 6$. Geometrically $f'(x) = 3x^2 + 3 > 0$ everywhere, so f is strictly increasing with a single real root; the splitting field also contains the two complex roots, confirming $[K : \mathbb{Q}] > 3$. *Check.* $D < 0$ means exactly one real root and a non-real conjugate pair, the signature of an S_3 cubic over $\mathbb{Q}$.

Worked Example 14.11.3 ($x^3 - 3x + 1$ has Galois group A_3)**.** Determine $\mathrm{Gal}(K/\mathbb{Q})$ for $g(x) = x^3 - 3x + 1$, and exhibit the cyclic structure explicitly.

Recognition. Depressed cubic with $p = -3, q = 1$; check irreducibility, then compute D and apply Theorem 14.11.1.

Solution. The candidates ± 1 give $g(1) = -1 \neq 0$ and $g(-1) = 3 \neq 0$, so g is irreducible over $\mathbb{Q}$. The discriminant is

$$D = -4(-3)^3 - 27(1)^2 = 108 - 27 = 81 = 3^4 = 9^2,$$

a square in $\mathbb{Q}$. Theorem 14.11.1 gives $G = A_3 \cong \mathbb{Z}/3\mathbb{Z}$ and $[K : \mathbb{Q}] = 3$. Concretely, if α_1 is a root then $\alpha_2 = \alpha_1^2 - 2$ is another root: indeed $g(\alpha_1^2 - 2) = (\alpha_1^2 - 2)^3 - 3(\alpha_1^2 - 2) + 1$ reduces to 0 after using $\alpha_1^3 = 3\alpha_1 - 1$. Hence $K = \mathbb{Q}(\alpha_1)$ already, with the generator of G sending $\alpha_1 \mapsto \alpha_1^2 - 2$. *Check.* $\delta = \sqrt{81} = 9 \in \mathbb{Q}$, so no automorphism can negate δ; G contains only even permutations, i.e. $G = A_3$, consistent with $K = \mathbb{Q}(\alpha_1)$ being all of the splitting field.

The Lagrange resolvent and Cardano's formula

Now suppose $F \subseteq \mathbb{C}$ contains $\omega = e^{2\pi i/3}$, a primitive cube root of unity ($1 + \omega + \omega^2 = 0$). For a depressed irreducible cubic with $G = A_3 = \langle \sigma \rangle$, $\sigma = (1\,2\,3)$, Kummer's theorem says $K = F(\beta)$ with $\beta^3 \in F$; the eigenvector β is produced by a *Lagrange resolvent*. Following Artin's normalization, write the cubic as

$$f(x) = x^3 + 3px + 2q, \qquad s_1 = 0,\ s_2 = 3p,\ s_3 = -2q, \qquad D = -2^2 3^3 (q^2 + p^3),$$

with roots m_1, m_2, m_3 (numbered arbitrarily). Set the two resolvents

$$z = m_1 + \omega m_2 + \omega^2 m_3, \qquad z' = m_1 + \omega^2 m_2 + \omega m_3.$$

Proposition 14.11.4 (resolvents are eigenvectors)**.** *For $\sigma = (1\,2\,3)$ one has $\sigma(z) = \omega^{-1} z$ and $\sigma(z') = \omega z'$. Consequently z^3 and z'^3 are fixed by σ, hence lie in F, and*

$$m_1 = \tfrac{1}{3}(s_1 + z + z') = \tfrac{1}{3}(z + z').$$

Proof. The automorphism σ permutes the roots cyclically, $m_1 \mapsto m_2 \mapsto m_3 \mapsto m_1$, and fixes $\omega \in F$. Therefore

$$\sigma(z) = m_2 + \omega m_3 + \omega^2 m_1 = \omega^2(m_1 + \omega m_2 + \omega^2 m_3) = \omega^2 z = \omega^{-1} z,$$

using $\omega^3 = 1$. The same computation with ω and ω^2 swapped gives $\sigma(z') = \omega z'$. Cubing, $\sigma(z^3) = (\omega^{-1})^3 z^3 = z^3$ and likewise $\sigma(z'^3) = z'^3$; since σ generates G, both z^3, z'^3 lie in the fixed field F. Finally $z + z' = (m_1 + m_1) + (\omega + \omega^2)m_2 + (\omega^2 + \omega)m_3 = 2m_1 - m_2 - m_3$, and adding $s_1 = m_1 + m_2 + m_3 = 0$ gives $z + z' = 3m_1$, i.e. $m_1 = \frac{1}{3}(z + z')$. □

To evaluate z^3 and z'^3 explicitly, Artin introduces the two sums (each fixed by σ and interchanged by every transposition)

$$A = m_1^2 m_2 + m_2^2 m_3 + m_3^2 m_1, \qquad B = m_1 m_2^2 + m_2 m_3^2 + m_3 m_1^2,$$

which satisfy

$$A - B = (m_1 - m_2)(m_1 - m_3)(m_2 - m_3) = \delta = \sqrt{D}, \qquad A + B = s_1 s_2 - 3s_3 = 6q,$$

together with $m_1^3 + m_2^3 + m_3^3 = s_1^3 - 3s_1 s_2 + 3s_3 = -6q$. Solving for A, B and expanding z^3, z'^3 collapses everything into p, q and $\sqrt{q^2 + p^3}$. The result is *Cardano's formula.*

Theorem 14.11.5 (Cardano, after Artin 16.11.4–16.11.5)**.** *A root of $x^3 + 3px + 2q$ is*

$$m_1 = \sqrt[3]{-q + \sqrt{q^2 + p^3}} + \sqrt[3]{-q - \sqrt{q^2 + p^3}},$$

the two cube roots being chosen so that their product equals $-p$.

Sketch. By Proposition 14.11.4, z^3 and z'^3 are the two roots of a quadratic over F – the *resolvent quadratic* – whose coefficients are symmetric in the m_i up to δ. Carrying out the elimination using $A - B = \delta$ and $A + B = 6q$ shows

$$z^3,\ z'^3 = 27\big(-q \pm \sqrt{q^2 + p^3}\big),$$

so $z = 3\sqrt[3]{-q + \sqrt{q^2 + p^3}}$ and $z' = 3\sqrt[3]{-q - \sqrt{q^2 + p^3}}$. Substituting into $m_1 = \frac{1}{3}(z + z')$ yields the stated sum of cube roots. The product constraint $zz' = 9\sqrt[3]{q^2 - (q^2 + p^3)} = -9p$ (equivalently the cube-root product $= -p$) selects the three correct pairings out of the nine formal ones, giving exactly the three roots m_1, m_2, m_3. □

Remark 14.11.2. The formula is genuinely *ambiguous* if read naively: the inner square root has two values, and each cube root has three, so the right-hand term can be read six ways, as can the other – yet f has only three roots. The product condition $zz' = -9p$ (cube roots multiplying to $-p$) is what cuts the 9 formal pairings down to the 3 true roots. This is why a radical expression for a root, on its own, is of limited practical use.

Worked Example 14.11.6 (Cardano on x^3+3x+2)**.** Use Theorem 14.11.5 to write a root of $f(x) = x^3+3x+2$ in radicals.

Recognition. Match $x^3 + 3px + 2q$: here $3p = 3$ and $2q = 2$, so $p = 1, q = 1$; then plug into the boxed formula.

Solution. With $p = q = 1$ we get $q^2 + p^3 = 1 + 1 = 2$, so

$$m_1 = \sqrt[3]{-1 + \sqrt{2}} + \sqrt[3]{-1 - \sqrt{2}}.$$

The discriminant is $D = -2^2 3^3 (q^2 + p^3) = -4 \cdot 27 \cdot 2 = -216 < 0$, not a square, so $G = S_3$ over $\mathbb{Q}$ and the two cube-root terms are genuinely needed (one real root, two complex). *Check.* Numerically $-1 + \sqrt{2} \approx 0.4142$ and $-1 - \sqrt{2} \approx -2.4142$, with real cube roots ≈ 0.7454 and ≈ -1.3415; their sum ≈ -0.596 satisfies $(-0.596)^3 + 3(-0.596) + 2 \approx -0.21 - 1.79 + 2 \approx 0$. The cube roots' product is $\sqrt[3]{(-1)^2 - 2} = \sqrt[3]{-1} = -1 = -p$, as required.

Worked Example 14.11.7 (Deriving a root of $x^3 - 3x + 1$ through the resolvent)**.** For $g(x) = x^3 - 3x + 1$ (the A_3 cubic above), set up the resolvent and read off $m_1 = \frac{1}{3}(z + z')$.

Recognition. Write g as $x^3 + 3px + 2q$: then $3p = -3$ and $2q = 1$, so $p = -1$, $q = \frac{1}{2}$; apply Theorem 14.11.5 with these values, working over $F = \mathbb{Q}(\omega)$ so that z, z' exist.

Solution. Here $q^2 + p^3 = \frac{1}{4} - 1 = -\frac{3}{4}$, so the inner square root is $\sqrt{-3/4} = \frac{\sqrt{-3}}{2}$, which lies in $\mathbb{Q}(\omega)$ since $\sqrt{-3} = \omega - \omega^2 \in \mathbb{Q}(\omega)$. Then

$$z^3 = 27\big(-\tfrac{1}{2} + \tfrac{\sqrt{-3}}{2}\big) = 27\,\omega, \qquad z'^3 = 27\big(-\tfrac{1}{2} - \tfrac{\sqrt{-3}}{2}\big) = 27\,\omega^2,$$

because $-\frac{1}{2} \pm \frac{\sqrt{-3}}{2} = \omega, \omega^2$ exactly. Choosing $z = 3\sqrt[3]{\omega}$ and $z' = 3\sqrt[3]{\omega^2}$ with $zz' = -9p = 9$, a root is

$$m_1 = \tfrac{1}{3}(z + z') = \sqrt[3]{\omega} + \sqrt[3]{\omega^2} = 2\cos\Big(\tfrac{2\pi}{9}\Big) \approx 1.532.$$

Check. $D = 81 = 9^2$ is a square, confirming $G = A_3$; the resolvent cubes $z^3 = 27\omega$ and $z'^3 = 27\omega^2$ are 27 times the primitive cube roots of unity, so $z^3 z'^3 = 27^2$ matches $(zz')^3 = 9^3 = 729 = 27^2$. Numerically $g(1.532) \approx 3.596 - 4.596 + 1 \approx 0$.

Caution. The clean cube-root form requires $\omega \in F$. The discriminant test (Theorem 14.11.1) lives over the original F, but the Lagrange resolvent only diagonalizes σ after adjoining ω. For an A_3 cubic over $\mathbb{Q}$ such as $x^3 - 3x + 1$, the splitting field $K = \mathbb{Q}(\alpha_1)$ is real and does *not* contain ω; Cardano's formula then expresses the real root as a sum of cube roots of *complex* numbers (the casus irreducibilis), even though the root itself is real. The detour through non-real numbers is unavoidable: in the casus irreducibilis no expression of the root by real radicals exists.

14.12 Quartic Equations and the Resolvent Cubic

Quartic equations and the resolvent cubic

For a quartic the Galois group is hard to pin down by degree alone. Throughout this section F is a field of characteristic $\neq 2$. Let $f(x) \in F[x]$ be an irreducible separable quartic with (distinct) roots $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ in a splitting field K. Acting on the four roots represents $G = \mathrm{Gal}(K/F)$ as a *transitive* subgroup of S_4, and there are only five such up to conjugacy:

$$S_4, \quad A_4, \quad D_4, \quad C_4, \quad V_4.$$

Here D_4 is the dihedral group of order 8 (this is D&F's D_8), realized as the symmetries of the square 1 2 3 4; there are three conjugate copies of D_4 and three of C_4. The group $V_4 = \{\, e, (12)(34), (13)(24), (14)(23) \,\}$ is the Klein four-group of double transpositions – a *normal* subgroup of S_4 (Artin writes it D_2). The orders are $|S_4| = 24$, $|A_4| = 12$, $|D_4| = 8$, $|C_4| = |V_4| = 4$, so $|G| = [K : F]$ already separates S_4, A_4, D_4 but leaves the pair $\{C_4, V_4\}$ of order 4 undecided – and the order is itself awkward to compute. To resolve everything Artin uses two auxiliary quantities built from the roots: the square root of the discriminant, and Lagrange's *resolvent cubic*.

Definition 14.12.1. The *discriminant* of f is $D = \delta^2$, where

$$\delta = \prod_{i<j} (\alpha_i - \alpha_j) = (\alpha_1 - \alpha_2)(\alpha_1 - \alpha_3)(\alpha_1 - \alpha_4)(\alpha_2 - \alpha_3)(\alpha_2 - \alpha_4)(\alpha_3 - \alpha_4).$$

The roots being distinct, $\delta \neq 0$. A permutation σ of the roots multiplies δ by $\mathrm{sgn}(\sigma)$: even permutations fix δ, odd permutations negate it.

Proposition 14.12.2 (discriminant test, Artin 16.9.5)**.** *Let G be the Galois group of an irreducible quartic f. Then D is a square in F if and only if G contains no odd permutation. Consequently:*

- *If D is a square in F, then G is A_4 or V_4.*
- *If D is not a square in F, then G is S_4, D_4, or C_4.*

Proof. $D = \delta^2$ is a square in F exactly when $\delta \in F$, i.e. when δ is fixed by every element of G. The permutations fixing δ are precisely the even ones, so D is a square iff $G \leq A_4$. Among the five transitive subgroups, those lying in A_4 are A_4 itself and V_4 (its elements $(ij)(kl)$ are even); the ones containing an odd permutation are S_4, D_4 (which contains 4-cycles and transpositions, both odd), and C_4 (a 4-cycle is odd). Reading off the list of five transitive subgroups above gives the two cases. □

Remark 14.12.1. The same argument works in any degree: for an irreducible separable f of degree n over a field F of characteristic $\neq 2$, the group $\mathrm{Gal}(K/F) \leq A_n$ if and only if $\mathrm{disc}(f)$ is a square in F (Artin 16.9.6). The discriminant detects "even versus odd," nothing finer.

The discriminant alone cannot separate A_4 from V_4, nor S_4 from the pair $\{D_4, C_4\}$. Lagrange's expression, special to quartics, does the rest.

Definition 14.12.3. With the roots numbered $\alpha_1, \ldots, \alpha_4$, form the three *sums of opposite root-pairs*

$$\beta_1 = \alpha_1\alpha_2 + \alpha_3\alpha_4, \qquad \beta_2 = \alpha_1\alpha_3 + \alpha_2\alpha_4, \qquad \beta_3 = \alpha_1\alpha_4 + \alpha_2\alpha_3,$$

and set

$$g(x) = (x - \beta_1)(x - \beta_2)(x - \beta_3).$$

This g is the *resolvent cubic* of f.

Every permutation of $\alpha_1, \dots, \alpha_4$ merely permutes $\beta_1, \beta_2, \beta_3$ among themselves, so the coefficients of g are symmetric in the roots, hence elements of F: $g(x) \in F[x]$. Explicitly, if $f(x) = x^4 + px^2 + qx + r$ (we may depress to remove the cubic term), then

$$g(x) = x^3 - p\,x^2 - 4r\,x + (4pr - q^2).$$

Lemma 14.12.4 (the β_i are distinct)**.** *If the roots of f are distinct, then $\beta_1, \beta_2, \beta_3$ are distinct, so g has no repeated root.*

Proof. A short factorization does it:

$$\beta_1 - \beta_2 = \alpha_1\alpha_2 + \alpha_3\alpha_4 - \alpha_1\alpha_3 - \alpha_2\alpha_4 = (\alpha_1 - \alpha_4)(\alpha_2 - \alpha_3),$$

which is nonzero because the α_i are distinct; symmetrically $\beta_1 - \beta_3 = (\alpha_1 - \alpha_3)(\alpha_2 - \alpha_4)$ and $\beta_2 - \beta_3 = (\alpha_1 - \alpha_2)(\alpha_3 - \alpha_4)$ are nonzero. In fact multiplying these three differences reproduces $\pm\delta$, so $\operatorname{disc}(g) = \operatorname{disc}(f)$: the resolvent cubic has the *same* discriminant as f. □

The map $\sigma \mapsto$ (induced permutation of $\beta_1, \beta_2, \beta_3$) is a homomorphism $\varphi\colon S_4 \to S_3$, the classical surjection of Artin (2.5.13), whose kernel is exactly V_4. The behaviour of g therefore reports on the image $\varphi(G) \le S_3$, which is $G/(G \cap V_4)$.

Theorem 14.12.5 (resolvent cubic test, Artin 16.9.8)**.** *Let G be the Galois group of an irreducible quartic f with resolvent cubic g. Then g is irreducible over F if and only if $3 \mid |G|$. Moreover:*

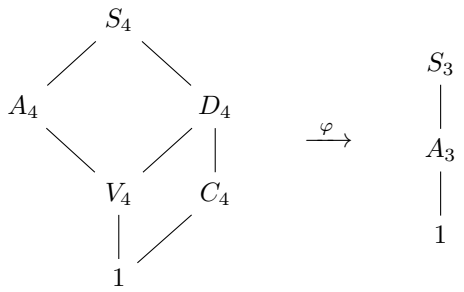
- *if g splits completely in F, then $G = V_4$;*
- *if g has exactly one root in F, then $G = D_4$ or C_4;*
- *if g is irreducible over F, then $G = S_4$ or A_4.*

Proof. Let $B = \{\, \beta_1, \beta_2, \beta_3 \,\}$, a set of size 3 by the Lemma. The action of S_4 on B is transitive with kernel V_4, giving $\varphi\colon S_4 \to S_3$. The roots of g are the β_i, so g splits in F iff G fixes every β_i, i.e. iff $G \le \ker\varphi = V_4$; since G is a transitive subgroup, this forces $G = V_4$.

If g is irreducible over F, then G acts transitively on its roots B, so $\varphi(G)$ is a transitive subgroup of S_3 and $3 \mid |\varphi(G)| \mid |G|$. Conversely, if $3 \mid |G|$ then G contains an element ρ of order 3 (Cauchy); $\rho \notin V_4 = \ker\varphi$, so $\varphi(\rho)$ is a 3-cycle permuting B cyclically, whence G acts transitively on B and g is irreducible. The transitive subgroups with $3 \mid |G|$ are exactly S_4 and A_4. The remaining case – g has one root in F and the other two are conjugate over a quadratic – leaves G of order divisible by 2 but not 3 and not all of V_4, which by the list of five transitive subgroups means $G = D_4$ or C_4. □

Combining the two tests yields Artin's classification table (16.9.9).

Method (Identifying $\mathrm{Gal}(f/F)$ for an irreducible quartic.)**.** (1) Compute the discriminant D and decide whether it is a square in F.



(2) Form the resolvent cubic g and find its factorization type over F (split / one root / irreducible).

(3) Read off G from the table:

	D a square	D not a square
g reducible	V_4	D_4 or C_4
g irreducible	A_4	S_4

The one residual ambiguity (D_4 vs. C_4, when D is not a square and g has a single root in F) is not resolved by any symmetric expression in the roots; one decides it directly, e.g. by checking whether f stays irreducible over $F(\sqrt{D})$, or whether a product like $\alpha_i\alpha_j$ lies in the relevant quadratic field.

The homomorphism $\varphi\colon S_4 \to S_3$ underlying the whole method is best pictured as a quotient lattice, with $V_4 = \ker\varphi$ at the bottom:

Under φ: $S_4 \twoheadrightarrow S_3$, $A_4 \twoheadrightarrow A_3 = C_3$, while D_4, C_4, V_4 all map into a single transposition-or-trivial image, which is why g fails to be irreducible exactly for these.

Diagram explanation. Objects: The left lattice has six nodes: the group S_4 (order 24) at the top; its subgroups A_4 (order 12, alternating) and D_4 (order 8, dihedral, one of three conjugate copies); then the Klein four-group $V_4 = \{e, (12)(34), (13)(24), (14)(23)\}$ (order 4, normal in S_4) and the cyclic C_4 (order 4); and the trivial group 1 at the bottom. The right lattice has three nodes: S_3 (order 6) at top, $A_3 = C_3$ (order 3, even permutations of the β_i) in the middle, and 1 at the bottom. The horizontal arrow φ between the two lattices is the surjective group homomorphism induced by the action of S_4 on $\{\beta_1, \beta_2, \beta_3\}$.

Arrows: Dashes in both lattices are inclusion arrows (subgroup containment), pointing downward by convention. The arrow $\xrightarrow{\varphi}$ between the diagrams is the surjection $\varphi\colon S_4 \twoheadrightarrow S_3$ sending each $\sigma \in S_4$ to the permutation it induces on the resolvent roots $\beta_1, \beta_2, \beta_3$; this is an induced map, and its kernel is precisely V_4 (the elements fixing all β_i).

What commutes: This is not a commutativity diagram but a correspondence diagram: the left lattice restricted to $G = \mathrm{Gal}(f/F) \le S_4$ maps via φ onto a subgroup $\varphi(G) \le S_3$, with $G \cap V_4 = \ker(\varphi|_G)$, yielding an isomorphism $G/(G \cap V_4) \cong \varphi(G)$. The key containments: $\varphi(S_4) = S_3$, $\varphi(A_4) = A_3$, $\varphi(V_4) = 1$, and $\varphi(D_4) = \varphi(C_4)$ is a subgroup of order 2 generated by a transposition (not all of S_3).

Why it commutes: Well-definedness of φ: we need $\sigma(\beta_i)$ to depend only on σ and not on a choice of representative, which is automatic since σ acts on roots directly. The key check is that $V_4 \trianglelefteq S_4$: any conjugate of an element of V_4 is again a double transposition, so V_4 is normal and $S_4/V_4 \cong S_3$ is a genuine quotient. For $\sigma \in D_4$ or C_4: these groups intersect V_4 in a subgroup of order ≥ 2, so $\varphi(\sigma)$ generates a proper subgroup of S_3 – it cannot act transitively on $\{\beta_1, \beta_2, \beta_3\}$.

Why this matters here: Immediately after the classification method, this diagram explains *why* the resolvent cubic g detects $3 \mid |G|$: g is irreducible iff G acts transitively on $\{\beta_1, \beta_2, \beta_3\}$ iff $\varphi(G)$ is transitive in S_3 iff $3 \mid |\varphi(G)|$ iff $3 \mid |G|$. The lattice picture makes visible exactly which of the five transitive subgroups of S_4 have 3-power in their image.

Concrete example: Take $G = A_4$. Its image $\varphi(A_4) = A_3 = C_3$ is transitive (order 3), so g is irreducible. Take $G = V_4$: $\varphi(V_4) = \{e\}$ (all elements are double transpositions fixing every β_i), so g splits completely. Take $G = D_4$: $\varphi(D_4)$ is generated by a single transposition, a subgroup of order 2 in S_3; transitivity fails, so g has exactly one rational root. These match the three rows of the classification table.

Common pitfall: Students often read the left lattice as a single subgroup chain $S_4 \supset A_4 \supset V_4 \supset 1$ and ignore D_4 and C_4. But the whole point of the diagram is that D_4 and C_4 *do not contain* A_4; they sit on a separate branch on the right, where D_4 contains V_4 but $C_4 \le D_4$ does not. Collapsing D_4 and C_4 into the A_4-chain gives the wrong lattice and misses the D_4/C_4 ambiguity entirely.

Takeaway: The point of this diagram is that the surjection $\varphi\colon S_4 \twoheadrightarrow S_3$ with kernel V_4 converts the question "which of the five transitive Galois groups does f have?" into the question "where does G sit in S_3?", and the resolvent cubic g reads off exactly that image by whether it is irreducible, has one root, or splits.

Worked Example 14.12.6 (A quartic with group D_4: $x^4 - 8x^2 + 11$)**.** Let $F = \mathbb{Q}$ and $\alpha = \sqrt{4 + \sqrt{5}}$, the nested radical. Verify $f(x) = x^4 - 8x^2 + 11$ is the minimal polynomial of α and show $\mathrm{Gal}(f/\mathbb{Q}) = D_4$ (order 8).

Recognition. Run the method. The roots are $\pm\alpha, \pm\alpha'$ with $\alpha' = \sqrt{4-\sqrt{5}}$; compute D (not a square) and g (one rational root), landing in the D_4-or-C_4 box, then break the tie via the degree $[K:\mathbb{Q}]$.

Solution. Guessing the roots $\pm\alpha, \pm\alpha'$ with $\alpha' = \sqrt{4-\sqrt{5}}$ and expanding,

$$f(x) = (x-\alpha)(x+\alpha)(x-\alpha')(x+\alpha') = (x^2-(4+\sqrt{5}))(x^2-(4-\sqrt{5})) = x^4 - 8x^2 + 11,$$

since $\alpha^2 + \alpha'^2 = 8$ and $\alpha^2\alpha'^2 = (4+\sqrt{5})(4-\sqrt{5}) = 16-5 = 11$. This f is irreducible over $\mathbb{Q}$ (it has no rational root, and no factorization into two rational quadratics: a factorization would be $(x^2+a)(x^2+b)$ with $a, b = -4 \pm \sqrt{5} \notin \mathbb{Q}$, or $(x^2+cx+d)(x^2-cx+d)$ with $d^2 = 11$, impossible over $\mathbb{Q}$). Number the roots $\alpha_1 = \alpha, \alpha_2 = \alpha', \alpha_3 = -\alpha, \alpha_4 = -\alpha'$.

Discriminant. The opposite-pair products are $\alpha_1\alpha_3 = -\alpha^2 = -(4+\sqrt{5})$ and $\alpha_2\alpha_4 = -\alpha'^2 = -(4-\sqrt{5})$, etc. For $f = x^4 + px^2 + qx + r$ with $p = -8, q = 0, r = 11$, the discriminant of a biquadratic $x^4 + px^2 + r$ is $16r(p^2-4r)^2 = 16 \cdot 11 \cdot (64-44)^2 = 176 \cdot 400 = 70400$, which is not a perfect square ($265^2 = 70225$, $266^2 = 70756$). So D is not a square in $\mathbb{Q}$: G is S_4, D_4, or C_4.

Resolvent cubic. With $p = -8, q = 0, r = 11$,

$$g(x) = x^3 - px^2 - 4rx + (4pr - q^2) = x^3 + 8x^2 - 44x - 352 = (x+8)(x^2-44),$$

which has exactly one rational root, $\beta = -8$ (since $\sqrt{44} \notin \mathbb{Q}$). One root in F puts $G \in \{D_4, C_4\}$.

Breaking the tie. Here $\alpha^2 = 4+\sqrt{5} \in \mathbb{Q}(\alpha)$, so $\sqrt{5} = \alpha^2 - 4 \in \mathbb{Q}(\alpha)$; and $\alpha\alpha' = \sqrt{(4+\sqrt{5})(4-\sqrt{5})} = \sqrt{11}$. We test whether $\alpha' \in \mathbb{Q}(\alpha)$: if it were, $\sqrt{11} = \alpha\alpha' \in \mathbb{Q}(\alpha)$, giving two independent quadratic subfields $\mathbb{Q}(\sqrt{5}), \mathbb{Q}(\sqrt{11})$ inside the degree-4 field $\mathbb{Q}(\alpha)$, forcing V_4 – but V_4 needs D a square, contradiction. So $\alpha' \notin \mathbb{Q}(\alpha)$, hence $[K:\mathbb{Q}(\alpha)] = 2$ and $[K:\mathbb{Q}] = 8$. The order-8 option in the $\{D_4, C_4\}$ box is D_4. Therefore $\mathrm{Gal}(f/\mathbb{Q}) = D_4$. *Check.* $|D_4| = 8 = [K:\mathbb{Q}]$, matching $K = \mathbb{Q}(\alpha, \alpha') = \mathbb{Q}(\sqrt{5}, \sqrt{11}, \alpha)$; the fixed field of $\rho = (13)(24)$ contains $\alpha^2 = 4+\sqrt{5}$ and $\alpha\alpha' = \sqrt{11}$, i.e. $\mathbb{Q}(\sqrt{5}, \sqrt{11})$ of degree 4, exactly the order-2 subgroup's fixed field – consistent.

Worked Example 14.12.7 (A quartic with group S_4: $x^4 - x - 1$)**.** Show $f(x) = x^4 - x - 1$ over $\mathbb{Q}$ has $\mathrm{Gal}(f/\mathbb{Q}) = S_4$.

Recognition. Method again: irreducibility, then D not a square and g irreducible places us in the bottom-right S_4 box.

Solution. Irreducible. f has no rational root ($f(\pm 1) = \mp 1 - 1 + \cdots \neq 0$: $f(1) = -1$, $f(-1) = 1$). Reducing mod 2, $x^4 + x + 1$ is irreducible over $\mathbb{F}_2$ (it has no root in $\mathbb{F}_2$ and is not $(x^2+x+1)^2 = x^4 + x^2 + 1$), so f is irreducible over $\mathbb{Q}$.

Discriminant. For the depressed quartic $x^4 + qx + r$ (here $p = 0, q = -1, r = -1$) the discriminant is $-27q^4 + 256r^3 = -27(1) + 256(-1) = -27 - 256 = -283$. A negative number is not a square in $\mathbb{Q}$, so D is not a square: $G \in \{S_4, D_4, C_4\}$.

Resolvent cubic. With $p = 0, q = -1, r = -1$,

$$g(x) = x^3 - px^2 - 4rx + (4pr - q^2) = x^3 + 4x - 1.$$

By the rational root test the only candidates are ± 1, and $g(1) = 4$, $g(-1) = -6$, neither zero; a cubic with no rational root is irreducible over $\mathbb{Q}$. Irreducible g puts $G \in \{S_4, A_4\}$.

Combining the two reductions: D not a square rules out A_4, and g irreducible rules out D_4, C_4. The only survivor is $\mathrm{Gal}(f/\mathbb{Q}) = S_4$. *Check.* $|S_4| = 24$, so $[K:\mathbb{Q}] = 24$; since $\mathrm{disc}(g) = \mathrm{disc}(f) = -283$ is not a square, $\mathrm{Gal}(g/\mathbb{Q}) = S_3$, consistent with $\varphi(S_4) = S_3$ and the bottom-right cell of the table.

Worked Example 14.12.8 (A quartic with group V_4: $x^4 - 8x^2 + 9$)**.** Let $\alpha = \sqrt{4+\sqrt{7}}$, with minimal polynomial $x^4 - 8x^2 + 9$. Show $\mathrm{Gal}(f/\mathbb{Q}) = V_4$.

Recognition. Biquadratic with $\alpha\alpha'$ rational forces all roots into $\mathbb{Q}(\alpha)$, so $[K:\mathbb{Q}] = 4$; the resolvent cubic should split completely.

Solution. Here $\alpha' = \sqrt{4-\sqrt{7}}$ and $\alpha\alpha' = \sqrt{16-7} = \sqrt{9} = 3 \in \mathbb{Q}$. So $\alpha' = 3/\alpha \in \mathbb{Q}(\alpha)$, whence $K = \mathbb{Q}(\alpha)$ has degree 4 and $|G| = 4$: G is C_4 or V_4.

Resolvent cubic. With $p = -8, q = 0, r = 9$,

$$g(x) = x^3 + 8x^2 - 36x - 288 = (x+8)(x^2-36) = (x+8)(x-6)(x+6),$$

which splits completely in $\mathbb{Q}$. By the theorem $G = V_4$. *Check.* $D = 16r(p^2-4r)^2 = 16 \cdot 9 \cdot (64-36)^2 = 144 \cdot 784 = 112896 = 336^2$, a perfect square, so D is a square in $\mathbb{Q}$ – consistent with $V_4 \leq A_4$ and with the top-left cell of the table. The degree-4 field $K = \mathbb{Q}(\sqrt{7}, \alpha)$ has three index-2 subfields, fixed by the three double transpositions: the hallmark of V_4.

Caution. The labels are a perennial trap. Artin's D_4 is the dihedral group of *order* 8 (D&F's D_8), and his D_2 is the Klein four-group V_4 of order 4. When you read off the table, match by *order* and by the resolvent's factorization, not by the name alone. A second trap: the resolvent cubic test classifies G only *up to the D_4 vs. C_4 ambiguity*; no symmetric function in the roots distinguishes those two, so that last step always needs an explicit degree or subfield computation.

14.13 Graded Problem Bank

Easy

DF 14.1.2 Let $\tau : \mathbb{C} \to \mathbb{C}$ be $\tau(a+bi) = a - bi$ (complex conjugation). Prove τ is an automorphism of $\mathbb{C}$.

DF 14.1.3 Determine the fixed field of complex conjugation on $\mathbb{C}$.

DF 14.1.4 Prove that $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{3})$ are not isomorphic.

DF 14.1.5 Determine explicitly the automorphisms of $\mathbb{Q}(\sqrt[4]{2})/\mathbb{Q}(\sqrt{2})$.

DF 14.1.9 Determine the fixed field of the automorphism $t \mapsto t+1$ of $k(t)$.

DF 14.2.1 Determine the minimal polynomial over $\mathbb{Q}$ of $\sqrt{2} + \sqrt{5}$.

DF 14.2.2 Determine the minimal polynomial over $\mathbb{Q}$ of $1 + \sqrt[3]{2} + \sqrt[3]{4}$.

DF 14.2.4 For a prime p, determine the elements of the Galois group of $x^p - 2$.

DF 14.3.1 Factor $x^8 - x$ into irreducibles in $\mathbb{Z}[x]$ and in $\mathbb{F}_2[x]$.

DF 14.3.2 Write out the multiplication tables for $\mathbb{F}_4$ and $\mathbb{F}_8$.

DF 14.3.3 Prove that an algebraically closed field must be infinite.

DF 14.5.4 Show that $\sigma_a \in \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$, defined by $\zeta_n \mapsto \zeta_n^a$ with $(a,n) = 1$, satisfies $\sigma_a(\zeta) = \zeta^a$ for every nth root of unity ζ.

DF 14.6.1 Show that a cubic in $\mathbb{Q}[x]$ with a multiple root has a linear factor. Is the same true for quartics?

DF 14.6.4 Determine the Galois group over $\mathbb{Q}$ of $x^4 - 25$.

DF 14.6.5 Determine the Galois group over $\mathbb{Q}$ of $x^4 + 4$.

DF 14.6.11 Show that an extension $F/\mathbb{Q}$ of degree 4 can be generated by a root of an irreducible biquadratic $x^4 + ax^2 + b$ if and only if F contains a quadratic extension of $\mathbb{Q}$.

DF 14.7.9 Let p, q, r be primes with $q \neq r$. Prove that $\mathbb{Q}(\sqrt[p]{q}) \neq \mathbb{Q}(\sqrt[p]{r})$.

Artin 2.1 Prove that the discriminant of a polynomial is a symmetric function of its roots.

Artin 2.2a Prove that the discriminant of a real cubic is non-negative if and only if the cubic has three real roots.

Artin 2.4 Use undetermined coefficients to determine the discriminant of $x^3 + px + q$, of $x^4 + px + q$, and of $x^5 + px + q$.

Artin 3.1 Let f have degree n with coefficients in F and let K be a splitting field of f over F. Prove that $[K : F]$ divides $n!$.

Artin 3.2 Determine the degrees of the splitting fields over $\mathbb{Q}$ of $x^3 - 2$, $x^4 - 1$, and $x^4 + 1$.

Artin 4.1a Determine all automorphisms of the field $\mathbb{Q}(\sqrt[3]{2})$ and of the field $\mathbb{Q}(\sqrt[3]{2}, \omega)$, where $\omega = e^{2\pi i/3}$.

Artin 6.2 Let $K = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$. Determine $[K : \mathbb{Q}]$, prove $K/\mathbb{Q}$ is Galois, and determine its Galois group.

Artin 7.4 Let $F = \mathbb{Q}$ and $K = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$. Determine all intermediate fields.

Artin 7.7a Determine the irreducible polynomial for $i + \sqrt{2}$ over $\mathbb{Q}$.

Artin 7.7b Prove that $\{1, i, \sqrt{2}, i\sqrt{2}\}$ is a basis for $\mathbb{Q}(i, \sqrt{2})$ over $\mathbb{Q}$.

Artin 8.2 Determine the Galois groups over $\mathbb{Q}$ of: (a) $x^3 - 2$; (b) $x^3 + 3x + 14$; (c) $x^3 - 3x^2 + 1$; (d) $x^3 - 21x + 7$; (e) $x^3 + x^2 - 2x - 1$; (f) $x^3 + x^2 - 2x + 1$.

Artin 9.6 Compute the discriminant of $x^4 + 1$ and determine its Galois group over $\mathbb{Q}$.

Artin 10.1 Determine the degree of ζ_7 over the field $\mathbb{Q}(\zeta_3)$.

Artin 10.3 Let $\zeta = \zeta_7$. Determine the degree over $\mathbb{Q}$ of (a) $\zeta + \zeta^5$; (b) $\zeta^3 + \zeta^4$; (c) $\zeta^3 + \zeta^5 + \zeta^6$.

Artin 10.8 Determine the Galois groups of $x^8 - 1$, $x^{12} - 1$, and $x^9 - 1$.

Artin 12.1 Is every Galois extension of degree 10 solvable?

Artin 12.2 Determine the transitive subgroups of S_5.

Fraleigh 43.1 Find all conjugates in $\mathbb{C}$ of $\sqrt{2}$ over $\mathbb{Q}$.

Fraleigh 43.2 Find all conjugates in $\mathbb{C}$ of $\sqrt{2}$ over $\mathbb{R}$.

Fraleigh 43.3 Find all conjugates in $\mathbb{C}$ of $3 + \sqrt{2}$ over $\mathbb{Q}$.

Fraleigh 43.4 Find all conjugates in $\mathbb{C}$ of $\sqrt{2} - \sqrt{3}$ over $\mathbb{Q}$.

Fraleigh 43.5 Find all conjugates in $\mathbb{C}$ of $\sqrt{2} + i$ over $\mathbb{Q}$.

Fraleigh 43.6 Find all conjugates in $\mathbb{C}$ of $\sqrt{2} + i$ over $\mathbb{R}$.

Fraleigh 43.7 Find all conjugates in $\mathbb{C}$ of $\sqrt{1 + \sqrt{2}}$ over $\mathbb{Q}$.

Fraleigh 43.8 Find all conjugates in $\mathbb{C}$ of $\sqrt{1 + \sqrt{2}}$ over $\mathbb{Q}(\sqrt{2})$.

Fraleigh 43.9 With $E = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$ and τ_2, τ_3, τ_5 the sign-changing automorphisms, compute $\tau_2(\sqrt{3})$.

Fraleigh 43.10 Compute $\tau_2(\sqrt{2} + \sqrt{5})$.

Fraleigh 43.11 Compute $(\tau_3\tau_2)(\sqrt{2} + 3\sqrt{5})$.

Fraleigh 43.12 Compute $(\tau_5\tau_3)\big((\sqrt{2} - 3\sqrt{5})/(2\sqrt{3} - \sqrt{2})\big)$.

Fraleigh 43.13 Compute $(\tau_5^2\tau_3\tau_2)(\sqrt{2} + \sqrt{45})$.

Fraleigh 43.14 Compute $\tau_3[\tau_5(\sqrt{2} - \sqrt{3}) + (\tau_2\tau_5)(\sqrt{30})]$.

Fraleigh 43.15 Compute $\tau_3\tau_5\tau_3^{-1}(\sqrt{3} - \sqrt{5})$.

Fraleigh 43.16 Find the fixed field of τ_3 in $E = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$.

Fraleigh 43.17 Find the fixed field of τ_3^2.

Fraleigh 43.18 Find the fixed field of $\{\tau_2, \tau_3\}$.

Fraleigh 43.19 Find the fixed field of $\tau_5\tau_2$.

Fraleigh 43.20 Find the fixed field of $\tau_5\tau_3\tau_2$.

Fraleigh 43.21 Find the fixed field of $\{\tau_2, \tau_3, \tau_5\}$.

Fraleigh 43.25 For $\alpha = 3 + \sqrt{2}$: (a) find a conjugate $\beta \neq \alpha$ over $\mathbb{Q}$; (b) compare the conjugation automorphism $\psi_{\sqrt{2},-\sqrt{2}}$ with $\psi_{\alpha,\beta}$.

Fraleigh 44.1 Find the degree over $\mathbb{Q}$ of the splitting field of $x^2 + 3$.

Fraleigh 44.2 Find the degree over $\mathbb{Q}$ of the splitting field of $x^4 - 1$.

Fraleigh 44.3 Find the degree over $\mathbb{Q}$ of the splitting field of $(x^2 - 2)(x^2 - 3)$.

Fraleigh 44.4 Find the degree over $\mathbb{Q}$ of the splitting field of $x^3 - 3$.

Fraleigh 44.5 Find the degree over $\mathbb{Q}$ of the splitting field of $x^3 - 1$.

Fraleigh 44.6 Find the degree over $\mathbb{Q}$ of the splitting field of $(x^2 - 2)(x^3 - 2)$.

Fraleigh 44.7 What is the order of $\mathrm{Gal}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q})$?

Fraleigh 44.8 What is the order of $\mathrm{Gal}(\mathbb{Q}(\sqrt[3]{2}, i\sqrt{3})/\mathbb{Q})$?

Fraleigh 44.9 What is the order of $\mathrm{Gal}(\mathbb{Q}(\sqrt[3]{2}, i\sqrt{3})/\mathbb{Q}(\sqrt[3]{2}))$?

Fraleigh 45.1 Find α with $\mathbb{Q}(\sqrt{2}, \sqrt[3]{2}) = \mathbb{Q}(\alpha)$ and verify the generators are polynomials in α.

Fraleigh 45.2 Find α with $\mathbb{Q}(\sqrt[4]{2}, \sqrt[6]{2}) = \mathbb{Q}(\alpha)$ and verify.

Fraleigh 45.3 Find α with $\mathbb{Q}(\sqrt{2}, \sqrt{5}) = \mathbb{Q}(\alpha)$ and verify.

Fraleigh 45.4 Find α with $\mathbb{Q}(i, \sqrt[3]{2}) = \mathbb{Q}(\alpha)$ and verify.

Fraleigh 46.1 With $K = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$, compute $[K : \mathbb{Q}(\sqrt{2})]$.

Fraleigh 46.2 Compute $|\mathrm{Gal}(K/\mathbb{Q})|$.

Fraleigh 46.3 Compute $|\lambda(\mathbb{Q})|$.

Fraleigh 46.4 Compute $|\lambda(\mathbb{Q}(\sqrt{2}, \sqrt{3}))|$.

Fraleigh 46.5 Compute $|\lambda(\mathbb{Q}(\sqrt{6}))|$.

Fraleigh 46.6 Compute $|\lambda(\mathbb{Q}(\sqrt{30}))|$.

Fraleigh 46.7 Compute $|\lambda(\mathbb{Q}(\sqrt{2} + \sqrt{6}))|$.

Fraleigh 46.8 Compute $|\lambda(K)|$.

Fraleigh 46.18 For $K = \mathbb{Q}(\sqrt{2}, \sqrt{3})$ compute the norms $\mathrm{N}_{K/\mathbb{Q}}$ and traces $\mathrm{Tr}_{K/\mathbb{Q}}$ of $\sqrt{2}$, $\sqrt{2} + \sqrt{3}$, $\sqrt{6}$, and 2.

Fraleigh 48.3 Compute $\varphi(60)$, $\varphi(1000)$, and $\varphi(8100)$ using the prime-factorization formula for $\varphi(n)$.

Fraleigh 48.9 Find the cyclotomic polynomials $\Phi_n(x)$ over $\mathbb{Q}$ for $n = 1, 2, 3, 4, 5, 6$.

Fraleigh 48.10 Find $\Phi_{12}(x)$ in $\mathbb{Q}[x]$.

Medium

DF 14.1.1 (a) If $K = F(\alpha_1, \ldots, \alpha_n)$, show an automorphism σ of K fixing F is determined by the values $\sigma(\alpha_i)$, hence fixes K iff it fixes a generating set. (b) For $G \leq \mathrm{Gal}(K/F)$ with generators $\sigma_1, \ldots, \sigma_k$, show a subfield E/F is fixed by G iff it is fixed by the generators.

DF 14.1.6 Let k be a field. (a) Show $\varphi(f(t)) = f(at + b)$ (fixed $a, b \in k$, $a \neq 0$) is an automorphism of $k[t]$ fixing k. (b) Conversely, every automorphism of $k[t]$ fixing k has this form.

DF 14.1.8 Prove that the automorphisms of $k(t)$ fixing k are exactly the fractional linear transformations $t \mapsto (at + b)/(ct + d)$ with $ad - bc \neq 0$.

DF 14.1.10 If $\varphi : K \to K'$ is an isomorphism carrying F onto F', prove $\sigma \mapsto \varphi\sigma\varphi^{-1}$ is a group isomorphism $\mathrm{Aut}(K/F) \to \mathrm{Aut}(K'/F')$.

DF 14.2.3 Determine the Galois group of $(x^2 - 2)(x^2 - 3)(x^2 - 5)$ and all subfields of its splitting field.

DF 14.2.5 Prove the Galois group of $x^p - 2$ (p prime) is isomorphic to the group of matrices $\left(\begin{smallmatrix} a & b \\ 0 & 1 \end{smallmatrix}\right)$ with $a, b \in \mathbb{F}_p$, $a \neq 0$.

DF 14.2.7 Determine all subfields of the splitting field of $x^8 - 2$ that are Galois over $\mathbb{Q}$.

DF 14.2.10 Determine the Galois group of the splitting field over $\mathbb{Q}$ of $x^8 - 3$.

DF 14.2.12 Determine the Galois group of the splitting field over $\mathbb{Q}$ of $x^4 - 14x^2 + 9$.

DF 14.2.13 Prove that if the Galois group of a cubic over $\mathbb{Q}$ is cyclic of order 3, then all roots of the cubic are real.

DF 14.2.14 Prove that $\mathbb{Q}(\sqrt{2+\sqrt{2}})$ is a cyclic quartic field.

DF 14.2.15 (Biquadratic extensions, $\operatorname{char} F \neq 2$.) (a) If none of D_1, D_2, D_1D_2 is a square in F, prove $K = F(\sqrt{D_1}, \sqrt{D_2})$ is Galois with group the Klein 4-group. (b) Conversely, a Klein-four Galois extension has this form.

DF 14.2.18 For a finite separable extension K/F, with the norm $\mathrm{N}_{K/F}$ defined as a product over embeddings: (a) prove $\mathrm{N}_{K/F}(\alpha) \in F$; (b) prove multiplicativity; (c) for $K = F(\sqrt{D})$ show $\mathrm{N}_{K/F}(a + b\sqrt{D}) = a^2 - Db^2$; (d) prove $\mathrm{N}_{K/F}(\alpha) = (-1)^n a_0^{n/d}$.

DF 14.2.19 With the trace $\mathrm{Tr}_{K/F}$: (a) prove $\mathrm{Tr}_{K/F}(\alpha) \in F$; (b) prove additivity; (c) for $K = F(\sqrt{D})$ show $\mathrm{Tr}_{K/F}(a + b\sqrt{D}) = 2a$; (d) prove $\mathrm{Tr}_{K/F}(\alpha) = -\frac{n}{d} a_{d-1}$.

DF 14.2.20 Show $\mathrm{N}_{K/F}(a\alpha) = a^n \mathrm{N}_{K/F}(\alpha)$ and $\mathrm{Tr}_{K/F}(a\alpha) = a \mathrm{Tr}_{K/F}(\alpha)$ for $a \in F$; in particular $\mathrm{N}_{K/F}(a) = a^n$, $\mathrm{Tr}_{K/F}(a) = na$.

DF 14.2.21 Show more generally that $\prod_\sigma (x - \sigma(\alpha)) = (m_\alpha(x))^{n/d}$.

DF 14.2.22 Use linear independence of characters to show that for any Galois K/F there is $\alpha \in K$ with $\mathrm{Tr}_{K/F}(\alpha) \neq 0$.

DF 14.2.23 For Galois K/F and σ in the group: (a) if $\alpha = \beta/\sigma\beta$ for some nonzero β then $\mathrm{N}_{K/F}(\alpha) = 1$; (b) if $\alpha = \beta - \sigma\beta$ then $\mathrm{Tr}_{K/F}(\alpha) = 0$.

DF 14.2.28 For a finite separable K/F of degree n and $\alpha \in K$: (a) left multiplication T_α is F-linear; (b) the minimal polynomial of α equals that of T_α; (c) $\mathrm{Tr}_{K/F}(\alpha) = \mathrm{tr}(T_\alpha)$ and $\mathrm{N}_{K/F}(\alpha) = \det(T_\alpha)$.

DF 14.3.4 Construct the finite field of 16 elements, find a generator of its multiplicative group, and count the generators.

DF 14.3.5 Exhibit an explicit isomorphism between the splitting fields of $x^3 - x + 1$ and $x^3 - x - 1$ over $\mathbb{F}_3$.

DF 14.3.7 Prove that one of $2, 3, 6$ is a square in $\mathbb{F}_p$ for every prime p, and conclude $(x^2 - 2)(x^2 - 3)(x^2 - 6)$ has a root mod p for every p but none in $\mathbb{Z}$.

DF 14.3.8 Determine the splitting field of $x^p - x - a$ over $\mathbb{F}_p$ ($a \neq 0$) and show its Galois group is cyclic (Artin–Schreier).

DF 14.3.9 For $q = p^m$ and $\sigma_q = \sigma_p^m$: (a) σ_q fixes $\mathbb{F}_q$; (b) every degree-n extension is the splitting field of $x^{q^n} - x$, hence unique; (c) such an extension is cyclic with generator σ_q; (d) its subfields correspond bijectively to divisors of n.

DF 14.3.10 Prove that n divides $\varphi(p^n - 1)$.

DF 14.4.1 Determine the Galois closure of $\mathbb{Q}(\sqrt{1+\sqrt{2}})$ over $\mathbb{Q}$.

DF 14.4.2 Find a primitive generator for $\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$ over $\mathbb{Q}$.

DF 14.4.3 If F is a field contained in the ring of $n \times n$ matrices over $\mathbb{Q}$, prove $[F : \mathbb{Q}] \leq n$.

DF 14.5.1 Determine the minimal polynomials of the primitive generators of the subfields of $\mathbb{Q}(\zeta_{13})$.

DF 14.5.2 Determine the subfields of $\mathbb{Q}(\zeta_8)$ generated by periods of ζ_8; show not every subfield has such a period as primitive element.

DF 14.5.3 Determine the quadratic satisfied by $\alpha = \zeta_5 + \zeta_5^{-1}$, the quadratic satisfied by ζ_5 over $\mathbb{Q}(\alpha)$, and solve explicitly for ζ_5.

DF 14.5.7 Show complex conjugation restricts to $\sigma_{-1} \in \mathrm{Gal}(\mathbb{Q}(\zeta_n)/\mathbb{Q})$, and that $K^+ = \mathbb{Q}(\zeta_n + \zeta_n^{-1})$ is the maximal real subfield of $\mathbb{Q}(\zeta_n)$.

DF 14.5.11 Prove that $\mathbb{Q}(\sqrt[3]{2})$ is not a subfield of any cyclotomic field over $\mathbb{Q}$.

DF 14.5.12 Prove the primitive nth roots of unity form a $\mathbb{Q}$-basis for $\mathbb{Q}(\zeta_n)$ iff n is squarefree.

DF 14.5.16 Prove $\tan 2\theta = a$ (with $0 < 2\theta < \pi/2$) implies $\tan\theta$ satisfies $x^2 + \frac{2}{a}x - 1 = 0$.

DF 14.5.17 Show the circle on diameter (h,k), $(0,1)$ meets the x-axis iff $h^2 - 4k \geq 0$, and that the intercepts are the roots of $x^2 - hx + k = 0$.

DF 14.6.2 Determine the Galois groups over $\mathbb{Q}$ of (a) $x^3 - x^2 - 4$; (b) $x^3 - 2x + 4$; (c) $x^3 - x + 1$; (d) $x^3 + x^2 - 2x - 1$.

DF 14.6.3 Prove that for $a, b \in \mathbb{F}_p$, if $x^3 + ax + b$ is irreducible then $-4a^3 - 27b^2$ is a square in $\mathbb{F}_p$.

DF 14.6.6 Determine the Galois group over $\mathbb{Q}$ of $x^4 + 3x^3 - 3x - 2$.

DF 14.6.7 Determine the Galois group over $\mathbb{Q}$ of $x^4 + 2x^2 + x + 3$.

DF 14.6.8 Determine the Galois group over $\mathbb{Q}$ of $x^4 + 8x + 12$.

DF 14.6.9 Determine the Galois group over $\mathbb{Q}$ of $x^4 + 4x - 1$.

DF 14.6.10 Determine the Galois group over $\mathbb{Q}$ of $x^5 + x - 1$.

DF 14.6.18 Let θ be a root of $x^3 - 3x + 1$. Prove the splitting field is $\mathbb{Q}(\theta)$ with cyclic Galois group of order 3, and determine the other roots explicitly in terms of θ.

DF 14.6.20 Determine the Galois group of $(x^3 - 2)(x^3 - 3)$ over $\mathbb{Q}$ and all subfields containing $\mathbb{Q}(\rho)$, ρ a primitive cube root of unity.

DF 14.6.21 Let $G \leq S_n$ with generators $\sigma_1, \ldots, \sigma_k$. If $f(x_1, \ldots, x_n)$ is fixed by the generators, show it is fixed by G.

DF 14.6.23a If $x + y + z = 1$, $x^2 + y^2 + z^2 = 2$, $x^3 + y^3 + z^3 = 3$, determine $x^4 + y^4 + z^4$.

DF 14.6.40 Express as polynomials in the elementary symmetric functions: (a) $(x_1 - x_2)^2$; (b) $x_1^3 + x_2^3 + x_3^3$; (c) $x_1^2x_2^2 + x_1^2x_3^2 + x_2^2x_3^2$.

DF 14.6.41 Express $\sum_{i \neq j} x_i^2 x_j$ as a polynomial in the elementary symmetric functions.

DF 14.6.44 Express in terms of the elementary symmetric functions: (a) $\sum_{i \neq j} x_i^2 x_j$; (b) $\sum_{i,j,k \text{ distinct}} x_i^2 x_j x_k$; (c) $\sum_{i,j,k \text{ distinct}} x_i^2 x_j^2 x_k^2$.

DF 14.6.45 Let $\alpha_1, \ldots, \alpha_4$ be the roots of a quartic over $\mathbb{Q}$. Show $\alpha_1\alpha_2 + \alpha_3\alpha_4$, $\alpha_1\alpha_3 + \alpha_2\alpha_4$, $\alpha_1\alpha_4 + \alpha_2\alpha_3$ are permuted by the Galois group, hence are roots of a rational cubic (the resolvent cubic).

DF 14.6.46 If $f(x) = x^3 + px + q \in \mathbb{Z}[x]$ is irreducible, prove its discriminant $D = -4p^3 - 27q^2$ is an integer not equal to $0, \pm 1$.

DF 14.6.49 Determine the Galois group of $x^6 - 4x^3 + 1$ (it is dihedral of order 12).

DF 14.7.2 For ζ_7 and $\alpha = \zeta_7 + \zeta_7^{-1}$: (a) show ζ_7 is a root of $z^2 - \alpha z + 1$ over $\mathbb{Q}(\alpha)$; (b) show α is a root of $x^3 + x^2 - 2x - 1$; (c) express ζ_7 in radicals.

DF 14.7.3 For $\operatorname{char} F \neq 2$, state and prove a necessary and sufficient condition on a, b for $F(\sqrt{a}) = F(\sqrt{b})$, and decide whether $\mathbb{Q}(\sqrt{1 - \sqrt{2}}) = \mathbb{Q}(i, \sqrt{2})$.

DF 14.7.4 Let $K = \mathbb{Q}(\sqrt[n]{a})$ with $a > 0$ and $[K : \mathbb{Q}] = n$. For a subfield E with $[E : \mathbb{Q}] = d$, prove $E = \mathbb{Q}(\sqrt[d]{a})$.

DF 14.7.5 With K as above, prove K has no nontrivial Galois subfield when n is odd, and only $\mathbb{Q}(\sqrt{a})$ when n is even.

DF 14.7.6 Let L be the splitting field of $x^n - a$ (Galois closure of K above). Prove $[L : \mathbb{Q}] = n\varphi(n)$ or $\frac{1}{2}n\varphi(n)$.

DF 14.7.10 Let $K = \mathbb{Q}(\zeta_p)$, $G = \operatorname{Gal}(K/\mathbb{Q})$, and ζ any pth root of unity. Prove $\sum_{\sigma \in G} \sigma(\zeta)$ is -1 if ζ is primitive and $p - 1$ otherwise.

DF 14.7.12 Let L be the Galois closure of $\mathbb{Q}(\alpha)/\mathbb{Q}$. For any prime $p \mid |\operatorname{Gal}(L/\mathbb{Q})|$, prove there is a subfield F of L with $[L : F] = p$ and $L = F(\alpha)$.

DF 14.7.13 Let $F \subseteq \mathbb{R}$, $a \in F$, $K = F(\sqrt[n]{a})$ (real root). Prove any Galois L/F with $L \subseteq K$ has $[L:F] \leq 2$.

DF 14.7.16 For nonzero $a \in \mathbb{Q}$: (a) determine when $\mathbb{Q}(\sqrt{ai})$ has degree 4 over $\mathbb{Q}$; (b) when so, show it is Galois with Klein-four group and determine the quadratic subfields.

DF 14.7.17 For squarefree $D \in \mathbb{Z}$ and nonzero $a \in \mathbb{Q}$, show $\mathbb{Q}(\sqrt{a\sqrt{D}})$ cannot be cyclic of degree 4 over $\mathbb{Q}$.

DF 14.7.18 For squarefree $D \in \mathbb{Z}$ with $D \neq 1$ and nonzero $a \in \mathbb{Q}$, prove that if $\mathbb{Q}(\sqrt{a\sqrt{D}})$ is Galois over $\mathbb{Q}$ then $D = -1$.

DF 14.8.1 For a prime p, prove $x^4 + 1$ splits mod p into two irreducible quadratics or into 4 linear factors, using that its Galois group is the Klein 4-group.

DF 14.8.9 Determine a polynomial of degree 7 whose Galois group is cyclic of order 7.

DF 14.8.10 Determine the probable Galois group of $x^7 - 7x + 3$.

DF 14.9.1 Prove that every purely inseparable extension is normal.

DF 14.9.7 Let k be the field of 4 elements, t transcendental, $F = k(t^4 + t)$, $K = k(t)$. (a) Show $[K:F] = 4$; (b) K/F is separable; (c) K/F is Galois; (d) describe the subgroup/subfield lattice, each subfield as $k(r)$.

DF 14.9.10 Let S be independent transcendentals over F and Ω an algebraic closure of $F(S)$. Prove any permutation of S extends to $\mathrm{Aut}(F(S)/F)$ and then to $\mathrm{Aut}(\Omega)$; deduce $\mathbb{C}$ has infinitely many automorphisms.

DF 14.9.13 Let K be the fixed field in $\mathbb{C}$ of an automorphism of $\mathbb{C}$. Prove every finite extension of K in $\mathbb{C}$ is cyclic.

DF 14.9.14 For K_n the splitting field of $(x^2 - p_1)\cdots(x^2 - p_n)$ over $\mathbb{Q}$ (first n primes), prove $\mathrm{Gal}(K_n/\mathbb{Q})$ is elementary abelian of order 2^n.

Artin 2.2b If a real quartic polynomial has positive discriminant, what can you say about its number of real roots?

Artin 2.3 (a) Prove the Tschirnhausen substitution does not change the discriminant of a cubic. (b) Determine the resulting p, q when it is applied to the general cubic.

Artin 4.1b Let K be the splitting field over $\mathbb{Q}$ of $(x^2 - 2x - 1)(x^2 - 2x - 7)$. Determine all automorphisms of K.

Artin 5.1 For each given set of automorphisms of $\mathbb{C}(t)$ determine the group they generate and its fixed field explicitly: (a) $t \mapsto t^{-1}$; (b) $t \mapsto it$; (c) $t \mapsto -t$, $t \mapsto t^{-1}$; (d) $t \mapsto \omega t$, $t \mapsto t^{-1}$ with $\omega = e^{2\pi i/3}$.

Artin 5.3 Let $F = \mathbb{C}(t)$. Prove that every element of F not in $\mathbb{C}$ is transcendental over $\mathbb{C}$.

Artin 6.1 Let α be a complex root of $x^3 + x + 1$ over $\mathbb{Q}$ and K its splitting field. Is $\sqrt{-31}$ in $\mathbb{Q}(\alpha)$? Is it in K?

Artin 6.3 Let $K \supset L \supset F$ be a chain of extensions of degree 2. Show K is generated over F by the root of an irreducible quartic of the form $x^4 + bx^2 + c$.

Artin 7.1 Determine the intermediate fields of an extension $F(\sqrt{a}, \sqrt{b})$ without appealing to the Main Theorem.

Artin 7.2 For Galois K/F with $G(K/F) \cong C_2 \times C_{12}$, count the intermediate fields L with (a) $[L:F] = 4$; (b) $[L:F] = 9$; (c) $G(K/L) \cong C_4$.

Artin 7.3 How many intermediate fields L with $[L:F] = 2$ are there when $G(K/F)$ is (a) A_4; (b) D_4?

Artin 7.5 Let f be an irreducible cubic over $\mathbb{Q}$ with Galois group S_3. Determine the possible Galois groups of $(x^3 - 1)f(x)$.

Artin 7.6 If K/F is Galois with group S_3, is K the splitting field of an irreducible cubic over F?

Artin 7.8 Let α be the positive real fourth root of 2. Factor $x^4 - 2$ into irreducibles over each of $\mathbb{Q}$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{2}, i)$, $\mathbb{Q}(\alpha)$, $\mathbb{Q}(\alpha, i)$.

Artin 7.9 Let $\zeta = e^{2\pi i/5}$. Prove $K = \mathbb{Q}(\zeta)$ is a splitting field of $x^5 - 1$, determine $[K:\mathbb{Q}]$, prove (without Theorem 16.7.1) that $K/\mathbb{Q}$ is Galois, and determine its group.

Artin 8.1 Let K/F be Galois with group the Klein four group D_2. Prove K is obtained by adjoining two square roots to F and explain how G acts on K.

Artin 8.3 Determine explicitly the quadratic polynomial $q(x)$ with $f(x) = (x - \alpha_1)q(x)$, in terms of α_1 and the coefficients of f.

Artin 8.4 Let $K = \mathbb{Q}(\alpha)$ with α a root of $x^3 + 2x + 1$, and $g(x) = x^3 + x + 1$. Does g have a root in K?

Artin 8.5 Let α_i be the roots of $f(x) = x^3 + px + q$. Find a formula for a second root α_2 in terms of α_1, δ, and the coefficients of f.

Artin 9.1 Let K/F be Galois with group S_4. Which integers occur as degrees of elements of K over F?

Artin 9.3 Can $\sqrt{4 + \sqrt{7}}$ be written in the form $\sqrt{a} + \sqrt{b}$ with rational a, b?

Artin 9.8 Decide whether each nested radical can be written with unnested square roots, and if so give the expression: (a) $\sqrt{2 + \sqrt{11}}$; (b) $\sqrt{10 + 5\sqrt{2}}$; (c) $\sqrt{11 + 6\sqrt{2}}$; (d) $\sqrt{6 + \sqrt{11}}$; (e) $\sqrt{11 + \sqrt{6}}$.

Artin 9.9 (a) Determine the discriminant and resolvent cubic of $f(x) = x^4 + rx + s$. (b) Determine the Galois groups of $x^4 + 8x + 12$ and $x^4 + 8x - 12$ over $\mathbb{Q}$. (c) Can the roots of $x^4 + x - 5$ be constructed by ruler and compass?

Artin 9.10 (a) What are the possible Galois groups of an irreducible quartic over $\mathbb{Q}$ with exactly two real roots? (b) What are the possible Galois groups when the discriminant is negative?

Artin 9.11 Let K be the splitting field of $x^4 - 2$ over $\mathbb{Q}$, roots $\alpha, -\alpha, i\alpha, -i\alpha$. (a) Determine $G = G(K/\mathbb{Q})$ and the subgroup $H = G(K/\mathbb{Q}(i))$. (b) Show how each element of H permutes the roots. (c) Find all intermediate fields.

Artin 9.12 Determine the Galois groups over $\mathbb{Q}$ of (a) $x^4 + 4x^2 + 2$; (b) $x^4 + 2x^2 + 4$; (c) $x^4 + 1$; (d) $x^4 + x + 1$; (e) $x^4 + x^3 + x^2 + x + 1$; (f) $x^4 + x^2 + 1$.

Artin 10.2 Let $\zeta = \zeta_{17}$. Find generators for the intermediate field L_2 described in Example 16.10.3.

Artin 10.4 Let $\zeta = \zeta_{13}$. Determine the degrees over $\mathbb{Q}$ of $\zeta + \zeta^{12}$, $\zeta + \zeta^2$, $\zeta + \zeta^5 + \zeta^8$, and the further sums listed.

Artin 10.5 Determine explicitly all intermediate fields of $K = \mathbb{Q}(\zeta_p)$ for (a) $p = 5$; (b) $p = 7$; (c) $p = 11$; (d) $p = 13$.

Artin 10.7 Let $\zeta_n = e^{2\pi i/n}$, $K = \mathbb{Q}(\zeta_n)$. (a) Prove $K/\mathbb{Q}$ is Galois. (b) Define an injective homomorphism $G(K/\mathbb{Q}) \to (\mathbb{Z}/n\mathbb{Z})^\times$. (c) Prove it is bijective for $n = 6, 8, 12$.

Artin 10.9 Let $f(x) = (x - \alpha_1) \cdots (x - \alpha_n)$. (a) Prove the discriminant equals $\pm f'(\alpha_1) \cdots f'(\alpha_n)$ and find the sign. (b) Use this to compute the discriminant of $x^p - 1$.

Artin 11.1 Prove that if the discriminant of an irreducible cubic in $F[x]$ is not a square in F, then its roots cannot be obtained by adjoining a single cube root to F.

Artin 11.2 (a) Prove Proposition 16.11.2 without using Galois theory. (b) For arbitrary F, prove that if $x^p - a$ is reducible in $F[x]$ then it has a root in F.

Artin 11.4 Carry out the computation arriving at Cardano's formula.

Artin 11.5 (a) How does Cardano's formula express the roots of $x^3 + 3x$, $x^3 + 2$, $x^3 - 3x + 2$? (b) What are the correct choices of roots?

Artin 12.3 Let G be the Galois group of an irreducible quintic. Show that if G contains an element of order 3, then G is S_5 or A_5.

Artin 12.8 Let p be prime. Prove S_p is generated by any p-cycle together with any transposition.

Artin M.1 Let $F_1 \subseteq F_2$ and f a polynomial over F_1, with K_2 a splitting field of f over F_2 containing a splitting field K_1 of f over F_1. What is the relation between $G(K_1/F_1)$ and $G(K_2/F_2)$?

Artin M.2 Let L/F and K/L be Galois extensions. Is K/F necessarily Galois?

Artin M.3 (Vandermonde determinant.) (a) Prove the determinant of the Vandermonde matrix in $u_1, \ldots, u_n$ is a constant multiple of the square root of the discriminant $\prod_{i<j}(u_i - u_j)$. (b) Determine the constant.

Artin M.5 Let $K = \mathbb{F}_q$, $q = p^r$. (a) Prove the Frobenius $\varphi(x) = x^p$ is an automorphism of K fixing $F = \mathbb{F}_p$. (b) Prove $G(K/F)$ is cyclic of order r generated by φ. (c) Prove the Main Theorem holds for K/F.

Fraleigh 43.30 Show the only subfields of $\mathbb{Q}(\sqrt{2}, \sqrt{3})$ are $\mathbb{Q}$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{3})$, $\mathbb{Q}(\sqrt{6})$, and $\mathbb{Q}(\sqrt{2}, \sqrt{3})$.

Fraleigh 43.31 Let α be algebraic of degree n over F. Show there are at most n distinct isomorphisms of $F(\alpha)$ into $\overline{F}$ fixing F.

Fraleigh 43.32 Show any automorphism σ of $F(\alpha_1, \ldots, \alpha_n)$ fixing F is determined by the n values $\sigma(\alpha_i)$.

Fraleigh 44.10 Let α be a zero of $x^3 + x^2 + 1$ over $\mathbb{Z}_2$. Show this polynomial splits in $\mathbb{Z}_2(\alpha)$.

Fraleigh 44.11 With $E = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$, give all extensions of the identity on $\mathbb{Q}(\sqrt{2}, \sqrt{15})$ to an isomorphism of E into $\mathbb{C}$, by their values on $\sqrt{2}, \sqrt{3}, \sqrt{5}$.

Fraleigh 44.12 Give all extensions of the map σ on $\mathbb{Q}(\sqrt{2}, \sqrt{15})$ with $\sigma(\sqrt{2}) = \sqrt{2}$, $\sigma(\sqrt{15}) = -\sqrt{15}$ to an isomorphism of E.

Fraleigh 44.13 Give all extensions of $\psi_{\sqrt{30}, -\sqrt{30}}$ on $\mathbb{Q}(\sqrt{30})$ to an isomorphism of E.

Fraleigh 44.14 Describe all extensions of the identity on $\mathbb{Q}$ to an isomorphism of $\mathbb{Q}(\sqrt[3]{2})$ into $\mathbb{C}$.

Fraleigh 44.15 Describe all extensions of the identity on $\mathbb{Q}$ to an isomorphism of $\mathbb{Q}(\sqrt{3}i, \sqrt[3]{2})$ into $\mathbb{C}$.

Fraleigh 44.16 Describe all extensions of the automorphism $\psi_{\sqrt{3}i, -\sqrt{3}i}$ on $\mathbb{Q}(\sqrt{3}i)$ to an isomorphism of $\mathbb{Q}(\sqrt{3}i, \sqrt[3]{2})$ into $\mathbb{C}$.

Fraleigh 44.17 Let σ be the automorphism of $\mathbb{Q}(\pi)$ with $\pi \mapsto -\pi$. (a) Describe its fixed field. (b) Describe all extensions of σ to an isomorphism of $\mathbb{Q}(\sqrt{\pi})$ into the splitting field of $x^2 + \pi$ over $\mathbb{Q}(\pi)$.

Fraleigh 44.24 Show that if $[E : F] = 2$ then E is a splitting field over F.

Fraleigh 44.26 Show the splitting field of $\{x^2 - 2, x^2 - 5\}$ over $\mathbb{Q}$ is $\mathbb{Q}(\sqrt{2} + \sqrt{5})$.

Fraleigh 44.27 Show $G(\mathbb{Q}(\sqrt[3]{2}, i\sqrt{3})/\mathbb{Q}(i\sqrt{3})) \cong \mathbb{Z}_3$.

Fraleigh 46.9 Describe the group of $x^4 - 1$ over $\mathbb{Q}$.

Fraleigh 46.10 Let G be the group of $x^3 + 2$ over $\mathbb{Q}$. Find $|G|$ and identify a well-known group isomorphic to G.

Fraleigh 46.11 Let K be the splitting field of $x^3 - 5$ over $\mathbb{Q}$. (a) Show $K = \mathbb{Q}(\sqrt[3]{5}, i\sqrt{3})$. (b) Describe the six elements of $G(K/\mathbb{Q})$ by their values on $\sqrt[3]{5}$, $i\sqrt{3}$. (c) Identify the group. (d) Give the subgroup/subfield diagrams.

Fraleigh 46.12 Describe the group of $x^4 - 5x^2 + 6$ over $\mathbb{Q}$.

Fraleigh 46.13 Describe the group of $x^3 - 1$ over $\mathbb{Q}$.

Fraleigh 46.19 For $K = F(\alpha)$ normal with $\text{irr}(\alpha, F) = x^n + a_{n-1}x^{n-1} + \cdots + a_0$, show $\text{N}_{K/F}(\alpha) = (-1)^n a_0$ and $\text{Tr}_{K/F}(\alpha) = -a_{n-1}$.

Fraleigh 47.4 Let ζ be a primitive 5th root of unity. (a) Show $\mathbb{Q}(\zeta)$ is the splitting field of $x^5 - 1$. (b) Show each automorphism sends ζ to a power ζ^r. (c) Describe $G(\mathbb{Q}(\zeta)/\mathbb{Q})$. (d) Give the group and field diagrams.

Fraleigh 47.5 Describe the group of $x^5 - 2$ over $\mathbb{Q}(\zeta)$, ζ a primitive 5th root of unity.

Fraleigh 47.6 Repeat the cyclotomic analysis for ζ a primitive 7th root of unity.

Fraleigh 47.7 In the easiest way, describe the group of $x^8 - 1$ over $\mathbb{Q}$.

Fraleigh 47.9 Express each symmetric function in y_1, y_2, y_3 as a rational function of s_1, s_2, s_3: (a) $y_1^2 + y_2^2 + y_3^2$; (b) $\sum_{i \neq j} y_i/y_j$.

Fraleigh 47.10 Let $\alpha_1, \alpha_2, \alpha_3$ be the zeros of $x^3 - 4x^2 + 6x - 2$. Find the polynomial whose zeros are (a) $\alpha_1 + \alpha_2 + \alpha_3$; (b) $\alpha_1^2, \alpha_2^2, \alpha_3^2$.

Fraleigh 48.1 Complete the computation of Example 48.3 showing $\Phi_8(x) = x^4 + 1$.

Fraleigh 48.2 Classify the group of $x^{20} - 1$ over $\mathbb{Q}$ via the structure theorem for finitely generated abelian groups.

Fraleigh 48.6 Let K be the splitting field of $x^{12}-1$ over $\mathbb{Q}$. (a) Find $[K:\mathbb{Q}]$. (b) Show $\sigma^2=\mathrm{id}$ for $\sigma\in G(K/\mathbb{Q})$ and classify $G(K/\mathbb{Q})$.

Fraleigh 48.11 Show in $\mathbb{Q}[x]$ that $\Phi_{2n}(x)=\Phi_n(-x)$ for odd $n>1$.

Fraleigh 48.12 For relatively prime n,m, show the splitting field of $x^{nm}-1$ over $\mathbb{Q}$ equals that of $(x^n-1)(x^m-1)$.

Fraleigh 49.1 Can the splitting field of x^2+x+1 over $\mathbb{Z}_2$ be obtained by adjoining a square root of an element of $\mathbb{Z}_2$? Is it an extension by radicals?

Fraleigh 49.4 Let $f(x)=ax^2+bx+c$ over F with $a\neq 0$. Show that if $\mathrm{char}\,F\neq 2$, the splitting field is $F(\sqrt{b^2-4ac})$.

Fraleigh 49.5 Show that if $\mathrm{char}\,F\neq 2$, then $f(x)=ax^4+bx^2+c$ $(a\neq 0)$ is solvable by radicals over F.

Hard

DF 14.1.7 Determine $\mathrm{Aut}(\mathbb{R}/\mathbb{Q})$: show any σ preserves order, hence is continuous, hence the identity, so $\mathrm{Aut}(\mathbb{R}/\mathbb{Q})=1$.

DF 14.2.6 Let $K=\mathbb{Q}(\sqrt[8]{2},i)$, $F_1=\mathbb{Q}(i)$, $F_2=\mathbb{Q}(\sqrt{2})$, $F_3=\mathbb{Q}(\sqrt{-2})$. Prove $\mathrm{Gal}(K/F_1)\cong Z_8$, $\mathrm{Gal}(K/F_2)\cong D_8$, $\mathrm{Gal}(K/F_3)\cong Q_8$.

DF 14.2.8 If K/F is Galois of degree p^n, show there exist Galois extensions of F inside K of degrees p and p^{n-1}.

DF 14.2.9 Give fields $\mathbb{Q}\subseteq F_1\subseteq F_2\subseteq F_3$ with $[F_3:\mathbb{Q}]=8$, each Galois over all its subfields except that F_2 is not Galois over $\mathbb{Q}$.

DF 14.2.11 Let $f\in\mathbb{Z}[x]$ be an irreducible quartic whose splitting field has group S_4, θ a root, $K=\mathbb{Q}(\theta)$. Prove $[K:\mathbb{Q}]=4$ with no proper subfields, and ask whether a degree-4 Galois extension with no proper subfields exists.

DF 14.2.16 (a) Prove x^4-2x^2-2 is irreducible over $\mathbb{Q}$. (b) Exhibit its four roots. (c)–(e) Show $K_1=\mathbb{Q}(\alpha_1)\neq K_2=\mathbb{Q}(\alpha_2)$ with $K_1\cap K_2=\mathbb{Q}(\sqrt{3})$, that $K_1K_2/\mathbb{Q}(\sqrt{3})$ is Klein-four Galois with its subgroup/subfield correspondence, and that the splitting field has degree 8 with dihedral group.

DF 14.2.17 (Hilbert's Theorem 90.) For K/F cyclic of order n generated by σ and α with $\mathrm{N}_{K/F}(\alpha)=1$, prove $\alpha=\beta/\sigma\beta$ for some nonzero $\beta\in K$.

DF 14.2.24 Prove the rational solutions of $a^2+b^2=1$ have the form $a=(s^2-t^2)/(s^2+t^2)$, $b=2st/(s^2+t^2)$, and deduce that every right triangle with integer sides has sides $((m^2-n^2)d,2mnd,(m^2+n^2)d)$ for some integers m,n,d.

DF 14.2.25 Generalize the previous problem to all rational solutions of $a^2+Db^2=1$ for $D>0$ not a perfect square.

DF 14.2.26 (Additive Hilbert's Theorem 90.) For K/F cyclic of order n generated by σ and α with $\mathrm{Tr}_{K/F}(\alpha)=0$, prove $\alpha=\beta-\sigma\beta$ for some $\beta\in K$.

DF 14.2.27 For $\alpha=\sqrt{(2+\sqrt{2})(3+\sqrt{3})}$ and $E=\mathbb{Q}(\alpha)$, prove $[E:\mathbb{Q}]=8$, that $E/\mathbb{Q}$ is Galois, and (via the relations on σ,τ) that $\mathrm{Gal}(E/\mathbb{Q})\cong Q_8$.

DF 14.2.29 Let $f\in F[x]$ be irreducible of degree n with splitting field L, root α, and $K\subseteq L$ Galois over F. Show f factors over K into m irreducibles of degree d, where $m=[F(\alpha)\cap K:F]$ and $d=[K(\alpha):K]$.

DF 14.2.30 Define $\sigma f(t)=f(1/(1-t))$ and $\tau f(t)=f(1/t)$ on $k(t)$. (a) Show σ,τ generate a group $\cong S_3$. (b) Show $I=(t^2-t+1)^3/(t^2(t-1)^2)$ is fixed by it. (c) Show $k(I)$ is exactly the fixed field.

DF 14.2.31 In the notation of the previous problem, determine the fixed fields of $\langle\tau\rangle$, $\langle\tau\sigma^2\rangle$, $\langle\tau\sigma\rangle$, and $\langle\sigma\rangle$.

DF 14.3.6 If $K=\mathbb{Q}(\theta)=\mathbb{Q}(\sqrt{D_1},\sqrt{D_2})$ is biquadratic with θ an integer combination, prove $m_\theta(x)$ is irreducible of degree 4 but reducible modulo every prime; in particular x^4-10x^2+1 is such.

DF 14.3.11 Prove $x^{p^n}-x+1$ is irreducible over $\mathbb{F}_p$ only when $n=1$ or $n=p=2$.

DF 14.3.12 (Berlekamp.) Show that factoring $f(x)$ into irreducibles in $\mathbb{F}_p[x]$ reduces to determining the prime-power factors $p_i(x)$, via checking pth powers and gcd's with derivatives.

DF 14.3.13 Prove the equivalence of the conditions $R(g(x^p)) = g(x)$; $f \mid \prod_s (g(x) - s)$; $p_i \mid g(x) - s_i$; existence of s_i with $g \equiv s_i \pmod{p_i}$.

DF 14.3.14 Prove the polynomials g of degree $< n$ satisfying the previous conditions form an $\mathbb{F}_p$-vector space V of dimension k.

DF 14.3.15 Using the reduction matrix A of $x^{pj} \bmod f$, show condition (a) is equivalent to $(A - I)B = 0$, conclude $\operatorname{rank}(A - I) = n - k$, and that this determines irreducibility.

DF 14.3.16 Prove the gcd procedure starting from $u = f$ and basis solutions g_i separates all irreducible factors $p_1, \ldots, p_k$.

DF 14.3.17 Carry out Berlekamp's algorithm to factor $f(x) = x^5 + x^2 + 4x + 6$ in $\mathbb{F}_7[x]$, obtaining $(x^2 + 3x + 5)(x^3 + 4x^2 + 4x + 4)$.

DF 14.4.4 Let $f \in F[x]$ be irreducible of degree n with splitting field L, root α, and K any Galois extension of F. Show f factors over K into m irreducibles of degree $d = [K(\alpha) : K] = [(L \cap K)(\alpha) : L \cap K]$, $m = n/d = [F(\alpha) \cap K : F]$.

DF 14.4.5 (p-extensions.) (a) If L is a p-extension of K and K/F is a p-extension, prove the Galois closure of L/F is a p-extension. (b) Give an example showing (a) fails if K/F is not Galois.

DF 14.4.6 Prove $K = \mathbb{F}_p(x, y)/\mathbb{F}_p(x^p, y^p)$ is not a simple extension by exhibiting infinitely many intermediate fields.

DF 14.4.7 For $F \subseteq K \subseteq L$ and $\theta \in L$ with $p(x) = m_{\theta,F}(x)$, prove $K \otimes_F F(\theta) \cong K[x]/(p(x))$ as K-algebras.

DF 14.4.8 For algebraic extensions K_1, K_2 of F in a characteristic-zero field L, prove $K_1 \otimes_F K_2$ has no nonzero nilpotents.

DF 14.5.5 For primitive pth roots ϵ_i and $p_n = \sum \epsilon_i^n$, prove $p_n = -1$ if $p \nmid n$ and $p_n = p - 1$ if $p \mid n$.

DF 14.5.6 Prove the trace of ζ_n from $\mathbb{Q}(\zeta_n)$ to $\mathbb{Q}$ is 1 if $n = 1$, 0 if n is divisible by a square, and $(-1)^r$ if n is a product of r distinct primes.

DF 14.5.8 For $K_n = \mathbb{Q}(\zeta_{2^{n+2}})$, $\alpha_n = \zeta_{2^{n+2}} + \zeta_{2^{n+2}}^{-1}$, $K_n^+ = \mathbb{Q}(\alpha_n)$: (a) compute the four listed degrees; (b) give the quadratic for $\zeta_{2^{n+2}}$ over K_n^+; (c) show $\alpha_{n+1}^2 = 2 + \alpha_n$ and the nested-radical formula.

DF 14.5.9 In the same notation: (a) prove $K_n^+/\mathbb{Q}$ is cyclic of degree 2^n; (b) prove K_n/K_{n-1}^+ is biquadratic with the stated intermediate fields and remaining cyclic field.

DF 14.5.10 Prove the characteristic polynomial of Frobenius on $\mathbb{F}_{p^n}$ (as $\mathbb{F}_p$-linear map) is $x^n - 1$, and determine when it is diagonalizable over $\mathbb{F}_p$ and over $\overline{\mathbb{F}_p}$.

DF 14.5.13 For $n = \prod p_i^{a_i}$, $\zeta_{p_i^{a_i}} = \zeta_n^{n/p_i^{a_i}}$: (a) show σ_a acts as $\sigma_{a \bmod p_i^{a_i}}$ on each factor; (b) identify the resulting map with the CRT isomorphism for $(\mathbb{Z}/n\mathbb{Z})^\times$.

DF 14.5.14 Establish that the listed periods of ζ_{17} are real with the stated approximate values, and prove the quadratic relations $x^2 + x - 4 = 0$, $x^2 - \eta_1 x - 1 = 0$, etc., among them.

DF 14.5.15 (Construction of the regular 17-gon.) Carry out the geometric construction and prove it yields the second vertex of a regular 17-gon, with the period interpretation of the intersection points.

DF 14.6.12 Let $\pm\alpha, \pm\beta$ be roots of $f(x) = x^4 + ax^2 + b \in \mathbb{Z}[x]$. (a) Show f is irreducible iff α^2, $\alpha \pm \beta \notin \mathbb{Q}$. (b) Classify the Galois group (V, C_4, or D_8) by square conditions on b and $b(a^2 - 4b)$.

DF 14.6.13 Prove $x^4 - px^2 + q$ is irreducible for distinct odd primes p, q and has Galois group D_8.

DF 14.6.14 Prove $x^4 + px + p$ is irreducible for every prime p, with group S_4 for $p \neq 3, 5$, dihedral of order 8 for $p = 3$, and cyclic of order 4 for $p = 5$.

DF 14.6.15 Determine the Galois group of $x^4 + 8x^2 + 8x + 4$ over $\mathbb{Q}$, identify which subfields are Galois over $\mathbb{Q}$, and give a polynomial having each as splitting field.

DF 14.6.16 Find the Galois group of $x^4 - 7$ over $\mathbb{Q}$ explicitly as a permutation group on the roots.

DF 14.6.17 Let f be an irreducible quartic over $\mathbb{Q}$ with discriminant D and splitting field $K \subseteq \mathbb{C}$. Prove $\mathbb{Q}(\sqrt{D}) \subseteq K$; analyze complex conjugation τ_K; show $D < 0$ forces K non-cyclic of degree 4; conclude $\mathbb{Q}(\sqrt{D})$ for squarefree $D < 0$ is not in a cyclic quartic.

DF 14.6.19 (Newton's formulas.) Prove $p_i - s_1 p_{i-1} + \cdots + (-1)^i i s_i = 0$ relating power sums and elementary symmetric functions.

DF 14.6.22 Prove x, y, z in 14.6.23 are not rational but $x^n + y^n + z^n$ is rational for every n.

DF 14.6.24 Prove a matrix A over a characteristic-zero field is nilpotent iff $\operatorname{tr}(A^k) = 0$ for all $k \geq 1$.

DF 14.6.25 Prove two matrices over a characteristic-zero field have the same characteristic polynomial iff $\operatorname{tr}(A^k) = \operatorname{tr}(B^k)$ for all k.

DF 14.6.26 Using $\operatorname{tr}(AB) = \operatorname{tr}(BA)$, show AB and BA have the same characteristic polynomial over a characteristic-zero field.

DF 14.6.27 (a) Show the discriminant D is the square of the Vandermonde determinant $\prod_{i>j}(\alpha_i - \alpha_j)$. (b) Derive the power-sum determinant formula for D.

DF 14.6.28 Let α be a root of irreducible $f \in F[x]$, $K = F(\alpha)$, D the discriminant. Prove $D = (-1)^{n(n-1)/2}\,\mathrm{N}_{K/F}(f'(\alpha))$.

DF 14.6.29 Prove the resultant $R(f, g)$ vanishes iff f, g have a common root, via the linear system from $a(x)f(x) = b(x)g(x)$ and the Sylvester determinant.

DF 14.6.30 (a) Establish the matrix equation $R \cdot (x^{n+m-1}, \ldots, 1)^{\mathrm{T}} = (x^{m-1}f, \ldots, g)^{\mathrm{T}}$. (b) Deduce $R(f, g) = r(x)f(x) + s(x)g(x)$ for some $r, s \in F[x]$.

DF 14.6.31 For general f, g with roots x_i, y_j: (a) show $R(f, g)$ is homogeneous of degrees m and n in the coefficients; (b)–(d) derive $R = a_n^m b_m^n \prod_{i,j}(x_i - y_j) = a_n^m \prod_i g(x_i) = (-1)^{nm} b_m^n \prod_j f(y_j)$.

DF 14.6.32 For $g = f'$ and roots α_i, using $R(f, f') = \prod_i f'(\alpha_i)$, prove $D = (-1)^{n(n-1)/2} R(f, f')$.

DF 14.6.33 (a) Prove the discriminant of $\Phi_p(x)$ is $(-1)^{(p-1)/2} p^{p-2}$ for odd prime p. (b) Conclude $\mathbb{Q}(\sqrt{(-1)^{(p-1)/2} p}) \subset \mathbb{Q}(\zeta_p)$.

DF 14.6.34 Use the previous exercise to prove every quadratic extension of $\mathbb{Q}$ lies in a cyclotomic extension (special case of Kronecker–Weber).

DF 14.6.35 Prove the discriminant of $x^n + px + q$ equals $(-1)^{n(n-1)/2} n^n q^{n-1} + (-1)^{(n-1)(n-2)/2} (n-1)^{n-1} p^n$.

DF 14.6.36 Prove the discriminant of $x^n + nx^{n-1} + n(n-1)x^{n-2} + \cdots + n!$ is $(-1)^{n(n-1)/2}(n!)^n$.

DF 14.6.37 (a) Show every polynomial is a sum of homogeneous polynomials, each symmetric if the original is. (b) Show $B\, s_1^{b_1} \cdots s_n^{b_n}$ is homogeneous of degree $\sum i b_i$ in the x_j.

DF 14.6.38 Prove the lexicographic subtraction algorithm expressing a symmetric polynomial in the elementary symmetric functions terminates.

DF 14.6.39 Use the algorithm of 14.6.38 to prove every symmetric polynomial is a polynomial in the elementary symmetric functions.

DF 14.6.42 Show $(x_1 + x_2 - x_3 - x_4)(x_1 + x_3 - x_2 - x_4)(x_1 + x_4 - x_2 - x_3)$ is symmetric in four variables and equals $s_1^3 - 4 s_1 s_2 + 8 s_3$.

DF 14.6.43 Prove that every finite group occurs as the Galois group of an extension $F(x_1, \ldots, x_n)/E$.

DF 14.6.47 Let F have characteristic 0 with every cubic having a root, and f an irreducible quartic over F with square discriminant. Determine the Galois group of f.

DF 14.6.48 Determine the splitting field K of $f(x) = x^6 - 2x^3 - 2$ over $\mathbb{Q}$: prove f irreducible, locate $\mathbb{Q}(\sqrt{-3})$, $\mathbb{Q}(\sqrt{3})$, $\sqrt[3]{2}$ in K, settle $[K : \mathbb{Q}] = 12$ vs 36, and show $G \cong S_3 \times S_3$ of order 36.

DF 14.6.50 (Galois group of a cubic over an arbitrary field.) For irreducible $f = x^3 + ax^2 + bx + c$ over a field K: (a) show $G = A_3$ iff a certain resolvent quadratic has a root in K; (b) in char $\neq 2$ relate this to the discriminant being a square; (c) treat char $= 2$ via the Artin–Schreier map; (d) verify the listed examples over $\mathbb{F}_2(t)$.

DF 14.6.51 (Sturm's Theorem.) Establish the properties of the Sturm sequence and prove the number of real zeros of f in $[a, b]$ is $V(a) - V(b)$; apply to $x^5 + px + q$.

DF 14.7.1 Use Cardano's formulas to solve $x^3 + x^2 - 2 = 0$, exhibit the real root in radicals, show the roots are $1, -1 \pm i$, and explain via $\sqrt[3]{26 \pm 15\sqrt{3}} = 2 \pm \sqrt{3}$.

DF 14.7.7 (Kummer generators.) For F of characteristic prime to n containing the nth roots of unity and K/F cyclic of degree $d \mid n$: (a) show $\sigma(\sqrt[d]{a}) = \zeta \sqrt[d]{a}$; (b)–(c) characterize when $F(\sqrt[d]{a}) = F(\sqrt[d]{b})$ in terms of $F^\times$ modulo dth powers.

DF 14.7.8 (Classical Gauss sum.) For $K = \mathbb{Q}(\zeta_p)$, p odd, H the index-2 subgroup, periods η_0, η_1, and the Gauss sum $g = \sum_{i=0}^{p-1} \zeta_p^{i^2}$: prove the period relations, $g = (\zeta_p, -1)$, $[\mathbb{Q}(g) : \mathbb{Q}] = 2$, and $g^2 = (-1)^{(p-1)/2} p$, giving the unique quadratic subfield.

DF 14.7.11 (Artin–Schreier.) For F of characteristic p and K/F cyclic of degree p, prove $K = F(\alpha)$ with α a root of $x^p - x - a$ for some $a \in F$.

DF 14.7.14 (Casus irreducibilis, general.) For irreducible $f \in \mathbb{Q}[x]$ with all roots real, one of which lies in a tower of real radical extensions, prove $\mathrm{Gal}(f)$ is a 2-group; conclude the real roots are constructible iff expressible by real radicals.

DF 14.7.15 (Cardano in characteristic 2.) For irreducible $f = x^3 + px + q$ over a field of characteristic 2, derive the formulas $\alpha = \theta_1 + \theta_2$, $\beta = \rho\alpha + \theta_1$, $\gamma = \alpha + \beta$ for its roots.

DF 14.7.19 For squarefree D and $K = \mathbb{Q}(\sqrt{D})$: (a) if $D = s^2 + t^2$, embed K in a cyclic degree-4 extension; (b) conversely such an embedding forces D a sum of two squares; (c) conclude $\mathbb{Q}(\sqrt{3})$ and $\mathbb{Q}(\sqrt{D})$ for $D < 0$ are never in a cyclic quartic.

DF 14.7.20 Show any solvable subgroup of S_p of order divisible by p lies in the normalizer of a Sylow p-subgroup (Frobenius group of order $p(p-1)$); conclude an irreducible degree-p polynomial is solvable by radicals iff its group lies in that Frobenius group.

DF 14.7.21 (Solvability of a quintic.) Using the associated degree-6 resolvent: (a) prove the Galois group of $x^5 - 5x + 12$ is D_{10}; (b) prove $x^5 - x - 1$ is not solvable by radicals.

DF 14.8.2 For the splitting field K of $x^6 - 2x^3 - 2$: (a) if $[K : \mathbb{Q}] = 12$, identify K and its generators over $F = \mathbb{Q}(i, \sqrt{3})$; (b) using the factorization over $\mathbb{F}_{13}$, show $[K : \mathbb{Q}] = 36$; (c) determine all elements of $G \cong S_3 \times S_3$.

DF 14.8.3 Prove the Galois group of $x^5 + 20x + 16$ is A_5.

DF 14.8.4 Prove the Galois group of $x^5 + x^4 - 4x^3 - 3x^2 + 3x + 1$ is cyclic of order 5 (it is the minimal polynomial of $\zeta_{11} + \zeta_{11}^{-1}$).

DF 14.8.5 Prove the Galois group of $x^5 + 11x + 44$ is the dihedral group D_{10}.

DF 14.8.6 Prove the Galois group of $x^5 + 15x + 12$ is the Frobenius group F_{20} of order 20.

DF 14.8.7 Prove the Galois group of $x^6 + 24x - 20$ is A_6.

DF 14.8.8 Prove the Galois group of $x^7 + 7x^4 + 14x + 3$ is A_7.

DF 14.9.2 For $K = \mathbb{F}_p(x, y)$ and $F = \mathbb{F}_p(x^p - x, y^p - x)$: (a) show $[K : F] = p^2$ with separable and inseparable degrees each p; (b) exhibit an intermediate purely inseparable E/F of degree p.

DF 14.9.3 For $F = \mathbb{F}_p(s, t)$, β a root of $x^2 - sx + t$, α a root of $x^p - \beta$, $E = F(\beta)$, $K = F(\alpha)$: (a) show E/F Galois of degree 2 and K/E purely inseparable of degree p; (b) show K/F not normal; (c) show no intermediate K_0 gives K_0/F purely inseparable and K/K_0 separable.

DF 14.9.4 Prove α, s is a separating transcendence base for K over $\mathbb{F}_p$ in the notation of 14.9.3.

DF 14.9.5 For K obtained by adjoining all p-power roots of t to $\mathbb{F}_p(t)$, prove K has transcendence degree 1 over $\mathbb{F}_p$ and no separating transcendence base.

DF 14.9.6 Show that if k is transcendental over $\mathbb{Q}$ then $\mathbb{Q}(k, \sqrt{k^3 - k})$ is not a purely transcendental extension of $\mathbb{Q}$ (an elliptic function field).

DF 14.9.8 For an odd prime p, k algebraically closed of characteristic p, t transcendental, and a degree-2 extension F of $k(t)$: write $F = k(t, y)$ with $y^2 \in k(t)$; for $y^2 = 4t^3 - t - 1$ find $[F : k(y)]$ and determine $k(t) \cap k(y)$.

DF 14.9.9 For $K = \mathbb{F}_3(t)$, $G = \mathrm{Aut}(K/\mathbb{F}_3)$, F its fixed field: (a) prove $G \cong S_4$ and there is a unique E with $[E : F] = 2$; (b) complete the lattice of subfields of K containing E, each as $E(r)$.

DF 14.9.11 Prove a purely transcendental proper extension of a field is never algebraically closed.

DF 14.9.12 Let $K \subseteq \mathbb{C}$ be maximal with $\sqrt{2} \notin K$. (a) Show such K exists; (b) $\mathbb{C}/K$ is algebraic; (c) every finite extension of K in $\mathbb{C}$ is Galois with cyclic 2-group; (d) $[\mathbb{C} : K]$ is countably infinite.

DF 14.9.15 Define K_{n+1} by adjoining all roots of all cubics over K_n, $K = \bigcup K_n$. Prove $K/\mathbb{Q}$ is Galois, every cubic over K splits, and there exist nontrivial abelian extensions of K.

DF 14.9.16 Let F be the composite of all splitting fields of irreducible cubics over $\mathbb{Q}$. Prove that F does contain all quadratic extensions of $\mathbb{Q}$. [One way is to consider the polynomials $x^3 + 3ax + 2a$ for $a \in \mathbb{Z}^+$.]

DF 14.9.17 Define K_{n+1} by adjoining all radicals of elements of K_n, $K = \bigcup K_n$. Prove $K/\mathbb{Q}$ is Galois, has no nontrivial solvable Galois extensions, but has nontrivial Galois extensions.

DF 14.9.18 Let $F_0 = \mathbb{Q}$ and define F_{n+1} by adjoining all real radicals of elements of F_n, $F = \bigcup F_n$. With K^+ the maximal real subfield of the field K of the previous exercise, prove $F \neq K^+$.

DF 14.9.19 Prove that for Galois K/F, $\mathrm{Gal}(K/F) \cong \varprojlim \mathrm{Gal}(L/F)$ over finite Galois $L \subseteq K$: define the restriction map, and prove it is a well-defined injective and surjective homomorphism.

Artin 2.5 Use the systematic method on the discriminant in four variables to determine the coefficients in $\Delta(s_1, \ldots, s_4)$ of all monomials not divisible by s_4.

Artin 2.6 Let $u_i' = u_i + t$. Compute the derivatives of the discriminant and use them to verify Formula 16.2.5 for the discriminant of a cubic.

Artin 2.7 With $m = u_1 u_2^2 u_3^3 \cdots u_{n-1}^{n-1}$ and $p(u) = \sum_{\sigma \in A_n} \sigma(m)$, whose S_n-orbit is $\{p, q\}$, prove $(p - q)^2 = D(u)$.

Artin 3.3 Let $F = \mathbb{F}_2(u)$ be the field of rational functions over $\mathbb{F}_2$. Prove $x^2 - u$ is irreducible over F and has a double root in a splitting field.

Artin 5.2 Show the automorphisms $\sigma(t) = (t + i)/(t - i)$ and $\tau(t) = (it - i)/(t + 1)$ of $\mathbb{C}(t)$ generate a group isomorphic to A_4, and determine the fixed field.

Artin 7.10 Let K/F be Galois with group G and $H \leq G$. Prove there exists $\beta \in K$ whose stabilizer equals H.

Artin 7.11 Let $\alpha = \sqrt[3]{2}$, $\beta = \sqrt{3}$, $\gamma = \alpha + \beta$, $L = \mathbb{Q}(\alpha, \beta)$, K the splitting field of $(x^3 - 2)(x^2 - 3)$. (a) Determine the irreducible polynomial of γ over $\mathbb{Q}$ and its roots. (b) Determine $G(K/\mathbb{Q})$.

Artin 9.2 In Example 16.9.2(a), write $\alpha + \alpha'$ as a nested square root and determine the other nested square roots in K.

Artin 9.4 (a) Prove $x^4 - 8x^2 + 11$ is irreducible over $\mathbb{Q}$ in two ways. (b) Do the same for $x^4 - 8x^2 + 9$. (c) Determine all intermediate fields when K is the splitting field of $x^4 - 8x^2 + 11$.

Artin 9.5 For a nested square root $\alpha = \sqrt{r + \sqrt{t}}$ of degree 4 over F with splitting field K: (a) compute the irreducible polynomial and show $G(K/F) \in \{D_4, C_4, D_2\}$; (b) determine the group via $r^2 - t$; (c) for D_4 give generators for all intermediate fields.

Artin 9.7 For $K = F(\sqrt{a}, \sqrt{b})$, determine all nested square roots $\sqrt{r + \sqrt{t}}$ in K with $r, t \in F$.

Artin 9.13 Let K be the splitting field over $\mathbb{Q}$ of $x^4 - 2x^2 - 1$. Determine $G(K/\mathbb{Q})$, find all intermediate fields, and match them with subgroups.

Artin 9.14 Let $F = \mathbb{Q}(\omega)$, $\omega = e^{2\pi i/3}$. Determine the Galois group over F of the splitting field of the indicated nested radicals.

Artin 9.15 Let K be the splitting field of an irreducible quartic f over F with roots α_i, and suppose the resolvent cubic has a root $\beta_1 = \alpha_1\alpha_2 + \alpha_3\alpha_4$ in F. Express the root α_1 explicitly in nested square roots.

Artin 9.16 Determine the resolvent cubic of the general quartic polynomial.

Artin 9.17 Determine the real numbers of degree 4 over $\mathbb{Q}$ constructible by ruler and compass, in terms of the Galois groups of their irreducible polynomials.

Artin 9.18 Prove any Galois extension whose group is D_4 is the splitting field of a polynomial of the form $x^4 + bx^2 + c$.

Artin 10.6 (a) Carry out the proof of Theorem 16.10.12. (b) Prove the Kronecker–Weber Theorem for quadratic extensions.

Artin 10.10 Regarding the eigenvector y at the end of Section 16.11, show that at least one of the elements $y_i = \alpha_1 + \zeta^i\alpha_2 + \cdots + \zeta^{(p-1)i}\alpha_p$ is nonzero.

Artin 11.3 Let $F \subseteq \mathbb{C}$ contain i and let K/F be Galois with group C_4. Is it true that $K = F(\alpha)$ with $\alpha^4 \in F$?

Artin 12.4 For elementary symmetric functions s_i in $u_1, \ldots, u_n$: (a) prove $F(u)/F(s_1, \ldots, s_n)$ is Galois with group S_n; (b) for $n = 5$ and $w = \sum u_iu_{i+1}$ (cyclic), determine $G(F(u)/F(s, w))$; (c) prove every finite group is a Galois group over some field.

Artin 12.5 Let $K/\mathbb{Q}$ be Galois of 2-power degree with $K \subseteq \mathbb{R}$. Prove the elements of K are constructible by ruler and compass.

Artin 12.6 Prove that if the Galois group of a polynomial f is a nonabelian simple group, then the roots are not solvable.

Artin 12.7 Find a polynomial of degree 7 over $\mathbb{Q}$ whose Galois group is S_7.

Artin M.4 Use the fact that the non-negative reals are exactly those with a real square root to prove $\mathbb{R}$ has no automorphism except the identity, and that $\mathbb{C}$ has no continuous automorphism other than the identity and complex conjugation.

Artin M.6 Let $K \subseteq \mathbb{C}$ with automorphism group G acting on polygons with vertices in K. (a) For $K = \mathbb{Q}(\zeta)$, ζ a primitive fifth root of 1, find the G-orbit of the regular pentagon with vertices $1, \zeta, \zeta^2, \zeta^3, \zeta^4$. (b) For side length a, show $a^2 \in K$ and find the irreducible equation for a over $\mathbb{Q}$.

Artin M.7 A polynomial is half-symmetric if fixed by every even permutation. (a) Prove $\sqrt{\text{disc}} = \prod_{i<j}(u_i - u_j)$ is skew-symmetric. (b) Prove every half-symmetric polynomial has the form $f + g\sqrt{\text{disc}}$ with f, g symmetric.

Artin M.8 With variables $u_0, \ldots, u_3$ and $P_i = (u_i - u_{i+1})(u_i - u_{i+2})(u_{i+1} - u_{i+2})$ (indices mod 4), determine (a) $\sum_{i=0}^{3} P_i$ and (b) $\sum_{i=0}^{3} P_i^2$.

Artin M.9 Let $f(t, x) \in \mathbb{C}[t, x]$ be irreducible, monic and cubic in x, with $f(t_0, x)$ having one simple and one double root for some t_0, and suppose the discriminant of f with respect to x has a simple zero at t_0. Prove the splitting field of f over $\mathbb{C}(t)$ has degree 6.

Artin M.10 Let K/F be finite and $f(x) \in K[x]$. Prove there is a nonzero $g(x) \in K[x]$ with $f(x)g(x) \in F[x]$.

Artin M.11 Let f be an irreducible quartic over F with roots α_i whose resolvent cubic has a root $\beta = \alpha_1\alpha_2 + \alpha_3\alpha_4$ in F but with non-square discriminant D (so G is C_4 or D_4). (a) Determine the stabilizer $H \leq S_4$ of β. (b)–(d) With $\gamma = \alpha_1\alpha_2 - \alpha_3\alpha_4$, $\epsilon = \alpha_1 + \alpha_2 - \alpha_3 - \alpha_4$, prove $\gamma^2, \epsilon^2 \in F$, settle when $\delta\gamma$ or $\delta\epsilon$ is a square, and that γ, ϵ are not both zero.

Artin M.12 Define a finite group to be solvable via a chain of subgroups with cyclic quotients. For irreducible f over F with Galois group G, prove the roots of f are solvable over F iff G is solvable.

Artin M.13 Let K/F be Galois with group G, viewed as a representation of G on the F-vector space K, with character χ. Show that if F contains enough roots of unity, then χ is the character of the regular representation.

Fraleigh 43.22 With $E = \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})$: (a) show τ_2, τ_3, τ_5 each have order 2 in $G(E/\mathbb{Q})$; (b) find and tabulate the subgroup H they generate; (c) argue $H = G(E/\mathbb{Q})$.

Fraleigh 44.22 Decide whether $|G(K/F)|$ is multiplicative for finite towers $F \leq E \leq K$, i.e. whether $|G(K/F)| = |G(K/E)| \cdot |G(E/F)|$, with justification.

Fraleigh 44.23 Show that if a finite extension E/F is a splitting field over F, then E is the splitting field of a single polynomial in $F[x]$.

Fraleigh 44.25 Show that for $F \leq E \leq \overline{F}$, E is a splitting field over F iff E contains all conjugates over F of each of its elements.

Fraleigh 44.28 (a) Show an automorphism of a splitting field E/F of $f \in F[x]$ fixing F permutes the zeros of f. (b) Show it is determined by that permutation.

Fraleigh 46.16 Call K/F abelian if $G(K/F)$ is abelian. Show that if K/F is abelian and $F \leq E \leq K$, then K/E and E/F are abelian.

Fraleigh 46.17 For normal K/F, prove the norm $\mathrm{N}_{K/F}(\alpha) = \prod_\sigma \sigma(\alpha)$ and trace $\mathrm{Tr}_{K/F}(\alpha) = \sum_\sigma \sigma(\alpha)$ lie in F.

Fraleigh 46.20 Let $f \in F[x]$ of degree n have every irreducible factor separable. Show the order of the group of f over F divides $n!$.

Fraleigh 46.23 Call K/F cyclic if $G(K/F)$ is cyclic. (a) Show cyclicity descends to E/F and K/E. (b) Show there is exactly one intermediate field of each degree $d \mid [K : F]$.

Fraleigh 46.24 For normal K/F and $\alpha \in K$: (a) show $f(x) = \prod_\sigma (x - \sigma(\alpha)) \in F[x]$; (b) show f is a power of $\mathrm{irr}(\alpha, F)$, with equality iff $K = F(\alpha)$.

Fraleigh 46.25 For normal K/F with intermediate fields E, L, describe $G(K/(E \vee L))$ in terms of $G(K/E)$ and $G(K/L)$.

Fraleigh 46.26 In the same setting, describe $G(K/(E \cap L))$ in terms of $G(K/E)$ and $G(K/L)$.

Fraleigh 47.1 Show $x^4 + 1$ is irreducible in $\mathbb{Q}[x]$.

Fraleigh 47.8 Find the splitting field K of $x^4 - 4x^2 - 1$ in $\mathbb{C}$, compute $G(K/\mathbb{Q})$, and exhibit the full subgroup-subfield correspondence.

Fraleigh 47.11 Show that every finite group is isomorphic to $G(K/F)$ for some finite normal extension K of some field F.

Fraleigh 48.13 For relatively prime n, m, show the group of $x^{nm} - 1$ over $\mathbb{Q}$ is isomorphic to the direct product of the groups of $x^n - 1$ and $x^m - 1$.

Fraleigh 49.8 Let p be prime and $f(x) = x^5 - p^2 x + p \in \mathbb{Q}[x]$. Prove f is not solvable by radicals.

Fraleigh 49.9 Construct a polynomial over a subfield $F \subseteq \mathbb{R}$ with Galois group S_5 via a transcendence-base argument: build transcendentals $y_1, \ldots, y_5$, set $K = \mathbb{Q}(y_1, \ldots, y_5)$, $f = \prod (x - y_i)$, $F = \mathbb{Q}(s_1, \ldots, s_5)$, and show $G(K/F) \cong S_5$.

Chapter 15

Commutative Rings and Algebraic Geometry

15.1 Rings, Ideals, the Nilradical and the Jacobson Radical

Rings, ideals, and the quotient correspondence

In this chapter and the next, "ring" means a commutative ring with identity 1 (the zero ring, in which $1 = 0$, is not excluded), and ring homomorphisms send 1 to 1. This is the Atiyah–Macdonald convention, and it is the right setting for commutative algebra: every ring will eventually be read *geometrically* as the ring of functions on a space, and the points of that space will turn out to be its prime ideals. We begin with the algebra and let the geometry surface as we go.

An *ideal* $\mathfrak{a}$ of a ring A is an additive subgroup with $A\mathfrak{a} \subseteq \mathfrak{a}$, i.e. $x \in \mathfrak{a},\ a \in A \Rightarrow ax \in \mathfrak{a}$. The quotient group $A/\mathfrak{a}$ inherits a multiplication making it a ring, the *quotient ring*, and the projection $\phi : A \to A/\mathfrak{a}$, $x \mapsto x + \mathfrak{a}$, is a surjective homomorphism with kernel $\mathfrak{a}$. The single most useful bookkeeping device in the subject is that ideals of $A/\mathfrak{a}$ are exactly the ideals of A that contain $\mathfrak{a}$.

Proposition 15.1.1 (the lattice-isomorphism / correspondence theorem)**.** *Let $\mathfrak{a}$ be an ideal of A and $\phi : A \to A/\mathfrak{a}$ the projection. There is a one-to-one, order-preserving correspondence*

$$\{\ \text{ideals } \mathfrak{b} \text{ of } A \text{ with } \mathfrak{b} \supseteq \mathfrak{a}\ \} \ \longleftrightarrow\ \{\ \text{ideals } \overline{\mathfrak{b}} \text{ of } A/\mathfrak{a}\ \}, \qquad \overline{\mathfrak{b}} = \phi(\mathfrak{b}), \quad \mathfrak{b} = \phi^{-1}(\overline{\mathfrak{b}}).$$

This correspondence preserves sums, products, intersections, and radicals, and matches prime (resp. maximal) ideals containing $\mathfrak{a}$ with prime (resp. maximal) ideals of $A/\mathfrak{a}$. More generally, if $f : A \to B$ is any homomorphism, then $\ker f$ is an ideal, $\operatorname{im} f = f(A)$ is a subring of B, and f induces an isomorphism $A/\ker f \cong f(A)$.

Idea. An ideal $\overline{\mathfrak{b}} \subseteq A/\mathfrak{a}$ pulls back to $\phi^{-1}(\overline{\mathfrak{b}})$, an ideal of A containing $\ker\phi = \mathfrak{a}$; conversely an ideal $\mathfrak{b} \supseteq \mathfrak{a}$ pushes forward to $\phi(\mathfrak{b})$. Because ϕ is surjective with kernel $\mathfrak{a}$, the two operations are mutually inverse on the indicated sets. The first-isomorphism statement is the usual factorization $A \to f(A)$ through $A/\ker f$. $\square$

Definition 15.1.2 (zero-divisors, nilpotents, idempotents, units)**.** An element $x \in A$ is a *zero-divisor* if $xy = 0$ for some $y \neq 0$. A ring $\neq 0$ with no nonzero zero-divisors is an *integral domain*. An element x is *nilpotent* if $x^n = 0$ for some $n > 0$ (every nilpotent $\neq 0$ is a zero-divisor, but not conversely). An *idempotent* satisfies $e^2 = e$. A *unit* is an x dividing 1, i.e. $xy = 1$ for some (necessarily unique) $y = x^{-1}$; the units form a group $A^\times$. A ring in which $1 \neq 0$ and every nonzero element is a unit is a *field*.

The smallest ideal containing x is the *principal* ideal $(x) = Ax = \langle x \rangle$. Two extreme ideals are always present: the zero ideal (0) and the unit ideal $(1) = A$. The next proposition is the algebraic skeleton of the slogan "a field has no room for ideals."

Proposition 15.1.3 (fields by their ideals)**.** *For a ring $A \neq 0$ the following are equivalent:* (i) *A is a field;* (ii) *the only ideals of A are (0) and (1);* (iii) *every homomorphism $f : A \to B$ into a nonzero ring B is injective.*

Idea. (i)⇒(ii): a nonzero ideal contains a unit, hence contains 1, hence is (1). (ii)⇒(iii): $\ker f$ is an ideal $\neq (1)$ (as $f(1) = 1 \neq 0$), so $\ker f = (0)$. (iii)⇒(i): for x a nonunit, $(x) \neq (1)$, so $A \to A/(x)$ is a homomorphism onto a nonzero ring; injectivity forces $(x) = (0)$, i.e. $x = 0$. Thus every nonzero element is a unit. □

Worked Example 15.1.4 (Ideals of $\mathbb{Z}$ and $k[x]$ are principal)**.** Show every ideal of $\mathbb{Z}$ is (n) for a unique $n \geq 0$, and every ideal of $k[x]$ (k a field) is (f) for a monic f or (0).

Recognition. Both rings are Euclidean (division with remainder), and in a Euclidean domain a least-positive / least-degree element generates.

Solution. In $\mathbb{Z}$, given an ideal $\mathfrak{a} \neq (0)$, pick the least positive $n \in \mathfrak{a}$. For any $m \in \mathfrak{a}$ write $m = qn + r$ with $0 \leq r < n$; then $r = m - qn \in \mathfrak{a}$, forcing $r = 0$, so $m \in (n)$ and $\mathfrak{a} = (n)$. Uniqueness: $(n) = (n')$ with $n, n' \geq 0$ gives $n \mid n'$ and $n' \mid n$. In $k[x]$ the same argument with the degree as size function gives $\mathfrak{a} = (f)$ for f of least degree, made monic by scaling (a unit of k). Sanity check: $(6) \cap (4) = (12) = (\text{lcm})$ and $(6) + (4) = (2) = (\text{gcd})$ in $\mathbb{Z}$, matching "$\cap$ = lcm, sum= gcd" for principal ideals.

Worked Example 15.1.5 (Nilpotent vs. zero-divisor: a sharp non-implication)**.** In $A = \mathbb{Z}/12\mathbb{Z}$, find a nilpotent, an idempotent $\neq 0, 1$, and a zero-divisor that is not nilpotent.

Recognition. Nilpotent means some power is 0; idempotent means $e^2 = e$; zero-divisors include all of these but more.

Solution. Nilpotent: 6, since $6^2 = 36 = 0$. Idempotent: 4, since $4^2 = 16 = 4$; also 9, since $9^2 = 81 = 9$ (and indeed $4 + 9 = 13 = 1$, $4 \cdot 9 = 36 = 0$, a complete orthogonal pair). Zero-divisor not nilpotent: 3, since $3 \cdot 4 = 12 = 0$ yet $3^n \in \{ 3, 9, 3, 9, \dots \}$ never hits 0. Sanity check: $12 = 4 \cdot 3$, so by CRT $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$; the nontrivial idempotents are exactly the images of $(1, 0)$ and $(0, 1)$, namely 9 and 4, confirming there are precisely two.

Prime and maximal ideals, and their existence

We now isolate the two classes of ideals on which the whole theory turns. The definitions are pure algebra, but each has a one-line "geometric" or "arithmetic" reading that we will return to.

Definition 15.1.6 (prime and maximal)**.** An ideal $\mathfrak{p} \neq (1)$ is *prime* if $xy \in \mathfrak{p} \Rightarrow x \in \mathfrak{p}$ or $y \in \mathfrak{p}$. An ideal $\mathfrak{m} \neq (1)$ is *maximal* if there is no ideal strictly between $\mathfrak{m}$ and (1). Equivalently, by the correspondence theorem,

$$\mathfrak{p} \text{ prime} \iff A/\mathfrak{p} \text{ is an integral domain}, \qquad \mathfrak{m} \text{ maximal} \iff A/\mathfrak{m} \text{ is a field}.$$

Since a field is a domain, *every maximal ideal is prime*; the converse fails (e.g. $(0) \subset \mathbb{Z}$ is prime but not maximal).

The slogan to keep in view: a prime ideal $\mathfrak{p}$ is simultaneously a *prime of arithmetic* (the primes $(p) \subset \mathbb{Z}$) and a *point of geometry* (the point a of a variety corresponds to the prime $\mathfrak{m}_a = \{ f : f(a) = 0 \}$ of the coordinate ring). A&M's central reframing is that $\operatorname{Spec} A$, the set of all prime ideals, *is* the space on which A is the ring of functions; the value of $f \in A$ "at the point $\mathfrak{p}$" is its image in the residue field of $A/\mathfrak{p}$. We make this precise at the end.

Theorem 15.1.7 (existence of maximal ideals, via Zorn)**.** *Every ring $A \neq 0$ has at least one maximal ideal. Consequently:*

(1) *if $\mathfrak{a} \neq (1)$ is an ideal, there is a maximal ideal containing $\mathfrak{a}$;*

(2) *every nonunit of A lies in some maximal ideal.*

Idea. Order the set Σ of ideals $\neq (1)$ by inclusion; $\Sigma \neq \varnothing$ since $(0) \in \Sigma$. A chain $(\mathfrak{a}_\alpha)$ has upper bound $\mathfrak{a} = \bigcup_\alpha \mathfrak{a}_\alpha$, which is an ideal and lies in Σ because $1 \notin \mathfrak{a}$ (else $1 \in \mathfrak{a}_\alpha$ for some single α). By Zorn's lemma Σ has a maximal element. For (1) apply this in $A/\mathfrak{a}$ and pull back via the correspondence theorem; (2) is (1) with $\mathfrak{a} = (x)$ for a nonunit x. □

Worked Example 15.1.8 (Spec of a field and of $\mathbb{Z}$)**.** Describe all prime ideals of a field k and of $\mathbb{Z}$.

Recognition. Primes correspond to domain quotients; in $\mathbb{Z}$ a quotient $\mathbb{Z}/n\mathbb{Z}$ is a domain iff $n = 0$ or n prime.

Solution. For a field k the only ideals are $(0), (1)$, and (0) is prime (the quotient is k, a domain), (1) excluded; so $\operatorname{Spec} k = \{\,(0)\,\}$, a single point. For $\mathbb{Z}$: $\mathbb{Z}/n\mathbb{Z}$ is a domain iff n is 0 or a rational prime p, so $\operatorname{Spec}\mathbb{Z} = \{\,(0)\,\} \cup \{\,(p) : p \text{ prime}\,\}$. The maximal ideals are exactly the (p) (residue field $\mathbb{F}_p$); the prime (0) is not maximal (residue field $\mathbb{Q}$, but $(0) \subset (p)$). Sanity check: the inclusion $(0) \subset (p)$ matches $\dim \mathbb{Z} = 1$ – a chain of primes of length one – the "arithmetic line."

Worked Example 15.1.9 (Maximal ideals of $k[x_1, \ldots, x_n]$ at a point)**.** For k a field and $a = (a_1, \ldots, a_n) \in k^n$, show $\mathfrak{m}_a = (x_1 - a_1, \ldots, x_n - a_n)$ is maximal with residue field k.

Recognition. Maximal $\iff$ quotient is a field; evaluation at a realizes the quotient.

Solution. The evaluation map $\mathrm{ev}_a : k[x_1, \ldots, x_n] \to k$, $f \mapsto f(a)$, is a surjective ring homomorphism with kernel containing each $x_i - a_i$, hence containing $\mathfrak{m}_a$. By Taylor expansion about a, any f equals $f(a)$ plus an element of $\mathfrak{m}_a$, so $\ker \mathrm{ev}_a = \mathfrak{m}_a$ and $k[x_1, \ldots, x_n]/\mathfrak{m}_a \cong k$, a field. Thus $\mathfrak{m}_a$ is maximal. Sanity check: this is exactly the "point a = maximal ideal" dictionary; over an algebraically closed k, Hilbert's Nullstellensatz says *all* maximal ideals arise this way, so $\mathrm{mSpec} = k^n$ literally is the geometric space.

Worked Example 15.1.10 (A prime that is not maximal, and a maximal that "looks" prime)**.** In $A = \mathbb{Z}[x]$ exhibit a chain $(0) \subset (p) \subset (p, x)$ of primes and identify which are maximal.

Recognition. Use $A/\mathfrak{p}$ is a domain (prime) vs. a field (maximal); compute the quotients.

Solution. $A/(0) = \mathbb{Z}[x]$, a domain, so (0) is prime, not maximal. $A/(p) = \mathbb{F}_p[x]$, a domain but not a field, so (p) is prime, not maximal. $A/(p, x) \cong \mathbb{F}_p$, a field, so (p, x) is maximal. Each inclusion is strict, giving a length-two chain of primes. Sanity check: this length-two chain matches $\dim \mathbb{Z}[x] = 2$; geometrically $\operatorname{Spec}\mathbb{Z}[x]$ is a two-dimensional "arithmetic surface," with (p, x) a closed point lying over the prime p of $\mathbb{Z}$.

The nilradical and the Jacobson radical

Two intersections of distinguished ideals control, respectively, the nilpotents and the "invisible" elements (those undetectable by maximal-ideal residue fields). The first is the bridge to geometry; the second is a tool for lifting units.

Proposition 15.1.11 (the nilradical is an ideal)**.** *The set* $\operatorname{nil}(A) = \{\, x \in A : x^n = 0 \text{ for some } n > 0 \,\}$ *of all nilpotents is an ideal, and* $A/\operatorname{nil}(A)$ *has no nonzero nilpotent element* (*it is* reduced)*.*

Idea. If $x^m = 0$ then $(ax)^m = a^m x^m = 0$. If $x^m = 0,\ y^n = 0$, the binomial theorem expands $(x + y)^{m+n-1}$ as a sum of multiples of $x^r y^s$ with $r + s = m + n - 1$; each term has $r \geq m$ or $s \geq n$, hence vanishes. So $\operatorname{nil}(A)$ is an ideal. If $\overline{x}^k = 0$ in $A/\operatorname{nil}(A)$ then $x^k \in \operatorname{nil}(A)$, so $(x^k)^N = 0$, so $x \in \operatorname{nil}(A)$, i.e. $\overline{x} = 0$. □

Theorem 15.1.12 (nilradical = intersection of all primes)**.** $\operatorname{nil}(A) = \bigcap_{\mathfrak{p} \in \operatorname{Spec} A} \mathfrak{p}$.

Idea. ($\subseteq$) If x is nilpotent, $x^n = 0 \in \mathfrak{p}$ for every prime $\mathfrak{p}$, and primeness forces $x \in \mathfrak{p}$. ($\supseteq$) Suppose f is *not* nilpotent. Let Σ be the set of ideals $\mathfrak{a}$ with $f^n \notin \mathfrak{a}$ for all $n > 0$; $\Sigma \neq \varnothing$ as $(0) \in \Sigma$. By Zorn, Σ has a maximal element $\mathfrak{p}$. We check $\mathfrak{p}$ is prime: if $x, y \notin \mathfrak{p}$ then $\mathfrak{p} + (x)$ and $\mathfrak{p} + (y)$ strictly contain $\mathfrak{p}$, so each meets some power of f; multiplying, $f^{m+n} \in \mathfrak{p} + (xy)$, so $\mathfrak{p} + (xy) \notin \Sigma$, forcing $xy \notin \mathfrak{p}$. Thus $\mathfrak{p}$ is a prime avoiding f, so $f \notin \bigcap \mathfrak{p}$. □

Definition 15.1.13 (Jacobson radical)**.** The *Jacobson radical* $\operatorname{Jac}(A)$ is the intersection of all maximal ideals of A. Since maximal ideals are prime, $\operatorname{nil}(A) \subseteq \operatorname{Jac}(A)$ always.

Proposition 15.1.14 (characterization of $\operatorname{Jac}(A)$)**.** $x \in \operatorname{Jac}(A) \iff 1 - xy \in A^\times$ *for all* $y \in A$*.*

Idea. ($\Rightarrow$) If $1 - xy$ were a nonunit it would lie in a maximal ideal $\mathfrak{m}$; but $x \in \mathfrak{m}$ too, so $1 = (1 - xy) + xy \in \mathfrak{m}$, absurd. ($\Leftarrow$) If $x \notin \mathfrak{m}$ for some maximal $\mathfrak{m}$, then $\mathfrak{m} + (x) = (1)$, so $u + xy = 1$ for some $u \in \mathfrak{m},\ y \in A$; then $1 - xy = u \in \mathfrak{m}$ is a nonunit, contradicting the hypothesis. □

The two radicals lie in a small lattice that recurs throughout the subject:

$$\begin{array}{c} (1) = A \\ | \\ \mathfrak{m} \\ | \\ \mathrm{Jac}(A) = \bigcap_{\mathfrak{m}} \mathfrak{m} \\ | \\ \mathrm{nil}(A) = \bigcap_{\mathfrak{p}} \mathfrak{p} \\ | \\ (0) \end{array}$$

with $\mathrm{nil}(A) \subseteq \mathrm{Jac}(A)$ (each node sits inside the one above it); equality holds in many rings of geometric origin (Jacobson rings), but not in general.

Worked Example 15.1.15 (Nilradical of $\mathbb{Z}/n\mathbb{Z}$)**.** Compute $\mathrm{nil}(\mathbb{Z}/n\mathbb{Z})$ for $n = p_1^{a_1} \cdots p_r^{a_r}$.

Recognition. nil $= \bigcap$primes; the primes of $\mathbb{Z}/n\mathbb{Z}$ correspond to the primes of $\mathbb{Z}$ containing (n), i.e. to the $p_i \mid n$.

Solution. The primes of $\mathbb{Z}/n\mathbb{Z}$ are the images of (p_i) for $p_i \mid n$, and their intersection is the image of $(p_1 \cdots p_r) = (\mathrm{rad}(n))$. So $\mathrm{nil}(\mathbb{Z}/n\mathbb{Z}) = (p_1 \cdots p_r)/(n)$, the multiples of the radical $p_1 \cdots p_r$. Concretely $\mathrm{nil}(\mathbb{Z}/12\mathbb{Z}) = (6)$: indeed $6^2 = 0$ in $\mathbb{Z}/12\mathbb{Z}$. Sanity check: $x \in \mathbb{Z}/n\mathbb{Z}$ is nilpotent iff every prime $p_i \mid n$ divides x, i.e. $\mathrm{rad}(n) \mid x$; for $n = 12$, $\mathrm{rad}(12) = 6$, matching nil $= (6)$.

Worked Example 15.1.16 (nil $\subsetneq$ Jac in a local ring)**.** In $A = \mathbb{Z}_{(p)}$ (integers localized at p, i.e. fractions a/b with $p \nmid b$), show $\mathrm{Jac}(A) = pA$ but $\mathrm{nil}(A) = (0)$.

Recognition. nil is the intersection of all primes; Jac of the maximals. A domain has nil $= (0)$; a local ring has a single maximal ideal equal to Jac.

Solution. A is a domain (subring of $\mathbb{Q}$), so it has no nonzero nilpotents: $\mathrm{nil}(A) = (0)$. Its nonunits are exactly the fractions a/b with $p \mid a$, $p \nmid b$, which form the ideal pA; this is the unique maximal ideal, so $\mathrm{Jac}(A) = pA \neq (0)$. Sanity check: for $y = c/d \in A$ ($p \nmid d$), $1 - py = (d - pc)/d$ has denominator prime to p and numerator $d - pc \equiv d \not\equiv 0 \pmod{p}$, hence is a unit of A for all y, confirming $p \in \mathrm{Jac}(A)$ via the unit criterion.

Worked Example 15.1.17 (Nilpotents lift units)**.** If $x \in \mathrm{nil}(A)$, show $1 - x$ is a unit, and more generally $u + x \in A^\times$ for any unit u.

Recognition. Nilpotents lie in $\mathrm{Jac}(A)$, and the Jacobson criterion gives $1 - (\mathrm{Jac}) \cdot y$ a unit; or sum a finite geometric series.

Solution. If $x^n = 0$ then $(1 - x)(1 + x + x^2 + \cdots + x^{n-1}) = 1 - x^n = 1$, so $1 - x$ is a unit. For a unit u, $u + x = u(1 + u^{-1}x)$ and $u^{-1}x$ is nilpotent, so $1 + u^{-1}x = 1 - (-u^{-1}x)$ is a unit, hence so is $u + x$. Sanity check: in $\mathbb{Z}/8\mathbb{Z}$, $x = 2$ is nilpotent ($2^3 = 8 = 0$), so $1 - 2 = -1 = 7$ is a unit ($7 \cdot 7 = 49 = 1$); consistent.

Local rings, idempotents, and prime avoidance

Definition 15.1.18 (local and semilocal)**.** A ring with exactly one maximal ideal $\mathfrak{m}$ is *local*; the field $k = A/\mathfrak{m}$ is its *residue field*. A ring with finitely many maximal ideals is *semilocal*. In a local ring, $\mathrm{Jac}(A) = \mathfrak{m}$ and every element outside $\mathfrak{m}$ is a unit.

Proposition 15.1.19 (recognizing local rings)**.** *Let $A \neq 0$.*

(i) *If $\mathfrak{m} \neq (1)$ is an ideal and every $x \in A \setminus \mathfrak{m}$ is a unit, then A is local with maximal ideal $\mathfrak{m}$. Equivalently, A is local iff the nonunits of A form an ideal.*

(ii) *If $\mathfrak{m}$ is maximal and every element of $1 + \mathfrak{m}$ is a unit, then A is local with maximal ideal $\mathfrak{m}$.*

Idea. (i) Every proper ideal consists of nonunits, hence lies in $\mathfrak{m}$; so $\mathfrak{m}$ is the unique maximal ideal. The "equivalently": nonunits forming an ideal is exactly the hypothesis that $A \setminus$ (that ideal) are units. (ii) For $x \notin \mathfrak{m}$, maximality gives $(x) + \mathfrak{m} = (1)$, so $xy + t = 1$ with $t \in \mathfrak{m}$; then $xy = 1 - t \in 1 + \mathfrak{m}$ is a unit, so x is a unit, and (i) applies. □

Proposition 15.1.20 (idempotents split the ring)**.** *A has a nontrivial idempotent e ($e \neq 0, 1$, $e^2 = e$) iff $A \cong A_1 \times A_2$ as a product of two nonzero rings; then $e = (1, 0)$. In particular a local ring has no nontrivial idempotents* (Spec A *is connected*)*.*

Idea. Given e, set $e' = 1 - e$; then $ee' = 0$ and $e + e' = 1$, so $A \cong Ae \times Ae'$ with units e, e'. Conversely a product has the orthogonal idempotents $(1, 0), (0, 1)$. If A is local with maximal $\mathfrak{m}$ and $e^2 = e$, then $e(1 - e) = 0$; one of $e, 1 - e$ is outside $\mathfrak{m}$, hence a unit, forcing the other to be 0. □

Proposition 15.1.21 (prime avoidance)**.** *Let $\mathfrak{p}_1, \ldots, \mathfrak{p}_n$ be ideals, at most two of which are not prime, and let $\mathfrak{a}$ be an ideal with $\mathfrak{a} \subseteq \bigcup_{i=1}^{n} \mathfrak{p}_i$. Then $\mathfrak{a} \subseteq \mathfrak{p}_i$ for some single i.* (*Contrapositive: an ideal not contained in any one of finitely many primes is not contained in their union.*)

Idea. Induct on n. If $\mathfrak{a} \subseteq \bigcup_i \mathfrak{p}_i$ but $\mathfrak{a} \not\subseteq \mathfrak{p}_j$ for each j, pick $x_j \in \mathfrak{a}$ avoiding all $\mathfrak{p}_i$ with $i \neq j$ (possible by induction on the union with $\mathfrak{p}_j$ removed). If some $x_j \notin \mathfrak{p}_j$, then $x_j \in \mathfrak{a}$ lies in no $\mathfrak{p}_i$, a contradiction; so each $x_j \in \mathfrak{p}_j$. For $n = 2$ the element $y = x_1 + x_2 \in \mathfrak{a}$ lies in neither $\mathfrak{p}_1$ nor $\mathfrak{p}_2$. For $n \geq 3$ some $\mathfrak{p}_i$ is prime, say $\mathfrak{p}_n$, and $y = x_n + x_1 x_2 \cdots x_{n-1} \in \mathfrak{a}$ lies in no $\mathfrak{p}_i$: for $i < n$ because $x_n \notin \mathfrak{p}_i$ while $x_1 \cdots x_{n-1} \in \mathfrak{p}_i$, and for $i = n$ because $x_n \in \mathfrak{p}_n$ while $x_1 \cdots x_{n-1} \notin \mathfrak{p}_n$ by primeness of $\mathfrak{p}_n$. Either way this contradicts $\mathfrak{a} \subseteq \bigcup_i \mathfrak{p}_i$. □

Worked Example 15.1.22 (A local ring recognized by its nonunits)**.** Show the formal power series ring $A = k[[t]]$ is local with maximal ideal $\mathfrak{m} = (t)$.

Recognition. Use the recognition criterion: if everything outside (t) is a unit, A is local with maximal ideal (t).

Solution. A series $f = \sum_{n \geq 0} a_n t^n$ is a unit iff $a_0 \neq 0$: when $a_0 \neq 0$ one solves $fg = 1$ recursively for the coefficients of g; when $a_0 = 0$, $f \in (t)$ is a nonunit. Thus the nonunits are exactly (t), an ideal, so A is local with $\mathfrak{m} = (t)$ and residue field $A/(t) \cong k$. Sanity check: $1 - t \cdot y$ has constant term $1 \neq 0$ for every $y \in A$, hence is a unit, confirming $t \in \mathrm{Jac}(A) = (t)$ via the unit criterion.

Worked Example 15.1.23 (Idempotents and the structure of $\mathbb{Z}/12\mathbb{Z}$)**.** Find all idempotents of $\mathbb{Z}/12\mathbb{Z}$ and the corresponding product decomposition.

Recognition. Idempotents correspond to ways of writing Spec as a disjoint union; by CRT they come from the prime-power factorization.

Solution. $12 = 4 \cdot 3$ with $\gcd(4, 3) = 1$, so CRT gives $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. The idempotents of a product are coordinatewise idempotents; since $\mathbb{Z}/4\mathbb{Z}$ and $\mathbb{Z}/3\mathbb{Z}$ are local (only idempotents $0, 1$), the idempotents are $(0, 0), (1, 0), (0, 1), (1, 1)$, i.e. $0, 9, 4, 1$ in $\mathbb{Z}/12\mathbb{Z}$. The nontrivial pair $4, 9$ gives $\mathbb{Z}/12\mathbb{Z} \cong 4A \times 9A \cong \mathbb{Z}/3\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$. Sanity check: $4 + 9 = 13 = 1$ and $4 \cdot 9 = 36 = 0$, the defining orthogonality $e + e' = 1,\ ee' = 0$.

Worked Example 15.1.24 (Prime avoidance in action)**.** In $A = k[x, y]$, show the ideal $\mathfrak{a} = (x, y)$ is not contained in the union $(x) \cup (y)$ of the two primes $(x), (y)$.

Recognition. If $\mathfrak{a}$ were inside the union of two primes, avoidance would put $\mathfrak{a}$ inside one of them; check that fails.

Solution. $\mathfrak{a} = (x, y) \not\subseteq (x)$ since $y \notin (x)$, and $\mathfrak{a} \not\subseteq (y)$ since $x \notin (y)$. By prime avoidance $\mathfrak{a} \not\subseteq (x) \cup (y)$. Concretely the element $x + y \in \mathfrak{a}$ lies in neither (x) nor (y): if $x + y = xg$ then setting $x = 0$ gives $y = 0$, false. Sanity check: $(x), (y)$ are prime ($A/(x) \cong k[y]$ a domain), and the witness $x + y$ is exactly the kind of "diagonal" element avoidance predicts must exist.

Operations on ideals: sum, product, intersection, quotient, radical

Definition 15.1.25 (the operations)**.** For ideals $\mathfrak{a}, \mathfrak{b}$ (and a family $(\mathfrak{a}_i)_{i \in I}$):

- *Sum* $\mathfrak{a} + \mathfrak{b} = \{\, x + y : x \in \mathfrak{a},\ y \in \mathfrak{b} \,\}$, the smallest ideal containing both; more generally $\sum_i \mathfrak{a}_i$ consists of all *finite* sums $\sum x_i$ with $x_i \in \mathfrak{a}_i$.

- *Intersection* $\bigcap_i \mathfrak{a}_i$, again an ideal.
- *Product* $\mathfrak{ab}$ = the ideal generated by all products xy ($x \in \mathfrak{a},\ y \in \mathfrak{b}$), i.e. finite sums $\sum x_k y_k$; powers $\mathfrak{a}^n$ are defined likewise, $\mathfrak{a}^0 = (1)$.
- *Ideal quotient* $(\mathfrak{a} : \mathfrak{b}) = \{\, x \in A : x\mathfrak{b} \subseteq \mathfrak{a} \,\}$, an ideal containing $\mathfrak{a}$; the special case $(0 : \mathfrak{b}) = \operatorname{Ann}(\mathfrak{b})$ is the *annihilator*.
- *Radical* $r(\mathfrak{a}) = \{\, x \in A : x^n \in \mathfrak{a} \text{ for some } n > 0 \,\}$, an ideal containing $\mathfrak{a}$; note $r(\mathfrak{a})/\mathfrak{a} = \operatorname{nil}(A/\mathfrak{a})$, so $r((0)) = \operatorname{nil}(A)$.

Sum, intersection, and product are commutative and associative; product distributes over sum, $\mathfrak{a}(\mathfrak{b}+\mathfrak{c}) = \mathfrak{ab}+\mathfrak{ac}$. One always has $\mathfrak{ab} \subseteq \mathfrak{a} \cap \mathfrak{b}$, with equality when $\mathfrak{a}+\mathfrak{b} = (1)$ (the ideals are *coprime*). Intersection and sum satisfy only the *modular law* $\mathfrak{a} \cap (\mathfrak{b}+\mathfrak{c}) = \mathfrak{a}\cap\mathfrak{b} + \mathfrak{a}\cap\mathfrak{c}$ when $\mathfrak{a} \supseteq \mathfrak{b}$ or $\mathfrak{a} \supseteq \mathfrak{c}$ – they do not distribute in general.

Proposition 15.1.26 (properties of radical)**.** (i) $r(\mathfrak{a}) \supseteq \mathfrak{a}$ *and* $r(r(\mathfrak{a})) = r(\mathfrak{a})$. (ii) $r(\mathfrak{ab}) = r(\mathfrak{a}\cap\mathfrak{b}) = r(\mathfrak{a}) \cap r(\mathfrak{b})$. (iii) $r(\mathfrak{a}) = (1) \iff \mathfrak{a} = (1)$. (iv) $r(\mathfrak{a}+\mathfrak{b}) = r(r(\mathfrak{a}) + r(\mathfrak{b}))$. (v) *If* $\mathfrak{p}$ *is prime,* $r(\mathfrak{p}^n) = \mathfrak{p}$ *for all* $n > 0$. (vi) *The radical of* $\mathfrak{a}$ *is the intersection of the prime ideals containing* $\mathfrak{a}$*:*

$$r(\mathfrak{a}) = \bigcap_{\mathfrak{p} \supseteq \mathfrak{a},\ \mathfrak{p}\ \text{prime}} \mathfrak{p}.$$

Idea. (vi) is the nilradical theorem applied in $A/\mathfrak{a}$: $r(\mathfrak{a})/\mathfrak{a} = \operatorname{nil}(A/\mathfrak{a}) = \bigcap(\text{primes of } A/\mathfrak{a})$, and primes of $A/\mathfrak{a}$ are primes of A containing $\mathfrak{a}$ by the correspondence theorem. The rest are direct computations: e.g. for (ii), $x^n \in \mathfrak{a}\cap\mathfrak{b}$ for some n iff $x^m \in \mathfrak{a}$ and $x^k \in \mathfrak{b}$ for some m, k, take $n = \max$. □

This identity (vi) is the algebraic heart of the Nullstellensatz and of the map $\mathfrak{a} \mapsto V(\mathfrak{a})$ below: passing to the radical loses no geometric information, because $V(\mathfrak{a}) = V(r(\mathfrak{a}))$.

Worked Example 15.1.27 (Computing a radical in $\mathbb{Z}$)**.** Compute $r((72))$ in $\mathbb{Z}$.

Recognition. In $\mathbb{Z}$ the radical of (n) is $(\operatorname{rad} n)$, the product of distinct primes dividing n; equivalently $r((n)) = \bigcap_{p \mid n}(p)$.

Solution. $72 = 2^3 \cdot 3^2$, so the primes dividing 72 are $2, 3$, and $r((72)) = (2) \cap (3) = (6)$. Indeed $x^n \in (72)$ for some n iff $2 \mid x$ and $3 \mid x$, i.e. $6 \mid x$. Sanity check: $6^2 = 36 \notin (72)$ but $6^3 = 216 = 3 \cdot 72 \in (72)$, so $6 \in r((72))$; and $r((72)) = (6)$ matches "intersection of primes $(2), (3)$ containing (72)."

Worked Example 15.1.28 (An ideal quotient $(\mathfrak{a} : \mathfrak{b})$ in a polynomial ring)**.** In $A = k[x, y]$, compute $((x^2, xy) : (x))$.

Recognition. $(\mathfrak{a} : \mathfrak{b}) = \{\, f : f\mathfrak{b} \subseteq \mathfrak{a} \,\}$; here we need f with $fx \in (x^2, xy) = x(x, y)$.

Solution. $fx \in x(x, y)$ means $fx = x \cdot g$ with $g \in (x, y)$; since A is a domain we cancel x to get $f = g \in (x, y)$. Conversely any $f \in (x, y)$ has $fx \in x(x, y) = (x^2, xy)$. So $((x^2, xy) : (x)) = (x, y)$. Sanity check: (x, y) is the maximal ideal at the origin, and indeed $(x^2, xy) = x \cdot (x, y)$ collapses upon dividing by (x) to (x, y), consistent with $(\mathfrak{a} : \mathfrak{b}) \supseteq \mathfrak{a}$ and here strictly larger.

Worked Example 15.1.29 (Coprime ideals: product equals intersection)**.** In $\mathbb{Z}$, verify $(4) \cap (9) = (4)(9)$ and contrast with $(4) \cap (6)$.

Recognition. $\mathfrak{ab} = \mathfrak{a} \cap \mathfrak{b}$ precisely when $\mathfrak{a} + \mathfrak{b} = (1)$; check coprimality via gcd.

Solution. $(4) + (9) = (\gcd(4, 9)) = (1)$, coprime, so $(4) \cap (9) = (\operatorname{lcm}(4, 9)) = (36) = (4)(9)$. By contrast $(4) + (6) = (2) \neq (1)$: here $(4)(6) = (24)$ but $(4) \cap (6) = (\operatorname{lcm}(4, 6)) = (12) \neq (24)$, so product $\subsetneq$ intersection. Sanity check: $(4)(6) = (24) \subseteq (12) = (4) \cap (6)$, the general inclusion $\mathfrak{ab} \subseteq \mathfrak{a} \cap \mathfrak{b}$, strict exactly because $4, 6$ are not coprime.

Worked Example 15.1.30 (Radical of a sum need not be the sum of radicals)**.** In $A = k[x, y]$, let $\mathfrak{a} = (x^2 - y),\ \mathfrak{b} = (y)$. Show $r(\mathfrak{a}) = \mathfrak{a},\ r(\mathfrak{b}) = \mathfrak{b}$, but $r(\mathfrak{a} + \mathfrak{b}) \neq \mathfrak{a} + \mathfrak{b}$.

Recognition. Use $r(\mathfrak{a} + \mathfrak{b}) = r(r(\mathfrak{a}) + r(\mathfrak{b}))$; the failure of $r(\mathfrak{a} + \mathfrak{b}) = \mathfrak{a} + \mathfrak{b}$ shows "r of a sum" is subtle.

Solution. $\mathfrak{a} = (x^2 - y)$ is prime (the quotient $k[x,y]/(x^2-y) \cong k[x]$ via $y \mapsto x^2$ is a domain), so $r(\mathfrak{a}) = \mathfrak{a}$; likewise $\mathfrak{b} = (y)$ is prime with $r(\mathfrak{b}) = \mathfrak{b}$. Now $\mathfrak{a} + \mathfrak{b} = (x^2 - y,\, y) = (x^2,\, y)$, whose radical is $r((x^2, y)) = (x, y) \neq (x^2, y)$ since $x \in r$ but $x \notin (x^2, y)$. Sanity check: $(x, y) = r((x^2) + (y)) = r(r(\mathfrak{a}) + r(\mathfrak{b}))$ exactly as the proposition predicts; geometrically $V(\mathfrak{a}) \cap V(\mathfrak{b})$ is the single (fat) point at the origin, whose reduced ideal is (x, y).

Extension, contraction, and product rings (CRT)

Let $f : A \to B$ be a ring homomorphism. It moves ideals in two directions, and the interplay is the algebraic shadow of the geometric map $\operatorname{Spec} B \to \operatorname{Spec} A$.

Definition 15.1.31 (extension and contraction)**.** For an ideal $\mathfrak{a} \subseteq A$, its *extension* is $\mathfrak{a}^e = Bf(\mathfrak{a})$, the ideal of B generated by $f(\mathfrak{a})$. For an ideal $\mathfrak{b} \subseteq B$, its *contraction* is $\mathfrak{b}^c = f^{-1}(\mathfrak{b})$, always an ideal of A. One has $\mathfrak{a} \subseteq \mathfrak{a}^{ec}$, $\mathfrak{b} \supseteq \mathfrak{b}^{ce}$, and the idempotent identities $\mathfrak{a}^e = \mathfrak{a}^{ece}$, $\mathfrak{b}^c = \mathfrak{b}^{cec}$.

Proposition 15.1.32 (contraction of a prime is prime)**.** *If $\mathfrak{q} \subseteq B$ is prime, then $\mathfrak{q}^c = f^{-1}(\mathfrak{q})$ is prime in A. (This is the well-definedness of the induced map $\operatorname{Spec} B \to \operatorname{Spec} A$, $\mathfrak{q} \mapsto f^{-1}(\mathfrak{q})$.) Extension of a prime, by contrast, need not be prime.*

Idea. f induces an injection $A/\mathfrak{q}^c \hookrightarrow B/\mathfrak{q}$; since $B/\mathfrak{q}$ is a domain and a subring of a domain is a domain, $A/\mathfrak{q}^c$ is a domain, so $\mathfrak{q}^c$ is prime. Equivalently: $xy \in f^{-1}(\mathfrak{q}) \Rightarrow f(x)f(y) \in \mathfrak{q} \Rightarrow f(x) \in \mathfrak{q}$ or $f(y) \in \mathfrak{q} \Rightarrow x \in f^{-1}(\mathfrak{q})$ or $y \in f^{-1}(\mathfrak{q})$. □

The contraction map on spectra and the two basic homomorphisms (projection, inclusion) fit the square below: the upper map is a quotient $A \to A/\mathfrak{a}$, the left map a ring homomorphism $f : A \to B$ (for instance an inclusion into a localization or extension), and contracting primes commutes with these.

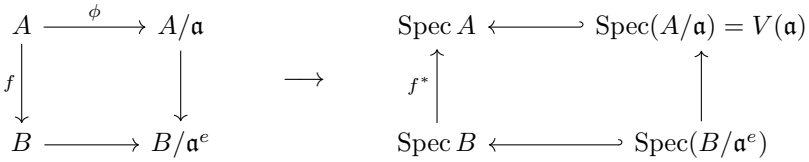


Diagram explanation. Objects: Left square (algebra): A and B are commutative rings, $A/\mathfrak{a}$ is the quotient ring by the ideal $\mathfrak{a} \subseteq A$, and $B/\mathfrak{a}^e$ is the quotient of B by the extended ideal $\mathfrak{a}^e = Bf(\mathfrak{a})$. Right square (geometry): $\operatorname{Spec} A$, $\operatorname{Spec} B$ are sets of prime ideals; $\operatorname{Spec}(A/\mathfrak{a}) = V(\mathfrak{a}) \subseteq \operatorname{Spec} A$ is the closed subset of primes containing $\mathfrak{a}$; $\operatorname{Spec}(B/\mathfrak{a}^e) = V(\mathfrak{a}^e) \subseteq \operatorname{Spec} B$ is the corresponding closed subset.

Arrows: Left square: $\phi : A \to A/\mathfrak{a}$ is the canonical surjection (quotient map) with kernel $\mathfrak{a}$; $f : A \to B$ is an arbitrary ring homomorphism; the bottom map $B \to B/\mathfrak{a}^e$ is the canonical surjection with kernel $\mathfrak{a}^e$; the right vertical $A/\mathfrak{a} \to B/\mathfrak{a}^e$ is the induced map $a + \mathfrak{a} \mapsto f(a) + \mathfrak{a}^e$, obtained by applying f then projecting. Right square: $f^* : \operatorname{Spec} B \to \operatorname{Spec} A$ is the contraction map $\mathfrak{q} \mapsto f^{-1}(\mathfrak{q})$; the two horizontal inclusions are the closed immersions $V(\mathfrak{a}) \hookrightarrow \operatorname{Spec} A$ and $V(\mathfrak{a}^e) \hookrightarrow \operatorname{Spec} B$; the right vertical $\operatorname{Spec}(B/\mathfrak{a}^e) \to V(\mathfrak{a})$ is induced by f.

What commutes: Left square: both paths $A \to B/\mathfrak{a}^e$ agree, i.e. (project then induce) = (apply f then project): for all $a \in A$, going right-then-down gives $(f(a) + \mathfrak{a}^e)$, going down-then-right also gives $f(a) + \mathfrak{a}^e$. Right square: f^* restricted to $V(\mathfrak{a}^e)$ lands in $V(\mathfrak{a})$, and the two paths from $\operatorname{Spec}(B/\mathfrak{a}^e)$ to $\operatorname{Spec} A$ agree: include into $\operatorname{Spec} B$ then apply f^* equals apply the induced map then include into $\operatorname{Spec} A$.

Why it commutes: For the algebra square, the induced right vertical is well-defined precisely because $a \in \mathfrak{a} \Rightarrow f(a) \in f(\mathfrak{a}) \subseteq \mathfrak{a}^e$, so different coset representatives of $a + \mathfrak{a}$ map to the same coset in $B/\mathfrak{a}^e$. Chasing: take $a \in A$; right-then-down sends $a \mapsto a + \mathfrak{a} \mapsto f(a) + \mathfrak{a}^e$; down-then-right sends $a \mapsto f(a) \mapsto f(a) + \mathfrak{a}^e$; these are equal. For the Spec square: if $\mathfrak{q} \supseteq \mathfrak{a}^e$ (so $\mathfrak{q} \in V(\mathfrak{a}^e)$) then $f^{-1}(\mathfrak{q}) \supseteq f^{-1}(\mathfrak{a}^e) \supseteq \mathfrak{a}$ (since $f(a) \in \mathfrak{a}^e \subseteq \mathfrak{q}$ for all $a \in \mathfrak{a}$), so $f^*(\mathfrak{q}) \in V(\mathfrak{a})$, confirming the geometric square commutes.

Why this matters here: This double diagram is placed immediately after the proof that contraction of a prime is prime (f^* is well-defined on $\operatorname{Spec} B \to \operatorname{Spec} A$). It organizes the two fundamental operations – quotient and extension/contraction – into a single picture, showing that every ring map $f : A \to B$ simultaneously

(1) descends to a map of quotients and (2) dualizes to a map of Specs that intertwines the closed subsets $V(\mathfrak{a})$ and $V(\mathfrak{a}^e)$. This is the algebraic backbone of the slogan "a map of rings induces a map of spaces in the opposite direction."

Concrete example: Take $A = \mathbb{Z}$, $B = \mathbb{Z}[i]$, f the inclusion, $\mathfrak{a} = (5)$. Then $\mathfrak{a}^e = (5)\mathbb{Z}[i]$, and the algebra square gives $\mathbb{Z}/(5) = \mathbb{F}_5 \to \mathbb{Z}[i]/(5) \cong \mathbb{F}_5 \times \mathbb{F}_5$. The Spec square: $V((5)) = \{(5)\} \subset \operatorname{Spec}\mathbb{Z}$, and $V((5)\mathbb{Z}[i]) = \{(2+i), (2-i)\} \subset \operatorname{Spec}\mathbb{Z}[i]$, with f^* sending both $(2 \pm i)$ to (5), illustrating the "split prime" geometry.

Common pitfall: Students often think the right vertical map $A/\mathfrak{a} \to B/\mathfrak{a}^e$ always exists automatically. It requires the explicit well-definedness check: $f(\mathfrak{a}) \subseteq \mathfrak{a}^e$ by definition of extension, so the map is well-defined; and likewise, for a prime $\mathfrak{q} \subseteq B$, the induced map goes $A/\mathfrak{q}^c \hookrightarrow B/\mathfrak{q}$ (well defined and injective because $\mathfrak{q}^c = f^{-1}(\mathfrak{q})$, as in the proof of the proposition above), whereas in general no map $B/\mathfrak{q} \to A/\mathfrak{q}^c$ is induced.

Takeaway: The point of this diagram is that every ring homomorphism $f : A \to B$ simultaneously induces a compatible map of quotient rings (algebra square) and a contraction map on prime spectra that carries $V(\mathfrak{a}^e)$ into $V(\mathfrak{a})$, indeed $(f^*)^{-1}(V(\mathfrak{a})) = V(\mathfrak{a}^e)$ (Spec square), encoding in one picture the algebra-geometry duality at the heart of commutative algebra.

Theorem 15.1.33 (Chinese Remainder Theorem)**.** *Let $\mathfrak{a}_1, \dots, \mathfrak{a}_n$ be pairwise coprime ideals of A ($\mathfrak{a}_i + \mathfrak{a}_j = (1)$ for $i \neq j$). Then the natural map*

$$A/\bigcap_{i=1}^{n} \mathfrak{a}_i \xrightarrow{\cong} \prod_{i=1}^{n} A/\mathfrak{a}_i, \qquad x \mapsto (x + \mathfrak{a}_1, \dots, x + \mathfrak{a}_n),$$

is an isomorphism, and moreover $\bigcap_i \mathfrak{a}_i = \prod_i \mathfrak{a}_i$ under pairwise coprimality.

Idea. The map into $\prod A/\mathfrak{a}_i$ has kernel $\bigcap \mathfrak{a}_i$. Surjectivity reduces (by the standard interpolation) to hitting $(1, 0, \dots, 0)$: coprimality of $\mathfrak{a}_1$ with each $\mathfrak{a}_j$ $(j \neq 1)$ gives $u_j \in \mathfrak{a}_1$, $v_j \in \mathfrak{a}_j$ with $u_j + v_j = 1$; the product $\prod_{j \neq 1} v_j \equiv 1 \pmod{\mathfrak{a}_1}$ and $\equiv 0 \pmod{\mathfrak{a}_j}$. Pairwise coprimality also forces $\bigcap \mathfrak{a}_i = \prod \mathfrak{a}_i$ by induction (using $\mathfrak{a} \cap \mathfrak{b} = \mathfrak{a}\mathfrak{b}$ when $\mathfrak{a} + \mathfrak{b} = (1)$, together with $\mathfrak{a}_1 + \prod_{j \geq 2} \mathfrak{a}_j = (1)$). □

Worked Example 15.1.34 (CRT recovers $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$)**.** Apply CRT to $\mathfrak{a}_1 = (4)$, $\mathfrak{a}_2 = (3)$ in $\mathbb{Z}$.

Recognition. Coprime ideals $(4), (3)$ give $\mathbb{Z}/(4) \cap (3) \cong \mathbb{Z}/(4) \times \mathbb{Z}/(3)$, with $\bigcap = \prod$.

Solution. $(4) + (3) = (\gcd(4, 3)) = (1)$, coprime. So $(4) \cap (3) = (4)(3) = (12)$ and $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. The idempotent $(1, 0)$ pulls back to 9 (since $9 \equiv 1 \bmod 4$, $9 \equiv 0 \bmod 3$) and $(0, 1)$ to 4. Sanity check: $|\mathbb{Z}/12\mathbb{Z}| = 12 = 4 \cdot 3 = |\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}|$, and the idempotents $4, 9$ found here match the structure computation done earlier.

Worked Example 15.1.35 (Contraction of primes under $\mathbb{Z} \hookrightarrow \mathbb{Z}[i]$)**.** Identify the contraction to $\mathbb{Z}$ of a prime $\mathfrak{q} \subseteq \mathbb{Z}[i]$, and check $\mathfrak{q}^c$ is prime.

Recognition. Contraction of a prime is prime; for $\mathbb{Z} \hookrightarrow \mathbb{Z}[i]$ the contraction of $\mathfrak{q}$ is $\mathfrak{q} \cap \mathbb{Z} = (p)$ for the rational prime p below $\mathfrak{q}$.

Solution. $\mathbb{Z}[i]$ is a PID; its primes lying over a rational prime p are: $(1+i)$ over 2 (ramified), the two conjugate primes $(\pi), (\overline{\pi})$ with $\pi\overline{\pi} = p$ over $p \equiv 1 \pmod 4$ (split), and (p) itself over $p \equiv 3 \pmod 4$ (inert). In each case $\mathfrak{q} \cap \mathbb{Z} = (p)$, a prime of $\mathbb{Z}$. For instance $(1+i) \cap \mathbb{Z} = (2)$ since $(1+i)^2 = 2i$ gives $2 \in (1+i)$, while $1 \notin (1+i)$. Sanity check: $\mathbb{Z}/(2) \hookrightarrow \mathbb{Z}[i]/(1+i)$; the latter is $\mathbb{F}_2$ (since $|\mathbb{Z}[i]/(1+i)| = N(1+i) = 2$), a field, and $\mathbb{Z}/(2) = \mathbb{F}_2$ injects into it – a domain inside a domain, confirming $\mathfrak{q}^c = (2)$ is prime.

Worked Example 15.1.36 (Extension of a prime need not be prime)**.** With $f : \mathbb{Z} \hookrightarrow \mathbb{Z}[i]$, show $(5)^e = (5)\mathbb{Z}[i]$ is not prime, though (5) is prime in $\mathbb{Z}$.

Recognition. Extension is generated by the image; whether it stays prime is governed by how 5 factors upstairs.

Solution. In $\mathbb{Z}[i]$, $5 = (2+i)(2-i)$ with $2 \pm i$ non-associate primes. So $(5)^e = (2+i)(2-i)$ is a product of two distinct primes, hence not prime: $(2+i)(2-i) \in (5)^e$ yet neither factor lies in $(5)^e$ (each generates a strictly larger prime). Sanity check: $\mathbb{Z}[i]/(5) \cong \mathbb{Z}[i]/(2+i) \times \mathbb{Z}[i]/(2-i) \cong \mathbb{F}_5 \times \mathbb{F}_5$ by CRT, which has zero-divisors $(1, 0), (0, 1)$, so $(5)^e$ is not prime – the "split prime" phenomenon.

Worked Example 15.1.37 ($\mathfrak{a} \subseteq \mathfrak{a}^{ec}$ can be strict)**.** Let $f : \mathbb{Z} \to \mathbb{Q}$ be the inclusion. Compute $\mathfrak{a}^e$ and $\mathfrak{a}^{ec}$ for $\mathfrak{a} = (2)$.

Recognition. Extension into a field collapses any proper nonzero ideal to (1); contraction of (1) is (1).

Solution. $\mathfrak{a}^e = (2)\mathbb{Q} = \mathbb{Q} = (1)$ since 2 is a unit in $\mathbb{Q}$. Then $\mathfrak{a}^{ec} = f^{-1}(\mathbb{Q}) = \mathbb{Z} = (1)$. So $\mathfrak{a} = (2) \subsetneq (1) = \mathfrak{a}^{ec}$, a strict inclusion. Sanity check: geometrically $\operatorname{Spec}\mathbb{Q} \to \operatorname{Spec}\mathbb{Z}$ hits only the generic point (0), so the prime (2) has empty preimage and its extension "sees nothing," consistent with $(2)^e = (1)$ being the unit ideal.

The geometry: $V(\mathfrak{a})$ and primes as points

We close by making the geometric dictionary explicit, as A&M does in the exercises. For an ideal $\mathfrak{a} \subseteq A$ define its *vanishing set* inside $\operatorname{Spec} A$:

$$V(\mathfrak{a}) = \{\, \mathfrak{p} \in \operatorname{Spec} A : \mathfrak{p} \supseteq \mathfrak{a} \,\}.$$

Reading $\mathfrak{p}$ as a point and $f \in A$ as a function whose "value at $\mathfrak{p}$" is the image f mod $\mathfrak{p}$ in the residue field of $A/\mathfrak{p}$, the condition $\mathfrak{p} \supseteq \mathfrak{a}$ says "every $f \in \mathfrak{a}$ vanishes at $\mathfrak{p}$."

Proposition 15.1.38 (V defines the Zariski topology)**.** *The sets $V(\mathfrak{a})$ are the closed sets of a topology on* $\operatorname{Spec} A$*:*

$$V(0) = \operatorname{Spec} A, \quad V(1) = \varnothing, \quad \bigcap_i V(\mathfrak{a}_i) = V\Big(\sum_i \mathfrak{a}_i\Big), \quad V(\mathfrak{a}) \cup V(\mathfrak{b}) = V(\mathfrak{a} \cap \mathfrak{b}) = V(\mathfrak{a}\mathfrak{b}),$$

and $V(\mathfrak{a}) = V(r(\mathfrak{a}))$, so closed sets depend only on the radical.

Idea. Each identity is a direct unwinding of "$\mathfrak{p} \supseteq$". For the union: $\mathfrak{p} \supseteq \mathfrak{a}\mathfrak{b}$ and $\mathfrak{p}$ prime force $\mathfrak{p} \supseteq \mathfrak{a}$ or $\mathfrak{p} \supseteq \mathfrak{b}$. For the radical: $\mathfrak{p} \supseteq \mathfrak{a} \iff \mathfrak{p} \supseteq r(\mathfrak{a})$ because $r(\mathfrak{a}) = \bigcap_{\mathfrak{p} \supseteq \mathfrak{a}} \mathfrak{p}$. □

Worked Example 15.1.39 (V of the two coordinate axes)**.** In $A = k[x, y]$, describe $V((xy))$ and relate it to $V((x))$ and $V((y))$.

Recognition. $V(\mathfrak{a}\mathfrak{b}) = V(\mathfrak{a}) \cup V(\mathfrak{b})$; the ideal $(xy) = (x)(y)$ should give the union of the two axes.

Solution. $V((xy)) = V((x)(y)) = V((x)) \cup V((y))$. The closed set $V((x))$ consists of primes containing x – geometrically the line $x = 0$ (the y-axis), with generic point (x) and closed points $(x, y - b)$; similarly $V((y))$ is the x-axis. So $V((xy))$ is the union of the two axes. Sanity check: (xy) is not prime (it is not radical-prime: $r((xy)) = (xy)$ here, but (xy) fails primeness since $x \cdot y \in (xy)$ with $x, y \notin (xy)$), matching that $V((xy))$ is reducible – a union of two irreducible components.

Worked Example 15.1.40 (Irreducible closed sets are $V(\mathfrak{p})$ for $\mathfrak{p}$ prime)**.** Show that $V(\mathfrak{a})$ is irreducible (nonempty and not a union of two proper closed subsets) iff $r(\mathfrak{a})$ is prime; in particular $V(\mathfrak{p})$ is irreducible for every prime $\mathfrak{p}$, and $\overline{\{\,\mathfrak{p}\,\}} = V(\mathfrak{p})$.

Recognition. Irreducibility of $V(\mathfrak{a})$ corresponds to $r(\mathfrak{a})$ being prime; the closure of a point $\mathfrak{p}$ is the smallest V containing it.

Solution. The closure of $\{\,\mathfrak{p}\,\}$ is the intersection of all closed sets containing $\mathfrak{p}$, namely $V(\mathfrak{p})$ itself (the smallest $V(\mathfrak{a})$ with $\mathfrak{p} \in V(\mathfrak{a})$ is $V(\mathfrak{p})$). If $\mathfrak{p}$ is prime and $V(\mathfrak{p}) = V(\mathfrak{b}) \cup V(\mathfrak{c}) = V(\mathfrak{b}\mathfrak{c})$, then $r(\mathfrak{b}\mathfrak{c}) = r(\mathfrak{p}) = \mathfrak{p}$, so $\mathfrak{p} \supseteq \mathfrak{b}\mathfrak{c}$, forcing $\mathfrak{p} \supseteq \mathfrak{b}$ or $\mathfrak{p} \supseteq \mathfrak{c}$, i.e. one piece is all of $V(\mathfrak{p})$; since $V(\mathfrak{a}) = V(r(\mathfrak{a}))$, this covers every $\mathfrak{a}$ with $r(\mathfrak{a})$ prime. Conversely, if $r(\mathfrak{a})$ is not prime, then either $r(\mathfrak{a}) = (1)$ and $V(\mathfrak{a}) = \varnothing$, or there are $x, y \notin r(\mathfrak{a})$ with $xy \in r(\mathfrak{a})$; then $V(\mathfrak{a}) = V(\mathfrak{a} + (x)) \cup V(\mathfrak{a} + (y))$ (a prime containing $\mathfrak{a}$ contains xy, hence x or y), and both pieces are proper since $x, y \notin r(\mathfrak{a}) = \bigcap_{\mathfrak{p} \supseteq \mathfrak{a}} \mathfrak{p}$. Sanity check: the generic point (0) of $\operatorname{Spec}\mathbb{Z}$ has closure $V((0)) = \operatorname{Spec}\mathbb{Z}$ – it is dense – exactly because (0) is the minimal prime of the domain $\mathbb{Z}$, the geometric counterpart of "Spec of a domain is irreducible."

Worked Example 15.1.41 (Closed points are the maximal ideals)**.** Show $\{\,\mathfrak{p}\,\}$ is closed in $\operatorname{Spec} A$ iff $\mathfrak{p}$ is maximal.

Recognition. $\overline{\{\,\mathfrak{p}\,\}} = V(\mathfrak{p})$, which is a single point iff no prime strictly contains $\mathfrak{p}$.

Solution. $\{\mathfrak{p}\}$ is closed iff $V(\mathfrak{p}) = \{\mathfrak{p}\}$, i.e. iff the only prime containing $\mathfrak{p}$ is $\mathfrak{p}$ itself; that is exactly maximality of $\mathfrak{p}$ (any proper containment would land in some maximal ideal $\supsetneq \mathfrak{p}$). Sanity check: in $\operatorname{Spec}\mathbb{Z}$ the closed points are the (p) (maximal), while (0) is not closed – its closure is the whole line – recovering "maximal ideal = classical point, prime ideal = irreducible subvariety / generic point."

Exercises (Atiyah & Macdonald).

1. Let x be a nilpotent element of a ring A. Show that $1 + x$ is a unit of A. Deduce that the sum of a nilpotent element and a unit is a unit.

2. Let A be a ring and let $A[x]$ be the ring of polynomials in an indeterminate x, with coefficients in A. Let $f = a_0 + a_1x + \cdots + a_nx^n \in A[x]$. Prove that

   i) f is a unit in $A[x] \iff a_0$ is a unit in A and $a_1, \ldots, a_n$ are nilpotent. [*If $b_0 + b_1x + \cdots + b_mx^m$ is the inverse of f, prove by induction on r that $a_n^{r+1}b_{m-r} = 0$. Hence show that a_n is nilpotent, and then use Ex. 1.*]

   ii) f is nilpotent $\iff a_0, a_1, \ldots, a_n$ are nilpotent.

   iii) f is a zero-divisor $\iff$ there exists $a \neq 0$ in A such that $af = 0$. [*Choose a polynomial $g = b_0 + b_1x + \cdots + b_mx^m$ of least degree m such that $fg = 0$. Then $a_nb_m = 0$, hence $a_ng = 0$ (because a_ng annihilates f and has degree $< m$). Now show by induction that $a_{n-r}g = 0$ $(0 \leq r \leq n)$.*]

   iv) f is said to be *primitive* if $(a_0, a_1, \ldots, a_n) = (1)$. Prove that if $f, g \in A[x]$, then fg is primitive $\iff$ f and g are primitive.

3. Generalize the results of Exercise 2 to a polynomial ring $A[x_1, \ldots, x_r]$ in several indeterminates.

4. In the ring $A[x]$, the Jacobson radical is equal to the nilradical.

5. Let A be a ring and let $A[[x]]$ be the ring of formal power series $f = \sum_{n=0}^{\infty} a_nx^n$ with coefficients in A. Show that

   i) f is a unit in $A[[x]] \iff a_0$ is a unit in A.

   ii) If f is nilpotent, then a_n is nilpotent for all $n \geq 0$. Is the converse true? (See Chapter 7, Exercise 2.)

   iii) f belongs to the Jacobson radical of $A[[x]] \iff a_0$ belongs to the Jacobson radical of A.

   iv) The contraction of a maximal ideal $\mathfrak{m}$ of $A[[x]]$ is a maximal ideal of A, and $\mathfrak{m}$ is generated by $\mathfrak{m}^c$ and x.

   v) Every prime ideal of A is the contraction of a prime ideal of $A[[x]]$.

6. A ring A is such that every ideal not contained in the nilradical contains a nonzero idempotent (that is, an element e such that $e^2 = e \neq 0$). Prove that the nilradical and Jacobson radical of A are equal.

7. Let A be a ring in which every element x satisfies $x^n = x$ for some $n > 1$ (depending on x). Show that every prime ideal of A is maximal.

8. Let A be a ring $\neq 0$. Show that the set of prime ideals of A has minimal elements with respect to inclusion.

9. Let $\mathfrak{a}$ be an ideal $\neq (1)$ in a ring A. Show that $\mathfrak{a} = r(\mathfrak{a}) \iff \mathfrak{a}$ is an intersection of prime ideals.

10. Let A be a ring, $\mathfrak{N}$ its nilradical. Show that the following are equivalent:

    i) A has exactly one prime ideal;

    ii) every element of A is either a unit or nilpotent;

    iii) $A/\mathfrak{N}$ is a field.

11. A ring A is *Boolean* if $x^2 = x$ for all $x \in A$. In a Boolean ring A, show that

    i) $2x = 0$ for all $x \in A$;

    ii) every prime ideal $\mathfrak{p}$ is maximal, and $A/\mathfrak{p}$ is a field with two elements;

iii) every finitely generated ideal in A is principal.

12. A local ring contains no idempotent $\neq 0, 1$.

Construction of an algebraic closure of a field (E. Artin).

13. Let K be a field and let Σ be the set of all irreducible monic polynomials f in one indeterminate with coefficients in K. Let A be the polynomial ring over K generated by indeterminates x_f, one for each $f \in \Sigma$. Let $\mathfrak{a}$ be the ideal of A generated by the polynomials $f(x_f)$ for all $f \in \Sigma$. Show that $\mathfrak{a} \neq (1)$.

    Let $\mathfrak{m}$ be a maximal ideal of A containing $\mathfrak{a}$, and let $K_1 = A/\mathfrak{m}$. Then K_1 is an extension field of K in which each $f \in \Sigma$ has a root. Repeat the construction with K_1 in place of K, obtaining a field K_2, and so on. Let $L = \bigcup_{n=1}^{\infty} K_n$. Then L is a field in which each $f \in \Sigma$ splits completely into linear factors. Let $\bar{K}$ be the set of all elements of L which are algebraic over K. Then $\bar{K}$ is an algebraic closure of K.

14. In a ring A, let Σ be the set of all ideals in which every element is a zero-divisor. Show that the set Σ has maximal elements and that every maximal element of Σ is a prime ideal. Hence the set of zero-divisors in A is a union of prime ideals.

Practice problems.

1. In $A = \mathbb{Z}/72\mathbb{Z}$, compute $\mathrm{nil}(A)$, list every idempotent of A, and use the orthogonal idempotents to write A explicitly as a product of local rings. Verify that the number of idempotents equals 2^r where r is the number of distinct primes dividing 72.

2. Let $A = k[x, y]$ with k a field. Compute the ideal quotient $((x^3, x^2y) : (x^2))$ and the radical $r((x^4y^2))$. In each case identify the answer with a single explicit ideal and justify the equality.

3. Determine all prime ideals of $A = \mathbb{Z}/12\mathbb{Z} \times \mathbb{F}_5$. For each, state whether it is maximal, and identify the residue field $A/\mathfrak{p}$. Compute $\mathrm{nil}(A)$ and $\mathrm{Jac}(A)$ and confirm that they are equal here (every prime of this finite ring is maximal).

4. In $A = k[x]$, let $\mathfrak{a} = (x^2(x-1))$. Describe $\mathrm{Spec}(A/\mathfrak{a})$, decompose $A/\mathfrak{a}$ as a product of local rings via CRT, and compute $\mathrm{nil}(A/\mathfrak{a})$ and $\mathrm{Jac}(A/\mathfrak{a})$. Show the two radicals coincide in this ring.

5. Let A be a ring and $e \in A$ an idempotent with $e \neq 0, 1$. Prove that $e \notin \mathrm{Jac}(A)$ and that e is a zero-divisor. Then show that no idempotent other than 0 is nilpotent.

6. In $A = \mathbb{Z}[i]$, let $\mathfrak{a} = (3)$ and $\mathfrak{b} = (2 + i)$. Decide for each whether it is prime, maximal, both, or neither, and identify the residue field $A/\mathfrak{a}$ (resp. $A/\mathfrak{b}$). Compute the contraction of each to $\mathbb{Z}$ and confirm the contraction is prime.

7. Let A be a ring in which $\mathrm{nil}(A) = \mathrm{Jac}(A)$. Suppose $\mathfrak{m}$ is a maximal ideal with $\mathfrak{m} = \mathrm{nil}(A)$. Prove that A is local, that every nonunit of A is nilpotent, and that $A/\mathrm{nil}(A)$ is a field. (This is the "one prime" situation; do not merely cite it – prove the three claims.)

8. In $A = k[x, y]/(xy)$ with k a field, let $\bar{x}, \bar{y}$ be the images of x, y. Show $\bar{x}, \bar{y}$ are zero-divisors, that A is reduced (i.e. $\mathrm{nil}(A) = (0)$), and that $\mathrm{Spec}\, A$ is reducible by exhibiting the two minimal primes of A explicitly.

Additional exercises.

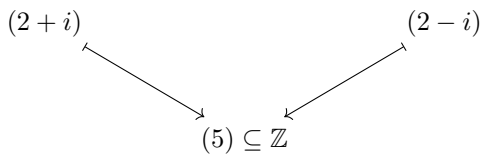
1. Let A be a ring and $\mathfrak{a}$ an ideal. Prove that $r(\mathfrak{a}) = A$ iff $\mathfrak{a} = A$, and that for any two ideals $r(\mathfrak{a} + \mathfrak{b}) = r\big(r(\mathfrak{a}) + r(\mathfrak{b})\big)$. Give an explicit example in $k[x, y]$ with $r(\mathfrak{a}) = \mathfrak{a}$, $r(\mathfrak{b}) = \mathfrak{b}$, yet $r(\mathfrak{a} + \mathfrak{b}) \neq \mathfrak{a} + \mathfrak{b}$, and identify $r(\mathfrak{a} + \mathfrak{b})$.

2. Prove that for any ring A, an element x lies in $\mathrm{Jac}(A)$ iff $1 - xy$ is a unit for every $y \in A$. Deduce that if $x \in \mathrm{Jac}(A)$ and x is idempotent then $x = 0$, and that $\mathrm{Jac}(A)$ contains no nonzero idempotent.

3. Let $A \to B$ be a surjective ring homomorphism with kernel $\mathfrak{a}$. Prove that the induced map $\mathrm{Spec}\, B \to \mathrm{Spec}\, A$ is a homeomorphism onto the closed set $V(\mathfrak{a}) \subseteq \mathrm{Spec}\, A$, and that under this identification the minimal primes of B correspond to the primes of A that are minimal among those containing $\mathfrak{a}$.

4. Let A be a ring such that $\operatorname{Spec} A$ is a finite set $\{\mathfrak{m}_1, \dots, \mathfrak{m}_n\}$ of maximal ideals (so A is semilocal with $\dim A = 0$). Prove that $\operatorname{nil}(A) = \operatorname{Jac}(A) = \bigcap_i \mathfrak{m}_i$, that the $\mathfrak{m}_i$ are pairwise coprime, and conclude via CRT that $A/\operatorname{nil}(A) \cong \prod_i A/\mathfrak{m}_i$, a finite product of fields.

5. Let A be a ring and $S \subseteq A$ a set of nilpotent elements that is closed under multiplication and contains a finite generating set $s_1, \dots, s_m$ for an ideal $\mathfrak{a}$. Prove that $\mathfrak{a} \subseteq \operatorname{nil}(A)$, that $\mathfrak{a}$ is a nilpotent ideal (some power $\mathfrak{a}^N = (0)$), and that A and $A/\mathfrak{a}$ have the same prime ideals via the correspondence theorem.



Commutative-diagram exercises.

1. Let A be a ring, $\mathfrak{a}$ an ideal, and $\phi : A \to A/\mathfrak{a}$ the projection. Complete the square below, in which the horizontal maps are the projections and the vertical maps are induced by ϕ on prime/ideal lattices, and prove it commutes:

$$\begin{array}{ccc} A & \xrightarrow{\ \phi\ } & A/\mathfrak{a} \\ {\scriptstyle\psi}\downarrow & & \downarrow{\scriptstyle\bar{\psi}} \\ A/\mathfrak{b} & \xrightarrow[\ \overline{\phi}\ ]{} & A/(\mathfrak{a}+\mathfrak{b}) \end{array}$$

   Here $\mathfrak{b} \supseteq \mathfrak{a}$ is a second ideal, $\psi : A \to A/\mathfrak{b}$ is its projection, and the right vertical map is induced. Prove that the induced map $A/\mathfrak{a} \to A/(\mathfrak{a}+\mathfrak{b})$ is surjective with kernel $(\mathfrak{a}+\mathfrak{b})/\mathfrak{a}$, and deduce that contracting prime ideals along the square commutes (the corresponding diagram of Spec's commutes).

2. Let $f : \mathbb{Z} \hookrightarrow \mathbb{Z}[i]$ be the inclusion. Draw the diagram of Spec maps over the rational prime 5, completing the skeleton below, where f^* is the contraction map $\mathfrak{q} \mapsto \mathfrak{q} \cap \mathbb{Z}$:

   Prove that both $(2+i)$ and $(2-i)$ contract to (5), that they are the only primes of $\mathbb{Z}[i]$ doing so, and that $\mathbb{Z}[i]/(5) \cong \mathbb{F}_5 \times \mathbb{F}_5$ via CRT. Conclude that the extension $(5)^e$ is not prime.

3. Let A be a ring with a nontrivial idempotent e, so $A \cong A_1 \times A_2$ with $A_1 = Ae$, $A_2 = A(1-e)$. Complete the diagram relating the projections to the spectrum decomposition, and prove that $\operatorname{Spec} A = \operatorname{Spec} A_1 \sqcup \operatorname{Spec} A_2$ (a disjoint union of two closed sets):

   Identify the kernels of π_1, π_2 as the ideals $(1-e)$ and (e), prove these are coprime, and explain why every prime of A contains exactly one of e, $1-e$ (hence lands in exactly one of the two closed pieces).

15.2 Noetherian Rings, the Hilbert Basis Theorem, and Affine Algebraic Sets

Chain conditions: ACC, DCC, and the maximal-element principle

The whole section rests on a single combinatorial device. Let Σ be a set partially ordered by a relation $\leq$. We say Σ satisfies the *ascending chain condition* (ACC) if every increasing sequence $x_1 \leq x_2 \leq \cdots$ is eventually *stationary*, meaning there is N with $x_n = x_N$ for all $n \geq N$; dually Σ satisfies the *descending chain condition*

(DCC) if every decreasing sequence stabilizes. Atiyah and Macdonald isolate the formal symmetry between the ascending and descending cases at the level of an abstract poset, before specializing to modules and rings – a symmetry that will break in later chapters but is exact here.

Proposition 15.2.1 (ACC = maximal-element condition; Atiyah–Macdonald 6.1)**.** *For a partially ordered set Σ the following are equivalent:*

(i) *every increasing sequence $x_1 \le x_2 \le \cdots$ in Σ is stationary;*

(ii) *every nonempty subset of Σ has a maximal element.*

Idea. (i)⇒(ii): if some nonempty $T \subseteq \Sigma$ had no maximal element, then from any $x_0 \in T$ one could choose $x_1 > x_0$, then $x_2 > x_1$, and so on, building a strictly increasing sequence that never stabilizes – contradicting (i). (Choosing the x_n uses the axiom of dependent choice.) (ii)⇒(i): the set $\{\, x_n : n \ge 1 \,\}$ of terms of an increasing sequence has a maximal element x_N, and $x_n \ge x_N$ for $n \ge N$ forces $x_n = x_N$. □

Apply this with Σ the set of submodules of a module M (over a commutative ring R), ordered by inclusion. A module satisfying ACC on submodules is *Noetherian* (after Emmy Noether); one satisfying DCC on submodules is *Artinian* (after Emil Artin). The same applied to the set of *ideals* of R – which are exactly the submodules of R regarded as a module over itself – defines a Noetherian (resp. Artinian) *ring*. By the proposition, "R is Noetherian" has three equivalent formulations, the workhorse statement of the section.

Theorem 15.2.2 (three faces of Noetherian; D&F 15.1.2)**.** *For a commutative ring R the following are equivalent:*

(1) *R satisfies ACC on ideals (no infinite strictly increasing chain $\mathfrak{a}_1 \subsetneq \mathfrak{a}_2 \subsetneq \cdots$);*

(2) *every nonempty set of ideals of R contains a maximal element under inclusion;*

(3) *every ideal of R is finitely generated.*

Idea. (1)⇔(2) is the abstract proposition above with Σ the ideals of R. (3)⇒(1): given a chain $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \cdots$, the union $\mathfrak{a} = \bigcup_n \mathfrak{a}_n$ is an ideal, finitely generated say by $g_1, \dots, g_r$; each g_i lies in some $\mathfrak{a}_{n_i}$, so all lie in $\mathfrak{a}_N$ with $N = \max n_i$, whence $\mathfrak{a} = \mathfrak{a}_N$ and the chain stops. (1)⇒(3): if some ideal $\mathfrak{a}$ were not finitely generated, pick $a_1 \in \mathfrak{a}$, then $a_2 \in \mathfrak{a} \setminus (a_1)$, then $a_3 \in \mathfrak{a} \setminus (a_1, a_2)$, and so on; the ideals $(a_1) \subsetneq (a_1, a_2) \subsetneq \cdots$ violate ACC. (Equivalently, by (2) the set of finitely generated subideals of $\mathfrak{a}$ has a maximal element, which must be $\mathfrak{a}$ itself.) □

A warning that orients the rest of the chapter: ACC and DCC are genuinely different conditions. The ring $\mathbb{Z}$ is Noetherian (it is a PID, so condition (3) holds) yet has the infinite *descending* chain $(2) \supsetneq (4) \supsetneq (8) \supsetneq \cdots$, so $\mathbb{Z}$ is not Artinian. Atiyah and Macdonald prove later (their 8.5) that a ring with DCC necessarily has ACC; the converse fails, exactly as $\mathbb{Z}$ shows. We record the philosophical point now: ACC is a *finiteness* condition ("every ideal is built from finitely many generators"), while DCC is a *smallness* condition that, for rings, turns out to force dimension zero.

Worked Example 15.2.3 (Every PID is Noetherian; $\mathbb{Z}$, $k[x]$, $\mathbb{Z}[i]$)**.** Show directly that a principal ideal domain satisfies ACC on ideals.

Recognition. Use criterion (3): in a PID every ideal is generated by one element, so a fortiori finitely generated.

Solution. Let R be a PID and $\mathfrak{a} \subseteq R$ an ideal. By definition $\mathfrak{a} = (a)$ for a single $a \in R$, so $\mathfrak{a}$ is generated by the finite (one-element) set $\{\, a \,\}$. By Theorem 15.2.2 this is exactly the Noetherian condition. Concretely $\mathbb{Z}$, the polynomial ring $k[x]$ over a field k, and the Gaussian integers $\mathbb{Z}[i]$ are all PIDs, hence Noetherian. Sanity check: the ascending chain $(12) \subseteq (6) \subseteq (2) \subseteq (1)$ in $\mathbb{Z}$ is finite and stabilizes at $(1) = \mathbb{Z}$; divisibility runs the opposite way to inclusion, and a strictly increasing chain of principal ideals $(a_1) \subsetneq (a_2) \subsetneq \cdots$ would give a strictly decreasing chain of divisors, impossible since a nonzero integer has finitely many divisors.

Worked Example 15.2.4 (A non-Noetherian ring: $k[x_1, x_2, \dots]$)**.** Exhibit an infinite strictly ascending chain of ideals in the polynomial ring in countably many variables.

Recognition. ACC fails iff some ideal is not finitely generated; the irrelevant ideal $(x_1, x_2, \dots)$ is the natural candidate.

Solution. In $R = k[x_1, x_2, \dots]$ set $\mathfrak{a}_n = (x_1, \dots, x_n)$. Then $\mathfrak{a}_1 \subsetneq \mathfrak{a}_2 \subsetneq \mathfrak{a}_3 \subsetneq \cdots$ is strictly increasing: $x_{n+1} \notin \mathfrak{a}_n$ because every element of $\mathfrak{a}_n$ is a combination of $x_1, \dots, x_n$ and so has no pure x_{n+1} term. The chain never stabilizes, so R is not Noetherian; equivalently the ideal $\bigcup_n \mathfrak{a}_n = (x_1, x_2, \dots)$ cannot be finitely generated, since any finite set of polynomials involves only finitely many of the variables. Sanity check: this is consistent with the Hilbert Basis Theorem below, which only manufactures Noetherian polynomial rings in *finitely* many variables – adjoining infinitely many variables is precisely where finiteness is lost.

Worked Example 15.2.5 (A subgroup of $\mathbb{Q}/\mathbb{Z}$ with DCC but not ACC)**.** Let p be prime and $G \subseteq \mathbb{Q}/\mathbb{Z}$ the subgroup of all elements whose order is a power of p (the Prüfer group $\mathbb{Z}(p^\infty)$). Show G satisfies DCC but not ACC on subgroups.

Recognition. View G as a $\mathbb{Z}$-module; its subgroups form a chain indexed by exponents, so chains in one direction are infinite and in the other are finite.

Solution. The proper subgroups of G are exactly $G_n = \{\, x \in G : p^n x = 0 \,\}$, the cyclic group of order p^n, and they sit in one increasing chain $G_0 \subsetneq G_1 \subsetneq G_2 \subsetneq \cdots$ with $\bigcup_n G_n = G$. Thus ACC fails (this is a strictly increasing infinite chain). But any *descending* chain of subgroups, each being some G_n or G itself, can only step down through finitely many of the well-ordered values $\cdots > G_2 > G_1 > G_0 = 0$, so DCC holds. Sanity check: G is the dual phenomenon to $\mathbb{Z}$ (which has ACC but not DCC); together they show ACC and DCC are logically independent for modules, even though for rings DCC will turn out to imply ACC.

Worked Example 15.2.6 (A finite-dimensional k-algebra has both ACC and DCC)**.** Let R be a k-algebra that is finite dimensional as a k-vector space, e.g. $R = k[x]/(f(x))$ for nonzero f. Show R satisfies both chain conditions on ideals.

Recognition. Ideals are in particular k-subspaces, and a chain of subspaces of a $\dim_k R$-dimensional space has bounded length.

Solution. Each ideal $\mathfrak{a} \subseteq R$ is a k-subspace, and in a strict chain $\mathfrak{a}_0 \subsetneq \mathfrak{a}_1 \subsetneq \cdots$ the dimensions $\dim_k \mathfrak{a}_i$ strictly increase, so the chain has at most $\dim_k R + 1$ terms. Hence both ascending and descending chains terminate: R is Noetherian and Artinian. For $R = k[x]/(f)$ with $\deg f = n$, $\dim_k R = n$, so every chain of ideals has at most $n + 1$ links. Sanity check: $\mathbb{Z}/12\mathbb{Z}$ has ideals $0, (6), (4), (3), (2), (1)$ corresponding to divisors of 12 – only finitely many, confirming both chain conditions for this finite ring.

Noetherian modules: behavior in exact sequences

The reason to phrase the theory for *modules*, as Atiyah and Macdonald insist, is that the class of Noetherian modules is closed under the basic operations – submodule, quotient, extension – and this stability is what lets one bootstrap from simple rings to complicated ones. The module-level criterion mirrors the ring-level one.

Proposition 15.2.7 (Noetherian module = ACC = f.g. submodules; A–M 6.2)**.** *An R-module M is Noetherian if and only if every submodule of M is finitely generated.*

Idea. ($\Rightarrow$) Given a submodule N, the set Σ of finitely generated submodules of N is nonempty (it contains 0), so by ACC it has a maximal element N_0; if some $x \in N \setminus N_0$ existed, $N_0 + Rx$ would be a strictly larger finitely generated submodule, a contradiction, so $N_0 = N$ is finitely generated. ($\Leftarrow$) Given an ascending chain $M_1 \subseteq M_2 \subseteq \cdots$, the union $N = \bigcup_n M_n$ is a submodule, finitely generated say by $x_1, \dots, x_r$; each $x_i \in M_{n_i}$, so all lie in M_N with $N = \max n_i$, forcing the chain stationary. □

Proposition 15.2.8 (the two-out-of-three property; A–M 6.3)**.** *Let $0 \to M' \xrightarrow{\alpha} M \xrightarrow{\beta} M'' \to 0$ be a short exact sequence of R-modules. Then M is Noetherian if and only if both M' and M'' are Noetherian; likewise with "Artinian".*

Idea. ($\Rightarrow$) An ascending chain in M' (resp. in M'') pushes forward to a chain in M via α (resp. pulls back via β^{-1}), which stabilizes, so the original does. ($\Leftarrow$) Given an ascending chain (L_n) in M, the chains $(\alpha^{-1}(L_n))$ in M' and $(\beta(L_n))$ in M'' both stabilize for n large; a standard diagram chase (if $\alpha^{-1}(L_n) = \alpha^{-1}(L_{n+1})$ and $\beta(L_n) = \beta(L_{n+1})$ then $L_n = L_{n+1}$) shows (L_n) stabilizes too. □

Corollary 15.2.9 (finite direct sums; A–M 6.4)**.** *If $M_1, \dots, M_n$ are Noetherian (resp. Artinian) R-modules, so is $\bigoplus_{i=1}^n M_i$.*

These propositions are the engine behind the ring-theoretic results below: they let us reduce "M Noetherian" to pieces, and via the next two statements transfer the Noetherian property between a ring and its finitely generated modules.

Proposition 15.2.10 (f.g. modules over a Noetherian ring; A–M 6.5)**.** *If R is a Noetherian ring and M is a finitely generated R-module, then M is a Noetherian module. (Likewise Artinian.)*

Idea. A finitely generated M is a quotient of R^n for some n; R is Noetherian as a module over itself, so R^n is Noetherian by the direct-sum corollary, and a quotient of a Noetherian module is Noetherian by the exact-sequence proposition. □

Worked Example 15.2.11 (Quotients of a Noetherian ring are Noetherian)**.** If R is Noetherian and $\mathfrak{a} \subseteq R$ an ideal, show $R/\mathfrak{a}$ is Noetherian; deduce every homomorphic image of a Noetherian ring is Noetherian.

Recognition. Ideals of $R/\mathfrak{a}$ correspond, by the Lattice Isomorphism Theorem, to ideals of R containing $\mathfrak{a}$, so chains downstairs lift to chains upstairs.

Solution. An ascending chain of ideals of $R/\mathfrak{a}$ pulls back to an ascending chain of ideals of R (each containing $\mathfrak{a}$); the latter stabilizes since R is Noetherian, hence so does the former. Thus $R/\mathfrak{a}$ is Noetherian. For a general homomorphic image: if $\phi : R \to S$ is a surjective ring map then $S \cong R/\ker\phi$ by the First Isomorphism Theorem, which is Noetherian by the case just done. Sanity check: $\mathbb{Z}/n\mathbb{Z}$ is a quotient of the Noetherian $\mathbb{Z}$, and indeed it is finite hence Noetherian; and $k[x,y]/(xy)$ is a quotient of $k[x,y]$ (Noetherian by Hilbert below), hence Noetherian despite not being a domain.

Worked Example 15.2.12 (A subring of a Noetherian ring need not be Noetherian)**.** Show that being Noetherian does not pass to subrings, in contrast to quotients.

Recognition. The polynomial ring $k[x_1, x_2, \dots]$ embeds in its fraction field, which is Noetherian (a field), yet the subring is not.

Solution. The fraction field $K = \mathrm{Frac}\big(k[x_1, x_2, \dots]\big)$ is a field, so its only ideals are 0 and K – trivially Noetherian. But the subring $k[x_1, x_2, \dots] \subseteq K$ is not Noetherian, as Worked Example 15.2.4 showed via the chain $(x_1) \subsetneq (x_1, x_2) \subsetneq \cdots$. Sanity check: a positive result needs a *module-finiteness* hypothesis – if B is Noetherian as an A-module then its A-submodule A is a Noetherian ring – and a bare subring inclusion is not enough. (A–M 7.2 goes the other way: A Noetherian and B finitely generated as an A-module force B Noetherian.)

Worked Example 15.2.13 ($C(X)$ for X compact infinite Hausdorff is not Noetherian)**.** Let X be a compact infinite Hausdorff space and $C(X)$ the ring of real-valued continuous functions. Exhibit a strictly increasing chain of ideals.

Recognition. Vanishing loci give ideals; a strictly decreasing chain of closed sets produces a strictly increasing chain of "functions vanishing there."

Solution. Pick a strictly decreasing chain of nonempty closed sets $F_1 \supsetneq F_2 \supsetneq \cdots$ in X (possible since X is infinite and Hausdorff). Let $\mathfrak{a}_n = \{\, f \in C(X) : f(F_n) = 0 \,\}$. Since closed sets are separated by Urysohn functions, $F_n \supsetneq F_{n+1}$ yields a function vanishing on F_{n+1} but not on F_n, so $\mathfrak{a}_n \subsetneq \mathfrak{a}_{n+1}$ strictly. The chain never stabilizes, so $C(X)$ is not Noetherian. Sanity check: this matches D&F's remark that the ring of continuous functions on $[0,1]$ is non-Noetherian; the analytic flabbiness of $C(X)$ is the opposite of the polynomial rigidity that the Basis Theorem exploits.

Worked Example 15.2.14 (Fitting's Lemma: an injective endomorphism trick)**.** Let M be a Noetherian R-module and $\theta : M \to M$ an R-module endomorphism. Show $\ker(\theta^n) \cap \mathrm{im}(\theta^n) = 0$ for n large, and that if θ is surjective it is an isomorphism.

Recognition. Kernels of iterates ascend; ACC stabilizes them, and stabilization of kernels forces injectivity on the stable image.

Solution. The kernels ascend: $\ker\theta \subseteq \ker\theta^2 \subseteq \cdots$, so by ACC there is n with $\ker\theta^n = \ker\theta^{2n}$. Take $x \in \ker\theta^n \cap \mathrm{im}\,\theta^n$, say $x = \theta^n(y)$; then $\theta^n(x) = 0$ gives $\theta^{2n}(y) = 0$, so $y \in \ker\theta^{2n} = \ker\theta^n$, whence $x = \theta^n(y) = 0$. Thus the intersection is 0. If θ is surjective then $\mathrm{im}\,\theta^n = M$, so $\ker\theta^n = \ker\theta^n \cap M = 0$, forcing $\ker\theta = 0$, i.e. θ injective, hence bijective. Sanity check: surjectivity alone gives isomorphism only with a finiteness hypothesis – the shift map on $R^{(\infty)}$ is surjective but not injective, and indeed that module is not Noetherian.

The Hilbert basis theorem and finitely generated algebras

We now reach the structural centerpiece: Noetherianness is preserved by adjoining a variable. This is the mechanism by which all the rings of algebraic geometry – finitely generated algebras over a field – inherit ACC, and it is, as D&F note, one of the original motivations for the theorem: it guarantees that a system of polynomial equations, however it is presented, is equivalent to a *finite* subsystem.

Theorem 15.2.15 (Hilbert Basis Theorem; D&F 15.1.3, A–M 7.5)**.** *If R is a Noetherian ring, then the polynomial ring $R[x]$ is Noetherian.*

Idea. Let $\mathfrak{a} \subseteq R[x]$ be an ideal. Let L be the set of leading coefficients of elements of $\mathfrak{a}$ (together with 0); L is an ideal of R, hence finitely generated, say $L = (a_1, \dots, a_n)$ with a_i the leading coefficient of some $f_i \in \mathfrak{a}$ of degree d_i. Put $r = \max d_i$. Given any $f \in \mathfrak{a}$ of degree $m \geq r$ with leading coefficient a, write $a = \sum u_i a_i$; then $f - \sum u_i x^{m-d_i} f_i$ lies in $\mathfrak{a}$ with strictly smaller degree. Iterating, every $f \in \mathfrak{a}$ reduces modulo $(f_1, \dots, f_n)$ to a polynomial of degree $< r$. The elements of $\mathfrak{a}$ of degree $< r$ lie in the finitely generated R-module $M = R \cdot 1 + R \cdot x + \cdots + R \cdot x^{r-1}$; since R is Noetherian, M is a Noetherian module, so the submodule $\mathfrak{a} \cap M$ is finitely generated, say by $g_1, \dots, g_m$. Then $f_1, \dots, f_n, g_1, \dots, g_m$ generate $\mathfrak{a}$, so $\mathfrak{a}$ is finitely generated and $R[x]$ is Noetherian. □

Corollary 15.2.16 (polynomial rings in finitely many variables; D&F 15.1.4, A–M 7.6)**.** *If R is Noetherian then so is $R[x_1, \dots, x_n]$. In particular $k[x_1, \dots, x_n]$ over a field k is Noetherian, as is $\mathbb{Z}[x_1, \dots, x_n]$.*

Idea. Induct on n, writing $R[x_1, \dots, x_n] = \big(R[x_1, \dots, x_{n-1}]\big)[x_n]$ and applying the Basis Theorem at each step. □

A ring R containing a field k in its center, with the same identity, is a *k-algebra*; it is *finitely generated as a k-algebra* if $R = k[r_1, \dots, r_n]$ for finitely many ring generators r_i (this is far weaker than being finite dimensional as a vector space). The following corollary is the statement that "every ring you can write down with finitely many generators and relations over a field is Noetherian."

Corollary 15.2.17 (finitely generated algebras are Noetherian; D&F 15.1.5, A–M 7.7)**.** *R is a finitely generated k-algebra if and only if there is a surjective k-algebra homomorphism $\varphi : k[x_1, \dots, x_n] \twoheadrightarrow R$ for some n. Consequently every finitely generated k-algebra is Noetherian. More generally any finitely generated algebra over a Noetherian ring is Noetherian.*

Idea. If $R = k[r_1, \dots, r_n]$, define $\varphi(x_i) = r_i$ and $\varphi|_k = \mathrm{id}$; this extends uniquely to a surjection. Conversely the images $\varphi(x_i)$ generate R. Either way $R \cong k[x_1, \dots, x_n]/\ker\varphi$ is a quotient of a Noetherian ring (by the Corollary), hence Noetherian. □

Remark 15.2.1. The Basis Theorem also holds for the formal power series ring: R Noetherian $\Rightarrow R[[x]]$ Noetherian. The proof is the same in spirit but uses the coefficient of *lowest* degree (the order of a series) where the polynomial proof uses the leading coefficient. By contrast the field of rational functions $k(x) = \mathrm{Frac}\, k[x]$ is *not* a finitely generated k-algebra (its denominators involve infinitely many irreducible polynomials), though it is trivially Noetherian as a field.

Worked Example 15.2.18 ($\mathbb{Z}[x,y]/(x^2+y^2-1)$ is Noetherian)**.** Show the coordinate ring of the circle over $\mathbb{Z}$ is Noetherian.

Recognition. It is a finitely generated $\mathbb{Z}$-algebra; $\mathbb{Z}$ is Noetherian, so the Basis Theorem applies.

Solution. By the Corollary, $\mathbb{Z}[x,y] = (\mathbb{Z}[x])[y]$ is Noetherian (apply the Basis Theorem twice, starting from the Noetherian $\mathbb{Z}$). Then $\mathbb{Z}[x,y]/(x^2+y^2-1)$ is a quotient of a Noetherian ring, hence Noetherian. Sanity check: it is finitely generated as a $\mathbb{Z}$-algebra by the images of x, y and equals a quotient of $\mathbb{Z}[x_1, x_2]$, matching the surjective-homomorphism criterion; no claim of finite *dimensionality* is made, and indeed it is infinite as a $\mathbb{Z}$-module.

Worked Example 15.2.19 (The converse of Hilbert: $R[x]$ Noetherian $\Rightarrow R$ Noetherian)**.** Prove the converse direction of the Basis Theorem.

Recognition. R is a quotient of $R[x]$ via the evaluation $x \mapsto 0$, and quotients of Noetherian rings are Noetherian.

Solution. The map $R[x] \to R$, $f(x) \mapsto f(0)$, is a surjective ring homomorphism with kernel (x), so $R \cong R[x]/(x)$. If $R[x]$ is Noetherian then this quotient is Noetherian by Worked Example 15.2.11. Sanity check: combined with the Basis Theorem this gives the clean biconditional R Noetherian $\iff$ $R[x]$ Noetherian, so adjoining or deleting one variable preserves the property exactly.

Worked Example 15.2.20 (Finite-dimensional algebras are finitely generated as algebras)**.** If the k-algebra R is finite dimensional as a k-vector space, show R is a finitely generated k-algebra (and Noetherian).

Recognition. A vector-space basis is in particular a set of ring generators, so finitely many of them generate R as an algebra.

Solution. Let $e_1, \dots, e_d$ be a k-basis of R. Every element of R is a k-linear combination of the e_i, hence certainly lies in the subring $k[e_1, \dots, e_d]$; so $R = k[e_1, \dots, e_d]$ is a finitely generated k-algebra, and by the Corollary it is Noetherian. (In fact it is also Artinian, by Worked Example 15.2.6.) Sanity check: $R = k[x]/(f)$ with $\deg f = n$ has k-basis $1, x, \dots, x^{n-1}$ and is generated as an algebra by the single element x – one generator suffices even though the dimension is n.

Worked Example 15.2.21 ($\mathbb{Z}[\sqrt{-5}]$ is Noetherian but not a UFD)**.** Show the ring of integers $\mathbb{Z}[\sqrt{-5}]$ is Noetherian, even though it fails unique factorization.

Recognition. It is a finitely generated $\mathbb{Z}$-algebra (indeed module-finite over $\mathbb{Z}$), so the Basis Theorem / quotient argument applies; Noetherianness has nothing to do with the UFD property.

Solution. $\mathbb{Z}[\sqrt{-5}] \cong \mathbb{Z}[x]/(x^2+5)$ is a quotient of the Noetherian ring $\mathbb{Z}[x]$, hence Noetherian. Yet $6 = 2 \cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$ gives two genuinely different factorizations into irreducibles, so it is not a UFD. Sanity check: this separates two finiteness notions – Noetherian (ACC, always holds here) versus unique factorization (fails here); a Dedekind domain like this one recovers uniqueness only at the level of *ideals*, studied in Chapter 16.

The Zariski topology and Noetherian induction

We now make the leap A&M and D&F both emphasize: the prime ideal is the common generalization of the "primes of arithmetic" and the "points of geometry." Fix a field k and let $\mathbb{A}^n = k^n$ be affine n-space. A polynomial $f \in k[x_1, \dots, x_n]$ is a k-valued function on $\mathbb{A}^n$; the ring of all such is the *coordinate ring* $k[\mathbb{A}^n] = k[x_1, \dots, x_n]$. For a set S of polynomials, its common zero locus

$$\mathcal{Z}(S) = \{\, a \in \mathbb{A}^n : f(a) = 0 \text{ for all } f \in S \,\}$$

is an *affine algebraic set*, and these are the closed sets of the *Zariski topology*. The geometry is governed entirely by ideals via two contravariant maps

$$\mathcal{Z} : \{\, \text{ideals of } k[\mathbb{A}^n] \,\} \longrightarrow \{\, \text{algebraic sets in } \mathbb{A}^n \,\}, \qquad \mathcal{I} : \{\, \text{subsets of } \mathbb{A}^n \,\} \longrightarrow \{\, \text{ideals of } k[\mathbb{A}^n] \,\},$$

where $\mathcal{I}(A) = \{\, f : f|_A \equiv 0 \,\}$ is the largest ideal vanishing on A.

Proposition 15.2.22 (the Zariski-closed sets form a topology)**.** *The algebraic sets in $\mathbb{A}^n$ satisfy: $\mathcal{Z}(0) = \mathbb{A}^n$ and $\mathcal{Z}(1) = \varnothing$; an arbitrary intersection $\bigcap_j \mathcal{Z}(S_j) = \mathcal{Z}\big(\bigcup_j S_j\big)$ is algebraic; and a finite union $\mathcal{Z}(\mathfrak{a}) \cup \mathcal{Z}(\mathfrak{b}) = \mathcal{Z}(\mathfrak{a}\mathfrak{b}) = \mathcal{Z}(\mathfrak{a} \cap \mathfrak{b})$ is algebraic. Hence they are the closed sets of a topology on $\mathbb{A}^n$, the* Zariski topology*. Moreover $\mathcal{Z}$ is inclusion-reversing and $\mathcal{Z}(S) = \mathcal{Z}\big((S)\big)$ depends only on the ideal generated by S.*

Idea. Intersections: a point kills $\bigcup_j S_j$ iff it kills every S_j. Unions: if a is a zero of neither $\mathfrak{a}$ nor $\mathfrak{b}$, pick $f \in \mathfrak{a}, g \in \mathfrak{b}$ with $f(a), g(a) \neq 0$; then $fg \in \mathfrak{a}\mathfrak{b}$ has $(fg)(a) \neq 0$, so $a \notin \mathcal{Z}(\mathfrak{a}\mathfrak{b})$; conversely $\mathfrak{a}\mathfrak{b} \subseteq \mathfrak{a}$ and $\mathfrak{a}\mathfrak{b} \subseteq \mathfrak{b}$ make $\mathcal{Z}(\mathfrak{a}\mathfrak{b}) \supseteq \mathcal{Z}(\mathfrak{a}) \cup \mathcal{Z}(\mathfrak{b})$. The two boundary cases are immediate. □

The Noetherian property of $k[x_1, \dots, x_n]$ now has a purely geometric consequence: a coordinate-free statement that affine space satisfies the *descending* chain condition on closed sets.

Theorem 15.2.23 (DCC on Zariski-closed sets)**.** *In $\mathbb{A}^n$ over any field k, every descending chain of algebraic sets $V_1 \supseteq V_2 \supseteq V_3 \supseteq \cdots$ is stationary. Equivalently, $\mathbb{A}^n$ is a* Noetherian topological space*: it has no infinite strictly descending chain of closed sets, and every nonempty family of closed sets has a minimal element.*

Idea. Apply $\mathcal{I}$: a descending chain of closed sets gives an *ascending* chain of ideals $\mathcal{I}(V_1) \subseteq \mathcal{I}(V_2) \subseteq \cdots$ in $k[x_1, \ldots, x_n]$ (the map is inclusion-reversing). Since $k[x_1, \ldots, x_n]$ is Noetherian by Hilbert's Basis Theorem, this ideal chain stabilizes; and because $V_i = \mathcal{Z}(\mathcal{I}(V_i))$ for algebraic sets (a "geometric closure" identity), the original chain of closed sets stabilizes too. □

Remark 15.2.2. The point worth underscoring, in the spirit of A&M's geometric program: a *geometric* finiteness phenomenon (no infinite descent of varieties) is forced by an *algebraic* one (ACC in the coordinate ring), itself forced by the Basis Theorem. Each affine algebraic set is even the intersection of *finitely many* hypersurfaces, because the defining ideal $\mathfrak{a} = (f_1, \ldots, f_q)$ is finitely generated, so $\mathcal{Z}(\mathfrak{a}) = \mathcal{Z}(f_1) \cap \cdots \cap \mathcal{Z}(f_q)$. This is the translation table:

$$\{\text{ ideals of } k[x_1, \ldots, x_n]\} \underset{\mathcal{I}}{\overset{\mathcal{Z}}{\rightleftarrows}} \{\text{ algebraic sets in } \mathbb{A}^n\}$$

$$\text{ACC (Noetherian ring)} \longleftrightarrow \text{DCC (Noetherian space)}$$

Diagram explanation. Objects: The four nodes are two collections and two chain conditions. Top-left: the set of all ideals of the polynomial ring $k[x_1, \ldots, x_n]$ (a ring-theoretic object). Top-right: the set of all algebraic sets (Zariski-closed subsets) in affine n-space $\mathbb{A}^n$ (a geometric object). Bottom-left: the property "ACC on ideals," i.e. the Noetherian condition on the ring. Bottom-right: the property "DCC on closed sets," i.e. the Noetherian condition on the topological space $\mathbb{A}^n$.

Arrows: The top row carries two contravariant maps between the two collections. $\mathcal{Z}$ (going right) sends an ideal $\mathfrak{a}$ to its zero locus $\mathcal{Z}(\mathfrak{a}) = \{a \in \mathbb{A}^n : f(a) = 0 \ \forall f \in \mathfrak{a}\}$, a closed set. $\mathcal{I}$ (going left) sends a subset $A \subseteq \mathbb{A}^n$ to the vanishing ideal $\mathcal{I}(A) = \{f : f|_A \equiv 0\}$. Both maps are inclusion-reversing: $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \Rightarrow \mathcal{Z}(\mathfrak{a}_1) \supseteq \mathcal{Z}(\mathfrak{a}_2)$, and $A_1 \subseteq A_2 \Rightarrow \mathcal{I}(A_1) \supseteq \mathcal{I}(A_2)$. The bottom double arrow records the logical equivalence: ACC in the ring $\iff$ DCC in the space.

What commutes: The bottom double arrow is the key commutativity: an ascending chain of ideals $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \cdots$ corresponds, under $\mathcal{Z}$, to a *descending* chain of closed sets $\mathcal{Z}(\mathfrak{a}_1) \supseteq \mathcal{Z}(\mathfrak{a}_2) \supseteq \cdots$, and vice versa under $\mathcal{I}$. Thus ACC on the left side forces DCC on the right, and the two finiteness conditions are opposite sides of the same coin.

Why it commutes: Chase a chain: if $\mathfrak{a}_1 \subseteq \mathfrak{a}_2$ then any a killing all of $\mathfrak{a}_2$ also kills all of $\mathfrak{a}_1$, so $\mathcal{Z}(\mathfrak{a}_1) \supseteq \mathcal{Z}(\mathfrak{a}_2)$ – each inclusion reverses. Therefore an ascending chain of ideals that stabilizes forces the corresponding descending chain of closed sets to stabilize, and every descending chain of closed sets arises in this way, because $V = \mathcal{Z}(\mathcal{I}(V))$ for every algebraic set V. (Over a general field only $\mathcal{I}(\mathcal{Z}(\mathfrak{a})) \supseteq \operatorname{rad}(\mathfrak{a})$ holds, with equality when k is algebraically closed by the Nullstellensatz, so the transfer runs from ideals to closed sets.)

Why this matters here: This diagram is the punchline of the Basis-Theorem discussion: the algebraic theorem (Hilbert, giving ACC in $k[x_1, \ldots, x_n]$) *automatically* yields a geometric theorem (DCC on varieties in $\mathbb{A}^n$, no infinite descent of closed sets). The author places it here to show the reader that the chain conditions are not just ring-theoretic bookkeeping – they govern the global finiteness of affine geometry.

Concrete example: In $\mathbb{A}^1$ over an infinite field k: an ascending chain of ideals $(f_1) \subseteq (f_2) \subseteq \cdots$ (each f_{i+1} divides f_i) corresponds under $\mathcal{Z}$ to a descending chain of finite root sets $\mathcal{Z}(f_1) \supseteq \mathcal{Z}(f_2) \supseteq \cdots$; since root sets are finite, any descending chain of them stabilizes, matching DCC on closed sets in $\mathbb{A}^1$.

Common pitfall: Students often think the top arrows $\mathcal{Z}$ and $\mathcal{I}$ are inverse bijections. They are not in general: $\mathcal{I}(\mathcal{Z}(\mathfrak{a})) \supseteq \operatorname{rad}(\mathfrak{a}) \supseteq \mathfrak{a}$, and both inclusions can be strict ($\mathfrak{a} = (x^2)$ in $k[x]$; $\mathfrak{a} = (x^2 + 1)$ in $\mathbb{R}[x]$, where $\mathcal{Z}(\mathfrak{a}) = \varnothing$). They become inverse bijections only after restricting to radical ideals and algebraic sets (the Nullstellensatz, over algebraically closed fields), which is a later and deeper result than what is being recorded here.

Takeaway: The point of this diagram is that the inclusion-reversing pair $(\mathcal{Z}, \mathcal{I})$ converts Noetherianness of the ring (ACC on ideals) into Noetherianness of the space (DCC on closed sets), so a single algebraic theorem – Hilbert's Basis Theorem – controls the finiteness of the entire Zariski topology.

Because $\mathbb{A}^n$ (indeed any Noetherian space, and any Noetherian ring) has the minimal-element property on closed sets, it admits a proof technique dual to ordinary induction.

Method (Noetherian induction.)**.** To prove a property P holds for *every* closed subset V of a Noetherian space (or every ideal of a Noetherian ring): assume, for contradiction, that the family $\mathcal{F} = \{\, V : P(V) \text{ fails} \,\}$ is nonempty. By DCC on closed sets (resp. the maximal-element principle for ideals), $\mathcal{F}$ has a minimal element V_0 (resp. maximal ideal $\mathfrak{a}_0$ among counterexamples). Now derive $P(V_0)$ from the assumption that P holds for all closed sets *strictly smaller* than V_0 (resp. all ideals strictly larger than $\mathfrak{a}_0$) – which holds by minimality (resp. maximality). This contradicts $V_0 \in \mathcal{F}$, so $\mathcal{F} = \varnothing$.

Caution. Noetherian induction inducts "downward" on closed sets but "upward" on ideals – the inclusion-reversing duality between $\mathcal{Z}$ and $\mathcal{I}$ flips the direction. A common slip is to look for a *minimal* counterexample ideal: there need not be one, since ideals satisfy ACC, not DCC. Always take the *maximal* bad ideal and argue using the strictly larger (hence good) ideals.

Worked Example 15.2.24 (Zariski topology on $\mathbb{A}^1$: closed sets are finite or all of k)**.** Describe the Zariski-closed subsets of the affine line.

Recognition. A closed set is $\mathcal{Z}(\mathfrak{a})$ for an ideal $\mathfrak{a} \subseteq k[x]$; since $k[x]$ is a PID, $\mathfrak{a} = (f)$, and $\mathcal{Z}(f)$ is the (finite) root set of f.

Solution. Every ideal of $k[x]$ is principal, $\mathfrak{a} = (f)$. If $f = 0$ then $\mathcal{Z}(f) = \mathbb{A}^1$. If $f \neq 0$ then f has at most $\deg f$ roots, so $\mathcal{Z}(f)$ is finite. Conversely every finite set $\{\, a_1, \dots, a_m \,\}$ is closed, being $\mathcal{Z}\big((x-a_1)\cdots(x-a_m)\big)$, and $\varnothing$ is $\mathcal{Z}(1)$. Hence the Zariski-closed sets of $\mathbb{A}^1$ are exactly $\varnothing$, the finite subsets, and $\mathbb{A}^1$ itself. Sanity check: any strictly descending chain of closed sets $\mathbb{A}^1 \supsetneq F_1 \supsetneq F_2 \supsetneq \cdots$ must, after the first step, consist of finite sets of strictly decreasing cardinality, so it terminates – DCC holds, as the theorem demands. When k is infinite this topology is *not* Hausdorff: any two nonempty open sets (complements of finite sets) meet; when k is finite it is discrete (Worked Example 15.2.26).

Worked Example 15.2.25 ($\mathcal{Z}(\mathfrak{ab}) = \mathcal{Z}(\mathfrak{a}) \cup \mathcal{Z}(\mathfrak{b})$ in a concrete case)**.** With $\mathfrak{a} = (x)$ and $\mathfrak{b} = (y)$ in $k[x, y]$, verify the union law for the two coordinate axes.

Recognition. $\mathcal{Z}(x)$ and $\mathcal{Z}(y)$ are the y- and x-axes; their union should be cut out by the product ideal $\mathfrak{ab} = (xy)$.

Solution. $\mathcal{Z}(x) = \{\, (0, b) : b \in k \,\}$ (the y-axis) and $\mathcal{Z}(y) = \{\, (a, 0) : a \in k \,\}$ (the x-axis). The product $\mathfrak{ab} = (xy)$, and $\mathcal{Z}(xy) = \{\, (a, b) : ab = 0 \,\} = \{\, a = 0 \text{ or } b = 0 \,\}$, which is exactly the union of the two axes. Sanity check: xy vanishes precisely when one factor does, matching the set-theoretic union; note $\mathfrak{ab} = (xy)$ and $\mathfrak{a} \cap \mathfrak{b} = (xy)$ agree here, illustrating $\mathcal{Z}(\mathfrak{ab}) = \mathcal{Z}(\mathfrak{a} \cap \mathfrak{b})$, and the union of two algebraic sets is again algebraic.

Worked Example 15.2.26 (Over a finite field every subset is closed)**.** If $k = \mathbb{F}_q$ is finite, show every subset of $\mathbb{A}^n$ is Zariski-closed.

Recognition. A single point is closed; arbitrary subsets are finite (since $\mathbb{A}^n$ is finite), and finite unions of closed sets are closed.

Solution. The point $a = (a_1, \dots, a_n)$ is $\mathcal{Z}(x_1 - a_1, \dots, x_n - a_n)$, hence closed. When $k = \mathbb{F}_q$, $\mathbb{A}^n = \mathbb{F}_q^n$ has only q^n points, so any subset is finite, hence a finite union of points, hence closed (finite unions of closed sets are closed). Sanity check: this is consistent with $\mathcal{I}(\mathbb{A}^1) = (x^q - x)$ over $\mathbb{F}_q$ – the polynomial $x^q - x$ vanishes at every point of $\mathbb{F}_q$, so over a finite field the relation $\mathcal{I}(\mathbb{A}^n) = 0$ (valid for infinite k) fails; finiteness of k makes the topology discrete.

Worked Example 15.2.27 (Noetherian induction: every closed set is a finite union of irreducibles)**.** Use Noetherian induction to prove that every nonempty algebraic set $V \subseteq \mathbb{A}^n$ is a finite union of irreducible closed sets (those not expressible as a union of two strictly smaller closed sets).

Recognition. Run the method on the family of closed sets that are *not* finite unions of irreducibles; a minimal counterexample yields a contradiction.

Solution. Suppose the family $\mathcal{F}$ of closed sets that are not finite unions of irreducibles is nonempty. By DCC on closed sets (Theorem 15.2.23) it has a minimal element V_0. Then V_0 is not itself irreducible (an irreducible set is trivially such a union), so $V_0 = V' \cup V''$ with $V', V'' \subsetneq V_0$ closed. By minimality $V' \notin \mathcal{F}$ and $V'' \notin \mathcal{F}$, so each is a finite union of irreducibles; but then so is $V_0 = V' \cup V''$, contradicting $V_0 \in \mathcal{F}$. Hence $\mathcal{F} = \varnothing$. Sanity check: applied to $\mathcal{Z}(xy) \subseteq \mathbb{A}^2$ this recovers the decomposition into the two axes $\mathcal{Z}(x) \cup \mathcal{Z}(y)$, each irreducible since (x) and (y) are prime; the decomposition into irreducible components is the geometric shadow of (minimal) primary decomposition.

Artinian rings, primary decomposition, and a preview

The chain conditions are not symmetric for rings, but the asymmetry is itself a theorem. A field satisfies both ACC and DCC (its only ideals are 0 and itself). Among modules over a field – i.e. vector spaces – all the finiteness conditions coincide.

Proposition 15.2.28 (finiteness conditions for vector spaces; A–M 6.10)**.** *For a vector space V over a field k the following are equivalent: (i) finite dimension; (ii) finite length; (iii) ACC on subspaces; (iv) DCC on subspaces. When they hold,* $\mathrm{length}(V) = \dim_k V$.

Idea. (i)⇒(ii) is the existence of a composition series $0 \subsetneq \langle e_1\rangle \subsetneq \langle e_1, e_2\rangle \subsetneq \cdots \subsetneq V$. (ii)⇒(iii),(iv) is general for modules of finite length. For (iii)⇒(i) and (iv)⇒(i): if $\dim V = \infty$, choose linearly independent $x_1, x_2, \ldots$; the subspaces $\langle x_1, \ldots, x_n\rangle$ strictly ascend and the subspaces $\langle x_{n+1}, x_{n+2}, \ldots\rangle$ strictly descend, violating ACC and DCC respectively. □

A ring satisfying DCC on ideals is *Artinian*. The decisive structural fact – proved in A&M's Chapter 8 – is that DCC is the stronger condition: an Artinian ring is automatically Noetherian (it is in fact a finite product of Artinian local rings of dimension zero). The example $\mathbb{Z}$ shows the converse fails. The next proposition is the converse implication at the level of a single product-of-maximals condition.

Proposition 15.2.29 (a product of maximal ideals controls both chains; A–M 6.11)**.** *Let A be a ring in which the zero ideal is a product of (not necessarily distinct) maximal ideals, $0 = \mathfrak{m}_1\mathfrak{m}_2\cdots\mathfrak{m}_n$. Then A is Noetherian if and only if A is Artinian.*

Idea. Filter A by the chain $A \supseteq \mathfrak{m}_1 \supseteq \mathfrak{m}_1\mathfrak{m}_2 \supseteq \cdots \supseteq \mathfrak{m}_1\cdots\mathfrak{m}_n = 0$. Each successive quotient $\mathfrak{m}_1\cdots\mathfrak{m}_{i-1}/\mathfrak{m}_1\cdots\mathfrak{m}_i$ is a vector space over the field $A/\mathfrak{m}_i$, so by the previous proposition it has ACC iff it has DCC. Splicing the factors together via the exact-sequence proposition, A has ACC iff each factor does iff each factor has DCC iff A has DCC. □

Atiyah and Macdonald close their Noetherian chapter with the existence of primary decomposition, which the present section can only preview; the full machinery occupies the next section. We state the chain of lemmas, since they show *why* Noetherianness is exactly the hypothesis that makes decomposition exist.

Theorem 15.2.30 (primary decomposition exists in Noetherian rings; A–M 7.13)**.** *In a Noetherian ring A every ideal is a finite intersection of primary ideals. The proof proceeds in two Noetherian-induction steps:*

(a) (A–M 7.11) *every ideal is a finite intersection of* irreducible *ideals (those $\mathfrak{a}$ with $\mathfrak{a} = \mathfrak{b}\cap\mathfrak{c} \Rightarrow \mathfrak{a} = \mathfrak{b}$ or $\mathfrak{a} = \mathfrak{c}$);*

(b) (A–M 7.12) *in a Noetherian ring every irreducible ideal is primary.*

Combining (a) and (b) gives the decomposition.

Idea. (a) is pure Noetherian induction: if the set of ideals failing to be a finite intersection of irreducibles were nonempty, take a maximal such $\mathfrak{a}$; it is not itself irreducible, so $\mathfrak{a} = \mathfrak{b}\cap\mathfrak{c}$ with $\mathfrak{b}, \mathfrak{c} \supsetneq \mathfrak{a}$, each (by maximality) a finite intersection of irreducibles, whence so is $\mathfrak{a}$ – contradiction. (b) reduces, on passing to $A/\mathfrak{a}$, to showing the zero ideal is primary when irreducible; if $xy = 0$ with $y \neq 0$, the ascending chain $\mathrm{Ann}(x) \subseteq \mathrm{Ann}(x^2) \subseteq \cdots$ stabilizes (ACC!), and one checks $(x^n)\cap(y) = 0$, forcing $0 = (x^n)\cap(y)$ to break the irreducibility unless x is nilpotent. □

Corollary 15.2.31 ($\mathfrak{a} \supseteq$ a power of its radical; A–M 7.14–7.15)**.** *In a Noetherian ring A, every ideal $\mathfrak{a}$ contains a power of its radical:* $\mathrm{rad}(\mathfrak{a})^m \subseteq \mathfrak{a}$ *for some $m \geq 1$. In particular the nilradical* $\mathrm{nil}(A) = \mathrm{rad}(0)$ *is nilpotent.*

Idea. Let $x_1, \ldots, x_k$ generate $\mathrm{rad}(\mathfrak{a})$, with $x_i^{n_i} \in \mathfrak{a}$. Set $m = \sum(n_i - 1) + 1$. Any monomial of total degree m in the x_i has some exponent $\geq n_i$, hence lies in $\mathfrak{a}$; since $\mathrm{rad}(\mathfrak{a})^m$ is generated by such monomials, $\mathrm{rad}(\mathfrak{a})^m \subseteq \mathfrak{a}$. □

Worked Example 15.2.32 (An Artinian ring is Noetherian: $\mathbb{Z}/n\mathbb{Z}$)**.** Verify on $\mathbb{Z}/n\mathbb{Z}$ that the Artinian (DCC) and Noetherian (ACC) conditions both hold, illustrating the implication DCC $\Rightarrow$ ACC.

Recognition. $\mathbb{Z}/n\mathbb{Z}$ is finite, so it trivially has both chain conditions; structurally 0 is a product of maximal ideals, matching A–M 6.11.

Solution. $\mathbb{Z}/n\mathbb{Z}$ has only finitely many ideals (one for each divisor of n), so every chain of ideals, ascending or descending, is finite – both ACC and DCC hold. Writing $n = p_1^{e_1} \cdots p_r^{e_r}$, the zero ideal of $\mathbb{Z}/n\mathbb{Z}$ is $\prod_i (p_i)^{e_i}$, a product of maximal ideals $(p_i) = \mathfrak{m}_i$ repeated e_i times, so Proposition 15.2.29 applies and predicts ACC $\iff$ DCC, both true. Sanity check: by CRT $\mathbb{Z}/n\mathbb{Z} \cong \prod_i \mathbb{Z}/p_i^{e_i}\mathbb{Z}$, a finite product of Artinian local rings $\mathbb{Z}/p_i^{e_i}\mathbb{Z}$ each of dimension 0 – exactly the structure theorem for Artinian rings previewed here.

Worked Example 15.2.33 (A power of the radical: $\mathfrak{a} = (x^2, xy, y^3)$ in $k[x, y]$)**.** Find $\operatorname{rad}(\mathfrak{a})$ and the least m with $\operatorname{rad}(\mathfrak{a})^m \subseteq \mathfrak{a}$ for $\mathfrak{a} = (x^2, xy, y^3) \subseteq k[x, y]$.

Recognition. $\operatorname{rad}(\mathfrak{a})$ is the set of elements some power of which lies in $\mathfrak{a}$; since $x^2, y^3 \in \mathfrak{a}$, both $x, y \in \operatorname{rad}(\mathfrak{a})$, so $\operatorname{rad}(\mathfrak{a}) = (x, y)$. Then bound the power by A–M 7.14.

Solution. Since $x^2 \in \mathfrak{a}$ and $y^3 \in \mathfrak{a}$ we have $x, y \in \operatorname{rad}(\mathfrak{a})$, so $\operatorname{rad}(\mathfrak{a}) \supseteq (x, y)$; and $\operatorname{rad}(\mathfrak{a}) \subseteq (x, y)$ because $\mathfrak{a} \subseteq (x, y)$ and (x, y) is prime (radical). Thus $\operatorname{rad}(\mathfrak{a}) = (x, y) = \mathfrak{m}$, the maximal ideal at the origin. Now $\mathfrak{m}^m$ is generated by the monomials $x^i y^j$ with $i + j = m$. For $m = 3$ the four generators all lie in $\mathfrak{a}$: $x^3 = x \cdot x^2$ and $x^2 y = y \cdot x^2$ carry the factor x^2, $xy^2 = y \cdot (xy)$ carries xy, and $y^3 \in \mathfrak{a}$ outright; hence $\mathfrak{m}^3 \subseteq \mathfrak{a}$. But $\mathfrak{m}^2 \not\subseteq \mathfrak{a}$: the generator y^2 of $\mathfrak{m}^2$ is divisible by none of x^2, xy, y^3, so $y^2 \notin \mathfrak{a}$. Therefore the least power is $m = 3$. Sanity check: A–M's bound gives $m \leq (2 - 1) + (3 - 1) + 1 = 4$ from the generators x, y of $\operatorname{rad}(\mathfrak{a})$ with $x^2, y^3 \in \mathfrak{a}$, and the true value 3 is within that bound; every degree-3 monomial in x, y indeed reduces into $\mathfrak{a}$.

Worked Example 15.2.34 (Nilradical nilpotent in a Noetherian ring: $k[x]/(x^5)$)**.** Confirm in $A = k[x]/(x^5)$ that the nilradical is nilpotent, as Corollary 15.2.31 guarantees.

Recognition. The nilradical is the set of nilpotents; in A it is $(\bar{x})$, and some power is zero because A is Noetherian (a finitely generated k-algebra).

Solution. Let $\bar{x}$ be the image of x. Then $\bar{x}^5 = 0$, so $\bar{x}$ is nilpotent, and $\operatorname{nil}(A) = (\bar{x}) = \operatorname{rad}(0)$ since any element $a_0 + a_1\bar{x} + \cdots$ is nilpotent iff its constant term $a_0 = 0$. The fifth power $\operatorname{nil}(A)^5 = (\bar{x}^5) = (0)$, so the nilradical is nilpotent with $\operatorname{nil}(A)^5 = 0$ (and $\operatorname{nil}(A)^4 = (\bar{x}^4) \neq 0$). Sanity check: A is Noetherian as a quotient of $k[x]$, the only hypothesis the corollary needs; over a non-Noetherian ring nilpotents can fail to be uniformly nilpotent (e.g. $k[x_1, x_2, \dots]/(x_1, x_2^2, x_3^3, \dots)$ has a non-nilpotent nilradical), so Noetherianness is essential.

Worked Example 15.2.35 (Composition series and length are additive)**.** Let $0 \to M' \to M \to M'' \to 0$ be exact with all three of finite length. Show $\operatorname{length}(M) = \operatorname{length}(M') + \operatorname{length}(M'')$, and compute length for $M = \mathbb{Z}/12\mathbb{Z}$ as a $\mathbb{Z}$-module.

Recognition. Length is additive on short exact sequences (A–M 6.9); for $\mathbb{Z}/n\mathbb{Z}$ the length is the number of prime factors of n counted with multiplicity.

Solution. Splice a composition series of M' (length $\operatorname{length} M'$) with the preimage of a composition series of M'' (length $\operatorname{length} M''$): the result is a composition series of M of length $\operatorname{length} M' + \operatorname{length} M''$, and by Jordan–Hölder the length is well defined. For $M = \mathbb{Z}/12\mathbb{Z}$ with $12 = 2^2 \cdot 3$: a composition series is $0 \subsetneq 6\mathbb{Z}/12\mathbb{Z} \subsetneq 3\mathbb{Z}/12\mathbb{Z} \subsetneq \mathbb{Z}/12\mathbb{Z}$ (quotients $\mathbb{Z}/2, \mathbb{Z}/2, \mathbb{Z}/3$, all simple), so $\operatorname{length}(\mathbb{Z}/12\mathbb{Z}) = 3$, equal to the number of prime factors $2 + 1$ of 12. Sanity check: the exact sequence $0 \to 3\mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}/12\mathbb{Z} \to \mathbb{Z}/3\mathbb{Z} \to 0$ gives $\operatorname{length}(\mathbb{Z}/12\mathbb{Z}) = \operatorname{length}(\mathbb{Z}/2^2\mathbb{Z}) + \operatorname{length}(\mathbb{Z}/3\mathbb{Z}) = 2 + 1 = 3$, matching; length here plays for finite abelian groups exactly the role dimension plays for vector spaces.

Exercises (Dummit & Foote).

1. Prove the converse to Hilbert's Basis Theorem: if the polynomial ring $R[x]$ is Noetherian, then R is Noetherian.
2. Show that each of the following rings are not Noetherian by exhibiting an explicit infinite increasing chain of ideals:
   (a) the ring of continuous real valued functions on $[0, 1]$,
   (b) the ring of all functions from any infinite set X to $\mathbb{Z}/2\mathbb{Z}$.

3. Prove that the field $k(x)$ of rational functions over k in the variable x is not a finitely generated k-algebra. (Recall that $k(x)$ is the field of fractions of the polynomial ring $k[x]$. Note that $k(x)$ is a finitely generated field extension over k.)

4. Prove that if R is Noetherian, then so is the ring $R[[x]]$ of formal power series in the variable x with coefficients from R (cf. Exercise 3, Section 7.2). [Mimic the proof of Hilbert's Basis Theorem.]

5. (*Fitting's Lemma*) Suppose M is a Noetherian R-module and $\varphi : M \to M$ is an R-module endomorphism of M. Prove that $\ker(\varphi^n) \cap \text{image}(\varphi^n) = 0$ for n sufficiently large. Show that if φ is surjective, then φ is an isomorphism. [Observe that $\ker(\varphi) \subseteq \ker(\varphi^2) \subseteq \cdots$.]

6. Suppose that $0 \to M' \to M \to M'' \to 0$ is an exact sequence of R-modules. Prove that M is a Noetherian R-module if and only if M' and M'' are Noetherian R-modules.

7. Prove that submodules, quotient modules, and finite direct sums of Noetherian R-modules are again Noetherian R-modules.

8. If R is a Noetherian ring, prove that M is a Noetherian R-module if and only if M is a finitely generated R-module. (Thus any submodule of a finitely generated module over a Noetherian ring is also finitely generated.)

9. For k a field show that any subring of the polynomial ring $k[x]$ containing k is Noetherian. Give an example to show such subrings need not be U.F.D.s. [If $k \subseteq R \subseteq k[x]$ and $y \in R - k$ show that $k[x]$ is a finitely generated $k[y]$-module; then use the previous two exercises. For the second, consider $k[x^2, x^3]$.]

10. Prove that the subring $k[x, x^2y, x^3y^2, \ldots, x^iy^{i-1}, \ldots]$ of the polynomial ring $k[x, y]$ is not a Noetherian ring, hence not a finitely generated k-algebra. (Thus subrings of Noetherian rings need not be Noetherian and subalgebras of finitely generated k-algebras need not be finitely generated.)

11. Suppose R is a commutative ring in which all the prime ideals are finitely generated. This exercise proves that R is Noetherian.

    (a) Prove that if the collection of ideals of R that are not finitely generated is nonempty, then it contains a maximal element I, and that R/I is a Noetherian ring.

    (b) Prove that there are finitely generated ideals I_1 and I_2 containing I with $I_1I_2 \subseteq I$ and that I_1I_2 is finitely generated. [Observe that I is not a prime ideal.]

    (c) Prove that I/I_1I_2 is a finitely generated R/I-submodule of I_1/I_1I_2. [Use Exercise 8.]

    (d) Show that (c) implies the contradiction that I would be finitely generated over R and deduce that R is Noetherian.

12. Suppose R is a Noetherian ring and S is a finitely generated R-algebra. If $T \subseteq S$ is an R-algebra such that S is a finitely generated T-module, prove that T is a finitely generated R-algebra. [If $s_1, \ldots, s_r$ generate S as an R-algebra, and $s'_1, \ldots, s'_m$ generate S as a T-module, show that the elements s_i and $s'_js'_i$ can be written as finite T-linear combinations of the s'_i. If T_0 is the R-subalgebra generated by the coefficients of these linear combinations, show S (hence T_0) is finitely generated (by the s'_i) as a T_0-module, and conclude that T is finitely generated as an R-algebra.]

13. Verify properties (1) to (10) of the maps Z and I.

14. Show that the affine algebraic sets in $\mathbb{A}^1$ over any field k are $\varnothing$, k, and finite subsets of k.

15. If $k = \mathbb{F}_2$ and $V = \{ (0,0), (1,1) \} \subseteq \mathbb{A}^2$, show that $I(V)$ is the product ideal $\mathfrak{m}_1\mathfrak{m}_2$ where $\mathfrak{m}_1 = (x, y)$ and $\mathfrak{m}_2 = (x - 1, y - 1)$.

16. Suppose that V is a finite algebraic set in $\mathbb{A}^n$. If V has m points, prove that $k[V]$ is isomorphic as a k-algebra to k^m. [Use the Chinese Remainder Theorem.]

17. If k is a finite field show that every subset of $\mathbb{A}^n$ is an affine algebraic set.

18. If $k = \mathbb{F}_q$ is the finite field with q elements show that $I(\mathbb{A}^1) = (x^q - x) \subseteq k[x]$.

19. For each nonconstant $f \in k[x]$ describe $Z(f) \subseteq \mathbb{A}^1$ in terms of the unique factorization of f in $k[x]$, and then use this to describe $I(Z(f))$. Deduce that $I(Z(f)) = (f)$ if and only if f is the product of distinct linear factors in $k[x]$.

20. If f and g are irreducible polynomials in $k[x, y]$ that are not associates (do not divide each other), show that $Z((f, g))$ is either $\varnothing$ or a finite set in $\mathbb{A}^2$. [If $(f, g) \neq (1)$, show (f, g) contains a nonzero polynomial in $k[x]$ (and similarly a nonzero polynomial in $k[y]$) by letting $R = k[x]$, $F = k(x)$, and applying Gauss's Lemma to show f and g are relatively prime in $F[y]$.]

21. Identify each 2×2 matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ with entries from k with the point (a, b, c, d) in $\mathbb{A}^4$. Show that the group $\mathrm{SL}_2(k)$ of matrices of determinant 1 is an algebraic set in $\mathbb{A}^4$.

22. Prove that $\mathrm{SL}_n(k)$ is an affine algebraic set in $\mathbb{A}^{n^2}$. [Generalize the preceding exercise.]

23. Let V be any line in $\mathbb{R}^2$ (the zero set of any nonzero linear polynomial $ax + by - c$). Prove that $\mathbb{R}[V]$ is isomorphic as an $\mathbb{R}$-algebra to the polynomial ring $\mathbb{R}[x]$, and give the corresponding isomorphism from $\mathbb{A}^1$ to V.

24. Let $V = Z(xy - z) \subseteq \mathbb{A}^3$. Prove that V is isomorphic to $\mathbb{A}^2$ and provide an explicit isomorphism φ and associated k-algebra isomorphism $\overline{\varphi}$ from $k[V]$ to $k[\mathbb{A}^2]$, along with their inverses. Is $V = Z(xy - z^2)$ isomorphic to $\mathbb{A}^2$?

25. Suppose $V \subseteq \mathbb{A}^n$ is an affine algebraic set and $f \in k[V]$. The graph of f is the collection of points $\{ (a_1, \ldots, a_n, f(a_1, \ldots, a_n)) \}$ in $\mathbb{A}^{n+1}$. Prove that the graph of f is an affine algebraic set isomorphic to V. [The morphism in one direction maps $(a_1, \ldots, a_n)$ to $(a_1, \ldots, a_n, f(a_1, \ldots, a_n))$.]

26. Let $V = Z(xz - y^2, yz - x^3, z^2 - x^2y) \subseteq \mathbb{A}^3$.

    (a) Prove that the map $\varphi : \mathbb{A}^1 \to V$ defined by $\varphi(t) = (t^3, t^4, t^5)$ is a surjective morphism. [For the surjectivity, if $(x, y, z) \neq (0, 0, 0)$, let $t = y/x$.]

    (b) Describe the corresponding k-algebra homomorphism $\overline{\varphi} : k[V] \to k[\mathbb{A}^1]$ explicitly.

    (c) Prove that φ is not an isomorphism.

27. Suppose $\varphi : V \to W$ is a morphism of affine algebraic sets. If W' is an affine algebraic subset of W prove that the preimage $V' = \varphi^{-1}(W')$ of W' in V is an affine algebraic subset of V. If $W' = Z(I)$ show that $V' = Z(\overline{\varphi}(I))$ for the corresponding morphism $\overline{\varphi} : k[W] \to k[V]$.

28. Prove that if V and W are affine algebraic sets, then so is $V \times W$ and $k[V \times W] \cong k[V] \otimes_k k[W]$.

29. If $R = \mathbb{Z}$ and $M = \mathbb{Z}/n\mathbb{Z}$, show that $\mathrm{Ass}_R(M)$ consists of the prime ideals (p) for the prime divisors p of n.

30. If M is the union of some collection of submodules M_i, prove that $\mathrm{Ass}_R(M)$ is the union of the collection $\mathrm{Ass}_R(M_i)$.

31. Suppose that $\mathrm{Ann}(m) = P$, i.e., that $Rm \cong R/P$. Prove that if $0 \neq m' \in Rm$ then $\mathrm{Ann}(m') = P$. Deduce that $\mathrm{Ass}_R(R/P) = \{ P \}$. [Observe that R/P is an integral domain.]

32. Suppose that M is an R-module and that P is a maximal element in the collection of ideals of the form $\mathrm{Ann}(m)$, for nonzero $m \in M$. Prove that P is a prime ideal. [If $P = \mathrm{Ann}(m)$ and $ab \in P$, show that $bm \neq 0$ implies $\mathrm{Ann}(m) \subseteq \mathrm{Ann}(bm)$ and use the maximality of P to deduce that $a \in \mathrm{Ann}(bm) = P$.]

33. Suppose R is a Noetherian ring and $M \neq 0$ is an R-module. Prove that $\mathrm{Ass}_R(M) \neq \varnothing$. [Use Exercise 32.]

34. If L is a submodule of M with quotient $N \cong M/L$, prove that there are containments $\mathrm{Ass}_R(L) \subseteq \mathrm{Ass}_R(M) \subseteq \mathrm{Ass}_R(L) \cup \mathrm{Ass}_R(N)$, and show that both containments can be proper. [If $Rm \cong R/P$, show that $Rm \cap L = 0$ implies $P \in \mathrm{Ass}_R(N)$ and if $Rm \cap L \neq 0$ then $P \in \mathrm{Ass}_R(L)$ (by Exercise 31). For the second statement, consider $n\mathbb{Z} \subseteq \mathbb{Z}$.]

35. Suppose M is an R-module and let S be a subset of the prime ideals in $\mathrm{Ass}_R(M)$. Prove there is a submodule N of M with $\mathrm{Ass}_R(N) = S$ and $\mathrm{Ass}_R(M/N) = \mathrm{Ass}_R(M) - S$. [Consider the collection of submodules N' of M with $\mathrm{Ass}_R(N') \subseteq S$. Use Exercise 30 and Zorn's Lemma to show that there is a

maximal submodule N subject to $\mathrm{Ass}_R(N) \subseteq S$. If $P \in \mathrm{Ass}_R(M/N)$, there is a submodule $M'/N \cong R/P$. Use the previous exercise to show that $\mathrm{Ass}_R(M') \subseteq \mathrm{Ass}_R(N) \cup \{ P \}$ and then use maximality of N to show $P \in \mathrm{Ass}_R(M) - S$, so that $\mathrm{Ass}_R(M/N) \subseteq \mathrm{Ass}_R(M) - S$ and $\mathrm{Ass}_R(N) \subseteq S$. Use the previous exercise again to conclude that equality holds in each.]

36. (a) Show that the Fitting ideal of M is also the ideal in R generated by all the $n \times n$ minors of all $p \times n$ matrices $A = (r_{ij})$ for $p \geq 1$ whose rows consist of the coefficients in R of relations among the generators m_i.

    (b) Let A be a fixed $p \times n$ matrix as in (a) and let A' be a $p \times n$ matrix obtained from A by any elementary row or column operation. Show that the ideal in R generated by all the $n \times n$ minors of A is the same as the ideal in R generated by all the $n \times n$ minors of A'.

37. Suppose $m_1, \ldots, m_n$ and $m'_1, \ldots, m'_{n'}$ are two sets of R-module generators for M. Let $\mathcal{F}$ denote the Fitting ideal for M computed using the generators $m_1, \ldots, m_n$ and let $\mathcal{F}'$ denote the Fitting ideal for M computed using the generators $m_1, \ldots, m_n, m'_1, \ldots, m'_{n'}$.

    (a) Show that $m'_s = a_{s'1}m_1 + \cdots + a_{s'n}m_n$ for some $a_{s'1}, \ldots, a_{s'n} \in R$, and deduce that $(-a_{s'1}, \ldots, -a_{s'n}, 0, \ldots, 0, 1, 0, \ldots, 0)$ is a relation among $m_1, \ldots, m_n, m'_1, \ldots, m'_{n'}$.

    (b) If $A = (r_{ij})$ is an $n \times n$ matrix whose rows are the coefficients of relations among $m_1, \ldots, m_n$ show that $\det A = \det A'$ where A' is an $(n + n') \times (n + n')$ matrix whose rows are the coefficients of relations among $m_1, \ldots, m_n, m'_1, \ldots, m'_{n'}$. Deduce that $\mathcal{F} \subseteq \mathcal{F}'$. [Use (a) to find a block upper triangular A' having A in the upper left block and the $n' \times n'$ identity matrix in the lower right block.]

    (c) Prove that $\mathcal{F}' \subseteq \mathcal{F}$ and conclude that $\mathcal{F}' = \mathcal{F}$. [Use the previous exercise.]

    (d) Deduce from (c) that the Fitting ideal $\mathcal{F}_R(M)$ of M is an invariant of M that does not depend on the choice of generators for M used to compute it.

38. All modules in this exercise are assumed finitely generated.

    (a) If M can be generated by n elements prove that $\mathrm{Ann}(M)^n \subseteq \mathcal{F}_R(M) \subseteq \mathrm{Ann}(M)$, where $\mathrm{Ann}(M)$ is the annihilator of M in R. [If A is an $n \times n$ relations matrix for M, then $AX = 0$, where X is the column matrix whose entries are $m_1, \ldots, m_n$. Multiply by the adjoint of A to deduce that $\det A$ annihilates M.]

    (b) If $M = M_1 \times M_2$ is the direct product of the R-modules M_1 and M_2 prove that $\mathcal{F}_R(M) = \mathcal{F}_R(M_1)\mathcal{F}_R(M_2)$.

    (c) If $M = (R/I_1) \times \cdots \times (R/I_n)$ is the direct product of cyclic R-modules for ideals I_i in R prove that $\mathcal{F}_R(M) = I_1 I_2 \cdots I_n$.

    (d) If $R = \mathbb{Z}$ and M is a finitely generated abelian group show that $\mathcal{F}_{\mathbb{Z}}(M) = 0$ if M is infinite and $\mathcal{F}_{\mathbb{Z}}(M) = |M|\mathbb{Z}$ if M is finite.

    (e) If I is an ideal in R prove that the image of $\mathcal{F}_R(M)$ in the quotient R/I is $\mathcal{F}_{R/I}(M/IM)$.

    (f) Prove that $\mathcal{F}_R(M/IM) \subseteq (\mathcal{F}_R(M), I) \subseteq R$.

    (g) If $\varphi : M \to M'$ is a surjective R-module homomorphism prove $\mathcal{F}_R(M) \subseteq \mathcal{F}_R(M')$.

    (h) If $0 \to L \to M \to N \to 0$ is a short exact sequence of R-modules, prove that $\mathcal{F}_R(L)\mathcal{F}_R(N) \subseteq \mathcal{F}_R(M)$.

    (i) Suppose R is the polynomial ring $k[x, y, z]$ over the field k. Let $M = R/(x, y^2, yz, z^2)$ and let L be the submodule $(x, y, z)/(x, y^2, yz, z^2)$ of M. Prove that $\mathcal{F}_R(M)$ is (x, y^2, yz, z^2) and $\mathcal{F}_R(L)$ is $(x, y, z)^2$. (This shows that in general the Fitting ideal of a submodule L of M need not contain the Fitting ideal for M.)

39. Suppose M is an R-module and that $\varphi : R^n \to M$ is a surjective R-module homomorphism (i.e., M can be generated by n elements). Let $L = \ker \varphi$. Prove that the image of the R-module homomorphism from $\bigwedge^n(L) \to \bigwedge^n(R^n) \cong R$ induced by the inclusion of L in R^n is the Fitting ideal $\mathcal{F}_R(M)$.

40. Suppose R and S are commutative rings, $\varphi : R \to S$ is a ring homomorphism, M is a finitely generated R-module, and $M' = S \otimes_R M$ is the S-module obtained by extending scalars from R to S. Prove that the Fitting ideal $\mathcal{F}_S(M')$ for M' over S is the extension to S of the Fitting ideal $\mathcal{F}_R(M)$ for M over R.

41. Suppose $\{ g_1, \ldots, g_m \}$ is a Grobner basis for the ideal I in $k[x_1, \ldots, x_n]$. Prove that the monomials m not divisible by any $\mathrm{LT}(g_i)$, $1 \leq i \leq m$, give a k-vector space basis for the quotient $k[x_1, \ldots, x_n]/I$.

42. Let $I = (x^3y - xy^2 + 1, x^2y^2 - y^3 - 1)$ as in Example 1 following Proposition 9.26.

    (a) Use the previous exercise to show that $\{ 1, y, y^2, y^3 \}$ is a basis for the k-vector space $k[x, y]/I$.

    (b) Compute the 4×4 multiplication table for the basis vectors in (a).

43. Suppose $K[x_1, \ldots, x_n]$ is a polynomial ring in n variables over a field K and k is a subfield of K. If I is an ideal in $k[x_1, \ldots, x_n]$, let I' be the ideal generated by I in $K[x_1, \ldots, x_n]$.

    (a) If G is a Grobner basis for the ideal I in $k[x_1, \ldots, x_n]$ with respect to some monomial ordering, show that G is also a Grobner basis for the ideal I' in $K[x_1, \ldots, x_n]$ with respect to the same monomial ordering. [Use Buchberger's Criterion.]

    (b) Prove that the dimension of the quotient $k[x_1, \ldots, x_n]/I$ as a vector space over k is the same as the dimension of the quotient $K[x_1, \ldots, x_n]/I'$ as a vector space over K. [One method: use (a) and Exercise 41.]

    (c) Prove that $I = k[x_1, \ldots, x_n]$ if and only if $I' = K[x_1, \ldots, x_n]$.

44. Let $V = Z(x^3 - x^2z - y^2z)$ and $W = Z(x^2 + y^2 - z^2)$ in $\mathbb{C}^3$. Then $I(V) = (x^3 - x^2z - y^2z)$ and $I(W) = (x^2 + y^2 - z^2)$ in $\mathbb{C}[x, y, z]$ (cf. Exercise 23 in Section 3). Show that $\varphi((a, b, c)) = (a^2c - b^2c, 2abc, -a^3)$ defines a morphism from V to W.

45. Let $V = Z(x^3 + y^3 + 7z^3) \subseteq \mathbb{C}^3$. Then $I(V) = (x^3 + y^3 + 7z^3)$ in $\mathbb{C}[x, y, z]$ (cf. Exercise 24 in Section 3).

    (a) Show that $\overline{\varphi}(x) = x(y^3 - 7z^3)$, $\overline{\varphi}(y) = y(7z^3 - x^3)$, $\overline{\varphi}(z) = z(x^3 - y^3)$ defines a $\mathbb{C}$-algebra homomorphism from $k[V]$ to itself.

    (b) Let $\varphi : V \to V$ be the morphism corresponding to $\overline{\varphi}$. Observe that $(-2, 1, 1) \in V$ and compute $\varphi((-2, 1, 1)) \in V$.

    (c) Prove there are infinitely many points (a, b, c) on V with $a, b, c \in \mathbb{Z}$ and the greatest common divisor of a, b, and c is 1.

46. Let $V = Z(xz + y^2 + z^2, xy - xz + yz - 2z^2) \subseteq \mathbb{C}^3$ and $W = Z(u^3 - uv^2 + v^3) \subseteq \mathbb{C}^2$ as in Example 2 following Corollary 9. Show that the map $\varphi((a, b)) = (-2a^2 + ab, ab - b^2, a^2 - ab)$ defines a morphism from W to V. Show the corresponding $\mathbb{C}$-algebra homomorphism from $k[V]$ to $k[W]$ has a kernel generated by $x^2 - 3y^2 + yz$.

47. Define $\Phi : \mathbb{Q}[u, v, w] \to \mathbb{Q}[x, y]$ by $\Phi(u) = x^2 + y$, $\Phi(v) = x + y^2$, and $\Phi(w) = x - y$. Show that neither x nor y is in the image of Φ. Show that $f = 2x^3 - 4xy - 2y^3 - 4y$ is in the image of Φ and find a polynomial in $\mathbb{Q}[u, v, w]$ mapping to f. Show that $\ker \Phi$ is the ideal generated by

$$u^2 - 2uv - 2uw^2 + 4uw + v^2 - 2vw^2 - 4vw + w^4 + 3w^2.$$

48. Suppose α is a root of the irreducible polynomial $p(x) \in k[x]$ and $\beta = f(\alpha)/g(\alpha)$ with polynomials $f(x), g(x) \in k[x]$ where $g(\alpha) \neq 0$.

    (a) Show $ag + bp = 1$ for some polynomials $a, b \in k[x]$ and show $\beta = h(\alpha)$ where $h = af$.

    (b) Show that the ideals $(p, y - h)$ and $(p, gy - f)$ are equal in $k[x, y]$.

    (c) Conclude that the minimal polynomial for β is the monic polynomial in $G \cap k[y]$ where G is the reduced Grobner basis for the ideal $(p, gy - f)$ in $k[x, y]$ for the lexicographic monomial ordering $x > y$.

    (d) Find the minimal polynomial over $\mathbb{Q}$ of $(3 - \sqrt[3]{2} + \sqrt[3]{4})/(1 + 3\sqrt[3]{2} - 3\sqrt[3]{4})$.

Exercises (Atiyah & Macdonald).

1. Let M be a Noetherian A-module and $u : M \to M$ a module homomorphism.

   (i) If u is surjective, then u is an isomorphism.

   (ii) If M is Artinian and u is injective, then again u is an isomorphism.

   [For (i), consider the chain modules $\ker(u^n)$; for (ii), the quotient modules $\mathrm{Coker}(u^n)$.]

2. Let M be an A-module. If every non-empty set of finitely generated submodules of M has a maximal element, then M is Noetherian.

3. Let M be an A-module and let N_1, N_2 be submodules of M. If M/N_1 and M/N_2 are Noetherian, so is $M/(N_1 \cap N_2)$. Similarly with Artinian in place of Noetherian.

4. Let M be a Noetherian A-module and let $\mathfrak{a}$ be the annihilator of M in A. Prove that $A/\mathfrak{a}$ is a Noetherian ring. If we replace "Noetherian" by "Artinian" in this result, is it still true?

5. A topological space X is said to be *Noetherian* if the open subsets of X satisfy the ascending chain condition (or, equivalently, the maximal condition). Since closed sets are complements of open subsets, it comes to the same thing to say that the closed subsets of X satisfy the descending chain condition (or, equivalently, the minimal condition). Show that, if X is Noetherian, then every subspace of X is Noetherian, and that X is quasi-compact.

6. Prove that the following are equivalent:

   (i) X is Noetherian.

   (ii) Every open subspace of X is quasi-compact.

   (iii) Every subspace of X is quasi-compact.

7. A Noetherian space is a finite union of irreducible closed subspaces. [Consider the set Σ of closed subsets of X which are not finite unions of irreducible closed subspaces.] Hence the set of irreducible components of a Noetherian space is finite.

8. If A is a Noetherian ring then $\mathrm{Spec}(A)$ is a Noetherian topological space. Is the converse true?

9. Deduce from Exercise 8 that the set of minimal prime ideals in a Noetherian ring is finite.

10. If M is a Noetherian module (over an arbitrary ring A) then $\mathrm{Supp}(M)$ is a closed Noetherian subspace of $\mathrm{Spec}(A)$.

11. Let $f : A \to B$ be a ring homomorphism and suppose that $\mathrm{Spec}(B)$ is a Noetherian space (Exercise 5). Prove that $f^* : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is a closed mapping if and only if f has the going-up property (Chapter 5, Exercise 10).

12. Let A be a ring such that $\mathrm{Spec}(A)$ is a Noetherian space. Show that the set of prime ideals of A satisfies the ascending chain condition. Is the converse true?

Exercises (Atiyah & Macdonald), Chapter 7.

1. Let A be a non-Noetherian ring and let Σ be the set of ideals in A which are not finitely generated. Show that Σ has maximal elements and that the maximal elements of Σ are prime ideals.

   [Let $\mathfrak{a}$ be a maximal element of Σ, and suppose that there exist $x, y \in A$ such that $x \notin \mathfrak{a}$ and $y \notin \mathfrak{a}$ and $xy \in \mathfrak{a}$. Show that there exists a finitely generated ideal $\mathfrak{a}_0 \subseteq \mathfrak{a}$ such that $\mathfrak{a}_0 + (x) = \mathfrak{a} + (x)$, and that $\mathfrak{a} = \mathfrak{a}_0 + x \cdot (\mathfrak{a} : x)$. Since $(\mathfrak{a} : x)$ strictly contains $\mathfrak{a}$, it is finitely generated and therefore so is $\mathfrak{a}$.]

   Hence a ring in which every prime ideal is finitely generated is Noetherian (I. S. Cohen).

2. Let A be a Noetherian ring and let $f = \sum_{n=0}^{\infty} a_n x^n \in A[[x]]$. Prove that f is nilpotent in $A[[x]]$ if and only if each a_n is nilpotent.

3. Let $\mathfrak{a}$ be an irreducible ideal in a ring A. Then the following are equivalent:

(i) $\mathfrak{a}$ is primary;

(ii) for every multiplicatively closed subset S of A we have $(S^{-1}\mathfrak{a})^c = (\mathfrak{a} : x)$ for some $x \in S$;

(iii) the sequence $(\mathfrak{a} : x^n)$ is stationary, for every $x \in A$.

4. Which of the following rings are Noetherian?

(i) The ring of rational functions of z having no pole on the circle $|z| = 1$.

(ii) The ring of power series in z with a positive radius of convergence.

(iii) The ring of power series in z with an infinite radius of convergence.

(iv) The ring of polynomials in z whose first k derivatives vanish at the origin (k being a fixed integer).

(v) The ring of polynomials in z, w all of whose partial derivatives with respect to w vanish for $z = 0$.

In all cases the coefficients are complex numbers.

5. Let A be a Noetherian ring, B a finitely generated A-algebra, G a finite group of A-automorphisms of B, and B^G the set of all elements of B which are left fixed by every element of G. Show that B^G is a finitely generated A-algebra.

6. If a finitely generated ring K (that is, a finitely generated $\mathbb{Z}$-algebra) is a field, it is a finite field.

[If K has characteristic 0, we have $\mathbb{Z} \subseteq \mathbb{Q} \subseteq K$. Since K is finitely generated over $\mathbb{Z}$ it is finitely generated over $\mathbb{Q}$, hence by (7.9) is a finitely generated $\mathbb{Q}$-module. Now apply (7.8) to obtain a contradiction. Hence K is of characteristic $p > 0$, hence is finitely generated as a $\mathbb{Z}/(p)$-algebra. Use (7.9) to complete the proof.]

7. Let X be an affine algebraic variety given by a family of equations $f_\alpha(t_1, \ldots, t_n) = 0$ ($\alpha \in I$) (Chapter 1, Exercise 27). Show that there exists a finite subset I_0 of I such that X is given by the equations $f_\alpha(t_1, \ldots, t_n) = 0$ for $\alpha \in I_0$.

8. If $A[x]$ is Noetherian, is A necessarily Noetherian?

9. Let A be a ring such that

(1) for each maximal ideal $\mathfrak{m}$ of A, the local ring $A_\mathfrak{m}$ is Noetherian;

(2) for each $x \neq 0$ in A, the set of maximal ideals of A which contain x is finite.

Show that A is Noetherian.

[Let $\mathfrak{a} \neq 0$ be an ideal in A. Let $\mathfrak{m}_1, \ldots, \mathfrak{m}_r$ be the maximal ideals which contain $\mathfrak{a}$. Choose $x_0 \neq 0$ in $\mathfrak{a}$ and let $\mathfrak{m}_1, \ldots, \mathfrak{m}_{r+s}$ be the maximal ideals which contain x_0. Since $\mathfrak{m}_{r+1}, \ldots, \mathfrak{m}_{r+s}$ do not contain $\mathfrak{a}$ there exist $x_j \in \mathfrak{a}$ such that $x_j \notin \mathfrak{m}_{r+j}$ ($1 \leq j \leq s$). Since each $A_{\mathfrak{m}_i}$ ($1 \leq i \leq r$) is Noetherian, the extension of $\mathfrak{a}$ in $A_{\mathfrak{m}_i}$ is finitely generated. Choose elements $x_{s+1}, \ldots, x_t$ in $\mathfrak{a}$ whose images in $A_{\mathfrak{m}_i}$ generate $A_{\mathfrak{m}_i}\mathfrak{a}$ for $i = 1, \ldots, r$. Let $\mathfrak{a}_0 = (x_0, \ldots, x_t)$. Show that $\mathfrak{a}_0$ and $\mathfrak{a}$ have the same extension in $A_\mathfrak{m}$ for every maximal ideal $\mathfrak{m}$, and deduce by (3.9) that $\mathfrak{a}_0 = \mathfrak{a}$.]

10. Let M be a Noetherian A-module. Show that $M[x]$ (Chapter 2, Exercise 6) is a Noetherian $A[x]$-module.

11. Let A be a ring such that each local ring $A_\mathfrak{p}$ is Noetherian. Is A necessarily Noetherian?

12. Let A be a ring and A' a faithfully flat A-algebra (Chapter 3, Exercise 16). If A' is Noetherian, show that A is Noetherian. [Use the ascending chain condition.]

13. Let $f : A \to B$ be a ring homomorphism of finite type and let $f^* : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ be the mapping associated with f. Show that the fibres of f^* are Noetherian subspaces of $\mathrm{Spec}(B)$.

14. *(Nullstellensatz, strong form.)* Let k be an algebraically closed field, let A denote the polynomial ring $k[t_1, \ldots, t_n]$ and let $\mathfrak{a}$ be an ideal in A. Let V be the variety in k^n defined by the ideal $\mathfrak{a}$, so that V is the set of all $x = (x_1, \ldots, x_n) \in k^n$ such that $f(x) = 0$ for all $f \in \mathfrak{a}$. Let $I(V)$ be the ideal of V, i.e. the ideal of all polynomials $g \in A$ such that $g(x) = 0$ for all $x \in V$. Then $I(V) = r(\mathfrak{a})$.

[It is clear that $r(\mathfrak{a}) \subseteq I(V)$. Conversely, let $f \notin r(\mathfrak{a})$, then there is a prime ideal $\mathfrak{p}$ containing $\mathfrak{a}$ such that $f \notin \mathfrak{p}$. Let $\overline{f}$ be the image of f in $B = A/\mathfrak{p}$, let $C = B_{\overline{f}} = B[1/\overline{f}]$, and let $\mathfrak{m}$ be a maximal ideal of C. Since C is a finitely generated k-algebra we have $C/\mathfrak{m} \cong k$, by (7.9). The images x_i in $C/\mathfrak{m}$ of the generators t_i of A thus define a point $x = (x_1, \ldots, x_n) \in k^n$, and the construction shows that $x \in V$ and $f(x) \neq 0$.]

15. Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal and k its residue field, and let M be a finitely generated A-module. Then the following are equivalent:

    (i) M is free;

    (ii) M is flat;

    (iii) the mapping of $\mathfrak{m} \otimes M$ into $A \otimes M$ is injective;

    (iv) $\mathrm{Tor}_1^A(k, M) = 0$.

    [To show that (iv) $\Rightarrow$ (i), let $x_1, \ldots, x_n$ be elements of M whose images in $M/\mathfrak{m}M$ form a k-basis of this vector space. By (2.8), the x_i generate M. Let F be a free A-module with basis $e_1, \ldots, e_n$ and define $\phi : F \to M$ by $\phi(e_i) = x_i$. Let $E = \ker(\phi)$. Then the exact sequence $0 \to E \to F \to M \to 0$ gives an exact sequence

    $$0 \to k \otimes_A E \to k \otimes_A F \xrightarrow{1 \otimes \phi} k \otimes_A M \to 0.$$

    Since $k \otimes F$ and $k \otimes M$ are vector spaces over k of the same dimension over k, it follows that $1 \otimes \phi$ is an isomorphism, hence $k \otimes E = 0$, hence $E = 0$ by Nakayama's Lemma (E is finitely generated because it is a submodule of F, and A is Noetherian).]

16. Let A be a Noetherian ring, M a finitely generated A-module. Then the following are equivalent:

    (i) M is a flat A-module;

    (ii) $M_{\mathfrak{p}}$ is a free $A_{\mathfrak{p}}$-module, for all prime ideals $\mathfrak{p}$;

    (iii) $M_{\mathfrak{m}}$ is a free $A_{\mathfrak{m}}$-module, for all maximal ideals $\mathfrak{m}$.

    In other words, flat = locally free. [Use Exercise 15.]

17. Let A be a ring and M a Noetherian A-module. Show (by imitating the proofs of (7.11) and (7.12)) that every submodule N of M has a primary decomposition (Chapter 4, Exercises 20–23).

18. Let A be a Noetherian ring, $\mathfrak{p}$ a prime ideal of A, and M a finitely generated A-module. Show that the following are equivalent:

    (i) $\mathfrak{p}$ belongs to 0 in M;

    (ii) there exists $x \in M$ such that $\mathrm{Ann}(x) = \mathfrak{p}$;

    (iii) there exists a submodule of M isomorphic to $A/\mathfrak{p}$.

    Deduce that there exists a chain of submodules

    $$0 = M_0 \subseteq M_1 \subseteq \cdots \subseteq M_r = M$$

    such that each quotient M_i/M_{i-1} is of the form $A/\mathfrak{p}_i$, where $\mathfrak{p}_i$ is a prime ideal of A.

19. Let $\mathfrak{a}$ be an ideal in a Noetherian ring A. Let

    $$\mathfrak{a} = \bigcap_{i=1}^{r} \mathfrak{b}_i = \bigcap_{j=1}^{s} \mathfrak{c}_j$$

    be two minimal decompositions of $\mathfrak{a}$ as intersections of *irreducible* ideals. Prove that $r = s$ and that (possibly after re-indexing the $\mathfrak{c}_j$) we have $r(\mathfrak{b}_i) = r(\mathfrak{c}_i)$ for all i. [Show that for each $i = 1, \ldots, r$ there exists a j such that

    $$\mathfrak{a} = \mathfrak{b}_1 \cap \cdots \cap \mathfrak{b}_{i-1} \cap \mathfrak{c}_j \cap \mathfrak{b}_{i+1} \cap \cdots \cap \mathfrak{b}_r.]$$

    State and prove an analogous result for modules.

20. Let X be a topological space and let $\mathcal{F}$ be the smallest collection of subsets of X which contains all open subsets of X and is closed with respect to the formation of finite intersections and complements.

    (i) Show that a subset E of X belongs to $\mathcal{F}$ if and only if E is a finite union of sets of the form $U \cap C$, where U is open and C is closed.

    (ii) Suppose that X is irreducible and let $E \in \mathcal{F}$. Show that E is dense in X (i.e., that $\overline{E} = X$) if and only if E contains a non-empty open set in X.

21. Let X be a Noetherian topological space (Chapter 6, Exercise 5) and let $E \subseteq X$. Show that $E \in \mathcal{F}$ if and only if, for each irreducible closed subset X_0 of X, either $\overline{E \cap X_0} \neq X_0$ or else $E \cap X_0$ contains a non-empty open subset of X_0. [Suppose $E \notin \mathcal{F}$. Then the collection of closed sets $X' \subseteq X$ such that $E \cap X' \notin \mathcal{F}$ is not empty and therefore has a minimal element X_0. Show that X_0 is irreducible and then that each of the alternatives leads to the conclusion that $E \cap X_0 \in \mathcal{F}$.] The sets belonging to $\mathcal{F}$ are called the *constructible* subsets of X.

22. Let X be a Noetherian topological space and let E be a subset of X. Show that E is open in X if and only if, for each irreducible closed subset X_0 in X, either $E \cap X_0 = \varnothing$ or else $E \cap X_0$ contains a non-empty open subset of X_0. [The proof is similar to that of Exercise 21.]

23. Let A be a Noetherian ring, $f : A \to B$ a ring homomorphism of finite type (so that B is Noetherian). Let $X = \mathrm{Spec}(A)$, $Y = \mathrm{Spec}(B)$, and let $f^* : Y \to X$ be the mapping associated with f. Then the image under f^* of a constructible subset E of Y is a constructible subset of X.

    [By Exercise 20 it is enough to take $E = U \cap C$ where U is open and C is closed in Y; thus, replacing B by a homomorphic image, we reduce to the case where E is open in Y. Since Y is Noetherian, E is quasi-compact, and therefore E is the finite union of open sets of the form $\mathrm{Spec}(B_g)$. Hence reduce to the case $E = Y$. To show that $f^*(Y)$ is constructible, use the criterion of Exercise 21. Let X_0 be an irreducible closed subset of X such that $f^*(Y) \cap X_0$ is dense in X_0. We have $f^*(Y) \cap X_0 = f^*(f^{*-1}(X_0))$, and $f^{*-1}(X_0) = \mathrm{Spec}((A/\mathfrak{p}) \otimes_A B)$, where $X_0 = \mathrm{Spec}(A/\mathfrak{p})$ with $\mathfrak{p}$ prime. Hence reduce to the case where A is an integral domain and f is injective. If $Y_1, \ldots, Y_n$ are the irreducible components of Y, it is enough to show that some $f^*(Y_i)$ contains a non-empty open set in X. So finally we are brought down to the situation in which A, B are integral domains and f is injective (and still of finite type); now use Chapter 5, Exercise 21 to complete the proof.]

24. With the notation and hypotheses of Exercise 23, f^* is an open mapping $\Leftrightarrow$ f has the going-down property (Chapter 5, Exercise 10). [Suppose f has the going-down property. As in Exercise 23, reduce to proving that $E = f^*(Y)$ is open in X. The going-down property asserts that if $\mathfrak{p} \in E$ and $\mathfrak{p}' \subseteq \mathfrak{p}$, then $\mathfrak{p}' \in E$: in other words, that if X_0 is an irreducible closed subset of X and X_0 meets E, then $E \cap X_0$ is dense in X_0. By Exercises 20 and 22, E is open in X.]

25. Let A be Noetherian, $f : A \to B$ of finite type and *flat* (i.e., B is flat as an A-module). Then $f^* : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is an open mapping. [Exercise 24 and Chapter 5, Exercise 11.]

26. (*Grothendieck groups.*) Let A be a Noetherian ring and let $F(A)$ denote the set of all isomorphism classes of finitely generated A-modules. Let C be the free abelian group generated by $F(A)$. With each short exact sequence $0 \to M' \to M \to M'' \to 0$ of finitely generated A-modules we associate the element $(M') - (M) + (M'')$ of C, where (M) is the isomorphism class of M. Let D be the subgroup of C generated by these elements, for all short exact sequences. C/D is called the *Grothendieck group* of A, and is denoted by $K(A)$. If M is a finitely generated A-module, let $\gamma(M)$, or $\gamma_A(M)$ denote the image of M in $K(A)$.

    (i) Show that $K(A)$ has the following universal property: for each additive function λ on the class of finitely generated A-modules, with values in an abelian group G, there exists a unique homomorphism $\lambda_0 : K(A) \to G$ such that $\lambda(M) = \lambda_0(\gamma(M))$ for all M.

    (ii) Show that $K(A)$ is generated by the elements $\gamma(A/\mathfrak{p})$, where $\mathfrak{p}$ is a prime ideal of A. [Use Exercise 18.]

    (iii) If A is a field, or more generally if A is a principal ideal domain, then $K(A) \cong \mathbb{Z}$.

(iv) Let $f : A \to B$ be a *finite* ring homomorphism. Show that restriction of scalars gives rise to a homomorphism $f_! : K(B) \to K(A)$ such that $f_!(\gamma_B(N)) = \gamma_A(N)$ for a B-module N. If $g : B \to C$ is another finite ring homomorphism, show that $(g \circ f)_! = f_! \circ g_!$.

27. Let A be a Noetherian ring and let $F_1(A)$ be the set of all isomorphism classes of finitely generated flat A-modules. Repeating the construction of Exercise 26 we obtain a group $K_1(A)$. Let $\gamma_1(M)$ denote the image of (M) in $K_1(A)$.

(i) Show that tensor product of modules over A induces a commutative ring structure on $K_1(A)$, such that $\gamma_1(M) \cdot \gamma_1(N) = \gamma_1(M \otimes N)$. The identity element of this ring is $\gamma_1(A)$.

(ii) Show that tensor product induces a $K_1(A)$-module structure on the group $K(A)$, such that $\gamma_1(M) \cdot \gamma(N) = \gamma(M \otimes N)$.

(iii) If A is a (Noetherian) local ring, then $K_1(A) \cong \mathbb{Z}$.

(iv) Let $f : A \to B$ be a ring homomorphism, B Noetherian. Show that extension of scalars gives rise to a ring homomorphism $f^! : K_1(A) \to K_1(B)$ such that $f^!(\gamma_1(M)) = \gamma_1(B \otimes_A M)$. [If M is flat and finitely generated over A, then $B \otimes_A M$ is flat and finitely generated over B.] If $g : B \to C$ is another ring homomorphism (with C Noetherian), then $(g \circ f)^! = g^! \circ f^!$.

(v) If $f : A \to B$ is a finite ring homomorphism then

$$f_!(f^!(x)y) = x f_!(y)$$

for $x \in K_1(A)$, $y \in K(B)$. In other words, regarding $K(B)$ as a $K_1(A)$-module by restriction of scalars, the homomorphism $f_!$ is a $K_1(A)$-module homomorphism.

Remark. Since $F_1(A)$ is a subset of $F(A)$, there is a group homomorphism $\epsilon : K_1(A) \to K(A)$, given by $\epsilon(\gamma_1(M)) = \gamma(M)$. If the ring A is finite-dimensional and regular, i.e., if all its local rings $A_{\mathfrak{p}}$ are regular (Chapter 11), then ϵ is an isomorphism.

Practice problems.

1. In $R = k[x_1, x_2, x_3, \dots]$ consider the ideal $\mathfrak{a} = (x_1^2,\, x_2^2,\, x_3^2, \dots)$. Exhibit an explicit infinite strictly ascending chain of ideals contained in $\mathfrak{a}$, conclude that R is not Noetherian, and show in addition that $\mathfrak{a}$ itself is not finitely generated.

2. Let $\mathfrak{a} = (x^3,\, x^2y,\, y^4) \subseteq k[x, y]$. Compute $\operatorname{rad}(\mathfrak{a})$ and find the least integer m with $\operatorname{rad}(\mathfrak{a})^m \subseteq \mathfrak{a}$. Verify that m does not exceed the bound from the radical-power corollary, and exhibit one monomial in $\operatorname{rad}(\mathfrak{a})^{m-1}$ that lies outside $\mathfrak{a}$.

3. Show that the ring $R = \{\, f/g \in \mathbb{Q}(x) \,:\, g(0) \neq 0 \,\}$ (rational functions with no pole at 0) is Noetherian by identifying it as a localization of $\mathbb{Q}[x]$ and describing all of its ideals; in particular list every ideal and verify the ascending chain condition directly.

4. Let $V = \mathcal{Z}(y - x^2) \subseteq \mathbb{A}^2$ over an infinite field k (a parabola). Prove that the coordinate ring $k[V] = k[x, y]/(y - x^2)$ is isomorphic as a k-algebra to $k[t]$, and exhibit the mutually inverse morphisms between V and $\mathbb{A}^1$ realizing this isomorphism.

5. Decompose the algebraic set $V = \mathcal{Z}\big((x^2 - y) \cdot (x^2 + y)\big) \subseteq \mathbb{A}^2$ over $\mathbb{R}$ into its irreducible components, name the prime ideal cutting out each component, and confirm that the decomposition is the geometric form of the factorization $\mathcal{Z}(\mathfrak{a}\mathfrak{b}) = \mathcal{Z}(\mathfrak{a}) \cup \mathcal{Z}(\mathfrak{b})$.

6. Let $\theta : M \to M$ be an R-module endomorphism of a Noetherian module M. Prove that the descending chain $\operatorname{im}\theta \supseteq \operatorname{im}\theta^2 \supseteq \cdots$ need not stabilize in general, but that if M is also Artinian then θ injective forces θ surjective. Give a Noetherian-but-not-Artinian M and an injective θ that is not surjective.

7. Let R be Noetherian and $S = R[x_1, \dots, x_n]$. Prove that every radical ideal of S is the intersection of finitely many prime ideals, and illustrate with $\mathfrak{a} = (x^2y,\, xy^2) \subseteq k[x, y]$ by computing $\operatorname{rad}(\mathfrak{a})$ as such an intersection.

8. Over $k = \mathbb{F}_2$ let $V = \{\,(0,0),(1,0),(0,1)\,\} \subseteq \mathbb{A}^2$. Compute the vanishing ideal $\mathcal{I}(V)$ explicitly, verify that $\mathcal{I}(V)$ is the intersection of the three maximal ideals at these points, and confirm $\dim_k\big(k[x,y]/\mathcal{I}(V)\big) = 3$ using the Chinese Remainder Theorem.

Additional exercises.

1. Prove that a quotient $R/\mathfrak{a}$ of a Noetherian ring is Noetherian by showing that every ideal of $R/\mathfrak{a}$ is finitely generated, working entirely through the finite-generation criterion (do not invoke the ascending chain condition directly). Deduce that every homomorphic image of a Noetherian ring is Noetherian, and give an example of a Noetherian ring with a non-Noetherian subring.

2. Let R be a commutative ring such that $R[[x]]$ is Noetherian. Prove that R is Noetherian. (Use the evaluation-at-zero map and the fact that quotients of Noetherian rings are Noetherian; do not assume the Hilbert Basis Theorem for power series.)

3. Let X be a Noetherian topological space. Prove that X has only finitely many irreducible components and that X is quasi-compact (every open cover has a finite subcover). Then show that the Zariski space $\mathbb{A}^n$ over any field k is quasi-compact, even though it is not Hausdorff when k is infinite.

4. Suppose $0 \to M' \xrightarrow{\alpha} M \xrightarrow{\beta} M'' \to 0$ is a short exact sequence of R-modules in which M' and M'' are Noetherian. Prove M is Noetherian by the diagram-chase argument: given an ascending chain (L_n) in M, show that $\alpha^{-1}(L_n)$ stationary and $\beta(L_n)$ stationary together force L_n stationary. Then deduce that a finite direct sum of Noetherian modules is Noetherian.

5. Let R be a Noetherian integral domain and $f \in R$ a nonzero nonunit. Prove that there are only finitely many primes $\mathfrak{p}$ minimal over (f), that their intersection equals $\operatorname{rad}((f))$, and that (f) contains a power of this intersection (Corollary 15.2.31), although in general no power of an individual $\mathfrak{p}$ (consider $f = xy$ in $k[x,y]$). [Use that $\operatorname{Spec} R$ is a Noetherian space and that minimal primes over (f) correspond to irreducible components of $\mathcal{Z}((f))$.]

Commutative-diagram exercises.

1. Let R be Noetherian and $\mathfrak{a} \subseteq R$ an ideal, with $S = R/\mathfrak{a}$ and $\pi : R \twoheadrightarrow S$ the quotient map. The induced map on spectra $\pi^* : \operatorname{Spec} S \to \operatorname{Spec} R$ is the closed immersion onto $\mathcal{Z}(\mathfrak{a})$. Complete and prove commutativity of the square below, in which the horizontal arrows are the inclusion-reversing maps $\mathcal{Z}$ and the vertical arrows are induced by π:

$$\begin{array}{ccc} \{\,\text{ideals of } R \text{ containing } \mathfrak{a}\,\} & \xrightarrow{\ \mathcal{Z}\ } & \{\,\text{closed sets in } \mathcal{Z}(\mathfrak{a})\,\} \\ \Big\downarrow{\scriptstyle \bmod \mathfrak{a}} & & \Big\| \\ \{\,\text{ideals of } S\,\} & \xrightarrow[\ \mathcal{Z}\ ]{} & \{\,\text{closed sets in } \operatorname{Spec} S\,\} \end{array}$$

   Prove that the left vertical map is an inclusion-preserving bijection (Lattice Isomorphism Theorem), conclude that $\operatorname{Spec} S$ inherits the descending chain condition on closed sets, and identify the image $\pi^*(\operatorname{Spec} S) \subseteq \operatorname{Spec} R$.

2. Let R be Noetherian and let $T = R[x]$ with the inclusion $\iota : R \hookrightarrow T$ and the evaluation $\varepsilon : T \twoheadrightarrow R$, $f(x) \mapsto f(0)$, so that $\varepsilon \circ \iota = \mathrm{id}_R$. Complete the diagram of spectra below and prove it commutes:

$$\begin{array}{ccc} \operatorname{Spec} R & \xhookrightarrow{\ \varepsilon^*\ } & \operatorname{Spec} R[x] \\ & {\scriptstyle \mathrm{id}^*}\searrow & \Big\downarrow{\scriptstyle \iota^*} \\ & & \operatorname{Spec} R \end{array}$$

   Identify ε^* as the closed immersion $\mathcal{Z}((x)) \hookrightarrow \operatorname{Spec} R[x]$, prove $\iota^* \circ \varepsilon^* = \mathrm{id}$ on $\operatorname{Spec} R$, and use the Hilbert Basis Theorem to conclude that $\operatorname{Spec} R[x]$ is a Noetherian topological space.

3. Let $V \xrightarrow{\varphi} W$ be a morphism of affine algebraic sets over k, with associated k-algebra map $\overline{\varphi} : k[W] \to k[V]$, and let $W' = \mathcal{Z}(\mathfrak{a}) \subseteq W$ be a closed subset. Complete the square below (vertical arrows the inclusions, horizontal arrows φ and its restriction) and prove it is a pullback:

$$\begin{array}{ccc} \varphi^{-1}(W') & \xrightarrow{\ \varphi\ } & W' \\ \downarrow & & \downarrow \\ V & \xrightarrow[\ \varphi\ ]{} & W \end{array}$$

   Prove that $\varphi^{-1}(W')$ is an affine algebraic subset of V equal to $\mathcal{Z}\big(\overline{\varphi}(\mathfrak{a})\big)$, and deduce that a morphism of affine algebraic sets is continuous for the Zariski topology.

4. For a Noetherian ring R and the chain of quotients $R \twoheadrightarrow R/\mathfrak{a}_1 \twoheadrightarrow R/\mathfrak{a}_2 \twoheadrightarrow \cdots$ arising from an ascending chain of ideals $\mathfrak{a}_1 \subseteq \mathfrak{a}_2 \subseteq \cdots$, the spectra form a tower of closed immersions. Complete the inverse-limit tower below (horizontal arrows the spectrum maps induced by the quotient maps) and prove the indicated stabilization:

$$\operatorname{Spec}(R/\mathfrak{a}_1) \longleftarrow \operatorname{Spec}(R/\mathfrak{a}_2) \longleftarrow \operatorname{Spec}(R/\mathfrak{a}_3) \longleftarrow \cdots$$

   Prove that, because R is Noetherian, this tower of closed immersions is eventually all isomorphisms, identify the common value $\varprojlim$ with $\mathcal{Z}(\bigcup_n \mathfrak{a}_n)$, and state which property of R (ascending chain condition versus finite generation) is doing the work.

15.3 Radicals and Affine Varieties

The radical of an ideal; reduced rings

The starting observation is geometric: a polynomial f and its powers $f^2, f^3, \ldots$ have exactly the same zero locus, so many different ideals of $k[x_1, \ldots, x_n]$ cut out the same algebraic set. The algebraic device that erases this redundancy is the radical. It is defined in any commutative ring R (all rings here have 1).

Definition 15.3.1. Let $\mathfrak{a}$ be an ideal of a commutative ring R. The *radical* of $\mathfrak{a}$ is

$$\operatorname{rad}\mathfrak{a} = \{\, a \in R : a^k \in \mathfrak{a} \text{ for some } k \geq 1 \,\}.$$

The radical of the zero ideal, $\operatorname{rad}(0) = \{\, a \in R : a^k = 0 \text{ for some } k \geq 1 \,\}$, is the *nilradical* $\operatorname{nil}(R)$ (written $\mathfrak{N}$ in the Atiyah–Macdonald convention): the set of all nilpotent elements. An ideal with $\mathfrak{a} = \operatorname{rad}\mathfrak{a}$ is a *radical ideal*, and a ring with $\operatorname{nil}(R) = 0$ – no nonzero nilpotents – is called *reduced*.

Proposition 15.3.2 ($\operatorname{rad}\mathfrak{a}$ is an ideal; $\operatorname{nil}(R/\mathfrak{a}) = (\operatorname{rad}\mathfrak{a})/\mathfrak{a}$)**.** *For any ideal $\mathfrak{a}$ of R, $\operatorname{rad}\mathfrak{a}$ is an ideal containing $\mathfrak{a}$, and $(\operatorname{rad}\mathfrak{a})/\mathfrak{a}$ is the nilradical of $R/\mathfrak{a}$. In particular $R/\mathfrak{a}$ is reduced if and only if $\mathfrak{a}$ is a radical ideal.*

Idea. Clearly $\mathfrak{a} \subseteq \operatorname{rad}\mathfrak{a}$. The nilradical of $R/\mathfrak{a}$ consists of cosets some power of which is 0, which under the Lattice Isomorphism Theorem corresponds exactly to elements of R some power of which lies in $\mathfrak{a}$, i.e. to $\operatorname{rad}\mathfrak{a}$. So it suffices to see $\operatorname{nil}(R)$ is an ideal. It is closed under multiplication by R since $(ra)^n = r^n a^n$, and closed under addition by the Binomial Theorem: if $a^n = 0$ and $b^m = 0$ then in $(a+b)^{n+m} = \sum_i \binom{n+m}{i} a^i b^{n+m-i}$ every term has $i \geq n$ (so $a^i = 0$) or $n + m - i \geq m$ (so $b^{n+m-i} = 0$), forcing $(a+b)^{n+m} = 0$. $\square$

The single most useful description of the radical is intrinsic: it is the intersection of the primes lying over $\mathfrak{a}$. This is the first appearance of the central A&M idea that the prime ideals are the points at which we test membership.

Theorem 15.3.3 (radical = intersection of containing primes)**.** *Let $\mathfrak{a}$ be a proper ideal of R. Then*

$$\operatorname{rad}\mathfrak{a} = \bigcap_{\mathfrak{p} \supseteq \mathfrak{a},\ \mathfrak{p}\ \text{prime}} \mathfrak{p}.$$

In particular the nilradical is the intersection of all *prime ideals of R.*

Idea. Passing to $R/\mathfrak{a}$ reduces to the case $\mathfrak{a} = 0$: show $\operatorname{nil}(R) = \bigcap_{\mathfrak{p}} \mathfrak{p}$. If a is nilpotent, $a^k = 0 \in \mathfrak{p}$ for every prime $\mathfrak{p}$; taking the least n with $a^n \in \mathfrak{p}$ and factoring $a^{n-1} \cdot a \in \mathfrak{p}$ forces $a \in \mathfrak{p}$ by primality, so a lies in every prime. Conversely if a is *not* nilpotent, the multiplicative set $\{1, a, a^2, \dots\}$ misses 0; the family of ideals meeting no power of a is nonempty (0 is in it) and closed under unions of chains, so Zorn's Lemma yields a maximal such ideal $\mathfrak{p}$, which one checks is prime and avoids a. Hence $a \notin \bigcap_{\mathfrak{p}} \mathfrak{p}$. □

Corollary 15.3.4 (primes are radical)**.** *Every prime ideal $\mathfrak{p}$ is radical (it is the intersection of the primes containing it, the smallest of which is $\mathfrak{p}$). Hence maximal ideals are radical too.*

Remark 15.3.1. The geometric reading is the heart of A&M's philosophy: a prime ideal is simultaneously a "prime of arithmetic" (in $\mathbb{Z}$ the primes containing (a) are the (p) with $p \mid a$) and a "point of geometry" (for k algebraically closed, the maximal ideals of $k[V]$ are the points of V). The radical collects exactly the information visible at every point: $a \in \operatorname{rad} \mathfrak{a}$ iff a vanishes at every prime over $\mathfrak{a}$. Over $k[x_1, \dots, x_n]$ with k algebraically closed this will become "a vanishes on the zero set $V(\mathfrak{a})$," the Nullstellensatz.

Worked Example 15.3.5 (Radical of a principal ideal in $\mathbb{Z}$)**.** Compute $\operatorname{rad}(180)$ in $\mathbb{Z}$ and identify the primes over (180).

Recognition. In a U.F.D., if $a = p_1^{e_1} \cdots p_r^{e_r}$ then $\operatorname{rad}(a) = (p_1 \cdots p_r)$; the minimal primes over (a) are the (p_i) (in $\mathbb{Z}$ these are all the primes over (a)).

Solution. Factor $180 = 2^2 \cdot 3^2 \cdot 5$, so the distinct prime divisors are $2, 3, 5$ and $\operatorname{rad}(180) = (2 \cdot 3 \cdot 5) = (30)$. The primes containing (180) are $(2), (3), (5)$, and $(2) \cap (3) \cap (5) = (\operatorname{lcm}(2, 3, 5)) = (30)$, matching the theorem. Sanity check: $30^2 = 900 = 5 \cdot 180 \in (180)$ so $30 \in \operatorname{rad}(180)$; and $\operatorname{rad}(180)$ is itself radical since $30 = 2 \cdot 3 \cdot 5$ is squarefree, so $\operatorname{rad} \operatorname{rad}(180) = (30)$.

Worked Example 15.3.6 (A radical ideal need not be prime)**.** In $k[x, y]$ show $\operatorname{rad}(xy) = (xy)$ is radical but not prime.

Recognition. An ideal is radical iff the quotient has no nilpotents; it is prime iff the quotient is a domain.

Solution. Since xy is squarefree (product of the distinct irreducibles x, y), $(xy) = (x) \cap (y)$ and $\operatorname{rad}(xy) = (x) \cap (y) = (xy)$, a radical ideal. But it is not prime: $x \cdot y \in (xy)$ while neither x nor y lies in (xy) (degree reasons). Sanity check: $k[x, y]/(xy)$ has no nilpotents (a polynomial whose square is divisible by xy is itself divisible by both x and y off the axes), confirming radical, yet it has the zero divisors $\bar{x}, \bar{y}$, confirming non-prime.

Worked Example 15.3.7 (Nilradical of $\mathbb{Z}/12\mathbb{Z}$)**.** Find the nilpotent elements of $R = \mathbb{Z}/12\mathbb{Z}$ and exhibit $\operatorname{nil}(R)$ as an intersection of primes.

Recognition. $\operatorname{nil}(R) = \operatorname{rad}(0) = \bigcap \mathfrak{p}$; in $\mathbb{Z}/n\mathbb{Z}$ the primes are $(p)/n\mathbb{Z}$ for $p \mid n$.

Solution. $12 = 2^2 \cdot 3$, so $\operatorname{rad}(0)$ in $\mathbb{Z}$ pulled to the quotient is $(6)/12\mathbb{Z} = \{0, 6\}$. Indeed $6^2 = 36 \equiv 0$, while $2, 3, 4$ are not nilpotent (2^k cycles through $2, 4, 8, 4, \dots$). The primes of $\mathbb{Z}/12\mathbb{Z}$ are (2) and (3), and $(2) \cap (3) = (6)$. Sanity check: $\{0, 6\}$ is closed under addition and absorbs multiplication, and $(\bar{6})^2 = \bar{0}$, so it is the nilradical; the quotient $\mathbb{Z}/12\mathbb{Z}$ is not reduced precisely because 12 is not squarefree.

Worked Example 15.3.8 (Powers of the radical: the Noetherian case)**.** If R is Noetherian, show some power of $\operatorname{rad} \mathfrak{a}$ lies in $\mathfrak{a}$; deduce the nilradical is nilpotent.

Recognition. In a Noetherian ring $\operatorname{rad} \mathfrak{a}$ is finitely generated, so finitely many of its generators' powers land in $\mathfrak{a}$.

Solution. Write $\operatorname{rad} \mathfrak{a} = (a_1, \dots, a_m)$ with $a_i^{k_i} \in \mathfrak{a}$, and put $k = \max_i k_i$. Then $(\operatorname{rad} \mathfrak{a})^{km}$ is generated by products $a_1^{d_1} \cdots a_m^{d_m}$ with $\sum d_i = km$, and by pigeonhole some $d_i \geq k$, so each generator has a factor $a_i^{d_i} \in \mathfrak{a}$; hence $(\operatorname{rad} \mathfrak{a})^{km} \subseteq \mathfrak{a}$. Taking $\mathfrak{a} = 0$ gives $\operatorname{nil}(R)^{km} = 0$. Sanity check: in $\mathbb{Z}/p^e\mathbb{Z}$ the nilradical is (p) and $(p)^e = 0$, exactly a finite power vanishing; over a non-Noetherian ring this can fail, e.g. $k[x_1, x_2, \dots]/(x_1, x_2^2, x_3^3, \dots)$ has a non-nilpotent nilradical.

The maps $I(\cdot)$ and $V(\cdot)$: a Galois connection

Fix a field k and write $\mathbb{A}^n = \mathbb{A}^n_k$ for affine n-space, the set k^n. (We follow A&M and D&F in working with k-rational points; the scheme-theoretic upgrade replacing points by primes appears in Section 8.) Two maps tie subsets of $\mathbb{A}^n$ to ideals of $k[x_1, \dots, x_n]$.

Definition 15.3.9. For an ideal $\mathfrak{a} \subseteq k[x_1, \dots, x_n]$ (or any subset of polynomials), the *zero set* (variety) is

$$V(\mathfrak{a}) = \{\, P \in \mathbb{A}^n : f(P) = 0 \text{ for all } f \in \mathfrak{a} \,\}.$$

For a subset $A \subseteq \mathbb{A}^n$, the *ideal of* A is

$$I(A) = \{\, f \in k[x_1, \dots, x_n] : f(P) = 0 \text{ for all } P \in A \,\}.$$

A subset of the form $V(\mathfrak{a})$ is an *affine algebraic set*.

Proposition 15.3.10 (the Galois connection)**.** *The maps V and I are inclusion-reversing and satisfy, for all ideals $\mathfrak{a}$ and subsets A,*

$$\mathfrak{a} \subseteq I(V(\mathfrak{a})), \qquad A \subseteq V(I(A)), \qquad V(I(V(\mathfrak{a}))) = V(\mathfrak{a}), \qquad I(V(I(A))) = I(A).$$

Consequently V and I restrict to mutually inverse, order-reversing bijections between the algebraic sets $V(\mathfrak{a})$ and the ideals of the form $I(A)$. Moreover $I(A)$ is always a radical ideal.

Idea. Order-reversal and the unit inequalities $\mathfrak{a} \subseteq IV(\mathfrak{a})$, $A \subseteq VI(A)$ are immediate from the definitions; these are exactly the axioms of a (contravariant) Galois connection, and the two "triangle" identities follow formally by applying V to $A \subseteq VI(A)$ and using order-reversal both ways. That $I(A)$ is radical: if f^k vanishes on A then $f(P)^k = 0$ in the field k forces $f(P) = 0$, so $f \in I(A)$. □

The composite $\mathfrak{a} \mapsto I(V(\mathfrak{a}))$ is the closure operator of this Galois connection. The content of the Nullstellensatz, below, is to compute it: over an algebraically closed field it is exactly the radical.

Worked Example 15.3.11 (V collapses an ideal and its radical)**.** Show $V(\mathfrak{a}) = V(\operatorname{rad}\mathfrak{a})$ for every ideal $\mathfrak{a}$, with the explicit case $\mathfrak{a} = (x^2)$ in $k[x]$.

Recognition. A point kills f iff it kills f^k; so passing to radicals does not change zero sets.

Solution. If $a \in \operatorname{rad}\mathfrak{a}$ then $a^k \in \mathfrak{a}$, and $a^k(P) = 0$ on $V(\mathfrak{a})$ gives $a(P)^k = 0$, hence $a(P) = 0$; so $V(\mathfrak{a}) \subseteq V(\operatorname{rad}\mathfrak{a})$, and the reverse holds since $\mathfrak{a} \subseteq \operatorname{rad}\mathfrak{a}$ reverses. For $(x^2) \subseteq k[x]$: $\operatorname{rad}(x^2) = (x)$ and $V(x^2) = V(x) = \{\, 0 \,\}$. Sanity check: the "double point" (x^2) and the reduced point (x) have the same underlying set $\{\, 0 \,\}$; the radical forgets the multiplicity, exactly the redundancy the radical was invented to remove.

Worked Example 15.3.12 (I of a finite point set)**.** With k infinite, compute $I(\{\, (0,0), (1,0) \,\})$ in $k[x, y]$.

Recognition. $I(A)$ is the set of polynomials vanishing at every listed point; for finitely many points it is an intersection of the corresponding maximal ideals.

Solution. A point (a, b) has $I(\{\, (a,b) \,\}) = (x - a, y - b)$, the maximal ideal of functions vanishing there. So $I(\{\, (0,0), (1,0) \,\}) = (x, y) \cap (x - 1, y)$. A polynomial lies here iff it vanishes at both points; one checks this intersection equals $(y,\ x^2 - x) = (y,\ x(x-1))$. Sanity check: y vanishes on both, and $x(x-1)$ vanishes at $x = 0$ and $x = 1$; conversely modulo $(y, x(x-1))$ every class is represented by $c_0 + c_1 x$, a 2-dimensional k-space, matching the 2 points – the coordinate ring of two reduced points is $k \times k$.

Worked Example 15.3.13 (The closure operator VI in the non-closed case)**.** Over $k = \mathbb{R}$, show $I(V((x^2+1)))$ strictly exceeds $\operatorname{rad}(x^2 + 1)$.

Recognition. V over a non-algebraically-closed field can be empty even for a proper radical ideal; $I(\varnothing)$ is everything.

Solution. In $\mathbb{R}[x]$ the ideal $(x^2 + 1)$ is maximal (hence radical), but $V(x^2 + 1) = \varnothing$ since $x^2 + 1$ has no real root. Then $I(V(x^2 + 1)) = I(\varnothing) = \mathbb{R}[x] \supsetneq (x^2 + 1) = \operatorname{rad}(x^2 + 1)$. Sanity check: this is precisely the obstruction A&M and D&F flag – a one-variable polynomial with no zeros. Over $\mathbb{C}$ no such obstruction exists, and the Nullstellensatz below restores $I(V(\mathfrak{a})) = \operatorname{rad}\mathfrak{a}$.

Affine varieties, coordinate rings, and the prime/irreducible dictionary

We now ask when an algebraic set is "indecomposable." The answer is the keystone of the algebra–geometry dictionary: irreducibility of the set matches primality of its ideal.

Definition 15.3.14. A nonempty algebraic set V is *irreducible* if it cannot be written $V = V_1 \cup V_2$ with V_1, V_2 proper algebraic subsets. An irreducible algebraic set is an *affine variety*. Its *coordinate ring* is

$$k[V] = k[x_1, \dots, x_n]/I(V),$$

the ring of polynomial (k-valued) functions on V.

Theorem 15.3.15 (irreducible $\iff$ prime; unique decomposition)**.** *Let V be a nonempty algebraic set in $\mathbb{A}^n$.*

(1) *V is irreducible if and only if $I(V)$ is a prime ideal; equivalently iff $k[V]$ is an integral domain.*

(2) *V has a unique irredundant decomposition $V = V_1 \cup \cdots \cup V_q$ into varieties with $V_i \not\subseteq V_j$ for $i \neq j$. The V_i are the* irreducible components *of V.*

Idea. (1) If $V = V_1 \cup V_2$ properly, pick $f_1 \in I(V_1) \setminus I(V)$ and $f_2 \in I(V_2) \setminus I(V)$; then $f_1 f_2$ vanishes on V so $f_1 f_2 \in I(V)$ with neither factor in $I(V)$, so $I(V)$ is not prime. Conversely if $f_1 f_2 \in I(V)$ with $f_i \notin I(V)$, set $V_i = V \cap V(f_i)$: both are proper closed subsets and $V = V_1 \cup V_2$, so V is reducible. The translation to $k[V]$ is the standard fact that $R/\mathfrak{p}$ is a domain iff $\mathfrak{p}$ is prime. (2) Existence: were the family of algebraic sets with no finite decomposition into varieties nonempty, a maximal $I(V_0)$ (Noetherian!) gives a minimal bad V_0 which, being reducible, splits into strictly smaller pieces that *do* decompose – contradiction. Uniqueness: intersect one decomposition against the other and use irreducibility to match components. □

Remark 15.3.2. This is the order-reversing bijection of the Galois connection made precise on the irreducible level: varieties in $\mathbb{A}^n$ correspond to prime ideals that arise as $I(V)$. It refines the radical theorem – writing a radical ideal as $\bigcap \mathfrak{p}$ over its minimal primes is the algebraic shadow of decomposing V into components. (The general module/ideal version, primary decomposition, is developed in Section 6.)

Definition 15.3.16. For a variety V the domain $k[V]$ has a fraction field $k(V)$, the field of *rational functions* on V. The *dimension* of V is $\dim V = \operatorname{tr.deg}_k k(V)$.

Worked Example 15.3.17 (The cuspidal cubic is a variety)**.** With k infinite, show $V = V(y^2 - x^3) \subseteq \mathbb{A}^2$ is irreducible and compute its coordinate ring and dimension.

Recognition. V is a variety iff $I(V)$ is prime iff $k[V]$ is a domain; $\dim V = \operatorname{tr.deg}_k k(V)$.

Solution. $y^2 - x^3$ is irreducible in $k[x, y]$ (it is monic of degree 2 in y with no root in $k[x]$, as x^3 is not a square), so $(y^2 - x^3)$ is prime. It equals $I(V)$: if f vanishes on V, write $f \equiv a(x) + y\,b(x) \pmod{y^2 - x^3}$; then $a(t^2) + t^3 b(t^2) = 0$ for every t in the infinite field k, so this polynomial in t is 0, and comparing even and odd powers of t gives $a = b = 0$. Then $k[V] = k[x, y]/(y^2 - x^3)$ is a domain, so V is a variety. Setting $t = y/x$ in $k(V)$ gives $x = t^2,\ y = t^3$, so $k(V) = k(t)$ and $\dim V = \operatorname{tr.deg}_k k(t) = 1$. Sanity check: V is the image of the parametrization $t \mapsto (t^2, t^3)$, a curve, consistent with dimension 1; the cusp at the origin does not affect irreducibility or dimension.

Worked Example 15.3.18 (A union of axes is reducible)**.** With k infinite, decompose $V(xy) \subseteq \mathbb{A}^2$ into components and read off the coordinate ring's defect.

Recognition. $V(fg) = V(f) \cup V(g)$; the components are the $V(\mathfrak{p}_i)$ for the minimal primes $\mathfrak{p}_i$ over $I(V)$.

Solution. $V(xy) = V(x) \cup V(y)$, the union of the two coordinate axes. Since $(xy) = (x) \cap (y)$ with $(x), (y)$ prime and incomparable, the irredundant decomposition is into the y-axis $V(x)$ and the x-axis $V(y)$. The coordinate ring $k[x, y]/(xy)$ has the zero divisors $\bar{x}\bar{y} = 0$, so it is not a domain – exactly why $V(xy)$ is not a variety. Sanity check: two distinct minimal primes $(x), (y)$ over the radical ideal (xy) give exactly two components; the ring is reduced (radical ideal) but not a domain (reducible).

Worked Example 15.3.19 (Points are zero-dimensional varieties)**.** Show a single point $P = (a_1, \dots, a_n)$ is a variety and $\dim\{P\} = 0$.

Recognition. $I(\{P\}) = (x_1 - a_1, \dots, x_n - a_n)$ is maximal, hence prime; dimension is the transcendence degree of the residue field.

Solution. The ideal $\mathfrak{m}_P = (x_1 - a_1, \dots, x_n - a_n)$ is maximal with $k[x]/\mathfrak{m}_P \cong k$, so it is prime and $\{P\}$ is irreducible. Then $k[\{P\}] = k$ and $k(\{P\}) = k$, giving $\dim = \operatorname{tr.deg}_k k = 0$. Sanity check: a finite set $\{P_1, \dots, P_r\}$ decomposes into its singletons, each a 0-dimensional component, and its coordinate ring is k^r – r minimal primes, r points, dimension 0.

Worked Example 15.3.20 (Linear subspaces are varieties)**.** With k infinite, show the zero set V of linear polynomials $\ell_1, \dots, \ell_m$, when nonempty, is a variety.

Recognition. An ideal generated by linear forms (after translating to the origin) has domain quotient – a polynomial ring in the remaining coordinates.

Solution. After an affine change of coordinates, V is the linear subspace $x_{d+1} = \cdots = x_n = 0$, with $I(V) = (x_{d+1}, \dots, x_n)$, a prime ideal (the quotient is the domain $k[x_1, \dots, x_d]$). So V is a variety with $k[V] \cong k[x_1, \dots, x_d]$ and $\dim V = \operatorname{tr.deg}_k k(x_1, \dots, x_d) = d$. Sanity check: $\dim V = d$ matches the geometric dimension of a d-plane, and $k(V) = k(x_1, \dots, x_d)$ is a rational function field, the prototype of dimension d.

Worked Example 15.3.21 (The hyperbola and its rational function field)**.** With k infinite, show $V = V(xy - 1) \subseteq \mathbb{A}^2$ is a variety with $k[V] \cong k[x, x^{-1}]$.

Recognition. $V(xy - 1)$ is a variety iff $xy - 1$ is irreducible; the coordinate ring is the localization adjoining x^{-1}.

Solution. $xy - 1$ is irreducible (degree 1 in y, primitive), so $(xy - 1)$ is prime. It equals $I(V)$: if f vanishes on V then $f(t, t^{-1}) = 0$ for the infinitely many $t \in k^\times$, so $f(x, x^{-1}) = 0$ in $k[x, x^{-1}]$, i.e. $f \in \ker\big(k[x, y] \to k[x, x^{-1}],\ y \mapsto x^{-1}\big) = (xy - 1)$. Hence V is a variety. On V, $y = x^{-1}$, so $k[V] = k[x, y]/(xy - 1) \cong k[x, x^{-1}]$, a domain. Its fraction field is $k(x)$, so $\dim V = 1$. Sanity check: every point of V has $x \neq 0$, consistent with inverting x; and although over $\mathbb{R}$ the hyperbola has two visible "branches," they are *not* subvarieties – the Zariski topology cannot separate them since V is irreducible.

The Zariski topology, closure, and density

The algebraic sets are exactly the closed sets of a topology, the topology in which "closed = cut out by polynomial equations."

Proposition 15.3.22 (algebraic sets form the closed sets of a topology)**.** *On $\mathbb{A}^n$ the collection of affine algebraic sets satisfies the closed-set axioms:*

$$V(\mathfrak{a}) \cap V(\mathfrak{b}) = V(\mathfrak{a} + \mathfrak{b}) \text{ (arbitrary intersections)}, \quad V(\mathfrak{a}) \cup V(\mathfrak{b}) = V(\mathfrak{a}\mathfrak{b}) = V(\mathfrak{a} \cap \mathfrak{b}), \quad \varnothing = V(1),\ \mathbb{A}^n = V(0).$$

The resulting topology is the Zariski topology. *The same construction with $k[V]$ in place of $k[\mathbb{A}^n]$ topologizes any algebraic set V, intrinsically (independent of the embedding) and agreeing with the subspace topology.*

Idea. $\bigcap_i V(\mathfrak{a}_i) = V(\sum_i \mathfrak{a}_i)$ since a point kills $\sum \mathfrak{a}_i$ iff it kills every $\mathfrak{a}_i$. For finite unions, $V(\mathfrak{a}) \cup V(\mathfrak{b}) \subseteq V(\mathfrak{a} \cap \mathfrak{b}) \subseteq V(\mathfrak{a}\mathfrak{b})$ trivially, and conversely if $P \notin V(\mathfrak{a}) \cup V(\mathfrak{b})$ there are $f \in \mathfrak{a}, g \in \mathfrak{b}$ with $f(P)g(P) \neq 0$, so $fg \in \mathfrak{a}\mathfrak{b}$ does not vanish at P, i.e. $P \notin V(\mathfrak{a}\mathfrak{b})$. The endpoints are the unit and zero ideals. Intrinsicality follows because ideals of $k[V]$ are ideals of $k[\mathbb{A}^n]$ containing $I(V)$, taken mod $I(V)$, and the Lattice Isomorphism Theorem matches their loci. □

Remark 15.3.3. The Zariski topology is coarse and almost never Hausdorff. On $\mathbb{A}^1$ over an infinite field the only proper closed sets are the finite ones, so any two nonempty opens meet; points are closed (T_1) but no two points are separated by disjoint opens. This coarseness is the source of the slogan "nonempty open ⇒ dense" and is why irreducibility (a topological condition) is so strong. In Section 8 the same topology is placed on $\operatorname{Spec} R$, with prime ideals as points; the present picture is its k-rational shadow.

Proposition 15.3.23 (Zariski closure)**.** *For any subset $A \subseteq \mathbb{A}^n$ the Zariski closure (smallest algebraic set containing A) is $\overline{A} = V(I(A))$. Hence A is dense in a variety V iff $V(I(A)) = V$.*

Idea. $A \subseteq V(I(A))$, and if $W = V(\mathfrak{b}) \supseteq A$ is any algebraic set then $I(W) \subseteq I(A)$ so $V(I(A)) \subseteq V(I(W)) = W$; thus $V(I(A))$ is the smallest such. This is the closure operator of the Galois connection again, now read topologically. □

Worked Example 15.3.24 (The Zariski closure of the parabola-points)**.** Over $\mathbb{R}$, find the Zariski closure of $A = \{\,(a, a^2) : a \in \mathbb{R}\,\} \subseteq \mathbb{A}^2$.

Recognition. $\overline{A} = V(I(A))$; compute $I(A)$ as the polynomials vanishing along the parametrized set.

Solution. A polynomial f vanishes on A iff $f(a, a^2) = 0$ for all a, i.e. $f(x, y) \equiv 0 \pmod{y - x^2}$ since substituting $y = x^2$ kills it for the infinitely many a (and $\mathbb{R}$ is infinite). So $I(A) = (y - x^2)$ and $\overline{A} = V(y - x^2)$, the whole parabola. Sanity check: $y - x^2$ is irreducible, so $\overline{A}$ is a variety of dimension 1; the infinite set A is Zariski dense in it, illustrating that an infinite subset of a curve already determines the curve.

Worked Example 15.3.25 (Zariski versus Euclidean closed sets)**.** Over $\mathbb{R}$, show the interval $[0, 1] \subseteq \mathbb{A}^1$ is Euclidean-closed but not Zariski-closed.

Recognition. Zariski-closed sets in $\mathbb{A}^1$ over an infinite field are only $\varnothing$, all of $\mathbb{A}^1$, and finite sets.

Solution. $[0, 1]$ is infinite but is not all of $\mathbb{A}^1$, so it is not a Zariski-closed set; its Zariski closure is $V(I([0, 1])) = V(0) = \mathbb{A}^1$, since the only polynomial vanishing on an infinite set is 0. Yet $[0, 1]$ is closed in the Euclidean topology. Sanity check: this confirms the Euclidean topology is strictly finer; every Zariski-closed set (finite, or all of $\mathbb{R}$) is Euclidean-closed, but not conversely.

Worked Example 15.3.26 (Nonempty open sets are dense in a variety)**.** Let V be a variety and U_1, U_2 nonempty Zariski-open subsets of V. Show $U_1 \cap U_2 \neq \varnothing$, hence every nonempty open is dense.

Recognition. Irreducibility says V is not a union of two proper closed sets; complements translate this to opens.

Solution. If $U_1 \cap U_2 = \varnothing$ then $V = (V \setminus U_1) \cup (V \setminus U_2)$ writes V as a union of two closed sets, each proper since $U_i \neq \varnothing$. This contradicts irreducibility. Taking U_2 arbitrary nonempty open shows U_1 meets every nonempty open, i.e. $\overline{U_1} = V$. Sanity check: on $\mathbb{A}^1$ over $\mathbb{R}$ a nonempty open is $\mathbb{R}$ minus finitely many points; any two such overlap in cofinitely many points, exactly density. Reducible sets fail this: on $V(xy)$ the punctured axes give disjoint nonempty opens.

Worked Example 15.3.27 (An irreducible set is connected)**.** Deduce that a variety is connected in the Zariski topology.

Recognition. Connected means not a disjoint union of two nonempty opens; use that nonempty opens are dense.

Solution. If $V = U_1 \sqcup U_2$ with both U_i nonempty open and disjoint, then $U_1 \cap U_2 = \varnothing$ contradicts the previous example. So no such splitting exists and V is connected. Sanity check: connectedness is weaker than irreducibility – $V(xy)$ is connected (the axes meet at the origin) but reducible – so irreducible ⇒ connected is the expected one-way implication.

The Nullstellensatz: closing the dictionary

Over an arbitrary field the maps I, V need not be inverse bijections (Worked Example with $x^2 + 1$). The Nullstellensatz says the *only* obstruction is the failure of one-variable polynomials to have roots: over an algebraically closed field the closure operator $\mathfrak{a} \mapsto I(V(\mathfrak{a}))$ is exactly the radical.

Theorem 15.3.28 (Hilbert's Nullstellensatz)**.** *Let E be an algebraically closed field. For every ideal $\mathfrak{a}$ of $E[x_1, \ldots, x_n]$,*

$$I(V(\mathfrak{a})) = \operatorname{rad} \mathfrak{a}.$$

Consequently V and I are mutually inverse, order-reversing bijections

$$\{\,\textit{affine algebraic sets in } \mathbb{A}^n_E\,\} \underset{V}{\overset{I}{\longleftrightarrow}} \{\,\textit{radical ideals of } E[x_1, \ldots, x_n]\,\},$$

under which varieties correspond to prime ideals and points to maximal ideals.

Idea. The full proof is deferred to Section 7, where it follows from integral dependence and the "weak" Nullstellensatz (that the maximal ideals of $E[x_1, \dots, x_n]$ are exactly the $\mathfrak{m}_P = (x_1 - a_1, \dots, x_n - a_n)$ for $P \in \mathbb{A}^n_E$). Granting the weak form, the equality $I(V(\mathfrak{a})) = \operatorname{rad} \mathfrak{a}$ is obtained by the Rabinowitsch trick: a function g vanishing on $V(\mathfrak{a})$ is shown to satisfy $g^N \in \mathfrak{a}$ by introducing an extra variable t and the relation $1 - tg$, whose vanishing set forces g into the radical. □

The dictionary is now complete over $E = \overline{E}$: containment of algebraic sets is reverse-containment of radical ideals; irreducible components are minimal primes; the coordinate ring $E[V] = E[x]/I(V)$ is a reduced finitely generated E-algebra whose maximal ideals *are* the points of V.

$$\begin{array}{ccc} \{\text{ varieties }\} & \xleftrightarrow{\ I\ } & \{\text{ primes }\} \\ \cup\mathrel{|} & & \mathrel{|}\cap \\ \{\text{ points }\} & \xleftrightarrow[\ I\ ]{} & \{\text{ maximal ideals }\} \end{array}$$

Diagram explanation. Objects: Four collections, each a node. Top-left: the set of affine varieties in $\mathbb{A}^n_E$ (irreducible algebraic sets, i.e. algebraic sets whose ideal is prime). Top-right: the set of prime ideals of $E[x_1, \dots, x_n]$ that arise as $I(V)$ for some variety V – over $E = \overline{E}$ these are exactly all prime ideals by the Nullstellensatz. Bottom-left: the set of closed points, i.e. individual points $P = (a_1, \dots, a_n) \in \mathbb{A}^n_E$. Bottom-right: the set of maximal ideals of $E[x_1, \dots, x_n]$, which by the weak Nullstellensatz are exactly the $\mathfrak{m}_P = (x_1 - a_1, \dots, x_n - a_n)$.

Arrows: The top horizontal double arrow is the bijection $I\colon \{\text{ varieties }\} \leftrightarrow \{\text{ prime ideals }\}$ given by $V \mapsto I(V)$ and $\mathfrak{p} \mapsto V(\mathfrak{p})$; it reverses containment. The bottom horizontal double arrow is the same map I restricted to points and maximal ideals: $P \mapsto \mathfrak{m}_P$ and $\mathfrak{m} \mapsto V(\mathfrak{m})$, again a bijection by the weak Nullstellensatz. The left vertical symbol records that a point lies in a variety, $\{P\} \subseteq V$ (a single point is itself a 0-dimensional variety, so as collections $\{\text{ points }\} \subseteq \{\text{ varieties }\}$). The right vertical symbol records the reversed containment of the corresponding ideals, $I(V) \subseteq \mathfrak{m}_P$: the maximal ideal below contains the prime above. (As collections the inclusion goes the other way: maximal ideals are special primes, $\{\text{ maximal ideals }\} \subseteq \{\text{ prime ideals }\}$.) Neither vertical relation is a ring map.

What commutes: There is no composite of two arrows to equate in the usual sense; the diagram records that the bijection I on the top row *restricts* to the bijection I on the bottom row. Precisely: if $P \in \mathbb{A}^n_E$ is a point (bottom-left), its image under the bottom I is $\mathfrak{m}_P$ (bottom-right), and $\mathfrak{m}_P$ is also what the top I sends the variety $\{P\}$ to; so the two rows are compatible: $I(\{P\}) = \mathfrak{m}_P$ is both a prime (top-right entry) and a maximal ideal (bottom-right entry). Diagram compatibility: a point lying in a variety on the left, $\{P\} \subseteq V$, corresponds under the order-reversing bijection I to the maximal ideal containing the prime on the right, $I(V) \subseteq \mathfrak{m}_P$.

Why it commutes: A point P is a variety because $(x_1 - a_1, \dots, x_n - a_n)$ is maximal, hence prime, and $V(\mathfrak{m}_P) = \{P\}$ is irreducible. The fact that maximal ideals are prime is a basic ring-theory fact ($R/\mathfrak{m}$ is a field ⇒ domain ⇒ $\mathfrak{m}$ prime). The order-reversal: if $\{P\} \subseteq V$ (point inside variety) then $I(V) \subseteq I(\{P\}) = \mathfrak{m}_P$ (smaller set gives larger ideal), so a prime ideal is contained in a maximal ideal, matching the right-column $\supseteq$. Everything is consistent because I is an order-reversing bijection, guaranteed by the Nullstellensatz.

Why this matters here: This diagram is the final synthesis of the Nullstellensatz: it says the abstract bijection $\{\text{ radical ideals }\} \leftrightarrow \{\text{ algebraic sets }\}$ refines *level by level* to match geometric and algebraic structure. The topmost level (all algebraic sets ↔ radical ideals) restricts to the prime level (varieties ↔ primes) and further to the maximal level (points ↔ maximal ideals). The author places it here to make the full dictionary visible at a glance before the worked examples apply each row.

Concrete example: In $\mathbb{A}^2_{\mathbb{C}}$ with $E = \mathbb{C}$: the parabola $V = V(y - x^2)$ is a variety with $I(V) = (y - x^2)$ prime (top row). The origin $P = (0, 0)$ is a point inside V (left $\subseteq$) with $I(P) = (x, y)$ maximal (bottom row); and $(y - x^2) \subseteq (x, y)$ as ideals (right $\supseteq$), consistently with order-reversal.

Common pitfall: Students sometimes read the two horizontal arrows as a single composite map ("first apply the top I, then the bottom I"), which makes no sense since the codomains do not compose. The diagram does *not* commute in that sense; it records that one bijection restricts to another. A second pitfall: the left

column says $\{\text{ points }\} \subseteq \{\text{ varieties }\}$ as collections, not that there is an algebraic map of rings; similarly the right column records the containment $I(V) \subseteq \mathfrak{m}_P$ of ideals, not a localization or quotient map.

Takeaway: The point of this diagram is that the Nullstellensatz bijection is not just a set correspondence but a *dictionary that respects levels*: varieties (geometric irreducibles) match primes, and points (atomic geometric objects) match maximal ideals, with containment on the left mirrored by reverse containment on the right.

Method (Testing equality of algebraic sets and ideals over $\overline{E}$.)**.** To decide whether $V(\mathfrak{a}) = V(\mathfrak{b})$, compare radicals: $V(\mathfrak{a}) = V(\mathfrak{b}) \iff \operatorname{rad}\mathfrak{a} = \operatorname{rad}\mathfrak{b}$. To decide whether a function g vanishes on $V(\mathfrak{a})$, test whether $g \in \operatorname{rad}\mathfrak{a}$ (e.g. via a Gröbner-basis radical-membership computation, or by exhibiting $g^N \in \mathfrak{a}$). To find the components of $V(\mathfrak{a})$, compute the minimal primes over $\operatorname{rad}\mathfrak{a}$.

Caution. The Nullstellensatz requires E *algebraically closed*. Over $\mathbb{R}$ or $\mathbb{Q}$ it fails: (x^2+1) is its own radical yet $I(V(x^2+1)) = \mathbb{R}[x] \neq (x^2+1)$. Also, $V(\mathfrak{a}) \neq \varnothing$ for proper $\mathfrak{a}$ uses algebraic closure: the weak Nullstellensatz gives a common zero precisely because $\operatorname{rad}\mathfrak{a} \neq (1)$.

Worked Example 15.3.29 (Reading off components via the Nullstellensatz)**.** Over $\mathbb{C}$, find the irreducible components of $V(xz, yz) \subseteq \mathbb{A}^3$.

Recognition. Components $\leftrightarrow$ minimal primes over $\operatorname{rad}(xz, yz)$; compute the radical and factor it as an intersection of primes.

Solution. $(xz, yz) = (z) \cap (x, y)$: a polynomial vanishing wherever $z = 0$ or $x = y = 0$ lies in this intersection, and both (z) and (x, y) are prime. The ideal is already radical (intersection of primes), with minimal primes (z) and (x, y), which are incomparable. So $V(xz, yz) = V(z) \cup V(x, y)$ is the union of the plane $z = 0$ and the z-axis. Sanity check: the $z = 0$ plane has dimension 2 and the z-axis dimension 1; they are the two components, meeting in the origin – an embedded incidence but two genuine top-level components since neither prime contains the other.

Worked Example 15.3.30 (Radical membership decides vanishing)**.** Over $\mathbb{C}$, does $g = x^2y$ vanish on $V(\mathfrak{a})$ for $\mathfrak{a} = (x^3,\, xy^2)$? Compute $I(V(\mathfrak{a}))$.

Recognition. By the Nullstellensatz g vanishes on $V(\mathfrak{a})$ iff $g \in \operatorname{rad}\mathfrak{a}$; find $\operatorname{rad}\mathfrak{a}$ as an intersection of primes.

Solution. $V(\mathfrak{a}) = V(x^3) \cap V(xy^2) = V(x)$, the y-axis (the line $x = 0$ in $\mathbb{A}^2$). So $I(V(\mathfrak{a})) = I(V(x)) = (x) = \operatorname{rad}\mathfrak{a}$ (indeed $x \in \operatorname{rad}\mathfrak{a}$ since $x^3 \in \mathfrak{a}$). Now $g = x^2y \in (x)$, so g vanishes on $V(\mathfrak{a})$. Sanity check: directly, every point of $V(\mathfrak{a})$ has $x = 0$, so $x^2y = 0$ there; and $\operatorname{rad}(x^3, xy^2) = (x)$ because $x^3 \in \mathfrak{a}$ gives $x \in \operatorname{rad}\mathfrak{a}$, while $\mathfrak{a} \subseteq (x)$ gives $\operatorname{rad}\mathfrak{a} \subseteq \operatorname{rad}(x) = (x)$.

Worked Example 15.3.31 (Maximal ideals are points over $\mathbb{C}$)**.** Over $\mathbb{C}$, identify the maximal ideals of $\mathbb{C}[x, y]$ and the corresponding algebraic sets.

Recognition. The weak Nullstellensatz: every maximal ideal of $E[x_1, \ldots, x_n]$ with $E = \overline{E}$ is $\mathfrak{m}_P = (x_1 - a_1, \ldots, x_n - a_n)$.

Solution. Each point $P = (a, b) \in \mathbb{A}^2_{\mathbb{C}}$ gives the maximal ideal $\mathfrak{m}_P = (x - a, y - b)$ with $\mathbb{C}[x, y]/\mathfrak{m}_P \cong \mathbb{C}$, and $V(\mathfrak{m}_P) = \{ P \}$. Conversely every maximal ideal arises this way, so maximal ideals $\leftrightarrow$ points bijectively. Sanity check: this is the bottom row of the dictionary square; over $\mathbb{R}$ it fails, since $(x^2 + 1) \subseteq \mathbb{R}[x]$ is maximal but is no point's ideal – a maximal ideal with empty zero set, impossible over $\mathbb{C}$.

Worked Example 15.3.32 (The radical ideal $\leftrightarrow$ algebraic set bijection in action)**.** Over $\mathbb{C}$, verify V and I are inverse on $\mathfrak{a} = (x^2 - y)$ and on the set $A = V(\mathfrak{a})$.

Recognition. Check $I(V(\mathfrak{a})) = \operatorname{rad}\mathfrak{a}$ and $V(I(A)) = A$ for a specific prime (hence radical) ideal.

Solution. $x^2 - y$ is irreducible, so $(x^2 - y)$ is prime, hence radical, and $A = V(x^2 - y)$ is the parabola $y = x^2$. Then $I(A) = (x^2 - y)$ by the Nullstellensatz (it equals $\operatorname{rad}(x^2 - y) = (x^2 - y)$), and $V(I(A)) = V(x^2 - y) = A$. Sanity check: $(x^2 - y)$ prime $\Rightarrow A$ a variety; the round trips $\mathfrak{a} \mapsto V(\mathfrak{a}) \mapsto I(V(\mathfrak{a})) = \mathfrak{a}$ and $A \mapsto I(A) \mapsto V(I(A)) = A$ both close, exactly the bijection the Nullstellensatz asserts.

Exercises (Dummit & Foote).

1. Prove (3) of Corollary 22 directly by considering the collection S of ideals that do not contain a finite product of prime ideals. [If I is a maximal element in S, show that since I is not prime there are ideals J, K properly containing I (hence not in S) with $JK \subseteq I$.]

2. Let I and J be ideals in the ring R. Prove the following statements:

   (a) If $I^k \subseteq J$ for some $k \geq 1$ then $\operatorname{rad} I \subseteq \operatorname{rad} J$.

   (b) If $I^k \subseteq J \subseteq I$ for some $k \geq 1$ then $\operatorname{rad} I = \operatorname{rad} J$.

   (c) $\operatorname{rad}(IJ) = \operatorname{rad}(I \cap J) = \operatorname{rad} I \cap \operatorname{rad} J$.

   (d) $\operatorname{rad}(\operatorname{rad} I) = \operatorname{rad} I$.

   (e) $\operatorname{rad} I + \operatorname{rad} J \subseteq \operatorname{rad}(I + J)$ and $\operatorname{rad}(I + J) = \operatorname{rad}(\operatorname{rad} I + \operatorname{rad} J)$.

3. Prove that the intersection of two radical ideals is again a radical ideal.

4. Let $I = \mathfrak{m}_1\mathfrak{m}_2$ be the product of the ideals $\mathfrak{m}_1 = (x, y)$ and $\mathfrak{m}_2 = (x - 1, y - 1)$ in $\mathbb{F}_2[x, y]$. Prove that I is a radical ideal. Prove that the ideal $(x^3 - y^2)$ is a radical ideal in $\mathbb{F}_2[x, y]$.

5. If $I = (xy, (x - y)z) \subseteq k[x, y, z]$ prove that $\operatorname{rad} I = (xy, xz, yz)$. For this ideal prove directly that $\mathcal{Z}(I) = \mathcal{Z}(\operatorname{rad} I)$, that $\mathcal{Z}(I)$ is not irreducible, and that $\operatorname{rad} I$ is not prime.

6. Give an example to show that over a field k that is not algebraically closed the containment $I \subseteq \mathcal{I}(\mathcal{Z}(I))$ can be proper even when I is a radical ideal.

7. Suppose R and S are rings and $\varphi : R \to S$ is a ring homomorphism. If I is an ideal of R show that $\varphi(\operatorname{rad} I) \subseteq \operatorname{rad}(\varphi(I))$. If in addition φ is surjective and I contains the kernel of φ show that $\varphi(\operatorname{rad} I) = \operatorname{rad}(\varphi(I))$.

8. Suppose the prime ideal $\mathfrak{p}$ contains the ideal I. Prove that $\mathfrak{p}$ contains the radical of I.

9. Prove that for any field k the map $\mathcal{Z}$ in the Nullstellensatz is always surjective and the map $\mathcal{I}$ in the Nullstellensatz is always injective. [Use property (10) of the maps $\mathcal{Z}$ and $\mathcal{I}$ in Section 1.] Give examples (over a field k that is not algebraically closed) where $\mathcal{Z}$ is not injective and $\mathcal{I}$ is not surjective.

10. Prove that for k a finite field the Zariski topology is the same as the discrete topology: every subset is closed (and open).

11. Let V be a variety in $\mathbb{A}^n$ and let U_1 and U_2 be two subsets of $\mathbb{A}^n$ that are open in the Zariski topology. Prove that if $V \cap U_1 \neq \emptyset$ and $V \cap U_2 \neq \emptyset$ then $V \cap U_1 \cap U_2 \neq \emptyset$. Conclude that any nonempty open subset of a variety is everywhere dense in the Zariski topology (i.e., its closure is all of V).

12. Use the fact that nonempty open sets of an affine variety are everywhere dense to prove that an affine variety is connected in the Zariski topology. (A topological space is connected if it is not the union of two disjoint, proper, open subsets.)

13. Let V be a nonempty affine algebraic set. Prove that if $k[V]$ is a direct sum of two nonzero ideals, then V is not connected in the Zariski topology, and prove the converse when k is algebraically closed. [Use the weak form of Hilbert's Nullstellensatz.] Give a counterexample to the converse over a field k that is not algebraically closed.

14. Prove that if k is an infinite field, then the varieties in $\mathbb{A}^1$ are the whole space and the one point subsets. What are the varieties in $\mathbb{A}^1$ in the case of a finite field k?

15. Suppose V is a hypersurface in $\mathbb{A}^n$ and $\mathcal{I}(V) = (f)$ for some nonconstant polynomial $f \in k[x_1, x_2, \ldots, x_n]$. Prove that V is a variety if and only if f is irreducible.

16. Suppose $V \subseteq \mathbb{A}^n$ is an affine variety and $f \in k[V]$. Prove that the graph of f (cf. Exercise 25 in Section 1) is an affine variety.

17. Prove that any permutation of the elements of a field k is a continuous map from $\mathbb{A}^1$ to itself in the Zariski topology on $\mathbb{A}^1$. Deduce that if k is an infinite field, there are Zariski continuous maps from $\mathbb{A}^1$ to itself that are not polynomials.

18. Let V be an affine algebraic set in $\mathbb{A}^n$ over $k = \mathbb{C}$.

    (a) Prove that morphisms of algebraic sets over $\mathbb{C}$ are continuous in the Euclidean topology (the topology on $\mathbb{C}^n$ obtained by identifying $\mathbb{C}^n$ with $\mathbb{R}^{2n}$ with its usual Euclidean topology).

    (b) Prove that V is a closed set in the Euclidean topology on $\mathbb{C}^n$ (so the Zariski closed sets of $\mathbb{A}^n$ over $\mathbb{C}$ are also Euclidean closed).

    (c) Give an example of a set that is closed in the Euclidean topology but is not closed in the Zariski topology, i.e., is not an affine algebraic set (so the Euclidean topology is "finer" than the Zariski topology).

19. Give an example of an injective k-algebra homomorphism $\widetilde{\varphi} : k[W] \to k[V]$ whose associated morphism $\varphi : V \to W$ is not surjective.

20. Suppose $\varphi : V \to W$ is a surjective morphism of affine algebraic sets. Prove that if V is a variety then W is a variety.

21. Let V be an algebraic set in $\mathbb{A}^n$ and let $f \in k[V]$. Define $V_f = \{v \in V \mid f(v) \neq 0\}$.

    (a) Show that V_f is a Zariski open set in V (called a *principal open set* in V).

    (b) Let J be the ideal in $k[x_1, \ldots, x_n, x_{n+1}]$ generated by $\mathcal{I}(V)$ and $x_{n+1}f - 1$, and let $W = \mathcal{Z}(J) \subseteq \mathbb{A}^{n+1}$. Show that $J = \mathcal{I}(W)$ and that the map $\pi : \mathbb{A}^{n+1} \to \mathbb{A}^n$ by projection onto the first n coordinates is a Zariski continuous bijection from W onto V_f (so the principal open set V_f in V may be embedded as a closed set in some (larger) affine space).

    (c) If U is any open set in V show that $U = V_{f_1} \cup \cdots \cup V_{f_m}$ for some $f_1, \ldots, f_m \in k[V]$. (This shows that the principal open sets form a base for the Zariski topology.)

22. Prove that $\mathrm{GL}_n(k)$ is an open affine algebraic set in $\mathbb{A}^{n^2}$ and can be embedded as a closed affine algebraic set in $\mathbb{A}^{n^2+1}$. In particular, deduce that the set $k^\times$ of nonzero elements in $\mathbb{A}^1$ embeds into $\mathbb{A}^2$ as the hyperbola $xy = 1$. [Use the preceding exercise.]

23. Show that if k is infinite then $\{(a, a^2, a^3) \mid a \in k\} \subseteq \mathbb{A}^3$ is an affine algebraic variety. If k is finite show that this set is always reducible.

24. Let $V = \mathcal{Z}(xz - y^2, yz - x^3, z^2 - x^2y) \subseteq \mathbb{A}^3$. Show that if k is infinite then V is an affine variety. [Use Exercise 26 of Section 1 and Exercise 20.]

25. Suppose $f(x) = x^3 + ax^2 + bx + c$ is an irreducible cubic in $\mathbb{Q}[x]$ of discriminant D. Let $I = (x + y + z + a,\ xy + xz + yz - b,\ xyz + c)$ in $\mathbb{Q}[x, y, z]$.

    (a) Prove that I is a prime ideal if and only if D is not a square in $\mathbb{Q}$, in which case I is a maximal ideal and $\mathbb{Q}[x, y, z]/I$ is a splitting field for $f(x)$ over $\mathbb{Q}$.

    (b) If $D = r^2$, prove that the primary decomposition of I is $I = Q_+ \cap Q_-$ where $Q_\pm = (I,\ (x - y)(x - z)(y - z) \mp r)$. Prove Q_+ and Q_- are maximal ideals, and $\mathbb{Q}[x, y, z]$ modulo Q_+ or Q_- is a splitting field for $f(x)$ over $\mathbb{Q}$.

26. A topological space X is called *quasicompact* if whenever any collection of closed subsets V_i of X has empty intersection, then some finite number of these also has empty intersection, i.e.,

$$\text{whenever } \bigcap_i V_i = \emptyset \text{ there exists } V_{i_1}, V_{i_2}, \ldots, V_{i_N} \text{ such that } \bigcap_{j=1}^{N} V_{i_j} = \emptyset.$$

    Prove that every affine algebraic set is quasicompact. [Translate the definition into a property of ideals in $k[x_1, \ldots, x_n]$.] (A quasicompact and Hausdorff space is called *compact*.)

27. When k is an infinite field prove that the Zariski topology on k^2 is not the same as taking the Zariski topology on k and then forming the product topology on $k \times k$. [By Exercise 14 of Section 1, in the product topology on $k \times k$ the Zariski closed sets in $k \times k$ are finite unions of sets of the form $\{a\} \times \{b\}$, $\{a\} \times k$ and $k \times \{b\}$, for any $a, b \in k$.]

28. Prove that each of the following rings have infinitely many minimal prime ideals, and that (0) is not the intersection of any finite number of these (so (0) does not have a primary decomposition in these rings):

    (a) the infinite direct product ring $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \cdots$ (which is a Boolean ring, cf. Exercise 23 in Section 7.4).

    (b) $k[x_1, x_2, \ldots]/(x_1x_2, x_3x_4, \ldots, x_{2i-1}x_{2i}, \ldots)$, where $x_1, x_2, \ldots$ are independent variables over the field k.

29. Suppose that A and B are ideals with $AB \subseteq Q$ for a primary ideal Q. Prove that if $A \not\subseteq Q$ then $B \subseteq \operatorname{rad} Q$.

30. Let Q be a $\mathfrak{p}$-primary ideal and suppose A is an ideal not contained in Q. Define $A' = \{r \in R \mid rA \subseteq Q\}$ to be the elements of R that when multiplied by elements of A give elements of Q. Prove that A' is a $\mathfrak{p}$-primary ideal.

31. Prove that if Q_1 and Q_2 are primary ideals belonging to the same prime ideal $\mathfrak{p}$, then $Q_1 \cap Q_2$ is a primary ideal belonging to $\mathfrak{p}$. Conclude that a finite intersection of $\mathfrak{p}$-primary ideals is again $\mathfrak{p}$-primary.

32. Prove that if Q_1 and Q_2 are primary ideals belonging to the same maximal ideal $\mathfrak{m}$, then $Q_1 + Q_2$ and Q_1Q_2 are primary ideals belonging to $\mathfrak{m}$. Conclude that finite sums and finite products of $\mathfrak{m}$-primary ideals are again $\mathfrak{m}$-primary.

33. Let $I = (x^2, xy, xz, yz)$ in $k[x, y, z]$. Prove that a primary decomposition of I is $I = (x, y) \cap (x, z) \cap (x, y, z)^2$, determine the isolated and embedded primes of I, and find $\operatorname{rad} I$.

34. Suppose $\varphi : R \to S$ is a surjective ring homomorphism. Prove that an ideal Q in R containing the kernel of φ is primary if and only if $\varphi(Q)$ is primary in S, and when this is the case the prime associated to $\varphi(Q)$ is the image $\varphi(\mathfrak{p})$ of the prime $\mathfrak{p}$ associated to Q.

35. Suppose $\varphi : R \to S$ is a ring homomorphism.

    (a) Suppose I is an ideal of R containing $\ker \varphi$ with minimal primary decomposition $I = Q_1 \cap \cdots \cap Q_m$ with $\operatorname{rad} Q_i = \mathfrak{p}_i$. If φ is a surjective homomorphism prove that $\varphi(I) = \varphi(Q_1) \cap \cdots \cap \varphi(Q_m)$, where $\operatorname{rad} \varphi(Q_i)$ is given by $\varphi(\mathfrak{p}_i)$, is a minimal primary decomposition of $\varphi(I)$. [Use the previous exercise.]

    (b) Suppose I is an ideal of S with minimal primary decomposition $I = Q_1 \cap \cdots \cap Q_m$ with $\operatorname{rad} Q_i = \mathfrak{p}_i$. Prove that $\varphi^{-1}(I) = \varphi^{-1}(Q_1) \cap \cdots \cap \varphi^{-1}(Q_m)$, where $\operatorname{rad} \varphi^{-1}(Q_i)$ is given by $\varphi^{-1}(\mathfrak{p}_i)$, is a primary decomposition of $\varphi^{-1}(I)$, and is minimal if φ is surjective.

36. Let $I = (xy, x - yz)$ in $k[x, y, z]$. Prove that $(x, z) \cap (y^2, x - yz)$ is a minimal primary decomposition of I. [Consider the ring homomorphism $\varphi : k[x, y, z] \to k[y, z]$ given by mapping x to yz, y to y, and z to z and use the previous exercise.]

37. Prove that a prime ideal $\mathfrak{p}$ contains the ideal I if and only if $\mathfrak{p}$ contains one of the associated primes of a minimal primary decomposition of I. [Use Exercise 3 and Exercise 11 in Section 7.4.]

38. Show that every associated prime ideal for a radical ideal is isolated. [Suppose that $\mathfrak{p}_2 = \operatorname{rad} Q_2 \subseteq \mathfrak{p}_1 = \operatorname{rad} Q_1$ in the decomposition of Theorem 21 for the radical ideal I. Show that if $a \in Q_2 \cap \cdots \cap Q_m$ $(\subseteq \mathfrak{p}_2 \subseteq \mathfrak{p}_1)$ then $a^n \in I$ for some $n \geq 1$, conclude that $a \in Q_1$ and derive a contradiction to the minimality of the primary decomposition.]

39. Fix an element a in the ring R. For any ideal I in the ring R let $I_a = \{r \in R \mid ar \in I\}$.

    (a) Prove that I_a is an ideal and $I_a = R$ if and only if $a \in I$.

    (b) Prove that $(I \cap J)_a = I_a \cap J_a$ for ideals I and J.

    (c) Suppose that Q is a $\mathfrak{p}$-primary ideal and that $a \notin Q$. Prove that Q_a is a $\mathfrak{p}$-primary ideal and that $Q_a = Q$ if $a \notin \mathfrak{p}$.

40. With notation as in the previous exercise, suppose $I = Q_1 \cap \cdots \cap Q_m$ is a minimal primary decomposition of the ideal I and let $\mathfrak{p}_i$ be the prime ideal associated to Q_i.

    (a) Prove that $I_a = (Q_1)_a \cap \cdots \cap (Q_m)_a$ and that $\operatorname{rad}(I_a) = \operatorname{rad}((Q_1)_a) \cap \cdots \cap \operatorname{rad}((Q_m)_a)$.

(b) Prove that $\text{rad}(I_a)$ is the intersection of the prime ideals $\mathfrak{p}_i$ for which $a \notin Q_i$. [Use the previous exercise.]

(c) Prove that if $\text{rad}(I_a)$ is a prime ideal then $\text{rad}(I_a) = \mathfrak{p}_j$ for some j. [Use the fact that prime ideals are irreducible.]

(d) For each $i = 1, \ldots, m$, prove that $\text{rad}(I_a) = \mathfrak{p}_i$ for some $a \in R$. [Show there exists an $a \in R$ with $a \notin Q_i$ but $a \in Q_j$ for all $j \neq i$.]

(e) Show from (c) and (d) that the associated primes for a minimal primary decomposition are precisely the collection of prime ideals among the ideals $\text{rad}(I_a)$ for $a \in R$, and conclude that they are uniquely determined by I independent of the minimal primary decomposition.

41. Let $\mathfrak{p}_1, \ldots, \mathfrak{p}_m$ be the associated prime ideals of the ideal (0) in the Noetherian ring R.

(a) Show that $\mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_m$ is the collection of nilpotent elements in R. [Apply Corollary 22 to $I = (0)$.]

(b) Show that $\mathfrak{p}_1 \cup \cdots \cup \mathfrak{p}_m$ is the collection of zero divisors in R. [Let $I = (0)$ in the previous exercise and show that the set of zero divisors is given by the set $\bigcup_{a \in R-\{0\}} (0)_a = \bigcup_{a \in R-\{0\}} \text{rad}((0)_a)$.]

42. Suppose R is a Noetherian ring. Prove that R is either an integral domain, has nonzero nilpotent elements, or has at least two minimal prime ideals. [Use the previous exercise.]

43. Prove that the ideal I in the Noetherian ring R is radical if and only if the primary components of a minimal primary decomposition are all prime ideals, and conclude that in this case the minimal primary decomposition is unique. [If $I = Q_1 \cap \cdots \cap Q_m$ is radical with Q_i a $\mathfrak{p}_i$-primary component of a minimal decomposition, show that if $a \in \mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_m$ then some power of a is in I, hence $a \in I$ since I is radical. Deduce that $I = \mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_m$ and show that this is also a minimal primary decomposition, i.e., for any i there exists b with $b \notin \mathfrak{p}_i$, but $b \in \mathfrak{p}_j$ for $j \neq i$. If $a \in \mathfrak{p}_i$, show that $ab \in Q_i$, and that $a \in Q_i$. Conclude that $Q_i = \mathfrak{p}_i$.]

44. Prove that a Noetherian integral domain R is a U.F.D. if and only if for every $a \in R$ the isolated primes associated to the principal ideal (a) are principal ideals. [See Example 2 following Corollary 22. To prove R is a U.F.D., show that an irreducible $a \in R$ is prime and then follow the proof of Theorem 14 in Section 8.3.]

45. Let R be the ring of all real valued functions on the open interval $(-1, 1)$ that have derivatives of all orders (the ring of C^∞ functions). Let

$$F(x) = \begin{cases} e^{-1/x^4} & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$

(you may assume $F \in R$ and $F^{(n)}(0) = 0$ for all $n \geq 0$). Let (F) be the principal ideal generated by F and let $A = \text{rad}((F))$. Let $\mathfrak{m}$ be the (maximal) ideal of all functions in R that are zero at $x = 0$ and let $\mathfrak{p} = \bigcap_{n \geq 1} \mathfrak{m}^n$.

(a) Prove that $\mathfrak{m} = (x)$ is the ideal generated by the function x in R and that $\mathfrak{m}^n = (x^n)$ consists of the functions f with $f(0) = f'(0) = \cdots = f^{(n-1)}(0) = 0$.

(b) Prove that R is not Noetherian (compare Exercise 33 in Section 7.4). [One approach is the following: Let $G(x)$ be the function that is 0 for $x < 0$ and is equal to $F(x)$ for $x \geq 0$. Let I_n be the ideal of functions in R vanishing for all $x \leq 1/n$. Use translates of $G(x)$ to show that $I_1 \subset I_2 \subset I_3 \subset \cdots$ is an infinite ascending chain.]

(c) Prove that $\mathfrak{p}$ consists of the functions all of whose derivatives are zero at $x = 0$ (i.e., the functions whose associated Taylor series at $x = 0$ is identically zero), and that $\mathfrak{p}$ is a prime ideal.

(d) Prove that $F \in \mathfrak{p}$ and deduce that $A \subseteq \mathfrak{p}$.

(e) Prove that $A \neq \mathfrak{p}$. [Let $G(x) = e^{-1/x^2}$ when $x \neq 0$ and $G(0) = 0$. Show that $G \in \mathfrak{p}$ but $G \notin A$.]

(f) Show that there is a prime ideal $\mathfrak{q}$ containing (F) with $\mathfrak{q} \neq \mathfrak{p}, \mathfrak{m}$. Prove that $\mathfrak{q} \subset \mathfrak{p}$, i.e., there are nonzero prime ideals properly contained in $\mathfrak{p}$.

46. Let A be any ideal in $R = k[x_1, \ldots, x_n, y_1, \ldots, y_m]$.

    (a) Show that $\operatorname{rad}(A \cap k[y_1, \ldots, y_m]) = \operatorname{rad} A \cap k[y_1, \ldots, y_m]$.

    (b) Suppose $(f_1, \ldots, f_s)$ is an ideal in $k[x_1, \ldots, x_n]$. Let $F_1, \ldots, F_t$ be generators for the radical of $(f_1, \ldots, f_s)$, computed in $k[x_1, \ldots, x_n]$. Suppose J is an ideal in R and let $A = J + (f_1, \ldots, f_s)$, $B = J + (F_1, \ldots, F_t)$ as ideals in R. Prove that $\operatorname{rad} A = \operatorname{rad} B$.

    (c) Conclude from (a) and (b) that $A = (y_1 - x_1, \ldots, y_m - x_m, f_1, \ldots, f_s) \cap k[y_1, \ldots, y_m]$ and $B = (y_1 - x_1, \ldots, y_m - x_m, F_1, \ldots, F_t) \cap k[y_1, \ldots, y_m]$ have the same zero sets over an algebraically closed field k. [Use Hilbert's Nullstellensatz.]

47. Determine the Zariski closure in $\mathbb{C}^3$ of the points on the curve $\{(a^2, a^3, a^4) \mid a \in \mathbb{C}\}$.

48. Show that $\mathcal{Z}(x^3 - xyz + z^2)$ is the smallest algebraic set in $\mathbb{R}^3$ containing the points $\{(st, s+t, s^2t) \mid s, t \in \mathbb{R}\}$.

49. Show that $\mathcal{Z}(x^3z^2 - 3xy^2z^2 - y^6 - z^4)$ is the smallest algebraic set in $\mathbb{R}^3$ containing the points $\{(s^2+t^2, st, s^3) \mid s, t \in \mathbb{R}\}$.

50. Find equations defining the Zariski closure of the set of points $\{(s^4, s^3t, st^3, t^4) \mid s, t \in \mathbb{R}\}$.

51. Show that $V = \mathcal{Z}(x^2 - y^2z)$ (the *Whitney umbrella* surface) is the smallest algebraic set in $\mathbb{R}^3$ containing the points $S = \{(st, s, t^2) \mid s, t \in \mathbb{R}\}$. Show that S is not Zariski closed in V (the missing points explain the name for the surface). Do the same over $\mathbb{C}$, but show that in this case $S = V$ is closed.

52. Let $V = \mathcal{Z}(xz^2 - w^3,\ xw^2 - y^4,\ y^4z^2 - w^5) \subseteq \mathbb{C}^4$. Determine the Zariski closure of the image of V under the projection $\pi((x, y, z, w)) = (x, y, z)$.

53. Let $V = \mathcal{Z}(xy - 1)$ in $\mathbb{A}^2$ and let S be the projection of V onto the x-axis in $\mathbb{A}^1$.

    (a) If $k = \mathbb{R}$, show that $\mathcal{I}(V) = (xy - 1) \subseteq \mathbb{R}[x, y]$ and that $(u - x, xy - 1) \cap \mathbb{R}[u] = 0$ in $\mathbb{R}[x, y, u]$. Use Propositions 8 and 16 to conclude that the Zariski closure of S is $\mathbb{A}^1$ and show that S is not itself closed.

    (b) If $k = \mathbb{F}_3$, show that $\mathcal{I}(V) = (xy - 1, x^3 - x, y^3 - y) \subseteq \mathbb{F}_3[x, y]$ and that $(u - x, xy - 1, x^3 - x, y^3 - y) \cap \mathbb{F}_3[u] = (u^2 - 1)$ in $\mathbb{F}_3[x, y, u]$. Use Propositions 8 and 16 to conclude that S is Zariski closed in $\mathbb{A}^1$.

54. Recall the ideal quotient $(I : J) = \{r \in R \mid rJ \subseteq I\}$ of two ideals I, J in a ring R (cf. Exercise 34 ff. in Section 9.6). Clearly $I \subseteq (I : J)$.

    (a) Show that $\mathcal{Z}(I) - \mathcal{Z}(J)$, the set of elements of $\mathcal{Z}(I)$ not lying in $\mathcal{Z}(J)$, is contained in $\mathcal{Z}((I : J))$ and conclude that the Zariski closure of $\mathcal{Z}(I) - \mathcal{Z}(J)$ is contained in $\mathcal{Z}((I : J))$.

    (b) Show that if k is algebraically closed and I is a radical ideal then $\mathcal{Z}((I : J))$ is precisely the Zariski closure of $\mathcal{Z}(I) - \mathcal{Z}(J)$.

    (c) Show that if V and W are affine algebraic sets then $(\mathcal{I}(V) : \mathcal{I}(W)) = \mathcal{I}(V - W)$.

Practice problems.

1. Compute $\operatorname{rad} \mathfrak{a}$ in $\mathbb{Z}$ for $\mathfrak{a} = (2^3 \cdot 5^4 \cdot 7)$ and for $\mathfrak{a} = (0)$, expressing each as a principal ideal, and list the primes of $\mathbb{Z}$ containing $\mathfrak{a}$ in the first case. Verify directly that $\operatorname{rad} \mathfrak{a} = \bigcap_{\mathfrak{p} \supseteq \mathfrak{a}} \mathfrak{p}$ in the first case.

2. In $R = \mathbb{Z}/72\mathbb{Z}$ determine $\operatorname{nil}(R)$ explicitly as a set, write it as an intersection of the prime ideals of R, and decide whether R is reduced. State the least integer k with $\operatorname{nil}(R)^k = 0$.

3. In $k[x, y]$ show that $\mathfrak{a} = (x^2y,\ xy^3)$ has $\operatorname{rad} \mathfrak{a} = (xy)$, and exhibit the minimal primes over $\mathfrak{a}$. Confirm that $V(\mathfrak{a}) = V(xy)$ is the union of the two coordinate axes, and that $\mathfrak{a}$ itself is not radical.

4. Over $\mathbb{C}$, decompose $V(x^2 - yz,\ xy - z^2) \subseteq \mathbb{A}^3$ into irreducible components by computing the radical of the ideal as an intersection of primes, and give the dimension of each component.

5. Let $A = \{\, (t, t^2, t^3) : t \in \mathbb{C} \,\} \subseteq \mathbb{A}^3$ (the twisted cubic). Show that $I(A) = (y - x^2,\ z - x^3)$, that this ideal is prime, and conclude that the Zariski closure $\overline{A}$ is a variety; compute $\dim \overline{A}$ and identify $k(\overline{A})$.

6. Over $\mathbb{R}$, give an ideal $\mathfrak{a} \subseteq \mathbb{R}[x,y]$ that is radical (indeed prime) yet has $V(\mathfrak{a}) = \varnothing$, and an ideal $\mathfrak{b}$ that is radical with $V(\mathfrak{b})$ a single point but $I(V(\mathfrak{b})) \supsetneq \mathfrak{b}$. Explain in each case which hypothesis of the Nullstellensatz fails.

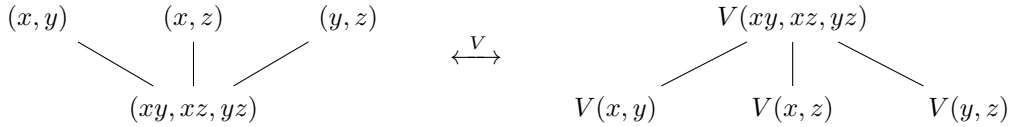
7. In $R = k[x,y]/(xy)$ with k a field, prove that R is reduced but not a domain, identify $\operatorname{nil}(R)$, and list the minimal prime ideals of R. Relate the count of minimal primes to the number of irreducible components of $V(xy)$.

8. Over $\mathbb{C}$ decide whether $g = x^3y^2$ vanishes on $V(\mathfrak{a})$ for $\mathfrak{a} = (x^4,\, x^2y)$ by computing $\operatorname{rad}\mathfrak{a}$, and write down $I(V(\mathfrak{a}))$ as a principal ideal.

Additional exercises.

1. Let $\mathfrak{a}, \mathfrak{b}$ be ideals of a commutative ring R. Prove $\operatorname{rad}(\mathfrak{a}\mathfrak{b}) = \operatorname{rad}(\mathfrak{a} \cap \mathfrak{b}) = \operatorname{rad}\mathfrak{a} \cap \operatorname{rad}\mathfrak{b}$, and prove $\operatorname{rad}(\mathfrak{a} + \mathfrak{b}) = \operatorname{rad}(\operatorname{rad}\mathfrak{a} + \operatorname{rad}\mathfrak{b})$. Give an example in $k[x,y]$ where $\operatorname{rad}\mathfrak{a} + \operatorname{rad}\mathfrak{b} \subsetneq \operatorname{rad}(\mathfrak{a} + \mathfrak{b})$.

2. Let R be a commutative ring. Prove that an element $u \in R$ is a unit if and only if its image is a unit in the reduced ring $R/\operatorname{nil}(R)$. Deduce that R is local if and only if $R/\operatorname{nil}(R)$ is local, and that the two rings have the same maximal ideals under the correspondence of the Lattice Isomorphism Theorem.



3. Let $V \subseteq \mathbb{A}^n$ be an affine variety over an algebraically closed field E and let $f, g \in E[V]$. Prove that $V_f \cap V_g \neq \varnothing$ whenever $f \neq 0$ and $g \neq 0$, where $V_h = \{\, P \in V : h(P) \neq 0 \,\}$, and conclude that $E[V]$ is an integral domain. (Use that nonempty opens are dense in an irreducible space.)

4. Let E be algebraically closed and $\mathfrak{a}$ a proper ideal of $E[x_1,\dots,x_n]$. Prove that $V(\mathfrak{a})$ is a finite set if and only if $E[x_1,\dots,x_n]/\operatorname{rad}\mathfrak{a}$ is a finite-dimensional E-vector space, and that in that case $|V(\mathfrak{a})| = \dim_E\big(E[x_1,\dots,x_n]/I(V(\mathfrak{a}))\big)$.

5. Let R be a commutative ring. Prove that R is reduced and has exactly one minimal prime ideal if and only if R is an integral domain. Then give, for each $m \geq 1$, a reduced ring with exactly m minimal primes, and identify its minimal primes geometrically as the components of an algebraic set.

Commutative-diagram exercises.

1. Over $\mathbb{C}$, let $\mathfrak{a} = (xy,\, xz,\, yz) \subseteq \mathbb{C}[x,y,z]$, whose zero set is the union of the three coordinate axes. Complete the lattice of minimal primes over $\mathfrak{a}$ and the matching diagram of irreducible components (ordered by inclusion), and prove the labelled correspondence is the order-reversing bijection of the Nullstellensatz:

   Identify each $V(\mathfrak{p}_i)$ as one of the coordinate axes, verify $\mathfrak{a} = \operatorname{rad}\mathfrak{a} = (x,y) \cap (x,z) \cap (y,z)$, and state the dimension of each component.

2. Let E be algebraically closed and $\varphi : E[y_1,\dots,y_m] \to E[x_1,\dots,x_n]$ an E-algebra homomorphism, inducing the polynomial map $\varphi^* : \mathbb{A}^n \to \mathbb{A}^m$ on points. Prove the square below commutes (top is $\mathfrak{b} \mapsto V(\mathfrak{b})$ in $\mathbb{A}^m$, bottom is $\mathfrak{a} \mapsto V(\mathfrak{a})$ in $\mathbb{A}^n$, left is extension $\mathfrak{b} \mapsto \varphi(\mathfrak{b})E[x]$, right is preimage under φ^*), and deduce that $\overline{\varphi^*(\mathbb{A}^n)} = V(\ker\varphi)$:

$$\begin{array}{ccc} \{\,\text{ideals of } E[y]\,\} & \xrightarrow{\;V\;} & \{\,\text{closed sets of } \mathbb{A}^m\,\} \\ {\scriptstyle \mathfrak{b}\mapsto\varphi(\mathfrak{b})E[x]}\downarrow & & \downarrow{\scriptstyle (\varphi^*)^{-1}} \\ \{\,\text{ideals of } E[x]\,\} & \xrightarrow[\;V\;]{} & \{\,\text{closed sets of } \mathbb{A}^n\,\} \end{array}$$

   Conclude that a polynomial map has Zariski-dense image exactly when the comorphism φ is injective.

3. Over an algebraically closed field E, let $\mathfrak{a} \subseteq \mathfrak{b}$ be radical ideals of $E[x_1,\dots,x_n]$, so $W = V(\mathfrak{b}) \subseteq V(\mathfrak{a}) = V$ is a closed algebraic subset. Writing $E[V] = E[x]/\mathfrak{a}$, complete the diagram relating coordinate rings to ideals

and prove every arrow is the natural one and the square is a pushout of rings, $E[W] \cong E[V] \otimes_{E[x]} E[x]/\mathfrak{b}$ (it is not a pullback unless $\mathfrak{a} = 0$):

$$\begin{array}{ccc} E[x] & \twoheadrightarrow & E[V] \\ \downarrow & & \downarrow \\ E[x]/\mathfrak{b} & = & E[W] \end{array}$$

Identify the kernel of $E[V] \twoheadrightarrow E[W]$ as $\mathfrak{b}/\mathfrak{a}$, prove it is a radical ideal of $E[V]$, and state the resulting inclusion-reversing bijection between closed algebraic subsets of V and radical ideals of $E[V]$ (under which the closed subvarieties correspond to the prime ideals).

4. Over $\mathbb{C}$, let $\mathfrak{a} = (x^2 - y) \subseteq \mathbb{C}[x, y]$ and let $\mathfrak{m}_P = (x - a,\, y - a^2)$ for a point $P = (a, a^2) \in V(\mathfrak{a})$. Complete the diagram exhibiting the quotient $\mathbb{C}[x, y] \to \mathbb{C}[V(\mathfrak{a})] \to \mathbb{C}[V(\mathfrak{a})]/(\mathfrak{m}_P/\mathfrak{a}) \cong \mathbb{C}$ and prove the composite is evaluation at P:

$$\begin{array}{ccc} \mathbb{C}[x,y] & \xrightarrow{\pi} & \mathbb{C}[V(\mathfrak{a})] \\ & \searrow^{\mathrm{ev}_P} & \downarrow{\scriptstyle \overline{\mathrm{ev}_P}} \\ & & \mathbb{C} \end{array}$$

Verify $\ker(\mathrm{ev}_P) = \mathfrak{m}_P$, that $\mathfrak{m}_P \supseteq \mathfrak{a}$, and that the maximal ideals of $\mathbb{C}[V(\mathfrak{a})]$ are exactly the $\mathfrak{m}_P/\mathfrak{a}$ for $P \in V(\mathfrak{a})$, so they biject with the points of the parabola.

15.4 Modules, Tensor Products, and Nakayama's Lemma

Modules: the common generalization

Atiyah and Macdonald open their chapter on modules with a slogan worth keeping in front of us: working with modules rather than just ideals gives extra "elbow-room", and with it greater clarity and simplicity. A vector space is a module over a field; an abelian group is a module over $\mathbb{Z}$; an ideal of a ring A is a module over A; the ring A itself is a module over A. The single notion of module unifies all of these, and – crucially for the geometric program – it is the right home for the functorial operations (quotient, localization, tensor, completion) that we will use to "concentrate near a point".

Definition 15.4.1 (A-module)**.** Let A be a commutative ring with 1. An *A-module* is an abelian group $(M, +)$ together with a scalar multiplication $A \times M \to M$, $(a, x) \mapsto ax$, satisfying for all $a, b \in A$ and $x, y \in M$:

$$a(x + y) = ax + ay, \quad (a + b)x = ax + bx, \quad (ab)x = a(bx), \quad 1x = x.$$

Equivalently, giving an A-module structure on the abelian group M is the same as giving a ring homomorphism $A \to \mathrm{End}(M)$ into the (in general noncommutative) ring $\mathrm{End}(M)$ of abelian-group endomorphisms of M: the image of a is the map $x \mapsto ax$.

Remark 15.4.1. The endomorphism-ring viewpoint is the conceptual core. A module is a ring acting on an abelian group; a representation of A. When $A = k[G]$ is the group ring of a finite group G over a field k, an A-module is exactly a k-linear representation of G – so representation theory is a chapter of module theory. When $A = k[x]$, an A-module is a k-vector space equipped with a single distinguished endomorphism (the action of x); the structure theory of such modules is the theory of rational/Jordan canonical forms in D&F Chapter 12.

Definition 15.4.2 (submodule, quotient, homomorphism)**.** A *submodule* $M' \subseteq M$ is a subgroup closed under the A-action; the quotient group M/M' then inherits an A-action $a(x + M') = ax + M'$ and is the *quotient module*. An *A-module homomorphism* (or A-linear map) $f : M \to N$ is an additive map with $f(ax) = a\, f(x)$ for all $a \in A$, $x \in M$. Its *kernel* $\ker f = \{\, x : f(x) = 0 \,\}$ is a submodule of M, its *image* $\mathrm{im}\, f = f(M)$ a submodule of N, and its *cokernel* $\mathrm{coker}\, f = N/\mathrm{im}\, f$ a quotient of N. The set $\mathrm{Hom}_A(M, N)$ of all A-linear maps is itself an A-module under $(f + g)(x) = f(x) + g(x)$ and $(af)(x) = a\, f(x)$.

The isomorphism theorems hold verbatim, as for groups and rings. The first is the workhorse: any A-linear $f : M \to N$ factors as $M \twoheadrightarrow M/\ker f \xrightarrow{\cong} \operatorname{im} f \hookrightarrow N$, so $M/\ker f \cong \operatorname{im} f$. There is a natural, much-used identification

$$\operatorname{Hom}_A(A, M) \;\cong\; M, \qquad f \longmapsto f(1),$$

because an A-linear map out of A is pinned down by where it sends 1.

Method (Building and recognizing modules)**.** To produce an A-module: take an abelian group on which A acts, or a quotient/submodule/Hom/direct sum of known modules. To recognize the action concretely, find the ring homomorphism $A \to \operatorname{End}(M)$. To verify a subset is a submodule, check it is a nonempty subgroup stable under multiplication by every $a \in A$ (it suffices to test the scalars in a ring-generating set of A, since stability propagates through sums and products of scalars; testing only the module generators is *not* enough – stability is required for all scalars).

Worked Example 15.4.3 (Ideals and quotients as modules)**.** Show that an ideal $\mathfrak{a} \subseteq A$ and the quotient $A/\mathfrak{a}$ are A-modules, and identify $\operatorname{Hom}_A(A/\mathfrak{a}, M)$.

Recognition. An ideal is exactly an additive subgroup stable under multiplication by all of A – precisely a submodule of A. The quotient module $A/\mathfrak{a}$ then carries the induced action.

Solution. $\mathfrak{a}$ is a subgroup of $(A, +)$ and $a \cdot x \in \mathfrak{a}$ for $a \in A$, $x \in \mathfrak{a}$ by the ideal axiom, so $\mathfrak{a}$ is a submodule of the A-module A. Hence $A/\mathfrak{a}$ is a quotient module; its A-action is $a(b + \mathfrak{a}) = ab + \mathfrak{a}$. An A-linear map $f : A/\mathfrak{a} \to M$ is determined by $m := f(1 + \mathfrak{a})$, and is well defined iff $\mathfrak{a}$ annihilates m, i.e. $\mathfrak{a}m = 0$. Thus

$$\operatorname{Hom}_A(A/\mathfrak{a}, M) \;\cong\; \{\, m \in M : \mathfrak{a}m = 0 \,\} = (0 :_M \mathfrak{a}),$$

the submodule of M killed by $\mathfrak{a}$. Sanity check: with $\mathfrak{a} = 0$ this recovers $\operatorname{Hom}_A(A, M) \cong M$; with $A = \mathbb{Z}$, $\mathfrak{a} = n\mathbb{Z}$, $M = \mathbb{Z}/m\mathbb{Z}$ it gives the n-torsion of $\mathbb{Z}/m\mathbb{Z}$, of order $\gcd(n, m)$.

Worked Example 15.4.4 (The annihilator and faithful modules)**.** Define $\operatorname{Ann}(M)$ and show M is naturally a faithful module over $A/\operatorname{Ann}(M)$.

Recognition. The annihilator $\operatorname{Ann}(M) = \{\, a \in A : aM = 0 \,\}$ measures "how much of A acts trivially"; quotienting it out makes the action faithful.

Solution. $\operatorname{Ann}(M) = \{\, a \in A : ax = 0 \ \forall x \in M \,\}$ is an ideal: if a, b kill M so does $a - b$, and if a kills M then so does ca for any c. The action factors through $A/\operatorname{Ann}(M)$ because $a \in \operatorname{Ann}(M)$ acts as 0; the induced module is *faithful*, meaning $\operatorname{Ann}_{A/\operatorname{Ann}(M)}(M) = 0$, since by construction nothing outside $\operatorname{Ann}(M)$ kills all of M. Sanity check: for $M = \mathbb{Z}/n\mathbb{Z}$ over $A = \mathbb{Z}$ we get $\operatorname{Ann}(M) = n\mathbb{Z}$ and M is faithful over $\mathbb{Z}/n\mathbb{Z}$; for a finite-dimensional $k[x]$-module, $\operatorname{Ann}(M) = (m(x))$ is generated by the minimal polynomial.

Worked Example 15.4.5 (Hom functoriality)**.** For $u : M' \to M$ and $v : N \to N''$, describe the induced maps on Hom and their variance.

Recognition. $\operatorname{Hom}_A(-, N)$ is contravariant and $\operatorname{Hom}_A(M, -)$ is covariant; precomposition reverses arrows, postcomposition preserves them.

Solution. Given $u : M' \to M$, define $\bar{u} : \operatorname{Hom}_A(M, N) \to \operatorname{Hom}_A(M', N)$ by $\bar{u}(f) = f \circ u$ (contravariant). Given $v : N \to N''$, define $\bar{v} : \operatorname{Hom}_A(M, N) \to \operatorname{Hom}_A(M, N'')$ by $\bar{v}(f) = v \circ f$ (covariant). Both are A-linear. Sanity check: identities go to identities and $\overline{u_1 u_2} = \bar{u}_2 \bar{u}_1$ (order reversed) while $\overline{v_1 v_2} = \bar{v}_1 \bar{v}_2$ (order preserved), the signature of contra- vs. covariance.

Exact sequences, the five lemma, and the snake lemma

A sequence of A-modules and homomorphisms $\cdots \to M_{i-1} \xrightarrow{f_{i-1}} M_i \xrightarrow{f_i} M_{i+1} \to \cdots$ is *exact at* M_i if $\operatorname{im} f_{i-1} = \ker f_i$, and *exact* if exact everywhere. The atomic cases:

$$0 \to M' \xrightarrow{f} M \text{ exact} \iff f \text{ injective}, \qquad M \xrightarrow{g} M'' \to 0 \text{ exact} \iff g \text{ surjective},$$

and a *short exact sequence*

$$0 \to M' \xrightarrow{f} M \xrightarrow{g} M'' \to 0$$

is exact iff f is injective, g is surjective, and g induces an isomorphism $\operatorname{coker} f = M/f(M') \cong M''$. Every long exact sequence splices together from short ones.

Proposition 15.4.6 (left-exactness of Hom)**.** *Let $M' \xrightarrow{u} M \xrightarrow{v} M'' \to 0$ be a sequence of A-modules. It is exact iff for every A-module N the sequence*

$$0 \to \mathrm{Hom}_A(M'', N) \xrightarrow{\bar{v}} \mathrm{Hom}_A(M, N) \xrightarrow{\bar{u}} \mathrm{Hom}_A(M', N)$$

is exact. Dually, $0 \to N' \xrightarrow{u} N \xrightarrow{v} N''$ is exact iff $0 \to \mathrm{Hom}_A(M, N') \to \mathrm{Hom}_A(M, N) \to \mathrm{Hom}_A(M, N'')$ is exact for all M.

Idea. These are pure diagram chases. For the first: a map $M'' \to N$ pulls back along v to a map $M \to N$ killing $\operatorname{im} u = \ker v$, and conversely a map $M \to N$ that kills $\ker v$ descends through the surjection v. Injectivity of $\bar{v}$ is surjectivity of v; exactness in the middle is $\operatorname{im} u = \ker v$. Note the right end is *not* surjective in general: not every $M' \to N$ extends. So Hom is only *left*-exact – the failure of right-exactness is measured by the Ext functors. □

Proposition 15.4.7 (snake lemma)**.** *Given a commutative diagram with exact rows*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & M' & \xhookrightarrow{u} & M & \xrightarrow{v} & M'' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f''} & & \\ 0 & \longrightarrow & N' & \xhookrightarrow{u'} & N & \xrightarrow{v'} & N'' & \longrightarrow & 0 \end{array}$$

Diagram explanation. Objects: Six A-modules arranged in two horizontal short exact sequences. Top row: 0, M', M, M'', 0. Bottom row: 0, N', N, N'', 0. Three vertical maps connect the rows: $f' : M' \to N'$, $f : M \to N$, $f'' : M'' \to N''$.

Arrows: Horizontal arrows $u : M' \hookrightarrow M$ and $v : M \twoheadrightarrow M''$ form the top short exact sequence; $u' : N' \hookrightarrow N$ and $v' : N \twoheadrightarrow N''$ form the bottom one. The vertical maps f', f, f'' are A-module homomorphisms (not assumed injective or surjective); they carry information about how the two sequences relate.

What commutes: The left square commutes: $f \circ u = u' \circ f'$, i.e. mapping M' to M then down equals mapping M' down then to N. The right square commutes: $f'' \circ v = v' \circ f$, i.e. mapping M to M'' then down equals mapping M down then to N''.

Why it commutes: Chase a generic $m' \in M'$: along the top-left square, $u(m')$ maps to $f(u(m'))$; along the bottom-left square, $f'(m')$ maps to $u'(f'(m'))$; these agree by hypothesis (commutativity is given as data, not derived). The diagram is a *hypothesis* of the snake lemma, not a conclusion.

Why this matters here: This commutative diagram is the input to the snake lemma. The two paths through each square being equal is exactly the condition that lets the connecting homomorphism $\delta : \ker f'' \to \operatorname{coker} f'$ be built by the "lift, apply, pull back" procedure described in the proof. Without commutativity, the lift would be ambiguous and δ would not be well defined.

Concrete example: Take $A = \mathbb{Z}$, both rows equal $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n \to 0$, and $f' = f = f''$ each equal to multiplication by 2. The left square: $f(n \cdot m') = 2nm' = n \cdot (2m') = u'(f'(m'))$. The connecting map $\delta : \ker(2 : \mathbb{Z}/n \to \mathbb{Z}/n) \to \operatorname{coker}(2 : \mathbb{Z} \to \mathbb{Z}) = \mathbb{Z}/2$ records the 2-torsion of $\mathbb{Z}/n$.

Common pitfall: Students often think the vertical maps must be injections or surjections. They need not be; the snake lemma extracts exact information from ker and coker of arbitrary f', f, f'' as long as the squares commute and the rows are exact.

Takeaway: The point of this diagram is that commutativity of the two squares, together with exactness of the rows, is precisely the data needed to define the connecting homomorphism δ and produce the six-term exact sequence on kernels and cokernels.

there is a natural connecting homomorphism $\delta : \ker f'' \to \operatorname{coker} f'$ *fitting into an exact sequence*

$$0 \to \ker f' \to \ker f \to \ker f'' \xrightarrow{\delta} \operatorname{coker} f' \to \operatorname{coker} f \to \operatorname{coker} f'' \to 0.$$

Idea. Atiyah–Macdonald's Proposition 2.10 is exactly this for the truncated version (rows $0 \to M' \to M \to M'' \to 0$). The map δ is built by the only route the diagram allows: take $x'' \in \ker f''$; lift it to $x \in M$ via the surjection v; then $f(x)$ maps to $f''(x'') = 0$ in N'', so $f(x) = u'(y')$ for a unique $y' \in N'$; set $\delta(x'') = y' + \operatorname{im} f'$. "Well-defined and exact" is the canonical diagram chase. The snake is the engine behind every long exact sequence in homological algebra. □

Proposition 15.4.8 (five lemma)**.** *In a commutative diagram with exact rows*

$$\begin{array}{ccccccccc} M_1 & \longrightarrow & M_2 & \longrightarrow & M_3 & \longrightarrow & M_4 & \longrightarrow & M_5 \\ \downarrow{\scriptstyle f_1} & & \downarrow{\scriptstyle f_2} & & \downarrow{\scriptstyle f_3} & & \downarrow{\scriptstyle f_4} & & \downarrow{\scriptstyle f_5} \\ N_1 & \longrightarrow & N_2 & \longrightarrow & N_3 & \longrightarrow & N_4 & \longrightarrow & N_5 \end{array}$$

Diagram explanation. Objects: Ten A-modules, $M_1, \dots, M_5$ forming the top exact row and $N_1, \dots, N_5$ forming the bottom exact row. Five vertical maps $f_i : M_i \to N_i$ $(i = 1, \dots, 5)$ connect corresponding positions.

Arrows: The horizontal arrows (unlabelled in this diagram) form two five-term exact sequences. The vertical arrows f_i are A-module homomorphisms with given properties: f_1 surjective, f_5 injective, f_2 and f_4 isomorphisms. The arrow f_3 is the one whose isomorphism the lemma concludes.

What commutes: Every square commutes: for each i, the horizontal map $M_i \to M_{i+1}$ followed by f_{i+1} equals f_i followed by the horizontal map $N_i \to N_{i+1}$. Exactness means $\operatorname{im}(M_{i-1} \to M_i) = \ker(M_i \to M_{i+1})$ at each M_i, and likewise for the N-row.

Why it commutes: Commutativity of each square is given as hypothesis. The argument for f_3 being an isomorphism is a four-step diagram chase: surjectivity of f_1 and injectivity of f_2 and f_4 give injectivity of f_3 ("four-lemma"); surjectivity of f_2 and f_4 and injectivity of f_5 give surjectivity of f_3 (the other four-lemma). A generic element in $\ker f_3$ is chased left to show it must be zero; a generic element in the image is lifted from the N-row upward.

Why this matters here: The five lemma is the standard tool for proving that a map between two exact sequences is an isomorphism by bootstrapping from known isomorphisms at adjacent positions. In this chapter it is used again for completions, to show that the natural map $\widehat{R} \otimes_R M \to \widehat{M}$ is an isomorphism for a finitely generated module M over a Noetherian ring R (Proposition 15.9.13).

Concrete example: Take both rows to be $\mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2 \to 0 \to 0$ and $f_1 = f_2 = f_4 = f_5 = \mathrm{id}$, f_3 the induced map $\mathbb{Z}/2 \to \mathbb{Z}/2$. Then f_3 is an isomorphism (the identity), consistent with the lemma.

Common pitfall: The hypothesis on f_1 is *surjectivity*, not injectivity, and on f_5 is *injectivity*, not surjectivity. Swapping these weakens the conclusion. Also, the lemma applies to two exact sequences of the same length five, not to arbitrary diagrams; adding or removing terms changes what is provable.

Takeaway: The point of this diagram is that knowing the four outer vertical maps are (nearly) isomorphisms forces the middle vertical map to be an isomorphism, with the proof being a purely formal element chase using exactness and commutativity.

if f_1 is surjective, f_5 is injective, and f_2, f_4 are isomorphisms, then f_3 is an isomorphism.

Worked Example 15.4.9 (Splicing a long exact sequence into short ones)**.** Given an exact sequence $\cdots \to M_{i-1} \to M_i \to M_{i+1} \to \cdots$, exhibit the short exact sequences whose images are the $\operatorname{im} f_i$.

Recognition. Set $N_i = \operatorname{im} f_i = \ker f_{i+1}$; exactness says each map factors surjection-then-inclusion through these images.

Solution. Each $f_i : M_i \to M_{i+1}$ factors as $M_i \twoheadrightarrow N_i \hookrightarrow M_{i+1}$ with $N_i = \operatorname{im} f_i$. Exactness at M_i is $N_{i-1} = \ker f_i$, so

$$0 \to N_{i-1} \to M_i \to N_i \to 0$$

is short exact for every i. Sanity check: reading dim (over a field) gives $\dim M_i = \dim N_{i-1} + \dim N_i$, which telescopes to the alternating-sum relation used next.

Worked Example 15.4.10 (Additive functions on short exact sequences)**.** Let λ be a $\mathbb{Z}$-valued function on a class $\mathcal{C}$ of modules, additive on short exact sequences whose terms lie in $\mathcal{C}$. Prove $\sum_{i=0}^{n} (-1)^i \lambda(M_i) = 0$ for an exact sequence $0 \to M_0 \to \cdots \to M_n \to 0$ in which all the M_i and all the kernels of the maps lie in $\mathcal{C}$.

Recognition. Additivity means $\lambda(M) = \lambda(M') + \lambda(M'')$ for $0 \to M' \to M \to M'' \to 0$; this is the abstract Euler characteristic / dimension count.

Solution. Splice into short exact sequences $0 \to N_{i-1} \to M_i \to N_i \to 0$ with $N_{-1} = 0 = N_n$ (A&M Prop. 2.11). Additivity gives $\lambda(M_i) = \lambda(N_{i-1}) + \lambda(N_i)$. Form $\sum (-1)^i \lambda(M_i) = \sum (-1)^i \big(\lambda(N_{i-1}) + \lambda(N_i)\big)$; the

N-terms telescope and cancel because each N_i appears once with sign $(-1)^i$ and once with $(-1)^{i+1}$, leaving 0. Sanity check: for $0 \to M' \to M \to M'' \to 0$ this is just additivity; for finite-dimensional k-vector spaces $\lambda = \dim$ recovers rank–nullity $\dim M = \dim\ker + \dim\mathrm{im}$.

Worked Example 15.4.11 (The connecting map in a concrete snake)**.** Compute δ for multiplication by 2 on $0 \to \mathbb{Z} \to \mathbb{Z} \to \mathbb{Z}/2 \to 0$.

Recognition. The snake's $\delta : \ker f'' \to \operatorname{coker} f'$ is built by lift-apply-pull back; here all three vertical maps are multiplication by 2.

Solution. Apply the snake to the commutative diagram whose two identical rows are $0 \to \mathbb{Z} \xrightarrow{n} \mathbb{Z} \to \mathbb{Z}/n \to 0$ and whose three vertical maps are all $\times 2$. On the two copies of $\mathbb{Z}$ the map $\times 2$ is injective, so $\ker f' = \ker f = 0$, while $\ker f'' = (\mathbb{Z}/n)[2]$ is the 2-torsion of $\mathbb{Z}/n$; the cokernels are $\operatorname{coker} f' = \operatorname{coker} f = \mathbb{Z}/2$ and $\operatorname{coker} f'' = (\mathbb{Z}/n)/2(\mathbb{Z}/n)$. The snake sequence is therefore

$$0 \to 0 \to 0 \to (\mathbb{Z}/n)[2] \xrightarrow{\delta} \mathbb{Z}/2 \to \mathbb{Z}/2 \to (\mathbb{Z}/n)/2(\mathbb{Z}/n) \to 0.$$

Sanity check: with $n = 2$ the 2-torsion $(\mathbb{Z}/2)[2] = \mathbb{Z}/2$ maps isomorphically by δ onto $\operatorname{coker} f' = \mathbb{Z}/2$, since exactness at $\ker f''$ with $\ker f = 0$ forces δ injective, and a count of orders $(2 = 2)$ then makes it onto.

Direct sums, products, and finite generation

Definition 15.4.12 (direct sum and product)**.** For a family $(M_i)_{i\in I}$ of A-modules, the *direct product* $\prod_{i\in I} M_i$ is the set of all families (x_i) with the componentwise operations; the *direct sum* $\bigoplus_{i\in I} M_i$ is the submodule of families (x_i) with $x_i = 0$ for all but finitely many i. For finite I the two coincide. A *free* module is one isomorphic to $\bigoplus_{i\in I} A$, written $A^{(I)}$; the finite free modules are A^n.

A module M is *finitely generated* (f.g.) if there exist $x_1, \dots, x_n \in M$ with $M = Ax_1 + \cdots + Ax_n$, equivalently if there is a surjection $A^n \twoheadrightarrow M$, equivalently if $M \cong A^n/K$ for some submodule K and some n (A&M Prop. 2.3). Generation by n elements is captured by the surjection $A^n \twoheadrightarrow M$; if its kernel is also finitely generated (automatic when A is Noetherian), M has a finite presentation $A^m \to A^n \to M \to 0$.

Worked Example 15.4.13 (Hom and direct sums vs. products)**.** Establish $\operatorname{Hom}_A\big(\bigoplus_i M_i, N\big) \cong \prod_i \operatorname{Hom}_A(M_i, N)$ and $\operatorname{Hom}_A\big(N, \prod_i M_i\big) \cong \prod_i \operatorname{Hom}_A(N, M_i)$.

Recognition. A map out of a direct sum is a tuple of maps on the summands (universal property of $\oplus$); a map into a product is a tuple of maps to the factors (universal property of $\prod$).

Solution. For the first, restrict $f : \bigoplus M_i \to N$ to each summand to get $(f|_{M_i})_i$; conversely glue (f_i) by $f((x_i)) = \sum_i f_i(x_i)$ – a *finite* sum since $(x_i) \in \bigoplus$. These are mutually inverse A-isomorphisms. For the second, post-compose $g : N \to \prod M_i$ with the projections π_i to get $(\pi_i g)_i$; conversely assemble. Sanity check: with $M_i = A$ for $i \in I$ we get $\operatorname{Hom}_A(A^{(I)}, N) \cong N^I = \prod_I N$, the "dual of free is product" statement; for finite I both sides are $N^{|I|}$.

Worked Example 15.4.14 (Quotient of A by an ideal as a sum decomposition (CRT))**.** For coprime ideals show $A/(\mathfrak{a} \cap \mathfrak{b}) \cong A/\mathfrak{a} \oplus A/\mathfrak{b}$ as A-modules.

Recognition. When $\mathfrak{a} + \mathfrak{b} = A$ the Chinese Remainder map is an isomorphism; this is a module (indeed ring) decomposition.

Solution. The map $A \to A/\mathfrak{a} \oplus A/\mathfrak{b}$, $x \mapsto (x + \mathfrak{a}, x + \mathfrak{b})$, is A-linear with kernel $\mathfrak{a} \cap \mathfrak{b}$. Coprimality $\mathfrak{a} + \mathfrak{b} = A$ gives surjectivity (pick $e \in \mathfrak{a}$, $f \in \mathfrak{b}$ with $e + f = 1$; then $f \equiv 1,\ e \equiv 0 \pmod{\mathfrak{a}}$ and vice versa, so any target $(\bar{s}, \bar{t})$ is hit by $sf + te$). Hence $A/(\mathfrak{a} \cap \mathfrak{b}) \cong A/\mathfrak{a} \oplus A/\mathfrak{b}$, and $\mathfrak{a} \cap \mathfrak{b} = \mathfrak{ab}$ in this case. Sanity check: $A = \mathbb{Z}$, $\mathfrak{a} = 3\mathbb{Z}$, $\mathfrak{b} = 5\mathbb{Z}$ gives $\mathbb{Z}/15 \cong \mathbb{Z}/3 \oplus \mathbb{Z}/5$, the classical CRT, an isomorphism of $\mathbb{Z}$-modules of order 15.

Worked Example 15.4.15 (Free of rank determined: $A^m \cong A^n \Rightarrow m = n$)**.** Show that over a nonzero commutative ring, free modules have a well-defined rank.

Recognition. Pass to a residue field: tensoring (or quotienting) by a maximal ideal turns A^n into a vector space of dimension n, and dimension is an invariant.

Solution. Let $\mathfrak{m}$ be a maximal ideal of A, $k = A/\mathfrak{m}$. An isomorphism $A^m \cong A^n$ induces, after reducing mod $\mathfrak{m}$ (i.e. applying $A/\mathfrak{m} \otimes_A -$, see below), an isomorphism of k-vector spaces $k^m \cong k^n$. Hence $m = \dim_k k^m = \dim_k k^n = n$. Sanity check: the argument needs $A \neq 0$ so that a maximal ideal exists; over the zero ring $A^m = 0 = A^n$ for all m, n and rank is meaningless, consistent with the hypothesis.

Cayley–Hamilton and Nakayama's lemma

The determinant trick is the technical heart of the chapter and the source of Nakayama's lemma – a result used again and again in the rest of this chapter. It is the commutative-algebra incarnation of the Cayley–Hamilton theorem.

Proposition 15.4.16 (determinant trick, A&M 2.4)**.** *Let M be a finitely generated A-module, $\mathfrak{a} \subseteq A$ an ideal, and $\phi : M \to M$ an A-endomorphism with $\phi(M) \subseteq \mathfrak{a}M$. Then ϕ satisfies an equation*

$$\phi^n + a_1\phi^{n-1} + \cdots + a_n = 0 \qquad (a_i \in \mathfrak{a})$$

as an endomorphism of M.

Idea. Pick generators $x_1, \ldots, x_n$ of M. Since $\phi(x_i) \in \mathfrak{a}M$, write $\phi(x_i) = \sum_j a_{ij}x_j$ with $a_{ij} \in \mathfrak{a}$. Then $\sum_j (\delta_{ij}\phi - a_{ij})x_j = 0$, i.e. the matrix $\Phi = (\delta_{ij}\phi - a_{ij})$ over the commutative ring $A[\phi]$ kills the vector $(x_1, \ldots, x_n)$. Multiply by the adjugate: $\operatorname{adj}(\Phi)\Phi = \det(\Phi) \cdot I$, so $\det(\delta_{ij}\phi - a_{ij})$ annihilates every x_j, hence all of M. Expanding the determinant gives the monic equation with coefficients in $\mathfrak{a}$. This is literally Cayley–Hamilton with entries in $A[\phi]$. □

Corollary 15.4.17 (A&M 2.5)**.** *If M is f.g. and $\mathfrak{a}M = M$ for an ideal $\mathfrak{a}$, then there exists $x \equiv 1 \pmod{\mathfrak{a}}$ (i.e. $x = 1 + a$, $a \in \mathfrak{a}$) with $xM = 0$.*

Apply the trick with $\phi = \mathrm{id}$: then $\mathrm{id} + a_1 \mathrm{id} + \cdots + a_n = 0$ on M, so $x = 1 + a_1 + \cdots + a_n$ kills M and $x \equiv 1 \pmod{\mathfrak{a}}$.

Theorem 15.4.18 (Nakayama's lemma)**.** *Let M be a finitely generated A-module and $\mathfrak{a} \subseteq \operatorname{Jac}(A)$ an ideal contained in the Jacobson radical. If $\mathfrak{a}M = M$ then $M = 0$.*

Idea. By the corollary there is $x = 1 + a$ with $a \in \mathfrak{a} \subseteq \operatorname{Jac}(A)$ and $xM = 0$. But $\operatorname{Jac}(A)$ is characterized as $\{\, a : 1 + ab \in A^\times \ \forall b \,\}$, so $x = 1 + a$ is a unit. Multiplying $xM = 0$ by x^{-1} gives $M = 0$. The finite-generation hypothesis is essential (see the pitfall). □

Corollary 15.4.19 (local form, A&M 2.6–2.8)**.** *Let $(A, \mathfrak{m}, k)$ be a local ring with maximal ideal $\mathfrak{m}$ and residue field $k = A/\mathfrak{m}$, and let M be a finitely generated A-module. Then:*

(1) *If $N \subseteq M$ is a submodule with $N + \mathfrak{m}M = M$, then $N = M$.*

(2) *Elements $x_1, \ldots, x_n \in M$ generate M as an A-module* iff *their images $\bar{x}_1, \ldots, \bar{x}_n$ span the k-vector space $M/\mathfrak{m}M$. In particular the images of a minimal generating set form a basis of $M/\mathfrak{m}M$, so every minimal generating set has the same size $\dim_k M/\mathfrak{m}M$.*

Idea. (1) Apply Nakayama to M/N, which is f.g. with $\mathfrak{m}(M/N) = M/N$, forcing $M/N = 0$. (2) The $\bar{x}_i$ span $M/\mathfrak{m}M$ iff $\sum Ax_i + \mathfrak{m}M = M$ iff (by (1)) $\sum Ax_i = M$; and a spanning set of the vector space $M/\mathfrak{m}M$ is a basis iff it is minimal. The point: *over a local ring, counting minimal generators of a f.g. module is linear algebra over the residue field.* □

Caution. Nakayama fails without finite generation. Take $A = \mathbb{Z}_{(p)}$ (local, $\mathfrak{m} = p\mathbb{Z}_{(p)}$) and $M = \mathbb{Q}$. Then $\mathfrak{m}M = p\mathbb{Q} = \mathbb{Q} = M$ but $M \neq 0$. The determinant trick needs a *finite* generating set to form the matrix; $\mathbb{Q}$ is not finitely generated over $\mathbb{Z}_{(p)}$. Likewise the hypothesis $\mathfrak{a} \subseteq \operatorname{Jac}(A)$ cannot be dropped: $\mathfrak{a} = A$ trivially has $\mathfrak{a}M = M$ for every M.

Worked Example 15.4.20 (Cayley–Hamilton recovered)**.** Recover the classical Cayley–Hamilton theorem from A&M 2.4.

Recognition. Take $A =$ the base ring, $M = A^n$ free with the standard basis, $\mathfrak{a} = A$, and ϕ a given matrix; the trick produces the characteristic-polynomial equation.

Solution. Let $T \in \mathrm{M}_n(A)$ act on $M = A^n$. With $\mathfrak{a} = A$ and generators the standard basis, the matrix in the proof is $tI - T$ evaluated at $t = \phi = T$, and $\det(tI - T) = \chi_T(t)$ is the characteristic polynomial. The determinant trick gives $\chi_T(T) = 0$. Sanity check: for $n = 1$, $T = (a)$, $\chi_T(t) = t - a$ and $\chi_T(T) = T - aI = 0$; the general statement is exactly Cayley–Hamilton.

Worked Example 15.4.21 (Surjective endomorphism of a f.g. module is injective)**.** Show every surjective A-endomorphism ϕ of a finitely generated A-module M is an isomorphism.

Recognition. View M as a module over $B = A[t]$ with t acting as ϕ; surjectivity says $tM = M$ over the ideal (t), and a Nakayama-style argument applies.

Solution. Regard M as an $A[t]$-module via $t \cdot x = \phi(x)$; M is f.g. over $A[t]$ (already over A). Surjectivity of ϕ means $(t)M = M$ where $(t) \subseteq A[t]$. By the determinant trick (A&M 2.4 with $\mathfrak{a} = (t)$ and the identity endomorphism) there is $x = 1 + t\,h(t)$ with $xM = 0$, i.e. $\big(1 + t\,h(t)\big)M = 0$. Reading off in terms of ϕ: $\mathrm{id} = -\phi\,h(\phi)$ on M, so ϕ has the two-sided inverse $-h(\phi)$, hence is injective and an isomorphism. Sanity check: this fails for non-f.g. modules – the shift $\phi(a_0, a_1, \dots) = (a_1, a_2, \dots)$ on $A^{(\mathbb{Z}^+)}$ is surjective but not injective.

Worked Example 15.4.22 (Minimal generators of a module over a local ring)**.** Let $A = k[x, y]_{(x,y)}$, $\mathfrak{m} = (x, y)$, and $M = \mathfrak{m}$. Compute the minimal number of generators of M.

Recognition. Over a local ring this number is $\dim_k M/\mathfrak{m}M$ by the local Nakayama corollary.

Solution. Here $M = \mathfrak{m} = (x, y)$ and $\mathfrak{m}M = \mathfrak{m}^2 = (x^2, xy, y^2)$. So $M/\mathfrak{m}M = \mathfrak{m}/\mathfrak{m}^2$ has k-basis the images of x, y, giving $\dim_k \mathfrak{m}/\mathfrak{m}^2 = 2$. Hence the minimal number of generators of $\mathfrak{m}$ is 2, realized by $\{\, x, y \,\}$. Sanity check: any single element $f \in \mathfrak{m}$ has $f \in \mathfrak{m}^2 + kx + ky$ but cannot span $\mathfrak{m}/\mathfrak{m}^2$ (dimension 2), so $\mathfrak{m}$ is not principal – correctly, the maximal ideal of a 2-dimensional regular local ring needs exactly 2 generators.

Worked Example 15.4.23 ($N + \mathfrak{m}M = M \Rightarrow N = M$ in practice)**.** With $A = \mathbb{Z}_{(2)}$, $M = A^2$, $N = A \cdot (1, 1) + A \cdot (0, 2)$, decide whether $N = M$.

Recognition. Reduce mod $\mathfrak{m} = 2A$: $N = M$ iff the images of the generators span $M/\mathfrak{m}M = k^2$, $k = \mathbb{F}_2$.

Solution. Mod 2, the generators become $(1, 1)$ and $(0, 0)$, spanning only a 1-dimensional subspace of $\mathbb{F}_2^2$. So $N + \mathfrak{m}M \neq M$, and indeed $N \neq M$ (e.g. $(1, 0) \notin N$, since $a(1, 1) + b(0, 2) = (a, a + 2b) = (1, 0)$ forces $a = 1$, $1 + 2b = 0$, impossible in $\mathbb{Z}_{(2)}$). Sanity check: had we used $(1, 1)$ and $(0, 1)$, the reductions $(1, 1), (0, 1)$ span $\mathbb{F}_2^2$, and then Nakayama gives $N = M$ – which one verifies directly since $(1, 0) = (1, 1) - (0, 1) \in N$.

Tensor products and the universal property

The tensor product converts bilinear maps into linear maps; it is the vehicle for base change, and – paired with localization in Section 15.5 – the way commutative algebra "moves a module to a point". Let M, N, P be A-modules. A map $f : M \times N \to P$ is *A-bilinear* if it is A-linear in each variable separately.

Theorem 15.4.24 (tensor product, A&M 2.12)**.** *There is a pair (T, g) – an A-module $T = M \otimes_A N$ and an A-bilinear map $g : M \times N \to T$, $g(x, y) = x \otimes y$ – with the universal property: for every A-module P and every A-bilinear $f : M \times N \to P$ there is a unique A-linear $f' : T \to P$ with $f = f' \circ g$. The pair is unique up to unique isomorphism.*

Idea. Existence: form the free module $C = A^{(M \times N)}$ on symbols (x, y), and quotient by the submodule D generated by all

$$(x + x', y) - (x, y) - (x', y),\ (x, y + y') - (x, y) - (x, y'),\ (ax, y) - a(x, y),\ (x, ay) - a(x, y).$$

Set $T = C/D$ and let $x \otimes y$ be the image of (x, y); the relations are exactly bilinearity. An A-bilinear f extends to an A-linear map on C that kills D, hence factors through T uniquely. Uniqueness is the usual universal-property argument. The elements $x \otimes y$ (the *simple* or *decomposable* tensors) *generate* T but are not all of T; a general element is a finite sum $\sum_i x_i \otimes y_i$. □

Caution. The notation $x \otimes y$ is ambiguous about the ambient tensor product, and "$x \otimes y = 0$" can change meaning under enlargement. Over $A = \mathbb{Z}$, take $M = \mathbb{Z}$, $N = \mathbb{Z}/2$. In $\mathbb{Z} \otimes \mathbb{Z}/2$ the element $2 \otimes x$ equals $1 \otimes 2x = 1 \otimes 0 = 0$. But the same symbol inside $2\mathbb{Z} \otimes \mathbb{Z}/2$ need not vanish (A&M, Remark ii after 2.12; cf. Cor. 2.13: if $\sum x_i \otimes y_i = 0$ in $M \otimes N$ it already vanishes in $M_0 \otimes N_0$ for some *finitely generated* submodules). Always name the tensor product you are in.

Proposition 15.4.25 (canonical isomorphisms, A&M 2.14)**.** *There are unique A-isomorphisms*

$$M\otimes N\xrightarrow{\cong} N\otimes M,\quad (M\otimes N)\otimes P\xrightarrow{\cong} M\otimes(N\otimes P),\quad (M\oplus N)\otimes P\xrightarrow{\cong}(M\otimes P)\oplus(N\otimes P),\quad A\otimes M\xrightarrow{\cong} M,$$

sending $x\otimes y\mapsto y\otimes x$; $(x\otimes y)\otimes z\mapsto x\otimes(y\otimes z)$; distributing over the sum; and $a\otimes x\mapsto ax$.

Worked Example 15.4.26 ($A\otimes_A M\cong M$ and $A/\mathfrak{a}\otimes_A M\cong M/\mathfrak{a}M$)**.** Prove the unit law and the base-change-to-a-quotient formula.

Recognition. Both follow from the universal property: a bilinear map out of $A\times M$ is determined by the action $a\cdot(-)$, and tensoring with $A/\mathfrak{a}$ imposes exactly the relations $\mathfrak{a}M=0$.

Solution. For $A\otimes_A M\cong M$: the bilinear map $(a,x)\mapsto ax$ induces $A\otimes M\to M$, $a\otimes x\mapsto ax$, with inverse $x\mapsto 1\otimes x$; these compose to identities. For $A/\mathfrak{a}\otimes_A M$: apply $-\otimes_A M$ to $0\to\mathfrak{a}\to A\to A/\mathfrak{a}\to 0$ (right-exactness, below) to get $\mathfrak{a}\otimes M\to M\to A/\mathfrak{a}\otimes M\to 0$. The image of $\mathfrak{a}\otimes M\to M$ is $\mathfrak{a}M$, so $A/\mathfrak{a}\otimes_A M\cong M/\mathfrak{a}M$. Sanity check: $\mathbb{Z}/n\otimes_{\mathbb{Z}}\mathbb{Z}/m\cong(\mathbb{Z}/m)/n(\mathbb{Z}/m)\cong\mathbb{Z}/\gcd(n,m)$ – e.g. $\mathbb{Z}/2\otimes\mathbb{Z}/3=0$ and $\mathbb{Z}/2\otimes\mathbb{Z}/4\cong\mathbb{Z}/2$.

Worked Example 15.4.27 (Tensor of free modules)**.** Show $A^m\otimes_A A^n\cong A^{mn}$, with basis $e_i\otimes f_j$.

Recognition. Tensor distributes over direct sums and $A\otimes A\cong A$, so a free-times-free is free of the product rank.

Solution. Using distributivity and $A\otimes A\cong A$:

$$A^m\otimes A^n=\Big(\bigoplus_{i=1}^{m}A\Big)\otimes\Big(\bigoplus_{j=1}^{n}A\Big)\cong\bigoplus_{i,j}(A\otimes A)\cong\bigoplus_{i,j}A=A^{mn}.$$

A basis is $\{\,e_i\otimes f_j\,\}$. Sanity check: a bilinear map $A^m\times A^n\to P$ is the same as an $m\times n$ array of elements of P, i.e. an element of P^{mn}, matching $\mathrm{Hom}_A(A^{mn},P)\cong P^{mn}$ – exactly the universal property.

Worked Example 15.4.28 (Tensor product of homomorphisms)**.** For $f:M\to M'$ and $g:N\to N'$, construct $f\otimes g:M\otimes N\to M'\otimes N'$ and verify functoriality.

Recognition. The map $(x,y)\mapsto f(x)\otimes g(y)$ is bilinear, so it induces a unique linear map on the tensor product.

Solution. Bilinearity of $(x,y)\mapsto f(x)\otimes g(y)$ gives a well-defined A-linear $f\otimes g$ with $(f\otimes g)(x\otimes y)=f(x)\otimes g(y)$. Since simple tensors generate, $f\otimes g$ is unique. Functoriality $(f'\circ f)\otimes(g'\circ g)=(f'\otimes g')\circ(f\otimes g)$ holds on simple tensors, hence everywhere. Sanity check: $\mathrm{id}_M\otimes\mathrm{id}_N=\mathrm{id}_{M\otimes N}$, and $f\otimes g=0$ whenever $f=0$ or $g=0$, consistent with $(0\otimes g)(x\otimes y)=0\otimes g(y)=0$.

Restriction, extension of scalars, right-exactness, and flatness

Let $f:A\to B$ be a ring homomorphism. There are two ways to move modules across f.

Definition 15.4.29 (restriction and extension of scalars)**.** *Restriction:* a B-module N becomes an A-module by $a\cdot x:=f(a)x$. *Extension (base change):* an A-module M becomes a B-module $M_B:=B\otimes_A M$, with B acting on the left factor, $b'(b\otimes x)=b'b\otimes x$. These are adjoint: $\mathrm{Hom}_B(B\otimes_A M,N)\cong\mathrm{Hom}_A(M,N)$ naturally (extension is left adjoint to restriction).

Proposition 15.4.30 (right-exactness of tensor, A&M 2.18)**.** *For any A-module N, the functor $-\otimes_A N$ is* right-exact*: if $M'\xrightarrow{u}M\xrightarrow{v}M''\to 0$ is exact, then*

$$M'\otimes N\xrightarrow{u\otimes 1}M\otimes N\xrightarrow{v\otimes 1}M''\otimes N\to 0$$

is exact. There is a canonical adjunction isomorphism $\mathrm{Hom}_A(M\otimes N,P)\cong\mathrm{Hom}_A\big(M,\mathrm{Hom}_A(N,P)\big)$*, so $-\otimes N$ is a left adjoint and hence right-exact.*

Idea. Adjunction: an A-bilinear map $M\times N\to P$ is the same as an A-linear $M\to\mathrm{Hom}_A(N,P)$ (curry the second variable), which is the same as an A-linear $M\otimes N\to P$. So $T(-)=-\otimes N$ is left adjoint to $\mathrm{Hom}_A(N,-)$. Left adjoints preserve cokernels (right-exactness): apply the left-exact $\mathrm{Hom}(-,\mathrm{Hom}(N,P))$ and the left-exactness of $\mathrm{Hom}(T(-),P)$ to deduce exactness of T on the right end, for all P. Tensoring need *not* preserve injections on the left. □

Definition 15.4.31 (flat module)**.** An A-module N is *flat* if $- \otimes_A N$ is exact, equivalently (A&M 2.19) if tensoring any *injection* $M' \hookrightarrow M$ with N stays injective; it suffices to test injections $\mathfrak{a} \hookrightarrow A$ with $\mathfrak{a}$ finitely generated. Free modules are flat; localizations $S^{-1}A$ are flat (Section 15.5); over a PID, flat = torsion-free.

Worked Example 15.4.32 (Tensor is not left-exact: a witness)**.** Exhibit an injection that fails to stay injective after tensoring.

Recognition. Right-exactness can drop an injection to a non-injection; the standard witness is multiplication by 2 tensored with $\mathbb{Z}/2$.

Solution. Take $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z}$ over $A = \mathbb{Z}$ and tensor with $N = \mathbb{Z}/2$. The map becomes $\mathbb{Z}/2 \xrightarrow{\bar{2}} \mathbb{Z}/2$, which is multiplication by $2 = 0$ on $\mathbb{Z}/2$, the zero map – not injective, although the original was. So $- \otimes \mathbb{Z}/2$ is not exact and $\mathbb{Z}/2$ is not a flat $\mathbb{Z}$-module. Sanity check: $\mathbb{Z}/2$ has 2-torsion, and over the PID $\mathbb{Z}$ "flat = torsion-free" predicts non-flatness; the right-exact sequence $\mathbb{Z} \xrightarrow{2} \mathbb{Z} \to \mathbb{Z}/2 \to 0$ tensored with $\mathbb{Z}/2$ correctly gives $\mathbb{Z}/2 \xrightarrow{0} \mathbb{Z}/2 \to \mathbb{Z}/2 \to 0$, exact only on the right.

Worked Example 15.4.33 (Free modules are flat)**.** Show A^n (and more generally any free module) is flat.

Recognition. Tensoring with A is the identity functor, and tensoring with a direct sum is the direct sum of the tensors; direct sums of exact sequences are exact.

Solution. For an injection $M' \hookrightarrow M$, tensoring with A gives $M' \hookrightarrow M$ unchanged (since $A \otimes - \cong \mathrm{id}$), still injective. Tensoring with $A^{(I)} = \bigoplus_I A$ gives $\bigoplus_I M' \hookrightarrow \bigoplus_I M$, injective because a direct sum of injections is injective. Hence every free module is flat. Sanity check: $\mathbb{Z}^n$ is torsion-free, consistent with flat = torsion-free over $\mathbb{Z}$; and the failure example above used the *non*-free $\mathbb{Z}/2$.

Worked Example 15.4.34 (Extension of scalars preserves finite generation)**.** If M is generated by $x_1, \ldots, x_n$ over A, show $M_B = B \otimes_A M$ is generated by $1 \otimes x_1, \ldots, 1 \otimes x_n$ over B.

Recognition. Simple tensors $b \otimes x$ generate M_B, and $b \otimes x$ rewrites in terms of the $1 \otimes x_i$ using bilinearity.

Solution. Any element of M_B is a finite sum $\sum b_j \otimes m_j$. Writing $m_j = \sum_i a_{ij} x_i$ with $a_{ij} \in A$ and pulling scalars across, $b_j \otimes m_j = \sum_i b_j \otimes a_{ij} x_i = \sum_i (b_j f(a_{ij}))(1 \otimes x_i)$. So everything is a B-combination of the $1 \otimes x_i$. Sanity check (A&M 2.16–2.17): if moreover B is f.g. as an A-module by $y_1, \ldots, y_m$, then the mn products $y_k x_i$ generate N over A whenever N is f.g. over B – the tower-of-generators principle.

Worked Example 15.4.35 (A torsion-free non-flat module needs a non-PID)**.** Over $A = k[x, y]$ show the ideal $\mathfrak{m} = (x, y)$ is torsion-free but not flat.

Recognition. Over a non-PID, torsion-free no longer forces flat; test flatness by tensoring the inclusion $\mathfrak{m} \hookrightarrow A$ or by finding a nonzero element of Tor_1.

Solution. $\mathfrak{m}$ is a submodule of the domain A, hence torsion-free. But consider the relation $y \cdot x - x \cdot y = 0$ among the generators x, y of $\mathfrak{m}$. In $\mathfrak{m} \otimes_A \mathfrak{m}$ the element $x \otimes y - y \otimes x$ is nonzero (it spans the kernel $\mathrm{Tor}_1^A(A/\mathfrak{m}, \mathfrak{m}) \cong \mathrm{Tor}_2^A(A/\mathfrak{m}, A/\mathfrak{m}) \cong k$ of $\mathfrak{m} \otimes_A \mathfrak{m} \to \mathfrak{m}$), so $- \otimes_A \mathfrak{m}$ does not stay injective on $\mathfrak{m} \hookrightarrow A$: the induced $\mathfrak{m} \otimes \mathfrak{m} \to A \otimes \mathfrak{m} = \mathfrak{m}$ kills $x \otimes y - y \otimes x \neq 0$. Hence $\mathfrak{m}$ is not flat. Sanity check: this is impossible over a PID, matching that $k[x, y]$ is not a PID; the obstruction lives exactly where $\mathfrak{m}$ fails to be free (it is not, by the local computation above needing 2 generators).

Algebras and tensor products of algebras

Definition 15.4.36 (A-algebra)**.** An *A-algebra* is a ring B together with a ring homomorphism $f : A \to B$; equivalently, a ring B that is also an A-module with compatible multiplication. An *A-algebra homomorphism* $h : B \to C$ is a ring map commuting with the structure maps, $h \circ f = g$. B is *finite* over A if it is f.g. as an A-module, and *of finite type* (finitely generated as an algebra) if $B = A[x_1, \ldots, x_n]$ for finitely many x_i, i.e. a quotient of a polynomial ring $A[t_1, \ldots, t_n] \twoheadrightarrow B$.

Remark 15.4.2. This is where arithmetic and geometry merge in the A&M sense. Every ring is uniquely a $\mathbb{Z}$-algebra (the map $n \mapsto n \cdot 1$), so commutative-ring theory *is* the theory of $\mathbb{Z}$-algebras. Geometrically, when k is algebraically closed and I is prime, a finite-type k-algebra $B = k[t_1, \ldots, t_n]/I$ is the coordinate ring of the affine variety $V(I) \subseteq \mathbb{A}_k^n$; an A-algebra map is a morphism of the associated Spec's in the opposite direction (Section 15.8). The two readings of $\mathrm{Spec}\, A$ – "primes of arithmetic" for $A = \mathbb{Z}$ and "points of geometry" for $A = k[t_1, \ldots, t_n]/I$ – are the same construction applied to two flavors of algebra.

Proposition 15.4.37 (tensor product of algebras)**.** *Let $f : A \to B$ and $g : A \to C$ be A-algebras. Then $D = B \otimes_A C$ is an A-algebra with multiplication determined by*

$$(b \otimes c)(b' \otimes c') = bb' \otimes cc',$$

and D is the coproduct *(pushout) of B and C over A: there are A-algebra maps $u : B \to D$, $u(b) = b \otimes 1$, and $v : C \to D$, $v(c) = 1 \otimes c$, universal among pairs of A-algebra maps out of B and C to a common target.*

$$\begin{array}{ccc} A & \xrightarrow{\ g\ } & C \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle v} \\ B & \xrightarrow[\ u\ ]{} & B \otimes_A C \end{array}$$

Diagram explanation. Objects: Four A-algebras at the corners of a commutative square: A (the base ring, top-left), C (top-right), B (bottom-left), and $B \otimes_A C$ (bottom-right, the coproduct/pushout). Every arrow is a ring homomorphism that is also A-linear.

Arrows: $g : A \to C$ is the structure map making C an A-algebra. $f : A \to B$ is the structure map making B an A-algebra. $v : C \to B \otimes_A C$ is the canonical map $c \mapsto 1 \otimes c$. $u : B \to B \otimes_A C$ is the canonical map $b \mapsto b \otimes 1$. Both u and v are A-algebra homomorphisms into the tensor product algebra.

What commutes: The square commutes: $v \circ g = u \circ f$. Concretely, for $a \in A$: along the top-right path, $a \mapsto g(a) \mapsto 1 \otimes g(a)$; along the bottom-left path, $a \mapsto f(a) \mapsto f(a) \otimes 1$. These are equal in $B \otimes_A C$ because $f(a) \otimes 1 = 1 \otimes g(a)$ is the defining relation of the tensor product over A (the scalar a can be moved across the $\otimes$ symbol).

Why it commutes: Well-definedness of $B \otimes_A C$ as an A-module means $f(a)b \otimes c = b \otimes g(a)c$ for all $a \in A$. Setting $b = 1$, $c = 1$: $f(a) \otimes 1 = 1 \otimes g(a)$, exactly the relation $u \circ f = v \circ g$. The key is that both $f(a)$ (as a left B-scalar) and $g(a)$ (as a left C-scalar) come from the same element $a \in A$, and the tensor product identifies them.

Why this matters here: This diagram encodes the universal property of the coproduct (pushout) of A-algebras: $B \otimes_A C$ is the initial A-algebra equipped with maps from both B and C that agree on the common subalgebra A. Any pair of A-algebra maps $B \to E$ and $C \to E$ factors uniquely through $B \otimes_A C$. The diagram is placed here to show that the tensor product of algebras is not just an A-module but satisfies the correct universal property in the category of A-algebras.

Concrete example: Take $A = \mathbb{R}$, $B = \mathbb{R}[x]$, $C = \mathbb{R}[y]$; then $B \otimes_{\mathbb{R}} C \cong \mathbb{R}[x, y]$, u sends $x \mapsto x \otimes 1 = x$, v sends $y \mapsto 1 \otimes y = y$, and $f = g$ are both the inclusion $\mathbb{R} \hookrightarrow \mathbb{R}[x]$ (resp. $\mathbb{R}[y]$). The square says the inclusion $\mathbb{R} \hookrightarrow \mathbb{R}[x, y]$ via x or via y agrees on scalars, i.e. $\mathbb{R}$ sits inside $\mathbb{R}[x, y]$ by a single canonical map.

Common pitfall: Students sometimes read u and v as inclusions and assume B and C are subobjects of $B \otimes_A C$; in general they need not be injective (if B or C is not flat over A the maps can have nontrivial kernel). Also, the multiplication rule $(b \otimes c)(b' \otimes c') = bb' \otimes cc'$ (which makes $B \otimes_A C$ a commutative ring) requires checking it is well defined on equivalence classes, which is the "only subtle point" cited in the proof.

Takeaway: The point of this diagram is that $B \otimes_A C$ is the pushout of B and C over A in the category of commutative A-algebras, making the square commute and satisfying the universal property that any compatible pair of A-algebra maps out of B and C factors uniquely through $B \otimes_A C$.

Idea. Well-definedness of the multiplication is the only subtle point: the naive formula on representatives must be checked independent of representatives, which A&M do by realizing it through the universal property in two stages ((2.12*) and (2.14)) rather than by hand. Once the product is defined, u, v are visibly A-algebra maps and any pair $B \to E$, $C \to E$ of A-algebra maps glues to $b \otimes c \mapsto$ (image of b)(image of c) on D. □

Worked Example 15.4.38 (Polynomial rings tensor to polynomial rings)**.** Compute $A[x] \otimes_A A[y]$.

Recognition. Tensor product of free algebras adds variables; the universal property says a map out is a choice of images for x and y.

Solution. $A[x] \otimes_A A[y] \cong A[x, y]$ via $x \otimes 1 \mapsto x$, $1 \otimes y \mapsto y$. As A-modules both sides are free on the monomials $x^i y^j$, and the multiplications match by the algebra-tensor rule $(x \otimes 1)(1 \otimes y) = x \otimes y \mapsto xy$. Sanity check:

this is the pushout/coproduct statement – $A[x,y]$ is the free A-algebra on $\{x, y\}$, exactly the coproduct of the free algebras on $\{x\}$ and $\{y\}$; geometrically $\mathbb{A}^1 \times_{\operatorname{Spec} A} \mathbb{A}^1 = \mathbb{A}^2$.

Worked Example 15.4.39 (Base change of a quotient algebra)**.** For an ideal $I \subseteq A[x]$, compute $B \otimes_A \big(A[x]/I\big)$.

Recognition. Extension of scalars commutes with quotients (right-exactness) and with adjoining variables, so it turns $A[x]/I$ into $B[x]/I^e$.

Solution. Right-exactness applied to $0 \to I \to A[x] \to A[x]/I \to 0$ tensored with B gives $B \otimes_A (A[x]/I) \cong (B \otimes_A A[x])/(\text{image of } B \otimes I) \cong B[x]/I^e$, where $I^e = I \cdot B[x]$ is the extension. Sanity check: $\mathbb{R} \otimes_{\mathbb{R}} \mathbb{R}[x]/(x^2+1) \cong \mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$, while $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}[x]/(x^2+1) \cong \mathbb{C}[x]/(x^2+1) \cong \mathbb{C}[x]/((x-i)(x+i)) \cong \mathbb{C} \times \mathbb{C}$ – the extension splits, the geometric fibre over $\operatorname{Spec} \mathbb{R}$ acquires two points after base change to $\mathbb{C}$.

Worked Example 15.4.40 (A tensor product of fields that is not a field)**.** Show $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C} \cong \mathbb{C} \times \mathbb{C}$.

Recognition. Write one factor as $\mathbb{R}[x]/(x^2+1)$ and base-change; the quadratic splits over $\mathbb{C}$, so the tensor product breaks into a product.

Solution. $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C} \cong \mathbb{C} \otimes_{\mathbb{R}} \mathbb{R}[x]/(x^2+1) \cong \mathbb{C}[x]/(x^2+1) \cong \mathbb{C}[x]/(x-i) \times \mathbb{C}[x]/(x+i) \cong \mathbb{C} \times \mathbb{C}$ by CRT (the factors $(x-i), (x+i)$ are coprime in $\mathbb{C}[x]$). Sanity check: as $\mathbb{R}$-vector spaces both sides have dimension 4; and $\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C}$ has nonzero zero-divisors (the idempotents $\frac{1}{2}(1 \otimes 1 \mp i \otimes i)$), so it is not a field even though both factors are – tensor of fields over a subfield need not be a field. Geometrically $\operatorname{Spec}(\mathbb{C} \otimes_{\mathbb{R}} \mathbb{C})$ is two points: the two ways to embed $\mathbb{C}$ into $\mathbb{C}$ over $\mathbb{R}$.

Worked Example 15.4.41 (Localization as base change and its flatness)**.** Realize the ring of fractions $S^{-1}M$ as $S^{-1}A \otimes_A M$, anticipating Section 15.5.

Recognition. Localization is extension of scalars along $A \to S^{-1}A$; the resulting functor is exact, which is the flatness of $S^{-1}A$.

Solution. For a multiplicative set $S \subseteq A$, there is a natural isomorphism $S^{-1}A \otimes_A M \cong S^{-1}M$, $(\frac{a}{s}) \otimes x \mapsto \frac{ax}{s}$ (Section 15.5 makes this precise). Because localizing is exact – it preserves injections, surjections, kernels – $S^{-1}A$ is a *flat* A-module, and $- \otimes_A S^{-1}A = S^{-1}(-)$ is an exact functor. Sanity check: exactness is visible on the witness above – tensoring $0 \to \mathbb{Z} \xrightarrow{2} \mathbb{Z}$ with the flat module $\mathbb{Z}_{(3)} = S^{-1}\mathbb{Z}$ ($S = \mathbb{Z} \setminus 3\mathbb{Z}$) keeps 2 a unit times an injection, so injectivity survives, unlike tensoring with $\mathbb{Z}/2$. This interaction of tensor and localization is the technical bridge to the next section.

Exercises (Atiyah & Macdonald).

1. Show that $(\mathbb{Z}/m\mathbb{Z}) \otimes_{\mathbb{Z}} (\mathbb{Z}/n\mathbb{Z}) = 0$ if m, n are coprime.
2. Let A be a ring, $\mathfrak{a}$ an ideal, M an A-module. Show that $(A/\mathfrak{a}) \otimes_A M$ is isomorphic to $M/\mathfrak{a}M$. [Tensor the exact sequence $0 \to \mathfrak{a} \to A \to A/\mathfrak{a} \to 0$ with M.]
3. Let A be a local ring, M and N finitely generated A-modules. Prove that if $M \otimes_A N = 0$, then $M = 0$ or $N = 0$. [Let $\mathfrak{m}$ be the maximal ideal, $k = A/\mathfrak{m}$ the residue field. Let $M_k = k \otimes_A M \cong M/\mathfrak{m}M$ by Exercise 2. By Nakayama's lemma, $M_k = 0 \Rightarrow M = 0$. But $M \otimes_A N = 0 \Rightarrow (M \otimes_A N)_k = 0 \Rightarrow M_k \otimes_k N_k = 0 \Rightarrow M_k = 0$ or $N_k = 0$, since M_k, N_k are vector spaces over a field.]
4. Let M_i ($i \in I$) be any family of A-modules, and let M be their direct sum. Prove that M is flat $\iff$ each M_i is flat.
5. Let $A[x]$ be the ring of polynomials in one indeterminate over a ring A. Prove that $A[x]$ is a flat A-algebra. [Use Exercise 4.]
6. For any A-module M, let $M[x]$ denote the set of all polynomials in x with coefficients in M, that is to say expressions of the form
$$m_0 + m_1 x + \cdots + m_r x^r \qquad (m_i \in M).$$
Defining the product of an element of $A[x]$ and an element of $M[x]$ in the obvious way, show that $M[x]$ is an $A[x]$-module. Show that $M[x] \cong A[x] \otimes_A M$.

7. Let $\mathfrak{p}$ be a prime ideal in A. Show that $\mathfrak{p}[x]$ is a prime ideal in $A[x]$. If $\mathfrak{m}$ is a maximal ideal in A, is $\mathfrak{m}[x]$ a maximal ideal in $A[x]$?

8. i) If M and N are flat A-modules, then so is $M \otimes_A N$. ii) If B is a flat A-algebra and N is a flat B-module, then N is flat as an A-module.

9. Let $0 \to M' \to M \to M'' \to 0$ be an exact sequence of A-modules. If M' and M'' are finitely generated, then so is M.

10. Let A be a ring, $\mathfrak{a}$ an ideal contained in the Jacobson radical of A; let M be an A-module and N a finitely generated A-module, and let $u : M \to N$ be a homomorphism. If the induced homomorphism $M/\mathfrak{a}M \to N/\mathfrak{a}N$ is surjective, then u is surjective.

11. Let A be a ring $\neq 0$. Show that $A^m \cong A^n \Rightarrow m = n$. [Let $\mathfrak{m}$ be a maximal ideal of A and let $\phi : A^m \to A^n$ be an isomorphism. Then $1 \otimes \phi : (A/\mathfrak{m}) \otimes A^m \to (A/\mathfrak{m}) \otimes A^n$ is an isomorphism between vector spaces of dimensions m and n over the field $k = A/\mathfrak{m}$. Hence $m = n$.] (Cf. Chapter 3, Exercise 15.) If $\phi : A^m \to A^n$ is surjective, then $m \geq n$. If $\phi : A^m \to A^n$ is injective, is it always the case that $m \leq n$?

12. Let M be a finitely generated A-module and $\phi : M \to A^n$ a surjective homomorphism. Show that $\mathrm{Ker}(\phi)$ is finitely generated. [Let $e_1, \ldots, e_n$ be a basis of A^n and choose $u_i \in M$ such that $\phi(u_i) = e_i$ $(1 \leq i \leq n)$. Show that M is the direct sum of $\mathrm{Ker}(\phi)$ and the submodule generated by $u_1, \ldots, u_n$.]

13. Let $f : A \to B$ be a ring homomorphism, and let N be a B-module. Regarding N as an A-module by restriction of scalars, form the B-module $N_B = B \otimes_A N$. Show that the homomorphism $g : N \to N_B$ which maps y to $1 \otimes y$ is injective and that $g(N)$ is a direct summand of N_B. [Define $p : N_B \to N$ by $p(b \otimes y) = by$, and show that $N_B = \mathrm{Im}(g) \oplus \mathrm{Ker}(p)$.]

Direct limits

14. A partially ordered set I is said to be a *directed set* if for each pair i, j in I there exists $k \in I$ such that $i \leq k$ and $j \leq k$.

Let A be a ring, let I be a directed set and let $(M_i)_{i \in I}$ be a family of A-modules indexed by I. For each pair i, j in I such that $i \leq j$, let $\mu_{ij} : M_i \to M_j$ be an A-homomorphism, and suppose that the following axioms are satisfied:

(1) μ_{ii} is the identity mapping of M_i, for all $i \in I$;

(2) $\mu_{ik} = \mu_{jk} \circ \mu_{ij}$ whenever $i \leq j \leq k$.

Then the modules M_i and homomorphisms μ_{ij} are said to form a *direct system* $\mathbf{M} = (M_i, \mu_{ij})$ over the directed set I.

We shall construct an A-module M called the *direct limit* of the direct system $\mathbf{M}$. Let C be the direct sum of the M_i, and identify each module M_i with its canonical image in C. Let D be the submodule of C generated by all elements of the form $x_i - \mu_{ij}(x_i)$ where $i \leq j$ and $x_i \in M_i$. Let $M = C/D$, and let $\mu : C \to M$ be the projection and let μ_i be the restriction of μ to M_i.

The module M, or more correctly the pair consisting of M and the family of homomorphisms $\mu_i : M_i \to M$, is called the *direct limit* of the direct system $\mathbf{M}$, and is written $\varinjlim M_i$. From the construction it is clear that $\mu_i = \mu_j \circ \mu_{ij}$ whenever $i \leq j$.

15. In the situation of Exercise 14, show that every element of M can be written in the form $\mu_i(x_i)$ for some $i \in I$ and some $x_i \in M_i$. Show also that if $\mu_i(x_i) = 0$ then there exists $j \geq i$ such that $\mu_{ij}(x_i) = 0$ in M_j.

16. Show that the direct limit is characterized (up to isomorphism) by the following property. Let N be an A-module and for each $i \in I$ let $\alpha_i : M_i \to N$ be an A-module homomorphism such that $\alpha_i = \alpha_j \circ \mu_{ij}$ whenever $i \leq j$. Then there exists a unique homomorphism $\alpha : M \to N$ such that $\alpha_i = \alpha \circ \mu_i$ for all $i \in I$.

17. Let $(M_i)_{i \in I}$ be a family of submodules of an A-module, such that for each pair of indices i, j in I there exists $k \in I$ such that $M_i + M_j \subseteq M_k$. Define $i \leq j$ to mean $M_i \subseteq M_j$ and let $\mu_{ij} : M_i \to M_j$ be the embedding of M_i in M_j. Show that

$$\varinjlim M_i = \sum M_i = \bigcup_i M_i.$$

In particular, any A-module is the direct limit of its finitely generated submodules.

18. Let $\mathbf{M} = (M_i, \mu_{ij})$, $\mathbf{N} = (N_i, \nu_{ij})$ be direct systems of A-modules over the same directed set. Let M, N be the direct limits and $\mu_i : M_i \to M$, $\nu_i : N_i \to N$ the associated homomorphisms. A *homomorphism* $\Phi : \mathbf{M} \to \mathbf{N}$ is by definition a family of A-module homomorphisms $\phi_i : M_i \to N_i$ such that $\phi_j \circ \mu_{ij} = \nu_{ij} \circ \phi_i$ whenever $i \leq j$. Show that Φ defines a unique homomorphism $\phi = \varinjlim \phi_i : M \to N$ such that $\phi \circ \mu_i = \nu_i \circ \phi_i$ for all $i \in I$.

19. A sequence of direct systems and homomorphisms

$$\mathbf{M} \to \mathbf{N} \to \mathbf{P}$$

is *exact* if the corresponding sequence of modules and module homomorphisms is exact for each $i \in I$. Show that the sequence $M \to N \to P$ of direct limits is then exact. [Use Exercise 15.]

Tensor products commute with direct limits

20. Keeping the same notation as in Exercise 14, let N be any A-module. Then $(M_i \otimes N, \mu_{ij} \otimes 1)$ is a direct system; let $P = \varinjlim(M_i \otimes N)$ be its direct limit. For each $i \in I$ we have a homomorphism $\mu_i \otimes 1 : M_i \otimes N \to M \otimes N$, hence by Exercise 16 a homomorphism $\psi : P \to M \otimes N$. Show that ψ is an isomorphism, so that

$$\varinjlim(M_i \otimes N) \cong (\varinjlim M_i) \otimes N.$$

[For each $i \in I$ let $g_i : M_i \times N \to M_i \otimes N$ be the canonical bilinear mapping. Passing to the limit we obtain a mapping $g : M \times N \to P$. Show that g is A-bilinear and hence define a homomorphism $\phi : M \otimes N \to P$. Verify that $\phi \circ \psi$ and $\psi \circ \phi$ are identity mappings.]

21. Let (A_i, α_{ij}) be a direct system of rings indexed by a directed set I, and for each $i \leq j$ in I let $\alpha_{ij} : A_i \to A_j$ be a ring homomorphism, satisfying conditions (1) and (2) of Exercise 14. Regarding each A_i as a $\mathbb{Z}$-module we can then form the direct limit $A = \varinjlim A_i$. Show that A inherits a ring structure from the A_i so that the mappings $A_i \to A$ are ring homomorphisms. The ring A is the *direct limit* of the system (A_i, α_{ij}). If $A = 0$ prove that $A_i = 0$ for some $i \in I$. [Remember that all rings have identity elements!]

22. Let (A_i, α_{ij}) be a direct system of rings and let $\mathfrak{N}_i$ be the nilradical of A_i. Show that $\varinjlim \mathfrak{N}_i$ is the nilradical of $\varinjlim A_i$. If each A_i is an integral domain, then $\varinjlim A_i$ is an integral domain.

23. Let $(B_\lambda)_{\lambda \in \Lambda}$ be a family of A-algebras. For each finite subset J of Λ let B_J denote the tensor product (over A) of the B_λ for $\lambda \in J$. If J' is another finite subset of Λ and $J \subseteq J'$, there is a canonical A-algebra homomorphism $B_J \to B_{J'}$. Let B denote the direct limit of the rings B_J as J runs through all finite subsets of Λ. The ring B has a natural A-algebra structure for which the homomorphisms $B_J \to B$ are A-algebra homomorphisms. The A-algebra B is the *tensor product* of the family $(B_\lambda)_{\lambda \in \Lambda}$.

Flatness and the Tor functor

24. In these Exercises it will be assumed that the reader is familiar with the definition and basic properties of the Tor functor.

If M is an A-module, the following are equivalent:

i) M is flat;
ii) $\mathrm{Tor}_n^A(M, N) = 0$ for all $n > 0$ and all A-modules N;
iii) $\mathrm{Tor}_1^A(M, N) = 0$ for all A-modules N.

[To show that (i) $\Rightarrow$ (ii), take a free resolution of N and tensor it with M. Since M is flat, the resulting sequence is exact and therefore its homology groups, which are the $\mathrm{Tor}_n^A(M, N)$, are zero for $n > 0$. To show that (iii) $\Rightarrow$ (i), for the exact sequence

$$0 \to N' \to N \to N'' \to 0$$

take the Tor exact sequence

$$\mathrm{Tor}_1(M, N'') \to M \otimes N' \to M \otimes N \to M \otimes N'' \to 0 :$$

since $\mathrm{Tor}_1(M, N'') = 0$ it follows that M is flat.]

25. Let $0 \to N' \to N \to N'' \to 0$ be an exact sequence, with N'' flat. Then N' is flat $\iff$ N is flat. [Use Exercise 24 and the Tor exact sequence.]

26. Let N be an A-module. Then N is flat $\iff$ $\mathrm{Tor}_1(A/\mathfrak{a}, N) = 0$ for all finitely generated ideals $\mathfrak{a}$. [Show first that $\mathrm{Tor}_1(M, N) = 0$ for all finitely generated A-modules M, then for all A-modules M. If M is finitely generated, let $x_1, \ldots, x_n$ be a set of generators of M, and let M_i be the submodule generated by $x_1, \ldots, x_i$. By considering the successive quotients M_i/M_{i-1} and using Exercise 25, deduce that $\mathrm{Tor}_1(M, N) = 0$ whenever $\mathrm{Tor}_1(A/\mathfrak{a}, N) = 0$ for all ideals $\mathfrak{a}$ (each M_i/M_{i-1} is cyclic, hence isomorphic to some $A/\mathfrak{a}$). So that N is flat $\iff$ $\mathrm{Tor}_1(A/\mathfrak{a}, N) = 0$ for all finitely generated ideals $\mathfrak{a}$. Finally use (2.19) to reduce to the case where $\mathfrak{a}$ is a finitely generated ideal.]

27. A ring A is *absolutely flat* if every A-module is flat. Prove that the following are equivalent:

    i) A is absolutely flat;

    ii) Every principal ideal is idempotent;

    iii) Every finitely generated ideal is a direct summand of A.

    [i) $\Rightarrow$ ii). Let $x \in A$. Then $A/(x)$ is a flat A-module, hence in the diagram

$$\begin{array}{ccc} (x) & \xrightarrow{p} & (x) \otimes A/(x) \\ \downarrow & & \downarrow{\scriptstyle i^*} \\ A & \longrightarrow & A/(x) \end{array}$$

    the mapping i^* is injective. Hence $\mathrm{Im}(p) = 0$ (as $i^* \circ p$ is the zero map $(x) \to A/(x)$), so $(x) \otimes A/(x) \cong (x)/(x^2)$ is 0, i.e. $(x) = (x^2)$. ii) $\Rightarrow$ iii). Let $x \in A$. Then $x = ax^2$ for some $a \in A$, hence $e = ax$ is idempotent and $(e) = (x)$. Now if e, f are idempotents, then $(e, f) = (e + f - ef)$. Hence finitely generated ideal is principal, and generated by an idempotent e, hence is a direct summand because $A = (e) \oplus (1 - e)$. iii) $\Rightarrow$ i). Use the criterion of Exercise 26.]

28. A Boolean ring is absolutely flat. The ring of Chapter 1, Exercise 7 is absolutely flat. Every homomorphic image of an absolutely flat ring is absolutely flat. If a local ring is absolutely flat, then it is a field. If A is absolutely flat, every non-unit in A is a zero-divisor.

Practice problems.

1. Over $A = \mathbb{Z}$, compute the abelian group $\mathbb{Z}/12 \otimes_{\mathbb{Z}} \mathbb{Z}/18$ and identify it as $\mathbb{Z}/d\mathbb{Z}$ for the correct d; then compute $\mathrm{Hom}_{\mathbb{Z}}(\mathbb{Z}/12, \mathbb{Z}/18)$ and verify that it too is cyclic of order $\gcd(12, 18) = 6$, so that the two groups are (non-canonically) isomorphic, and exhibit an explicit isomorphism.

2. Let A be a commutative ring and M an A-module. Compute $\mathrm{Ann}(M \oplus N)$ in terms of $\mathrm{Ann}(M)$ and $\mathrm{Ann}(N)$, and show by example over $A = \mathbb{Z}$ that $\mathrm{Ann}(M \otimes_A N)$ can be strictly larger than $\mathrm{Ann}(M) + \mathrm{Ann}(N)$. (Try $M = \mathbb{Q}$, $N = \mathbb{Z}/2$.)

3. Let $(A, \mathfrak{m}, k)$ be a local ring and M a finitely generated A-module with $\dim_k(M/\mathfrak{m}M) = 3$. Decide, with proof, which of the following must hold: (a) M is generated by exactly 3 elements and no fewer; (b) every generating set of M has at least 3 elements; (c) $M \cong A^3$. Give a counterexample to any that fails.

4. Take $A = \mathbb{Z}$ and the short exact sequence $0 \to \mathbb{Z} \xrightarrow{6} \mathbb{Z} \to \mathbb{Z}/6 \to 0$. Apply $- \otimes_{\mathbb{Z}} \mathbb{Z}/4$ and write out the resulting right-exact sequence with all maps computed; identify the kernel of the leftmost map and explain why it is exactly $\mathrm{Tor}_1^{\mathbb{Z}}(\mathbb{Z}/6, \mathbb{Z}/4)$.

5. Let $\phi : M \to M$ be an A-endomorphism of a finitely generated A-module with $\phi(M) \subseteq \mathfrak{a}M$ for an ideal $\mathfrak{a}$, and let $\phi^n + a_1\phi^{n-1} + \cdots + a_n = 0$ ($a_i \in \mathfrak{a}$) be the relation given by the determinant trick. Writing $\phi = \mathrm{id}_M - \psi$, show that $\psi\, q(\psi) = -(1 + a_1 + \cdots + a_n)\,\mathrm{id}_M$ for some $q \in A[t]$, and deduce that if the coefficient sum $1 + a_1 + \cdots + a_n$ is a unit (for instance if $\mathfrak{a} \subseteq \mathrm{Jac}(A)$) then $\mathrm{id}_M - \phi$ is an automorphism of M, whereas ϕ itself need not be injective (take $\phi = 0$ and $M \neq 0$). When $M = A^r$ ($r \geq 1$) is free, show also that $\det(\phi) \in \mathfrak{a}$.

6. Over $A = k[t]$, regard a finite-dimensional k-vector space V with a linear operator T as an A-module M_T. Show $M_T \otimes_{k[t]} k[t]/(t-\lambda) \cong V/(T-\lambda)V$ and identify this quotient with the cokernel of $T - \lambda$; deduce that λ is an eigenvalue of T iff this tensor product is nonzero.

7. Let $f : A \to B$ be a ring homomorphism and M an A-module. Prove the projection formula in the special case: for an ideal $\mathfrak{a} \subseteq A$, $B \otimes_A (M/\mathfrak{a}M) \cong (B \otimes_A M)/\mathfrak{a}^e(B \otimes_A M)$ where $\mathfrak{a}^e = \mathfrak{a}B$. Verify it on $A = \mathbb{Z}$, $B = \mathbb{Z}/4$, $M = \mathbb{Z}$, $\mathfrak{a} = 2\mathbb{Z}$.

8. Show that $\mathbb{Q} \otimes_{\mathbb{Z}} \mathbb{Q} \cong \mathbb{Q}$ as $\mathbb{Q}$-vector spaces and as rings, but that $\mathbb{Q} \otimes_{\mathbb{Z}} (\mathbb{Z}/n) = 0$ for every $n \geq 1$. Conclude that $\mathbb{Q}$ is a flat but not faithfully flat $\mathbb{Z}$-module by exhibiting a nonzero module killed by $\mathbb{Q} \otimes_{\mathbb{Z}} -$.

Additional exercises.

1. Let A be a commutative ring and M a finitely presented A-module: $A^m \xrightarrow{\psi} A^n \to M \to 0$ exact. Prove that for any flat A-module F, the natural map $F \otimes_A \mathrm{Hom}_A(M, A) \to \mathrm{Hom}_A(M, F)$ is an isomorphism: first when M is finite free, then in general by applying $\mathrm{Hom}_A(-, A)$, $F \otimes_A -$ and $\mathrm{Hom}_A(-, F)$ to the presentation. State precisely where finite presentation and flatness enter, give the map explicitly, and show that the map need not be an isomorphism when F is not flat (take $A = \mathbb{Z}$, $M = F = \mathbb{Z}/2$).

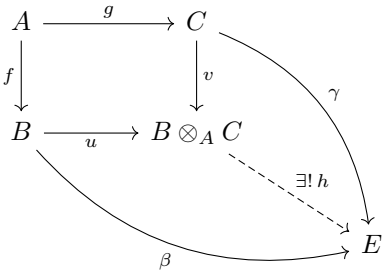
2. Let $(A, \mathfrak{m}, k)$ be local and $u : M \to N$ a homomorphism of finitely generated A-modules. Prove that u is surjective iff the induced map $\bar{u} : M/\mathfrak{m}M \to N/\mathfrak{m}N$ of k-vector spaces is surjective. Then show by example that the analogous statement for injectivity is false (find local A and an injective $\bar{u}$ with u not injective).

3. Let N be an A-module. Prove that N is flat iff for every relation $\sum_{i=1}^{n} a_i x_i = 0$ with $a_i \in A$, $x_i \in N$, there exist $y_1, \dots, y_m \in N$ and $b_{ij} \in A$ with $x_i = \sum_j b_{ij} y_j$ and $\sum_i a_i b_{ij} = 0$ for all j (the equational criterion for flatness). Use this to re-derive that $\mathbb{Z}/2$ is not a flat $\mathbb{Z}$-module from the relation $2 \cdot \bar{1} = 0$.

4. Let B and C be A-algebras with A a field k. Prove that $\dim_k(B \otimes_k C) = (\dim_k B)(\dim_k C)$ when both are finite-dimensional, and that $B \otimes_k C$ is reduced when B, C are reduced and k is perfect; give a counterexample over an imperfect field $k = \mathbb{F}_p(t)$ with $B = C = k(t^{1/p})$ showing the tensor product can have nonzero nilpotents.

5. Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of A-modules with M'' flat. Prove that for every A-module N the sequence $0 \to M' \otimes N \to M \otimes N \to M'' \otimes N \to 0$ is exact (i.e. flatness of M'' makes the sequence universally left-exact too), and deduce that an extension of a flat module by a flat module is flat.

Commutative-diagram exercises.



1. For a ring map $f : A \to B$, extension of scalars $M \mapsto B \otimes_A M$ is left adjoint to restriction. Complete the naturality square below for an A-linear map $g : M \to M'$ (vertical maps are the unit $\eta_M : M \to B \otimes_A M$, $x \mapsto 1 \otimes x$, of the adjunction; horizontal maps are g and $1 \otimes g$), prove it commutes, and prove the universal property $\mathrm{Hom}_B(B \otimes_A M, N) \cong \mathrm{Hom}_A(M, N)$ for a B-module N:

$$\begin{array}{ccc} M & \xrightarrow{\quad g \quad} & M' \\ {\scriptstyle \eta_M}\downarrow & & \downarrow{\scriptstyle \eta_{M'}} \\ B \otimes_A M & \xrightarrow[1 \otimes g]{} & B \otimes_A M' \end{array}$$

   Identify, in the universal property, the unique B-linear map induced by a given A-linear $M \to N$.

2. Let $f : A \to B$ and $g : A \to C$ be A-algebras. Complete the pushout square exhibiting $B \otimes_A C$ as the coproduct of B and C in the category of A-algebras, fill in the dashed universal arrow to an arbitrary A-algebra E receiving maps $\beta : B \to E$, $\gamma : C \to E$, and prove the induced map is the unique A-algebra

homomorphism making both triangles commute:

Specialize to $A = \mathbb{R}$, $B = C = \mathbb{C}$ and identify h when $E = \mathbb{C} \times \mathbb{C}$.

3. Let $\mathfrak{a} \subseteq A$ be an ideal and M an A-module. Complete the diagram below, in which the top row is the defining presentation of $A/\mathfrak{a} \otimes_A M$ obtained by tensoring $0 \to \mathfrak{a} \to A \to A/\mathfrak{a} \to 0$ with M, and prove the induced isomorphism $A/\mathfrak{a} \otimes_A M \cong M/\mathfrak{a}M$ (identify the dashed vertical isomorphism and show the right square commutes):

$$\begin{array}{ccccccc} \mathfrak{a} \otimes_A M & \longrightarrow & A \otimes_A M & \twoheadrightarrow & A/\mathfrak{a} \otimes_A M & \longrightarrow & 0 \\ \downarrow{\scriptstyle \mu} & & \downarrow{\scriptstyle \cong} & & \downarrow{\scriptstyle \exists!} & & \\ \mathfrak{a}M & \hookrightarrow & M & \twoheadrightarrow & M/\mathfrak{a}M & \longrightarrow & 0 \end{array}$$

Identify the image of μ inside M and explain why right-exactness of $- \otimes_A M$ guarantees the dashed map exists and is an isomorphism.

15.5 Localization: Rings and Modules of Fractions

Multiplicatively closed sets and the ring of fractions

The construction of fractions is the algebraist's tool for *inverting* a chosen set of elements. The model is the passage from $\mathbb{Z}$ to $\mathbb{Q}$: there one inverts every nonzero integer. The general construction lets us invert only a prescribed family S, and – crucially – it works even when R is not a domain. Atiyah and Macdonald frame the whole chapter geometrically: $\operatorname{Spec} R$ is a space whose points are the prime ideals of R, and forming fractions *concentrates attention near a point or on an open set.* This is the algebraic shadow of localizing a function $f(x)$ near a point of the real line in order to study its differentiability.

Definition 15.5.1 (multiplicatively closed set)**.** A subset $S \subseteq R$ of a commutative ring with 1 is *multiplicatively closed* (a *multiplicative set*) if $1 \in S$ and $a, b \in S \implies ab \in S$. (D&F write D for this set; A&M write S. We use S.)

The three motivating examples already cover most of the theory:

- $S = \{\, 1, f, f^2, f^3, \dots \,\}$ for a fixed $f \in R$ (inverting one element);
- $S = R \setminus \mathfrak{p}$ for a prime ideal $\mathfrak{p}$ (the complement of a prime is multiplicative *precisely because* $\mathfrak{p}$ is prime); this is localization *at a point* $\mathfrak{p} \in \operatorname{Spec} R$;
- $S = R \setminus \{\, \text{zero divisors} \,\}$, giving the total ring of fractions (when R is a domain, $S = R \setminus \{\, 0 \,\}$ and we recover $\operatorname{Frac} R$).

Theorem 15.5.2 (ring of fractions and its universal property)**.** *Let R be a commutative ring with* 1 *and $S \subseteq R$ multiplicatively closed. There is a commutative ring $S^{-1}R$ and a ring homomorphism $\pi \colon R \to S^{-1}R$, $\pi(r) = r/1$, with the following* universal property*: for every ring homomorphism $\psi \colon R \to T$ (sending* 1 *to* 1*) such that $\psi(s)$ is a unit in T for all $s \in S$, there is a* unique *ring homomorphism $\Psi \colon S^{-1}R \to T$ with $\Psi \circ \pi = \psi$. Moreover:*

(1) $\ker \pi = \{\, r \in R :\ sr = 0 \text{ for some } s \in S \,\}$; *thus* π *is injective iff* S *contains no zero divisor of* R.

(2) $S^{-1}R = 0$ *iff* $0 \in S$.

Idea. On $R \times S$ put $(r, s) \sim (r', s')$ iff $x(s'r - sr') = 0$ for *some* $x \in S$. The extra factor x – absent in the domain case – is exactly what repairs transitivity when R has zero divisors. Write r/s for the class, set

$$\frac{r}{s} + \frac{r'}{s'} = \frac{s'r + sr'}{ss'}, \qquad \frac{r}{s} \cdot \frac{r'}{s'} = \frac{rr'}{ss'},$$

and check these are well defined; $1 = 1/1$, and each $s/1$ is a unit with inverse $1/s$. Given ψ with $\psi(S) \subseteq T^\times$, the only possible extension is $\Psi(r/s) = \psi(r)\psi(s)^{-1}$; one checks it is well defined and a homomorphism, and uniqueness is forced because every element of $S^{-1}R$ is $(r/1)(s/1)^{-1}$. □

Remark 15.5.1 (philosophy: Spec and concentration). The universal property says $S^{-1}R$ is the *universal* (initial) R-algebra in which the elements of S become invertible. Geometrically, the map $\pi^*\colon \operatorname{Spec}(S^{-1}R) \to \operatorname{Spec} R$ realizes $\operatorname{Spec}(S^{-1}R)$ as the subset of points (primes) that "survive" inverting S – those missing S. Inverting f keeps the open set where $f \neq 0$; inverting $R \setminus \mathfrak{p}$ keeps only the primes contained in $\mathfrak{p}$, i.e. concentrates on an infinitesimal neighborhood of the point $\mathfrak{p}$. This is the recurring A&M slogan: *the prime ideal is the common generalization of a prime of arithmetic and a point of geometry, and localization concentrates near such a point.*

Method (Computing in $S^{-1}R$)**.** To test $r/s = r'/s'$, clear denominators *with a slack factor*: find $x \in S$ with $x(s'r - sr') = 0$. To test $r/s = 0$, find $s' \in S$ with $s'r = 0$. To invert: $s/1$ has inverse $1/s$. Never assume $R \hookrightarrow S^{-1}R$ – that holds only when S has no zero divisors.

Worked Example 15.5.3 (The slack factor is necessary)**.** In $R = k[x, y]/(xy)$ with $S = \{\, 1, x, x^2, \dots \,\}$, show $y/1 = 0$ in $S^{-1}R = R_x$.

Recognition. Use $\ker \pi = \{\, r :\ sr = 0,\ s \in S \,\}$; here $x \cdot y = 0$ in R and $x \in S$.

Solution. Since $xy = 0$ in R and $x \in S$, the element y lies in $\ker \pi$, so $y/1 = 0/1$ in R_x. Concretely $y = xy/x = 0/x = 0$. Hence $\pi\colon R \to R_x$ is not injective: x is a zero divisor of R. In fact $\pi(R) = k[x]$ and $R_x = k[x, x^{-1}]$, the Laurent polynomials. Sanity check: the only obstruction $0 \in S$ would force $R_x = 0$; but x is not nilpotent, so $R_x \neq 0$, and indeed $k[x, x^{-1}] \neq 0$.

Worked Example 15.5.4 ($R_f \cong R[t]/(tf - 1)$)**.** For $f \in R$ and $S = \{\, f^n \,\}$, identify R_f with a quotient of a polynomial ring.

Recognition. Inverting f means adjoining a formal inverse t with $tf = 1$; the universal property pins down the isomorphism.

Solution. Let $T = R[t]/(tf - 1)$, with $\bar{t}$ the class of t, so $\bar{t}\, f = 1$ in T: thus f is a unit in T. The map $R \to T$ inverts f, so by the universal property factors uniquely through $R_f \to T$, $1/f \mapsto \bar{t}$. Conversely $R \to R_f$ sends f to a unit, so $R[t] \to R_f$, $t \mapsto 1/f$, kills $tf - 1$ and factors through $T \to R_f$. These are mutually inverse, so $R_f \cong R[t]/(tf - 1)$. Sanity check: if f is nilpotent, $f^n = 0 \in S$ forces $R_f = 0$; correspondingly $T = R[t]/(tf - 1)$ collapses, since in T we have $1 = (tf)^n = t^n f^n = t^n \cdot 0 = 0$, so $R[t]/(tf - 1) = 0$, matching.

Worked Example 15.5.5 ($\mathbb{Z}_{(p)}$ and $\mathbb{Z}[1/p]$: localizing at vs. away from (p))**.** Describe $S^{-1}\mathbb{Z}$ for $S = \mathbb{Z} \setminus (p)$, and for $S = \{\, 1, p, p^2, \dots \,\}$.

Recognition. $\mathfrak{p} = (p)$ is prime, so $S = \mathbb{Z} \setminus (p)$ is multiplicative; localizing at it inverts every integer *not* divisible by p. Inverting the powers of p does the opposite.

Solution. $\mathbb{Z}_{(p)} = \{\, a/b \in \mathbb{Q} :\ p \nmid b \,\}$: the rationals with denominator prime to p. Its unique maximal ideal is $p\mathbb{Z}_{(p)} = \{\, a/b :\ p \mid a,\ p \nmid b \,\}$, and every b with $p \nmid b$ is a unit. By contrast $\mathbb{Z}[1/p] = \{\, a/p^n \,\}$ inverts p and keeps all primes $\neq (p)$. Sanity check: (p) is the only prime meeting $S = \{\, p^n \,\}$, so $\operatorname{Spec}\mathbb{Z}[1/p]$ is $\operatorname{Spec}\mathbb{Z}$ minus the point (p); whereas $\operatorname{Spec}\mathbb{Z}_{(p)} = \{\, (0), (p) \,\}$, the two primes contained in (p) – concentration near the point (p).

Worked Example 15.5.6 (Localizing a ring of functions at a point)**.** Let R be a ring of k-valued functions on a set V containing the constants, and for $a \in V$ let $\mathfrak{m}_a = \{\, f : \ f(a) = 0 \,\}$. Identify $R_{\mathfrak{m}_a}$.

Recognition. Evaluation at a is a surjection $R \to k$ with kernel $\mathfrak{m}_a$, so $\mathfrak{m}_a$ is maximal; $S = R \setminus \mathfrak{m}_a$ consists of functions *nonvanishing* at a.

Solution. $R_{\mathfrak{m}_a} = \{\, f/g : \ f, g \in R,\ g(a) \neq 0 \,\}$. Each such fraction has a well-defined value $(f/g)(a) = f(a)/g(a) \in k$ independent of representative, so $R_{\mathfrak{m}_a}$ is a ring of "rational functions defined at a." Sanity check: the residue field is $R_{\mathfrak{m}_a}/\mathfrak{m}_a R_{\mathfrak{m}_a} \cong k$ via $f/g \mapsto f(a)/g(a)$ – evaluation at the point survives localization, which is precisely the meaning of "germ at a."

Modules of fractions and exactness

Everything above globalizes from rings to modules, and the single most important formal fact emerges: S^{-1} is an *exact* functor. A&M build the entire local theory on this one proposition.

Definition 15.5.7 (module of fractions)**.** Let M be an R-module. On $S \times M$ put $(s, m) \sim (s', m')$ iff $x(s'm - sm') = 0$ for some $x \in S$. Writing m/s for the class, the set $S^{-1}M$ of classes is an $S^{-1}R$-module under

$$\frac{m}{s} + \frac{m'}{s'} = \frac{s'm + sm'}{ss'}, \qquad \frac{r}{s} \cdot \frac{m}{s'} = \frac{rm}{ss'} \quad (r/s \in S^{-1}R).$$

There is an R-homomorphism $\pi\colon M \to S^{-1}M$, $m \mapsto m/1$, with $\ker \pi = \{\, m : \ sm = 0 \text{ for some } s \in S \,\}$. When $S = R \setminus \mathfrak{p}$ we write $M_{\mathfrak{p}}$; when $S = \{\, f^n \,\}$ we write M_f.

Proposition 15.5.8 ($S^{-1}M \cong S^{-1}R \otimes_R M$)**.** *For any R-module M there is a natural isomorphism of $S^{-1}R$-modules*

$$S^{-1}M \ \cong \ S^{-1}R \otimes_R M, \qquad m/s \ \longleftrightarrow \ (1/s) \otimes m.$$

Thus $S^{-1}M$ is obtained from M by extension of scalars *along $\pi\colon R \to S^{-1}R$.*

Idea. The map $S^{-1}R \times M \to S^{-1}M$, $(r/s, m) \mapsto rm/s$, is R-bilinear, inducing $S^{-1}R \otimes_R M \to S^{-1}M$; the rule $m/s \mapsto (1/s) \otimes m$ is a well-defined inverse (one checks independence of representative using the slack factor). Both directions are $S^{-1}R$-linear, so they are mutually inverse isomorphisms. □

Theorem 15.5.9 (exactness of localization; $S^{-1}R$ is flat)**.** *The functor $M \mapsto S^{-1}M$ is exact: if $0 \to M' \xrightarrow{f} M \xrightarrow{g} M'' \to 0$ is a short exact sequence of R-modules, then*

$$0 \to S^{-1}M' \xrightarrow{S^{-1}f} S^{-1}M \xrightarrow{S^{-1}g} S^{-1}M'' \to 0$$

is exact. Equivalently, $S^{-1}R$ is a flat *R-module, and $S^{-1}(\cdot) = S^{-1}R \otimes_R (\cdot)$ preserves injections.*

Idea. It suffices (A&M 3.3) to show S^{-1} preserves *exactness at a single spot*: if $M' \xrightarrow{f} M \xrightarrow{g} M''$ is exact at M then so is the localized sequence. "$\supseteq$": $gf = 0$ gives $S^{-1}g\, S^{-1}f = 0$. "$\subseteq$": if $(S^{-1}g)(m/s) = g(m)/s = 0$, then $t\, g(m) = 0 = g(tm)$ for some $t \in S$, so $tm = f(m')$ by exactness, whence $m/s = f(m')/(ts) = (S^{-1}f)(m'/ts)$. Applying this to $0 \to M' \to M$ shows $S^{-1}f$ is injective, giving full short-exactness; flatness is the tensor restatement. □

Remark 15.5.2 (why flatness matters)*.* Flatness is exactly the statement that localizing never creates spurious relations: a relation among fractions can always be cleared (multiply by a common $s \in S$) back to a relation in M. This is the technical engine behind every local-global principle below. A&M emphasize that flatness, injectivity of a map, and being zero are all properties that can be *checked locally.*

Worked Example 15.5.10 (Localization kills S-torsion)**.** Show $S^{-1}M = 0$ iff every $m \in M$ is annihilated by some $s \in S$ (i.e. M is S-torsion).

Recognition. $m/1 = 0$ in $S^{-1}M$ iff $sm = 0$ for some $s \in S$; $S^{-1}M = 0$ means every $m/1$, hence every m/t, is zero.

Solution. If $S^{-1}M = 0$ then $m/1 = 0$ for all m, so each m has $s_m \in S$ with $s_m m = 0$. Conversely if each m is S-torsion, then any $m/t = 0$ since $s_m(m) = 0$. Sanity check: for $R = \mathbb{Z}$, $M = \mathbb{Z}/6\mathbb{Z}$, $S = \mathbb{Z} \setminus (2)$: every element is killed by $3 \in S$? No – $3 \cdot \bar{1} = \bar{3} \neq 0$, but $3 \cdot \bar{2} = \bar{0}$; the 2-torsion-free part dies. Indeed $M_{(2)} = \mathbb{Z}/2\mathbb{Z} \neq 0$, consistent with M *not* being S-torsion. (Compare the next example.)

Worked Example 15.5.11 (Localizing a finite abelian group at a prime)**.** For $M = \mathbb{Z}/6\mathbb{Z}$ as a $\mathbb{Z}$-module, compute $M_{(p)}$ for each prime p and $M_{(0)}$.

Recognition. $M_{(p)}$ inverts all integers prime to p; this projects M onto its p-primary component (Sylow p-subgroup).

Solution. $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$. Inverting $S = \mathbb{Z} \setminus (2)$ makes 3 a unit, so the $\mathbb{Z}/3\mathbb{Z}$ summand (killed by $3 \in S$) dies: $M_{(2)} \cong \mathbb{Z}/2\mathbb{Z}$. Symmetrically $M_{(3)} \cong \mathbb{Z}/3\mathbb{Z}$. For $p \notin \{2, 3\}$, both $2, 3 \in S$ are units, so all of M is S-torsion and $M_{(p)} = 0$. At $\mathfrak{p} = (0)$, $S = \mathbb{Z} \setminus \{0\}$ inverts everything, killing the entire torsion group: $M_{(0)} = 0$. Sanity check: $M_{(p)}$ is the p-primary component, nonzero only for $p \in \{2, 3\}$, exactly the primes dividing 6.

Worked Example 15.5.12 (Localization commutes with direct sums and quotients)**.** Verify $S^{-1}(M \oplus N) \cong S^{-1}M \oplus S^{-1}N$ and $S^{-1}(M/N) \cong S^{-1}M/S^{-1}N$.

Recognition. Both follow from exactness (or from $S^{-1}R \otimes_R (\cdot)$ commuting with $\oplus$ and right-exactness).

Solution. For sums: $(m, n)/s \mapsto (m/s, n/s)$ is an $S^{-1}R$-isomorphism. For quotients: apply the exact functor S^{-1} to $0 \to N \to M \to M/N \to 0$, getting $0 \to S^{-1}N \to S^{-1}M \to S^{-1}(M/N) \to 0$, so $S^{-1}(M/N) \cong S^{-1}M/S^{-1}N$ with $S^{-1}N \subseteq S^{-1}M$ a submodule. Sanity check: take $R = \mathbb{Z}$, $M = \mathbb{Z}$, $N = 6\mathbb{Z}$, $S = \mathbb{Z} \setminus (2)$. Then $S^{-1}M = \mathbb{Z}_{(2)}$, $S^{-1}N = 6\mathbb{Z}_{(2)} = 2\mathbb{Z}_{(2)}$ (since 3 is a unit), and $\mathbb{Z}_{(2)}/2\mathbb{Z}_{(2)} \cong \mathbb{Z}/2\mathbb{Z} \cong (\mathbb{Z}/6\mathbb{Z})_{(2)}$, matching.

Worked Example 15.5.13 ($S^{-1}(\operatorname{Ann} M) = \operatorname{Ann}(S^{-1}M)$ for finitely generated M)**.** Show that for finitely generated M, localization commutes with the annihilator.

Recognition. For a *single* generator $\operatorname{Ann}(Rm)$ this is clear; reduce a finite generating set via $\operatorname{Ann}(M + N) = \operatorname{Ann} M \cap \operatorname{Ann} N$ and the fact that S^{-1} commutes with finite intersections.

Solution. If $M = Rm$ then $\operatorname{Ann}(S^{-1}M) = \{ r/s : (r/s)(m/1) = 0 \} = \{ r/s : s'rm = 0 \} = S^{-1} \operatorname{Ann}(M)$. For $M = \sum_{i=1}^{n} Rm_i$, write $\operatorname{Ann} M = \bigcap_i \operatorname{Ann}(Rm_i)$; since S^{-1} commutes with finite intersections, $S^{-1} \operatorname{Ann} M = \bigcap_i S^{-1} \operatorname{Ann}(Rm_i) = \bigcap_i \operatorname{Ann}(S^{-1}Rm_i) = \operatorname{Ann}(S^{-1}M)$. Sanity check: finiteness is needed – for $M = \bigoplus_p \mathbb{Z}/p\mathbb{Z}$ over $\mathbb{Z}$, $\operatorname{Ann} M = 0$ but $S^{-1}M$ can have nonzero annihilator after localizing away infinitely many torsion pieces.

Extension and contraction of ideals

Write $\mathfrak{a}^e = S^{-1}\mathfrak{a}$ for the extension of an ideal $\mathfrak{a} \subseteq R$ to $S^{-1}R$ (every element is a/s with $a \in \mathfrak{a}$, $s \in S$), and $\mathfrak{b}^c = \pi^{-1}(\mathfrak{b})$ for the contraction of $\mathfrak{b} \subseteq S^{-1}R$ back to R. The interaction is asymmetric and is governed by the following result.

Proposition 15.5.14 (extension/contraction under S^{-1})**.** *With the notation above:*

(1) *Every ideal $\mathfrak{b}$ of $S^{-1}R$ is extended: $\mathfrak{b} = (\mathfrak{b}^c)^e$. Hence distinct ideals of $S^{-1}R$ have distinct contractions.*

(2) *For an ideal $\mathfrak{a}$ of R, the contraction of its extension is the* saturation

$$\mathfrak{a}^{ec} = \bigcup_{s \in S} (\mathfrak{a} : s) = \{ r \in R : \ sr \in \mathfrak{a} \text{ for some } s \in S \}.$$

Moreover $\mathfrak{a}^e = S^{-1}R$ (the whole ring) iff $\mathfrak{a} \cap S \neq \varnothing$.

(3) *S^{-1} commutes with finite sums, finite intersections, products and radicals of ideals; and $S^{-1}R/S^{-1}\mathfrak{a} \cong S^{-1}(R/\mathfrak{a})$.*

(4) *If R is Noetherian (resp. Artinian), so is $S^{-1}R$.*

Idea. (1) Given $a/s \in \mathfrak{b}$, also $a/1 = s(a/s) \in \mathfrak{b}$, so $a \in \mathfrak{b}^c$ and $a/s \in (\mathfrak{b}^c)^e$; the reverse inclusion is clear. (2) $r \in \mathfrak{a}^{ec} \iff r/1 \in S^{-1}\mathfrak{a} \iff r/1 = a/s$ with $a \in \mathfrak{a} \iff x(sr - a) = 0$ some $x \in S \iff (xs)r \in \mathfrak{a}$, i.e. $r \in (\mathfrak{a} : xs)$. (3) Sums/intersections/products: clear denominators with a common s. Radicals: $(a/s)^n = a^n/s^n \in S^{-1}\mathfrak{a} \iff ta^n \in \mathfrak{a}$ some $t \iff (ta)^n \in \mathfrak{a} \iff ta \in \operatorname{rad} \mathfrak{a}$, giving $\operatorname{rad}(S^{-1}\mathfrak{a}) = S^{-1}(\operatorname{rad} \mathfrak{a})$. The quotient formula is exactness applied to $0 \to \mathfrak{a} \to R \to R/\mathfrak{a} \to 0$. (4) Chains in $S^{-1}R$ contract (injectively, by (1)) to chains in R. □

Remark 15.5.3 (saturation, geometrically). Loosely, $\mathfrak{a}^{ec}$ collects the elements that *would* lie in $\mathfrak{a}$ if denominators from S were allowed. Ideals meeting S "blow up" to the unit ideal – they vanish from $\operatorname{Spec}(S^{-1}R)$ – while primes disjoint from S are the ones localization remembers (a non-prime ideal disjoint from S can still grow under $\mathfrak{a} \mapsto \mathfrak{a}^{ec}$, as the next example shows). This is why A&M say localization *cuts out* the part of $\operatorname{Spec} R$ disjoint from S.

Worked Example 15.5.15 (Saturation that strictly enlarges $\mathfrak{a}$)**.** In $R = \mathbb{Z}$, $S = \mathbb{Z} \setminus (2)$, compute the saturation of $\mathfrak{a} = (12)$.

Recognition. $\mathfrak{a}^{ec} = \{\, r : \ sr \in (12),\ s \in S \,\}$; inverting odd numbers should strip the odd part 3 from $12 = 2^2 \cdot 3$.

Solution. With $s = 3 \in S$ and $r = 4$: $3 \cdot 4 = 12 \in (12)$, so $4 \in \mathfrak{a}^{ec}$, though $4 \notin (12)$. In general $r \in \mathfrak{a}^{ec} \iff$ some odd multiple of r is divisible by $12 = 2^2 \cdot 3 \iff 4 \mid r$ (the odd factor 3 is absorbed by S). Hence $\mathfrak{a}^{ec} = (4)$, the 2-primary part of (12). Sanity check: in $\mathbb{Z}_{(2)}$, 3 is a unit, so $(12)^e = (4 \cdot 3)^e = (4)^e$, and contracting $(4)\mathbb{Z}_{(2)}$ gives back (4) – exactly the saturation.

Worked Example 15.5.16 (An ideal that becomes the whole ring)**.** With $R = \mathbb{Z}$, $S = \mathbb{Z} \setminus (2)$, show $(3)^e = \mathbb{Z}_{(2)}$.

Recognition. $\mathfrak{a}^e = S^{-1}R$ iff $\mathfrak{a} \cap S \neq \varnothing$; here $3 \in (3) \cap S$.

Solution. Since $3 \in (3)$ and $3 \in S = \mathbb{Z} \setminus (2)$, we have $3 \in (3) \cap S$, so $(3)^e$ contains the unit $3/1$, forcing $(3)^e = \mathbb{Z}_{(2)}$. Sanity check: (3) corresponds to the point $(3) \in \operatorname{Spec}\mathbb{Z}$, which is *not* contained in (2), so it disappears when we concentrate near (2) – its extension is the unit ideal.

Worked Example 15.5.17 (Localization commutes with radicals)**.** In $R = k[x, y]$, $S = \{\, 1, y, y^2, \dots \}$, verify $\operatorname{rad}((x^2)^e) = ((x))^e$ in R_y.

Recognition. $S^{-1}(\operatorname{rad}\mathfrak{a}) = \operatorname{rad}(S^{-1}\mathfrak{a})$; here $\operatorname{rad}(x^2) = (x)$ in $k[x, y]$.

Solution. In R, $\operatorname{rad}(x^2) = (x)$. Extending: $\operatorname{rad}((x^2)^e) = (\operatorname{rad}(x^2))^e = (x)^e$ in $R_y = k[x, y, y^{-1}]$. Directly: $(x/1)^2 = x^2/1$ generates $(x^2)^e$, and its radical is generated by $x/1$. Sanity check: y is a unit in R_y and $y \notin (x)$, so the extension is a proper prime ideal (it is $(x)R_y$, with quotient $R_y/(x)R_y \cong k[y, y^{-1}]$, a domain), confirming $(x)^e$ is radical (indeed prime).

The prime correspondence and localization at a prime

The deepest structural fact is that localization *sorts the primes*: $\operatorname{Spec}(S^{-1}R)$ is exactly the part of $\operatorname{Spec} R$ disjoint from S. Specializing $S = R \setminus \mathfrak{p}$ produces a *local* ring whose single closed point is $\mathfrak{p}$ – the algebraic "germ" at the point $\mathfrak{p} \in \operatorname{Spec} R$.

Theorem 15.5.18 (prime correspondence)**.** *Extension and contraction are mutually inverse, inclusion-preserving bijections*

$$\{\, \textit{primes } \mathfrak{q} \textit{ of } R \textit{ with } \mathfrak{q} \cap S = \varnothing \,\} \ \underset{c}{\overset{e}{\rightleftharpoons}} \ \{\, \textit{primes of } S^{-1}R \,\}.$$

A prime $\mathfrak{q}$ disjoint from S extends to the prime $S^{-1}\mathfrak{q}$; conversely every prime of $S^{-1}R$ contracts to such a $\mathfrak{q}$, and $\mathfrak{q}^{ec} = \mathfrak{q}$. Primary ideals correspond to primary ideals under the same maps.

Idea. The contraction of a prime is always prime, and lands in a prime disjoint from S (else its extension is the unit ideal). For $\mathfrak{q}$ prime with $\mathfrak{q} \cap S = \varnothing$: if $(a/s)(b/t) \in S^{-1}\mathfrak{q}$, clear denominators to get $x\,ab \in \mathfrak{q}$ for some $x \in S$; since $x \notin \mathfrak{q}$ and $\mathfrak{q}$ is prime, $ab \in \mathfrak{q}$, hence $a \in \mathfrak{q}$ or $b \in \mathfrak{q}$, so a/s or $b/t \in S^{-1}\mathfrak{q}$ – thus $S^{-1}\mathfrak{q}$ is prime. Finally $\mathfrak{q}^{ec} = \mathfrak{q}$ by the saturation formula and primality. □

Theorem 15.5.19 ($R_\mathfrak{p}$ is a local ring)**.** *Let $\mathfrak{p}$ be a prime of R and $S = R \setminus \mathfrak{p}$. Then $R_\mathfrak{p} = S^{-1}R$ is a* local ring*: it has a unique maximal ideal, namely $\mathfrak{p}^e = S^{-1}\mathfrak{p} = \{\, a/s : \ a \in \mathfrak{p},\ s \notin \mathfrak{p} \,\}$. Its residue field is*

$$R_\mathfrak{p}/\mathfrak{p}R_\mathfrak{p} \ \cong \ \operatorname{Frac}(R/\mathfrak{p}),$$

the field of fractions of the domain $R/\mathfrak{p}$. The primes of $R_\mathfrak{p}$ correspond bijectively to the primes of R contained in $\mathfrak{p}$.

Idea. A prime $\mathfrak{q}$ is disjoint from $S = R \setminus \mathfrak{p}$ iff $\mathfrak{q} \subseteq \mathfrak{p}$. Among these, $\mathfrak{p}$ itself is the largest, so $S^{-1}\mathfrak{p}$ is the largest – hence unique maximal – ideal of $R_{\mathfrak{p}}$. Equivalently, every a/s with $a \notin \mathfrak{p}$ has $a \in S$, so a/s is a unit; the nonunits are exactly $S^{-1}\mathfrak{p}$, which is therefore an ideal (Prop. on local rings). The residue field statement is the quotient formula $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}} \cong S^{-1}(R/\mathfrak{p}) = \mathrm{Frac}(R/\mathfrak{p})$. □

Remark 15.5.4 (the local ring is the germ at a point). $\operatorname{Spec} R_{\mathfrak{p}}$ is the set of primes $\subseteq \mathfrak{p}$ – the points of $\operatorname{Spec} R$ that *specialize to* $\mathfrak{p}$, i.e. an infinitesimal neighborhood of the point $\mathfrak{p}$. The closed point is $\mathfrak{p}R_{\mathfrak{p}}$, the generic point is (0) when R is a domain. The residue field $\mathrm{Frac}(R/\mathfrak{p})$ is the field of values "at the point." This is the precise sense in which $R_{\mathfrak{p}}$ is the ring of germs of functions near $\mathfrak{p}$.

Worked Example 15.5.20 ($\operatorname{Spec} R_{\mathfrak{p}}$ for $R = k[x, y]$, $\mathfrak{p} = (x)$)**.** Identify the primes of the local ring $R_{(x)}$ and its residue field.

Recognition. Primes of $R_{\mathfrak{p}} \leftrightarrow$ primes $\mathfrak{q} \subseteq \mathfrak{p} = (x)$ of $k[x, y]$.

Solution. The primes of $k[x, y]$ contained in (x) are (0) and (x) itself (a prime $\mathfrak{q}$ with $(0) \subsetneq \mathfrak{q} \subsetneq (x)$ would give $\mathrm{ht}(x) \geq 2$, but (x) has height 1). So $\operatorname{Spec} R_{(x)} = \{\, (0) \subsetneq (x)R_{(x)} \,\}$, a chain of length one. The residue field is $R_{(x)}/(x)R_{(x)} \cong \mathrm{Frac}(k[x, y]/(x)) = \mathrm{Frac}(k[y]) = k(y)$. Sanity check: $\dim R_{(x)} = \mathrm{ht}(x) = 1$, matching the length-one chain of primes; the residue field $k(y)$ records the coordinate y left free along the line $x = 0$ (the transverse coordinate x vanishes there).

Worked Example 15.5.21 (Localizing at a maximal ideal: residue field k)**.** For $R = k[x, y]$ ($k = \bar{k}$) and $\mathfrak{m} = (x - a, y - b)$, compute the residue field of $R_{\mathfrak{m}}$.

Recognition. $\mathfrak{m}$ is maximal with $R/\mathfrak{m} \cong k$ (evaluation at (a, b)); localizing keeps the functions defined at the point (a, b).

Solution. $R_{\mathfrak{m}} = \{\, f/g : \ g(a, b) \neq 0 \,\}$ is the ring of rational functions regular at (a, b). Its maximal ideal is $\mathfrak{m}R_{\mathfrak{m}} = \{\, f/g : \ f(a, b) = 0 \,\}$ and the residue field is $R_{\mathfrak{m}}/\mathfrak{m}R_{\mathfrak{m}} \cong \mathrm{Frac}(R/\mathfrak{m}) = \mathrm{Frac}(k) = k$. Sanity check: evaluation $f/g \mapsto f(a, b)/g(a, b) \in k$ is a surjective ring map with kernel $\mathfrak{m}R_{\mathfrak{m}}$, and over $k = \bar{k}$ the residue field at a closed point is k itself (Nullstellensatz).

Worked Example 15.5.22 (Prime correspondence for R_f)**.** With $R = k[x]$, $f = x$, list the primes of $R_x = k[x, x^{-1}]$.

Recognition. Primes of $R_f \leftrightarrow$ primes $\mathfrak{q}$ with $\mathfrak{q} \cap \{\, 1, x, x^2, \dots \,\} = \varnothing$, i.e. primes not containing x.

Solution. Primes of $k[x]$ are (0) and the maximals $(p(x))$ for monic irreducible p. Those meeting $S = \{\, x^n \,\}$ are exactly the ones containing x, namely (x). So $\operatorname{Spec} R_x = \{\, (0) \,\} \cup \{\, (p(x)) : \ p \neq x \,\}$ – all primes except (x). Sanity check: geometrically $\operatorname{Spec} k[x, x^{-1}] = \mathbb{A}^1 \setminus \{\, 0 \,\}$, the punctured line; removing the origin (x) is exactly inverting x.

Worked Example 15.5.23 (A localization with a unique nonzero prime)**.** If $\mathfrak{p}$ is a height-one prime of a domain R that is minimal among nonzero primes, show $R_{\mathfrak{p}}$ has exactly one nonzero prime.

Recognition. Primes of $R_{\mathfrak{p}} \leftrightarrow$ primes $\subseteq \mathfrak{p}$; minimality of $\mathfrak{p}$ over (0) leaves only (0) and $\mathfrak{p}$.

Solution. The primes of R contained in $\mathfrak{p}$ are (0) (since R is a domain) and $\mathfrak{p}$ (if $\mathfrak{p}$ is minimal nonzero, nothing sits strictly between). Hence $\operatorname{Spec} R_{\mathfrak{p}} = \{\, (0), \mathfrak{p}R_{\mathfrak{p}} \,\}$, so $R_{\mathfrak{p}}$ has the single nonzero prime $\mathfrak{p}R_{\mathfrak{p}}$, which is also maximal. Sanity check: $R = \mathbb{Z}$, $\mathfrak{p} = (p)$ gives $R_{\mathfrak{p}} = \mathbb{Z}_{(p)}$, a DVR with the unique nonzero prime $(p)\mathbb{Z}_{(p)}$ – the prototypical local ring of dimension one.

The local-global principle

The payoff of all the above is a dictionary: many properties of a module or a map hold globally *iff* they hold at every localization. "Being zero," injectivity, surjectivity, and flatness are all *local* properties. This is the technique A&M call passing between local and global, and it underlies essentially all of dimension theory.

Theorem 15.5.24 ($M = 0$ is local)**.** *Let M be an R-module. The following are equivalent:*

(1) $M = 0$*;*

(2) $M_{\mathfrak{p}} = 0$ *for every prime $\mathfrak{p}$ of R;*

(3) $M_{\mathfrak{m}} = 0$ *for every maximal ideal* $\mathfrak{m}$ *of* R.

Idea. (1)$\Rightarrow$(2)$\Rightarrow$(3) are trivial. For (3)$\Rightarrow$(1): if $0 \neq m \in M$, then $\operatorname{Ann}(m)$ is a proper ideal, so it lies in some maximal $\mathfrak{m}$. In $M_{\mathfrak{m}}$, the class $m/1 = 0$ would give $sm = 0$ for some $s \notin \mathfrak{m}$ – but then $s \in \operatorname{Ann}(m) \subseteq \mathfrak{m}$, a contradiction. So $M_{\mathfrak{m}} \neq 0$, against (3). Hence $M = 0$. □

Corollary 15.5.25 (injectivity and surjectivity are local)**.** *An R-module map $\varphi\colon M \to N$ is injective (resp. surjective, resp. an isomorphism) iff $\varphi_{\mathfrak{m}}\colon M_{\mathfrak{m}} \to N_{\mathfrak{m}}$ is injective (resp. surjective, iso) for every maximal ideal $\mathfrak{m}$.*

Idea. By exactness, $(\ker\varphi)_{\mathfrak{m}} = \ker(\varphi_{\mathfrak{m}})$ and $(\operatorname{coker}\varphi)_{\mathfrak{m}} = \operatorname{coker}(\varphi_{\mathfrak{m}})$. Apply the theorem to $\ker\varphi$ (resp. $\operatorname{coker}\varphi$): it is 0 iff all its localizations vanish iff each $\varphi_{\mathfrak{m}}$ is injective (resp. surjective). □

Remark 15.5.5 (flatness is local too). A&M record (3.10) that flatness of M is equivalent to flatness of every $M_{\mathfrak{p}}$, equivalently every $M_{\mathfrak{m}}$. The proof is the same localize-the-kernel argument applied to the criterion "$N \to P$ injective $\Rightarrow M \otimes N \to M \otimes P$ injective," using that $\otimes$ commutes with localization. The pattern – *a property is global iff local at every maximal ideal* – is the organizing principle of commutative algebra.

Proposition 15.5.26 (a domain is the intersection of its localizations)**.** *If R is an integral domain with fraction field F, then inside F,*

$$R = \bigcap_{\mathfrak{p}} R_{\mathfrak{p}} = \bigcap_{\mathfrak{m}} R_{\mathfrak{m}},$$

the intersection over all primes, equivalently over all maximal ideals.

Idea. Clearly $R \subseteq \bigcap_{\mathfrak{m}} R_{\mathfrak{m}}$. If $a \in F$ lies in every $R_{\mathfrak{m}}$, set $\mathfrak{a} = \{\, d \in R : \ da \in R \,\}$, an ideal with $a \in R \iff \mathfrak{a} = R$. If $\mathfrak{a} \neq R$, pick a maximal $\mathfrak{m} \supseteq \mathfrak{a}$; since $a \in R_{\mathfrak{m}}$, $a = r/d$ with $d \notin \mathfrak{m}$, so $d \in \mathfrak{a} \setminus \mathfrak{m}$, contradiction. Hence $\mathfrak{a} = R$ and $a \in R$. □

Worked Example 15.5.27 (Detecting $M = 0$ locally)**.** Let $R = \mathbb{Z}$ and M an abelian group with $M_{(p)} = 0$ for all primes p and $M_{(0)} = 0$. Conclude $M = 0$.

Recognition. The local-global principle: $M = 0 \iff M_{\mathfrak{m}} = 0$ for all maximal $\mathfrak{m}$; the maximal ideals of $\mathbb{Z}$ are the (p).

Solution. Every maximal ideal of $\mathbb{Z}$ is (p) for a prime p, and by hypothesis each $M_{(p)} = 0$. By the theorem, $M = 0$. Sanity check: contrapositively, if $M \neq 0$ pick $0 \neq m$; $\operatorname{Ann}(m) = (n)$ for some $n \geq 0$; choose a prime $p \mid n$ (or p arbitrary if $n = 0$) with $(p) \supseteq \operatorname{Ann}(m)$ – then $m/1 \neq 0$ in $M_{(p)}$, contradicting $M_{(p)} = 0$.

Worked Example 15.5.28 (Local-global for injectivity)**.** Show $\varphi\colon \mathbb{Z} \xrightarrow{2} \mathbb{Z}$ is injective by checking it locally.

Recognition. Injectivity is local: φ injective iff $\varphi_{(p)}$ injective for all primes p.

Solution. At (2): $\varphi_{(2)}\colon \mathbb{Z}_{(2)} \to \mathbb{Z}_{(2)}$ is multiplication by 2, injective on the domain $\mathbb{Z}_{(2)}$ (no zero divisors). At (p), $p \neq 2$: 2 is a unit in $\mathbb{Z}_{(p)}$, so $\varphi_{(p)}$ is an isomorphism, hence injective. At (0): multiplication by 2 on $\mathbb{Q}$ is injective. All localizations injective $\Rightarrow \varphi$ injective. Sanity check: $\operatorname{coker}\varphi = \mathbb{Z}/2\mathbb{Z}$ is *not* zero, so φ is not surjective – and indeed $\operatorname{coker}(\varphi_{(2)}) = \mathbb{Z}_{(2)}/2\mathbb{Z}_{(2)} \cong \mathbb{Z}/2\mathbb{Z} \neq 0$, correctly detecting non-surjectivity at the single prime (2).

Worked Example 15.5.29 ($\mathbb{Z} = \bigcap_p \mathbb{Z}_{(p)}$ concretely)**.** Verify that a rational a/b (in lowest terms) lies in every $\mathbb{Z}_{(p)}$ iff $a/b \in \mathbb{Z}$.

Recognition. $\mathbb{Z} = \bigcap_{\mathfrak{m}} \mathbb{Z}_{(\mathfrak{m})}$; $a/b \in \mathbb{Z}_{(p)} \iff p \nmid b$.

Solution. If a/b in lowest terms has $b > 1$, take a prime $p \mid b$; then $a/b \notin \mathbb{Z}_{(p)}$, so a/b fails to be in the intersection. If $b = 1$, then $a/b = a \in \mathbb{Z} \subseteq \mathbb{Z}_{(p)}$ for all p. Hence $\bigcap_p \mathbb{Z}_{(p)} = \mathbb{Z}$. Sanity check: $1/6 \notin \mathbb{Z}_{(2)}$ and $\notin \mathbb{Z}_{(3)}$ (caught at the primes dividing the denominator), but $1/6 \in \mathbb{Z}_{(5)}$ – so $1/6$ is excluded from the intersection exactly because it is not an integer.

Worked Example 15.5.30 (Normality is local)**.** State and use the criterion: a domain R is integrally closed iff every $R_{\mathfrak{m}}$ is.

Recognition. Like $M = 0$, integral closure is detected at maximal ideals, via $R = \bigcap_{\mathfrak{m}} R_{\mathfrak{m}}$.

Solution. If R is normal and $y \in F$ is integral over $R_{\mathfrak{p}}$, clearing the (finitely many) denominators $d_i \notin \mathfrak{p}$ shows $y' = y(d_0 \cdots d_{n-1})^n$ is integral over R, hence $y' \in R$, hence $y \in R_{\mathfrak{p}}$: so $R_{\mathfrak{p}}$ is normal. Conversely if each $R_{\mathfrak{m}}$ is normal and $y \in F$ is integral over R, then y is integral over each $R_{\mathfrak{m}}$, so $y \in R_{\mathfrak{m}}$ for all $\mathfrak{m}$, whence $y \in \bigcap_{\mathfrak{m}} R_{\mathfrak{m}} = R$: R is normal. Sanity check: $R = k[t^2, t^3]$ is not normal; its non-normality localizes to the single maximal ideal $\mathfrak{m} = (t^2, t^3)$, where $R_{\mathfrak{m}}$ fails to be integrally closed ($t = t^3/t^2$ is integral but not in $R_{\mathfrak{m}}$), pinpointing the singular point.

Synthesis: localization as a map of spectra

All the threads converge in one commutative-algebra-meets-geometry picture. The ring map $\pi\colon R \to S^{-1}R$ induces $\operatorname{Spec}(S^{-1}R) \hookrightarrow \operatorname{Spec} R$ identifying $\operatorname{Spec}(S^{-1}R)$ with the primes disjoint from S; for $S = R \setminus \mathfrak{p}$ this is the inclusion of the local primes $\{\, \mathfrak{q} \subseteq \mathfrak{p} \,\}$, and for $S = \{\, f^n \,\}$ it is the distinguished open $D(f) = \{\, \mathfrak{q} :\ f \notin \mathfrak{q} \,\}$. The square below shows how localizing at $\mathfrak{p}$ *factors* through localizing at f for $f \notin \mathfrak{p}$ (a smaller open set containing the point $\mathfrak{p}$), with the same local ring $R_{\mathfrak{p}}$ (residue field $\kappa(\mathfrak{p}) = \operatorname{Frac}(R/\mathfrak{p})$) recovered at the bottom.

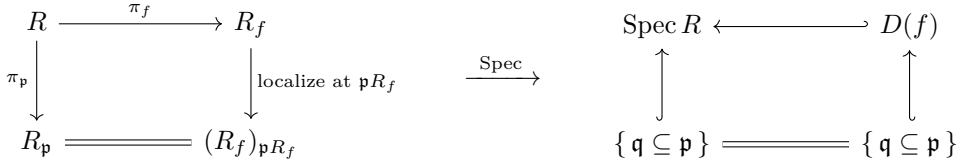


Diagram explanation. Objects: There are two paired diagrams. In the ring square (left): R is the base commutative ring; $R_f = S^{-1}R$ with $S = \{f^n\}$ is the localization inverting f; $R_{\mathfrak{p}} = (R \setminus \mathfrak{p})^{-1}R$ is the localization at the prime $\mathfrak{p}$; $(R_f)_{\mathfrak{p}R_f}$ is R_f further localized at the prime $\mathfrak{p}R_f$ of R_f (the image of $\mathfrak{p}$ in R_f, which is prime because $f \notin \mathfrak{p}$ ensures $\mathfrak{p}$ survives to R_f). In the Spec square (right): $\operatorname{Spec} R$ is the full prime spectrum; $D(f)$ is the distinguished open set $\{\mathfrak{q} \in \operatorname{Spec} R : f \notin \mathfrak{q}\}$, the image of $\operatorname{Spec} R_f$; the two copies of $\{\mathfrak{q} \subseteq \mathfrak{p}\}$ are the Spec of $R_{\mathfrak{p}}$, the set of primes contained in $\mathfrak{p}$.

Arrows: Ring square: $\pi_f\colon R \to R_f$, $r \mapsto r/1$, is the canonical localization map inverting f; $\pi_{\mathfrak{p}}\colon R \to R_{\mathfrak{p}}$, $r \mapsto r/1$, is the canonical localization map inverting $R \setminus \mathfrak{p}$; the right vertical arrow localizes R_f at $\mathfrak{p}R_f$, sending $r/f^n \mapsto (r/f^n)/1$; the bottom equality asserts the two iterated localizations coincide. Spec square: $D(f) \hookrightarrow \operatorname{Spec} R$ is the open immersion, the injection on spectra induced by π_f; the left vertical inclusion $\{\mathfrak{q} \subseteq \mathfrak{p}\} \hookrightarrow \operatorname{Spec} R$ is the injection on spectra induced by $\pi_{\mathfrak{p}}$; the equality on the bottom says $\operatorname{Spec} R_{\mathfrak{p}}$ is the same subset whether reached via R or via R_f first; the right vertical inclusion $\{\mathfrak{q} \subseteq \mathfrak{p}\} \hookrightarrow D(f)$ holds because any $\mathfrak{q} \subseteq \mathfrak{p}$ satisfies $f \notin \mathfrak{q}$ (since $f \in \mathfrak{q}$ would give $f \in \mathfrak{q} \subseteq \mathfrak{p}$, contradicting $f \notin \mathfrak{p}$).

What commutes: In the ring square, down-then-right equals right-then-down: (localize at $\mathfrak{p}R_f$) $\circ\, \pi_f = \pi_{\mathfrak{p}}$, i.e., $(R_f)_{\mathfrak{p}R_f} = R_{\mathfrak{p}}$ as R-algebras. Concretely: any r/s with $s \notin \mathfrak{p}$ can be reached from R either by first inverting f (giving $r/1$ and $s/1$ in R_f) then localizing at $\mathfrak{p}R_f$, where $s/1$ becomes a unit, or directly as r/s in $R_{\mathfrak{p}}$. In the Spec square, both paths from the lower-right corner to the upper-left corner $\operatorname{Spec} R$ give the same inclusion: the primes $\subseteq \mathfrak{p}$ that miss f sit inside $D(f)$ inside $\operatorname{Spec} R$.

Why it commutes: Chase a generic element $r/s \in R_{\mathfrak{p}}$ (so $r \in R$, $s \notin \mathfrak{p}$). Via the right-then-down path: first map r to $r/1 \in R_f$, then to $(r/1)/1 \in (R_f)_{\mathfrak{p}R_f}$; s maps to $s/1 \in R_f$, which is a unit in $(R_f)_{\mathfrak{p}R_f}$ because $s \notin \mathfrak{p}$ means $s/1 \notin \mathfrak{p}R_f$, so $(r/1)/(s/1) = r/s$ in $(R_f)_{\mathfrak{p}R_f}$. Via the left-then-bottom path: the canonical map $R \to R_{\mathfrak{p}}$ sends $r \mapsto r/s \cdot s/1$; inverting s gives r/s. The universal property of localization ensures uniqueness: both $(R_f)_{\mathfrak{p}R_f}$ and $R_{\mathfrak{p}}$ invert exactly $R \setminus \mathfrak{p}$, so by universality there is a unique isomorphism between them compatible with the maps from R. Well-definedness of the induced map $(R_f)_{\mathfrak{p}R_f} \to R_{\mathfrak{p}}$ requires checking that a fraction r/s with $s/1 \in \mathfrak{p}R_f$ cannot arise when $s \notin \mathfrak{p}$ – indeed $s/1 \in \mathfrak{p}R_f$ iff $s \in \mathfrak{p}$, so the condition exactly matches.

Why this matters here: This diagram crystallizes the synthesis paragraph's key claim: localizing at a prime $\mathfrak{p}$ is a two-step process – first restrict to the open set $D(f)$ containing $\mathfrak{p}$ (by inverting f), then localize the resulting ring at its prime $\mathfrak{p}R_f$. It shows that the global prime $\mathfrak{p}$ and the local prime $\mathfrak{p}R_f$ encode the same data, and that the local ring $R_{\mathfrak{p}}$ (with residue field $\kappa(\mathfrak{p}) = \operatorname{Frac}(R/\mathfrak{p})$) is the common value at the bottom of both paths. The Spec dual makes the geometric content visible: the infinitesimal neighborhood $\{\mathfrak{q} \subseteq \mathfrak{p}\}$ of the point $\mathfrak{p}$ is equally well described as the intersection $D(f) \cap \operatorname{Spec} R_{\mathfrak{p}}$.

Concrete example: Take $R = \mathbb{Z}$, $\mathfrak{p} = (2)$, $f = 3$. Then $R_f = \mathbb{Z}[1/3]$ and $\mathfrak{p}R_f = 2\mathbb{Z}[1/3]$. Localizing at $\mathfrak{p}R_f$: $(\mathbb{Z}[1/3])_{(2)} = \{a/b \in \mathbb{Q} : b \text{ odd}\} = \mathbb{Z}_{(2)}$, which equals $R_\mathfrak{p} = \mathbb{Z}_{(2)}$ directly. Spec side: $D(3) = \operatorname{Spec}\mathbb{Z} \setminus \{(3)\}$ contains (2), and $\operatorname{Spec}\mathbb{Z}_{(2)} = \{(0), (2)\} \subseteq D(3) \subseteq \operatorname{Spec}\mathbb{Z}$, with all three inclusions matching the diagram.

Common pitfall: Students often think $(R_f)_{\mathfrak{p}R_f}$ is a further localization that *strictly* enlarges $R_\mathfrak{p}$, inverting more elements. In fact it inverts exactly the same set $R \setminus \mathfrak{p}$ as $R_\mathfrak{p}$ does, so both sides are the same ring by the universal property. The equality arrow on the bottom of the ring square is a genuine identity of R-algebras, not merely a map – do not treat it as an inclusion or an approximation.

Takeaway: The point of this diagram is that localizing at a prime $\mathfrak{p}$ factors through any distinguished open $D(f)$ containing $\mathfrak{p}$, so $R_\mathfrak{p}$ can be computed in stages, and the geometric picture (an infinitesimal neighborhood of $\mathfrak{p}$ inside $\operatorname{Spec} R$) is faithfully captured by either route.

Caution. Localization need not be surjective on rings (e.g. $\mathbb{Z} \to \mathbb{Z}_{(2)}$ misses $1/3$) and need not be injective: $R \to S^{-1}R$ has kernel the S-torsion. And "local property" is one-directional in subtlety: $M = 0$, injectivity, flatness localize correctly, but properties like "R is a domain" do *not* – every $R_\mathfrak{m}$ can be a domain while R is not (e.g. $R = \mathbb{Z}/6\mathbb{Z}$: $R_{(2)} \cong \mathbb{Z}/2\mathbb{Z}$ and $R_{(3)} \cong \mathbb{Z}/3\mathbb{Z}$ are fields, yet R has zero divisors). Always check whether the property you want is genuinely local.

Worked Example 15.5.31 (Reading the spectrum of R_f as a distinguished open)**.** For $R = k[x, y]$, $f = x$, describe $\operatorname{Spec} R_x$ as an open subset of $\operatorname{Spec} R$ and find its dimension.

Recognition. $\operatorname{Spec} R_f = D(f) = \{\, \mathfrak{q} : \ f \notin \mathfrak{q} \,\}$; inverting x removes exactly the primes containing x.

Solution. The primes containing x are those of $k[x, y]$ with $x \in \mathfrak{q}$, i.e. the primes of $k[x, y]/(x) \cong k[y]$ pulled back – the line $V(x)$. So $\operatorname{Spec} R_x = \operatorname{Spec} k[x, y] \setminus V(x) = \mathbb{A}^2 \setminus \{\, x = 0 \,\}$, the complement of a line. Its dimension is still 2 (an open dense subset of the plane). Sanity check: $\dim R_x \le \dim k[x, y] = 2$ because the primes of R_x correspond to primes of $k[x, y]$ (preserving inclusions), and the chain $(0) \subsetneq (y) \subsetneq (x - 1, y)$ of primes not containing x gives $\dim R_x \ge 2$; so $\dim R_x = 2$. (For a general domain, inverting one nonzero element can lower the dimension: $\dim \mathbb{Z}_{(2)} = 1$ but $\mathbb{Z}_{(2)}[1/2] = \mathbb{Q}$ has dimension 0.)

Worked Example 15.5.32 (Factoring $R_\mathfrak{p}$ through R_f)**.** Show that for $f \notin \mathfrak{p}$, $R_\mathfrak{p} = (R_f)_{\mathfrak{p}R_f}$, i.e. localizing at $\mathfrak{p}$ is unchanged by first inverting an $f \notin \mathfrak{p}$.

Recognition. Both rings invert exactly $R \setminus \mathfrak{p}$: in R_f, the prime $\mathfrak{p}R_f$ has complement $S_f = \{\, g/f^n : \ g \notin \mathfrak{p} \,\}$, and re-localizing inverts these.

Solution. The composite $R \to R_f \to (R_f)_{\mathfrak{p}R_f}$ inverts every element of $R \setminus \mathfrak{p}$ (since $f \notin \mathfrak{p}$ is already inverted, and everything outside $\mathfrak{p}R_f$ is inverted in the second step). By the universal property there is a unique map $R_\mathfrak{p} \to (R_f)_{\mathfrak{p}R_f}$; conversely $(R_f)_{\mathfrak{p}R_f}$ inverts only elements that are units in $R_\mathfrak{p}$, giving the inverse. Hence the two coincide. Sanity check: take $R = \mathbb{Z}$, $\mathfrak{p} = (2)$, $f = 3$. Then $R_f = \mathbb{Z}[1/3]$ and $(\mathbb{Z}[1/3])_{(2)} = \{\, a/b : \ b \text{ odd} \,\} = \mathbb{Z}_{(2)}$, since inverting 3 then localizing at 2 recovers exactly the integers localized at 2. Matches.

Worked Example 15.5.33 (Primary ideals under localization)**.** Let $\mathfrak{q}$ be $\mathfrak{p}$-primary in R and S a multiplicative set. Describe $S^{-1}\mathfrak{q}$ in the two cases $S \cap \mathfrak{p} = \varnothing$ and $S \cap \mathfrak{p} \neq \varnothing$.

Recognition. Primary ideals correspond to primary ideals when their radical misses S; if the radical meets S, the extension is the whole ring.

Solution. If $S \cap \mathfrak{p} \neq \varnothing$, pick $s \in S \cap \mathfrak{p}$; some power $s^n \in \mathfrak{q}$ (as $\mathfrak{p} = \operatorname{rad}\mathfrak{q}$), and $s^n \in S$, so $S^{-1}\mathfrak{q} = S^{-1}R$. If $S \cap \mathfrak{p} = \varnothing$, then $S^{-1}\mathfrak{p}$ is prime and $S^{-1}\mathfrak{q}$ is $S^{-1}\mathfrak{p}$-primary with contraction back to R equal to $\mathfrak{q}$ (using that $dr \in \mathfrak{q}$, $d \notin \mathfrak{p}$ force $r \in \mathfrak{q}$ by primariness). Sanity check: $R = \mathbb{Z}$, $\mathfrak{q} = (4)$ (which is (2)-primary), $S = \mathbb{Z} \setminus (2)$ gives $S^{-1}(4) = 4\mathbb{Z}_{(2)}$, still $(2)\mathbb{Z}_{(2)}$-primary, contracting to (4); whereas $S = \mathbb{Z} \setminus (3)$ meets (2) at 2, and $2 \in S$ inverts, so $S^{-1}(4) = \mathbb{Z}_{(3)}$, the whole ring.

Worked Example 15.5.34 (Localization and minimal primary decomposition)**.** For a minimal primary decomposition $\mathfrak{a} = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_m$ in a Noetherian R with $\mathfrak{q}_i$ being $\mathfrak{p}_i$-primary, describe $S^{-1}\mathfrak{a}$ when S misses $\mathfrak{p}_1, \ldots, \mathfrak{p}_t$ and meets $\mathfrak{p}_{t+1}, \ldots, \mathfrak{p}_m$.

Recognition. S^{-1} commutes with finite intersection; components whose radical meets S extend to the unit ideal and drop out.

Solution. Since $S^{-1}(\mathfrak{q}_i) = S^{-1}R$ for $i > t$ (their primes meet S) and these are units in the intersection, $S^{-1}\mathfrak{a} = S^{-1}\mathfrak{q}_1 \cap \cdots \cap S^{-1}\mathfrak{q}_t$, a minimal primary decomposition in $S^{-1}R$ with $S^{-1}\mathfrak{q}_i$ being $S^{-1}\mathfrak{p}_i$-primary. Contracting back, $(S^{-1}\mathfrak{a})^c = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_t$. Sanity check: taking $S = R \setminus \mathfrak{p}$ for a *minimal* prime $\mathfrak{p}$ of $\mathfrak{a}$ keeps only the single component $\mathfrak{q}$ belonging to $\mathfrak{p}$, which proves the primary component at an isolated prime is uniquely determined by $\mathfrak{a}$ – the local characterization of the isolated components.

As usual R is a commutative ring with 1 and D is a multiplicatively closed set in R.

Exercises (Dummit & Foote).

1. Suppose M is a finitely generated R-module. Prove that $D^{-1}M = 0$ if and only if $dM = 0$ for some $d \in D$.
2. Let I be an ideal in R, let D be a multiplicatively closed subset of R with ring of fractions $D^{-1}R$, and let $c(eI)$ be the saturation of I with respect to D.
   (a) Prove that $c(eI) = R$ if and only if $eI = D^{-1}R$ if and only if $I \cap D \neq \emptyset$.
   (b) Prove that $I = c(eI)$ is saturated if and only if for every $d \in D$, if $da \in I$ then $a \in I$.
   (c) Prove that extension and contraction define inverse bijections between the ideals of R saturated with respect to D and the ideals of $D^{-1}R$.
   (d) Let $I = (2x, 3y) \subseteq \mathbb{Z}[x, y]$. Show the saturation of I with respect to $\mathbb{Z} - \{0\}$ is (x, y).
3. If I is an ideal in the commutative ring R let $\varphi : R[x_1, \ldots, x_n] \to (R/I)[x_1, \ldots, x_n]$ be the ring homomorphism with kernel $I[x_1, \ldots, x_n]$ given by reducing coefficients modulo I. If $\overline{A}$ is an ideal in $(R/I)[x_1, \ldots, x_n]$, let A denote the inverse image of $\overline{A}$ under φ.
   (a) For any $i \geq 1$ show that the inverse image under φ of the subring $(R/I)[x_1, \ldots, x_i]$ is $R[x_1, \ldots, x_i] + I[x_1, \ldots, x_n]$.
   (b) Prove that $\varphi(A \cap R[x_1, \ldots, x_i]) = \overline{A} \cap (R/I)[x_1, \ldots, x_i]$.
4. Let $f = y^5 - z^4$, viewed as a polynomial in y with coefficients in $\mathbb{Q}[z]$.
   (a) Prove that f has no roots in $\mathbb{Q}[z]$.
   (b) Suppose $f = (y^2 + ay + b)(y^3 + cy^2 + dy + e)$. Show that a, b, c, d, e satisfy the system of equations
   $$a + c = 0, \quad ac + b + d = 0, \quad ad + bc + e = 0, \quad ae + bd = 0, \quad be + z^4 = 0.$$
   Deduce that $e^5 = -z^{12}$ and conclude that f is irreducible in $\mathbb{Q}[y, z]$. [Use elimination.]
5. Suppose R is a U.F.D. with field of fractions F and $p \in R[x]$ is a monic polynomial.
   (a) Show that the ideal $pR[x]$ generated by p in $R[x]$ is prime if and only if the ideal $pF[x]$ generated by p in $F[x]$ is prime. [Use Gauss' Lemma.]
   (b) Show that $pR[x]$ is saturated, i.e., that $pF[x] \cap R[x] = pR[x]$.
6. Show that $I = (y^3 - xz, xy^2 - z^2)$ is not a prime ideal in $\mathbb{Q}[x, y, z]$ and find explicit elements $a, b \in \mathbb{Q}[x, y, z]$ with $ab \in I$ but $a \notin I$ and $b \notin I$.
7. Show that $P = (y^3 - xz, xy^2 - z^2, x^2 - yz)$ is a prime ideal in $\mathbb{Q}[x, y, z]$.
8. Show that $P = (x^2 - yz, w^2 - x^4 z)$ is a prime ideal in $\mathbb{Q}[x, y, z, w]$.
9. Show that $P = (xz^2 - w^3, xw^2 - y^4, y^4 z^2 - w^5)$ is a prime ideal in $\mathbb{Q}[x, y, z, w]$.
10. Show that $I = (xy - w^3, y^2 - zw)$ is not a prime ideal in $\mathbb{Q}[x, y, z, w]$ and find a, b with $ab \in I$ but $a, b \notin I$.
11. Let R_P be the localization of R at the prime P. Prove that if Q is a P-primary ideal of R then $Q = c(eQ)$ with respect to the extension and contraction of Q to R_P. Show the same result holds if Q is P'-primary for some prime P' contained in P.
12. Let $R = \mathbb{R}[x, y, z]/(xy - z^2)$, let $P = (\bar{x}, \bar{z})$ be the prime ideal generated by the images of x and z in R, and let R_P be the localization of R at P. Prove that $P^2 R_P \cap R = (\bar{x})$ and is strictly larger than P^2.

13. Prove that if N and N' are two R-submodules of an R-module M with $N_P = N'_P$ in the localization M_P for every prime ideal P of R (or just for every maximal ideal) then $N = N'$.

14. Suppose $\varphi : M \to N$ is an R-module homomorphism. Prove that φ is injective (respectively, surjective) if and only if the induced R_P-module homomorphism $\varphi : M_P \to N_P$ is injective (respectively, surjective) for every prime ideal P of R (or just for every maximal ideal of R).

15. Let $R = \mathbb{Z}[\sqrt{-5}]$ be the ring of integers in the quadratic field $\mathbb{Q}(\sqrt{-5})$ and let I be the prime ideal $(2, 1 + \sqrt{-5})$ of R generated by 2 and $1 + \sqrt{-5}$ (cf. Exercise 5, Section 8.2). Recall that every nonzero prime ideal P of R contains a prime $p \in \mathbb{Z}$.

    (a) If P is a prime ideal of R not containing 2 prove that $I_P = R_P$.

    (b) If P is a prime ideal of R containing 2 prove that $P = I$ and that $I_P = (1 + \sqrt{-5})R_P$.

    (c) Prove that $I_P \cong R_P$ as R_P-modules for every prime ideal P of R but that I and R are not isomorphic R-modules. (This example shows that it is important in Exercise 14 to be given the R-module homomorphism φ.) [Observe that $I \cong R$ as R-modules if and only if I is a principal ideal.]

16. Prove that localization commutes with tensor products: there is a unique isomorphism of $D^{-1}R$-modules $\varphi : (D^{-1}M) \otimes_{D^{-1}R} (D^{-1}N) \to D^{-1}(M \otimes_R N)$ with $\varphi((m/d) \otimes (n/d')) = (m \otimes n)/dd'$ for any R-modules M, N, and multiplicatively closed set D in R.

17. Prove that the R-module A is a flat R-module if and only if A_P is a flat R_P-module for every prime ideal P of R (or just for every maximal ideal of R). [Use Proposition 41, Exercises 14 and 16, and the exactness properties of localization.]

18. In the notation of Example 2 following Corollary 37, prove that $R_f \cong R[x]/(fx - 1)$ if f is not nilpotent in R. [Show that the map $\varphi : R[x] \to R_f$ defined by $\varphi(r) = r/1$ and $\varphi(x) = 1/f$ gives a surjective ring homomorphism and the universal property in Theorem 36 gives an inverse.]

19. Prove that if R is an integrally closed integral domain and D is any multiplicatively closed subset of R containing 1, then $D^{-1}R$ is integrally closed.

20. Suppose that R is a subring of the ring S with $1 \in R$ and that S is integral over R. If D is any multiplicatively closed subset of R, prove that $D^{-1}S$ is integral over $D^{-1}R$.

21. Suppose $\varphi : R \to S$ is a ring homomorphism and D' is a multiplicatively closed subset of S. Let $D = \varphi^{-1}(D')$. Prove that D is a multiplicatively closed subset of R and that the map $\varphi' : D^{-1}R \to D'^{-1}S$ given by $\varphi'(r/d) = \varphi(r)/\varphi(d)$ is a ring homomorphism.

22. Suppose $P \subseteq Q$ are prime ideals in R and let R_Q be the localization of R at Q. Prove that the localization R_P is isomorphic to the localization of R_Q at the prime ideal PR_Q (cf. the preceding exercise).

23. Let $\varphi : A \to B$ be a homomorphism of commutative rings with $\varphi(1_A) = 1_B$, and let P be a prime ideal of A. Let contraction and extension of ideals with respect to φ be denoted by superscripts c and e respectively. Prove that P is the contraction of a prime ideal in B if and only if $P = (P^e)^c$. [Localize B at $\varphi(A - P)$.]

24. *(The Going-down Theorem)* Let S be an integral domain, let R be an integrally closed subring of S containing 1_S such that S is integral over R, and let k be the field of fractions of R. Suppose that $P_2 \subseteq P_1$ are prime ideals in R and that Q_1 is a prime ideal in S with $Q_1 \cap R = P_1$. Let S_{Q_1} be the localization of S at Q_1.

    (a) Show that $P_2 \subseteq P_2 S_{Q_1} \cap R$.

    (b) Suppose that $a \in P_2 S_{Q_1} \cap R$ and write $a = s/d$ with $s \in P_2 S$ and $d \in S$, $d \notin Q_1$. If the minimal polynomial of s over k is $x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$ with $a_0, \ldots, a_{n-1} \in P_2$ (cf. Exercise 12 in Section 3) show that the minimal polynomial of d over k is $x^n + b_{n-1}x^{n-1} + \cdots + b_1 x + b_0$ where $b_i = a_i/a^{n-i}$ and conclude that $b_i \in R$. [Use Exercise 10 in Section 3.]

    (c) Show that $a \in P_2$ and conclude that $P_2 S_{Q_1} \cap R = P_2$. [Show $a \notin P_2$ implies $b_i \in P_2$ for $i = 0, 1, \ldots, n-1$, which would imply $d^n \in P_2 S \subseteq P_1 S \subseteq Q_1$ and so $d \in Q_1$.]

(d) Prove that $P_2 S_{Q_1}$ is contained in a prime ideal P of S_{Q_1} with $P \cap R = P_2$. [Use (c) and the previous exercise for $\varphi : R \to S_{Q_1}$.]

(e) Let $Q_2 = P \cap S$. Prove that $Q_2 \subseteq Q_1$ and that $Q_2 \cap R = P_2$.

(f) Use induction together with the previous result to prove the Going-down Theorem: Theorem 26(4).

25. Let k be an algebraically closed field and let $V = Z(xz - yw) \subseteq \mathbb{A}^4$. Prove that the set of points v where $f = x/y \in k(V)$ is regular is precisely the set of points (x, y, z, w) where $y \neq 0$ or $z \neq 0$. [If $f = a/b$ show that $ay - bx \in (xz - yw)$ as polynomials in $k[x, y, z, w]$ and conclude that $b \in (y, z)$.] Prove that there is no function $a/b \in k(V)$ with $b(v) \neq 0$ for every v where f is regular.

26. *(Differentials of Morphisms)* Let $\varphi : V \to W$ be a morphism of affine varieties over the algebraically closed field k and suppose $\varphi(v) = w$.

(a) Show that φ induces a linear map from the k-vector space M_w/M_w^2 to the k-vector space M_v/M_v^2 and use this to show that φ induces a linear map $d\varphi$ (called the *differential* of φ) from the k-vector space $\mathbb{T}_{v,V}$ to the k-vector space $\mathbb{T}_{w,W}$.

(b) Prove that if $V \subseteq \mathbb{A}^n$, $W \subseteq \mathbb{A}^m$ and $\varphi = (F_1(x_1, \ldots, x_n), \ldots, F_m(x_1, \ldots, x_n))$ then $d\varphi : \mathbb{T}_{v,V} \to \mathbb{T}_{w,W}$ is given explicitly by

$$(d\varphi)(a_1, \ldots, a_n) = (D_v(F_1)(a_1, \ldots, a_n), \ldots, D_v(F_m)(a_1, \ldots, a_n)).$$

[If $g = g(y_1, \ldots, y_m)$ show that the chain rule implies

$$\frac{\partial(g \circ \varphi)}{\partial x_i}(v) = \sum_{j=1}^{m} \frac{\partial g}{\partial y_j}(w) \frac{\partial F_j}{\partial x_i}(v),$$

so that $D_v(g \circ \varphi)(a_1, \ldots, a_n) = D_w(g)(b_1, \ldots, b_m)$ where $b_j = D_v(F_j)(a_1, \ldots, a_n)$. Then use the fact that $g \circ \varphi \in I(V)$ if $g \in I(W)$.]

(c) If $\psi : U \to V$ is another morphism with $\psi(u) = v$, prove that the associated $d(\varphi \circ \psi) : \mathbb{T}_{u,U} \to \mathbb{T}_{w,W}$ is the same as $d\varphi \circ d\psi$.

(d) Prove that if φ is an isomorphism then $d\varphi$ is a vector space isomorphism from $\mathbb{T}_{v,V}$ to $\mathbb{T}_{w,W}$ for every $\varphi(v) = w$.

27. Let $V = \mathbb{A}^1$ and $W = Z(xz - y^2, yz - x^3, z^2 - x^2 y) \subseteq \mathbb{A}^3$. Let $\varphi : V \to W$ be the surjective morphism $\varphi(t) = (t^3, t^4, t^5)$ (cf. Exercise 26 in Section 1). For each $t \in \mathbb{A}^1$ describe the differential $d\varphi : \mathbb{T}_{t,\mathbb{A}^1} \to \mathbb{T}_{(t^3,t^4,t^5),W}$ in the previous exercise explicitly; in particular prove that $d\varphi$ is an isomorphism of vector spaces for all $t \neq 0$ and is the zero map for $t = 0$. Use this to prove that V and W are not isomorphic.

28. If k is a field, the quotient $k[x]/(x^2)$ is called the *ring of dual numbers* over k. If V is an affine algebraic set over k, show that a k-algebra homomorphism from $k[V]$ to $k[x]/(x^2)$ is equivalent to specifying a point $v \in V$ with $\mathcal{O}_{v,V}/\mathfrak{m}_{v,V} = k$ (called a k-rational point of V) together with an element in the tangent space $\mathbb{T}_{v,V}$ of V at v.

29. *(Computing the dimension of a variety)* Let P be a prime ideal in $k[x_1, \ldots, x_n]$, set $P_0 = 0$ and let $P_i = P \cap k[x_1, \ldots, x_i]$. Define the varieties $V_i = Z(P_i) \subseteq \mathbb{A}^i$ with V_0 the zero-dimensional variety consisting of a single point and coordinate ring k.

(a) Show that $\dim V_{i-1} \leq \dim V_i \leq \dim V_{i-1} + 1$. [First exhibit an injection from $k[V_{i-1}]$ into $k[V_i]$; then show that $k[V_i]$ is a k-algebra generated by $k[V_{i-1}]$ and one additional generator.]

(b) If the ideal generated by P_{i-1} in $k[x_1, \ldots, x_i]$ equals P_i, show that $V_i \cong V_{i-1} \times \mathbb{A}^1$ and deduce that $\dim V_i = \dim V_{i-1} + 1$.

(c) If the ideal generated by P_{i-1} in $k[x_1, \ldots, x_i]$ is properly contained in P_i, show that $\dim V_i = \dim V_{i-1}$.

(d) Show that $\dim V$ equals the number of $i \in \{1, 2, \ldots, n\}$ such that the ideal generated by P_{i-1} in $k[x_1, \ldots, x_i]$ equals the ideal P_i. Deduce that if G is the reduced Grobner basis for P with respect to the lexicographic monomial ordering $x_n > \cdots > x_1$ and $G_i = G \cap k[x_1, \ldots, x_i]$ where $G_0 = \emptyset$, and N is the number of i with $G_i \neq G_{i-1}$ for $1 \leq i \leq n$, then $\dim V = n - N$.

30. Prove that $M = 0$ if and only if $\text{Supp}(M) = \emptyset$. [Use Proposition 47.]

31. If $0 \to L \to M \to N \to 0$ is an exact sequence of R-modules, prove that the localization M_P is nonzero if and only if one of the localizations N_P and L_P is nonzero and deduce that $\text{Supp}(M) = \text{Supp}(L) \cup \text{Supp}(N)$. In particular, if $M = M_1 \oplus \cdots \oplus M_n$ prove that $\text{Supp}(M) = \text{Supp}(M_1) \cup \cdots \cup \text{Supp}(M_n)$.

32. Suppose $P \subseteq Q$ are prime ideals in R and that M is an R-module. Prove that the localization of the R-module M_Q at P is the localization M_P, i.e., $(M_Q)_P = M_P$. [Argue directly, or use Proposition 41 and the associativity of the tensor product.]

33. Suppose $P \subseteq Q$ are prime ideals in R and that M is an R-module. Prove that if $P \in \text{Supp}(M)$ then $Q \in \text{Supp}(M)$. [Use the previous exercise.]

34. (a) Suppose $M = Rm$ is a cyclic R-module. Prove that $M_P = 0$ if and only if there is an element $r \in R$, $r \notin P$ with $rm = 0$. Deduce that $P \in \text{Supp}(M)$ if and only if P contains the annihilator of m in R (cf. Exercise 10 in Section 10.1).

    (b) If $M = Rm_1 + \cdots + Rm_n$ is a finitely generated R-module prove that $P \in \text{Supp}(M)$ if and only if P is contained in $\text{Supp}(Rm_i)$ for some $i = 1, \ldots, n$. [Use Proposition 42.] Deduce that $P \in \text{Supp}(M)$ if and only if P contains the annihilator $\text{Ann}(M)$ of M in R. [Note $\text{Ann}(M) = \cap_{i=1}^n \text{Ann}(Rm_i)$, then use (a) and Exercise 11 of Section 7.4.]

35. Suppose P is a prime ideal of R with $P \cap D = \emptyset$. Prove that if $P \in \text{Ass}_R(M)$ then $D^{-1}P \in \text{Ass}_{D^{-1}R}(D^{-1}M)$. [Use Proposition 38(3) and Proposition 42.]

36. Suppose $D^{-1}P \in \text{Ass}_{D^{-1}R}(D^{-1}M)$ where $P = (a_1, \ldots, a_n)$ is a finitely generated prime ideal in R with $P \cap D = \emptyset$.

    (a) Suppose $m/d \in D^{-1}M$ has annihilator $D^{-1}P$ in $D^{-1}R$. Show that $d_i a_i m = 0 \in R$ for some $d_1, \ldots, d_n \in D$.

    (b) Let $d' = d_1 d_2 \cdots d_n$. Show that $P = \text{Ann}(d'm)$ and conclude that $P \in \text{Ass}_R(M)$. [The inclusion $P \subseteq \text{Ann}(d'm)$ is immediate. For the reverse inclusion, show that $b \in \text{Ann}(d'm)$ implies that $b/1$ annihilates m/d in $D^{-1}M$, hence $b/1 \in D^{-1}P$, and conclude $b \in P$.]

37. Suppose M is a module over the Noetherian ring R. Use the previous two exercises to show that under the bijection of Proposition 38(3) the prime ideals P of $\text{Ass}_R(M)$ with $P \cap D = \emptyset$ correspond bijectively with the prime ideals of $\text{Ass}_{D^{-1}R}(D^{-1}M)$.

38. Suppose M is a module over the Noetherian ring R and D is a multiplicatively closed subset of R. Let S be the subset of prime ideals P in $\text{Ass}_R(M)$ with $P \cap D \neq \emptyset$. This exercise proves that the kernel N of the localization map $M \to D^{-1}M$ is the unique submodule N of M with $\text{Ass}_R(N) = S$ and $\text{Ass}_R(M/N) = \text{Ass}_R(M) - S$.

    (a) If N' is a submodule of M with $\text{Ass}_R(N') = S$ and $\text{Ass}_R(M/N') = \text{Ass}_R(M) - S$ as in Exercise 35 in Section 1, prove that the diagram

$$\begin{array}{ccc} M & \xrightarrow{\pi} & M/N' \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\varphi'} \\ D^{-1}M & \xrightarrow[\pi']{} & D^{-1}(M/N') \end{array}$$

    is commutative, where π and π' are the natural projections (cf. Proposition 42(6)) and φ, φ' are the localization homomorphisms.

    (b) Show that $\text{Ass}_{D^{-1}R}(D^{-1}N') = \emptyset$ and conclude that $D^{-1}N' = 0$ and that π' is injective. [Use the previous exercise, the definition of S, and Exercise 34 in Section 1.]

    (c) If x is in the kernel K of φ' show that $\text{Ann}(x) \cap D \neq \emptyset$ and that $\text{Ass}_R(K) \subseteq S$. Show that $\text{Ass}_R(K) \subseteq \text{Ass}_R(M/N')$ implies that $\text{Ass}_R(K) = \emptyset$, and deduce that $K = 0$.

    (d) Prove φ and π have the same kernel, i.e., $N = N'$, and this submodule of M is unique.

39. Prove that $\mathrm{Ass}_R(M) \subseteq \mathrm{Supp}(M)$. [If $Rm \cong R/P$ use Proposition 42(4) and Proposition 46(1) to show that $0 \neq (Rm)_P \subseteq M_P$.]

40. Suppose that R is Noetherian and M is an R-module.

    (a) If $P \in \mathrm{Supp}(M)$ prove that P contains a prime ideal Q with $Q \in \mathrm{Ass}_R(M)$.

    (b) If P is a minimal prime in $\mathrm{Supp}(M)$, show that $P \in \mathrm{Ass}_R(M)$. [Use Exercise 33 in Section 1 to show that $\mathrm{Ass}_{R_P}(M_P) \neq \emptyset$ and then use Exercise 37.]

    (c) Conclude that $\mathrm{Ass}_R(M) \subseteq \mathrm{Supp}(M)$ and that these two sets have the same minimal elements.

Exercises (Atiyah & Macdonald).

1. Let S be a multiplicatively closed subset of a ring A, and let M be a finitely generated A-module. Prove that $S^{-1}M = 0$ if and only if there exists $s \in S$ such that $sM = 0$.

2. Let $\mathfrak{a}$ be an ideal of a ring A, and let $S = 1 + \mathfrak{a}$, that is the set of all $1 + x$ where $x \in \mathfrak{a}$. Show that $S^{-1}\mathfrak{a}$ is contained in the Jacobson radical of $S^{-1}A$.

   Use this result and Nakayama's lemma to give a proof of (2.5) which does not depend on determinants. [If $M = \mathfrak{a}M$, then $S^{-1}M = (S^{-1}\mathfrak{a})(S^{-1}M)$, hence by Nakayama we have $S^{-1}M = 0$. Now use Exercise 1.]

3. Let A be a ring, let S and T be two multiplicatively closed subsets of A, and let U be the image of T in $S^{-1}A$. Show that the rings $(ST)^{-1}A$ and $U^{-1}(S^{-1}A)$ are isomorphic.

4. Let $f : A \to B$ be a homomorphism of rings and let S be a multiplicatively closed subset of A. Let $T = f(S)$. Show that $S^{-1}B$ and $T^{-1}B$ are isomorphic as $S^{-1}A$-modules.

5. Let A be a ring. Suppose that, for each prime ideal $\mathfrak{p}$, the local ring $A_\mathfrak{p}$ has no nilpotent element $\neq 0$. Show that A has no nilpotent element $\neq 0$. If each $A_\mathfrak{p}$ is an integral domain, is A necessarily an integral domain?

6. Let A be a ring $\neq 0$ and let Σ be the set of all multiplicatively closed subsets S of A such that $0 \notin S$. Show that Σ has maximal elements, and that $S \in \Sigma$ is maximal if and only if $A - S$ is a minimal prime ideal of A.

7. A multiplicatively closed subset S of a ring A is said to be *saturated* if

$$xy \in S \iff x \in S \text{ and } y \in S.$$

   Prove that

   i) S is saturated $\iff$ $A - S$ is a union of prime ideals.

   ii) If S is any multiplicatively closed subset of A, there is a unique smallest saturated multiplicatively closed subset $\overline{S}$ containing S, and that $\overline{S}$ is the complement in A of the union of the prime ideals which do not meet S. ($\overline{S}$ is called the *saturation* of S.)

   If $S = 1 + \mathfrak{a}$, where $\mathfrak{a}$ is an ideal of A, find $\overline{S}$.

8. Let S, T be multiplicatively closed subsets of A, such that $S \subseteq T$. Let $\phi : S^{-1}A \to T^{-1}A$ be the homomorphism which maps each $a/s \in S^{-1}A$ to a/s considered as an element of $T^{-1}A$. Show that the following statements are equivalent:

   i) ϕ is bijective.

   ii) For each $t \in T$, $t/1$ is a unit in $S^{-1}A$.

   iii) For each $t \in T$ there exists $x \in A$ such that $xt \in S$.

   iv) T is contained in the saturation of S (Exercise 7).

   v) Every prime ideal which meets T also meets S.

9. Let A be a ring, and let S_0 be the set of all non-zero-divisors in A. Show that S_0 is a saturated multiplicatively closed subset of A. Hence the set D of zero-divisors in A is a union of prime ideals (see Chapter 1, Exercise 14). Show that every minimal prime ideal of A is contained in D. [Use Exercise 6.]

   The ring $S_0^{-1}A$ is called the *total ring of fractions* of A. Prove that

   i) S_0 is the largest multiplicatively closed subset of A for which the homomorphism $A \to S_0^{-1}A$ is injective.

   ii) Every element in $S_0^{-1}A$ is either a zero-divisor or a unit.

   iii) Every ring in which every non-unit is a zero-divisor is equal to its total ring of fractions (i.e., $A \to S_0^{-1}A$ is bijective).

10. Let A be a ring.

   i) If A is absolutely flat (Chapter 2, Exercise 27) and S is any multiplicatively closed subset of A, then $S^{-1}A$ is absolutely flat.

   ii) A is absolutely flat $\iff$ $A_\mathfrak{m}$ is a field for each maximal ideal $\mathfrak{m}$.

11. Let A be a ring. Prove that the following are equivalent:

   i) $A/\mathfrak{N}$ is absolutely flat ($\mathfrak{N}$ being the nilradical of A).

   ii) Every prime ideal of A is maximal.

   iii) $\mathrm{Spec}(A)$ is a T_1-space (i.e., every subset consisting of a single point is closed).

   iv) $\mathrm{Spec}(A)$ is Hausdorff.

   If these conditions are satisfied, show that $\mathrm{Spec}(A)$ is compact and totally disconnected (i.e. the only connected subsets of $\mathrm{Spec}(A)$ are those consisting of a single point).

12. Let A be an integral domain and M an A-module. An element $x \in M$ is a *torsion element* of M if $\mathrm{Ann}(x) \neq 0$, that is if x is killed by some non-zero element of A. Show that the torsion elements of M form a submodule of M. This submodule is called the *torsion submodule* of M and is denoted by $T(M)$. If $T(M) = 0$, the module M is said to be *torsion-free*. Show that

   i) If M is any module, then $M/T(M)$ is torsion-free.

   ii) If $f : M \to N$ is a module homomorphism, then $f(T(M)) \subseteq T(N)$.

   iii) If $0 \to M' \to M \to M''$ is an exact sequence, then the sequence $0 \to T(M') \to T(M) \to T(M'')$ is exact.

   iv) If M is any A-module, then $T(M)$ is the kernel of the mapping $x \mapsto 1 \otimes x$ of M into $K \otimes_A M$, where K is the field of fractions of A.

   [For iv), show that K may be regarded as the direct limit of its submodules $A\xi$ ($\xi \in K$); using Chapter 1, Exercise 15 and Exercise 20, show that if $1 \otimes x = 0$ in $K \otimes M$ then $1 \otimes x = 0$ in $A\xi \otimes M$ for some $\xi \neq 0$. Deduce that $\xi^{-1}x = 0$.]

13. Let S be a multiplicatively closed subset of an integral domain A. In the notation of Exercise 12, show that $T(S^{-1}M) = S^{-1}(TM)$. Deduce that the following are equivalent:

   i) M is torsion-free.

   ii) $M_\mathfrak{p}$ is torsion-free for all primes ideals $\mathfrak{p}$.

   iii) $M_\mathfrak{m}$ is torsion-free for all maximal ideals $\mathfrak{m}$.

14. Let M be an A-module and $\mathfrak{a}$ an ideal of A. Suppose that $M_\mathfrak{m} = 0$ for all maximal ideals $\mathfrak{m} \supseteq \mathfrak{a}$. Prove that $M = \mathfrak{a}M$. [Pass to the $A/\mathfrak{a}$-module $M/\mathfrak{a}M$ and use (3.8).]

15. Let A be a ring, and let F be the A-module A^n. Show that every set of n generators of F is a basis of F. [Let $x_1, \ldots, x_n$ be a set of generators and $e_1, \ldots, e_n$ the canonical basis of F. Define $\phi : F \to F$ by $\phi(e_i) = x_i$. Then ϕ is surjective and we have to prove that it is an isomorphism. By (3.9) we may assume that A is a local ring. Let N be the kernel of ϕ and let $k = A/\mathfrak{m}$ be the residue field of A. Since F is a flat A-module, the exact sequence $0 \to N \to F \xrightarrow{\phi} F \to 0$ gives an exact sequence $0 \to k \otimes N \to k \otimes F \xrightarrow{1\otimes\phi} k \otimes F \to 0$. Now $k \otimes F = k^n$ is an n-dimensional vector space over k; $1 \otimes \phi$ is surjective, hence bijective, hence $k \otimes N = 0$.

    Also N is finitely generated, by Chapter 2, Exercise 12, hence $N = 0$ by Nakayama's lemma. Hence ϕ is an isomorphism.]

    Deduce that every set of generators of F has at least n elements.

16. Let B be a flat A-algebra. Then the following conditions are equivalent:

    i) $\mathfrak{a}^{ec} = \mathfrak{a}$ for all ideals $\mathfrak{a}$ of A.

    ii) $\mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is surjective.

    iii) For every maximal ideal $\mathfrak{m}$ of A we have $\mathfrak{m}^e \neq (1)$.

    iv) If M is any non-zero A-module, then $M_B \neq 0$.

    v) For every A-module M, the mapping $x \mapsto 1 \otimes x$ of M into M_B is injective.

    [For i) $\Rightarrow$ ii), use (3.16). ii) $\Rightarrow$ iii) is clear.

    iii) $\Rightarrow$ iv): Let M be a non-zero A-module, let x be a non-zero element of M and let $M' = Ax$. Since B is flat over A it is enough to show that $M'_B \neq 0$. We have $M' \cong A/\mathfrak{a}$ for some ideal $\mathfrak{a} \neq (1)$; let $\mathfrak{m}$ be some maximal ideal $\supseteq \mathfrak{a}$. Then $\mathfrak{a}^e \subseteq \mathfrak{m}^e \neq B$. Hence $M'_B \neq 0$.

    iv) $\Rightarrow$ v): Let M' be the kernel of $M \to M_B$. Since B is flat over A, the sequence $0 \to M'_B \to M_B \to (M_B)_B$ is exact. By (Chapter 2, Exercise 13, with $N = M_B$) the mapping $M_B \to (M_B)_B$ is injective, hence $M'_B = 0$ and therefore $M' = 0$.

    v) $\Rightarrow$ i): Take $M = A/\mathfrak{a}$.]

    B is said to be *faithfully flat* over A.

17. Let $A \xrightarrow{f} B \xrightarrow{g} C$ be ring homomorphisms. If $g \circ f$ is flat and g is faithfully flat, then f is flat.

18. Let $f : A \to B$ be a flat homomorphism of rings, let $\mathfrak{q}$ be a prime ideal of B and let $\mathfrak{p} = \mathfrak{q}^c$. Then $f^* : \mathrm{Spec}(B_\mathfrak{q}) \to \mathrm{Spec}(A_\mathfrak{p})$ is surjective. [For $B_\mathfrak{p}$ is flat over $A_\mathfrak{p}$ by (3.10), and $B_\mathfrak{q}$ is a local ring of $B_\mathfrak{p}$, hence is flat over $B_\mathfrak{p}$. Hence $B_\mathfrak{q}$ is flat over $A_\mathfrak{p}$ and satisfies condition iii) of Exercise 16.]

19. Let A be a ring, M an A-module. The *support* of M is defined to be the set $\mathrm{Supp}(M)$ of prime ideals $\mathfrak{p}$ of A such that $M_\mathfrak{p} \neq 0$. Prove the following results:

    i) $M \neq 0 \iff \mathrm{Supp}(M) \neq \emptyset$.

    ii) $V(\mathfrak{a}) = \mathrm{Supp}(A/\mathfrak{a})$.

    iii) If $0 \to M' \to M \to M'' \to 0$ is an exact sequence, then $\mathrm{Supp}(M) = \mathrm{Supp}(M') \cup \mathrm{Supp}(M'')$.

    iv) If $M = \sum M_i$, then $\mathrm{Supp}(M) = \bigcup \mathrm{Supp}(M_i)$.

    v) If M is finitely generated, then $\mathrm{Supp}(M) = V(\mathrm{Ann}(M))$ (and is therefore a closed subset of $\mathrm{Spec}(A)$).

    vi) If M, N are finitely generated, then $\mathrm{Supp}(M \otimes_A N) = \mathrm{Supp}(M) \cap \mathrm{Supp}(N)$. [Use Chapter 2, Exercise 3.]

    vii) If M is finitely generated and $\mathfrak{a}$ is an ideal of A, then $\mathrm{Supp}(M/\mathfrak{a}M) = V(\mathfrak{a} + \mathrm{Ann}(M))$.

    viii) If $f : A \to B$ is a ring homomorphism and M is a finitely generated A-module, then $\mathrm{Supp}(B \otimes_A M) = f^{*-1}(\mathrm{Supp}(M))$.

20. Let A be a ring, $f : A \to B$ a ring homomorphism, $f^* : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ the associated mapping. Show that

i) Every prime ideal of A is a contracted ideal $\iff$ f^* is surjective.

ii) Every prime ideal of B is an extended ideal $\Rightarrow$ f^* is injective.

Is the converse of ii) true?

21. Let A be a ring, S a multiplicatively closed subset of A, and $\phi : A \to S^{-1}A$ the canonical homomorphism. Show that $\phi^* : \mathrm{Spec}(S^{-1}A) \to \mathrm{Spec}(A)$ is a homeomorphism of $\mathrm{Spec}(S^{-1}A)$ onto its image in $X = \mathrm{Spec}(A)$. Let this image be denoted by $S^{-1}X$.

In particular, if $f \in A$, the image of $\mathrm{Spec}(A_f)$ in X is the basic open set X_f (Chapter 1, Exercise 17).

ii) Let $f : A \to B$ be a ring homomorphism. Let $X = \mathrm{Spec}(A)$ and $Y = \mathrm{Spec}(B)$, and let $f^* : Y \to X$ be the mapping associated with f. Identifying $\mathrm{Spec}(S^{-1}A)$ with its canonical image $S^{-1}X$ in X, and $\mathrm{Spec}(S^{-1}B)$ $(= \mathrm{Spec}(f(S)^{-1}B))$ with its canonical image $S^{-1}Y$ in Y, show that $S^{-1}f^* : \mathrm{Spec}(S^{-1}B) \to \mathrm{Spec}(S^{-1}A)$ is the restriction of f^* to $S^{-1}Y$, and that $S^{-1}Y = f^{*-1}(S^{-1}X)$.

iii) Let $\mathfrak{a}$ be an ideal of A and let $\mathfrak{b} = \mathfrak{a}^e$ be its extension in B. Let $\overline{f} : A/\mathfrak{a} \to B/\mathfrak{b}$ be the homomorphism induced by f. Then $\mathrm{Spec}(A/\mathfrak{a})$ is identified with the closed subspace $V(\mathfrak{a})$ in X, and $\mathrm{Spec}(B/\mathfrak{b})$ with $V(\mathfrak{b})$ in Y. Show that $\overline{f}^*$ is the restriction of f^* to $V(\mathfrak{b})$.

iv) Let $\mathfrak{p}$ be a prime ideal of A. Take $S = A - \mathfrak{p}$ in ii) and then reduce mod $\mathfrak{p}$ as in iii). Deduce that the subspace $f^{*-1}(\mathfrak{p})$ of Y is naturally homeomorphic to $\mathrm{Spec}(B_\mathfrak{p}/\mathfrak{p}B_\mathfrak{p}) = \mathrm{Spec}(k(\mathfrak{p}) \otimes_A B)$, where $k(\mathfrak{p})$ is the residue field of the local ring $A_\mathfrak{p}$.

$\mathrm{Spec}(k(\mathfrak{p}) \otimes_A B)$ is called the *fiber* of f^* over $\mathfrak{p}$.

22. Let A be a ring and $\mathfrak{p}$ a prime ideal of A. Then the canonical image of $\mathrm{Spec}(A_\mathfrak{p})$ in $\mathrm{Spec}(A)$ is equal to the intersection of all the open neighborhoods of $\mathfrak{p}$ in $\mathrm{Spec}(A)$.

23. Let A be a ring, let $X = \mathrm{Spec}(A)$ and let U be a basic open set in X (i.e., $U = X_f$ for some $f \in A$: Chapter 1, Exercise 17).

i) If $U = X_f$, show that the ring $A(U) = A_f$ depends only on U and not on f.

ii) Let $U' = X_g$ be another basic open set such that $U' \subseteq U$. Show that there is an equation of the form $g^n = uf$ for some integer $n > 0$ and some $u \in A$, and use this to define a homomorphism $\rho : A(U) \to A(U')$ (i.e., $A_f \to A_g$) by mapping a/f^m to au^m/g^{nm}. Show that ρ depends only on U and U'. This homomorphism is called the *restriction* homomorphism.

iii) If $U = U'$, then ρ is the identity map.

iv) If $U \supseteq U' \supseteq U''$ are basic open sets in X, show that the diagram

$$\begin{array}{ccc} A(U) & \longrightarrow & A(U'') \\ & \searrow \quad \nearrow & \\ & A(U') & \end{array}$$

(in which the arrows are restriction homomorphisms) is commutative.

v) Let $x(= \mathfrak{p})$ be a point of X. Show that

$$\varinjlim_{U \ni x} A(U) \cong A_\mathfrak{p}.$$

The assignment of the ring $A(U)$ to each basic open set U of X, and the restriction homomorphisms ρ, satisfying the conditions iii) and iv), constitutes a *presheaf of rings* on the basis of open sets $(X_f)_{f \in A}$. v) says that the stalk of this presheaf at $x \in X$ is the corresponding local ring $A_\mathfrak{p}$.

24. Show that the presheaf of Exercise 23 has the following property. Let $(U_i)_{i \in I}$ be a covering of X by basic open sets. For each $i \in I$ let $s_i \in A(U_i)$ be such that, for each pair of indices i, j, the images of s_i and s_j in $A(U_i \cap U_j)$ are equal. Then there exists a unique $s \in A(= A(X))$ whose image in $A(U_i)$ is s_i, for all $i \in I$. (This essentially implies that the presheaf is a *sheaf*.)

25. Let $f : A \to B$, $g : A \to C$ be ring homomorphisms and let $h : A \to B \otimes_A C$ be defined by $h(x) = f(x) \otimes 1 = 1 \otimes g(x)$. Let X, Y, Z, T be the prime spectra of $A, B, C, B \otimes_A C$ respectively. Then $h^*(T) = f^*(Y) \cap g^*(Z)$. [Let $\mathfrak{p} \in X$, and let $k = k(\mathfrak{p})$ be the residue field at $\mathfrak{p}$. By Exercise 21, the fiber $h^{*-1}(\mathfrak{p})$ is the spectrum of $(B \otimes_A C) \otimes_A k(\mathfrak{p}) \cong (B \otimes_A k) \otimes_k (C \otimes_A k)$. Hence $\mathfrak{p} \in h^*(T) \iff (B \otimes_A k) \otimes_k (C \otimes_A k) \neq 0 \iff B \otimes_A k \neq 0$ and $C \otimes_A k \neq 0 \iff \mathfrak{p} \in f^*(Y) \cap g^*(Z)$.]

26. Let $(B_\alpha, g_{\alpha\beta})$ be a direct system of rings and B the direct limit. For each α, let $f_\alpha : A \to B_\alpha$ be a ring homomorphism such that $g_{\alpha\beta} \circ f_\alpha = f_\beta$ whenever $\alpha \leq \beta$ (i.e. the B_α form a direct system of A-algebras), and let $f : A \to B$ be the homomorphism induced by the f_α. Show that

$$f^*(\mathrm{Spec}(B)) = \bigcap_\alpha f_\alpha^*(\mathrm{Spec}(B_\alpha)).$$

[Let $\mathfrak{p} \in \mathrm{Spec}(A)$. Then $f^{*-1}(\mathfrak{p})$ is the spectrum of $B \otimes_A k(\mathfrak{p}) = \varinjlim(B_\alpha \otimes_A k(\mathfrak{p}))$ (since tensor products commute with direct limits: Chapter 2, Exercise 20). By Exercise 21 of Chapter 2 it follows that $f^{*-1}(\mathfrak{p}) = \emptyset$ if and only if $B_\alpha \otimes_A k(\mathfrak{p}) = 0$ for some α, i.e., if and only if $f_\alpha^{*-1}(\mathfrak{p}) = \emptyset$.]

27. i) Let $f_\alpha : A \to B_\alpha$ be any family of A-algebras and let $f : A \to B$ be their tensor product over A (Chapter 2, Exercise 23). Then

$$f^*(\mathrm{Spec}(B)) = \bigcap_\alpha f_\alpha^*(\mathrm{Spec}(B_\alpha)).$$

[Use Examples 25 and 26.]

ii) Let $f_\alpha : A \to B_\alpha$ be any finite family of A-algebras and let $B = \prod_\alpha B_\alpha$. Define $f : A \to B$ by $f(x) = (f_\alpha(x))$. Then $f^*(\mathrm{Spec}(B)) = \bigcup_\alpha f_\alpha^*(\mathrm{Spec}(B_\alpha))$.

iii) Hence the subsets of $X = \mathrm{Spec}(A)$ of the form $f^*(\mathrm{Spec}(B))$, where $f : A \to B$ is a ring homomorphism, satisfy the axioms for closed sets in a topological space. The associated topology is the *constructible topology* on X. It is finer than the Zariski topology (i.e., there are more open sets, or equivalently more closed sets).

iv) Let X_C denote the set X endowed with the constructible topology. Show that X_C is quasi-compact.

28. *(Continuation of Exercise 27.)*

i) For each $g \in A$, the set X_g (Chapter 1, Exercise 17) is both open and closed in the constructible topology.

ii) Let C' denote the smallest topology on X for which the sets X_g are both open and closed, and let $X_{C'}$ denote the set X endowed with this topology. Show that $X_{C'}$ is Hausdorff.

iii) Deduce that the identity mapping $X_C \to X_{C'}$ is a homeomorphism. Hence a subset E of X is of the form $f^*(\mathrm{Spec}(B))$ for some $f : A \to B$ if and only if it is closed in the topology C'.

iv) The topological space X_C is compact, Hausdorff and totally disconnected.

29. Let $f : A \to B$ be a ring homomorphism. Show that $f^* : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is a continuous *closed* mapping (i.e., maps closed sets to closed sets) for the constructible topology.

30. Show that the Zariski topology and the constructible topology on $\mathrm{Spec}(A)$ are the same if and only if $A/\mathfrak{N}$ is absolutely flat (where $\mathfrak{N}$ is the nilradical of A). [Use Exercise 11.]

Throughout, R is a commutative ring with 1 and $S \subseteq R$ is a multiplicatively closed set; $\mathfrak{p}, \mathfrak{q}, \mathfrak{m}$ denote primes/maximals.

Practice problems.

1. Let $R = k[x, y]/(xy)$ and $S = \{1, x, x^2, \dots\}$. Determine $\ker(\pi\colon R \to S^{-1}R)$ explicitly, identify the image $\pi(R)$ inside R_x, and prove that $R_x \cong k[x, x^{-1}]$. Decide whether π is injective and justify your answer using the kernel formula.

2. In $R=\mathbb{Z}$ with $S=\mathbb{Z}\setminus(5)$, compute the saturation $(\,(450)\,)^{ec}$ of the ideal (450), where $450=2\cdot 3^2\cdot 5^2$. Express your answer as a principal ideal (n) and explain which prime-power factors of 450 are stripped off and why.

3. Let $M=\mathbb{Z}/12\mathbb{Z}$ as a $\mathbb{Z}$-module. For each prime p, compute the localization $M_{(p)}$ and $M_{(0)}$, identifying each as a finite abelian group. State for exactly which primes p the localization is nonzero and relate this to the prime factorization of 12.

4. Let $R=k[x]$ and $f=x^2-x=x(x-1)$. Describe $\operatorname{Spec} R_f$ as a subset of $\operatorname{Spec} R$, prove that $R_f\cong k[x,t]/(t(x^2-x)-1)$, and show that the primes of R_f are exactly those primes of $k[x]$ that contain neither x nor $x-1$.

5. Let R be a domain with fraction field F and let $a=f/g\in F$ in lowest terms with g a nonunit. Prove that $a\notin R_{\mathfrak{m}}$ for some maximal ideal $\mathfrak{m}$, and conclude directly from $R=\bigcap_{\mathfrak{m}} R_{\mathfrak{m}}$ that $a\notin R$. Illustrate with $R=k[x,y]$ and $a=1/y$.

6. Let $\mathfrak{q}=(8)$ in $R=\mathbb{Z}$, which is (2)-primary. For $S_1=\mathbb{Z}\setminus(2)$ and $S_2=\mathbb{Z}\setminus(3)$, compute $S_1^{-1}\mathfrak{q}$ and $S_2^{-1}\mathfrak{q}$, identify the radical of each extension, and state which of the two extensions is the unit ideal and why (use $\mathfrak{q}\cap S\neq\varnothing$).

7. Let $\varphi\colon\mathbb{Z}\to\mathbb{Z}$ be multiplication by 6. Compute the kernel and cokernel of the localized map $\varphi_{(p)}\colon\mathbb{Z}_{(p)}\to\mathbb{Z}_{(p)}$ for $p=2,3$ and for $p\notin\{\,2,3\,\}$, and use the local-global criterion to determine whether φ is injective and whether it is surjective.

8. In $R=k[x,y]$ let $\mathfrak{p}=(x)$. Determine all primes of the local ring $R_{\mathfrak{p}}$, compute the residue field $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}}$, and state $\operatorname{ht}\mathfrak{p}$ and $\dim R_{\mathfrak{p}}$. Verify that these two numbers agree with the length of the longest chain of primes you found.

Additional exercises.

1. Let $S\subseteq R$ be multiplicatively closed and let $N\subseteq M$ be R-modules. Prove that $S^{-1}N$ is naturally identified with an $S^{-1}R$-submodule of $S^{-1}M$, and that under this identification $S^{-1}(M/N)\cong S^{-1}M/S^{-1}N$. Deduce that if $N_1,N_2\subseteq M$ then $S^{-1}(N_1\cap N_2)=S^{-1}N_1\cap S^{-1}N_2$ and $S^{-1}(N_1+N_2)=S^{-1}N_1+S^{-1}N_2$.

2. Let R be Noetherian, M a finitely generated R-module, and S multiplicatively closed. Prove that $S^{-1}\operatorname{Ann}(M)=\operatorname{Ann}(S^{-1}M)$. Then give an example with M *not* finitely generated where this fails, and pinpoint which step of your proof breaks without the finiteness hypothesis.

3. Let $\mathfrak{p}\subseteq\mathfrak{q}$ be primes of R. Prove that the localization of the local ring $R_{\mathfrak{q}}$ at the prime $\mathfrak{p}R_{\mathfrak{q}}$ is canonically isomorphic to $R_{\mathfrak{p}}$. As a corollary, show that for an R-module M one has $(M_{\mathfrak{q}})_{\mathfrak{p}R_{\mathfrak{q}}}\cong M_{\mathfrak{p}}$, and use this to prove that $\mathfrak{p}\in\operatorname{Supp}(M)$ and $\mathfrak{p}\subseteq\mathfrak{q}$ together force $\mathfrak{q}\in\operatorname{Supp}(M)$.

4. Let R be an integral domain and M an R-module. Define the torsion submodule $T(M)=\{\,m\in M:\ rm=0 \text{ for some } r\neq 0\,\}$. Prove that for any multiplicatively closed S with $0\notin S$ one has $T(S^{-1}M)=S^{-1}(T(M))$, and conclude that M is torsion-free iff $M_{\mathfrak{m}}$ is torsion-free for every maximal ideal $\mathfrak{m}$.

5. Let $f\in R$ be a non-nilpotent element and $S=\{\,f^n\,\}$. Prove that the primes of R_f are in inclusion-preserving bijection with the primes of R not containing f, and that this bijection identifies the minimal primes of R_f with the minimal primes of R contained in the distinguished open $D(f)$. Apply this to $R=k[x,y]/(xy)$, $f=x$, to list the minimal primes of R_x.

Commutative-diagram exercises.

1. For a prime $\mathfrak{p}$ of R and an $f\notin\mathfrak{p}$, complete the localization square below (the maps are the canonical localization homomorphisms; π_f inverts f and the right vertical map localizes at $\mathfrak{p}R_f$). Prove the square commutes and that the induced map $R_{\mathfrak{p}}\to(R_f)_{\mathfrak{p}R_f}$ is an isomorphism, so localizing at $\mathfrak{p}$ factors through

inverting any single $f \notin \mathfrak{p}$:

$$\begin{array}{ccc} R & \xrightarrow{\pi_f} & R_f \\ {\scriptstyle \pi_{\mathfrak{p}}}\downarrow & & \downarrow \\ R_{\mathfrak{p}} & \xrightarrow[\exists!\,\cong]{} & (R_f)_{\mathfrak{p}R_f} \end{array}$$

Then take $R = \mathbb{Z}$, $\mathfrak{p} = (2)$, $f = 3$, and verify the isomorphism concretely by identifying both bottom rings as $\mathbb{Z}_{(2)}$.

2. Let $S \subseteq R$ be multiplicatively closed with canonical map $\pi\colon R \to S^{-1}R$, and let $\pi^*\colon \operatorname{Spec}(S^{-1}R) \to \operatorname{Spec} R$ be the induced map of spectra. Complete the diagram and prove that π^* is a homeomorphism onto the subspace $\{\, \mathfrak{q} \in \operatorname{Spec} R : \ \mathfrak{q} \cap S = \varnothing \,\}$, with inverse given by extension $\mathfrak{q} \mapsto S^{-1}\mathfrak{q}$:

$$\begin{array}{ccc} \operatorname{Spec}(S^{-1}R) & \xrightarrow{\pi^*} & \operatorname{Spec} R \\ & {\scriptstyle \cong}\searrow & \uparrow \\ & & \{\, \mathfrak{q} : \ \mathfrak{q} \cap S = \varnothing \,\} \end{array}$$

Specialize to $S = \{\, f^n \,\}$ to identify the image with the distinguished open $D(f)$, and to $S = R \setminus \mathfrak{p}$ to identify it with $\{\, \mathfrak{q} \subseteq \mathfrak{p} \,\}$.

3. Let $0 \to L \xrightarrow{f} M \xrightarrow{g} N \to 0$ be a short exact sequence of R-modules and S a multiplicatively closed set. Complete the diagram below so that the rows are exact and the vertical localization maps make every square commute; then prove that the bottom row is exact (i.e. that S^{-1} is an exact functor):

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L & \xrightarrow{f} & M & \xrightarrow{g} & N & \longrightarrow & 0 \\ & & {\scriptstyle \pi_L}\downarrow & & {\scriptstyle \pi_M}\downarrow & & {\scriptstyle \pi_N}\downarrow & & \\ 0 & \longrightarrow & S^{-1}L & \xrightarrow[S^{-1}f]{} & S^{-1}M & \xrightarrow[S^{-1}g]{} & S^{-1}N & \longrightarrow & 0 \end{array}$$

Use exactness to deduce that $\operatorname{coker}(\varphi)_{\mathfrak{m}} \cong \operatorname{coker}(\varphi_{\mathfrak{m}})$ for any map $\varphi\colon M \to N$ and any maximal ideal $\mathfrak{m}$, and hence that surjectivity of φ is a local property.

4. For $f \in R$ and a basic open $D(g) \subseteq D(f)$ of $\operatorname{Spec} R$ (so $g^n = uf$ for some n and u), complete the restriction diagram of the structure presheaf and prove it commutes; then, for a point $\mathfrak{p} \in D(g)$, prove that the stalk at $\mathfrak{p}$ is the local ring $R_{\mathfrak{p}}$ by exhibiting the colimit:

$$\begin{array}{ccc} R_f & \xrightarrow{\rho_g^f} & R_g \\ & \searrow \quad \swarrow & \\ & \varinjlim_{\mathfrak{p} \in D(h)} R_h & \\ & {\scriptstyle \cong}\downarrow & \\ & R_{\mathfrak{p}} & \end{array}$$

Identify the restriction map $\rho_g^f\colon R_f \to R_g$ explicitly on a fraction a/f^m, and prove the colimit over all basic opens $D(h)$ containing $\mathfrak{p}$ is $R_{\mathfrak{p}}$.

15.6 Primary Decomposition

Primary ideals: prime powers, generalized

Primary decomposition is the ideal-theoretic shadow of two classical facts: the factorization of an integer $n \in \mathbb{Z}$ into prime powers, and the decomposition of an algebraic set into irreducible components. Atiyah–Macdonald state the analogy bluntly: a prime ideal is a generalization of a prime number, and *a primary ideal is a generalization of a prime power*. The whole subject is a "unique factorization" theorem for *ideals* (not elements) that survives in rings far wilder than UFDs — in particular in all Noetherian rings, where $\mathbb{Z}[\sqrt{-5}]$ (in which 6 has two genuinely distinct element-factorizations $2 \cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$) is tamed at the level of ideals.

Throughout, R is a commutative ring with 1. We write $\operatorname{rad}\mathfrak{a} = \{\, x \in R : x^n \in \mathfrak{a} \text{ for some } n \geq 1 \,\}$ for the radical and recall $\operatorname{rad}\mathfrak{a} = \bigcap_{\mathfrak{p} \supseteq \mathfrak{a}} \mathfrak{p}$ (intersection over primes containing $\mathfrak{a}$). For an ideal $\mathfrak{a}$ and $x \in R$, the *colon* (or quotient) ideal is $(\mathfrak{a} : x) = \{\, r \in R : rx \in \mathfrak{a} \,\}$.

Definition 15.6.1 (primary ideal)**.** A proper ideal $\mathfrak{q} \subsetneq R$ is *primary* if

$$xy \in \mathfrak{q} \text{ and } x \notin \mathfrak{q} \quad \Longrightarrow \quad y^n \in \mathfrak{q} \text{ for some } n \geq 1,$$

equivalently $y \in \operatorname{rad}\mathfrak{q}$. Phrased in the quotient: $\mathfrak{q}$ is primary iff in $R/\mathfrak{q}$ *every zero-divisor is nilpotent.*

The quotient formulation is the conceptual one. A prime ideal is exactly one whose quotient has *no* zero-divisors at all (an integral domain); a primary ideal relaxes this to "every zero-divisor is nilpotent." This is precisely the gap between $R/\mathfrak{p}$ being a domain and $R/\mathfrak{q}$ being a ring in which nilpotents are the only obstruction to being a domain.

Proposition 15.6.2 (the radical of a primary ideal)**.** *Let $\mathfrak{q}$ be primary. Then $\mathfrak{p} = \operatorname{rad}\mathfrak{q}$ is prime, and is the* smallest *prime ideal containing $\mathfrak{q}$. We then say $\mathfrak{q}$ is* $\mathfrak{p}$-primary *and call $\mathfrak{p}$ the prime* belonging to $\mathfrak{q}$.

Idea. If $xy \in \operatorname{rad}\mathfrak{q}$ then $(xy)^m = x^m y^m \in \mathfrak{q}$; since $\mathfrak{q}$ is primary, either $x^m \in \mathfrak{q}$ (so $x \in \operatorname{rad}\mathfrak{q}$) or $(y^m)^n \in \mathfrak{q}$ for some n (so $y \in \operatorname{rad}\mathfrak{q}$). Hence $\operatorname{rad}\mathfrak{q}$ is prime. It is the smallest prime over $\mathfrak{q}$ because $\operatorname{rad}\mathfrak{q}$ is the intersection of all such primes. □

Proposition 15.6.3 (useful recognition criteria)**.** (1) *Every prime ideal is primary.*

(2) *If* $\operatorname{rad}\mathfrak{q} = \mathfrak{m}$ *is* maximal*, then $\mathfrak{q}$ is primary (an $\mathfrak{m}$-primary ideal). In particular every power $\mathfrak{m}^n$ of a maximal ideal is $\mathfrak{m}$-primary.*

(3) *More precisely, for $\mathfrak{m}$ maximal: if $\mathfrak{m}^n \subseteq \mathfrak{q} \subseteq \mathfrak{m}$ for some $n \geq 1$, then $\mathfrak{q}$ is $\mathfrak{m}$-primary; the converse holds when R is Noetherian (every ideal of a Noetherian ring contains a power of its radical).*

Idea. (2) Pass to $A = R/\mathfrak{q}$; then $\operatorname{rad}(0) = \mathfrak{m}/\mathfrak{q}$ is maximal, hence is the *unique* prime of A (the nilradical sits in every prime). So every non-unit of A lies in this maximal ideal, i.e. is nilpotent; thus every zero-divisor is nilpotent and $\mathfrak{q}$ is primary. (3) $\mathfrak{m}^n \subseteq \mathfrak{q}$ gives $\mathfrak{m} \subseteq \operatorname{rad}\mathfrak{q}$ and $\mathfrak{q} \subseteq \mathfrak{m}$ gives $\operatorname{rad}\mathfrak{q} \subseteq \mathfrak{m}$, so $\operatorname{rad}\mathfrak{q} = \mathfrak{m}$; apply (2). □

Caution. Two converses fail, and both failures are the heart of the theory. *(i) A primary ideal need not be a prime power.* In $k[x,y]$ the ideal $\mathfrak{q} = (x^2, y)$ is (x,y)-primary (its radical is the maximal ideal (x,y)) yet is not $\mathfrak{p}^n$ for any prime $\mathfrak{p}$: if $(x^2,y) = \mathfrak{p}^n$ then $x^2, y \in \mathfrak{p}$ force $\mathfrak{p} = (x,y)$, but $y \notin (x,y)^2$ rules out $n \geq 2$ and $x \notin (x^2,y)$ rules out $n = 1$. *(ii) A prime power need not be primary.* In $R = k[x,y,z]/(xy - z^2)$ the ideal $\mathfrak{p} = (\bar{x}, \bar{z})$ is prime, but $\mathfrak{p}^2$ is not primary: $\bar{x}\bar{y} = \bar{z}^2 \in \mathfrak{p}^2$ while $\bar{x} \notin \mathfrak{p}^2$ and no power of $\bar{y}$ lies in $\mathfrak{p}^2$. So "primary" is genuinely between "prime" and "prime power."

Worked Example 15.6.4 (The primary ideals of $\mathbb{Z}$)**.** Determine all primary ideals of $\mathbb{Z}$ and identify the prime each belongs to.

Recognition. In a PID/UFD, (π^n) should be (π)-primary; conversely every primary ideal of $\mathbb{Z}$ should be a prime power.

Solution. The proper ideals of $\mathbb{Z}$ are (0) and (m) for $m \geq 2$. (0) is prime, hence primary. For (m) with $m = p_1^{e_1} \cdots p_r^{e_r}$: if $r \geq 2$ then $p_1^{e_1} \cdot (m/p_1^{e_1}) \in (m)$ but neither factor nor any power of the second lies in (m),

so (m) is not primary. If $m = p^e$, then $\operatorname{rad}(p^e) = (p)$ is maximal, so (p^e) is (p)-primary by the criterion. Thus the primary ideals of $\mathbb{Z}$ are exactly (0) and the prime powers (p^e), p prime, $e \geq 1$. Sanity check: $(12) = (2^2) \cap (3)$ is the intersection of the primary ideals (4) and (3) — a primary decomposition mirroring $12 = 2^2 \cdot 3$, exactly the arithmetic prototype.

Worked Example 15.6.5 ((x^2, y) is primary but not a prime power)**.** Show $\mathfrak{q} = (x^2, y) \subseteq k[x, y]$ is primary and find its prime.

Recognition. $\operatorname{rad}\mathfrak{q}$ should be the maximal ideal (x, y); an ideal whose radical is maximal is automatically primary.

Solution. The quotient is $k[x, y]/(x^2, y) \cong k[x]/(x^2)$, a local ring with maximal ideal $(\bar{x})$ and $\bar{x}$ nilpotent. Every element is $a + b\bar{x}$; it is a zero-divisor iff $a = 0$ iff it is nilpotent. So $\mathfrak{q}$ is primary. Its radical: $\operatorname{rad}\mathfrak{q} = \operatorname{rad}(x^2, y) = (x, y)$ since $x \in \operatorname{rad}$ ($x^2 \in \mathfrak{q}$) and $y \in \mathfrak{q}$, and (x, y) is maximal. Hence $\mathfrak{q}$ is (x, y)-primary. Sanity check: the inclusions $(x, y)^2 = (x^2, xy, y^2) \subseteq (x^2, y) \subseteq (x, y)$ exhibit $\mathfrak{m}^2 \subseteq \mathfrak{q} \subseteq \mathfrak{m}$, confirming primary via the maximal-radical criterion.

Worked Example 15.6.6 (A prime power that fails to be primary)**.** In $R = k[x, y, z]/(xy - z^2)$ verify $\mathfrak{p} = (\bar{x}, \bar{z})$ is prime but $\mathfrak{p}^2$ is not primary.

Recognition. Compute $R/\mathfrak{p}$ to test primality; then find an element exhibiting the primary-failure $ab \in \mathfrak{p}^2$, $a \notin \mathfrak{p}^2$, $b \notin \operatorname{rad}\mathfrak{p}^2$.

Solution. $R/\mathfrak{p} \cong k[x, y, z]/(x, z) \cong k[y]$, an integral domain, so $\mathfrak{p}$ is prime. Now $\mathfrak{p}^2 = (\bar{x}^2, \bar{x}\bar{z}, \bar{z}^2)$, and using $\bar{z}^2 = \bar{x}\bar{y}$ we get $\mathfrak{p}^2 = (\bar{x}^2, \bar{x}\bar{z}, \bar{x}\bar{y}) = \bar{x}(\bar{x}, \bar{y}, \bar{z})$. Then $\bar{x}\bar{y} = \bar{z}^2 \in \mathfrak{p}^2$, but $\bar{x} \notin \mathfrak{p}^2$ (it is not in $\bar{x}(\bar{x}, \bar{y}, \bar{z})$ since $1 \notin (\bar{x}, \bar{y}, \bar{z})$), and $\bar{y} \notin \operatorname{rad}\mathfrak{p}^2 = \mathfrak{p}$ (as $\bar{y} \notin (\bar{x}, \bar{z})$). So $\mathfrak{p}^2$ is not primary. Sanity check: geometrically $\mathfrak{p}$ cuts out the line $x = z = 0$ on the quadric cone $z^2 = xy$; the cone is singular along no line but the squared ideal "sees" the embedded origin, which is exactly why primariness fails.

Primary decomposition and minimality

We now assemble primary ideals the way primes assemble in arithmetic, but using *intersection* (the ideal-theoretic analogue of the least common multiple; geometrically $Z(\mathfrak{a} \cap \mathfrak{b}) = Z(\mathfrak{a}) \cup Z(\mathfrak{b})$ is the *union* of the zero loci) rather than product.

Definition 15.6.7 (primary decomposition)**.** A *primary decomposition* of an ideal $\mathfrak{a}$ is an expression

$$\mathfrak{a} = \mathfrak{q}_1 \cap \mathfrak{q}_2 \cap \cdots \cap \mathfrak{q}_n, \qquad \mathfrak{q}_i \text{ primary.}$$

If such an expression exists, $\mathfrak{a}$ is *decomposable*. The decomposition is *minimal* (also *reduced* or *irredundant*) if:

(a) the radicals $\mathfrak{p}_i = \operatorname{rad}\mathfrak{q}_i$ are all *distinct*, and

(b) no component is superfluous: $\mathfrak{q}_i \not\supseteq \bigcap_{j \neq i} \mathfrak{q}_j$ for every i.

Any decomposition can be reduced to a minimal one. Condition (a) is achievable because a finite intersection of $\mathfrak{p}$-primary ideals (same $\mathfrak{p}$) is again $\mathfrak{p}$-primary, so we may group components with equal radical into one. Condition (b) is achievable by simply discarding any $\mathfrak{q}_i$ containing the intersection of the rest.

Lemma 15.6.8 (intersections and colons of primary ideals)**.** (1) *If $\mathfrak{q}_1, \ldots, \mathfrak{q}_m$ are all $\mathfrak{p}$-primary, then $\mathfrak{q} = \bigcap_i \mathfrak{q}_i$ is $\mathfrak{p}$-primary.*

(2) *Let $\mathfrak{q}$ be $\mathfrak{p}$-primary and $x \in R$. Then: $x \in \mathfrak{q} \Rightarrow (\mathfrak{q} : x) = R$; $x \notin \mathfrak{q} \Rightarrow (\mathfrak{q} : x)$ is $\mathfrak{p}$-primary, hence $\operatorname{rad}(\mathfrak{q} : x) = \mathfrak{p}$; $x \notin \mathfrak{p} \Rightarrow (\mathfrak{q} : x) = \mathfrak{q}$.*

Idea. (1) $\operatorname{rad}\mathfrak{q} = \bigcap \operatorname{rad}\mathfrak{q}_i = \mathfrak{p}$; if $xy \in \mathfrak{q}$, $y \notin \mathfrak{p}$, then $y \notin \operatorname{rad}\mathfrak{q}_i$ so $x \in \mathfrak{q}_i$ for every i, giving $x \in \mathfrak{q}$. (2) The middle claim: if $x \notin \mathfrak{q}$ and $yz \in (\mathfrak{q} : x)$ with $z \notin \mathfrak{p}$, then $xyz \in \mathfrak{q}$ and $z \notin \operatorname{rad}\mathfrak{q}$ force $xy \in \mathfrak{q}$, i.e. $y \in (\mathfrak{q} : x)$; and $\mathfrak{q} \subseteq (\mathfrak{q} : x) \subseteq \operatorname{rad} = \mathfrak{p}$ gives the radical. The colon ideals are the engine of the uniqueness theorem. □

Worked Example 15.6.9 (Two minimal decompositions of (x^2, xy))**.** Find primary decompositions of $\mathfrak{a} = (x^2, xy) \subseteq k[x, y]$ and show minimality.

Recognition. $\mathfrak{a}$ is not primary ($xy \in \mathfrak{a}$, $x \notin \mathfrak{a}$, no power of y in $\mathfrak{a}$); look to write it as (prime) $\cap$ (maximal-radical primary).

Solution. Factor out the common x: $\mathfrak{a} = (x) \cap (x^2, y) = (x) \cap (x^2, xy, y^2, \dots)$. Check: $(x) \cap (x^2, y)$ consists of multiples of x that also lie in (x^2, y); $f = xg \in (x^2, y)$ means $xg \equiv 0$ in $k[x, y]/(x^2, y) = k[x]/(x^2)$, i.e. $g \in (x, y)$, so $f \in (x^2, xy) = \mathfrak{a}$. Both pieces are primary: (x) is prime, (x^2, y) is (x, y)-primary. A *different* minimal decomposition is $\mathfrak{a} = (x) \cap (x, y)^2$, since $(x) \cap (x, y)^2 = (x^2, xy)$ likewise. Sanity check: radicals are (x) and (x, y) in both, distinct, and neither component contains the other, so both are minimal — yet the (x, y)-primary component differs ((x^2, y) vs. $(x, y)^2$). Non-uniqueness of components is real.

Worked Example 15.6.10 (A three-component decomposition)**.** Give a minimal primary decomposition of $\mathfrak{a} = (x^2, xy, xz, yz) \subseteq k[x, y, z]$ and list its primes.

Recognition. Look for the irreducible pieces of $Z(\mathfrak{a})$: where does $x^2 = xy = xz = yz = 0$ vanish? On $\{ x = y = 0 \} \cup \{ x = z = 0 \}$ plus possibly an embedded point.

Solution. One checks $\mathfrak{a} = (x, y) \cap (x, z) \cap (x, y, z)^2$. Indeed $(x, y) \cap (x, z) = (x, yz)$ (modulo x this is $(y) \cap (z) = (yz)$ in $k[y, z]$), so an element of the right side is $f = xg + yzh$; since $f \in (x, y, z)^2$ has no linear term, g has zero constant term, i.e. $g \in (x, y, z)$, and $f \in x(x, y, z) + (yz) = \mathfrak{a}$. Conversely each generator of $\mathfrak{a}$ lies in all three. The radicals are (x, y) (prime), (x, z) (prime), and $\operatorname{rad}(x, y, z)^2 = (x, y, z)$ (maximal). Sanity check: $Z(\mathfrak{a})$ is the union of the two lines $\{ x = y = 0 \}$ (the z-axis) and $\{ x = z = 0 \}$ (the y-axis); these are the loci of the isolated primes (x, y) and (x, z), while (x, y, z) is the embedded origin where the two lines cross — three primes, two of dimension 1 and one embedded point.

Worked Example 15.6.11 (Decomposing a principal ideal in a UFD)**.** For $a = p_1^{e_1} \cdots p_m^{e_m}$ in a UFD R (distinct irreducibles p_i), give the minimal primary decomposition of (a).

Recognition. Each $(p_i^{e_i})$ is (p_i)-primary; their intersection should be (lcm) $= (a)$.

Solution. $(a) = (p_1^{e_1}) \cap \cdots \cap (p_m^{e_m})$. Since the p_i are pairwise non-associate, the intersection of the $(p_i^{e_i})$ is generated by their lcm, which is a. Each $(p_i^{e_i})$ is (p_i)-primary (its radical (p_i) is prime, indeed maximal in $\mathbb{Z}$; in a general UFD one checks directly that $\pi^n \mid ab$, $\pi^n \nmid a$ force $\pi \mid b$), the radicals (p_i) are distinct, and no factor is redundant (dropping $(p_i^{e_i})$ enlarges the intersection to $(a/p_i^{e_i}) \neq (a)$). All primes (p_i) are isolated — none contains another. Sanity check: with $R = \mathbb{Z}$, $a = 180 = 2^2 \cdot 3^2 \cdot 5$ gives $(180) = (4) \cap (9) \cap (5)$, $\operatorname{rad}(180) = (2) \cap (3) \cap (5) = (30)$, matching $\operatorname{rad}(180) = (2 \cdot 3 \cdot 5)$.

Associated primes and the first uniqueness theorem

The radicals $\mathfrak{p}_i = \operatorname{rad} \mathfrak{q}_i$ appearing in a minimal decomposition turn out to be canonical: they depend only on $\mathfrak{a}$, not on the chosen decomposition. This is the *first uniqueness theorem*, and the mechanism is the colon ideal.

Definition 15.6.12 (associated primes of an ideal)**.** If $\mathfrak{a} = \bigcap_i \mathfrak{q}_i$ is a minimal primary decomposition, the primes $\mathfrak{p}_i = \operatorname{rad} \mathfrak{q}_i$ are the *associated primes of* $\mathfrak{a}$, written $\operatorname{Ass}(\mathfrak{a})$ (D&F: the associated primes; A&M: the primes belonging to $\mathfrak{a}$). Equivalently — and this is what makes them well-defined —

$$\mathfrak{p} \in \operatorname{Ass}(\mathfrak{a}) \quad \Longleftrightarrow \quad \mathfrak{p} = \operatorname{rad}(\mathfrak{a} : x) \text{ is prime for some } x \in R.$$

Theorem 15.6.13 (First Uniqueness Theorem)**.** *Let $\mathfrak{a}$ be decomposable, $\mathfrak{a} = \bigcap_{i=1}^{n} \mathfrak{q}_i$ a minimal primary decomposition, $\mathfrak{p}_i = \operatorname{rad} \mathfrak{q}_i$. Then the set $\{ \mathfrak{p}_1, \dots, \mathfrak{p}_n \}$ is exactly the set of prime ideals occurring among the ideals $\operatorname{rad}(\mathfrak{a} : x)$ as x ranges over R. Consequently $\operatorname{Ass}(\mathfrak{a})$ is independent of the chosen minimal decomposition.*

Idea. For $x \in R$, $(\mathfrak{a} : x) = \bigcap_i (\mathfrak{q}_i : x)$, so by the colon lemma $\operatorname{rad}(\mathfrak{a} : x) = \bigcap_{x \notin \mathfrak{q}_j} \mathfrak{p}_j$. If this radical is prime it must equal one of the $\mathfrak{p}_j$ (a prime containing a finite intersection contains a factor; primeness pins it to a single $\mathfrak{p}_j$). Conversely, minimality (b) lets us pick, for each i, an $x_i \in \bigcap_{j \neq i} \mathfrak{q}_j \setminus \mathfrak{q}_i$; then $\operatorname{rad}(\mathfrak{a} : x_i) = \mathfrak{p}_i$. So the primes among $\{ \operatorname{rad}(\mathfrak{a} : x) \}$ are precisely $\{ \mathfrak{p}_i \}$. □

Remark 15.6.1. This is the module-theoretic associated-prime set in disguise. Recall $\mathfrak{p}$ is associated to an R-module M if $\mathfrak{p} = \operatorname{Ann}(m)$ for some $m \in M$, i.e. M contains a copy of $R/\mathfrak{p}$. Applying this to $M = R/\mathfrak{a}$: since $\operatorname{Ann}(x + \mathfrak{a}) = (\mathfrak{a} : x)$, the first uniqueness theorem says that $\operatorname{Ass}(\mathfrak{a})$ consists of the primes that are *radicals* of annihilators of elements of $R/\mathfrak{a}$. When R is Noetherian each of these primes is itself such an annihilator (A&M Proposition 7.17), so $\operatorname{Ass}(\mathfrak{a}) = \operatorname{Ass}_R(R/\mathfrak{a})$; for non-Noetherian R the two sets can differ. The geometric reading: Ass records the "components and embedded data" that $\mathfrak{a}$ remembers about its zero locus.

Definition 15.6.14 (isolated and embedded primes)**.** A prime in $\operatorname{Ass}(\mathfrak{a})$ is *isolated* (or *minimal*) if it is minimal in $\operatorname{Ass}(\mathfrak{a})$ with respect to inclusion; otherwise it is *embedded*. The isolated primes are exactly the minimal primes over $\mathfrak{a}$.

Proposition 15.6.15 (isolated primes = minimal primes over $\mathfrak{a}$; radical and zero-divisors)**.** *Let $\mathfrak{a}$ be decomposable,* $\operatorname{Ass}(\mathfrak{a}) = \{\, \mathfrak{p}_1, \dots, \mathfrak{p}_n \,\}$.

(1) *A prime $\mathfrak{p}$ contains $\mathfrak{a}$ iff $\mathfrak{p} \supseteq \mathfrak{p}_i$ for some i; hence the minimal primes over $\mathfrak{a}$ are exactly the isolated members of* $\operatorname{Ass}(\mathfrak{a})$. *In particular $\mathfrak{a}$ has only finitely many minimal primes.*

(2) $\operatorname{rad}\mathfrak{a} = \bigcap_i \mathfrak{p}_i = \bigcap(\textit{isolated } \mathfrak{p}_i)$.

(3) *If $\mathfrak{a} = 0$: the set of zero-divisors of R is $\bigcup_i \mathfrak{p}_i = \bigcup_{x \neq 0} \operatorname{rad}(0 : x)$, and the set of nilpotents is $\bigcap_i \mathfrak{p}_i$.*

Idea. (1) $\mathfrak{p} \supseteq \mathfrak{a} = \bigcap \mathfrak{q}_i$ gives $\mathfrak{p} \supseteq \mathfrak{q}_i$ (a prime containing a finite intersection contains a factor), hence $\mathfrak{p} \supseteq \operatorname{rad}\mathfrak{q}_i = \mathfrak{p}_i$; the minimal such $\mathfrak{p}$ are the minimal $\mathfrak{p}_i$. (2) Radical commutes with finite intersection. (3) For $\mathfrak{a} = 0$ each $\mathfrak{q}_i$ has $\operatorname{rad}\mathfrak{q}_i = \mathfrak{p}_i$ and $0 = \bigcap \mathfrak{q}_i$; the colon description $D = \bigcup_{x \neq 0} \operatorname{rad}(0 : x) = \bigcup \mathfrak{p}_i$ identifies zero-divisors, while nilpotents form $\operatorname{rad}(0) = \bigcap \mathfrak{p}_i$. □

Worked Example 15.6.16 (Associated primes via colon ideals)**.** For $\mathfrak{a} = (x^2, xy) = (x) \cap (x, y)^2$ in $k[x, y]$, compute $\operatorname{Ass}(\mathfrak{a})$ and classify each prime.

Recognition. Use $\operatorname{rad}(\mathfrak{a} : f)$ for cleverly chosen f; the isolated prime is the minimal one.

Solution. The decomposition has radicals (x) and (x, y). Take $f = x$: $(\mathfrak{a} : x) = \{\, g : xg \in (x^2, xy) \,\} = \{\, g : g \in (x, y) \,\} = (x, y)$, so $\operatorname{rad}(\mathfrak{a} : x) = (x, y)$, an associated prime. Take $f = y$: $(\mathfrak{a} : y) = \{\, g : yg \in (x^2, xy) \,\}$; $yg \in (x^2, xy) = x(x, y)$ forces $x \mid g$, giving $(\mathfrak{a} : y) = (x)$, prime. So $\operatorname{Ass}(\mathfrak{a}) = \{\, (x), (x, y) \,\}$. Since $(x) \subsetneq (x, y)$, (x) is isolated (minimal) and (x, y) is embedded. Sanity check: $\operatorname{rad}\mathfrak{a} = (x) \cap (x, y) = (x)$, matching "radical = intersection of isolated primes," and $Z(\mathfrak{a})$ = the y-axis (locus of (x)) with the origin (locus of (x, y)) embedded in it.

Worked Example 15.6.17 (Associated primes of $\mathbb{Z}/n\mathbb{Z}$ as a module)**.** For $R = \mathbb{Z}$ and $M = \mathbb{Z}/n\mathbb{Z}$, compute $\operatorname{Ass}_R(M)$, and reconcile with Ass of the ideal (n).

Recognition. $\mathfrak{p} = \operatorname{Ann}(m)$ prime; cyclic submodules of $\mathbb{Z}/n\mathbb{Z}$ are $\mathbb{Z}/d\mathbb{Z}$ for $d \mid n$, with annihilator (d), which is prime iff $d = p$.

Solution. An element $\bar{m} \in \mathbb{Z}/n\mathbb{Z}$ of additive order d generates a copy of $\mathbb{Z}/d\mathbb{Z}$ with $\operatorname{Ann}(\bar{m}) = (d)$. This is prime iff d is prime. For each prime $p \mid n$ there is an element of order p (namely $\overline{n/p}$), giving $(p) \in \operatorname{Ass}_R(M)$; and these are the only primes arising. So $\operatorname{Ass}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) = \{\, (p) : p \mid n \,\}$. Sanity check: this matches Ass of the ideal (n), whose minimal primary decomposition $(n) = \bigcap_p (p^{e_p})$ has radicals (p) for $p \mid n$ — all isolated, no embedded primes, consistent with (n) being far from radical yet having a "square-free" set of primes.

Worked Example 15.6.18 (Minimal primes of an ideal in $k[x, y, z]$)**.** Find the minimal primes over $\mathfrak{a} = (xy, xz) \subseteq k[x, y, z]$ and hence $\operatorname{rad}\mathfrak{a}$.

Recognition. Minimal primes over $\mathfrak{a}$ = isolated associated primes, matching (for k algebraically closed) the irreducible components of $Z(\mathfrak{a})$. Factor $\mathfrak{a} = (x) \cap (y, z)$.

Solution. $xy, xz \in \mathfrak{a}$ vanish where $x = 0$ or where $y = z = 0$. Indeed $\mathfrak{a} = (x) \cap (y, z)$: an element divisible by x and lying in (y, z) — check generators $xy = x \cdot y \in (x) \cap (y, z)$, etc.; conversely $(x) \cap (y, z) \subseteq (xy, xz)$ since $f \in (x)$ means $f = xg$, and $f \in (y, z)$ forces $g \in (y, z)$, so $f \in x(y, z) = (xy, xz)$. Both (x) and (y, z) are prime, incomparable, hence both isolated; there are no embedded primes here. Thus the minimal primes are $(x), (y, z)$ and $\operatorname{rad}\mathfrak{a} = (x) \cap (y, z) = \mathfrak{a}$ (so $\mathfrak{a}$ is radical). Sanity check: $Z(\mathfrak{a})$ is the plane $x = 0$ together with the line $y = z = 0$ (the x-axis), the two irreducible components matching the two minimal primes; $\mathfrak{a}$ radical $\iff$ all components prime, consistent.

The second uniqueness theorem: isolated components

The embedded components are genuinely non-unique (the (x,y)-component of (x^2,xy) was (x^2,y) or $(x,y)^2$). But the components attached to *isolated* primes are forced. The clean proof goes through localization — exactly A&M's emphasis that "localizing concentrates attention near a prime," here killing every component not supported at the chosen prime.

Proposition 15.6.19 (primary ideals under localization)**.** *Let $S \subseteq R$ be multiplicatively closed, $\mathfrak{q}$ a $\mathfrak{p}$-primary ideal, and S^{-1} extension / contraction between R and $S^{-1}R$. Then:*

(1) *If $S \cap \mathfrak{p} \neq \varnothing$, then $S^{-1}\mathfrak{q} = S^{-1}R$ (the component is "blown away").*

(2) *If $S \cap \mathfrak{p} = \varnothing$, then $S^{-1}\mathfrak{q}$ is $S^{-1}\mathfrak{p}$-primary, and its contraction to R is $\mathfrak{q}$ again: $S(\mathfrak{q}) = (S^{-1}\mathfrak{q})^c = \mathfrak{q}$. Contraction gives an inclusion-preserving bijection between $\mathfrak{p}$-primary ideals of R (with $\mathfrak{p} \cap S = \varnothing$) and $S^{-1}\mathfrak{p}$-primary ideals of $S^{-1}R$.*

Idea. (1) If $s \in S \cap \mathfrak{p}$ then $s^n \in \mathfrak{q}$ for some n, and s^n becomes a unit in $S^{-1}R$, so $S^{-1}\mathfrak{q}$ contains a unit. (2) Standard localization compatibilities: rad and primary survive, and for $\mathfrak{p} \cap S = \varnothing$ no element of S is a zero-divisor mod $\mathfrak{q}$, so contraction recovers $\mathfrak{q}$. □

Theorem 15.6.20 (Second Uniqueness Theorem)**.** *Let $\mathfrak{a}$ be decomposable with minimal primary decomposition $\mathfrak{a} = \bigcap_{i=1}^{n} \mathfrak{q}_i$, $\mathfrak{p}_i = \operatorname{rad} \mathfrak{q}_i$. If $\mathfrak{p}_{i_1}, \dots, \mathfrak{p}_{i_r}$ is an* isolated set *of primes (a subset closed downward in* $\operatorname{Ass}(\mathfrak{a})$*: $\mathfrak{p}_j \subseteq \mathfrak{p}_{i_k} \Rightarrow \mathfrak{p}_j$ is in the set), then $\mathfrak{q}_{i_1} \cap \cdots \cap \mathfrak{q}_{i_r}$ is independent of the decomposition. In particular, each primary component $\mathfrak{q}_i$ belonging to an* isolated *(minimal) prime $\mathfrak{p}_i$ is uniquely determined by $\mathfrak{a}$:*

$$\mathfrak{q}_i = S_i(\mathfrak{a}) = \left(S_i^{-1}\mathfrak{a}\right)^c, \qquad S_i = R \setminus \mathfrak{p}_i.$$

Idea. Localize at $S = R \setminus \bigcup_k \mathfrak{p}_{i_k}$. By the localization proposition, $S^{-1}\mathfrak{q}_j = S^{-1}R$ exactly when $\mathfrak{p}_j \not\subseteq \bigcup \mathfrak{p}_{i_k}$ (prime avoidance: $\mathfrak{p}_j \subseteq \bigcup \mathfrak{p}_{i_k} \iff \mathfrak{p}_j \subseteq$ some $\mathfrak{p}_{i_k} \iff \mathfrak{p}_j$ in the isolated set). So contracting $S^{-1}\mathfrak{a}$ kills all components outside the set and recovers $\bigcap_k \mathfrak{q}_{i_k}$, an expression in terms of $\mathfrak{a}$ and the $\mathfrak{p}_{i_k}$ alone — hence independent of the decomposition. For a single minimal prime $\mathfrak{p}_i$ take $S_i = R \setminus \mathfrak{p}_i$. □

Remark 15.6.2. Together the two theorems give the precise statement of "unique factorization of ideals": the *set* of associated primes is unique (first), and the primary components at *minimal* primes are unique (second), while embedded components carry the only genuine ambiguity. This is the exact ideal-theoretic analogue of: the primes dividing n are unique, and so are the exact prime-power factors — but in the ideal world the "higher-order" embedded data can wobble.

Worked Example 15.6.21 (Recovering the isolated component by localization)**.** For $\mathfrak{a} = (x^2, xy)$ in $k[x,y]$, recover the (x)-primary (isolated) component as $S^{-1}\mathfrak{a}$ contracted, $S = k[x,y] \setminus (x)$.

Recognition. The isolated prime is (x); localizing at $S = R \setminus (x)$ inverts everything outside (x), in particular makes y a unit, blowing away the (x,y)-component.

Solution. In $S^{-1}R = R_{(x)}$, the element $y \notin (x)$ becomes a unit. The component $(x,y)^2$ (or (x^2,y)) localizes to the unit ideal because its radical (x,y) meets S (indeed $y \in S \cap (x,y)$). Hence $S^{-1}\mathfrak{a} = S^{-1}(x) = (x)R_{(x)}$, and contracting back: $(x)R_{(x)} \cap R = (x)$ (since (x) is prime, its contraction from the localization at (x) is itself). So $S_{(x)}(\mathfrak{a}) = (x)$, the unique isolated component. Sanity check: this matches both decompositions $(x) \cap (x,y)^2$ and $(x) \cap (x^2,y)$ — the (x)-component is (x) in each, exactly as the second uniqueness theorem predicts.

Worked Example 15.6.22 (Embedded component is not recoverable)**.** Explain, using the same $\mathfrak{a} = (x^2, xy)$, why localizing cannot pin down the embedded (x,y)-component.

Recognition. Localize at $S = R \setminus (x,y)$ (i.e. pass to $R_{(x,y)}$) and watch *neither* component get inverted: both radicals (x) and (x,y) lie inside (x,y), so the isolated component survives alongside the embedded one.

Solution. At $\mathfrak{p} = (x,y)$ the set $S = R \setminus (x,y)$ inverts elements outside the maximal ideal. The isolated component (x) has radical (x), and here $(x) \subseteq (x,y)$, so $S \cap (x) = \varnothing$ and (x) does *not* get blown away; we get $S^{-1}\mathfrak{a} = S^{-1}\big((x) \cap \mathfrak{q}_{(x,y)}\big)$ involving *both* components. So localization at the embedded prime does not isolate $\mathfrak{q}_{(x,y)}$. Concretely $(S^{-1}\mathfrak{a})^c$ recovers $\mathfrak{a}$ itself, not a single primary ideal, because (x,y) is not minimal. Sanity check: consistent with the explicit ambiguity $\mathfrak{q}_{(x,y)} \in \{\, (x,y)^2, (x^2,y) \,\}$ — there is no canonical choice, so no localization could return one.

Existence in Noetherian rings; Supp, Ass, and symbolic powers

The decompositions above presuppose a decomposition exists. In a Noetherian ring it always does — this is the Lasker–Noether theorem. The route is through *irreducible* ideals.

Definition 15.6.23 (irreducible ideal)**.** A proper ideal $\mathfrak{a}$ is *irreducible* if $\mathfrak{a} = \mathfrak{b} \cap \mathfrak{c}$ (ideals) implies $\mathfrak{a} = \mathfrak{b}$ or $\mathfrak{a} = \mathfrak{c}$.

Lemma 15.6.24 (two Noetherian lemmas)**.** *In a Noetherian ring R:*

(1) *every proper ideal is a finite intersection of irreducible ideals;*

(2) *every irreducible ideal is primary.*

Idea. (1) If the set of proper ideals *not* so expressible were nonempty, Noetherianity gives a maximal counterexample $\mathfrak{a}$; $\mathfrak{a}$ is not irreducible, so $\mathfrak{a} = \mathfrak{b} \cap \mathfrak{c}$ properly, each of $\mathfrak{b}, \mathfrak{c}$ is a finite intersection of irreducibles, hence so is $\mathfrak{a}$ — contradiction. (2) Pass to $R/\mathfrak{a}$ and show 0 irreducible $\Rightarrow$ 0 primary: if $xy = 0$, $y \neq 0$, the ascending chain $\operatorname{Ann}(x) \subseteq \operatorname{Ann}(x^2) \subseteq \cdots$ stabilizes at $\operatorname{Ann}(x^n)$; then $(x^n) \cap (y) = 0$, and irreducibility with $(y) \neq 0$ forces $x^n = 0$. □

Theorem 15.6.25 (Lasker–Noether: existence)**.** *In a Noetherian ring R every proper ideal has a (minimal) primary decomposition. Consequently every proper ideal has finitely many associated primes, finitely many minimal primes, and a well-defined* $\operatorname{Ass}(\mathfrak{a})$.

Idea. Combine the two lemmas: finite intersection of irreducibles = finite intersection of primary ideals; then reduce to a minimal decomposition by grouping equal radicals and discarding redundant components. □

Remark 15.6.3 (the module picture: Supp and Ass). For a finitely generated module M over a Noetherian ring, the *support* is $\operatorname{Supp}(M) = \{\, \mathfrak{p} \in \operatorname{Spec} R : M_{\mathfrak{p}} \neq 0 \,\} = V(\operatorname{Ann} M)$, the closed subset of $\operatorname{Spec} R$ where M "lives." It relates to $\operatorname{Ass}(M)$ by:

(1) $\operatorname{Ass}(M) \subseteq \operatorname{Supp}(M)$, and the *minimal* elements of the two sets coincide;

(2) $\operatorname{Supp}(M) = \bigcup_{\mathfrak{p} \in \operatorname{Ass}(M)} V(\mathfrak{p})$, the union of the closed sets cut out by the associated primes;

(3) the isolated primes of $\mathfrak{a}$ are the minimal primes of $\operatorname{Supp}(R/\mathfrak{a}) = V(\mathfrak{a})$ — recovering, for $R = k[x_1, \ldots, x_n]$ with k algebraically closed, "isolated primes = irreducible components of $Z(\mathfrak{a})$."

This is A&M's geometric punchline: Ass records the embedded data, Supp records the underlying space, and the two agree exactly on the components.

$$\operatorname{Ass}(M) \text{ (associated primes)} \quad \subseteq \quad \operatorname{Supp}(M) = V(\operatorname{Ann} M) \text{ (support)}$$

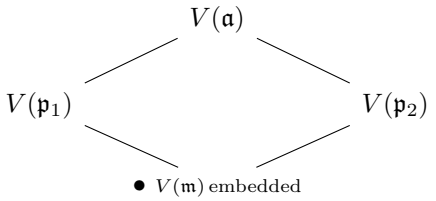

Diagram explanation. Objects: Left sub-diagram: two objects arranged vertically. Top node: $\operatorname{Ass}(M)$, the finite set of primes $\mathfrak{p}$ of R such that $\mathfrak{p} = \operatorname{Ann}_R(m)$ for some $m \in M$ (equivalently, M contains a copy of $R/\mathfrak{p}$). Bottom node: $\operatorname{Supp}(M) = V(\operatorname{Ann} M)$, the support of M, a closed subset of $\operatorname{Spec} R$ consisting of all primes $\mathfrak{p}$ at which the localization $M_{\mathfrak{p}} \neq 0$; it equals the closed set cut out by $\operatorname{Ann}_R(M)$.

Arrows: The single arrow is a phantom arrow carrying the label $\subseteq$: it is not a ring map or module map, but a set-theoretic containment statement $\operatorname{Ass}(M) \subseteq \operatorname{Supp}(M)$, printed as the symbol $\subseteq$ between the two nodes (no arrow is drawn) to signal that $\operatorname{Ass}(M)$ sits inside the larger locus $\operatorname{Supp}(M)$. The phantom style means the arrow contributes no actual morphism to the diagram; it is purely notational, flagging an inclusion of sets of prime ideals.

What commutes: There is no composite to equate; the diagram records a single containment. The relevant assertion is: if $\mathfrak{p} \in \operatorname{Ass}(M)$ then $M_{\mathfrak{p}} \neq 0$, so $\mathfrak{p} \in \operatorname{Supp}(M)$. Equivalently, $\operatorname{Ann}_R(M) \subseteq \operatorname{Ann}_R(m)$ gives $\mathfrak{p} = \operatorname{Ann}_R(m) \supseteq \operatorname{Ann}_R(M)$, so $\mathfrak{p} \in V(\operatorname{Ann} M)$.

Why it commutes: Take any $\mathfrak{p} = \operatorname{Ann}_R(m) \in \operatorname{Ass}(M)$. Then $rm = 0$ for all $r \in \operatorname{Ann}_R(M)$, so $\operatorname{Ann}_R(M) \subseteq \mathfrak{p}$, meaning $\mathfrak{p} \supseteq \operatorname{Ann}_R(M)$, i.e. $\mathfrak{p} \in V(\operatorname{Ann} M) = \operatorname{Supp}(M)$. The reverse containment fails in general: a prime can support M without annihilating any single element.

Why this matters here: The remark identifies Supp and Ass as the two layers of geometric data attached to a module. The diagram makes the hierarchy visual: Ass is a subset of Supp (usually a proper one), recording the embedded data, while Supp is the full geometric locus. The minimality statement (both have the same minimal elements) is the key reconciliation, explained immediately after by the pairing with $V(\mathfrak{p}_i)$ on the right.

Concrete example: Take $R = k[x, y]$, $M = R/\mathfrak{a}$ with $\mathfrak{a} = (x) \cap (x, y)^2$. Then $\operatorname{Ass}(M) = \{(x), (x, y)\}$ while $\operatorname{Supp}(M) = V((x))$, the y-axis in $\operatorname{Spec} k[x, y]$. Both elements of Ass lie in Supp: $(x) \in V((x))$ obviously, and $(x, y) \in V((x))$ since $(x, y) \supseteq (x)$. The containment Ass $\subseteq$ Supp holds with the embedded prime (x, y) contributing no new geometric locus.

Common pitfall: Students often read $\operatorname{Ass}(M) \subseteq \operatorname{Supp}(M)$ as an equality and conclude that every prime in the support annihilates some element. This fails: a prime can localize M nontrivially without being an annihilator prime. In the example above, every prime $(x, y - c)$ with $c \neq 0$ lies in $\operatorname{Supp}(M) = V((x))$ but is not associated. The embedded prime (x, y) is associated (it is the annihilator of the coset of x), yet the point (x, y) is already in the support via the component $V((x))$; it contributes no new locus.

Takeaway: The point of this diagram is that $\operatorname{Ass}(M)$ sits inside $\operatorname{Supp}(M)$ (usually as a proper subset), with both recording the same minimal primes but Ass additionally tagging the embedded primes that carry nilpotent or higher-order information without enlarging the support.

Diagram explanation. Objects: Four nodes forming a diamond. Top: $V(\mathfrak{a})$, the full closed set (variety) of $\mathfrak{a}$ in $\operatorname{Spec} R$, i.e. all primes containing $\mathfrak{a}$. Left and right: $V(\mathfrak{p}_1)$ and $V(\mathfrak{p}_2)$, the two irreducible closed subsets corresponding to the two isolated (minimal) associated primes $\mathfrak{p}_1, \mathfrak{p}_2$ of $\mathfrak{a}$; geometrically these are the irreducible components of $V(\mathfrak{a})$. Bottom: $\bullet$ labeled $V(\mathfrak{m})_{\text{embedded}}$, the closed point corresponding to the embedded prime $\mathfrak{m}$ (a maximal ideal, or at least a non-minimal associated prime), which sits at the intersection of the two components.

Arrows: All four edges are plain solid lines (no arrowheads), encoding *specialization*: an edge from A down to B means $B \supseteq A$ as ideals, i.e. $V(B) \subseteq V(A)$ (the variety of the smaller ideal contains the variety of the larger ideal as a subspace). $V(\mathfrak{p}_1) \subseteq V(\mathfrak{a})$ and $V(\mathfrak{p}_2) \subseteq V(\mathfrak{a})$ because $\mathfrak{p}_1, \mathfrak{p}_2$ contain $\mathfrak{a}$. $V(\mathfrak{m}) \subseteq V(\mathfrak{p}_1)$ and $V(\mathfrak{m}) \subseteq V(\mathfrak{p}_2)$ because $\mathfrak{m} \supseteq \mathfrak{p}_1$ and $\mathfrak{m} \supseteq \mathfrak{p}_2$ (the embedded prime is larger than both minimal primes).

What commutes: No arrows compose (this is a partial order / Hasse diagram, not a commutative square), but the key containments read off are: $V(\mathfrak{m}) \subseteq V(\mathfrak{p}_1) \cap V(\mathfrak{p}_2)$ (the embedded point sits on the intersection of the two components) and $V(\mathfrak{a}) = V(\mathfrak{p}_1) \cup V(\mathfrak{p}_2)$ (the support is the union of irreducible components, as stated in the remark). The diamond shape encodes that $V(\mathfrak{a})$ is the join and $V(\mathfrak{m})$ is the meet in the specialization order.

Why it commutes: Because $\mathfrak{a} = \mathfrak{q}_1 \cap \mathfrak{q}_2 \cap \mathfrak{q}_3$ with $\operatorname{rad} \mathfrak{q}_i = \mathfrak{p}_i$ (resp. $\mathfrak{m}$), we get $V(\mathfrak{a}) = V(\mathfrak{q}_1) \cup V(\mathfrak{q}_2) \cup V(\mathfrak{q}_3) = V(\mathfrak{p}_1) \cup V(\mathfrak{p}_2) \cup V(\mathfrak{m})$; since $V(\mathfrak{m}) \subseteq V(\mathfrak{p}_1) \cap V(\mathfrak{p}_2)$, the union collapses to $V(\mathfrak{p}_1) \cup V(\mathfrak{p}_2)$. The embedded prime $\mathfrak{m}$ sits at the intersection because it contains both $\mathfrak{p}_1$ and $\mathfrak{p}_2$, making $\mathfrak{m} \in V(\mathfrak{p}_1) \cap V(\mathfrak{p}_2)$.

Why this matters here: This diagram is the geometric punchline of the entire section: primary decomposition in R is the algebraic counterpart of decomposing a variety into irreducible components plus embedded subvarieties. The isolated primes $\mathfrak{p}_1, \mathfrak{p}_2$ give the two components; the embedded prime $\mathfrak{m}$ marks the extra data attached at their intersection. All three primes are determined by $\mathfrak{a}$ (first uniqueness theorem), and so are the isolated components (second uniqueness theorem); only the embedded component $\mathfrak{q}_3$ can change with the decomposition (below, $\mathfrak{m}^2$ may be replaced by (x^2, y, z)). It makes visible why the theory has two kinds of primes.

Concrete example: Take $R = k[x, y, z]$, $\mathfrak{a} = (x, y) \cap (x, z) \cap (x, y, z)^2$ from the three-component example. Then $\mathfrak{p}_1 = (x, y)$ (the z-axis), $\mathfrak{p}_2 = (x, z)$ (the y-axis), $\mathfrak{m} = (x, y, z)$ (the origin). $V(\mathfrak{p}_1) \cup V(\mathfrak{p}_2)$ is the union of the two lines; $V(\mathfrak{m}) = \{(x, y, z)\}$ is the origin, which lies on both lines. The diamond displays the specialization lattice of $\operatorname{Ass}(\mathfrak{a}) = \{\mathfrak{p}_1, \mathfrak{p}_2, \mathfrak{m}\}$ inside $\operatorname{Spec} R$.

Common pitfall: Students mistake the embedded prime $V(\mathfrak{m})$ for a separate geometric component, counting three components instead of two. The embedded prime contributes no new points to $\mathrm{Supp}(M)$ (since $V(\mathfrak{m}) \subseteq V(\mathfrak{p}_1) \cap V(\mathfrak{p}_2) \subseteq V(\mathfrak{p}_1)$); its primary component $\mathfrak{q}_3$ records higher-order intersection data (like a fat point at the origin) that does not change the underlying set $V(\mathfrak{a})$ but does affect the scheme structure.

Takeaway: The point of this diagram is that the associated primes of $\mathfrak{a}$ fall into two levels – the isolated primes at the top giving the irreducible geometric components of $V(\mathfrak{a})$, and the embedded primes at the bottom sitting invisibly inside those components – and the diamond shape makes this two-tier structure and the specialization order between them explicit.

Definition 15.6.26 (symbolic power)**.** For a prime $\mathfrak{p}$ and $n \geq 1$, the *n-th symbolic power* is the $\mathfrak{p}$-primary contraction of $\mathfrak{p}^n$ from the localization $R_{\mathfrak{p}}$:

$$\mathfrak{p}^{(n)} = \left(\mathfrak{p}^n R_{\mathfrak{p}}\right)^c = \{\, x \in R : sx \in \mathfrak{p}^n \text{ for some } s \notin \mathfrak{p} \,\} = S_{\mathfrak{p}}(\mathfrak{p}^n), \quad S_{\mathfrak{p}} = R \setminus \mathfrak{p}.$$

It is the *$\mathfrak{p}$-primary component* of $\mathfrak{p}^n$ (the isolated one) — in general $\mathfrak{p}^n \subseteq \mathfrak{p}^{(n)}$, with equality iff $\mathfrak{p}^n$ is already $\mathfrak{p}$-primary.

Worked Example 15.6.27 (Existence forced by Noetherianity, failure without it)**.** Show (0) has no primary decomposition in $R = k[x_1, x_2, \dots]/(x_1x_2, x_3x_4, x_5x_6, \dots)$.

Recognition. Lasker–Noether needs Noetherian; this R has infinitely many minimal primes, so (0) cannot be a finite intersection of primaries.

Solution. Every prime of R contains $\bar{x}_{2i-1}$ or $\bar{x}_{2i}$ for each i (their product is 0), and for every choice of one variable from each pair the ideal generated by the chosen variables is prime (the quotient is a polynomial ring in the remaining variables); so these ideals are exactly the minimal primes of R, and there are infinitely many of them, pairwise incomparable. If $(0) = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_m$ were a finite primary decomposition, then by the proposition on isolated primes (the minimal primes over a decomposable ideal are its isolated associated primes) (0) would have only finitely many minimal primes (the isolated $\operatorname{rad} \mathfrak{q}_i$). But it has infinitely many. Contradiction. Sanity check: R is non-Noetherian (the ideal $(x_1, x_3, x_5, \dots)$ is not finitely generated), so the existence theorem simply does not apply — exactly the hypothesis that fails.

Worked Example 15.6.28 (A primary ideal that is not irreducible)**.** Show the primary ideal $(x, y)^2 \subseteq k[x, y]$ is *not* irreducible (so irreducible $\Rightarrow$ primary has no converse).

Recognition. The lemma gives irreducible $\Rightarrow$ primary, not the converse; exhibit $(x, y)^2$ as a proper intersection.

Solution. $(x, y)^2 = (x^2, xy, y^2)$ is (x, y)-primary (power of a maximal ideal). But

$$(x, y)^2 = (x, y^2) \cap (y, x^2) :$$

each generator x^2, xy, y^2 lies in both factors, and conversely an element in $(x, y^2) \cap (y, x^2)$ has no pure linear term and its quadratic part lies in (x^2, xy, y^2). Both factors strictly contain $(x, y)^2$ (e.g. $x \in (x, y^2)$ but $x \notin (x, y)^2$), so this is a nontrivial decomposition. Hence $(x, y)^2$ is reducible though primary. Sanity check: (x, y^2) and (y, x^2) are both (x, y)-primary, so their intersection is again (x, y)-primary — consistent with $(x, y)^2$ being (x, y)-primary, and showing why minimality groups same-radical components.

Worked Example 15.6.29 (Symbolic powers differ from ordinary powers)**.** In $R = k[x, y, z]/(xy - z^2)$ with $\mathfrak{p} = (\bar{x}, \bar{z})$, compare $\mathfrak{p}^2$ and $\mathfrak{p}^{(2)}$.

Recognition. $\mathfrak{p}^2$ was shown non-primary (embedded origin); $\mathfrak{p}^{(2)}$ is its isolated $\mathfrak{p}$-primary component, so they should differ.

Solution. We found $\mathfrak{p}^2 = \bar{x}(\bar{x}, \bar{y}, \bar{z})$ is not primary, with $\bar{y}$ a zero-divisor mod $\mathfrak{p}^2$ that is not nilpotent. The symbolic power $\mathfrak{p}^{(2)} = (\mathfrak{p}^2 R_{\mathfrak{p}})^c = \{\, r : sr \in \mathfrak{p}^2,\ s \notin \mathfrak{p} \,\}$. Since $\bar{y} \notin \mathfrak{p}$, the relation $\bar{y} \cdot \bar{x} = \bar{z}^2 \in \mathfrak{p}^2$ shows $\bar{x} \in \mathfrak{p}^{(2)}$, whereas $\bar{x} \notin \mathfrak{p}^2$. Thus $\mathfrak{p}^2 \subsetneq \mathfrak{p}^{(2)}$, and $\mathfrak{p}^{(2)}$ is the genuine $\mathfrak{p}$-primary component (one checks $\mathfrak{p}^{(2)} = (\bar{x}, \bar{z}^2)$-type primary, the contraction making $\bar{y}$ a unit). Sanity check: $\mathfrak{p}^2 \subseteq \mathfrak{p}^{(2)} \subseteq \mathfrak{p}$ with strict first inclusion, exactly the predicted behavior $\mathfrak{p}^n \subseteq \mathfrak{p}^{(n)}$ with equality failing precisely when $\mathfrak{p}^n$ is not primary.

Worked Example 15.6.30 (Support equals the union of components)**.** For $M = R/\mathfrak{a}$ with $\mathfrak{a} = (x) \cap (x, y)^2$ in $R = k[x, y]$, describe $\mathrm{Supp}(M)$ and confirm it is $\bigcup_{\mathfrak{p} \in \mathrm{Ass}} V(\mathfrak{p})$.

Recognition. $\operatorname{Supp}(R/\mathfrak{a}) = V(\mathfrak{a}) = V(\operatorname{rad}\mathfrak{a})$ as a set; $\operatorname{Ass}(\mathfrak{a}) = \{(x), (x,y)\}$.

Solution. $\operatorname{Supp}(R/\mathfrak{a}) = V(\operatorname{Ann}(R/\mathfrak{a})) = V(\mathfrak{a})$, and as a topological subset of $\operatorname{Spec} R$ this equals $V(\operatorname{rad}\mathfrak{a}) = V((x))$, the y-axis line in $\operatorname{Spec} k[x,y]$ (all primes containing x). Now $\bigcup_{\mathfrak{p}\in\operatorname{Ass}} V(\mathfrak{p}) = V((x)) \cup V((x,y)) = V((x)) \cup \{(x,y)\} = V((x))$, since the point (x,y) already lies on the line $V((x))$. So $\operatorname{Supp}(M) = V((x)) = \bigcup_{\mathfrak{p}} V(\mathfrak{p})$. Sanity check: the embedded prime (x,y) contributes *no new points* to the support — it sits inside the component $V((x))$ — which is exactly why Supp sees only the underlying space while Ass additionally records the embedded (x,y).

Worked Example 15.6.31 (Zero-divisors and nilpotents via associated primes)**.** Let $R = k[x,y]/(x^2, xy)$. Using Ass of the lifted ideal, describe the zero-divisors and nilpotents of R.

Recognition. For $(0) = \bigcap_i \mathfrak{q}_i$ minimal in a Noetherian ring, zero-divisors $= \bigcup \mathfrak{p}_i$ and nilpotents $= \bigcap \mathfrak{p}_i = \operatorname{rad}(0)$.

Solution. Lift to $\mathfrak{a} = (x^2, xy)$ in $k[x,y]$ with $\operatorname{Ass}(\mathfrak{a}) = \{(x), (x,y)\}$. In R the zero-divisors are the image of $(x) \cup (x,y) = (x,y)$ and the nilpotents are the image of $(x) \cap (x,y) = (x)$, i.e. $\bar{x}$ generates the nilradical ($\bar{x}^2 = 0$). Sanity check: directly $\bar{x}^2 = 0$ so $\bar{x}$ is nilpotent (hence a zero-divisor), $\bar{y}\bar{x} = 0$ so $\bar{y}$ is a zero-divisor; and $\bar{y}$ is not nilpotent ($y^n \notin (x^2, xy)$), matching $\bar{y} \in \bigcup \mathfrak{p}_i \setminus \bigcap \mathfrak{p}_i$.

Exercises (Dummit & Foote).

1. Prove (3) of Corollary 22 directly by considering the collection S of ideals that do not contain a finite product of prime ideals. [If I is a maximal element in S, show that since I is not prime there are ideals J, K properly containing I (hence not in S) with $JK \subseteq I$.]
2. Let I and J be ideals in the ring R. Prove the following statements:
   (a) If $J^k \subseteq I$ for some $k \geq 1$ then $\operatorname{rad} I \supseteq \operatorname{rad} J$.
   (b) If $I^k \subseteq J \subseteq I$ for some $k \geq 1$ then $\operatorname{rad} I = \operatorname{rad} J$.
   (c) $\operatorname{rad}(IJ) = \operatorname{rad}(I \cap J) = \operatorname{rad} I \cap \operatorname{rad} J$.
   (d) $\operatorname{rad}(\operatorname{rad} I) = \operatorname{rad} I$.
   (e) $\operatorname{rad} I + \operatorname{rad} J \subseteq \operatorname{rad}(I + J)$ and $\operatorname{rad}(I + J) = \operatorname{rad}(\operatorname{rad} I + \operatorname{rad} J)$.
3. Prove that the intersection of two radical ideals is again a radical ideal.
4. Let $I = \mathfrak{m}_1\mathfrak{m}_2$ be the product of the ideals $\mathfrak{m}_1 = (x,y)$ and $\mathfrak{m}_2 = (x-1, y-1)$ in $\mathbb{F}_2[x,y]$. Prove that I is a radical ideal. Prove that the ideal $(x^3 - y^2)$ is a radical ideal in $\mathbb{F}_2[x,y]$.
5. If $I = (xy, (x-y)z) \subseteq k[x,y,z]$ prove that $\operatorname{rad} I = (xy, xz, yz)$. For this ideal prove directly that $Z(I) = Z(\operatorname{rad} I)$, that $Z(I)$ is not irreducible, and that $\operatorname{rad} I$ is not prime.
6. Give an example to show that over a field k that is not algebraically closed the containment $I \subseteq I(Z(I))$ can be proper even when I is a radical ideal.
7. Suppose R and S are rings and $\varphi : R \to S$ is a ring homomorphism. If I is an ideal of R show that $\varphi(\operatorname{rad} I) \subseteq \operatorname{rad}(\varphi(I))$. If in addition φ is surjective and I contains the kernel of φ show that $\varphi(\operatorname{rad} I) = \operatorname{rad}(\varphi(I))$.
8. Suppose the prime ideal P contains the ideal I. Prove that P contains the radical of I.
9. Prove that for any field k the map Z in the Nullstellensatz is always surjective and the map I in the Nullstellensatz is always injective. [Use property (10) of the maps Z and I in Section 1.] Give examples (over a field k that is not algebraically closed) where Z is not injective and I is not surjective.
10. Prove that for k a finite field the Zariski topology is the same as the discrete topology: every subset is closed (and open).
11. Let V be a variety in $\mathbb{A}^n$ and let U_1 and U_2 be two subsets of $\mathbb{A}^n$ that are open in the Zariski topology. Prove that if $V \cap U_1 \neq \emptyset$ and $V \cap U_2 \neq \emptyset$ then $V \cap U_1 \cap U_2 \neq \emptyset$. Conclude that any nonempty open subset of a variety is everywhere dense in the Zariski topology (i.e., its closure is all of V).

12. Use the fact that nonempty open sets of an affine variety are everywhere dense to prove that an affine variety is connected in the Zariski topology. (A topological space is connected if it is not the union of two disjoint, proper, open subsets.)

13. Let V be a nonempty affine algebraic set. Prove that if $k[V]$ is a direct sum of two nonzero ideals, then V is not connected in the Zariski topology, and prove the converse when k is algebraically closed. [Use the weak form of Hilbert's Nullstellensatz.] Give a counterexample to the converse over a field k that is not algebraically closed.

14. Prove that if k is an infinite field, then the varieties in $\mathbb{A}^1$ are the whole space and the one point subsets. What are the varieties in $\mathbb{A}^1$ in the case of a finite field k?

15. Suppose V is a hypersurface in $\mathbb{A}^n$ and $I(V) = (f)$ for some nonconstant polynomial $f \in k[x_1, x_2, \ldots, x_n]$. Prove that V is a variety if and only if f is irreducible.

16. Suppose $V \subseteq \mathbb{A}^n$ is an affine variety and $f \in k[V]$. Prove that the graph of f (cf. Exercise 25 in Section 1) is an affine variety.

17. Prove that any permutation of the elements of a field k is a continuous map from $\mathbb{A}^1$ to itself in the Zariski topology on $\mathbb{A}^1$. Deduce that if k is an infinite field, there are Zariski continuous maps from $\mathbb{A}^1$ to itself that are not polynomials.

18. Let V be an affine algebraic set in $\mathbb{A}^n$ over $k = \mathbb{C}$.

    (a) Prove that morphisms of algebraic sets over $\mathbb{C}$ are continuous in the Euclidean topology (the topology on $\mathbb{C}^n$ obtained by identifying $\mathbb{C}^n$ with $\mathbb{R}^{2n}$ with its usual Euclidean topology).

    (b) Prove that V is a closed set in the Euclidean topology on $\mathbb{C}^n$ (so the Zariski closed sets of $\mathbb{A}^n$ over $\mathbb{C}$ are also Euclidean closed).

    (c) Give an example of a set that is closed in the Euclidean topology but is not closed in the Zariski topology, i.e., is not an affine algebraic set (so the Euclidean topology is "finer" than the Zariski topology).

19. Give an example of an injective k-algebra homomorphism $\widetilde{\varphi} : k[W] \to k[V]$ whose associated morphism $\varphi : V \to W$ is not surjective.

20. Suppose $\varphi : V \to W$ is a surjective morphism of affine algebraic sets. Prove that if V is a variety then W is a variety.

21. Let V be an algebraic set in $\mathbb{A}^n$ and let $f \in k[V]$. Define $V_f = \{\, v \in V \mid f(v) \neq 0 \,\}$.

    (a) Show that V_f is a Zariski open set in V (called a *principal open set* in V).

    (b) Let J be the ideal in $k[x_1, \ldots, x_n, x_{n+1}]$ generated by $I(V)$ and $x_{n+1}f - 1$, and let $W = Z(J) \subseteq \mathbb{A}^{n+1}$. Show that $J = I(W)$ and that the map $\pi : \mathbb{A}^{n+1} \to \mathbb{A}^n$ by projection onto the first n coordinates is a Zariski continuous bijection from W onto V_f (so the principal open set V_f in V may be embedded as a closed set in some (larger) affine space).

    (c) If U is any open set in V show that $U = V_{f_1} \cup \cdots \cup V_{f_m}$ for some $f_1, \ldots, f_m \in k[V]$. (This shows that the principal open sets form a base for the Zariski topology.)

22. Prove that $\mathrm{GL}_n(k)$ is an open affine algebraic set in $\mathbb{A}^{n^2}$ and can be embedded as a closed affine algebraic set in $\mathbb{A}^{n^2+1}$. In particular, deduce that the set $k^\times$ of nonzero elements in $\mathbb{A}^1$ embeds into $\mathbb{A}^2$ as the hyperbola $xy = 1$. [Use the preceding exercise.]

23. Show that if k is infinite then $\{\, (a, a^2, a^3) \mid a \in k \,\} \subseteq \mathbb{A}^3$ is an affine algebraic variety. If k is finite show that this set is always reducible.

24. Let $V = Z(xz - y^2, yz - x^3, z^2 - x^2y) \subseteq \mathbb{A}^3$. Show that if k is infinite then V is an affine variety. [Use Exercise 26 of Section 1 and Exercise 20.]

25. Suppose $f(x) = x^3 + ax^2 + bx + c$ is an irreducible cubic in $\mathbb{Q}[x]$ of discriminant D. Let $I = (x + y + z + a,\ xy + xz + yz - b,\ xyz + c)$ in $\mathbb{Q}[x, y, z]$.

(a) Prove that I is a prime ideal if and only if D is not a square in $\mathbb{Q}$, in which case I is a maximal ideal and $\mathbb{Q}[x,y,z]/I$ is a splitting field for $f(x)$ over $\mathbb{Q}$.

(b) If $D = r^2$, prove that the primary decomposition of I is $I = Q_+ \cap Q_-$ where $Q_\pm = (I,\ (x-y)(x-z)(y-z) \mp r)$. Prove Q_+ and Q_- are maximal ideals, and $\mathbb{Q}[x,y,z]$ modulo Q_+ or Q_- is a splitting field for $f(x)$ over $\mathbb{Q}$.

26. A topological space X is called *quasicompact* if whenever any collection of closed subsets V_i of X has empty intersection, then some finite number of these also has empty intersection, i.e.,

$$\text{whenever } \bigcap_i V_i = \emptyset \text{ there exists } V_{i_1}, V_{i_2}, \ldots, V_{i_N} \text{ such that } \bigcap_{j=1}^{N} V_{i_j} = \emptyset.$$

Prove that every affine algebraic set is quasicompact. [Translate the definition into a property of ideals in $k[x_1,\ldots,x_n]$.] (A quasicompact and Hausdorff space is called *compact*.)

27. When k is an infinite field prove that the Zariski topology on k^2 is not the same as taking the Zariski topology on k and then forming the product topology on $k \times k$. [By Exercise 14 of Section 1, in the product topology on $k \times k$ the Zariski closed sets in $k \times k$ are finite unions of sets of the form $\{\,a\,\} \times \{\,b\,\}$, $\{\,a\,\} \times k$ and $k \times \{\,b\,\}$, for any $a, b \in k$.]

28. Prove that each of the following rings have infinitely many minimal prime ideals, and that (0) is not the intersection of any finite number of these (so (0) does not have a primary decomposition in these rings):

(a) the infinite direct product ring $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \cdots$ (which is a Boolean ring, cf. Exercise 23 in Section 7.4).

(b) $k[x_1, x_2, \ldots]/(x_1x_2, x_3x_4, \ldots, x_{2i-1}x_{2i}, \ldots)$, where $x_1, x_2, \ldots$ are independent variables over the field k.

29. Suppose that A and B are ideals with $AB \subseteq Q$ for a primary ideal Q. Prove that if $A \not\subseteq Q$ then $B \subseteq \operatorname{rad} Q$.

30. Let Q be a P-primary ideal and suppose A is an ideal not contained in Q. Define $A' = \{\, r \in R \mid rA \subseteq Q \,\}$ to be the elements of R that when multiplied by elements of A give elements of Q. Prove that A' is a P-primary ideal.

31. Prove that if Q_1 and Q_2 are primary ideals belonging to the same prime ideal P, then $Q_1 \cap Q_2$ is a primary ideal belonging to P. Conclude that a finite intersection of P-primary ideals is again P-primary.

32. Prove that if Q_1 and Q_2 are primary ideals belonging to the same maximal ideal M, then $Q_1 + Q_2$ and Q_1Q_2 are primary ideals belonging to M. Conclude that finite sums and finite products of M-primary ideals are again M-primary.

33. Let $I = (x^2, xy, xz, yz)$ in $k[x,y,z]$. Prove that a primary decomposition of I is $I = (x,y) \cap (x,z) \cap (x,y,z)^2$, determine the isolated and embedded primes of I, and find $\operatorname{rad} I$.

34. Suppose $\varphi : R \to S$ is a surjective ring homomorphism. Prove that an ideal Q in R containing the kernel of φ is primary if and only if $\varphi(Q)$ is primary in S, and when this is the case the prime associated to $\varphi(Q)$ is the image $\varphi(P)$ of the prime P associated to Q.

35. Suppose $\varphi : R \to S$ is a ring homomorphism.

(a) Suppose I is an ideal of R containing $\ker \varphi$ with minimal primary decomposition $I = Q_1 \cap \cdots \cap Q_m$ with $\operatorname{rad} Q_i = P_i$. If φ is a surjective homomorphism prove that $\varphi(I) = \varphi(Q_1) \cap \cdots \cap \varphi(Q_m)$, where $\operatorname{rad} \varphi(Q_i)$ is given by $\varphi(P_i)$, is a minimal primary decomposition of $\varphi(I)$. [Use the previous exercise.]

(b) Suppose I is an ideal of S with minimal primary decomposition $I = Q_1 \cap \cdots \cap Q_m$ with $\operatorname{rad} Q_i = P_i$. Prove that $\varphi^{-1}(I) = \varphi^{-1}(Q_1) \cap \cdots \cap \varphi^{-1}(Q_m)$, where $\operatorname{rad} \varphi^{-1}(Q_i)$ is given by $\varphi^{-1}(P_i)$, is a primary decomposition of $\varphi^{-1}(I)$, and is minimal if φ is surjective.

36. Let $I = (xy, x - yz)$ in $k[x,y,z]$. Prove that $(x,z) \cap (y^2, x - yz)$ is a minimal primary decomposition of I. [Consider the ring homomorphism $\varphi : k[x,y,z] \to k[y,z]$ given by mapping x to yz, y to y, and z to z and use the previous exercise.]

37. Prove that a prime ideal P contains the ideal I if and only if P contains one of the associated primes of a minimal primary decomposition of I. [Use Exercise 3 and Exercise 11 in Section 7.4.]

38. Show that every associated prime ideal for a radical ideal is isolated. [Suppose that $P_2 = \operatorname{rad} Q_2 \subseteq P_1 = \operatorname{rad} Q_1$ in the decomposition of Theorem 21 for the radical ideal I. Show that if $a \in Q_2 \cap \cdots \cap Q_m$ $(\subseteq P_2 \subseteq P_1)$ then $a^n \in I$ for some $n \geq 1$, conclude that $a \in Q_1$ and derive a contradiction to the minimality of the primary decomposition.]

39. Fix an element a in the ring R. For any ideal I in the ring R let $I_a = \{ r \in R \mid ar \in I \}$.

    (a) Prove that I_a is an ideal and $I_a = R$ if and only if $a \in I$.

    (b) Prove that $(I \cap J)_a = I_a \cap J_a$ for ideals I and J.

    (c) Suppose that Q is a P-primary ideal and that $a \notin Q$. Prove that Q_a is a P-primary ideal and that $Q_a = Q$ if $a \notin P$.

40. With notation as in the previous exercise, suppose $I = Q_1 \cap \cdots \cap Q_m$ is a minimal primary decomposition of the ideal I and let P_i be the prime ideal associated to Q_i.

    (a) Prove that $I_a = (Q_1)_a \cap \cdots \cap (Q_m)_a$ and that $\operatorname{rad}(I_a) = \operatorname{rad}((Q_1)_a) \cap \cdots \cap \operatorname{rad}((Q_m)_a)$.

    (b) Prove that $\operatorname{rad}(I_a)$ is the intersection of the prime ideals P_i for which $a \notin Q_i$. [Use the previous exercise.]

    (c) Prove that if $\operatorname{rad}(I_a)$ is a prime ideal then $\operatorname{rad}(I_a) = P_j$ for some j. [Use the fact that prime ideals are irreducible.]

    (d) For each $i = 1, \ldots, m$, prove that $\operatorname{rad}(I_a) = P_i$ for some $a \in R$. [Show there exists an $a \in R$ with $a \notin Q_i$ but $a \in Q_j$ for all $j \neq i$.]

    (e) Show from (c) and (d) that the associated primes for a minimal primary decomposition are precisely the collection of prime ideals among the ideals $\operatorname{rad}(I_a)$ for $a \in R$, and conclude that they are uniquely determined by I independent of the minimal primary decomposition.

41. Let $P_1, \ldots, P_m$ be the associated prime ideals of the ideal (0) in the Noetherian ring R.

    (a) Show that $P_1 \cap \cdots \cap P_m$ is the collection of nilpotent elements in R. [Apply Corollary 22 to $I = (0)$.]

    (b) Show that $P_1 \cup \cdots \cup P_m$ is the collection of zero divisors in R. [Let $I = (0)$ in the previous exercise and show that the set of zero divisors is given by the set $\bigcup_{a \in R - \{0\}} (0)_a = \bigcup_{a \in R - \{0\}} \operatorname{rad}((0)_a)$.]

42. Suppose R is a Noetherian ring. Prove that R is either an integral domain, has nonzero nilpotent elements, or has at least two minimal prime ideals. [Use the previous exercise.]

43. Prove that the ideal I in the Noetherian ring R is radical if and only if the primary components of a minimal primary decomposition are all prime ideals, and conclude that in this case the minimal primary decomposition is unique. [If $I = Q_1 \cap \cdots \cap Q_m$ is radical with Q_i a P_i-primary component of a minimal decomposition, show that if $a \in P_1 \cap \cdots \cap P_m$ then some power of a is in I, hence $a \in I$ since I is radical. Deduce that $I = P_1 \cap \cdots \cap P_m$ and show that this is also a minimal primary decomposition, i.e., for any i there exists b with $b \notin P_i$, but $b \in P_j$ for $j \neq i$. If $a \in P_i$, show that $ab \in Q_i$, and that $a \in Q_i$. Conclude that $Q_i = P_i$.]

44. Prove that a Noetherian integral domain R is a U.F.D. if and only if for every $a \in R$ the isolated primes associated to the principal ideal (a) are principal ideals. [See Example 2 following Corollary 22. To prove R is a U.F.D., show that an irreducible $a \in R$ is prime and then follow the proof of Theorem 14 in Section 8.3.]

45. Let R be the ring of all real valued functions on the open interval $(-1, 1)$ that have derivatives of all orders (the ring of C^∞ functions). Let

$$F(x) = \begin{cases} e^{-1/x^4} & \text{if } x \neq 0 \\ 0 & \text{if } x = 0 \end{cases}$$

(you may assume $F \in R$ and $F^{(n)}(0) = 0$ for all $n \geq 0$). Let (F) be the principal ideal generated by F and let $A = \text{rad}((F))$. Let M be the (maximal) ideal of all functions in R that are zero at $x = 0$ and let $P = \bigcap_{n \geq 1} M^n$.

(a) Prove that $M = (x)$ is the ideal generated by the function x in R and that $M^n = (x^n)$ consists of the functions f with $f(0) = f'(0) = \cdots = f^{(n-1)}(0) = 0$.

(b) Prove that R is not Noetherian (compare Exercise 33 in Section 7.4). [One approach is the following: Let $G(x)$ be the function that is 0 for $x < 0$ and is equal to $F(x)$ for $x \geq 0$. Let I_n be the ideal of functions in R vanishing for all $x \leq 1/n$. Use translates of $G(x)$ to show that $I_1 \subset I_2 \subset I_3 \subset \cdots$ is an infinite ascending chain.]

(c) Prove that P consists of the functions all of whose derivatives are zero at $x = 0$ (i.e., the functions whose associated Taylor series at $x = 0$ is identically zero), and that P is a prime ideal.

(d) Prove that $F \in P$ and deduce that $A \subseteq P$.

(e) Prove that $A \neq P$. [Let $G(x) = e^{-1/x^2}$ when $x \neq 0$ and $G(0) = 0$. Show that $G \in P$ but $G \notin A$.]

(f) Show that there is a prime ideal Q containing (F) with $Q \neq P, M$. Prove that $Q \subset P$, i.e., there are nonzero prime ideals properly contained in P.

46. Let A be any ideal in $R = k[x_1, \ldots, x_n, y_1, \ldots, y_m]$.

(a) Show that $\text{rad}(A \cap k[y_1, \ldots, y_m]) = \text{rad}\, A \cap k[y_1, \ldots, y_m]$.

(b) Suppose $(f_1, \ldots, f_s)$ is an ideal in $k[x_1, \ldots, x_n]$. Let $F_1, \ldots, F_t$ be generators for the radical of $(f_1, \ldots, f_s)$, computed in $k[x_1, \ldots, x_n]$. Suppose J is an ideal in R and let $\mathcal{A} = J + (f_1, \ldots, f_s)$, $\mathcal{B} = J + (F_1, \ldots, F_t)$ as ideals in R. Prove that $\text{rad}\, \mathcal{A} = \text{rad}\, \mathcal{B}$.

(c) Conclude from (a) and (b) that $\mathcal{A} = (y_1 - x_1, \ldots, y_m - x_m, f_1, \ldots, f_s) \cap k[y_1, \ldots, y_m]$ and $\mathcal{B} = (y_1 - x_1, \ldots, y_m - x_m, F_1, \ldots, F_t) \cap k[y_1, \ldots, y_m]$ have the same zero sets over an algebraically closed field k. [Use Hilbert's Nullstellensatz.]

47. Determine the Zariski closure in $\mathbb{C}^3$ of the points on the curve $\{ (a^2, a^3, a^4) \mid a \in \mathbb{C} \}$.

48. Show that $Z(x^3 - xyz + z^2)$ is the smallest algebraic set in $\mathbb{R}^3$ containing the points $\{ (st, s+t, s^2t) \mid s, t \in \mathbb{R} \}$.

49. Show that $Z(x^3z^2 - 3xy^2z^2 - y^6 - z^4)$ is the smallest algebraic set in $\mathbb{R}^3$ containing the points $\{ (s^2 + t^2, st, s^3) \mid s, t \in \mathbb{R} \}$.

50. Find equations defining the Zariski closure of the set of points $\{ (s^4, s^3t, st^3, t^4) \mid s, t \in \mathbb{R} \}$.

51. Show that $V = Z(x^2 - y^2z)$ (the Whitney umbrella surface) is the smallest algebraic set in $\mathbb{R}^3$ containing the points $S = \{ (st, s, t^2) \mid s, t \in \mathbb{R} \}$. Show that S is not Zariski closed in V (the missing points explain the name for the surface). Do the same over $\mathbb{C}$, but show that in this case $S = V$ is closed.

52. Let $V = Z(xz^2 - w^3,\ xw^2 - y^4,\ y^4z^2 - w^5) \subseteq \mathbb{C}^4$. Determine the Zariski closure of the image of V under the projection $\pi((x, y, z, w)) = (x, y, z)$.

53. Let $V = Z(xy - 1)$ in $\mathbb{A}^2$ and let S be the projection of V onto the x-axis in $\mathbb{A}^1$.

(a) If $k = \mathbb{R}$, show that $I(V) = (xy - 1) \subseteq \mathbb{R}[x, y]$ and that $(u - x, xy - 1) \cap \mathbb{R}[u] = 0$ in $\mathbb{R}[x, y, u]$. Use Propositions 8 and 16 to conclude that the Zariski closure of S is $\mathbb{A}^1$ and show that S is not itself closed.

(b) If $k = \mathbb{F}_3$, show that $I(V) = (xy - 1, x^3 - x, y^3 - y) \subseteq \mathbb{F}_3[x, y]$ and that $(u - x, xy - 1, x^3 - x, y^3 - y) \cap \mathbb{F}_3[u] = (u^2 - 1)$ in $\mathbb{F}_3[x, y, u]$. Use Propositions 8 and 16 to conclude that S is Zariski closed in $\mathbb{A}^1$.

54. Recall the ideal quotient $(I : J) = \{ r \in R \mid rJ \subseteq I \}$ of two ideals I, J in a ring R (cf. Exercise 34 ff. in Section 9.6). Clearly $I \subseteq (I : J)$.

(a) Show that $Z(I) - Z(J)$, the set of elements of $Z(I)$ not lying in $Z(J)$, is contained in $Z((I : J))$ and conclude that the Zariski closure of $Z(I) - Z(J)$ is contained in $Z((I : J))$.

(b) Show that if k is algebraically closed and I is a radical ideal then $Z((I:J))$ is precisely the Zariski closure of $Z(I) - Z(J)$.

(c) Show that if V and W are affine algebraic sets then $(I(V) : I(W)) = I(V - W)$.

Exercises (Atiyah & Macdonald).

1. If an ideal $\mathfrak{a}$ has a primary decomposition, then $\operatorname{Spec}(A/\mathfrak{a})$ has only finitely many irreducible components.
2. If $\mathfrak{a} = \operatorname{rad}(\mathfrak{a})$, then $\mathfrak{a}$ has no embedded prime ideals.
3. If A is absolutely flat, every primary ideal is maximal.
4. In the polynomial ring $\mathbb{Z}[t]$, the ideal $\mathfrak{m} = (2, t)$ is maximal and the ideal $\mathfrak{q} = (4, t)$ is $\mathfrak{m}$-primary, but is not a power of $\mathfrak{m}$.
5. In the polynomial ring $K[x, y, z]$ where K is a field and x, y, z are independent indeterminates, let $\mathfrak{p}_1 = (x, y)$, $\mathfrak{p}_2 = (x, z)$, $\mathfrak{m} = (x, y, z)$; $\mathfrak{p}_1$ and $\mathfrak{p}_2$ are prime, and $\mathfrak{m}$ is maximal. Let $\mathfrak{a} = \mathfrak{p}_1\mathfrak{p}_2$. Show that $\mathfrak{a} = \mathfrak{p}_1 \cap \mathfrak{p}_2 \cap \mathfrak{m}^2$ is a reduced primary decomposition of $\mathfrak{a}$. Which components are isolated and which are embedded?
6. Let X be an infinite compact Hausdorff space, $C(X)$ the ring of real-valued continuous functions on X (Chapter 1, Exercise 26). Is the zero ideal decomposable in this ring?
7. Let A be a ring and let $A[x]$ denote the ring of polynomials in one indeterminate over A. For each ideal $\mathfrak{a}$ of A, let $\mathfrak{a}[x]$ denote the set of all polynomials in $A[x]$ with coefficients in $\mathfrak{a}$.

   i) $\mathfrak{a}[x]$ is the extension of $\mathfrak{a}$ to $A[x]$.

   ii) If $\mathfrak{p}$ is a prime ideal in A, then $\mathfrak{p}[x]$ is a prime ideal in $A[x]$.

   iii) If $\mathfrak{q}$ is a $\mathfrak{p}$-primary ideal in A, then $\mathfrak{q}[x]$ is a $\mathfrak{p}[x]$-primary ideal in $A[x]$. [Use Chapter 1, Exercise 2.]

   iv) If $\mathfrak{a} = \bigcap_{i=1}^{n} \mathfrak{q}_i$ is a minimal primary decomposition in A, then $\mathfrak{a}[x] = \bigcap_{i=1}^{n} \mathfrak{q}_i[x]$ is a minimal primary decomposition in $A[x]$.

   v) If $\mathfrak{p}$ is a minimal prime ideal of $\mathfrak{a}$, then $\mathfrak{p}[x]$ is a minimal prime ideal of $\mathfrak{a}[x]$.
8. Let k be a field. Show that in the polynomial ring $k[x_1, \ldots, x_n]$ the ideals $\mathfrak{p}_i = (x_1, \ldots, x_i)$ $(1 \leq i \leq n)$ are prime and all their powers are primary. [Use Exercise 7.]
9. In a ring A, let $D(A)$ denote the set of prime ideals $\mathfrak{p}$ which satisfy the following condition: there exists $a \in A$ such that $\mathfrak{p}$ is minimal in the set of prime ideals containing $(0 : a)$. Show that $x \in A$ is a zero-divisor $\Leftrightarrow x \in \mathfrak{p}$ for some $\mathfrak{p} \in D(A)$.

   Let S be a multiplicatively closed subset of A, and identify $\operatorname{Spec}(S^{-1}A)$ with its image in $\operatorname{Spec}(A)$ (Chapter 3, Exercise 21). Show that
   $$D(S^{-1}A) = D(A) \cap \operatorname{Spec}(S^{-1}A).$$
   If the zero ideal has a primary decomposition, show that $D(A)$ is the set of associated prime ideals of 0.
10. For any prime ideal $\mathfrak{p}$ in a ring A, let $S_{\mathfrak{p}}(0)$ denote the kernel of the homomorphism $A \to A_{\mathfrak{p}}$. Prove that

    i) $S_{\mathfrak{p}}(0) \subseteq \mathfrak{p}$.

    ii) $\operatorname{rad}(S_{\mathfrak{p}}(0)) = \mathfrak{p} \Leftrightarrow \mathfrak{p}$ is a minimal prime ideal of A.

    iii) If $\mathfrak{p} \supseteq \mathfrak{p}'$, then $S_{\mathfrak{p}}(0) \subseteq S_{\mathfrak{p}'}(0)$.

    iv) $\bigcap_{\mathfrak{p} \in D(A)} S_{\mathfrak{p}}(0) = 0$, where $D(A)$ is defined in Exercise 9.
11. If $\mathfrak{p}$ is a minimal prime ideal of a ring A, show that $S_{\mathfrak{p}}(0)$ (Exercise 10) is the smallest $\mathfrak{p}$-primary ideal.

    Let $\mathfrak{a}$ be the intersection of the ideals $S_{\mathfrak{p}}(0)$ as $\mathfrak{p}$ runs through the minimal prime ideals of A. Show that $\mathfrak{a}$ is contained in the nilradical of A.

    Suppose that the zero ideal is decomposable. Prove that $\mathfrak{a} = 0$ if and only if every prime ideal of 0 is isolated.

12. Let A be a ring, S a multiplicatively closed subset of A. For any ideal $\mathfrak{a}$, let $S(\mathfrak{a})$ denote the contraction of $S^{-1}\mathfrak{a}$ in A. The ideal $S(\mathfrak{a})$ is called the *saturation* of $\mathfrak{a}$ with respect to S. Prove that

    i) $S(\mathfrak{a}) \cap S(\mathfrak{b}) = S(\mathfrak{a} \cap \mathfrak{b})$.

    ii) $S(\mathrm{rad}(\mathfrak{a})) = \mathrm{rad}(S(\mathfrak{a}))$.

    iii) $S(\mathfrak{a}) = (1) \Leftrightarrow \mathfrak{a}$ meets S.

    iv) $S_1(S_2(\mathfrak{a})) = (S_1S_2)(\mathfrak{a})$.

    If $\mathfrak{a}$ has a primary decomposition, prove that the set of ideals $S(\mathfrak{a})$ (where S runs through all multiplicatively closed subsets of A) is finite.

13. Let A be a ring and $\mathfrak{p}$ a prime ideal of A. The nth *symbolic power* of $\mathfrak{p}$ is defined to be the ideal (in the notation of Exercise 12)

$$\mathfrak{p}^{(n)} = S_{\mathfrak{p}}(\mathfrak{p}^n)$$

    where $S_{\mathfrak{p}} = A - \mathfrak{p}$. Show that

    i) $\mathfrak{p}^{(n)}$ is a $\mathfrak{p}$-primary ideal;

    ii) if $\mathfrak{p}^n$ has a primary decomposition, then $\mathfrak{p}^{(n)}$ is its $\mathfrak{p}$-primary component;

    iii) if $\mathfrak{p}^{(m)}\mathfrak{p}^{(n)}$ has a primary decomposition, then $\mathfrak{p}^{(m+n)}$ is its $\mathfrak{p}$-primary component;

    iv) $\mathfrak{p}^{(n)} = \mathfrak{p}^n \Leftrightarrow \mathfrak{p}^n$ is $\mathfrak{p}$-primary.

14. Let $\mathfrak{a}$ be a decomposable ideal in a ring A and let $\mathfrak{p}$ be a maximal element of the set of ideals $(\mathfrak{a} : x)$, where $x \in A$ and $x \notin \mathfrak{a}$. Show that $\mathfrak{p}$ is a prime ideal belonging to $\mathfrak{a}$.

15. Let $\mathfrak{a}$ be a decomposable ideal in a ring A, let Σ be an isolated set of prime ideals belonging to $\mathfrak{a}$, and let $\mathfrak{q}_\Sigma$ be the intersection of the corresponding primary components. Let f be an element of A such that, for each prime ideal $\mathfrak{p}$ belonging to $\mathfrak{a}$, we have $f \in \mathfrak{p} \Leftrightarrow \mathfrak{p} \notin \Sigma$, and let S_f be the set of all powers of f. Show that $\mathfrak{q}_\Sigma = S_f(\mathfrak{a}) = (\mathfrak{a} : f^n)$ for all large n.

16. If A is a ring in which every ideal has a primary decomposition, show that every ring of fractions $S^{-1}A$ has the same property.

17. Let A be a ring with the following property.

    > (L1) For every ideal $\mathfrak{a} \neq (1)$ in A and every prime ideal $\mathfrak{p}$, there exists $x \notin \mathfrak{p}$ such that $S_{\mathfrak{p}}(\mathfrak{a}) = (\mathfrak{a} : x)$, where $S_{\mathfrak{p}} = A - \mathfrak{p}$.

    Then every ideal in A is an intersection of (possibly infinitely many) primary ideals.

    [Let $\mathfrak{a} \neq (1)$ and let $\mathfrak{p}_1$ be a minimal prime ideal containing $\mathfrak{a}$. By Exercise 11 (applied in $A/\mathfrak{a}$) the ideal $\mathfrak{q}_1 = S_{\mathfrak{p}_1}(\mathfrak{a})$ is $\mathfrak{p}_1$-primary, and by (L1) $\mathfrak{q}_1 = (\mathfrak{a} : x)$ for some $x \notin \mathfrak{p}_1$. Check that $\mathfrak{a} = \mathfrak{q}_1 \cap (\mathfrak{a} + (x))$. By Zorn's lemma choose $\mathfrak{a}_1 \supseteq \mathfrak{a} + (x)$ maximal among the ideals $\mathfrak{b} \supseteq \mathfrak{a}$ with $\mathfrak{q}_1 \cap \mathfrak{b} = \mathfrak{a}$; since $x \in \mathfrak{a}_1$, $\mathfrak{a}_1 \not\subseteq \mathfrak{p}_1$. Repeat the construction with $\mathfrak{a}_1$ in place of $\mathfrak{a}$, and so on: after n steps $\mathfrak{a} = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_n \cap \mathfrak{a}_n$, where each $\mathfrak{q}_i$ is $\mathfrak{p}_i$-primary, $\mathfrak{a}_{n-1} = \mathfrak{q}_n \cap \mathfrak{a}_n$ and $\mathfrak{a}_n \not\subseteq \mathfrak{p}_n$. If some $\mathfrak{a}_n = (1)$, the process stops and $\mathfrak{a}$ is a finite intersection of primary ideals; otherwise continue by transfinite induction, noting that each $\mathfrak{a}_n$ strictly contains $\mathfrak{a}_{n-1}$.]

18. Consider the following condition on a ring A:

    > (L2) Given an ideal $\mathfrak{a}$ and a descending chain $S_1 \supseteq S_2 \supseteq \cdots \supseteq S_n \supseteq \cdots$ of multiplicatively closed subsets of A, there exists an integer n such that $S_n(\mathfrak{a}) = S_{n+1}(\mathfrak{a}) = \cdots$.

    Prove that the following are equivalent:

    i) Every ideal in A has a primary decomposition;

    ii) A satisfies (L1) and (L2).

[For i) $\Rightarrow$ ii), use Exercises 12 and 15. For ii) $\Rightarrow$ i), in the notation of the hint to Exercise 17 put $S_n = S_{\mathfrak{p}_1} \cap \cdots \cap S_{\mathfrak{p}_n}$; since $\mathfrak{a}_n \supseteq \mathfrak{a}_i \not\subseteq \mathfrak{p}_i$ for $i \leq n$, S_n meets $\mathfrak{a}_n$ (prime avoidance), so $S_n(\mathfrak{a}_n) = (1)$ and therefore $S_n(\mathfrak{a}) = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_n$. Now use (L2) to show that the construction must terminate after a finite number of steps.]

19. Let A be a ring and $\mathfrak{p}$ a prime ideal of A. Show that every $\mathfrak{p}$-primary ideal contains $S_{\mathfrak{p}}(0)$, the kernel of the canonical homomorphism $A \to A_{\mathfrak{p}}$.

    Suppose that A satisfies the following condition: for every prime ideal $\mathfrak{p}$, the intersection of all $\mathfrak{p}$-primary ideals of A is equal to $S_{\mathfrak{p}}(0)$. (Noetherian rings satisfy this condition: see Chapter 10.) Let $\mathfrak{p}_1, \ldots, \mathfrak{p}_n$ be distinct prime ideals, none of which is a minimal prime ideal of A. Then there exists an ideal $\mathfrak{a}$ in A whose associated prime ideals are $\mathfrak{p}_1, \ldots, \mathfrak{p}_n$.

    [Proof by induction on n. The case $n = 1$ is trivial (take $\mathfrak{a} = \mathfrak{p}_1$). Suppose $n > 1$ and let $\mathfrak{p}_n$ be maximal in the set $\{ \mathfrak{p}_1, \ldots, \mathfrak{p}_n \}$. By the inductive hypothesis there exists an ideal $\mathfrak{b}$ and a minimal primary decomposition $\mathfrak{b} = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_{n-1}$, where $\mathfrak{q}_i$ is $\mathfrak{p}_i$-primary. If $\mathfrak{b} \subseteq S_{\mathfrak{p}_n}(0)$, let $\mathfrak{p}$ be a minimal prime ideal of A contained in $\mathfrak{p}_n$. Then $S_{\mathfrak{p}_n}(0) \subseteq S_{\mathfrak{p}}(0)$, hence $\mathfrak{b} \subseteq S_{\mathfrak{p}}(0)$. Taking radicals and using Exercise 10, we have $\mathfrak{p}_1 \cap \cdots \cap \mathfrak{p}_{n-1} \subseteq \mathfrak{p}$, hence (since $\mathfrak{p}$ is a prime ideal) $\mathfrak{p}_i \subseteq \mathfrak{p}$ for some i, hence $\mathfrak{p}_i = \mathfrak{p}$ since $\mathfrak{p}$ is minimal. This is a contradiction since no $\mathfrak{p}_i$ is minimal. Hence $\mathfrak{b} \not\subseteq S_{\mathfrak{p}_n}(0)$ and therefore there exists a $\mathfrak{p}_n$-primary ideal $\mathfrak{q}_n$ such that $\mathfrak{b} \not\subseteq \mathfrak{q}_n$. Show that $\mathfrak{a} = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_n$ has the required properties.]

20. Let M be a fixed A-module, N a submodule of M. The *radical* of N in M is defined to be

$$r_M(N) = \{ x \in A \mid x^q M \subseteq N \text{ for some } q > 0 \}.$$

    Show that $r_M(N) = r(N : M) = r(\mathrm{Ann}(M/N))$. In particular, $r_M(N)$ is an ideal.

    State and prove the formulas for $r_M(N)$ analogous to (1.13).

21. An element $x \in A$ defines an endomorphism ϕ_x of M, namely $m \mapsto xm$. The element x is said to be a *zero-divisor* (resp. *nilpotent*) in M if ϕ_x is not injective (resp. is nilpotent). A submodule Q of M is *primary* in M if $Q \neq M$ and every zero-divisor in M/Q is nilpotent.

    Show that if Q is primary in M, then $(Q : M)$ is a primary ideal and hence $r_M(Q)$ is a prime ideal $\mathfrak{p}$. We say that Q is $\mathfrak{p}$-primary (in M).

    Prove the analogues of (4.3) and (4.4).

22. A *primary decomposition* of N in M is a representation of N as an intersection

$$N = Q_1 \cap \cdots \cap Q_n$$

    of primary submodules of M; it is a *minimal primary decomposition* if the ideals $\mathfrak{p}_i = r_M(Q_i)$ are all distinct and if none of the components Q_i can be omitted from the intersection, that is if $Q_i \not\supseteq \bigcap_{j \neq i} Q_j$ $(1 \leq i \leq n)$.

    Prove the analogue of (4.5), that the prime ideals $\mathfrak{p}_i$ depend only on N (and M). They are called the *prime ideals belonging to* N in M. Show that they are also the prime ideals belonging to 0 in M/N.

23. State and prove the analogues of (4.6)–(4.11) inclusive. (There is no loss of generality in taking $N = 0$.)

Practice problems.

1. In $\mathbb{Z}$ give the minimal primary decomposition of the ideal (360), identify the prime belonging to each component, and verify that rad(360) is the squarefree radical of 360. Then decide which (if any) of the associated primes are embedded.

2. In $k[x, y]$ let $\mathfrak{q} = (x^3, xy, y^2)$. Compute the quotient ring $k[x, y]/\mathfrak{q}$ explicitly as a finite-dimensional k-vector space, give a basis, and use the description "every zero-divisor is nilpotent" to decide whether $\mathfrak{q}$ is primary. If it is, name the prime $\mathfrak{p} = \operatorname{rad} \mathfrak{q}$ to which it belongs.

3. Let $R = k[x, y, z]$ and $\mathfrak{a} = (xy, yz, zx)$. Show $\mathfrak{a} = (x, y) \cap (y, z) \cap (z, x)$, conclude that $\mathfrak{a}$ is radical, and list the minimal primes of $\mathfrak{a}$. Describe $Z(\mathfrak{a}) \subseteq \mathbb{A}^3$ as a union of irreducible components and match each component to its prime.

4. Let $\mathfrak{q}$ be a $\mathfrak{p}$-primary ideal and let $x \in R$ with $x \notin \mathfrak{p}$. Using only the definition of primary, prove directly that the colon ideal $(\mathfrak{q} : x)$ equals $\mathfrak{q}$. Then exhibit, in $k[x, y]$ with $\mathfrak{q} = (x^2, y)$, an element $f \in \mathfrak{q}$ for which $(\mathfrak{q} : f) = R$.

5. In $R = k[x, y]$ consider $\mathfrak{a} = (x^2,\, xy^2)$. Find a minimal primary decomposition of $\mathfrak{a}$ with exactly two components, identify the isolated and embedded primes, and compute $\operatorname{rad}\mathfrak{a}$. Confirm your decomposition by checking that each given generator of $\mathfrak{a}$ lies in both primary components.

6. Let $\mathfrak{p} = (x, z)$ in $R = k[x, y, z]/(z^2 - x^2 y)$ (the Whitney-umbrella coordinate ring). Show $\mathfrak{p}$ is prime by exhibiting $R/\mathfrak{p}$ as a polynomial ring, and decide whether $\mathfrak{p}^2$ is primary by testing the relation $\bar{z}^2 = \bar{x}^2\bar{y}$ against the primary definition.

7. Let $A = \mathbb{Z}/12\mathbb{Z}$ regarded as a $\mathbb{Z}$-module. Compute $\operatorname{Ass}_{\mathbb{Z}}(A)$ by finding, for each prime $p \mid 12$, an element of A whose annihilator is (p). Then reconcile your answer with the minimal primary decomposition of the ideal $(12) \subseteq \mathbb{Z}$.

8. Let $\mathfrak{q}_1, \ldots, \mathfrak{q}_r$ all be $\mathfrak{p}$-primary in a ring R. Prove that $\mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_r$ is again $\mathfrak{p}$-primary, and give an example in $k[x, y]$ of two distinct (x, y)-primary ideals whose intersection is strictly smaller than either.

Additional exercises.

1. Let $\mathfrak{p}$ be a prime ideal of a Noetherian ring R. Prove that $\mathfrak{p}^n \subseteq \mathfrak{p}^{(n)}$ for all $n \geq 1$ and that equality holds for every n if and only if $\mathfrak{p}^n$ is $\mathfrak{p}$-primary for every n. Then show that in any PID every symbolic power coincides with the ordinary power. [Use the localization description $\mathfrak{p}^{(n)} = (\mathfrak{p}^n R_{\mathfrak{p}})^c$.]

2. Let $\mathfrak{a}$ be a decomposable ideal of R with $\operatorname{Ass}(\mathfrak{a}) = \{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_n \,\}$. Prove that the set of elements $x \in R$ that are zero-divisors on $R/\mathfrak{a}$ (i.e. $x + \mathfrak{a}$ is a zero-divisor in $R/\mathfrak{a}$) equals $\bigcup_{i=1}^{n} \mathfrak{p}_i$. Deduce that $R/\mathfrak{a}$ is an integral domain if and only if $\mathfrak{a}$ is prime, and that $R/\mathfrak{a}$ is reduced if and only if $\mathfrak{a}$ is radical.

3. Suppose $\mathfrak{a} = \mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_n$ is a minimal primary decomposition with $\mathfrak{p}_i = \operatorname{rad}\mathfrak{q}_i$, and let $\mathfrak{p}_1$ be a minimal (isolated) element of $\{\, \mathfrak{p}_1, \ldots, \mathfrak{p}_n \,\}$. Prove that the isolated component $\mathfrak{q}_1$ is recovered by the colon formula $\mathfrak{q}_1 = \bigcup_{m \geq 1} (\mathfrak{a} : x^m)$ for any $x \in \bigcap_{j \neq 1} \mathfrak{p}_j$ with $x \notin \mathfrak{p}_1$, and that this is independent of the chosen minimal decomposition.

4. Let R be Noetherian and $\mathfrak{a}$ a proper ideal. Prove that $\mathfrak{a}$ is irreducible implies $\mathfrak{a}$ is primary, and give an explicit example in $k[x, y]$ of a primary ideal that is *not* irreducible, exhibiting it as a proper intersection of two strictly larger ideals belonging to the same prime.

5. Let $\varphi\colon R \to S$ be a surjective ring homomorphism and let $\mathfrak{b} = \mathfrak{Q}_1 \cap \cdots \cap \mathfrak{Q}_n$ be a minimal primary decomposition of an ideal $\mathfrak{b} \subseteq S$. Prove that $\varphi^{-1}(\mathfrak{b}) = \varphi^{-1}(\mathfrak{Q}_1) \cap \cdots \cap \varphi^{-1}(\mathfrak{Q}_n)$ is a minimal primary decomposition of $\varphi^{-1}(\mathfrak{b})$ in R, and that the associated primes of $\varphi^{-1}(\mathfrak{b})$ are exactly the ideals $\varphi^{-1}(\operatorname{rad}\mathfrak{Q}_i)$.

Commutative-diagram exercises.

1. Let $\mathfrak{a} = (x) \cap (x, y)^2$ in $R = k[x, y]$, with associated primes $\mathfrak{p}_1 = (x)$ (isolated) and $\mathfrak{p}_2 = (x, y)$ (embedded). On the prime spectrum draw the inclusion poset of closed sets and prove the indicated containment. Complete the skeleton, labelling each arrow with the inclusion of vanishing loci, and prove that $V(\mathfrak{p}_2) \subseteq V(\mathfrak{p}_1)$ so the embedded point adds no new support:

$$\mathfrak{p}_1 = (x) \hookleftarrow \mathfrak{p}_2 = (x, y)$$

$$V(\mathfrak{p}_1) \hookrightarrow V(\mathfrak{p}_2)$$

   Conclude that $\operatorname{Supp}(R/\mathfrak{a}) = V(\mathfrak{a}) = V(\mathfrak{p}_1) = V(\mathfrak{p}_1) \cup V(\mathfrak{p}_2)$ and explain why $\operatorname{Ass}(\mathfrak{a})$ nonetheless records both primes.

2. Let $\mathfrak{p}$ be a minimal (isolated) prime of a decomposable ideal $\mathfrak{a}$, and put $S = R \setminus \mathfrak{p}$. The second uniqueness theorem says the isolated component is $\mathfrak{q}_{\mathfrak{p}} = (S^{-1}\mathfrak{a})^c$. Complete the localization square below (horizontal

maps are the localization $R \to S^{-1}R$, vertical maps the quotients by $\mathfrak{a}$ and its extension), prove it commutes, and prove that contracting $S^{-1}\mathfrak{a}$ back to R kills every component $\mathfrak{q}_j$ with $\mathfrak{p}_j \not\subseteq \mathfrak{p}$:

$$\begin{array}{ccc} R & \xrightarrow{\ \lambda\ } & S^{-1}R \\ \downarrow & & \downarrow \\ R/\mathfrak{a} & \xrightarrow[\ \overline{\lambda}\ ]{} & S^{-1}R\,/\,S^{-1}\mathfrak{a} \end{array}$$

Deduce that $\mathfrak{q}_{\mathfrak{p}}$ depends only on $\mathfrak{a}$ and $\mathfrak{p}$, not on the chosen minimal decomposition.

3. Let R be Noetherian and $\mathfrak{p} \in \operatorname{Spec} R$. Complete the inverse-limit tower of symbolic powers and the parallel tower of ordinary powers, with horizontal maps the natural surjections $R/\mathfrak{p}^{(n+1)} \twoheadrightarrow R/\mathfrak{p}^{(n)}$ (and $R/\mathfrak{p}^{n+1} \twoheadrightarrow R/\mathfrak{p}^{n}$) and the vertical maps $R/\mathfrak{p}^{n} \to R/\mathfrak{p}^{(n)}$ induced by $\mathfrak{p}^n \subseteq \mathfrak{p}^{(n)}$:

$$\begin{array}{ccccccc} \cdots & \twoheadrightarrow & R/\mathfrak{p}^{(3)} & \twoheadrightarrow & R/\mathfrak{p}^{(2)} & \twoheadrightarrow & R/\mathfrak{p}^{(1)} \\ & & \uparrow & & \uparrow & & \| \\ \cdots & \twoheadrightarrow & R/\mathfrak{p}^{3} & \twoheadrightarrow & R/\mathfrak{p}^{2} & \twoheadrightarrow & R/\mathfrak{p} \end{array}$$

Prove each vertical map is well defined, that the rightmost map is an isomorphism (so $\mathfrak{p}^{(1)} = \mathfrak{p}$), and give a prime $\mathfrak{p}$ in some R for which the map $R/\mathfrak{p}^2 \to R/\mathfrak{p}^{(2)}$ is *not* injective.

15.7 Integral Dependence, Valuation Rings, and Hilbert's Nullstellensatz

Integral elements: the geometry of a ramified cover

In classical algebraic geometry one frequently studies a curve as a (ramified) covering of the line: a finite map $C \to \mathbb{A}^1$ presenting the function field of C as a finite extension of $k(t)$. Algebraically this is the relation between a ring and a subring expressed by *integral dependence*. Integrality is to ring extensions what *algebraicity* is to field extensions, with one crucial sharpening: we demand a *monic* equation, not merely a nonzero one. This single adjustment – forcing the leading coefficient to be 1 – is what makes the theory control prime ideals so tightly (Lying Over, Going Up, Going Down), and it is the algebraic engine behind Hilbert's Nullstellensatz: the dictionary between the geometry of points in $\mathbb{A}^n$ and the maximal ideals of $k[x_1, \dots, x_n]$.

Throughout, $A \subseteq B$ are commutative rings with $1 \in A$. We freely identify "A a subring of B" with the inclusion homomorphism; the general statements about a homomorphism $\varphi : A \to B$ follow by replacing A with $\varphi(A)$.

Definition 15.7.1 (integral element, integral extension, integral closure)**.** Let $A \subseteq B$.

(1) An element $x \in B$ is *integral over* A if x is a root of a *monic* polynomial with coefficients in A:

$$x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 = 0, \qquad a_i \in A.$$

(2) B is *integral over* A (an *integral extension*) if every $x \in B$ is integral over A.

(3) The *integral closure of A in B* is $\overline{A} = \{\, x \in B : x \text{ integral over } A \,\}$. If $\overline{A} = A$, then A is *integrally closed in B*.

(4) For a domain A with fraction field $K = \operatorname{Frac}(A)$, the integral closure of A in K is the *normalization* of A; A is *integrally closed* (or *normal*) if it equals its normalization.

The next proposition is the cornerstone. It converts the single-element condition "x satisfies a monic equation" into the finiteness of a module, which is stable under the ring operations – this is exactly why the integral elements form a ring. It is the determinant-trick (Cayley–Hamilton) lurking behind every later theorem.

Proposition 15.7.2 (characterizations of integrality; A&M 5.1)**.** *Let $A \subseteq B$ and $x \in B$. The following are equivalent:*

(i) *x is integral over A;*

(ii) *$A[x]$ is a finitely generated A-module;*

(iii) *$A[x]$ is contained in a subring C with $A \subseteq C \subseteq B$ that is a finitely generated A-module;*

(iv) *there is a faithful $A[x]$-module M that is finitely generated as an A-module.*

Idea. (i)⇒(ii): the monic relation lets one rewrite x^n, hence every x^{n+r}, as an A-combination of $1, x, \dots, x^{n-1}$, so $A[x] = A1 + Ax + \cdots + Ax^{n-1}$. (ii)⇒(iii): take $C = A[x]$. (iii)⇒(iv): take $M = C$, faithful because $1 \in C$. (iv)⇒(i) is the determinant trick: multiplication by x on the finitely generated module $M = Av_1 + \cdots + Av_n$ gives $xv_i = \sum_j a_{ij} v_j$, so $(xI - (a_{ij}))v = 0$; multiplying by the adjugate yields $\det(xI - (a_{ij})) \cdot v_i = 0$ for all i. Faithfulness forces $\det(xI - (a_{ij})) = 0$, a monic equation for x over A. □

Corollary 15.7.3 (the integral closure is a ring; transitivity; A&M 5.2–5.6)**.** *Let $A \subseteq B$ and $x, y \in B$ integral over A.*

(1) *$x \pm y$ and xy are integral over A; hence $\overline{A}$ is a subring of B containing A.*

(2) (Tower / finite type + integral = finite.) *If $B = A[x_1, \dots, x_n]$ with each x_i integral over A, then B is a finitely generated A-module.*

(3) (Transitivity.) *If $A \subseteq B \subseteq C$ with C integral over B and B integral over A, then C is integral over A.*

(4) *$\overline{A}$ is integrally closed in B (the closure stops after one step).*

Idea. For (1): $A[x]$ and $A[y]$ are finite A-modules, so $A[x, y] = \sum_{i,j} Ax^i y^j$ is too; it contains $x \pm y$ and xy, so (iii) of the proposition applies. (2) iterates (1) up the tower $A[x_1] \subseteq A[x_1, x_2] \subseteq \cdots$. (3): if $x \in C$ satisfies a monic equation with coefficients $b_i \in B$, then $A[b_0, \dots, b_{n-1}]$ is a finite A-module and $A[b_0, \dots, b_{n-1}][x]$ is a finite module over it; transitivity of finiteness of modules and (iii) give the claim. (4) is (3) read with $C = \overline{\overline{A}}$. □

Remark 15.7.1 (A&M's slogan). Corollary (2) is the identity **finite type + integral = finite**: a ring extension that is both finitely generated as an algebra and integral is finitely generated as a module. This is the precise sense in which a ramified cover $C \to \mathbb{A}^1$ is "finite over the base."

Worked Example 15.7.4 ($\sqrt{2}$ is an algebraic integer; 1/2 is not)**.** Decide which of $\sqrt{2}$, $\frac{1+\sqrt{5}}{2}$, $\frac{1}{2} \in \mathbb{Q}$ are integral over $\mathbb{Z}$.

Recognition. An element of $\mathbb{Q}$ is integral over the UFD $\mathbb{Z}$ iff it lies in $\mathbb{Z}$ (rational root test); for irrationals, exhibit a monic integer equation.

Solution. $\sqrt{2}$ satisfies $x^2 - 2 = 0$, monic over $\mathbb{Z}$, so it is integral. The golden ratio $\tau = \frac{1+\sqrt{5}}{2}$ satisfies $x^2 - x - 1 = 0$, monic over $\mathbb{Z}$, so it is integral. But $\frac{1}{2}$ is integral over $\mathbb{Z}$ iff $\frac{1}{2} \in \mathbb{Z}$ (since $\mathbb{Z}$ is a UFD, hence integrally closed): if $(1/2)^n + a_{n-1}(1/2)^{n-1} + \cdots + a_0 = 0$ then clearing denominators gives $1 = -2(a_{n-1} + \cdots + 2^{n-1} a_0)$, forcing $2 \mid 1$, impossible. Sanity check: the minimal polynomial of $\frac{1}{2}$ over $\mathbb{Q}$ is $x - \frac{1}{2}$, not monic over $\mathbb{Z}$, matching Proposition 28 of D&F that α is an algebraic integer iff $m_{\alpha,\mathbb{Q}} \in \mathbb{Z}[x]$.

Worked Example 15.7.5 (Integral closure need not equal the subring: the cuspidal cubic)**.** Let $R = k[x, y]/(x^2 - y^3) = k[\bar{x}, \bar{y}]$. Show R is not integrally closed in its fraction field.

Recognition. Look for an element of $\mathrm{Frac}(R)$ satisfying a monic equation over R but lying outside R; the cusp at the origin is the geometric obstruction.

Solution. In $\mathrm{Frac}(R)$ set $t = \bar{x}/\bar{y}$. Then $t^2 = \bar{x}^2/\bar{y}^2 = \bar{y}^3/\bar{y}^2 = \bar{y}$, so t satisfies the monic equation $T^2 - \bar{y} = 0$ over R; hence t is integral over R. But $t = \bar{x}/\bar{y} \notin R$: the parametrization $\bar{x} \mapsto s^3$, $\bar{y} \mapsto s^2$ identifies R with $k[s^2, s^3] \subseteq k[s]$, and $t \mapsto s \notin k[s^2, s^3]$. The normalization is $k[s] = k[t]$, the smooth line resolving the cusp. Sanity check: t also satisfies $T^3 - \bar{x} = 0$ (since $t^3 = \bar{x}^3/\bar{y}^3 = \bar{x}^3/\bar{x}^2 = \bar{x}$), a second monic witness; and R being non-normal forces it to be a non-UFD, consistent with $\bar{x}^2 = \bar{y}^3$ giving two distinct factorizations of the same element.

Worked Example 15.7.6 (Every UFD is integrally closed)**.** Show that a UFD A is integrally closed in $\mathrm{Frac}(A)$.

Recognition. Use the rational root argument: a fraction in lowest terms satisfying a monic equation must have unit denominator.

Solution. Let $a/b \in \mathrm{Frac}(A)$ in lowest terms ($\gcd(a,b)=1$) satisfy $(a/b)^n + r_{n-1}(a/b)^{n-1} + \cdots + r_0 = 0$ with $r_i \in A$. Clearing b^n: $a^n = -b(r_{n-1}a^{n-1} + \cdots + r_0 b^{n-1})$, so every irreducible dividing b divides a^n, hence divides a. Since $\gcd(a,b)=1$, b has no irreducible factors, i.e. b is a unit and $a/b \in A$. Sanity check: $\mathbb{Z}$, $k[x]$, and $k[x_1,\ldots,x_n]$ are all UFDs, hence all integrally closed – recovering Example (1) above and the normality of polynomial rings used in the Nullstellensatz.

Worked Example 15.7.7 (The ring of integers of $\mathbb{Q}(\sqrt{D})$)**.** For squarefree D, compute the normalization of $\mathbb{Z}$ in $\mathbb{Q}(\sqrt{D})$.

Recognition. Test $\alpha = a + b\sqrt{D}$ ($a, b \in \mathbb{Q}$): integral iff its $\mathbb{Q}$-minimal polynomial $x^2 - 2ax + (a^2 - b^2 D)$ has integer coefficients.

Solution. Integrality forces $2a \in \mathbb{Z}$ and $a^2 - b^2 D \in \mathbb{Z}$; then $(2b)^2 D = (2a)^2 - 4(a^2 - b^2 D) \in \mathbb{Z}$, and as D is squarefree this forces $2b \in \mathbb{Z}$. Writing $a = x/2,\ b = y/2$ with $x, y \in \mathbb{Z}$ gives $x^2 - y^2 D \equiv 0 \pmod 4$. As squares are $0, 1 \bmod 4$ and D is squarefree, either $D \equiv 2, 3 \pmod 4$ with x, y both even (so $a, b \in \mathbb{Z}$), or $D \equiv 1 \pmod 4$ with x, y of equal parity. Hence

$$\mathcal{O}_{\mathbb{Q}(\sqrt{D})} = \begin{cases} \mathbb{Z}[\sqrt{D}], & D \equiv 2,3 \pmod 4, \\ \mathbb{Z}\left[\frac{1+\sqrt{D}}{2}\right], & D \equiv 1 \pmod 4. \end{cases}$$

Sanity check: for $D = 5$, $\frac{1+\sqrt{5}}{2}$ is integral (Worked Example above), so $\mathbb{Z}[\sqrt{5}] \subsetneq \mathcal{O}_{\mathbb{Q}(\sqrt{5})}$ – $\mathbb{Z}[\sqrt{5}]$ is the non-maximal, non-integrally-closed order, and adjoining the golden ratio normalizes it.

Lying over, going up, going down: prime ideals as points

A&M's central philosophy is that a prime ideal is the common generalization of "a prime of arithmetic" and "a point of geometry," and that a ring map $A \to B$ is to be read geometrically as a map of spaces $\operatorname{Spec} B \to \operatorname{Spec} A$, $\mathfrak{q} \mapsto \mathfrak{q} \cap A$ (contraction). For a *finite* (integral, finite-type) map this is the algebra of a ramified cover, and the three classical theorems say the fibers and chains behave as a covering should: every point of the base is hit (Lying Over), chains lift upward (Going Up), and – when the base is normal – chains lift downward (Going Down). We write $\mathfrak{q} \cap A$ for the contraction $\varphi^{-1}(\mathfrak{q})$ when $A \subseteq B$.

Theorem 15.7.8 (integral extensions: field, Lying Over, Going Up, Going Down; D&F 26)**.** *Let $A \subseteq B$ be commutative rings with B integral over A.*

(1) (Fields together.) *If B is a domain, then A is a field iff B is a field.*

(2) (Lying Over.) *For every prime $\mathfrak{p} \subseteq A$ there is a prime $\mathfrak{q} \subseteq B$ with $\mathfrak{q} \cap A = \mathfrak{p}$. Moreover $\mathfrak{p}$ is maximal iff $\mathfrak{q}$ is maximal.*

(3) (Going Up.) *A chain $\mathfrak{p}_1 \subseteq \cdots \subseteq \mathfrak{p}_n$ of primes of A, partially lifted to $\mathfrak{q}_1 \subseteq \cdots \subseteq \mathfrak{q}_m$ in B ($m < n$, $\mathfrak{q}_i \cap A = \mathfrak{p}_i$), can be completed to $\mathfrak{q}_1 \subseteq \cdots \subseteq \mathfrak{q}_n$ with $\mathfrak{q}_i \cap A = \mathfrak{p}_i$.*

(4) (Going Down.) *If in addition B is a domain and A is integrally closed in its fraction field (i.e. A is normal), then a descending chain $\mathfrak{p}_1 \supseteq \cdots \supseteq \mathfrak{p}_n$ partially lifted to $\mathfrak{q}_1 \supseteq \cdots \supseteq \mathfrak{q}_m$ ($m < n$) can be completed downward.*

Idea. (1): if A is a field and $0 \neq s \in B$ satisfies a monic equation with nonzero constant term a_0, then $s \cdot (-a_0^{-1})(s^{n-1} + \cdots + a_1) = 1$ gives $s^{-1} \in B$. Conversely if B is a field and $0 \neq r \in A$, then $r^{-1} \in B$ is integral, and its monic equation rearranges to express r^{-1} as an A-combination of nonnegative powers of r, so $r^{-1} \in A$. (2): reduce mod the primes – $B/\mathfrak{q}$ is integral over $A/(\mathfrak{q} \cap A)$, so (1) gives the maximality statement; existence of *some* $\mathfrak{q}$ is the localization argument $S^{-1}A \subseteq S^{-1}B$ at $S = A \setminus \mathfrak{p}$ (a maximal ideal $\mathfrak{n}$ of $S^{-1}B$ contracts, by the maximality statement applied to the integral extension $S^{-1}A \subseteq S^{-1}B$, to the

maximal ideal $\mathfrak{p}S^{-1}A$ of the local ring $S^{-1}A$, so the contraction of $\mathfrak{n}$ to B is a prime of B lying over $\mathfrak{p}$). (3) is an induction reducing to $n = 2$, $m = 1$: pass to $\overline{A} = A/\mathfrak{p}_1 \subseteq \overline{B} = B/\mathfrak{q}_1$, apply Lying Over to $\mathfrak{p}_2/\mathfrak{p}_1$, and pull back. (4) is A&M 5.16: reduce to $n = 2$, $m = 1$; since A is integrally closed, A&M 5.15 is used to show that $\mathfrak{p}_2 B$ does *not* meet the multiplicative set $(A \setminus \mathfrak{p}_2)(B \setminus \mathfrak{q}_1)$, and an ideal of B maximal among those containing $\mathfrak{p}_2 B$ and disjoint from this set is a prime $\mathfrak{q}_2 \subseteq \mathfrak{q}_1$ with $\mathfrak{q}_2 \cap A = \mathfrak{p}_2$. □

Remark 15.7.2 (contraction is a continuous map of spectra). The assignment $\mathfrak{q} \mapsto \mathfrak{q} \cap A$ is the continuous map $\operatorname{Spec} B \to \operatorname{Spec} A$ induced by $A \hookrightarrow B$. Lying Over says it is *surjective*; Going Up says it is a *closed* map (A&M Ex. 5.1); Going Down says the generizations lift, which geometrically forbids the cover from "jumping" to a lower-dimensional sheet. For finite B over A, the fibers are finite and nonempty – a genuine branched covering of $\operatorname{Spec} A$.

Corollary 15.7.9 (finitely many primes over a maximal ideal; D&F 27)**.** *If B is integral and finitely generated as a ring over A, and $\mathfrak{m} \subseteq A$ is maximal, then the set of maximal ideals $\mathfrak{q} \subseteq B$ with $\mathfrak{q} \cap A = \mathfrak{m}$ is finite and nonempty.*

Worked Example 15.7.10 ($\mathbb{Z} \subseteq \mathbb{Z}[i]$: primes lying over (p))**.** Describe the primes of $\mathbb{Z}[i]$ lying over the rational primes $(2), (5), (7)$.

Recognition. $\mathbb{Z}[i]$ is integral over $\mathbb{Z}$ (each $a + bi$ satisfies a monic quadratic); Lying Over guarantees a prime over each (p), and the splitting type is read from $x^2 + 1 \bmod p$.

Solution. Since $\mathbb{Z}[i] \cong \mathbb{Z}[x]/(x^2+1)$, primes over (p) correspond to irreducible factors of x^2+1 in $\mathbb{F}_p[x]$. Over (5): $x^2 + 1 = (x - 2)(x + 2)$, so (5) *splits*: two primes $(2 + i), (2 - i)$ lie over it. Over (2): $x^2 + 1 = (x + 1)^2$, so (2) *ramifies*: the single prime $(1 + i)$ lies over it with $(2) = (1 + i)^2$ up to a unit. Over (7): $x^2 + 1$ is irreducible mod 7 (-1 is a non-residue), so (7) is *inert*: (7) stays prime in $\mathbb{Z}[i]$. Sanity check: each fiber is finite and nonempty (Corollary), and $\mathfrak{q} \cap \mathbb{Z} = (p)$ is maximal iff $\mathfrak{q}$ is maximal – indeed all three primes $(1 + i), (2 + i), (7)$ are maximal in the Dedekind domain $\mathbb{Z}[i]$.

Worked Example 15.7.11 (Lying Over can fail without monic: $\mathbb{Z} \subseteq \mathbb{Q}$)**.** Show $\mathbb{Q}$ is not integral over $\mathbb{Z}$, and that contraction $\operatorname{Spec} \mathbb{Q} \to \operatorname{Spec} \mathbb{Z}$ is not surjective.

Recognition. Integrality is essential in Lying Over; drop it and surjectivity dies.

Solution. $\mathbb{Q}$ is the localization $S^{-1}\mathbb{Z}$ at $S = \mathbb{Z} \setminus \{0\}$, a non-integral extension ($\frac{1}{2}$ is not integral, Worked Example above). $\operatorname{Spec} \mathbb{Q} = \{(0)\}$ has one point, and contraction sends it to $(0) \subsetneq \mathbb{Z}$; no rational prime (p) is hit. Sanity check: this matches the general principle that localization *removes* the closed points $V(p)$ – "concentrating near the generic point" – whereas integral extensions, by contrast, hit every point of the base.

Worked Example 15.7.12 (A field iff B field, in action)**.** Let $A = k$ a field and B a domain integral over k. Show B is a field.

Recognition. Apply the direction "A a field $\Rightarrow$ B a field" of part (1) of the theorem; it is the converse direction that kills the polynomial ring inside the Nullstellensatz proof.

Solution. By (1), $A = k$ a field and B a domain integral over A forces B to be a field. Concretely, each $0 \neq b \in B$ satisfies $b^n + a_{n-1}b^{n-1} + \cdots + a_0 = 0$ with $a_i \in k$; we may take $a_0 \neq 0$ (cancel powers of b in the domain B), and then $b^{-1} = -a_0^{-1}(b^{n-1} + \cdots + a_1) \in B$. Sanity check: if instead $B = k[y]$ (a polynomial ring), then y is transcendental over k, so it satisfies no monic equation over k and $k[y]$ is *not* integral over k; correspondingly $B = k[y]$ is not a field – consistent with the theorem, since its hypothesis fails. The contrapositive "B not a field $\Rightarrow$ B not integral over the field k" is the direction shown here; what forces $q = 0$ in the proof of Zariski's Lemma below is the converse direction of (1): a field that is integral over a subring forces that subring to be a field.

Noether normalization and Zariski's lemma

To prove the Nullstellensatz we need two algebraic facts. **Noether Normalization** says every finitely generated algebra over a field is a finite (integral) module over a polynomial subring – the algebraic form of "project a variety onto a coordinate subspace as a ramified cover." **Zariski's Lemma** (A&M Corollary 5.24) says a field that is finitely generated *as an algebra* over a subfield is finite *as an extension*, i.e. algebraic. Together they pin down the maximal ideals of $k[x_1, \ldots, x_n]$.

Definition 15.7.13 (algebraic independence)**.** Elements $y_1, \dots, y_q$ of a k-algebra are *algebraically independent over k* if no nonzero polynomial $p \in k[X_1, \dots, X_q]$ has $p(y_1, \dots, y_q) = 0$; equivalently $k[y_1, \dots, y_q] \cong k[X_1, \dots, X_q]$ as k-algebras.

Theorem 15.7.14 (Noether Normalization Lemma; D&F 30)**.** *Let k be a field and $A = k[r_1, \dots, r_m]$ a finitely generated k-algebra. Then there exist $0 \le q \le m$ and algebraically independent $y_1, \dots, y_q \in A$ such that A is integral over the polynomial subring $k[y_1, \dots, y_q]$.*

Idea. Induct on m. If the r_i are algebraically independent, take $y_i = r_i$. Otherwise a nonzero relation $f(r_1, \dots, r_m) = 0$ holds. The key move is a change of variables $X_i = x_i - x_m^{\alpha_i}$ with $\alpha_i = (1+d)^i$ (where $d = \deg f$): in base $b = d+1$ the exponents separate, so $g(X_1, \dots, X_{m-1}, x_m) = f(X_1 + x_m^{\alpha_1}, \dots, x_m)$ has a single highest pure power cx_m^N. Dividing by c makes r_m *monic*, hence integral, over $B = k[s_1, \dots, s_{m-1}]$ where $s_i = r_i - r_m^{\alpha_i}$; each r_i ($i < m$) is then integral over $B[r_m]$, so A is integral over B by transitivity. As B is generated by $m-1$ elements, induction finishes. □

Theorem 15.7.15 (Zariski's Lemma; A&M Cor. 5.24)**.** *Let k be a field and let $L \supseteq k$ be a field that is finitely generated as a k-*algebra*. Then L is a finite (hence algebraic) field extension of k.*

Idea. By Noether Normalization, $L = k[r_1, \dots, r_m]$ is integral over a polynomial ring $k[y_1, \dots, y_q]$. By the "fields together" theorem (part 1), since L is a field and integral over the domain $k[y_1, \dots, y_q]$, that subring must be a field too. But a polynomial ring in $q \ge 1$ variables is never a field. Hence $q = 0$, so L is integral over k, i.e. algebraic, and being finitely generated and algebraic it is finite over k. □

Remark 15.7.3 (A&M's transcendence-degree proof). A&M reach Zariski's Lemma without normalization, via Proposition 5.23 (extending homomorphisms to Ω): if $A \subseteq B$ are domains with B finitely generated over A, then there is $0 \ne u \in A$ such that, for any algebraically closed Ω, every homomorphism $\varphi : A \to \Omega$ with $\varphi(u) \ne 0$ extends to B. Applied with $A = k$ and $B = L$ (A&M Corollary 5.24), the inclusion $k \hookrightarrow \overline{k}$ extends to a homomorphism $L \to \overline{k}$, which is injective because L is a field; so L is algebraic over k. Both routes deliver the same arithmetic-geometry payoff.

Worked Example 15.7.16 (Normalizing $k[x,y]/(xy-1)$)**.** Exhibit a Noether normalization of $A = k[x,y]/(xy-1)$ (the hyperbola, $\cong k[t, t^{-1}]$).

Recognition. Find one algebraically independent element over which A is integral; the relation $xy = 1$ must be turned into a monic equation.

Solution. Here $\bar{x}, \bar{y}$ satisfy $\bar{x}\bar{y} = 1$, so they are algebraically dependent ($q < 2$). Set $u = \bar{x} + \bar{y}$. Then $\bar{x}, \bar{y}$ are the two roots of $T^2 - uT + 1 = 0$ (since $\bar{x} + \bar{y} = u$, $\bar{x}\bar{y} = 1$), a monic equation over $k[u]$; hence $A = k[u][\bar{x}]$ is integral over $k[u]$, and u is algebraically independent (transcendental) over k. So $q = 1$ and $k[u] \hookrightarrow A$ is a normalization. Sanity check: $\dim A = 1$ matches $q = 1$ (the number of normalizing parameters equals the Krull dimension); and $A = k[t, t^{-1}]$ is indeed integral over $k[t + t^{-1}]$, so the hyperbola is finite over the line with coordinate $u = \bar{x} + \bar{y}$ – but *not* over the x-axis, since $\bar{y} = \bar{x}^{-1}$ is not integral over the integrally closed ring $k[\bar{x}]$.

Worked Example 15.7.17 (Why a polynomial ring is never a field)**.** Verify the step "$q \ge 1 \Rightarrow k[y_1, \dots, y_q]$ not a field" used in Zariski's Lemma.

Recognition. A field has every nonzero element invertible; produce a non-invertible element of the polynomial ring.

Solution. In $k[y_1, \dots, y_q]$ with $q \ge 1$, the element y_1 is nonzero but not a unit: if $y_1 \cdot g = 1$ then comparing degrees gives $1 + \deg g = 0$, impossible. So $k[y_1, \dots, y_q]$ is not a field. Sanity check: this is precisely why $q = 0$ is forced, collapsing L to an algebraic extension of k – the linchpin of the weak Nullstellensatz.

Worked Example 15.7.18 (Noether normalization of a hypersurface)**.** Normalize $A = k[x,y]/(y^2 - x^3 - x)$ over an infinite field k.

Recognition. After a linear change ensuring the top-degree form is monic in one variable, that variable becomes integral over the others.

Solution. The relation $y^2 = x^3 + x$ is monic in y over $k[x]$ ($y^2 - (x^3 + x) = 0$), so $\bar{y}$ is integral over $k[\bar{x}]$, and $\bar{x}$ is transcendental over k (no relation in x alone). Thus $A = k[\bar{x}][\bar{y}]$ is integral over $k[\bar{x}]$ with $q = 1$.

Sanity check: A is a free $k[\bar{x}]$-module on $\{1, \bar{y}\}$ of rank 2 – for $\operatorname{char} k \neq 2$ the elliptic curve presents itself as a degree-2 ramified cover of the x-line, branched where $x^3 + x = 0$, exactly the "ramified covering" picture A&M opens the chapter with.

Hilbert's Nullstellensatz: the dictionary points $\leftrightarrow$ ideals

We can now state the theorem that fuses A&M's "prime = point" philosophy with D&F's concrete geometry. Over an algebraically closed field, maximal ideals of $k[x_1, \dots, x_n]$ are *exactly* the points of $\mathbb{A}^n$, and radical ideals are exactly the algebraic sets – the Zariski dictionary is a bijection. This ties directly back to the geometry of §15.2 ($\mathbb{A}^n$, $Z(\cdot)$, $I(\cdot)$, the Zariski topology).

Theorem 15.7.19 (Nullstellensatz, Weak Form; D&F 31)**.** *Let k be algebraically closed. The maximal ideals of $k[x_1, \dots, x_n]$ are exactly*

$$\mathfrak{m} = (x_1 - a_1, \dots, x_n - a_n), \qquad (a_1, \dots, a_n) \in \mathbb{A}^n,$$

so Z, I give a bijection $\{$ points of $\mathbb{A}^n \} \longleftrightarrow \{$ maximal ideals of $k[\mathbb{A}^n] \}$. Moreover every proper ideal I has $Z(I) \neq \varnothing$.

Idea. Each $(x_1 - a_1, \dots, x_n - a_n)$ is maximal (the quotient is k). Conversely, for maximal $\mathfrak{m}$, the field $E = k[x_1, \dots, x_n]/\mathfrak{m}$ is finitely generated as a k-algebra, so by Zariski's Lemma E is algebraic over k; as $k = \overline{k}$, $E = k$. Thus each x_i maps to some $a_i \in k$, giving $x_i - a_i \in \mathfrak{m}$, whence $\mathfrak{m} = (x_1 - a_1, \dots, x_n - a_n)$. For the last clause, a proper I lies in a maximal $\mathfrak{m} = (x_i - a_i)$, so $(a_1, \dots, a_n) \in Z(I)$. □

Theorem 15.7.20 (Nullstellensatz, Strong Form; D&F 32)**.** *Let k be algebraically closed. Then for every ideal $I \subseteq k[x_1, \dots, x_n]$,*

$$I\big(Z(I)\big) = \operatorname{rad} I,$$

and Z, I are mutually inverse, inclusion-reversing bijections

$$\{ \text{affine algebraic sets in } \mathbb{A}^n \} \underset{Z}{\overset{I}{\longleftrightarrow}} \{ \text{radical ideals of } k[x_1, \dots, x_n] \}.$$

Idea. $\operatorname{rad} I \subseteq I(Z(I))$ is clear. For the reverse, the *Rabinowitsch trick*: given $g \in I(Z(I))$ with $I = (f_1, \dots, f_m)$, the ideal $I' = (f_1, \dots, f_m, x_{n+1}g - 1)$ in $k[x_1, \dots, x_{n+1}]$ has empty zero set (wherever the f_i vanish, g vanishes, so $x_{n+1}g - 1$ cannot). By the Weak Form, $1 \in I'$; writing $1 = \sum a_i f_i + a_{m+1}(x_{n+1}g - 1)$, substituting $x_{n+1} = 1/g$ and clearing denominators yields $g^N \in I$, i.e. $g \in \operatorname{rad} I$. □

Remark 15.7.4 (the geometric dictionary, completed). Combined with §15.2: *points* $\leftrightarrow$ maximal ideals; *irreducible* algebraic sets $\leftrightarrow$ prime ideals; *algebraic sets* $\leftrightarrow$ radical ideals; and unique decomposition of an algebraic set into irreducible components mirrors the unique writing of a radical ideal as an irredundant intersection of finitely many primes (its minimal primes). The Nullstellensatz is the statement that $k[\mathbb{A}^n] \rightsquigarrow \mathbb{A}^n$ loses no information when $k = \overline{k}$: geometry and the algebra of $k[\mathbb{A}^n]$ are the same subject. The variant for arbitrary k (D&F Cor. 33) recovers $I_k(Z_{\overline{k}}(I)) = \operatorname{rad} I$ by base-changing to $\overline{k}$.

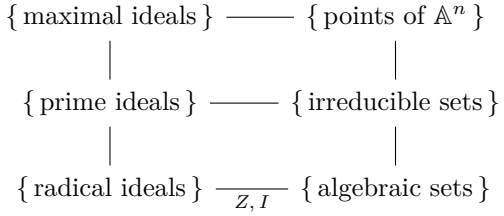

Diagram explanation. Objects: The left column lists three nested classes of ideals in $k[x_1, \dots, x_n]$ (k algebraically closed): maximal ideals $\subseteq$ prime ideals $\subseteq$ radical ideals. The right column lists the corresponding nested classes of subsets of $\mathbb{A}^n$: closed points $\subseteq$ irreducible closed sets $\subseteq$ arbitrary algebraic sets. Each row is a single class on each side; the vertical inclusions on both sides record the containment maximal $\subseteq$ prime $\subseteq$ radical and point $\subseteq$ irreducible $\subseteq$ algebraic set.

Arrows: Every horizontal dash in the diagram stands for the mutually inverse bijections $Z : I \mapsto \{\, a \in \mathbb{A}^n : f(a) = 0 \text{ for all } f \in I \,\}$ (zero-set) and $I : S \mapsto \{\, f \in k[x_1, \ldots, x_n] : f(a) = 0 \text{ for all } a \in S \,\}$ (ideal of a set). The label Z, I on the bottom horizontal dash makes this explicit. The vertical dashes are the forgetful inclusions: a maximal ideal is in particular a prime ideal (a prime ideal is in particular a radical ideal); a point is in particular an irreducible set. No arrow is an isomorphism of rings or a group homomorphism; each dash is a set-theoretic bijection between the indicated collections.

What commutes: The diagram commutes in the sense that the bijections Z and I are *compatible with the vertical inclusions*: if $\mathfrak{m}$ is a maximal ideal corresponding to the point $(a_1, \ldots, a_n)$ under the bijection, then reading $\mathfrak{m}$ as a prime ideal corresponds, under the prime-to-irreducible bijection, to the same point viewed as an irreducible set; and reading it as a radical ideal corresponds to the same point viewed as an algebraic set. Concretely: $Z(\mathfrak{m}) = \{(a_1, \ldots, a_n)\}$ and $Z(\mathfrak{m}) = Z(\mathfrak{m})$ as an algebraic set – the maps on each row restrict and agree across rows.

Why it commutes: For the top row, the Nullstellensatz Weak Form gives $\mathfrak{m} = (x_1 - a_1, \ldots, x_n - a_n)$ and $Z(\mathfrak{m}) = \{(a_1, \ldots, a_n)\}$, a single point. A single point is irreducible (its ideal is prime) and is an algebraic set (it is closed), so the single point sits in all three right-column classes. The vertical nesting is preserved because the three horizontal bijections are restrictions of a single one: by the Strong Form, Z and I are mutually inverse bijections between radical ideals and algebraic sets, and under this bijection the maximal ideals correspond to the points (Weak Form) and the prime ideals to the irreducible sets (a radical ideal is prime iff its zero set is irreducible).

Why this matters here: This diagram is the payoff of the entire section. It records, in one picture, the two-sided Nullstellensatz dictionary: the Weak Form identifies the top row (points $\leftrightarrow$ maximal ideals), the remark on irreducible components extends it to the middle row (irreducible sets $\leftrightarrow$ prime ideals), and the Strong Form ($I(Z(I)) = \operatorname{rad} I$) closes the bottom row. It also shows that Z and I are *not* just a random pair of maps but a hierarchy-preserving correspondence – the geometry of $\mathbb{A}^n$ and the algebra of $k[\mathbb{A}^n]$ are the same ordered structure.

Concrete example: Take $n = 1$, $k = \mathbb{C}$. Maximal ideals of $\mathbb{C}[x]$: $(x - a)$ for $a \in \mathbb{C}$; corresponding points: $\{a\} \subset \mathbb{A}^1$. Prime ideals: (0) and $(x - a)$; irreducible sets: $\mathbb{A}^1$ itself (corresponding to (0), the generic point) and individual points. Radical ideals: (0) and the ideals $((x - a_1) \cdots (x - a_r)) = (x - a_1) \cap \cdots \cap (x - a_r)$ with $a_1, \ldots, a_r$ distinct ($r = 0$ giving (1)); algebraic sets: $\mathbb{A}^1 = Z((0))$ and the finite subsets $\{a_1, \ldots, a_r\}$ of $\mathbb{C}$. In each row Z and I are mutually inverse, and the vertical inclusions on both sides are the natural ones.

Common pitfall: Students sometimes read the dashes as isomorphisms of rings, or think Z is a ring map. It is not: Z sends ideals to *sets of points*, and I sends sets to ideals, so the bijections live at the level of *collections of subsets*, not ring homomorphisms. A second pitfall: the middle row (prime $\leftrightarrow$ irreducible) is *not* stated in the two Nullstellensatz theorems above; it follows from combining the Strong Form with the general fact that a radical ideal is prime iff the algebraic set is irreducible. Do not cite the Nullstellensatz alone for the prime/irreducible bijection.

Takeaway: The point of this diagram is that the Nullstellensatz makes the entire three-level hierarchy of ideals (maximal, prime, radical) in $k[x_1, \ldots, x_n]$ mirror-image the entire three-level hierarchy of geometric objects (points, irreducible varieties, algebraic sets) in $\mathbb{A}^n$, with Z and I as the explicit, mutually inverse dictionaries.

Worked Example 15.7.21 (Maximal ideals of $\mathbb{C}[x, y]$)**.** List the maximal ideals of $\mathbb{C}[x, y]$ and identify the one at the origin.

Recognition. $\mathbb{C}$ is algebraically closed, so the Weak Nullstellensatz applies: maximal ideals are points.

Solution. Every maximal ideal of $\mathbb{C}[x, y]$ has the form $(x - a, y - b)$ for a unique $(a, b) \in \mathbb{C}^2$, with quotient $\mathbb{C}[x, y]/(x - a, y - b) \cong \mathbb{C}$ via $x \mapsto a,\ y \mapsto b$. The origin corresponds to (x, y). Sanity check: $(x - a, y - b)$ is the kernel of evaluation $\mathrm{ev}_{(a,b)} : \mathbb{C}[x, y] \to \mathbb{C}$, a surjection onto a field, so the kernel is maximal; and distinct points give distinct kernels, so the correspondence is a bijection.

Worked Example 15.7.22 (Weak Form fails over $\mathbb{R}$)**.** Show $(x^2 + 1) \subseteq \mathbb{R}[x]$ is maximal but not of the form $(x - a)$.

Recognition. Algebraic closure is essential; over $\mathbb{R}$, $E = \mathbb{R}[x]/\mathfrak{m}$ may be a proper algebraic extension of $\mathbb{R}$.

Solution. $\mathbb{R}[x]/(x^2+1) \cong \mathbb{C}$ is a field, so (x^2+1) is maximal, yet it is not $(x-a)$ for any $a \in \mathbb{R}$ (it has no real root). The Weak Nullstellensatz fails because $\mathbb{R} \neq \overline{\mathbb{R}}$: here $E = \mathbb{C}$ is algebraic over $\mathbb{R}$ of degree 2 but $\neq \mathbb{R}$. Sanity check: over $\mathbb{C}$, $x^2+1 = (x-i)(x+i)$ factors and the two maximal ideals $(x-i), (x+i)$ *are* points – the obstruction is purely the failure of $\mathbb{R}$ to be algebraically closed.

Worked Example 15.7.23 ($I(Z(I)) = \operatorname{rad} I$ on a concrete ideal)**.** For $I = (x^2, y) \subseteq \mathbb{C}[x, y]$, compute $Z(I)$, $I(Z(I))$, and $\operatorname{rad} I$, and check equality.

Recognition. Compute the zero set, take the ideal of that set, and independently compute the radical; the Strong Form predicts they match.

Solution. $Z(I) = \{\, (x, y) : x^2 = 0,\ y = 0 \,\} = \{\, (0, 0) \,\}$, the origin. Then $I(Z(I)) = I(\{\, (0, 0) \,\}) = (x, y)$, the maximal ideal at the origin. Independently $\operatorname{rad}(x^2, y) = (x, y)$: $x \in \operatorname{rad} I$ since $x^2 \in I$, and (x, y) is already prime (quotient $\cong \mathbb{C}$) hence radical, and contains I. So $I(Z(I)) = (x, y) = \operatorname{rad} I$. Sanity check: $I = (x^2, y) \subsetneq (x, y) = \operatorname{rad} I$ is a strict containment – the non-reducedness x^2 (a "double point" / embedded thickening) is invisible to Z, exactly what passing to the radical erases.

Worked Example 15.7.24 (A proper ideal with empty zero set forces $k \neq \overline{k}$)**.** Find a proper ideal $I \subseteq \mathbb{R}[x]$ with $Z(I) = \varnothing$ in $\mathbb{R}$, and reconcile with the Weak Form.

Recognition. The "moreover" clause $Z(I) \neq \varnothing$ for proper I requires $k = \overline{k}$.

Solution. Take $I = (x^2+1) \subseteq \mathbb{R}[x]$. It is proper (not all of $\mathbb{R}[x]$) yet $Z(I) = \{\, a \in \mathbb{R} : a^2 + 1 = 0 \,\} = \varnothing$. This does not contradict the theorem because $\mathbb{R}$ is not algebraically closed. Over $\mathbb{C}$, $Z(x^2+1) = \{\, i, -i \,\} \neq \varnothing$, restoring the conclusion. Sanity check: this is the one-variable shadow of why algebraic closure is a hypothesis – $1 \notin (x^2+1)$ but the ideal still "has no points" over the non-closed field $\mathbb{R}$.

Valuation rings and the integral closure as an intersection

A&M's deepest structural result here is that the integral closure of a domain A in a field K is the *intersection of all valuation rings of K containing A*. Valuation rings are the maximal local rings under *dominance*, the local incarnation of "a point on a curve," and they encode orders of vanishing. This section develops them and closes the circle back to §15.2's geometry: a Noetherian normal domain is the ring of functions regular at every codimension-one point.

Definition 15.7.25 (valuation ring; dominance)**.** Let K be a field. A subring $B \subseteq K$ is a *valuation ring of K* if for every $0 \neq x \in K$, at least one of $x,\ x^{-1}$ lies in B. Given local rings $A \subseteq B$ with maximal ideals $\mathfrak{m}_A, \mathfrak{m}_B$, we say B *dominates* A if $A \subseteq B$ and $\mathfrak{m}_B \cap A = \mathfrak{m}_A$.

Proposition 15.7.26 (characterization of valuation rings; A&M 5.18)**.** *Let B be a valuation ring of K. Then:*

(i) *B is a local ring (its non-units $\mathfrak{m} = \{\, x : x = 0$ or $x^{-1} \notin B \,\}$ form an ideal);*

(ii) *if $B \subseteq B' \subseteq K$ is any intermediate ring, then B' is again a valuation ring of K;*

(iii) *B is integrally closed in K (normal).*

Idea. (i): if x, y are non-units, then x/y or $y/x \in B$, say $x/y \in B$, whence $x + y = (1 + x/y)y \in By \subseteq \mathfrak{m}$; and $ax \in \mathfrak{m}$ for $a \in B$; so $\mathfrak{m}$ is an ideal, the unique maximal one. (ii): immediate from the definition, since x or x^{-1} already lies in $B \subseteq B'$. (iii): if $x \in K$ is integral over B, $x^n + b_{n-1}x^{n-1} + \cdots + b_0 = 0$; if $x \notin B$ then $x^{-1} \in B$, and multiplying by $x^{-(n-1)}$ gives $x = -(b_{n-1} + b_{n-2}x^{-1} + \cdots + b_0 x^{-(n-1)}) \in B$, a contradiction. So $x \in B$. □

Theorem 15.7.27 (maximal dominated rings are valuation rings; A&M 5.19–5.21)**.** *Let K be a field, Ω an algebraically closed field, and let Σ be the set of pairs (A, f) with A a subring of K and $f : A \to \Omega$ a homomorphism, ordered by extension. A maximal element $(B, g) \in \Sigma$ has B a valuation ring of K, with maximal ideal* $\ker g$*. Equivalently: the rings dominating a given local subring of K have, among them, valuation rings as the maximal elements under dominance.*

Idea. Zorn's Lemma gives a maximal (B, g); $\mathfrak{m} = \ker g$ is prime in B since $g(B) \subseteq \Omega$ is a domain inside a field; g extends to $B_{\mathfrak{m}}$, so maximality forces $B = B_{\mathfrak{m}}$, a local ring with maximal ideal $\mathfrak{m}$ (Lemma 5.19). For $x \neq 0$ in K, comparing the extensions of $\mathfrak{m}$ in $B[x]$ and $B[x^{-1}]$ shows at least one is proper, so g extends to $B[x]$ or $B[x^{-1}]$ (Lemma 5.20); maximality forces $x \in B$ or $x^{-1} \in B$. Hence B is a valuation ring. □

Theorem 15.7.28 (integral closure = intersection of valuation rings; A&M 5.22)**.** *Let A be a subring of a field K. Then the integral closure $\overline{A}$ of A in K is the intersection of all valuation rings of K that contain A:*

$$\overline{A} = \bigcap_{\substack{B \text{ valuation ring of } K \\ A \subseteq B}} B.$$

In particular, A is integrally closed in K iff A is an intersection of valuation rings.

Idea. ($\subseteq$) Every valuation ring $B \supseteq A$ is integrally closed (Prop. 5.18(iii)) and contains A, hence contains $\overline{A}$. ($\supseteq$) If $x \in K$ is *not* integral over A, then x^{-1} is a non-unit in $A' = A[x^{-1}]$, so x^{-1} lies in a maximal ideal $\mathfrak{m}'$; extending the residue map $A' \to A'/\mathfrak{m}' \hookrightarrow \Omega$ to a maximal pair gives a valuation ring $B \supseteq A$ with $x^{-1} \in \mathfrak{m}_B$, so $x \notin B$. Thus anything in every such B is integral. □

Remark 15.7.5 (orders of vanishing; tie-back to §15.2). A valuation ring of $k(C)$ (the function field of a curve) records, at a chosen point P, the *order of vanishing* of a rational function: $B = \{\, f : \operatorname{ord}_P(f) \geq 0 \,\}$ with maximal ideal $\{\, f : \operatorname{ord}_P(f) > 0 \,\}$. Dominance "$B$ dominates the local ring $\mathcal{O}_{C,P}$" is the algebraic statement "the valuation is centered at P." The theorem then reads: a function is integral over the coordinate ring iff it has nonnegative order at every point – i.e. *regular functions are those with no poles*, the bridge from this section's integrality to the §15.2 geometry of $Z(\cdot)$ and normal varieties.

Worked Example 15.7.29 ($\mathbb{Z}_{(p)}$ is a valuation ring of $\mathbb{Q}$)**.** Show the localization $\mathbb{Z}_{(p)} = \{\, a/b \in \mathbb{Q} : p \nmid b \,\}$ is a valuation ring of $\mathbb{Q}$, and identify its valuation.

Recognition. Check the defining dichotomy x or $x^{-1} \in B$ via the p-adic valuation v_p.

Solution. Write $0 \neq x = p^n \cdot u$ with $u \in \mathbb{Q}^\times$ a unit at p (numerator and denominator prime to p); set $v_p(x) = n$. Then $x \in \mathbb{Z}_{(p)} \iff v_p(x) \geq 0$, and x^{-1} has $v_p(x^{-1}) = -n$, so exactly one of $v_p(x), v_p(x^{-1})$ is ≥ 0 (both if $n = 0$). Hence x or $x^{-1} \in \mathbb{Z}_{(p)}$: it is a valuation ring. Its maximal ideal is $p\mathbb{Z}_{(p)} = \{\, x : v_p(x) > 0 \,\}$. Sanity check: $\mathbb{Z}_{(p)}$ is local with residue field $\mathbb{F}_p$, and it is integrally closed (it is a localization of the UFD $\mathbb{Z}$), matching Prop. 5.18(iii). The "point" it centers on is the prime $(p) \in \operatorname{Spec} \mathbb{Z}$.

Worked Example 15.7.30 ($k[x]_{(x)}$ as order of vanishing at 0)**.** Identify the valuation ring $k[x]_{(x)} \subseteq k(x)$ and its valuation geometrically.

Recognition. The local ring of the line at the origin records vanishing order at $x = 0$.

Solution. $B = k[x]_{(x)} = \{\, f/g : g(0) \neq 0 \,\}$. For $0 \neq h \in k(x)$ write $h = x^n \cdot (p/q)$ with $p(0), q(0) \neq 0$; then $\operatorname{ord}_0(h) = n$ and $h \in B \iff n \geq 0$. So h or $h^{-1} \in B$ always, and B is the valuation ring of order-of-vanishing at the origin, with maximal ideal (x) and residue field k. Sanity check: a rational function lies in B iff it has no pole at 0 – "regular at the origin" – the local-ring picture from §15.5 realized as a valuation; and $\bigcap_{a \in k} k[x]_{(x-a)} \supseteq k[x]$ recovers global regularity as "regular at every point."

Worked Example 15.7.31 (A non-valuation subring)**.** Show $k[x, y]_{(x,y)}$ is local but *not* a valuation ring of $k(x, y)$.

Recognition. Test the dichotomy on x/y: a valuation ring must contain x/y or y/x.

Solution. The element $x/y \in k(x, y)$ is not in $B = k[x, y]_{(x,y)}$ (its denominator y vanishes at the maximal ideal's point), and neither is y/x. So B fails the valuation dichotomy: B is a local ring that is *not* a valuation ring. Sanity check: this reflects that the local ring of the *plane* at the origin has dimension 2, whereas a rank-one (discrete) valuation records only codimension-one (order-one) data; one must *blow up* or pass to a curve through the origin to obtain an honest valuation dominating B – consistent with A&M 5.21, where valuation rings arise as maximal dominating rings, not arbitrary local rings.

Worked Example 15.7.32 ($\mathbb{Z}$ as an intersection of valuation rings)**.** Express $\mathbb{Z}$ as an intersection of valuation rings of $\mathbb{Q}$, illustrating Theorem 5.22.

Recognition. $\mathbb{Z}$ is integrally closed in $\mathbb{Q}$ (it is a UFD), so it must equal an intersection of valuation rings; the $\mathbb{Z}_{(p)}$ are the natural candidates.

Solution. $\bigcap_{p \text{ prime}} \mathbb{Z}_{(p)} = \{\, a/b \in \mathbb{Q} : p \nmid b \text{ for all } p \,\} = \{\, a/b : b = \pm 1 \,\} = \mathbb{Z}$. Each $\mathbb{Z}_{(p)}$ is a valuation ring containing $\mathbb{Z}$ (previous Worked Example), and an element of $\mathbb{Q}$ lies in all of them iff its reduced denominator has no prime factor, i.e. is a unit. Sanity check: this is Theorem 5.22 with $A = K \cap \mathbb{Z} = \mathbb{Z}$ already integrally closed – $\overline{\mathbb{Z}} = \mathbb{Z} = \bigcap_p \mathbb{Z}_{(p)}$ – and geometrically it says "an integer is a rational function on $\operatorname{Spec}\mathbb{Z}$ with no poles at any prime," the arithmetic analogue of a regular function on a curve.

Worked Example 15.7.33 (Going Down over a normal base, in $\mathbb{Z}[\sqrt{-5}]$)**.** Illustrate that normality of the base is what powers Going Down, using $\mathbb{Z} \subseteq \mathbb{Z}[\sqrt{-5}]$.

Recognition. Going Down needs A integrally closed in its fraction field (normal), not in B; $\mathbb{Z}$ is normal, so chains descend.

Solution. $\mathbb{Z}$ is integrally closed (UFD), and $\mathbb{Z}[\sqrt{-5}] = \mathcal{O}_{\mathbb{Q}(\sqrt{-5})}$ (here $-5 \equiv 3 \bmod 4$) is integral over $\mathbb{Z}$. Take the chain $(2) \supseteq (0)$ in $\mathbb{Z}$ and a prime $\mathfrak{q}_1 = (2, 1+\sqrt{-5})$ over (2). Going Down completes it downward: there is $\mathfrak{q}_2 \subseteq \mathfrak{q}_1$ with $\mathfrak{q}_2 \cap \mathbb{Z} = (0)$, namely $\mathfrak{q}_2 = (0)$ itself (a prime of the domain $\mathbb{Z}[\sqrt{-5}]$ contracting to (0)). Sanity check: had A been non-normal the descent could fail in general, but for this short chain the lower prime is automatic – $\mathfrak{q}_2 = (0)$ lies over (0) simply because $\mathbb{Z}[\sqrt{-5}]$ is a domain – and no valuation ring is involved; the hypothesis "A integrally closed" of A&M's Theorem 5.16 enters the general proof through A&M 5.15. Note $\mathfrak{q}_1^2 = (2)$ here since (2) ramifies as $(2) = (2, 1+\sqrt{-5})^2$, consistent with 2 being a ramified (non-split) prime.

Worked Example 15.7.34 (Integral closure of $k[x^2, x^3]$ via the valuation criterion)**.** Confirm the normalization of $A = k[x^2, x^3]$ is $k[x]$ using Theorem 5.22's "no poles" reading.

Recognition. An element of $k(x) = \operatorname{Frac}(A)$ is in $\overline{A}$ iff it lies in every valuation ring of $k(x)$ containing A; equivalently, it is a polynomial (no poles).

Solution. $\operatorname{Frac}(A) = k(x)$ since $x = x^3/x^2 \in \operatorname{Frac}(A)$. The nontrivial valuation rings of $k(x)/k$ are the localizations $k[x]_{(p)}$ at the monic irreducibles $p \in k[x]$ (the finite places, of which the $k[x]_{(x-a)}$ are the degree-one ones) together with the order-at-infinity ring $\{\, f/g : \deg f \le \deg g \,\}$; an element regular at every finite place and at infinity is a constant, but the ring at infinity does not contain A (x^2 has a pole at infinity), so the valuation rings containing A are $k(x)$ and the finite ones, leaving exactly the polynomials regular at all finite places: $\overline{A} = \bigcap_{p \text{ monic irred.}} k[x]_{(p)} = k[x]$. Indeed $x = x^3/x^2$ is integral over A (x satisfies $T^2 - x^2 = 0$). Sanity check: $A = k[x^2, x^3] = k[s,t]/(t^2 - s^3)$ is the cusp again; its normalization $k[x]$ smooths the cusp, matching the earlier direct computation and the geometric slogan "normalize = remove the singularity by demanding no poles."

Worked Example 15.7.35 (Algebraic integers form a ring – without finding a formula)**.** Show $\sqrt{2} + \sqrt{3}$ is an algebraic integer, using the "integral closure is a ring" corollary rather than computing a minimal polynomial by hand first.

Recognition. Sums and products of integral elements are integral (Corollary), so it suffices that $\sqrt{2}, \sqrt{3}$ are integral.

Solution. $\sqrt{2}$ and $\sqrt{3}$ are integral over $\mathbb{Z}$ (roots of $x^2 - 2,\ x^2 - 3$), and the integral closure $\overline{\mathbb{Z}}$ in $\overline{\mathbb{Q}}$ is a ring, so $\sqrt{2} + \sqrt{3} \in \overline{\mathbb{Z}}$ is an algebraic integer. To exhibit a witness: $\alpha = \sqrt{2} + \sqrt{3}$ gives $\alpha^2 = 5 + 2\sqrt{6}$, so $(\alpha^2 - 5)^2 = 24$, i.e. $\alpha^4 - 10\alpha^2 + 1 = 0$, monic over $\mathbb{Z}$. Sanity check: the abstract closure-is-a-ring argument predicts integrality before any computation; the explicit quartic $x^4 - 10x^2 + 1$ confirms it and is the minimal polynomial of $\sqrt{2} + \sqrt{3}$ over $\mathbb{Q}$, with integer coefficients as Proposition 28 demands.

Exercises (Dummit & Foote).

1. Use the fact that a U.F.D. is integrally closed to prove that the Gaussian integers $\mathbb{Z}[i]$ is the ring of integers in $\mathbb{Q}(i)$.

2. Suppose k is a field and let $t = x/y$ in the field of fractions of the integral domain $R = k[x,y]/(x^2 - y^3)$. Prove that $K = k(t)$ is the fraction field of R and $k[t]$ is the integral closure of R in K.

3. Suppose k is a field and i and j are relatively prime positive integers. Find the normalization of the integral domain $R = k[x, y]/(x^i - y^j)$ (cf. Exercise 14, Section 9.1).

4. Suppose k is a field and let P be the ideal $(y^2 - x^3 - x^2)$ in the polynomial ring $k[x, y]$. Prove that P is a prime ideal and find the normalization of the integral domain $R = k[x, y]/P$. [To prove P is prime, show that $y^2 - x^3 - x^2$ is irreducible in the U.F.D. $k[x, y]$. Then consider $t = y/x$ in the field of fractions of R.]

5. If R is an integral domain with field of fractions F, show that F is a finitely generated R-module if and only if $R = F$.

6. For each of the following give specific rings $R \subseteq S$ and explicit ideals in these rings that exhibit the specified relation:

   (a) an ideal I of R such that $I \neq IS \cap R$ (so the contraction of the extension of an ideal I need not equal I);

   (b) a prime ideal P of R such that there is no prime ideal Q of S with $P = Q \cap R$;

   (c) a maximal ideal M of S such that $M \cap R$ is not maximal in R;

   (d) a prime ideal P of R whose extension PS to S is not a prime ideal in S;

   (e) an ideal J of S such that $J \neq (J \cap R)S$ (so the extension of the contraction of an ideal J need not equal J).

7. Let $\mathcal{O}_K$ be the ring of integers in a number field K.

   (a) Suppose that every nonzero ideal I of $\mathcal{O}_K$ can be written as the product of powers of prime ideals. Prove that an ideal Q of $\mathcal{O}_K$ is P-primary if and only if $Q = P^m$ for some $m \geq 1$. [Show first that since nonzero primes in $\mathcal{O}_K$ are maximal that $P_1^{m_1} \subseteq P_2^{m_2}$ for distinct nonzero primes P_1, P_2 implies $P_1 = P_2$.]

   (b) Suppose that an ideal Q of $\mathcal{O}_K$ is P-primary if and only if $Q = P^m$ for some $m \geq 1$. Assuming all of Theorem 21, prove that every nonzero ideal I of $\mathcal{O}_K$ can be written uniquely as the product of powers of prime ideals. [Prove that $P_1^{m_1}$ and $P_2^{m_2}$ are comaximal ideals if P_1 and P_2 are distinct nonzero prime ideals and use the Chinese Remainder Theorem.]

8. Prove that if $s_1, \ldots, s_n \in S$ are integral over R, then the ring $R[s_1, \ldots, s_n]$ is a finitely generated R-module.

9. Suppose that S is integral over R and that P is a prime ideal in R. Prove that every element s in the ideal PS generated by P in S satisfies an equation $s^n + a_{n-1}s^{n-1} + \cdots + a_1 s + a_0 = 0$ where the coefficients $a_0, a_1, \ldots, a_{n-1}$ are elements of P. [If $s = p_1 s_1 + \cdots + p_m s_m \in PS$, show that $T = R[s_1, \ldots, s_m]$ satisfies the hypotheses in Proposition 23(3). Follow the proof in Proposition 23 that s is integral, noting that $s \in PT$ so that the a_{ij} are elements of P.]

10. Prove the following generalization of Proposition 28: Suppose R is an integrally closed integral domain with field of fractions k and α is an element of an extension field K of k. Show that α is integral over R if and only if α is algebraic over k and the minimal polynomial $m_{\alpha,k}(x)$ for α over k has coefficients in R. [If α is integral prove the conjugates of α, i.e., the roots of $m_{\alpha,k}(x)$, are also integral, so the elementary symmetric functions of the conjugates are elements of k that are integral over R.]

11. Suppose R is an integrally closed integral domain with field of fractions k and $p(x) \in R[x]$ is a monic polynomial. Show that if $p(x) = a(x)b(x)$ with monic polynomials $a(x), b(x) \in k[x]$ then $a(x), b(x) \in R[x]$ (compare to Gauss' Lemma, Proposition 5, Section 9.3). [See the previous exercise.]

12. Suppose S is an integral domain that is integral over a ring R as in the previous exercise. If P is a prime ideal in R, let s be any element in the ideal PS generated by P in S. Prove that, with the exception of the leading term, the coefficients of the minimal polynomial $m_{s,k}(x)$ for s over k are elements of P. [By Exercise 10, $m_{s,k}(x) \in R[x]$. Exercise 9 shows that s is a root of a monic polynomial $p(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_0$ with $a_0, \ldots, a_{n-1} \in P$. Use the previous exercise to show that $p(x) = m_{s,k}(x)b(x)$ with $b(x)$ in $R[x]$, and consider this equation in the integral domain $(R/P)[x]$.]

13. Let K be a field of characteristic 0 and let A be a subring of K maximal with respect to $1/2 \notin A$. (Such A exists by Zorn's Lemma.) Let F be the field of fractions of A in K.

(a) Show that K is algebraic over F. [If t is transcendental over F, show that $1/2 \notin A[t]$.]

(b) Show that A is integrally closed in K. [Show that $1/2$ is not in the integral closure of A in K.]

(c) Deduce from (a) and (b) that $K = F$.

14. Show that a field K is the field of fractions of some proper subring of K if and only if K is not a subfield of the algebraic closure of a finite field. [If K contains t transcendental over $\mathbb{F}_p$ argue as in the preceding exercise with $1/t$ in place of $1/2$ to show that K is the quotient field of some proper subring.]

15. Let V be an affine algebraic set over an algebraically closed field k. Prove that for some n there is a surjective morphism from V onto $\mathbb{A}^n$ with finite fibers, and that if V is a variety, then n can be taken to be the dimension of V. [By Noether's Normalization Lemma the finitely generated k-algebra $S = k[V]$ contains a polynomial subalgebra $R = k[x_1, x_2, \ldots, x_n]$ such that S is integral over R. Apply Theorem 6 to the inclusion of R in S to obtain a morphism φ from V to $\mathbb{A}^n$. To see that φ is surjective with finite fibers, apply Corollary 27 to the maximal ideal $(x_1 - a_1, \ldots, x_n - a_n)$ of R corresponding to a point $(a_1, \ldots, a_n)$ of $\mathbb{A}^n$.]

16. Let V be an affine algebraic set in $\mathbb{C}^n$. Prove that V is compact in the Euclidean topology (i.e., closed and bounded) if and only if it is finite. [Use Exercise 18 in Section 2, the previous exercise, and the behavior of compact sets with respect to continuous functions.]

17. Let R be a subring of the commutative ring S with $1_S \in R$ and suppose that S is integral over R. This exercise proves that R and S have the same Krull dimension, cf. Section 16.1.

(a) If $P_1 \subset P_2 \subset \cdots \subset P_n$ is a chain of distinct prime ideals in R prove that there is a chain $Q_1 \subset Q_2 \subset \cdots \subset Q_n$ of distinct prime ideals in S with $Q_i \cap R = P_i$.

(b) Prove conversely that if $Q_1 \subset Q_2 \subset \cdots \subset Q_n$ is a chain of distinct prime ideals in S and $P_i = Q_i \cap R$ then $P_1 \subset P_2 \subset \cdots \subset P_n$ is a chain of distinct prime ideals in R. [To prove the P_i are distinct, pass to a quotient and reduce the problem to showing that if Q is a nonzero prime ideal in the integral domain S then $Q \cap R$ is a nonzero prime ideal in R. In this case, if $s \in Q$ is nonzero, show that the constant coefficient of a polynomial of minimal degree in $R[x]$ satisfied by s is a nonzero element in $Q \cap R$.]

18. Let $V = Z(I)$ and $W = Z(J)$ where I is the ideal $(uv + v) \subseteq \mathbb{C}[u, v]$ and J is the ideal $(-2y - y^2 + 2z + z^2,\ 2x - yz - z^2) \subseteq \mathbb{C}[x, y, z]$.

(a) Show that I and J are radical ideals that are not prime. Conclude that $I = \mathcal{I}(V)$ and $J = \mathcal{I}(W)$ and that V and W are reducible algebraic sets.

(b) Show that the map $\varphi : V \to W$ defined by $\varphi((a_1, a_2)) = (a_1^2 + a_2,\ a_1 + a_2,\ a_1 - a_2)$ is an isomorphism.

19. Let $I = (x^3 + y^3 + z^3,\ x^2 + y^2 + z^2,\ (x + y + z)^3) \subseteq k[x, y, z]$. Use Grobner bases to show that $x, y, z \in \operatorname{rad} I$ if $\operatorname{char}(k) \neq 2, 3$.

20. Let $I = (x^3 + y^3 + z^3,\ xy + xz + yz,\ xyz) \subseteq k[x, y, z]$. Use Grobner bases to show that $x, y, z \in \operatorname{rad} I$.

21. Let $I = (x^4 + y^4 + z^4,\ x + y + z) \subseteq k[x, y, z]$.

(a) Use Grobner bases to show that $xy + xz + yz \in \operatorname{rad} I$ if $\operatorname{char}(k) \neq 2$ and determine the smallest power of $xy + xz + yz$ contained in I. Show that none of x, y or z is contained in $\operatorname{rad} I$.

(b) If $J = (x^4 + y^4 + z^4,\ x + y + z,\ xy + xz + yz)$ show that the reduced Grobner basis of J relative to the lexicographic ordering $x > y > z$ is $\{x + y + z,\ y^2 + yz + z^2\}$. Deduce that $k[x, y, z]/J \cong k[y, z]/(y^2 + yz + z^2)$ and that J is radical if $\operatorname{char}(k) \neq 3$.

(c) If $\operatorname{char}(k) \neq 2, 3$, show that $\operatorname{rad} I = J$.

(d) If $\operatorname{char}(k) = 3$, show that $\operatorname{rad} I = (x - y,\ y - z)$.

(e) If $\operatorname{char}(k) = 2$, show that $I = (x + y + z)$ is a prime, hence radical, ideal.

22. Let $I = (x^2 y + z^3,\ x + y^3 - z,\ 2y^4 z - yz^2 - z^3) \subseteq k[x, y, z]$. Use Grobner bases to show that $x, y, z \in \operatorname{rad} I$ and conclude that $\operatorname{rad} I = (x, y, z)$. Show that x^9, y^7, z^9 are the smallest powers of x, y, z, respectively, lying in I.

23. Let $V = Z(x^3 - x^2z - y^2z)$ and $W = Z(x^2 + y^2 - z^2)$ in $\mathbb{C}^3$. Show that $\mathcal{I}(V) = (x^3 - x^2z - y^2z)$ and $\mathcal{I}(W) = (x^2 + y^2 - z^2)$ in $\mathbb{C}[x, y, z]$.

24. Let $V = Z(x^3 + y^3 + 7z^3) \subseteq \mathbb{C}^3$. Show that $\mathcal{I}(V) = (x^3 + y^3 + 7z^3)$ in $\mathbb{C}[x, y, z]$.

25. Let $I = (xz + y^2 + z^2,\ xy - xz + yz - 2z^2)$ and let $K = I + (x^2 - 3y^2 + yz) \subseteq \mathbb{C}[x, y, z]$.

    (a) By Exercise 46 in Section 1, there is an injective $\mathbb{C}$-algebra homomorphism from $\mathbb{C}[x, y, z]/K$ to $\mathbb{C}[u, v]/(u^3 - uv^2 + v^3)$. Use this together with the example preceding Proposition 34 to prove that K is a radical ideal and deduce that $\operatorname{rad} I \subseteq K$.

    (b) Show that $\operatorname{rad} I \subseteq (y, z)$.

    (c) Show that $K \cap (y, z) = I$ and deduce that I is radical, so that $\mathcal{I}(V) = I$ if $V = Z(I)$.

    (d) Show that $y(x^2 - 3y^2 + yz)$ and $z(x^2 - 3y^2 + yz)$ are elements of I but none of y, z, or $x^2 - 3y^2 + yz$ is contained in I.

26. Let I be an ideal in $k[x_1, \ldots, x_n]$. Prove that the following are equivalent (an ideal satisfying any of these conditions is called a *zero-dimensional ideal* because of (d)):

    (a) The quotient $k[x_1, \ldots, x_n]/I$ has finite dimension as a vector space over k.

    (b) $I \cap k[x_i] \neq 0$ for each $i = 1, 2, \ldots, n$.

    (c) If G is any reduced Grobner basis for I then for each $i = 1, \ldots, n$, there is a $g_i \in G$ with leading term $x_i^{n_i}$ for some $n_i \geq 1$.

    (d) The set of common zeros $Z_{\bar{k}}(I)$ of the polynomials in I in an algebraic closure $\bar{k}$ of k is finite.

    [For (a) implies (b) use the injection $k[x_i]/(I \cap k[x_i]) \to k[x_1, \ldots, x_n]/I$. For (b) implies (c) note some $\operatorname{LT}(g_i)$ divides the leading term of a generator for $I \cap k[x_i]$. For (c) implies (a) use Exercise 37 in Section 9.6. Show (b) implies (d). For (d) implies (b) show the product $m_{a_1,k}(x_i) \cdots m_{a_N,k}(x_i)$ of the minimal polynomials of the ith coordinates $a_1, \ldots, a_N$ of the points in $Z_{\bar{k}}(I)$ is a nonzero polynomial in $\mathcal{I}(Z_{\bar{k}}(I))$ and apply Corollary 33.]

27. Let I be a zero-dimensional ideal in $k[x_1, \ldots, x_n]$ and let I' be the ideal generated by I in $\bar{k}[x_1, \ldots, x_n]$ where $\bar{k}$ is the algebraic closure of k. Let $Z(I)$ be the zero set of I in k^n and let $Z_{\bar{k}}(I)$ be the zero set of I (equivalently, of I') in $\bar{k}^n$.

    (a) Prove that $|Z_{\bar{k}}(I)| = \dim_{\bar{k}} \bar{k}[x_1, \ldots, x_n]/\operatorname{rad} I'$. [Show that $\operatorname{rad} I'$ is the product of the maximal ideals corresponding to the points in $Z_{\bar{k}}$ and use the Chinese Remainder Theorem.]

    (b) Show $|Z(I)| \leq \dim_k k[x_1, \ldots, x_n]/I$. [One approach: use Exercise 43 in Section 1 and observe that $\dim_{\bar{k}} \bar{k}[x_1, \ldots, x_n]/\operatorname{rad} I' \leq \dim_{\bar{k}} \bar{k}[x_1, \ldots, x_n]/I'$.]

28. Suppose I is a zero-dimensional ideal in $k[x_1, \ldots, x_n]$, and suppose $I \cap k[x_i]$ is generated by the nonzero polynomial h_i (cf. Exercise 26). Let r_i be the product of the irreducible factors of h_i (the 'squarefree part' of h_i).

    (a) Prove that $I + (r_1, \ldots, r_n) \subseteq \operatorname{rad} I$.

    (b) *(Radicals of zero-dimensional ideals for perfect fields)* If k is a perfect field, prove that $\operatorname{rad} I = I + (r_1, \ldots, r_n)$. [Use induction on n. Write $r_1 = p_1 \cdots p_\ell$ with distinct irreducibles p_i in $k[x_1]$. If $J = I + (r_1, \ldots, r_n)$ show that $J = J_1 \cap \cdots \cap J_\ell$ where $J_i = I + (p_i)$. Show for each i that reduction modulo p_i induces an isomorphism $k[x_1, \ldots, x_n]/J_i \cong K[x_2, \ldots, x_n]/J_i'$ where K is the extension field $k[x]/(p_i)$ and $J_i' \subseteq K[x_2, \ldots, x_n]$ is the reduction of the ideal J_i modulo (p_i). Use Exercise 11 of Section 13.5 to show that the image of r_j in $J_i' \cap K[x_j]$ remains a nonzero squarefree polynomial for each $j = 2, \ldots, n$ since k is perfect. Conclude by induction that J_i' is a radical ideal. Deduce that J_i is a radical ideal, and finally that J is a radical ideal.]

    (c) Find the radicals of $(x^7 + x + y^3,\ x^4 + y^3 + y)$, $(x^3 - xy^2 + x,\ x^2y + y^3)$, and $(x^4 + y^3,\ x^3 - xy + y^2)$ in $\mathbb{Q}[x, y]$ and of $(x^2 + y^2z,\ x^2y^2 + z^3,\ y^2 + z^2)$ in $\mathbb{Q}[x, y, z]$.

(d) Let $k = \mathbb{F}_p(t)$. Show that $I = (x^p + t,\ y^p - t)$ is a zero-dimensional ideal in $k[x, y]$ such that both $I \cap k[x]$ and $I \cap k[y]$ contain nonzero squarefree polynomials, but that I is not a radical ideal (so the result in (b) need not hold if k is not perfect). [Show that $x + y \in \operatorname{rad} I$ but $x + y \notin I$.]

Exercises (Atiyah & Macdonald).

1. Let $f : A \to B$ be an integral homomorphism of rings. Show that $f^* : \operatorname{Spec}(B) \to \operatorname{Spec}(A)$ is a *closed* mapping, i.e. that it maps closed sets to closed sets. (This is a geometrical equivalent of (5.10).)

2. Let A be a subring of a ring B such that B is integral over A, and let $f : A \to \Omega$ be a homomorphism of A into an algebraically closed field Ω. Show that f can be extended to a homomorphism of B into Ω. [Use (5.10).]

3. Let $f : B \to B'$ be a homomorphism of A-algebras, and let C be an A-algebra. If f is integral, prove that $f \otimes 1 : B \otimes_A C \to B' \otimes_A C$ is integral. (This includes (5.6)(ii) as a special case.)

4. Let A be a subring of a ring B such that B is integral over A. Let $\mathfrak{n}$ be a maximal ideal of B and let $\mathfrak{m} = \mathfrak{n} \cap A$ be the corresponding maximal ideal of A. Is $B_\mathfrak{n}$ necessarily integral over $A_\mathfrak{m}$? [Consider the subring $k[x^2 - 1]$ of $k[x]$, where k is a field, and let $\mathfrak{n} = (x - 1)$. Can the localization $1/(x + 1)$ be integral?]

5. Let $A \subseteq B$ be rings, B integral over A.

   (i) If $x \in A$ is a unit in B then it is a unit in A.

   (ii) The Jacobson radical of A is the contraction of the Jacobson radical of B.

6. Let $B_1, \ldots, B_n$ be integral A-algebras. Show that $\prod_{i=1}^n B_i$ is an integral A-algebra.

7. Let A be a subring of a ring B, such that the set $B - A$ is closed under multiplication. Show that A is integrally closed in B.

8. (i) Let A be a subring of an integral domain B, and let C be the integral closure of A in B. Let f, g be monic polynomials in $B[x]$ such that $fg \in C[x]$. Then f, g are in $C[x]$. [Take a field containing B in which the polynomials f, g split into linear factors: say $f = \prod_i (x - \xi_i)$, $g = \prod_j (x - \eta_j)$. Each ξ_i and each η_j is a root of fg, hence is integral over C. Hence the coefficients of f and g are integral over C.]

   (ii) Prove the same result without assuming that B (or A) is an integral domain.

9. Let A be a subring of a ring B and let C be the integral closure of A in B. Prove that $C[x]$ is the integral closure of $A[x]$ in $B[x]$. [If $f \in B[x]$ is integral over $A[x]$, then

$$f^m + g_1 f^{m-1} + \cdots + g_m = 0 \qquad (g_i \in A[x]).$$

   Let r be an integer larger than the degrees of $f, g_1, \ldots, g_m$ (so that $-f_1$ below is monic), and let $f_1 = f - x^r$, so that

$$(f_1 + x^r)^m + g_1 (f_1 + x^r)^{m-1} + \cdots + g_m = 0,$$

   or say

$$f_1^m + h_1 f_1^{m-1} + \cdots + h_m = 0,$$

   where $h_m = (x^r)^m + g_1 (x^r)^{m-1} + \cdots + g_m \in A[x]$. Now apply Exercise 8 to the polynomials $-f_1$ and $f_1^{m-1} + h_1 f_1^{m-2} + \cdots + h_{m-1}$.]

10. A ring homomorphism $f : A \to B$ is said to have the *going-up property* (resp. the *going-down property*) if the conclusion of the going-up theorem (5.11) (resp. the going-down theorem (5.16)) holds for B and its subring $f(A)$. Let $f^* : \operatorname{Spec}(B) \to \operatorname{Spec}(A)$ be the mapping associated with f.

    (i) Consider the following three statements:

    (a) f^* is a closed mapping.

    (b) f has the going-up property.

    (c) Let $\mathfrak{q}$ be any prime ideal of B and let $\mathfrak{p} = \mathfrak{q}^c$. Then $f^* : \operatorname{Spec}(B/\mathfrak{q}) \to \operatorname{Spec}(A/\mathfrak{p})$ is surjective.

    Prove that (a) $\Rightarrow$ (b) $\Rightarrow$ (c). (See also Chapter 6, Exercise 11.)

(ii) Consider the following three statements:

(a') f^* is an open mapping.

(b') f has the going-down property.

(c') For any prime ideal $\mathfrak{q}$ of B, if $\mathfrak{p} = \mathfrak{q}^c$, then $f^* : \mathrm{Spec}(B_\mathfrak{q}) \to \mathrm{Spec}(A_\mathfrak{p})$ is surjective.

Prove that (a') $\Rightarrow$ (b') $\Leftrightarrow$ (c'). (See also Chapter 7, Exercise 23.) [To prove that (a') $\Rightarrow$ (c'), observe that $B_\mathfrak{q}$ is the direct limit of the rings B_t where $t \in B - \mathfrak{q}$; hence, by Chapter 3, Exercise 26, we have $f^*(\mathrm{Spec}(B_\mathfrak{q})) = \bigcap_t f^*(\mathrm{Spec}(B_t)) = \bigcap_t f^*(Y_t)$. Since Y_t is an open neighborhood of $\mathfrak{q}$ in Y, and since f^* is open, it follows that $f^*(Y_t)$ is an open neighborhood of $\mathfrak{p}$ in X, and therefore contains $\mathrm{Spec}(A_\mathfrak{p})$.]

11. Let $f : A \to B$ be a flat homomorphism of rings. Then f has the going-down property. [Chapter 3, Exercise 18.]

12. Let G be a finite group of automorphisms of a ring A, and let A^G denote the subring of G-invariants, that is of all $x \in A$ such that $\sigma(x) = x$ for all $\sigma \in G$. Prove that A is integral over A^G. [If $x \in A$, observe that x is a root of the polynomial $\prod_{\sigma \in G}(t - \sigma(x))$.] Let S be a multiplicatively closed subset of A such that $\sigma(S) \subseteq S$ for all $\sigma \in G$, and let $S^G = S \cap A^G$. Show that the action of G on A extends to an action on $S^{-1}A$, and that $(S^G)^{-1}A^G \cong (S^{-1}A)^G$.

13. In the situation of Exercise 12, let $\mathfrak{p}$ be a prime ideal of A^G, and let P be the set of prime ideals of A whose contraction is $\mathfrak{p}$. Show that G acts transitively on P. In particular, P is finite.

14. Let A be an integrally closed domain, K its field of fractions and L a finite normal separable extension of K. Let G be the Galois group of L over K and let B be the integral closure of A in L. Show that $\sigma(B) = B$ for all $\sigma \in G$, and that $A = B^G$.

15. Let A, B, L be as in Exercise 14, but let L be any finite extension field of K, and let B be the integral closure of A in L. Show that, if $\mathfrak{p}$ is any prime ideal of A, then the set of prime ideals $\mathfrak{q}$ of B which contract to $\mathfrak{p}$ is finite (in other words, $\mathrm{Spec}(B) \to \mathrm{Spec}(A)$ has finite fibers). [Reduce to the two cases (a) L separable over K and (b) L purely inseparable over K. In case (a), embed L in a finite normal separable extension of K, and use Exercises 13 and 14. In case (b), if $\mathfrak{q}$ is a prime ideal of B such that $\mathfrak{q} \cap A = \mathfrak{p}$, show that $\mathfrak{q}$ is the set of all $x \in B$ such that $x^{p^m} \in \mathfrak{p}$ for some $m \geq 0$, where p is the characteristic of K, and hence that $\mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is bijective in this case.]

16. Let k be a field and let $A \neq 0$ be a finitely generated k-algebra. Then there exist elements $y_1, \ldots, y_r \in A$ which are algebraically independent over k and such that A is integral over $k[y_1, \ldots, y_r]$.

    We shall sketch a proof in which k is infinite. (The result is still true if k is finite, but a different proof is needed.) Let $x_1, \ldots, x_n$ generate A as a k-algebra. We can renumber the x_i so that $x_1, \ldots, x_r$ are algebraically independent over k and each of $x_{r+1}, \ldots, x_n$ is algebraic over $k[x_1, \ldots, x_r]$. Now proceed by induction on n. If $n = r$ there is nothing to do, so suppose $n > r$ and the result true for $n - 1$ generators. The generator x_n is algebraic over $k[x_1, \ldots, x_{n-1}]$, hence there exists a polynomial $f \neq 0$ in n variables such that $f(x_1, \ldots, x_{n-1}, x_n) = 0$. Let F be the homogeneous part of highest degree in f. Since k is infinite, there exist $\lambda_1, \ldots, \lambda_{n-1} \in k$ such that $F(\lambda_1, \ldots, \lambda_{n-1}, 1) \neq 0$. Put $x_i' = x_i - \lambda_i x_n$ $(1 \leq i \leq n-1)$. Show that x_n is integral over the ring $A' = k[x_1', \ldots, x_{n-1}']$, and hence that A is integral over A'. Then apply the inductive hypothesis to A' to complete the proof.

    From the proof it follows that $y_1, \ldots, y_r$ may be chosen to be linear combinations of $x_1, \ldots, x_n$. This has the following geometrical interpretation: if k is algebraically closed and X is an affine algebraic variety in k^n with coordinate ring $A \neq 0$, then there exists a linear subspace L of dimension r in k^n and a linear mapping of k^n onto L which maps X onto L. [Use Exercise 2.]

17. Deduce from Exercise 16 a proof of Hilbert's Nullstellensatz (over an algebraically closed field k) in the following form: if X is an affine algebraic variety in k^n, and $I(X)$ is the ideal of X in the polynomial ring $k[t_1, \ldots, t_n]$ (Chapter 1, Exercise 27), then $I(X) \neq (1)$ implies X is not empty. [Let $A = k[t_1, \ldots, t_n]/I(X)$ be the coordinate ring of X. Then $A \neq 0$, hence by Exercise 16 there exists a linear subspace L of dimension ≥ 0 in k^n and a mapping of X onto L. Hence $X \neq \varnothing$.]

18. Let k be a field and B a finitely generated k-algebra. Suppose that B is a field. Then B is a finite algebraic extension of k. (This is another version of Hilbert's Nullstellensatz. The following proof is due to Zariski. For other proofs, see (5.24), (7.9).)

    Let $x_1, \ldots, x_n$ generate B as a k-algebra. The proof is by induction on n. If $n = 1$ the result is clearly true, so assume $n > 1$. Let $A = k[x_1]$ and let $K = k(x_1)$ be the field of fractions of A. By the inductive hypothesis, B is a finite algebraic extension of K, hence each of $x_2, \ldots, x_n$ satisfies a monic polynomial equation with coefficients in K, that is coefficients of the form a/b where a and b are in A. If f is the product of the denominators of all these coefficients, then each of $x_2, \ldots, x_n$ is integral over A_f. Hence B and therefore K is integral over A_f.

    Suppose x_1 is transcendental over k. Then A is integrally closed, because it is a unique factorization domain. Hence A_f is integrally closed (5.12), and therefore $A_f = K$, which is clearly absurd. Hence x_1 is algebraic over k, hence K (and therefore B) is a finite extension of k.

19. Deduce the result of Exercise 17 from Exercise 18.

20. Let A be a subring of an integral domain B such that B is finitely generated over A. Show that there exists $s \neq 0$ in A and elements $y_1, \ldots, y_n$ in B, algebraically independent over A and such that B_s is integral over B'_s, where $B' = A[y_1, \ldots, y_n]$. [Let $S = A - \{0\}$ and let $K = S^{-1}A$, the field of fractions of A. Then $S^{-1}B$ is a finitely generated K-algebra and therefore by the normalization lemma (Exercise 16) there exist $x_1, \ldots, x_n \in S^{-1}B$, algebraically independent over K and such that $S^{-1}B$ is integral over $K[x_1, \ldots, x_n]$. Let $z_1, \ldots, z_m$ generate B as an A-algebra. Then each z_j (regarded as an element of $S^{-1}B$) is integral over $K[x_1, \ldots, x_n]$. By writing an equation of integral dependence for each z_j, show that there exists $s \in S$ such that $x_i = y_i/s$ $(1 \leq i \leq n)$ with $y_i \in B$, and such that each sz_j is integral over B'. Deduce that this s satisfies the conditions stated.]

21. Let A, B be as in Exercise 20. Show that there exists $s \neq 0$ in A such that, if Ω is an algebraically closed field and $f : A \to \Omega$ is a homomorphism for which $f(s) \neq 0$, then f can be extended to a homomorphism $B \to \Omega$. [With the notation of Exercise 20, f can be extended first of all to B', for example by mapping each y_i to 0; then to B'_s (because $f(s) \neq 0$), and finally to B_s (by Exercise 2, because B_s is integral over B'_s).]

22. Let A, B be as in Exercise 20. Show that if the Jacobson radical of A is zero, then so is the Jacobson radical of B. [Let $v \neq 0$ be an element of B. We have to show that there is a maximal ideal of B which does not contain v. By applying Exercise 21 to the ring B_v and its subring A, we obtain an element $s \neq 0$ in A. Let $\mathfrak{m}$ be a maximal ideal of A such that $s \notin \mathfrak{m}$, and let $k = A/\mathfrak{m}$. Then the canonical mapping $A \to k$ extends to a homomorphism g of B_v into an algebraic closure Ω of k. Show that $g(v) \neq 0$ and that $\mathrm{Ker}(g) \cap B$ is a maximal ideal of B.]

23. Let A be a ring. Show that the following are equivalent:

    (i) Every prime ideal in A is an intersection of maximal ideals.

    (ii) In every homomorphic image of A the nilradical is equal to the Jacobson radical.

    (iii) Every prime ideal in A which is not maximal is equal to the intersection of the prime ideals which contain it strictly.

    [The only hard part is (iii) $\Rightarrow$ (ii). Suppose (ii) false; then there is a prime ideal which is not an intersection of maximal ideals. Passing to the quotient ring, we may assume that A is an integral domain whose Jacobson radical $\mathfrak{R}$ is not zero. Let f be a non-zero element of $\mathfrak{R}$. Then $A_f \neq 0$, hence A_f has a maximal ideal, whose contraction in A is a prime ideal $\mathfrak{p}$ such that $f \notin \mathfrak{p}$, and is maximal with respect to this property. Then $\mathfrak{p}$ is not maximal and is not equal to the intersection of the prime ideals strictly containing $\mathfrak{p}$ (all of which contain f).] A ring A with the equivalent properties above is called a *Jacobson ring*.

24. Let A be a Jacobson ring (Exercise 23) and B an A-algebra. Show that if B is either (i) integral over A or (ii) finitely generated as an A-algebra, then B is Jacobson. [Use Exercise 22 for (ii).] In particular, every finitely generated ring, and every finitely generated algebra over a field, is a Jacobson ring.

25. Let A be a ring. Show that the following are equivalent:

(i) A is a Jacobson ring;

(ii) Every finitely generated A-algebra B which is a field is finite over A.

[(i) $\Rightarrow$ (ii). Reduce to the case where A is a subring of B, and use Exercise 21. If $s \in A$ is as in Exercise 21, then there exists a maximal ideal $\mathfrak{m}$ of A not containing s, and the homomorphism $A \to A/\mathfrak{m} = k$ extends to a homomorphism g of B into the algebraic closure of k. Since B is a field, g is injective, and $g(B)$ is algebraic over k, hence finite algebraic. (ii) $\Rightarrow$ (i). Use criterion (iii) of Exercise 23. Let $\mathfrak{p}$ be a prime ideal of A which is not maximal, and let $B = A/\mathfrak{p}$. Let f be a non-zero element of B. Then B_f is a finitely generated A-algebra. If B_f is a field it is finite over B, hence integral over B and therefore B is a field by (5.7), which is false. Hence B_f is not a field and therefore B_f has a non-zero prime ideal, whose contraction in B is a non-zero prime ideal $\mathfrak{p}'$ such that $f \notin \mathfrak{p}'$.]

26. Let X be a topological space. A subset X_0 of X is *locally closed* if it is the intersection of an open set and a closed set, or equivalently if it is open in its closure. The following conditions on a subset X_0 of X are equivalent:

(1) Every non-empty locally closed subset of X meets X_0;

(2) For every closed set E in X we have $\overline{E \cap X_0} = E$;

(3) The mapping $U \mapsto U \cap X_0$ of the collection of open sets of X onto the collection of open sets of X_0 is *bijective*.

A subset X_0 satisfying these conditions is said to be *very dense* in X.

If A is a ring, show that the following conditions are equivalent:

(i) A is a Jacobson ring;

(ii) The set of maximal ideals of A is very dense in $\mathrm{Spec}(A)$;

(iii) Every locally closed subset of $\mathrm{Spec}(A)$ consisting of a single point is closed.

[(ii) and (iii) are geometrical formulations of conditions (ii) and (iii) of Exercise 23.]

27. Let A, B be two local rings. B is said to *dominate* A if A is a subring of B and the maximal ideal $\mathfrak{m}$ of A is contained in the maximal ideal $\mathfrak{n}$ of B (or, equivalently, if $\mathfrak{m} = \mathfrak{n} \cap A$). Let K be a field and let Σ be the set of all local subrings of K. If Σ is ordered by the relation of domination, show that Σ has maximal elements and that $A \in \Sigma$ is maximal if and only if A is a valuation ring of K. [Use (5.21).]

28. Let A be an integral domain, K its field of fractions. Show that the following are equivalent:

(1) A is a valuation ring of K;

(2) If $\mathfrak{a}, \mathfrak{b}$ are any two ideals of A, then either $\mathfrak{a} \subseteq \mathfrak{b}$ or $\mathfrak{b} \subseteq \mathfrak{a}$.

Deduce that if A is a valuation ring and $\mathfrak{p}$ is a prime ideal of A, then $A_\mathfrak{p}$ and $A/\mathfrak{p}$ are valuation rings of their fields of fractions.

29. Let A be a valuation ring of a field K. Show that every subring of K which contains A is a local ring of A, i.e. of the form $A_\mathfrak{p}$ for a prime ideal $\mathfrak{p}$ of A.

30. Let A be a valuation ring of a field K. The group U of units of A is a subgroup of the multiplicative group K^* of K. The group $\Gamma = K^*/U$ is totally ordered as follows: if $\xi, \eta \in \Gamma$ are represented by $x, y \in K^*$, then $\xi \geq \eta$ is to mean $xy^{-1} \in A$. Show that this defines a total ordering on Γ which is compatible with the group structure (i.e., $\xi \geq \eta \Rightarrow \xi\omega \geq \eta\omega$ for all $\omega \in \Gamma$). In other words, Γ is a totally ordered abelian group. It is called the *value group* of A. Let $v : K^* \to \Gamma$ be the canonical homomorphism. Show that $v(x + y) \geq \min(v(x), v(y))$ for all $x, y \in K^*$.

31. Conversely, let Γ be a totally ordered abelian group (written *additively*), and let K be a field. A *valuation* of K with values in Γ is a mapping $v : K^* \to \Gamma$ such that

(1) $v(xy) = v(x) + v(y)$,

(2) $v(x+y) \geq \min(v(x), v(y))$,

for all $x, y \in K^*$. Show that the set consisting of 0 and the elements $x \in K^*$ such that $v(x) \geq 0$ is a valuation ring of K. This ring is called the *valuation ring of* v, and the subgroup $v(K^*)$ of Γ is the *value group* of v.

Thus the concepts of valuation ring and valuation are essentially equivalent.

32. Let Γ be a totally ordered abelian group. A subgroup Δ of Γ is *isolated* in Γ if, whenever $0 \leq \beta \leq \alpha$ and $\alpha \in \Delta$, we have $\beta \in \Delta$. Let A be a valuation ring of a field K, with value group Γ (Exercise 31). If $\mathfrak{p}$ is a prime ideal of A, show that $v(A - \mathfrak{p})$ is the set of elements ≥ 0 in an isolated subgroup Δ of Γ, and that the mapping so defined of $\mathrm{Spec}(A)$ into the set of isolated subgroups of Γ is bijective.

    If $\mathfrak{p}$ is a prime ideal of A and Δ is the corresponding isolated subgroup, show that the value groups of the valuation rings $A/\mathfrak{p}$ and $A_{\mathfrak{p}}$ are Δ and Γ/Δ respectively (up to isomorphism of ordered groups).

33. Let Γ be a totally ordered abelian group. We shall show how to construct a field K and a valuation v of K with Γ as value group. Let k be any field and let $A = k[\Gamma]$ be the group algebra of Γ over k. By definition, A is freely generated as a k-vector space by elements x_α ($\alpha \in \Gamma$) such that $x_\alpha x_\beta = x_{\alpha+\beta}$. Show that A is an integral domain. If $u = \lambda_1 x_{\alpha_1} + \cdots + \lambda_n x_{\alpha_n}$ is any non-zero element of A, where the λ_i are all $\neq 0$ and $\alpha_1 < \cdots < \alpha_n$, define $v_0(u)$ to be α_1. Show that the mapping $v_0 : A - \{0\} \to \Gamma$ satisfies conditions (1) and (2) of Exercise 31. Let K be the field of fractions of A. Show that v_0 can be uniquely extended to a valuation v of K, and that the value group of v is Γ.

34. Let A be a valuation ring and K its field of fractions. Let $f : A \to B$ be a ring homomorphism such that $f^* : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ is a *closed* mapping. Then if $g : B \to K$ is any A-algebra homomorphism (i.e., if $g \circ f$ is the embedding of A in K) we have $g(B) = A$. [Let $C = g(B)$; obviously $C \supseteq A$. Let $\mathfrak{n}$ be a maximal ideal of C. Since f^* is closed, $\mathfrak{m} = \mathfrak{n} \cap A$ is a maximal ideal of A, whence $A_{\mathfrak{m}} = A$. Also the local ring $C_{\mathfrak{n}}$ dominates $A_{\mathfrak{m}}$. Hence by Exercise 27 we have $C_{\mathfrak{n}} = A$ and therefore $C \subseteq A$.]

35. From Exercises 1 and 3 it follows that, if $f : A \to B$ is integral and C is any A-algebra, then the mapping $(f \otimes 1)^* : \mathrm{Spec}(B \otimes_A C) \to \mathrm{Spec}(C)$ is a closed map.

    Conversely, suppose that $f : A \to B$ has this property and that B is an integral domain. Then f is integral. [Replacing A by its image in B, reduce to the case where $A \subseteq B$ and f is the injection. Let K be the field of fractions of B and let A' be a valuation ring of K containing A. By (5.22) it is enough to show that A' contains B. By hypothesis $\mathrm{Spec}(B \otimes_A A') \to \mathrm{Spec}(A')$ is a closed map. Apply the result of Exercise 34 to the homomorphism $B \otimes_A A' \to K$ defined by $b \otimes a' \mapsto ba'$. It follows that $ba' \in A'$ for all $b \in B$ and all $a' \in A'$; taking $a' = 1$, we have what we want.]

    Show that the result just proved remains valid if B is a ring with only finitely many minimal prime ideals (e.g., if B is Noetherian). [Let $\mathfrak{p}_i$ be the minimal prime ideals. Then each composite homomorphism $A \to B \to B/\mathfrak{p}_i$ is integral, hence $A \to \prod_i (B/\mathfrak{p}_i)$ is integral, hence $A \to B/\mathfrak{N}$ is integral (where $\mathfrak{N}$ is the nilradical of B), hence finally $A \to B$ is integral.]

Practice problems.

1. Decide which of $\sqrt[3]{5}$, $\frac{3+\sqrt{13}}{2}$, $\frac{1+\sqrt{13}}{2}$, $\frac{7}{3}$ are integral over $\mathbb{Z}$. For each integral element exhibit an explicit monic equation over $\mathbb{Z}$, and for each non-integral element give the obstruction (use that $\mathbb{Z}$ is integrally closed).

2. Let $R = k[x,y]/(y^2 - x^5)$ with $\bar{x}, \bar{y}$ the images of x, y. Set $t = \bar{y}/\bar{x}^2 \in \mathrm{Frac}(R)$. Show that t is integral over R, that $t \notin R$, and that the normalization of R is $k[t]$. Identify the parametrization $\bar{x} \mapsto s^2$, $\bar{y} \mapsto s^5$ and locate the singular point geometrically.

3. Compute the normalization of $\mathbb{Z}$ in $\mathbb{Q}(\sqrt{-3})$, and verify directly that $\frac{1+\sqrt{-3}}{2}$ satisfies a monic quadratic over $\mathbb{Z}$ while $\sqrt{-3}$ alone generates a strictly smaller, non-normal order. Conclude $\mathbb{Z}[\sqrt{-3}] \subsetneq \mathcal{O}_{\mathbb{Q}(\sqrt{-3})}$.

4. In $\mathbb{Z}[i]$, determine the splitting type (split, inert, or ramified) of the rational primes $(3), (13), (2)$ by factoring $x^2 + 1$ modulo each, and list the prime(s) of $\mathbb{Z}[i]$ lying over each. Verify that every fiber is finite and nonempty, as Lying Over and the finite-fiber corollary require.

5. Let $A = k[x,y]/(xy - x)$ with k a field. Show that A is *not* a domain by exhibiting zero divisors, and find a Noether normalization: produce an algebraically independent set $\{y_1, \dots, y_q\}$ over which A is integral, and identify q.

6. Let $A = k[x,y,z]/(z^2 - xy)$ over an infinite field k. Show that $\bar{z}$ is integral over $k[\bar{x}, \bar{y}]$, that $\bar{x}, \bar{y}$ are algebraically independent over k, and hence that A is integral over the polynomial ring $k[\bar{x}, \bar{y}]$ with $q = 2$. Exhibit A as a finitely generated $k[\bar{x}, \bar{y}]$-module and give a generating set.

7. Show that $B = \{\, a/b \in \mathbb{Q} : b \text{ odd} \,\} = \mathbb{Z}_{(2)}$ is a valuation ring of $\mathbb{Q}$ by verifying the dichotomy $x \in B$ or $x^{-1} \in B$ via the 2-adic valuation v_2. Identify its maximal ideal, its units, and its residue field.

8. For the ideal $I = (x^3, xy) \subseteq \mathbb{C}[x,y]$ compute $Z(I)$, then $I(Z(I))$, and independently $\operatorname{rad} I$, and confirm the Strong Nullstellensatz prediction $I(Z(I)) = \operatorname{rad} I$. Identify which generator records non-reducedness invisible to Z.

Additional exercises.

1. Let $A \subseteq B$ with B integral over A, and let $x \in A$. Prove that if x is a unit in B then x is a unit in A. Deduce that the Jacobson radical of A is the contraction $\operatorname{Jac}(B) \cap A$ of the Jacobson radical of B. [Use that $x^{-1} \in B$ is integral over A.]

2. Let A be an integrally closed domain with fraction field K, let $K \subseteq L$ be a field extension, and let $\alpha \in L$ be algebraic over K with minimal polynomial $m_{\alpha,K}(x)$. Prove that α is integral over A if and only if $m_{\alpha,K}(x) \in A[x]$. [If α is integral, show every conjugate of α is integral, so the elementary symmetric functions – the coefficients of $m_{\alpha,K}$ – are integral elements of K, hence in A.]

3. Let B be a valuation ring of a field K with maximal ideal $\mathfrak{m}$. Prove that for any two ideals $\mathfrak{a}, \mathfrak{b}$ of B either $\mathfrak{a} \subseteq \mathfrak{b}$ or $\mathfrak{b} \subseteq \mathfrak{a}$ (the ideals are totally ordered by inclusion). Deduce that B is integrally closed in K and that every finitely generated ideal of B is principal.

4. Let A be a subring of a field K and let $\overline{A}$ be its integral closure in K. Prove that $x \in K$ fails to be integral over A if and only if there is a valuation ring B of K with $A \subseteq B$ and $x \notin B$. Conclude $\overline{A} = \bigcap_B B$, the intersection over all valuation rings B of K containing A. [For one direction, if x is not integral, x^{-1} is a non-unit of $A[x^{-1}]$; extend a residue homomorphism to a maximal pair.]

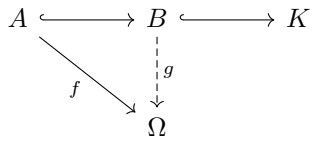
5. Let k be a field and let B be a finitely generated k-algebra that happens to be a field. Prove (Zariski's Lemma) that B is a finite, hence algebraic, extension of k. Then deduce the Weak Nullstellensatz: if $k = \overline{k}$, every maximal ideal of $k[x_1, \dots, x_n]$ has the form $(x_1 - a_1, \dots, x_n - a_n)$. [Use Noether Normalization and the "fields together" theorem to force the polynomial subring to have $q = 0$.]

Commutative-diagram exercises.

1. Let $A = \mathbb{Z}$ and $B = \mathbb{Z}[i]$, with the inclusion inducing the contraction map $\operatorname{Spec} B \to \operatorname{Spec} A$. Complete the diagram below recording the fibers over $(2), (5), (7)$, label each vertical edge with its splitting type (ramified, split, inert), and prove that each contracts to the correct rational prime:

$$\begin{array}{ccccc} (1+i) & & (2+i)\ \ (2-i) & & (7) \\ \Big| & & \Big| & & \Big| \\ (2) & & (5) & & (7) \end{array}$$

   Prove that $\mathfrak{q} \mapsto \mathfrak{q} \cap \mathbb{Z}$ is surjective onto $\operatorname{Spec} \mathbb{Z}$ (Lying Over) and that each fiber shown is finite and nonempty. State which primes are maximal.



2. Let A be a normal domain with fraction field K, let $A \subseteq B$ with B a domain integral over A, and let $\mathfrak{p}_1 \supseteq \mathfrak{p}_2$ be primes of A with a chosen $\mathfrak{q}_1$ over $\mathfrak{p}_1$. Complete the Going-Down square below (vertical arrows are the inclusions $A \hookrightarrow B$, horizontal arrows the localizations at $A \setminus \mathfrak{p}_2$) and prove there is a prime $\mathfrak{q}_2 \subseteq \mathfrak{q}_1$

of B with $\mathfrak{q}_2 \cap A = \mathfrak{p}_2$:

$$\begin{array}{ccc} A & \xrightarrow{\ell_A} & A_{\mathfrak{p}_2} \\ \downarrow & & \downarrow \\ B & \xrightarrow[\ell_B]{} & (A \setminus \mathfrak{p}_2)^{-1}B \end{array}$$

Identify where normality of A enters the argument, and explain via the valuation-ring criterion (integral closure = intersection of valuation rings) why dropping normality can break the descent.

3. Let A be a subring of a field K and Ω an algebraically closed field. Complete the extension diagram below, where (B, g) is a maximal element (under extension of homomorphisms $A' \to \Omega$, $A \subseteq A' \subseteq K$) and the dashed arrow is the extension to be constructed:

Prove that B is a valuation ring of K with maximal ideal $\ker g$, and that $\overline{A} = \bigcap_B B$ over all such valuation rings. Conclude that A is integrally closed in K if and only if A is an intersection of valuation rings of K.

4. Let $k = \overline{k}$ and let $V = Z(I) \subseteq \mathbb{A}^n$ be an affine algebraic set with coordinate ring $A = k[x_1, \dots, x_n]/\operatorname{rad} I$ (recall $I(V) = I(Z(I)) = \operatorname{rad} I$). Complete the dictionary diagram below and prove that the labelled correspondence is an inclusion-reversing bijection on the indicated classes:

$$\begin{array}{ccc} \{\text{ points of } V\} & \xrightarrow{Z,\, I} & \{\text{ maximal ideals of } A\} \\ \Big| & & \Big| \\ \{\text{ irreducible subsets of } V\} & \longrightarrow & \{\text{ prime ideals of } A\} \\ \Big| & & \Big| \\ \{\text{ closed subsets of } V\} & \xrightarrow[Z,\, I]{} & \{\text{ radical ideals of } A\} \end{array}$$

Prove the bottom correspondence using the Strong Nullstellensatz $I(Z(J)) = \operatorname{rad} J$, and prove that points correspond to maximal ideals using the Weak Form. Show the vertical inclusions on the left are reversed by Z, I into the vertical inclusions on the right.

15.8 The Prime Spectrum and the Zariski Topology

From points to primes: the spectrum as a set

Throughout, "ring" means commutative ring with 1 and every homomorphism $\varphi\colon R \to S$ sends 1_R to 1_S. The previous sections built a dictionary between an affine algebraic set V over an algebraically closed field k and its coordinate ring $k[V] = k[x_1, \dots, x_n]/I(V)$: by the Nullstellensatz the points of V are the maximal ideals $\mathfrak{m} = I(v)$ of $k[V]$, and a morphism $V \to W$ is a k-algebra map $k[W] \to k[V]$. We now reverse the arrow. Starting from *any* commutative ring R we manufacture a space whose "functions" are the elements of R.

The first guess – take the maximal ideals as "points" – fails functorially: the preimage of a maximal ideal under a ring map need not be maximal (e.g. under $\mathbb{Z} \hookrightarrow \mathbb{Q}$ the maximal ideal (0) of $\mathbb{Q}$ pulls back to (0), which is not maximal in $\mathbb{Z}$). But the preimage of a *prime* ideal is always prime. This forces the right definition.

Definition 15.8.1 (prime and maximal spectrum)**.** Let R be a commutative ring with 1. The *prime spectrum* (or *spectrum*) of R is the set

$$\operatorname{Spec} R = \{\, \mathfrak{p} \subseteq R : \mathfrak{p} \text{ is a prime ideal} \,\}.$$

The *maximal spectrum* $\operatorname{mSpec} R = \{\, \mathfrak{m} : \mathfrak{m} \text{ maximal} \,\}$ is the subset of maximal ideals. A prime $\mathfrak{p}$ is to be thought of as a "point" of the geometric object attached to R.

This is the central object of Atiyah–Macdonald's geometric program: a prime ideal is the common generalization of a *prime of arithmetic* (the points (p) of $\operatorname{Spec}\mathbb{Z}$) and a *point of geometry* (the maximal ideals $(x_1 - a_1, \dots, x_n - a_n)$ of $k[x_1, \dots, x_n]$). The single set $\operatorname{Spec} R$ houses both kinds of object and, crucially, also the "subvariety" points (non-maximal primes) that the classical picture suppressed.

Definition 15.8.2 (value of a function at a point)**.** For $f \in R$ and $\mathfrak{p} \in \operatorname{Spec} R$, the *value* of f at $\mathfrak{p}$ is the residue

$$f(\mathfrak{p}) = \overline{f} \in R/\mathfrak{p}, \qquad \text{an element of the integral domain } R/\mathfrak{p}.$$

Thus f is a function on $\operatorname{Spec} R$ whose values at different points lie in different domains. Two elements f, g have equal values at every $\mathfrak{p}$ iff $f - g$ lies in every prime, i.e. iff $f - g \in \operatorname{nil}(R)$ (the nilradical). So an element of R is determined by its values *only up to the nilradical*.

Worked Example 15.8.3 (Spec of a field and of $\mathbb{Z}$)**.** Describe $\operatorname{Spec} R$ and $\operatorname{mSpec} R$ for R a field and for $R = \mathbb{Z}$.

Recognition. A field has a unique prime (0); $\mathbb{Z}$ is a PID, so its nonzero primes are the (p).

Solution. If R is a field then (0) is its only proper ideal that is prime (it is even maximal), so $\operatorname{Spec} R = \operatorname{mSpec} R = \{\,(0)\,\}$, a one-point space. For $R = \mathbb{Z}$: the primes are (0) together with (p) for each rational prime $p > 0$. The maximal ideals are exactly the (p), so $\operatorname{mSpec}\mathbb{Z} = \operatorname{Spec}\mathbb{Z} \setminus \{\,(0)\,\}$. Sanity check: (0) is prime because $\mathbb{Z}$ is a domain but not maximal because $\mathbb{Z}$ is not a field; each (p) is maximal since $\mathbb{Z}/p\mathbb{Z} = \mathbb{F}_p$ is a field. The lone non-maximal prime (0) is the "generic point" we meet below.

Worked Example 15.8.4 ($\operatorname{Spec}\mathbb{Z}[x]$: the four families of primes)**.** List the prime ideals of $\mathbb{Z}[x]$ and identify the maximal ones.

Recognition. $\mathbb{Z}[x]$ has Krull dimension 2; primes come in chains of length ≤ 2 governed by "which integer prime, which polynomial mod it."

Solution. The primes of $\mathbb{Z}[x]$ are: (a) (0); (b) (p) for a rational prime p; (c) (f) where f has content 1 and is irreducible in $\mathbb{Q}[x]$; (d) (p, g) where p is prime and g is monic and irreducible modulo p. Only the type-(d) ideals are maximal: $\mathbb{Z}[x]/(p, g) \cong \mathbb{F}_p[x]/(\overline{g})$ is a finite field. Sanity check on dimension: a maximal chain is $(0) \subsetneq (p) \subsetneq (p, g)$ of length 2, matching $\dim \mathbb{Z}[x] = \dim \mathbb{Z} + 1 = 2$; and $(0) \subsetneq (f) \subsetneq (p, g)$ when $g \mid f \bmod p$ gives another length-2 chain.

The Zariski topology: closed sets and basic opens

We now topologize $\operatorname{Spec} R$ by mimicking the vanishing-set construction $Z(\cdot)$ and ideal-of-set construction $I(\cdot)$ of Sections 15.3 and 15.7. Write $X = \operatorname{Spec} R$.

Definition 15.8.5 ($V(\mathfrak{a})$ and the Zariski topology)**.** For a subset $E \subseteq R$ let

$$V(E) = \{\, \mathfrak{p} \in \operatorname{Spec} R : E \subseteq \mathfrak{p} \,\} \subseteq \operatorname{Spec} R.$$

Since $E \subseteq \mathfrak{p} \iff (E) \subseteq \mathfrak{p}$, we may and do assume $E = \mathfrak{a}$ is an ideal; $V(\mathfrak{a})$ is the set of points at which every $f \in \mathfrak{a}$ vanishes. For $Y \subseteq \operatorname{Spec} R$ set $I(Y) = \bigcap_{\mathfrak{p} \in Y} \mathfrak{p}$. The sets $V(\mathfrak{a})$ are the *closed sets* of the *Zariski topology* on $\operatorname{Spec} R$.

Proposition 15.8.6 (axioms for the closed sets; the V–I correspondence)**.** *Let R be a ring.*

(1) $V(0) = \operatorname{Spec} R$, $V(R) = \varnothing$; $V(\mathfrak{a}) = V(\operatorname{rad}\mathfrak{a})$ *and* $I(V(\mathfrak{a})) = \operatorname{rad}\mathfrak{a}$.

(2) $V(\mathfrak{a} \cap \mathfrak{b}) = V(\mathfrak{a}\mathfrak{b}) = V(\mathfrak{a}) \cup V(\mathfrak{b})$.

(3) *For any family* $\{\,\mathfrak{a}_i\,\}$, $V\big(\sum_i \mathfrak{a}_i\big) = \bigcap_i V(\mathfrak{a}_i)$.

Hence $\{\,V(\mathfrak{a})\,\}$ *is closed under finite unions and arbitrary intersections, defining a topology. The maps V, I are mutually inverse, inclusion-reversing bijections*

$$\{\,\textit{Zariski-closed subsets of } \operatorname{Spec} R\,\} \underset{V}{\overset{I}{\rightleftarrows}} \{\,\textit{radical ideals of } R\,\}.$$

Closed points correspond to maximal ideals; irreducible closed sets correspond to prime ideals.

Idea. $V(\mathfrak{a}) = V(\operatorname{rad}\mathfrak{a})$ because a prime containing $\mathfrak{a}$ contains $\operatorname{rad}\mathfrak{a}$; and $\operatorname{rad}\mathfrak{a} = \bigcap_{\mathfrak{a}\subseteq\mathfrak{p}}\mathfrak{p}$ (the radical is the intersection of the primes above it) gives $I(V(\mathfrak{a})) = \operatorname{rad}\mathfrak{a}$. For (2): $\mathfrak{p} \supseteq \mathfrak{a}\mathfrak{b}$ and $\mathfrak{p}$ prime force $\mathfrak{p} \supseteq \mathfrak{a}$ or $\mathfrak{p} \supseteq \mathfrak{b}$. Inclusion-reversal is immediate from $\mathfrak{a} \subseteq \mathfrak{b} \Rightarrow V(\mathfrak{b}) \subseteq V(\mathfrak{a})$. □

Definition 15.8.7 (basic open sets)**.** For $f \in R$ let

$$D(f) = \operatorname{Spec} R \setminus V(f) = \{\, \mathfrak{p} : f \notin \mathfrak{p} \,\} = \{\, \mathfrak{p} : f(\mathfrak{p}) \neq 0 \,\},$$

the set of points where f is nonzero. These *basic* (or *principal*) open sets form a basis for the Zariski topology: every open set is a union of $D(f)$'s, since the complement of $V(\mathfrak{a})$ is $\bigcup_{f\in\mathfrak{a}} D(f)$.

Proposition 15.8.8 (calculus of basic opens)**.** *Let $f, g, g_1, \dots, g_n \in R$, $X = \operatorname{Spec} R$.*

(1) *$D(f) = X \iff f$ is a unit; $D(f) = \varnothing \iff f$ is nilpotent.*

(2) *$D(f) \cap D(g) = D(fg)$.*

(3) *$D(f) \subseteq D(g_1) \cup \cdots \cup D(g_n) \iff f \in \operatorname{rad}(g_1, \dots, g_n)$; in particular $D(f) = D(g) \iff \operatorname{rad}(f) = \operatorname{rad}(g)$.*

(4) *The natural map $R \to R_f$ induces a homeomorphism $\operatorname{Spec} R_f \xrightarrow{\sim} D(f)$.*

(5) *$\operatorname{Spec} R$ is quasi-compact; hence each $D(f)$ is quasi-compact.*

Idea. (1) f a unit $\iff$ no prime contains it; f nilpotent $\iff$ every prime contains it ($\operatorname{nil} R = \bigcap \mathfrak{p}$). (3) $D(f) \subseteq \bigcup D(g_i)$ says every prime containing $(g_1, \dots, g_n)$ contains f, i.e. $f \in \bigcap_{(g_i)\subseteq\mathfrak{p}} \mathfrak{p} = \operatorname{rad}(g_1, \dots, g_n)$. (4) Localization $R \to R_f$ gives a bijection of primes of R_f with primes of R missing $\{\, 1, f, f^2, \dots \,\}$, i.e. with $D(f)$, and it is bicontinuous. (5) Quasi-compactness: if $X = \bigcup_i D(g_i)$ then $(g_i) = R$ (no prime contains all g_i), so $1 = \sum_{j=1}^{m} a_j g_{i_j}$ is a finite relation, and the corresponding $D(g_{i_1}), \dots, D(g_{i_m})$ already cover X. □

Method (Reading Spec from the ideal theory of R)**.** To analyze $\operatorname{Spec} R$ as a space: (i) closed points = maximal ideals; (ii) the closure of $\{\, \mathfrak{p} \,\}$ is $V(\mathfrak{p}) = \{\, \mathfrak{q} : \mathfrak{q} \supseteq \mathfrak{p} \,\}$, so smaller primes are "more generic"; (iii) X irreducible $\iff$ $\operatorname{nil} R$ prime; irreducible components $\leftrightarrow$ minimal primes of R; (iv) test separation/connectedness via idempotents and basic opens; (v) compute fibers of $\varphi^*\colon \operatorname{Spec} S \to \operatorname{Spec} R$ over $\mathfrak{p}$ by factoring in $S \otimes_R \kappa(\mathfrak{p})$, where $\kappa(\mathfrak{p}) = \operatorname{Frac}(R/\mathfrak{p})$.

Worked Example 15.8.9 (Closure of a point; closed points are maximal)**.** Compute the closure $\overline{\{\, \mathfrak{p} \,\}}$ of a point, and show $\mathfrak{p}$ is closed iff $\mathfrak{p}$ is maximal.

Recognition. The smallest closed set containing $\mathfrak{p}$ is $V(\mathfrak{p})$; a point is closed iff it equals its closure.

Solution. The closed sets containing $\mathfrak{p}$ are the $V(\mathfrak{a})$ with $\mathfrak{a} \subseteq \mathfrak{p}$, the smallest being $V(\mathfrak{p}) = \{\, \mathfrak{q} : \mathfrak{q} \supseteq \mathfrak{p} \,\}$. Hence $\overline{\{\, \mathfrak{p} \,\}} = V(\mathfrak{p})$. So $\{\, \mathfrak{p} \,\}$ is closed $\iff$ $V(\mathfrak{p}) = \{\, \mathfrak{p} \,\}$ $\iff$ no prime strictly contains $\mathfrak{p}$ $\iff$ $\mathfrak{p}$ is maximal. Sanity check: in $\operatorname{Spec}\mathbb{Z}$, $\overline{\{\, (0) \,\}} = V((0)) = \operatorname{Spec}\mathbb{Z}$ (so (0) is dense), while $\overline{\{\, (p) \,\}} = \{\, (p) \,\}$ since (p) is maximal. The topology is generally not T_1 (non-closed points exist) but it is always T_0.

Worked Example 15.8.10 ($\operatorname{Spec} R$ is T_0 but rarely Hausdorff)**.** Show any two distinct points of $\operatorname{Spec} R$ are topologically distinguishable, yet $\operatorname{Spec}\mathbb{Z}$ is not Hausdorff.

Recognition. T_0 means: for $\mathfrak{p} \neq \mathfrak{q}$ some open set contains one but not the other. Hausdorff fails because of the generic point.

Solution. If $\mathfrak{p} \neq \mathfrak{q}$, say $f \in \mathfrak{p} \setminus \mathfrak{q}$; then $D(f)$ contains $\mathfrak{q}$ but not $\mathfrak{p}$, giving T_0. For $\mathbb{Z}$: any nonempty open set is the complement of a finite set of closed points (since proper closed sets $V(\mathfrak{a})$, $\mathfrak{a} \neq 0$, are finite), so any two nonempty opens meet – no disjoint neighborhoods exist, hence not Hausdorff. Sanity check: in $\operatorname{Spec}\mathbb{Z}$ every nonempty open contains (0), the generic point, so opens can never be disjoint.

Worked Example 15.8.11 (Quasi-compact but not compact: an infinite cover with no finite subcover of an open subset)**.** Show $\operatorname{Spec} R$ is quasi-compact, but exhibit an open subset of some $\operatorname{Spec} R$ whose cover has no finite subcover.

Recognition. $\operatorname{Spec} R$ itself is always quasi-compact by the unit-relation argument; non-quasi-compact *open subsets* arise in non-Noetherian rings.

Solution. Quasi-compactness of X was proved above. For the failure on an open subset, take $R = k[x_1, x_2, \dots]$ (infinitely many variables) and $U = \bigcup_{i \geq 1} D(x_i)$, the complement of the closed set $V(x_1, x_2, \dots)$. Given any finite subfamily $D(x_{i_1}), \dots, D(x_{i_m})$, consider the prime $\mathfrak{p} = (x_{i_1}, \dots, x_{i_m})$ (prime since $R/\mathfrak{p} \cong k[x_k : k \notin \{ i_1, \dots, i_m \}]$ is a domain). It contains each x_{i_j}, so $\mathfrak{p} \notin D(x_{i_j})$ for every j; yet $\mathfrak{p} \in U$, since it omits any x_k with $k \notin \{ i_1, \dots, i_m \}$, whence $\mathfrak{p} \in D(x_k) \subseteq U$. Thus the finite union fails to cover U, and no finite subcover exists. Sanity check: U is quasi-compact iff it is a *finite* union of basic opens (Section 15.8, Exercise 12); here it is genuinely infinite, consistent with R non-Noetherian.

Irreducibility, components, and the nilradical

A closed set Y in a topological space is *irreducible* if $Y \neq \varnothing$ and Y is not the union of two proper closed subsets; equivalently every nonempty open subset of Y is dense in Y. This is the topological avatar of primality.

Theorem 15.8.12 (irreducible closed sets $\leftrightarrow$ primes; components $\leftrightarrow$ minimal primes)**.** *Let R be a ring, $X = \operatorname{Spec} R$.*

(1) *A closed set $V(\mathfrak{a})$ is irreducible $\iff$ $\operatorname{rad} \mathfrak{a} = I(V(\mathfrak{a}))$ is prime. Thus the irreducible closed subsets of X are exactly the $V(\mathfrak{p}) = \overline{\{ \mathfrak{p} \}}$ for $\mathfrak{p} \in \operatorname{Spec} R$, and $\mathfrak{p}$ is the unique* generic point *of $V(\mathfrak{p})$.*

(2) *X is irreducible $\iff$ $\operatorname{nil} R$ is prime.*

(3) *The irreducible components of X are the closures $V(\mathfrak{p})$ of the* minimal primes *$\mathfrak{p}$ of R.*

Idea. (1) If $\operatorname{rad} \mathfrak{a} = \mathfrak{p}$ is prime and $V(\mathfrak{p}) = V(\mathfrak{b}) \cup V(\mathfrak{c}) = V(\mathfrak{b} \cap \mathfrak{c})$, then $\mathfrak{p} = \operatorname{rad}(\mathfrak{b} \cap \mathfrak{c}) \supseteq \mathfrak{b}\mathfrak{c}$, so $\mathfrak{p} \supseteq \mathfrak{b}$ or $\mathfrak{p} \supseteq \mathfrak{c}$, forcing $V(\mathfrak{p})$ equal to one piece. Conversely if $\operatorname{rad} \mathfrak{a}$ is not prime, pick $fg \in \operatorname{rad} \mathfrak{a}$ with $f, g \notin \operatorname{rad} \mathfrak{a}$; then $V(\mathfrak{a}) = V(\mathfrak{a} + (f)) \cup V(\mathfrak{a} + (g))$ is a proper decomposition. (2) is (1) with $\mathfrak{a} = 0$. (3) An irreducible component is a maximal irreducible closed set $= V(\mathfrak{p})$ with $\mathfrak{p}$ minimal, since $V(\mathfrak{p}) \subseteq V(\mathfrak{q}) \iff \mathfrak{q} \subseteq \mathfrak{p}$. □

Theorem 15.8.13 ($\operatorname{Spec} R$ and $\operatorname{Spec} R_{\mathrm{red}}$ coincide)**.** *Let $\operatorname{nil} R$ be the nilradical and $R_{\mathrm{red}} = R/\operatorname{nil} R$ the associated reduced ring. The canonical surjection $R \to R_{\mathrm{red}}$ induces a homeomorphism*

$$\operatorname{Spec} R_{\mathrm{red}} \xrightarrow{\sim} \operatorname{Spec} R.$$

Topologically, nilpotents are invisible.

Idea. Primes of $R/\operatorname{nil} R$ correspond bijectively to primes of R containing $\operatorname{nil} R$ – but every prime contains the nilradical, so this is *all* primes. The correspondence preserves containments, hence the Zariski topology, so it is a homeomorphism. (This is the special case $\mathfrak{a} = \operatorname{nil} R$ of: $\operatorname{Spec}(R/\mathfrak{a}) \cong V(\mathfrak{a})$.) □

Worked Example 15.8.14 ($\operatorname{Spec} \mathbb{Z}/12\mathbb{Z}$ and the nilradical)**.** Compute $\operatorname{Spec}(\mathbb{Z}/12\mathbb{Z})$ as a topological space and verify it equals Spec of its reduction.

Recognition. $\mathbb{Z}/12\mathbb{Z}$ is Artinian; its primes are the maximal ideals coming from the prime divisors of 12. The nilradical kills the square factor.

Solution. $12 = 2^2 \cdot 3$, so $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ by CRT. Its primes are $(2)/(12)$ and $(3)/(12)$ – two points, both closed (maximal), with the discrete topology. The nilradical is $(6)/(12)$ (since $6^2 = 36 \equiv 0$), and $R_{\mathrm{red}} = \mathbb{Z}/12\mathbb{Z}/(6) \cong \mathbb{Z}/6\mathbb{Z} \cong \mathbb{F}_2 \times \mathbb{F}_3$, which again has exactly the two points $(2), (3)$. Sanity check: $|\operatorname{Spec}| = 2 =$ number of distinct prime divisors of 12; squaring the 2 (from 4) added nilpotents but no new points, confirming $\operatorname{Spec} R = \operatorname{Spec} R_{\mathrm{red}}$.

Worked Example 15.8.15 (Generic point of $\operatorname{Spec} k[x, y]$ and the curve points)**.** With $R = k[x, y]$ (k algebraically closed), identify the generic point and describe the closure of (f).

Recognition. Primes are (0), the (f) for f irreducible, and the maximals $(x - a, y - b)$; closure of $\mathfrak{p}$ is $V(\mathfrak{p})$.

Solution. (0) is prime (the domain $k[x, y]$), and $\overline{\{ (0) \}} = V(0) = \operatorname{Spec} R$, so (0) is the generic point of the irreducible space $\operatorname{Spec} k[x, y]$ (= the plane $\mathbb{A}^2$). For an irreducible f, $\overline{\{ (f) \}} = V(f) = \{ (f) \} \cup \{ (x - a, y - b) : f(a, b) = 0 \}$: the point (f) itself together with exactly the closed points lying on the curve $f = 0$. Sanity check: $V(f)$ is irreducible because (f) is prime; its generic point (f) is the curve "as a whole," its closed points are the geometric points on it – precisely the classical picture of Section 15.3 with one extra generic dot.

Worked Example 15.8.16 (An irreducible component count: $\operatorname{Spec} k[x,y]/(xy)$)**.** Show $X = \operatorname{Spec} k[x,y]/(xy)$ is connected but reducible, with two irreducible components.

Recognition. $(xy) = (x) \cap (y)$ is radical but not prime; minimal primes give components.

Solution. In $S = k[x,y]/(xy)$ the minimal primes are (x) and (y) (since $(xy) = (x) \cap (y)$ and $x \cdot y = 0$). Their closures $V(x)$ and $V(y)$ are the two coordinate axes, each homeomorphic to $\operatorname{Spec} k[x] \cong \mathbb{A}^1$. So $X = V(x) \cup V(y)$ is reducible with two components. It is connected because the two axes meet at the origin $(x,y)/(xy)$. Sanity check: $\operatorname{nil} S = 0$ (the ring is reduced) yet $\operatorname{nil} S$ is not prime, matching "X irreducible $\iff$ nil prime"; two minimal primes = two components.

Worked Example 15.8.17 ($\operatorname{Spec} R$ connected $\iff$ no nontrivial idempotent)**.** Show $\operatorname{Spec} R$ is disconnected iff $R \cong R_1 \times R_2$ with $R_i \neq 0$ iff R has an idempotent $e \neq 0, 1$.

Recognition. A clopen decomposition of X corresponds to a product decomposition of R via an idempotent.

Solution. If $R = R_1 \times R_2$ then $X = \operatorname{Spec} R$ is the disjoint union $V(0 \times R_2) \sqcup V(R_1 \times 0)$ of two nonempty clopen pieces $\cong \operatorname{Spec} R_1, \operatorname{Spec} R_2$ (a prime of a product lives in one factor). Conversely a disconnection $X = Y_1 \sqcup Y_2$ into clopen sets gives complementary idempotents: $Y_i = D(e_i) = V(1 - e_i)$ with $e_1 + e_2 = 1$, $e_1 e_2 = 0$, so $e = e_1$ is a nontrivial idempotent and $R \cong Re_1 \times Re_2$. Sanity check: a local ring or a domain has only the idempotents $0, 1$, so its spectrum is connected – e.g. $\operatorname{Spec} \mathbb{Z}$ is connected, with generic point (0) gluing all closed points together.

Worked Example 15.8.18 (Spec of a product is a disjoint union)**.** For $R = \mathbb{Z}/6\mathbb{Z} \cong \mathbb{F}_2 \times \mathbb{F}_3$ and for $R = k \times k \times k$, describe $\operatorname{Spec} R$ topologically.

Recognition. $\operatorname{Spec}(R_1 \times R_2) = \operatorname{Spec} R_1 \sqcup \operatorname{Spec} R_2$ as spaces, each piece clopen.

Solution. $\mathbb{Z}/6\mathbb{Z} \cong \mathbb{F}_2 \times \mathbb{F}_3$: $\operatorname{Spec} = \operatorname{Spec} \mathbb{F}_2 \sqcup \operatorname{Spec} \mathbb{F}_3 = \{ (2) \} \sqcup \{ (3) \}$, two isolated (clopen) points. For $k \times k \times k$: three isolated points, the discrete three-point space. Sanity check: $|\operatorname{Spec}(k^n)| = n$ with the discrete topology; idempotents $e_i = (0, \ldots, 1, \ldots, 0)$ are the nontrivial idempotents witnessing total disconnection, matching the previous example.

Functoriality: ring maps induce continuous Spec maps

The point of using Spec rather than mSpec is that it is a *contravariant functor*: every ring map yields a continuous map of spectra, pulling basic opens back to basic opens.

Theorem 15.8.19 (Spec is a contravariant functor to **Top**)**.** *Let $\varphi\colon R \to S$ be a ring homomorphism. Then $\mathfrak{q} \mapsto \varphi^{-1}(\mathfrak{q})$ defines a map*

$$\varphi^*\colon \operatorname{Spec} S \longrightarrow \operatorname{Spec} R, \qquad \varphi^*(\mathfrak{q}) = \varphi^{-1}(\mathfrak{q}),$$

which is continuous for the Zariski topologies. Concretely:

$$(\varphi^*)^{-1}\big(V(\mathfrak{a})\big) = V\big(\varphi(\mathfrak{a})S\big), \qquad (\varphi^*)^{-1}\big(D(f)\big) = D\big(\varphi(f)\big).$$

Moreover $(\psi \circ \varphi)^* = \varphi^* \circ \psi^*$ and $\mathrm{id}^* = \mathrm{id}$.

Idea. $\varphi^{-1}(\mathfrak{q})$ is prime: if $ab \in \varphi^{-1}(\mathfrak{q})$ then $\varphi(a)\varphi(b) \in \mathfrak{q}$, so one of $\varphi(a), \varphi(b) \in \mathfrak{q}$. The preimage formula: $\varphi^*(\mathfrak{q}) \in V(\mathfrak{a}) \iff \mathfrak{a} \subseteq \varphi^{-1}(\mathfrak{q}) \iff \varphi(\mathfrak{a}) \subseteq \mathfrak{q} \iff \mathfrak{q} \in V(\varphi(\mathfrak{a})S)$. Since preimages of closed sets are closed, φ^* is continuous; the basic-open statement is the special case $\mathfrak{a} = (f)$. □

Remark 15.8.1. This is exactly why primes, not maximals, are the right "points." Over an algebraically closed k, a k-algebra map between affine k-algebras does pull maximal ideals back to maximal ideals (Nullstellensatz), so for the geometric points the classical and the schematic pictures agree; but the spectrum also carries the non-closed primes corresponding to the *subvarieties* of V, and on those the functoriality is genuinely needed. The pair $(\operatorname{mSpec} R, R)$ is the "canonical model"; the equivalence of categories

$$\{ \text{affine algebraic sets}/k \} \;\leftrightarrow\; \{ \text{affine } k\text{-algebras} \}, \qquad V \mapsto k[V], \quad R \mapsto \operatorname{mSpec} R,$$

upgrades, for arbitrary rings, to the affine-scheme correspondence of Theorem 15.8.26 below.

Worked Example 15.8.20 (The inclusion $\mathbb{Z} \hookrightarrow \mathbb{Z}[i]$ and its fibers)**.** Describe $\varphi^*\colon \operatorname{Spec}\mathbb{Z}[i] \to \operatorname{Spec}\mathbb{Z}$ for $\varphi\colon \mathbb{Z} \hookrightarrow \mathbb{Z}[i]$, computing the fiber over each (p).

Recognition. Fibers of φ^* over (p) are read off from the factorization of p in the Gaussian integers, i.e. from p mod 4.

Solution. The fiber over (p) is $\{\,\mathfrak{q} \in \operatorname{Spec}\mathbb{Z}[i] : \mathfrak{q} \cap \mathbb{Z} = (p)\,\}$, the primes of $\mathbb{Z}[i]$ above p. By the theory of $\mathbb{Z}[i]$ (a PID): if $p = 2$, $2 = -i(1+i)^2$ is ramified, one point $(1+i)$; if $p \equiv 3 \pmod 4$, p is inert, one point (p); if $p \equiv 1 \pmod 4$, $p = \pi\overline{\pi}$ splits, two points $(\pi), (\overline{\pi})$. Over (0) lies the single generic point (0). Sanity check: the residue field $\mathbb{Z}[i]/\mathfrak{q}$ has order p^f with $f = 1$ (split/ramified) or $f = 2$ (inert), and $\sum_{\mathfrak{q}\mid p} e_{\mathfrak{q}} f_{\mathfrak{q}} = 2 = [\mathbb{Q}(i) : \mathbb{Q}]$ in each case ($e = 2, f = 1$ ramified; $e = f = 1$ twice split; $e = 1, f = 2$ inert).

Worked Example 15.8.21 (The projection $k[x] \hookrightarrow k[x,y]$ and vertical-line fibers)**.** For k algebraically closed and $\varphi\colon k[x] \hookrightarrow k[x,y]$, describe $\varphi^*\colon \operatorname{Spec}k[x,y] \to \operatorname{Spec}k[x]$ and the fiber over $(x-a)$.

Recognition. φ^* is the projection $\mathbb{A}^2 \to \mathbb{A}^1$; the fiber over a point of the line is the vertical line above it (plus its generic point).

Solution. $\varphi^*(\mathfrak{q}) = \mathfrak{q} \cap k[x]$. Over the closed point $(x-a) \in \operatorname{Spec}k[x]$ the fiber consists of the primes $\mathfrak{q}$ of $k[x,y]$ with $\mathfrak{q} \cap k[x] = (x-a)$: these are the maximal ideals $(x-a, y-b)$ for $b \in k$ together with the height-1 prime $(x-a)$ itself (the whole vertical line, its generic point). Over (0) the fiber adds the generic point (0) of the plane and all the "slanted" curve primes (f) with $f \notin k[x]$. Sanity check: setting $x = a$, the fiber ring is $k[x,y]/(x-a) \cong k[y]$, whose spectrum is the y-line $\{\,(y-b)\,\} \cup \{\,(0)\,\}$ – exactly the points found.

Worked Example 15.8.22 (Closed immersion: $\operatorname{Spec}R/\mathfrak{a} \hookrightarrow \operatorname{Spec}R$)**.** Show the quotient map $R \to R/\mathfrak{a}$ induces a homeomorphism of $\operatorname{Spec}R/\mathfrak{a}$ onto the closed set $V(\mathfrak{a}) \subseteq \operatorname{Spec}R$.

Recognition. Primes of $R/\mathfrak{a}$ correspond to primes of R containing $\mathfrak{a}$, order-preservingly.

Solution. By the correspondence theorem, $\pi\colon R \to R/\mathfrak{a}$ gives $\mathfrak{q} \mapsto \pi^{-1}(\mathfrak{q})$, a bijection from $\operatorname{Spec}R/\mathfrak{a}$ onto $\{\,\mathfrak{p} \supseteq \mathfrak{a}\,\} = V(\mathfrak{a})$, preserving inclusions and hence the subspace topology. Thus π^* is a homeomorphism onto $V(\mathfrak{a})$. Sanity check: taking $\mathfrak{a} = \operatorname{nil}R$ recovers $\operatorname{Spec}R_{\mathrm{red}} \cong \operatorname{Spec}R$ (here $V(\operatorname{nil}R) = X$); taking $\mathfrak{a} = \mathfrak{p}$ prime gives $\operatorname{Spec}R/\mathfrak{p} \cong V(\mathfrak{p}) = \overline{\{\,\mathfrak{p}\,\}}$, the irreducible closed set with generic point $\mathfrak{p}$.

Worked Example 15.8.23 (Localization as an open immersion: $\operatorname{Spec}R_f \hookrightarrow \operatorname{Spec}R$)**.** Show the localization map $R \to R_f$ realizes $\operatorname{Spec}R_f$ as the open set $D(f)$.

Recognition. Primes of R_f correspond to primes of R not containing f; that set is $D(f)$.

Solution. The map $R \to R_f$ inverts f, so $\mathfrak{q} \mapsto \mathfrak{q} \cap R$ is a bijection $\operatorname{Spec}R_f \to \{\,\mathfrak{p} : f \notin \mathfrak{p}\,\} = D(f)$, bicontinuous since every ideal of R_f is extended. Thus localization at f is the algebraic operation realizing the *open* subset $D(f)$, dual to quotient realizing the *closed* subset $V(\mathfrak{a})$. Sanity check: $R = \mathbb{Z}$, $f = 6$ gives $R_6 = \mathbb{Z}[1/6]$ and $D(6) = \operatorname{Spec}\mathbb{Z} \setminus \{\,(2),(3)\,\} = \{\,(0)\,\} \cup \{\,(p) : p \neq 2,3\,\}$ – precisely the primes missing 2 and 3, the points where 6 is invertible.

Worked Example 15.8.24 (A morphism with non-surjective φ^*, and a non-local subtlety)**.** For $\varphi\colon \mathbb{Z} \to \mathbb{Z}_{(2)}$ (localization at (2)), describe φ^* and note which primes of $\mathbb{Z}$ are hit.

Recognition. Localizing at the prime (2) keeps only primes contained in (2), i.e. (0) and (2).

Solution. $\mathbb{Z}_{(2)} = \{\,a/b : b \text{ odd}\,\}$ is local with maximal ideal $2\mathbb{Z}_{(2)}$ and primes $(0) \subsetneq (2)\mathbb{Z}_{(2)}$. So $\operatorname{Spec}\mathbb{Z}_{(2)} = \{\,(0),(2)\,\}$ and φ^* embeds it as the two points $(0), (2)$ of $\operatorname{Spec}\mathbb{Z}$; every other (p) is missed. Sanity check: Spec of a local ring has a unique closed point (here (2)) and is connected; φ^* here is the inclusion of the "germ of $\operatorname{Spec}\mathbb{Z}$ near (2)." This local example is the source of the local-homomorphism condition needed below for scheme morphisms.

The classical points and the structure sheaf: affine schemes

We close with A&M's geometric program: equip $\operatorname{Spec}R$ with a sheaf of rings so it becomes a ringed space, recovering the local rings $R_{\mathfrak{p}}$ as stalks and R itself as global functions. First the bridge back to classical varieties.

Theorem 15.8.25 (mSpec and the points of a variety)**.** *Let k be algebraically closed and $R = k[V] = k[x_1, \dots, x_n]/I(V)$ an affine k-algebra (finitely generated, reduced). Then by the Nullstellensatz:*

$$\operatorname{mSpec} R \;\xleftrightarrow{\sim}\; V, \qquad (x_1 - a_1, \dots, x_n - a_n) \bmod I(V) \;\longleftrightarrow\; (a_1, \dots, a_n) \in V,$$

and $\operatorname{Spec} R \leftrightarrow \{$ *subvarieties of* $V \}$ *(irreducible closed subsets via their generic primes). For a maximal ideal $\mathfrak{m}$, the residue field is $R/\mathfrak{m} \cong k$, so a closed point is a genuine k-valued point.*

Theorem 15.8.26 (the structure sheaf and affine schemes)**.** *Let $X = \operatorname{Spec} R$. For an open $U \subseteq X$ let $\mathcal{O}_X(U)$ be the ring of functions $s\colon U \to \coprod_{\mathfrak{p} \in U} R_{\mathfrak{p}}$ with $s(\mathfrak{p}) \in R_{\mathfrak{p}}$ and s* locally a fraction*: each point has a basic neighborhood $D(g) \subseteq U$ on which $s = a/g^n$ for fixed $a \in R$, $n \geq 0$. Then:*

(1) *$\mathcal{O}_X(D(f)) \cong R_f$; in particular the global sections are $\mathcal{O}_X(X) \cong R$.*

(2) *The stalk at $\mathfrak{p}$ is the local ring $\mathcal{O}_{X,\mathfrak{p}} \cong R_{\mathfrak{p}}$, with maximal ideal $\mathfrak{p}R_{\mathfrak{p}}$ and residue field $\kappa(\mathfrak{p}) = \operatorname{Frac}(R/\mathfrak{p})$.*

The pair $(\operatorname{Spec} R, \mathcal{O}_{\operatorname{Spec} R})$ is an affine scheme*. Every ring map $\varphi\colon R \to S$ induces a morphism of affine schemes $(\varphi^*, \varphi^{\#})\colon (\operatorname{Spec} S, \mathcal{O}_{\operatorname{Spec} S}) \to (\operatorname{Spec} R, \mathcal{O}_{\operatorname{Spec} R})$, where on stalks $\varphi^{\#}\colon R_{\mathfrak{p}} \to S_{\mathfrak{q}}$ is a* local *homomorphism; conversely every such morphism arises from a unique ring map. Thus*

$$\{\, \textit{commutative rings} \,\} \;\xleftrightarrow{\sim}\; \{\, \textit{affine schemes} \,\} \quad (\textit{contravariant}),$$

the founding equivalence of scheme theory.

Idea. $\mathcal{O}_X(D(f)) \cong R_f$ is a sheaf-gluing computation: a locally-fraction section on $D(f)$ is patched from compatible fractions a_i/g_i^n on a finite cover $D(g_i)$ (using quasi-compactness), and the identities $f^N = \sum b_i g_i^n$ assemble a single global a/f^M. The stalk is the direct limit $\varinjlim_{\mathfrak{p} \in D(f)} \mathcal{O}_X(D(f)) = \varinjlim_{f \notin \mathfrak{p}} R_f = R_{\mathfrak{p}}$. The local-homomorphism condition is forced because $\varphi^{-1}(\mathfrak{q}) = \mathfrak{p}$ means $\varphi_{\mathfrak{p}}^{-1}(\mathfrak{q}S_{\mathfrak{q}}) = \mathfrak{p}R_{\mathfrak{p}}$; the example $\mathbb{Z}_{(2)} \hookrightarrow \mathbb{Q}$ shows a non-local map of stalks does *not* come from a ring map of the right spectra. □

Remark 15.8.2. The terminology is geometric: above each point $\mathfrak{p}$ sits the local ring $R_{\mathfrak{p}}$ – the "stalk" (as of wheat) – and a section over U is a choice of germ at each point, locally given by one fraction; the totality is the "sheaf" (bundle) of stalks. Localization is literally "concentrating near a point": $R_{\mathfrak{p}}$ is the ring of rational functions defined in some Zariski neighborhood of $\mathfrak{p}$, and $\kappa(\mathfrak{p})$ is the field of values at the generic point of $V(\mathfrak{p})$. A scheme is glued from affine charts $(\operatorname{Spec} R_i, \mathcal{O})$ exactly as a manifold is glued from Euclidean charts.

Worked Example 15.8.27 (Structure sheaf on $\operatorname{Spec}\mathbb{Z}$)**.** Compute $\mathcal{O}(D(n))$, the global sections, and the stalks for $X = \operatorname{Spec}\mathbb{Z}$.

Recognition. $\mathbb{Z}$ is a PID, so every open is basic: $D(n) = \{\, \mathfrak{p} : n \notin \mathfrak{p} \,\}$, and $\mathcal{O}(D(n)) = \mathbb{Z}_n = \mathbb{Z}[1/n]$.

Solution. For $n \geq 1$, $D(n) = \{\, (p) : p \nmid n \,\} \cup \{\, (0) \,\}$ and $\mathcal{O}(D(n)) = \mathbb{Z}[1/n] = \{\, a/b \in \mathbb{Q} : p \mid b \Rightarrow p \mid n \,\}$. Global sections: $\mathcal{O}(X) = \mathcal{O}(D(1)) = \mathbb{Z}$. Stalks: $\mathcal{O}_{(p)} = \mathbb{Z}_{(p)}$ (rationals with denominator prime to p) and $\mathcal{O}_{(0)} = \mathbb{Z}_{(0)} = \mathbb{Q}$ at the generic point. All restriction maps are the evident inclusions inside $\mathbb{Q}$. Sanity check: $\mathcal{O}(X) = \mathbb{Z}$ recovers "functions regular everywhere = the ring," the arithmetic analogue of "polynomial functions on $\mathbb{A}^n$ regular everywhere are polynomials."

Worked Example 15.8.28 (Structure sheaf on Spec of a local ring)**.** For the local ring $R = \mathbb{Z}_{(2)}$ describe the open sets, sections, and stalks of $\operatorname{Spec} R$.

Recognition. $\operatorname{Spec} R = \{\, (0), (2) \,\}$ with (2) the unique closed point; $\{\, (0) \,\} = D(2)$ is the only nontrivial open.

Solution. Open sets: $\varnothing$, $\{\, (0) \,\} = D(2)$, and $X = \{\, (0), (2) \,\}$. Sections: $\mathcal{O}(X) = R = \mathbb{Z}_{(2)}$ (global sections = the ring) and $\mathcal{O}(D(2)) = R_2 = \mathbb{Q}$. Stalks: $\mathcal{O}_{(0)} = R_{(0)} = \mathbb{Q}$, $\mathcal{O}_{(2)} = R_{(2)} = R$ itself (already local). Sanity check: the stalk at the closed point of Spec of a local ring is the ring itself, and Spec is connected with a unique generic point (0) specializing to (2).

Worked Example 15.8.29 (Values, the nilradical, and functions not determined pointwise)**.** In $R = k[x]/(x^2)$ show two distinct elements have identical values at every point of $\operatorname{Spec} R$.

Recognition. $\operatorname{Spec} R$ is a single point; values lie in $R/\mathfrak{p}$, and the difference of equal-valued elements lies in $\operatorname{nil} R$.

Solution. $R = k[x]/(x^2)$ is local with unique prime $\mathfrak{p} = (x)$ (the nilradical), $R_{\mathrm{red}} = k$. So $\operatorname{Spec} R = \{(x)\}$ is one point and $\kappa(\mathfrak{p}) = R/(x) = k$. The elements 0 and $\overline{x}$ are distinct in R but both have value 0 in $R/(x) = k$, since $\overline{x} \in \operatorname{nil} R$. Sanity check: f, g agree at all points $\iff f - g \in \operatorname{nil} R$; here $\overline{x} - 0 = \overline{x}$ is nilpotent ($\overline{x}^2 = 0$), so the two functions are pointwise equal yet algebraically different – the nilpotent "thickening" invisible to Spec but recorded in $\mathcal{O}$.

Worked Example 15.8.30 ($\operatorname{Spec} \mathbb{Z}[x]$ fibered over $\operatorname{Spec} \mathbb{Z}$ via a cubic)**.** For $f = x^3 + x + 1$, locate the closed points of $V(f) \subseteq \operatorname{Spec} \mathbb{Z}[x]$ in the fibers over $(2), (3), (5)$.

Recognition. Closed points of $V(f)$ over (p) are the maximals (p, g) with $g \mid \overline{f}$ in $\mathbb{F}_p[x]$, one per irreducible factor.

Solution. Reduce f modulo each prime: $f \equiv x^3 + x + 1 \pmod 2$ is irreducible (no root in $\mathbb{F}_2$, since $f(0) = f(1) = 1$), giving one closed point $(2, x^3 + x + 1)$; modulo 3 the only root is $x = 1$ ($f(0) = 1$, $f(1) = 0$, $f(2) = 2$), so $f \equiv (x - 1)(x^2 + x + 2) \pmod 3$ with $x^2 + x + 2$ irreducible over $\mathbb{F}_3$, giving the two points $(3, x - 1)$ and $(3, x^2 + x + 2)$; modulo 5, f has no root ($f(0), \ldots, f(4) = 1, 3, 1, 1, 4$), so as a rootless cubic it is irreducible, giving one closed point $(5, x^3 + x + 1)$. Sanity check: the number of closed points over (p) equals the number of *distinct* irreducible factors of $f \bmod p$ $(1, 2, 1$ respectively), and the splitting type is governed by the Galois group of f over $\mathbb{Q}$ acting on the roots (f is irreducible over $\mathbb{Q}$, as it has no rational root).

Worked Example 15.8.31 ($\operatorname{Spec} k[x]$ over an algebraically closed k, and a non-closed comparison)**.** Describe $\operatorname{Spec} k[x]$ for k algebraically closed, and contrast with $\operatorname{Spec} \mathbb{R}[x]$.

Recognition. Over $\overline{k}$ every nonzero prime of $k[x]$ is $(x - a)$; over $\mathbb{R}$ there are also degree-2 primes.

Solution. For $k = \overline{k}$: $\operatorname{Spec} k[x] = \{(0)\} \cup \{(x - a) : a \in k\}$, the generic point plus the affine line $\mathbb{A}^1(k) = \operatorname{mSpec}$. For $R = \mathbb{R}[x]$: primes are (0), the $(x - a)$ with $a \in \mathbb{R}$ (residue field $\mathbb{R}$), and the $(x^2 + bx + c)$ with negative discriminant (residue field $\mathbb{C}$); the latter "hide" a conjugate pair of complex points. Sanity check: $\operatorname{Spec} \mathbb{R}[x] = \{(0)\} \sqcup \operatorname{mSpec} \mathbb{R}[x]$, where $\operatorname{mSpec} \mathbb{R}[x] = \mathbb{R} \sqcup \{\text{conjugate pairs in } \mathbb{C} \setminus \mathbb{R}\}$ is in bijection with $\mathbb{C}/(\text{complex conjugation})$ – exactly the failure of k not being algebraically closed, and the reason the Nullstellensatz bijection $\operatorname{mSpec} \leftrightarrow$ points needs $k = \overline{k}$.

A single diagram records the contravariant dictionary at the heart of the section: the algebraic operations on R on the left, their geometric meaning on $\operatorname{Spec} R$ on the right, with quotients giving closed pieces and localizations giving open pieces.

$$\begin{array}{ccccc} R/\mathfrak{a} & \xleftarrow{\text{quotient}} & R & \xrightarrow{\text{localize}} & R_f \\ \big| & & \big| & & \big| \\ V(\mathfrak{a})\ \text{(closed)} & & \operatorname{Spec} R & & D(f)\ \text{(open)} \end{array} \qquad \begin{array}{ccc} \operatorname{Spec} S & \xrightarrow{\varphi^*} & \operatorname{Spec} R \\ \big| & & \big| \\ \mathfrak{q} & \longmapsto & \varphi^{-1}(\mathfrak{q}) \end{array}$$

The left square shows the two ways to "cut out" a chart – closed via $R \twoheadrightarrow R/\mathfrak{a}$ realizing $V(\mathfrak{a})$, open via $R \to R_f$ realizing $D(f)$ – while the right square shows that a ring map runs functions backward (contravariance), the engine of the affine-scheme equivalence of Theorem 15.8.26.

Diagram explanation. Objects: Left square, top row: R (the base commutative ring), $R/\mathfrak{a}$ (the quotient ring by an ideal $\mathfrak{a} \subseteq R$), and R_f (the localization at a single element $f \in R$). Bottom row: $\operatorname{Spec} R$ (the full prime spectrum), $V(\mathfrak{a}) \subseteq \operatorname{Spec} R$ (the Zariski-closed set of primes containing $\mathfrak{a}$), and $D(f) \subseteq \operatorname{Spec} R$ (the basic open set of primes missing f). Right square: $\operatorname{Spec} S$ and $\operatorname{Spec} R$ are topological spaces (prime spectra of rings S and R linked by $\varphi\colon R \to S$); the bottom row displays generic elements $\mathfrak{q} \in \operatorname{Spec} S$ and its image $\varphi^{-1}(\mathfrak{q}) \in \operatorname{Spec} R$.

Arrows: In the left square: $R \twoheadrightarrow R/\mathfrak{a}$ is the surjective quotient map (kills $\mathfrak{a}$); $R \to R_f$ is the localization map (inverts powers of f); the three vertical undirected solid lines are not maps of rings but the dictionary correspondences linking each algebraic object to its geometric counterpart. In the right square: $\varphi^*\colon \operatorname{Spec} S \to \operatorname{Spec} R$ is the induced continuous map of spaces, sending $\mathfrak{q}$ to its contraction $\varphi^{-1}(\mathfrak{q})$; the bottom horizontal arrow records the same assignment at the element level via $\mapsto$.

What commutes: The left square is a correspondence table, not a commutative square of ring maps: each algebraic operation (quotient by $\mathfrak{a}$, localize at f) produces exactly one geometric piece ($V(\mathfrak{a})$ closed, $D(f)$ open), with $\operatorname{Spec} R$ in the center mediating both. The right square does commute as a diagram of spaces: the

top arrow φ^* and the bottom element-level arrow agree, i.e. $\varphi^*(\mathfrak{q}) = \varphi^{-1}(\mathfrak{q})$ for every $\mathfrak{q} \in \operatorname{Spec} S$, making the square a definition diagram rather than a commutativity condition to verify.

Why it commutes: For the right square, well-definedness of φ^* is the key: if $\mathfrak{q}$ is prime in S and $ab \in \varphi^{-1}(\mathfrak{q})$, then $\varphi(a)\varphi(b) \in \mathfrak{q}$, so $\varphi(a) \in \mathfrak{q}$ or $\varphi(b) \in \mathfrak{q}$ (since $\mathfrak{q}$ is prime), hence $a \in \varphi^{-1}(\mathfrak{q})$ or $b \in \varphi^{-1}(\mathfrak{q})$: the preimage of a prime is prime. For the left correspondence: $\pi^*(\mathfrak{q}) = \pi^{-1}(\mathfrak{q})$ for $\pi\colon R \to R/\mathfrak{a}$ lands in $V(\mathfrak{a})$ because $\mathfrak{a} \subseteq \pi^{-1}(\mathfrak{q})$ always; and the primes of R_f biject with primes of R not containing f, i.e. with $D(f)$.

Why this matters here: These two panels summarize the entire section in one picture. Every algebraic operation studied – quotient (closed immersion), localization (open immersion), ring map (continuous pullback) – has now been given a geometric meaning. The author places this diagram at the close of the section as a unified dictionary: the left panel shows how algebra carves out geometry, and the right panel shows how algebra maps run backward geometrically, which is the content of the contravariant functor Spec.

Concrete example: Take $R = \mathbb{Z}$, $\mathfrak{a} = (6)$, $f = 5$, and $\varphi\colon \mathbb{Z} \hookrightarrow \mathbb{Z}[i]$. Left panel: $R/\mathfrak{a} = \mathbb{Z}/6\mathbb{Z}$ corresponds to $V(6) = \{(2), (3)\}$ (closed, two points); $R_f = \mathbb{Z}[1/5]$ corresponds to $D(5) = \operatorname{Spec}\mathbb{Z} \setminus \{(5)\}$ (open). Right panel: $\varphi^*((2+i)\mathbb{Z}[i]) = (2+i)\mathbb{Z}[i] \cap \mathbb{Z} = (5)$; $\varphi^*(3\mathbb{Z}[i]) = (3)$; $\varphi^*(0) = (0)$ – primes of $\mathbb{Z}[i]$ pull back to the primes of $\mathbb{Z}$ they lie over.

Common pitfall: Students often confuse the vertical solid lines in the left panel with ring homomorphisms, reading "$R/\mathfrak{a} \to V(\mathfrak{a})$" as a map between algebraic and geometric objects of the same type. They are a dictionary correspondence, not a morphism; the actual maps are $\pi^*\colon \operatorname{Spec}(R/\mathfrak{a}) \xrightarrow{\sim} V(\mathfrak{a})$ and $\iota^*\colon \operatorname{Spec} R_f \xrightarrow{\sim} D(f)$, which are homeomorphisms of topological spaces, not ring maps. Collapsing this distinction causes confusion when one later writes $\mathcal{O}(V(\mathfrak{a}))$ versus $R/\mathfrak{a}$.

Takeaway: The point of this diagram is that the two fundamental algebraic operations – quotienting and localizing – are precisely the operations that carve out closed and open subsets of $\operatorname{Spec} R$, while any ring map φ automatically produces a continuous map of spectra running in the opposite direction, assembling algebra and geometry into a single contravariant dictionary.

Exercises (Dummit & Foote).

1. If $\mathfrak{N}$ is the nilradical of R, prove that $\operatorname{Spec} R$ and $\operatorname{Spec} R/\mathfrak{N}$ are homeomorphic. [Show that the natural homomorphism from R to $R/\mathfrak{N}$ induces a Zariski continuous isomorphism from $\operatorname{Spec} R/\mathfrak{N}$ to $\operatorname{Spec} R$.]

2. Let I be an ideal in the ring R. Prove that the continuous map from $\operatorname{Spec} R/I$ to $\operatorname{Spec} R$ induced by the canonical projection homomorphism $R \to R/I$ maps $\operatorname{Spec} R/I$ homeomorphically onto the closed set $Z(I)$ in $\operatorname{Spec} R$.

3. Prove that two elements $f, g \in R$ have the same values at all elements P in $\operatorname{Spec} R$ if and only if $f - g$ is contained in the nilradical of R. In particular, prove that an element in an affine k-algebra is uniquely determined by its values.

4. Let k be an arbitrary field, not necessarily algebraically closed. Prove that the prime ideals in $k[x, y]$ (i.e., the elements of $\operatorname{Spec} k[x, y]$) are

   (i) (0),

   (ii) (f) where f is an irreducible polynomial in $k[x, y]$, and

   (iii) $(p(x), g(x, y))$ where $p(x)$ is an irreducible polynomial in $k[x]$ and $g(x, y)$ is a polynomial in $k[x, y]$ that is irreducible modulo $p(x)$, i.e., $g(x, y)$ remains irreducible in the quotient $k[x, y]/(p(x))$.

   Prove that $\operatorname{mSpec} k[x, y]$ consists of the primes in (iii). [Use Exercise 20 in Section 1.]

5. Let $\mathfrak{m} = (p(x), g(x, y))$ be a maximal ideal in $k[x, y]$ as in the previous exercise. Show that $K = k[x, y]/\mathfrak{m}$ is an algebraic field extension of k, so that $k[x, y]$ can also be viewed as a subring of $K[x, y]$. If x, y are mapped to $\alpha, \beta \in K$, respectively, under the canonical homomorphism $k[x, y] \to k[x, y]/\mathfrak{m}$, prove that $\mathfrak{m} = k[x, y] \cap (x - \alpha, y - \beta) \subseteq K[x, y]$.

6. Describe the elements in $\operatorname{Spec}\mathbb{R}[x]$ and $\operatorname{Spec}\mathbb{C}[x]$. Describe the elements in $\operatorname{Spec}\mathbb{Z}_{(2)}[x]$ where $\mathbb{Z}_{(2)} = \{\, a/b \in \mathbb{Q} \mid b \text{ is odd} \,\}$ is the localization of $\mathbb{Z}$ at the prime (2).

7. Let $(f) = (x^5 + x + 1)$ in $\operatorname{Spec}\mathbb{Z}[x]$ viewed as fibered over $\operatorname{Spec}\mathbb{Z}$ as in Example 3 following Proposition 55. Show that there are two closed points in the fiber over (2), three closed points in the fiber over (5), four closed points in the fiber over (19), and five closed points in the fiber over (211).

8. Let $(f) = (x^4 + 1)$ in $\operatorname{Spec}\mathbb{Z}[x]$ viewed as fibered over $\operatorname{Spec}\mathbb{Z}$ as in Example 3 following Proposition 55. Prove that there is one closed point in the fiber over (2), four closed points in the fiber over p for p odd, $p \equiv 1 \pmod 8$, and two closed points in the fiber over p for all other odd primes p (cf. Corollary 16 in Section 3 of Chapter 14).

9. Prove that the elements in the fiber over (p) of the Zariski continuous map from $\operatorname{Spec}\mathbb{Z}[x]$ to $\operatorname{Spec}\mathbb{Z}$ are homeomorphic with the elements in $\operatorname{Spec}(\mathbb{Z}[x] \otimes_{\mathbb{Z}} \mathbb{F}_p)$.

10. Let $X = \operatorname{Spec} R$ and let X_f be the principal open set corresponding to $f \in R$. Prove that $X_f \cap X_g = X_{fg}$. Prove that $X_f = X$ if and only if f is a unit in R, and that $X_f = \varnothing$ if and only if f is nilpotent.

11. If X_f and X_g are principal open sets in $X = \operatorname{Spec} R$, prove that the open set $X_f \cup X_g$ is the complement of the closed set $Z(I)$ where $I = (f, g)$ is the ideal in R generated by f and g.

12. Prove that a Zariski open subset U of $X = \operatorname{Spec} R$ is quasicompact if and only if U is a finite union of principal open subsets. Give an example of a ring R, a Zariski open subset U of $\operatorname{Spec} R$, and a Zariski open covering of U that cannot be reduced to a finite subcovering.

13. Let $\varphi : R \to S$ be a homomorphism of rings. Prove that under the induced map φ^* from $Y = \operatorname{Spec} S$ to $X = \operatorname{Spec} R$ the full preimage of the principal open set X_f in X is the principal open set $Y_{\varphi(f)}$ in Y.

14. Suppose that $R = R_1 \times R_2$ is the direct product of the rings R_1 and R_2. Prove that $X = \operatorname{Spec} R$ is the disjoint union of open subspaces X_1, X_2 (which are therefore also closed), where X_1 is homeomorphic to $\operatorname{Spec} R_1$ and X_2 is homeomorphic to $\operatorname{Spec} R_2$.

15. Prove that $X = \operatorname{Spec} R$ is not connected if and only if R is the direct product of two nonzero rings if and only if R contains an idempotent e with $e \neq 0, 1$ (cf. the previous exercise).

16. Prove that $X = \operatorname{Spec} R$ is irreducible (i.e., any two nonempty open subsets have a nontrivial intersection) if and only if $X_f \cap X_g \neq \varnothing$ for any two nonempty principal open sets X_f and X_g. Deduce that $X = \operatorname{Spec} R$ is irreducible if and only if the nilradical of R is a prime ideal. [Use Exercise 10.]

17. Let $G = \langle a \rangle$ be a group of order 2, let $R = \mathbb{Z}[G] = \{\, m + na \mid m, n \in \mathbb{Z} \,\}$ be the corresponding group ring, and let $X = \operatorname{Spec} R$.

    (a) Prove that the nilradical of R is (0) but is not a prime ideal. Prove that $X = X^+ \cup X^-$ where $X^+ = Z(1 - a)$ and $X^- = Z(1 + a)$. [Use $(1 + a)(1 - a) = 0$.]

    (b) Prove that the homomorphism $\mathbb{Z}[G] \to \mathbb{Z}$ defined by mapping a to 1 induces a homeomorphism of X^+ with $\operatorname{Spec}\mathbb{Z}$, and the homomorphism mapping a to -1 induces a homeomorphism of X^- with $\operatorname{Spec}\mathbb{Z}$.

    (c) Prove that $X^+ \cap X^-$ consists of the single element $\mathfrak{m} = (1 + a, 1 - a) = (2, 1 - a)$ and that this is a closed point in X.

    (d) Show that $(1 - a)$ and $(1 + a)$ are the unique non-closed points in X, with closures X^+ and X^-, respectively. Describe the closed points, $\operatorname{mSpec} R$, in X and prove that $\operatorname{Spec}\mathbb{Z}[\langle a \rangle]$ can be pictured as fibered over $\operatorname{Spec}\mathbb{Z}$ with X^- containing $(1 + a), \mathfrak{m}, (3, 1 + a), (5, 1 + a), \ldots$ and X^+ containing $(1 - a), \mathfrak{m}, (3, 1 - a), (5, 1 - a), \ldots$ lying over the primes $(0), (2), (3), (5), \ldots$ of $\operatorname{Spec}\mathbb{Z}$ (the two lines cross at $\mathfrak{m}$).

18. Let $\mathcal{O}$ be the structure sheaf on $X = \operatorname{Spec} R$, let U be an open set in X, and suppose $s, t \in \mathcal{O}(U)$. If $s = a/f_1^n$ on X_{f_1} and $t = b/f_2^m$ on X_{f_2}, show that

$$st = (abf_1^m f_2^n)/(f_1 f_2)^{n+m} \quad \text{and} \quad s + t = (af_1^m f_2^{m+n} + bf_1^{m+n} f_2^n)/(f_1 f_2)^{n+m}$$

    on $X_{f_1 f_2}$. Deduce that $\mathcal{O}(U)$ is a commutative ring with identity.

19. Let $\mathcal{O}$ be the structure sheaf on $X = \operatorname{Spec} R$, let $V \subseteq U$ be open sets in X, and let $s \in \mathcal{O}(U)$. Suppose $P \in V$ and that $s = a/f^n$ on $X_f \subseteq U$.

(a) Show that there is a principal open set $X_{f'} \subseteq V \cap X_f$ containing P.

(b) Show that $(f')^m = bf$ for some $b \in R$.

(c) Show that $s = (ab^n)/(f')^{mn}$ on $X_{f'}$ and conclude that restricting s to V gives a well defined ring homomorphism from $\mathcal{O}(U)$ to $\mathcal{O}(V)$.

20. Let $\varphi : R \to S$ be a homomorphism of rings, let $X = \operatorname{Spec} R$, $Y = \operatorname{Spec} S$, and let $V \subseteq U$ be Zariski open subsets of X. Set $V' = (\varphi^*)^{-1}(V)$ and $U' = (\varphi^*)^{-1}(U)$, the corresponding Zariski open subsets of Y with respect to the continuous map $\varphi^* : Y \to X$ induced by φ. Prove that the induced map $\varphi^\# : \mathcal{O}_X(U) \to \mathcal{O}_Y(U')$ on sections is a ring homomorphism. Prove that $V' \subseteq U'$ and that $\varphi^\#$ is compatible with restriction, i.e., that the diagram

$$\begin{array}{ccc} \mathcal{O}_X(U) & \xrightarrow{\varphi^\#} & \mathcal{O}_Y(U') \\ \downarrow & & \downarrow \\ \mathcal{O}_X(V) & \xrightarrow[\varphi^\#]{} & \mathcal{O}_Y(V') \end{array}$$

is commutative, where the vertical maps are the restriction homomorphisms.

21. Suppose D is a multiplicatively closed subset of R. Show that the localization homomorphism $R \to D^{-1}R$ induces a homeomorphism from $\operatorname{Spec}(D^{-1}R)$ to the collection of prime ideals P of R with $P \cap D = \varnothing$.

22. Show that $\operatorname{Spec} k[x, y]/(xy)$ is connected but is the union of two proper closed subsets each homeomorphic to $\operatorname{Spec} k[x]$, hence is not irreducible (cf. Exercise 16).

23. For each of the following rings R exhibit the elements of $\operatorname{Spec} R$, the open sets U in $\operatorname{Spec} R$, the sections $\mathcal{O}(U)$ of the structure sheaf for $\operatorname{Spec} R$ for each open U, and the stalks $\mathcal{O}_P$ at each point $P \in \operatorname{Spec} R$:

(a) $\mathbb{Z}/4\mathbb{Z}$,

(b) $\mathbb{Z}/6\mathbb{Z}$,

(c) $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$,

(d) $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$.

24. (a) If every ideal of R is principal, show every open set in $\operatorname{Spec} R$ is a principal open set.

(b) Show that if $R = \mathbb{Z}[x]/(4, x^2)$ then R contains a nonprincipal ideal, but every open set in $\operatorname{Spec} R$ is a principal open set.

25. (a) If M is an R-module prove that $\operatorname{Supp}(M)$ is the union of the Zariski closed sets $Z(P)$, $P \in \operatorname{Supp}(M)$. [Use Exercise 33 of Section 4.] Show that $\operatorname{Supp}(M)$ need not be Zariski closed (consider the $\mathbb{Z}$-module $\bigoplus_p \mathbb{Z}/p\mathbb{Z}$).

(b) If M is a finitely generated R-module prove that $\operatorname{Supp}(M) = Z(\operatorname{Ann}(M)) \subseteq \operatorname{Spec} R$. [Use Exercise 34 of Section 4.]

26. Suppose M is a finitely generated module over the Noetherian ring R.

(a) Prove that there are finitely many minimal primes $P_1, \ldots, P_n$ containing $\operatorname{Ann}(M)$. [Use Corollary 22.]

(b) Prove that $\{ P_1, \ldots, P_n \}$ is also the set of minimal primes in $\operatorname{Ass}_R(M)$ and that $\operatorname{Supp}(M)$ is the union of the Zariski closed sets $Z(P_1), \ldots, Z(P_n)$ in $\operatorname{Spec} R$. [Use the previous exercise and Exercise 40 in Section 4.]

27. Let $R = k[x, y]$ and let M be the ideal (x, y) in R. Prove that $\operatorname{Supp}(M) = \operatorname{Spec} R$ and $\operatorname{Ass}_R(M) = \{ 0 \}$.

28. This exercise proves that the ideal Q in a Noetherian ring R is P-primary if and only if $\operatorname{Ass}_R(R/Q) = \{ P \}$.

(a) Suppose Q is a P-primary ideal and let M be the R-module R/Q. If $0 \neq m \in M$, show that $Q \subseteq \operatorname{Ann}(m) \subseteq P$ and that $\operatorname{rad} \operatorname{Ann}(m) = P$. Deduce that if $\operatorname{Ann}(m)$ is a prime ideal then it is equal to P and hence that $\operatorname{Ass}_R(R/Q) = \{ P \}$. [Use Exercise 33 in Section 1.]

(b) For any ideal Q of R, let $0 \neq M \subseteq R/Q$. Prove that the radical of $\mathrm{Ann}(M)$ is the intersection of the prime ideals in $\mathrm{Supp}(M)$. [Use Proposition 12 and Exercise 25.]

(c) For M as in (b), prove that the radical of $\mathrm{Ann}(M)$ is also the intersection of the prime ideals in $\mathrm{Ass}_R(M)$. [Use Exercise 26(b).]

(d) If Q is an ideal of R with $\mathrm{Ass}_R(R/Q) = \{ P \}$ prove that $\mathrm{rad}\, Q = P$. [Use the fact that $Q = \mathrm{Ann}(R/Q)$ and (c).]

(e) If Q is an ideal of R with $\mathrm{Ass}_R(R/Q) = \{ P \}$ prove that Q is P-primary. [If $ab \in Q$ with $a \notin Q$ consider $0 \neq M = (Ra + Q)/Q \subseteq R/Q$ and show that b is contained in $\mathrm{Ann}(M) \subseteq \mathrm{rad}\,\mathrm{Ann}(M)$. Use Exercises 33–34 in Section 1, to show that $\mathrm{Ass}_R(M) = \{ P \}$, then use (c) to show that $\mathrm{rad}\,\mathrm{Ann}(M) = P$, and conclude finally that $b \in P$.]

29. Suppose $I = Q_1 \cap \cdots \cap Q_n$ is a minimal primary decomposition of the ideal I in the Noetherian ring R with $P_i = \mathrm{rad}\, Q_i$, $i = 1, \ldots, n$. This exercise proves that $\mathrm{Ass}_R(R/I) = \{ P_1, \ldots, P_n \}$.

(a) Prove that the natural projection homomorphisms induce an injection of R/I into $R/Q_1 \oplus \cdots \oplus R/Q_n$ and deduce that $\mathrm{Ass}_R(R/I) \subseteq \{ P_1, \ldots, P_n \}$. [Use Exercise 34 in Section 1 and the previous exercise.]

(b) Let $Q_i' = \bigcap_{j \neq i} Q_j$. Show that the minimality of the decomposition implies that $0 \neq Q_i'/I = (Q_i' + Q_i)/Q_i \subseteq R/Q_i$. Deduce that $\mathrm{Ass}_R(Q_i'/I) = \{ P_i \}$. [Use Exercises 33–34 in Section 1 and the previous exercise.] Deduce that $P_i \in \mathrm{Ass}_R(R/I)$, so that $\mathrm{Ass}_R(R/I) = \{ P_1, \ldots, P_n \}$. [Use $Q_i'/I \subseteq R/I$ and Exercise 34 in Section 1.]

30. Let I be the ideal (x^2, xy, xz, yz) in $R = k[x, y, z]$. Prove that $\mathrm{Ass}_R(R/I)$ consists of the primes $\{ (x, y), (x, z), (x, y, z) \}$.

31. *(Spec for Quadratic Integer Rings)* Let R be the ring of integers in the quadratic field $K = \mathbb{Q}(\sqrt{D})$ where D is a squarefree integer and let P be a nonzero prime ideal in R. This exercise shows how the prime ideals in R are determined explicitly from the primes (p) in $\mathbb{Z}$, giving in particular a description of $\mathrm{Spec}\, R$ fibered over $\mathrm{Spec}\, \mathbb{Z}$. As in the discussion and example following Theorem 29, we have $R = \mathbb{Z}[\omega]$ where $\omega = \sqrt{D}$ if $D \equiv 2, 3 \pmod 4$ (respectively, $\omega = (1 + \sqrt{D})/2$ if $D \equiv 1 \pmod 4$), with minimal polynomial $m_\omega(x) = x^2 - D$ (respectively, $m_\omega(x) = x^2 - x + (1 - D)/4$), and $P \cap \mathbb{Z} = p\mathbb{Z}$ is a nonzero prime ideal of $\mathbb{Z}$.

(a) For any prime p in $\mathbb{Z}$ show that $R/pR \cong \mathbb{Z}[x]/(p, m_\omega(x)) \cong \mathbb{F}_p[x]/(\overline{m_\omega}(x))$ as rings, where $\overline{m_\omega}(x)$ is the reduction of $m_\omega(x)$ modulo p. Deduce that there is a prime ideal P in R with $P \cap \mathbb{Z} = (p)$ (this gives an alternate proof of Theorem 26(2) in this case).

(b) Use the isomorphism in (a) to prove that P is determined explicitly by the factorization of $\overline{m_\omega}(x)$ modulo p:

(i) If $\overline{m_\omega}(x) = (x - a)^2 \bmod p$ where $a \in \mathbb{Z}$ then $P = (p, \omega - a)$ and $pR = P^2$. Show that this case occurs only for the finitely many primes p dividing the discriminant of $m_\omega(x)$.

(ii) If $\overline{m_\omega}(x) = (x - a)(x - b) \bmod p$ with integers $a, b \in \mathbb{Z}$ that are distinct modulo p then P is either $P_1 = (p, \omega - a)$ or $P_2 = (p, \omega - b)$ and P_1, P_2 are distinct prime ideals in R with $pR = P_1 P_2$.

(iii) If $\overline{m_\omega}(x)$ is irreducible modulo p then $P = pR$.

(c) Show that the picture for $\mathrm{Spec}\, R$ over $\mathrm{Spec}\, \mathbb{Z}$ for any D is similar to that for the case $R = \mathbb{Z}[i]$ when $D = -1$: there is precisely one nonclosed point $(0) \in \mathrm{Spec}\, R$ over $(0) \in \mathrm{Spec}\, \mathbb{Z}$, precisely one closed point $P \in \mathrm{Spec}\, R$ over each of the primes (p) in $\mathrm{Spec}\, \mathbb{Z}$ in (i) (called ramified primes) and over the primes in (iii) (called inert primes), and precisely two closed points over the primes in (ii) (called split primes).

Exercises (Atiyah & Macdonald).

1. Let A be a ring and let X be the set of all prime ideals of A. For each subset E of A, let $V(E)$ denote the set of all prime ideals of A which contain E. Prove that

(i) if $\mathfrak{a}$ is the ideal generated by E, then $V(E) = V(\mathfrak{a}) = V(\mathrm{rad}(\mathfrak{a}))$;

(ii) $V(0) = X$, $V(1) = \varnothing$;

(iii) if $(E_i)_{i\in I}$ is any family of subsets of A, then

$$V\Big(\bigcup_{i\in I} E_i\Big) = \bigcap_{i\in I} V(E_i);$$

(iv) $V(\mathfrak{a}\cap\mathfrak{b}) = V(\mathfrak{a}\mathfrak{b}) = V(\mathfrak{a})\cup V(\mathfrak{b})$ for any ideals $\mathfrak{a}, \mathfrak{b}$ of A.

These results show that the sets $V(E)$ satisfy the axioms for closed sets in a topological space. The resulting topology is called the *Zariski topology*. The topological space X is called the *prime spectrum* of A, and is written $\mathrm{Spec}(A)$.

2. Draw pictures of $\mathrm{Spec}(\mathbb{Z})$, $\mathrm{Spec}(\mathbb{R})$, $\mathrm{Spec}(\mathbb{C}[x])$, $\mathrm{Spec}(\mathbb{R}[x])$, $\mathrm{Spec}(\mathbb{Z}[x])$.

3. For each $f \in A$, let X_f denote the complement of $V(f)$ in $X = \mathrm{Spec}(A)$. The sets X_f are open. Show that they form a basis of open sets for the Zariski topology, and that

(i) $X_f \cap X_g = X_{fg}$;

(ii) $X_f = \varnothing \Leftrightarrow f$ is nilpotent;

(iii) $X_f = X \Leftrightarrow f$ is a unit;

(iv) $X_f = X_g \Leftrightarrow \mathrm{rad}((f)) = \mathrm{rad}((g))$;

(v) X is quasi-compact (that is, every open covering of X has a finite subcovering);

(vi) more generally, each X_f is quasi-compact;

(vii) an open subset of X is quasi-compact if and only if it is a finite union of sets X_f.

The sets X_f are called *basic open sets* of $X = \mathrm{Spec}(A)$. [To prove (v), remark that it is enough to consider a covering of X by basic open sets X_{f_i} $(i \in I)$. Show that the f_i generate the unit ideal and hence that there is an equation of the form

$$1 = \sum_{i\in J} g_i f_i \qquad (g_i \in A)$$

where J is some finite subset of I. Then the X_{f_i} $(i \in J)$ cover X.]

4. For psychological reasons it is sometimes convenient to denote a prime ideal of A by a letter such as x or y when thinking of it as a point of $X = \mathrm{Spec}(A)$. When thinking of x as a prime ideal of A, we denote it by $\mathfrak{p}_x$ (logically, of course, it is the same thing). Show that

(i) the set $\{x\}$ is closed (we say that x is a "closed point") in $\mathrm{Spec}(A) \Leftrightarrow \mathfrak{p}_x$ is maximal;

(ii) $\overline{\{x\}} = V(\mathfrak{p}_x)$;

(iii) $y \in \overline{\{x\}} \Leftrightarrow \mathfrak{p}_x \subseteq \mathfrak{p}_y$;

(iv) X is a T_0-space (this means that if x, y are distinct points of X, then either there is a neighborhood of x which does not contain y, or else there is a neighborhood of y which does not contain x).

5. A topological space X is said to be *irreducible* if $X \neq \varnothing$ and if every pair of non-empty open sets in X intersect, or equivalently if every non-empty open set is dense in X. Show that $\mathrm{Spec}(A)$ is irreducible if and only if the nilradical of A is a prime ideal.

6. Let X be a topological space.

(i) If Y is an irreducible (Exercise 19) subspace of X, then the closure $\overline{Y}$ of Y in X is irreducible.

(ii) Every irreducible subspace of X is contained in a maximal irreducible subspace.

(iii) The maximal irreducible subspaces of X are closed and cover X. They are called the *irreducible components* of X. What are the irreducible components of a Hausdorff space?

(iv) If A is a ring and $X = \mathrm{Spec}(A)$, then the irreducible components of X are the closed sets $V(\mathfrak{p})$, where $\mathfrak{p}$ is a minimal prime ideal of A (Exercise 8).

7. Let $\phi : A \to B$ be a ring homomorphism. Let $X = \mathrm{Spec}(A)$ and $Y = \mathrm{Spec}(B)$. If $\mathfrak{q} \in Y$, then $\phi^{-1}(\mathfrak{q})$ is a prime ideal of A, i.e., a point of X. Hence ϕ induces a mapping $\phi^* : Y \to X$. Show that

   (i) If $f \in A$ then $(\phi^*)^{-1}(X_f) = Y_{\phi(f)}$, and hence that ϕ^* is continuous.

   (ii) If $\mathfrak{a}$ is an ideal of A, then $(\phi^*)^{-1}(V(\mathfrak{a})) = V(\mathfrak{a}^e)$.

   (iii) If $\mathfrak{b}$ is an ideal of B, then $\overline{\phi^*(V(\mathfrak{b}))} = V(\mathfrak{b}^c)$.

   (iv) If ϕ is surjective, then ϕ^* is a homeomorphism of Y onto the closed subset $V(\mathrm{Ker}(\phi))$ of X. (In particular, $\mathrm{Spec}(A)$ and $\mathrm{Spec}(A/\mathfrak{N})$ (where $\mathfrak{N}$ is the nilradical of A) are naturally homeomorphic.)

   (v) If ϕ is injective, then $\phi^*(Y)$ is dense in X. More precisely, $\phi^*(Y)$ is dense in $X \Leftrightarrow \mathrm{Ker}(\phi) \subseteq \mathfrak{N}$.

   (vi) Let $\psi : B \to C$ be another ring homomorphism. Then $(\psi \circ \phi)^* = \phi^* \circ \psi^*$.

   (vii) Let A be an integral domain with just one non-zero prime ideal $\mathfrak{p}$, and let K be the field of fractions of A. Let $B = (A/\mathfrak{p}) \times K$. Define $\phi : A \to B$ by $\phi(x) = (\overline{x}, x)$, where $\overline{x}$ is the image of x in $A/\mathfrak{p}$. Show that ϕ^* is bijective but not a homeomorphism.

8. Let $A = \prod_{i=1}^n A_i$ be the direct product of rings A_i. Show that $\mathrm{Spec}(A)$ is the disjoint union of open (and closed) subspaces X_i, where X_i is canonically homeomorphic with $\mathrm{Spec}(A_i)$.

9. Let A be a Boolean ring (Exercise 11), and let $X = \mathrm{Spec}(A)$.

   (i) For each $f \in A$, the set X_f (Exercise 17) is both open and closed in X.

   (ii) Let $f_1, \ldots, f_n \in A$. Show that $X_{f_1} \cup \cdots \cup X_{f_n} = X_f$ for some $f \in A$.

   (iii) The sets X_f are the only subsets of X which are both open and closed. [Let $Y \subseteq X$ be both open and closed. Since Y is open, Y is a union of basic open sets X_f. Since Y is closed and X is quasi-compact (Exercise 17), Y is quasi-compact. Hence Y is a finite union of basic open sets; now use (ii) above.]

   (iv) X is a compact Hausdorff space.

10. The subspace of $\mathrm{Spec}(A)$ consisting of the maximal ideals of A, with the induced topology, is called the *maximal spectrum* of A and is denoted by $\mathrm{Max}(A)$. For arbitrary commutative rings it does not have the nice functorial properties of $\mathrm{Spec}(A)$ (see Exercise 21), because the inverse image of a maximal ideal under a ring homomorphism need not be maximal. Let X be a compact Hausdorff space and let $C(X)$ denote the ring of all real-valued continuous functions on X. For each $x \in X$, let $\mathfrak{m}_x$ be the set of all $f \in C(X)$ such that $f(x) = 0$. The ideal $\mathfrak{m}_x$ is maximal, because it is the kernel of the (surjective) homomorphism $C(X) \to \mathbb{R}$ which takes f to $f(x)$. If $\overline{X}$ denotes $\mathrm{Max}(C(X))$, we have therefore defined a mapping $\mu : X \to \overline{X}$, namely $x \mapsto \mathfrak{m}_x$. Show that μ is a homeomorphism of X onto $\overline{X}$. Thus X can be reconstructed from the ring of functions $C(X)$.

   (i) Let $\mathfrak{m}$ be any maximal ideal of $C(X)$, and let $V = V(\mathfrak{m})$ be the set of common zeros of the functions in $\mathfrak{m}$: that is, $V = \{\, x \in X \mid f(x) = 0 \text{ for all } f \in \mathfrak{m} \,\}$. Suppose that V is empty. Then for each $x \in X$ there exists $f_x \in \mathfrak{m}$ such that $f_x(x) \neq 0$. Since f_x is continuous, there is an open neighborhood U_x of x in X on which f_x does not vanish. By compactness a finite number of the neighborhoods, say $U_{x_1}, \ldots, U_{x_n}$, cover X. Let
   $$f = f_{x_1}^2 + \cdots + f_{x_n}^2.$$
   Then f does not vanish at any point of X, hence is a unit in $C(X)$. But this contradicts $f \in \mathfrak{m}$, hence V is non-empty. Let x be a point of V. Then $\mathfrak{m} \subseteq \mathfrak{m}_x$, hence $\mathfrak{m} = \mathfrak{m}_x$ because $\mathfrak{m}$ is maximal. Hence μ is surjective.

   (ii) By Urysohn's lemma (this is the only non-trivial fact required in the argument) the continuous functions separate the points of X. Hence $x \neq y \Rightarrow \mathfrak{m}_x \neq \mathfrak{m}_y$ and therefore μ is injective.

   (iii) Let $f \in C(X)$; let $U_f = \{\, x \in X \mid f(x) \neq 0 \,\}$ and let $\overline{U}_f = \{\, \mathfrak{m} \in \overline{X} \mid f \notin \mathfrak{m} \,\}$. Show that $\mu(U_f) = \overline{U}_f$. The open sets U_f (resp. $\overline{U}_f$) form a basis of the topology of X (resp. $\overline{X}$) and therefore μ is a homeomorphism.

Practice problems.

1. Let $R = k[x,y,z]/(xy, xz)$ with k a field. Compute the minimal primes of R, describe the irreducible components of $X = \operatorname{Spec} R$ geometrically (as a union of a plane and a line meeting at the origin), and decide whether X is connected and whether it is irreducible. Identify the unique generic point of each component.

2. In $R = \mathbb{Z}/180\mathbb{Z}$ list every element of $\operatorname{Spec} R$, compute the nilradical $\operatorname{nil} R$, exhibit R_{red} explicitly as a product of finite fields, and confirm that $\operatorname{Spec} R$ and $\operatorname{Spec} R_{\mathrm{red}}$ have the same underlying set with the discrete topology. State $|\operatorname{Spec} R|$ and explain why it equals the number of distinct prime divisors of 180.

3. For $R = k[x,y]$ and $f = x^2 - y^3$, decide whether (f) is prime, identify the closure $\overline{\{(f)\}}$ as a closed subset of $\operatorname{Spec} R$, and determine the closed points of $V(f)$ when k is algebraically closed. Is (f) a closed point of $\operatorname{Spec} R$? Justify using the closure-of-a-point computation.

4. Let $X = \operatorname{Spec} R$ and let $f, g \in R$. Prove directly from the definitions that $D(f) \subseteq D(g)$ if and only if $f \in \operatorname{rad}(g)$, and that $D(f) = D(f^2)$ for every f. Deduce that the map $\operatorname{rad}(g) \mapsto D(g)$ is well defined on radicals, and use this to show $D(6) = D(12)$ in $\operatorname{Spec} \mathbb{Z}$ while $D(6) \neq D(2)$.

5. Consider the localization map $\varphi\colon \mathbb{Z} \to \mathbb{Z}[1/10]$. Describe $\varphi^*\colon \operatorname{Spec} \mathbb{Z}[1/10] \to \operatorname{Spec} \mathbb{Z}$ as a subset of $\operatorname{Spec} \mathbb{Z}$, identify which primes (p) lie in the image, and verify that the image equals the basic open set $D(10)$. State the global sections $\mathcal{O}_{\operatorname{Spec}\mathbb{Z}}(D(10))$ and the stalk at (7).

6. Let $\varphi\colon R \to S$ be a ring homomorphism with induced map $\varphi^*\colon \operatorname{Spec} S \to \operatorname{Spec} R$. Prove that if φ is surjective then φ^* is a homeomorphism of $\operatorname{Spec} S$ onto the closed set $V(\ker \varphi) \subseteq \operatorname{Spec} R$, and that if φ is the localization $R \to R_f$ then φ^* is a homeomorphism of $\operatorname{Spec} R_f$ onto the open set $D(f)$. Contrast the two cases (closed immersion versus open immersion).

7. In $R = k[x]/(x^2)$ (the dual numbers), show that $\operatorname{Spec} R$ is a single point $\mathfrak{p} = (\overline{x})$, compute the value $f(\mathfrak{p}) \in R/\mathfrak{p}$ of $f = a + b\overline{x}$, and exhibit two distinct elements of R with identical values at every point of $\operatorname{Spec} R$. Identify $\operatorname{nil} R$ and R_{red}, and explain what topological information about R is lost on passing to $\operatorname{Spec} R$.

8. Let $R = \prod_{i=1}^{n} k_i$ be a finite product of fields. Prove that $\operatorname{Spec} R$ is a discrete space on n points, exhibit the nontrivial idempotents witnessing the total disconnection, and show that the basic open set $D(e_i)$ for the standard idempotent e_i is the single point corresponding to the ith factor.

Additional exercises.

1. Prove that for ideals $\mathfrak{a}, \mathfrak{b}$ of a ring R one has $V(\mathfrak{a}) \subseteq V(\mathfrak{b})$ if and only if $\operatorname{rad}\mathfrak{b} \subseteq \operatorname{rad}\mathfrak{a}$, and that $V(\mathfrak{a}) = V(\mathfrak{b})$ if and only if $\operatorname{rad}\mathfrak{a} = \operatorname{rad}\mathfrak{b}$. Conclude that V and I restrict to mutually inverse, inclusion-reversing bijections between the Zariski-closed subsets of $\operatorname{Spec} R$ and the radical ideals of R.

2. Let $X = \operatorname{Spec} R$. Prove that a closed set $V(\mathfrak{a})$ is irreducible if and only if $\operatorname{rad}\mathfrak{a}$ is a prime ideal, and deduce that the irreducible components of X are exactly the closures $V(\mathfrak{p})$ of the minimal primes $\mathfrak{p}$ of R. Apply this to $R = k[x,y]/(x^2y, xy^2)$ to list the irreducible components.

3. Let $\mathfrak{p}$ be a prime of R and let $\kappa(\mathfrak{p}) = \operatorname{Frac}(R/\mathfrak{p})$ be its residue field. For a ring map $\varphi\colon R \to S$, prove that the fiber $(\varphi^*)^{-1}(\mathfrak{p}) \subseteq \operatorname{Spec} S$ is canonically homeomorphic to $\operatorname{Spec}\bigl(S \otimes_R \kappa(\mathfrak{p})\bigr)$. Use this to compute the number of points in the fiber of $\operatorname{Spec} \mathbb{Z}[x]/(f) \to \operatorname{Spec} \mathbb{Z}$ over (p) for $f = x^2 + 1$ when $p = 2$, $p \equiv 1 \pmod 4$, and $p \equiv 3 \pmod 4$.

4. Prove that $X = \operatorname{Spec} R$ is quasi-compact: every open cover by basic open sets $\{D(g_i)\}_{i \in I}$ admits a finite subcover, by showing that $X = \bigcup_i D(g_i)$ forces $(g_i : i \in I) = R$ and extracting a finite unit relation $1 = \sum_j a_j g_{i_j}$. Then exhibit a non-Noetherian ring R and an open subset $U \subseteq \operatorname{Spec} R$ that is *not* quasi-compact.

5. Prove that $\operatorname{Spec} R$ is disconnected if and only if R contains an idempotent e with $e \neq 0, 1$, by showing that a clopen decomposition $\operatorname{Spec} R = D(e) \sqcup D(1-e)$ corresponds to a ring decomposition $R \cong Re \times R(1-e)$. Deduce that the spectrum of any local ring or any integral domain is connected.

Commutative-diagram exercises.

1. Let R be a ring and $\mathfrak{a}$ an ideal, with quotient $\pi\colon R \twoheadrightarrow R/\mathfrak{a}$ and localization $\lambda\colon R \to R_f$. Complete the diagram below, in which the bottom row records the geometric pieces of $\operatorname{Spec} R$ cut out by these two algebraic operations. Prove that π^* is a homeomorphism onto the closed set $V(\mathfrak{a})$ and that λ^* is a homeomorphism onto the open set $D(f)$.

$$\begin{array}{ccccc} R/\mathfrak{a} & \xleftarrow{\ \pi\ } & R & \xrightarrow{\ \lambda\ } & R_f \\ \downarrow & & \downarrow & & \downarrow \\ V(\mathfrak{a}) & \xrightarrow[\ \pi^*\ ]{} & \operatorname{Spec} R & \xleftarrow{\ \lambda^*\ } & D(f) \end{array}$$

   Label the horizontal maps of the bottom row as closed immersion and open immersion respectively, and state the image of each.

2. For ring maps $\varphi\colon R \to S$ and $\psi\colon S \to T$, complete the triangle of induced spectrum maps below and prove that Spec is a contravariant functor, i.e. that $(\psi \circ \varphi)^* = \varphi^* \circ \psi^*$ and $\mathrm{id}^* = \mathrm{id}$. Prove also that each arrow is continuous by showing $(\varphi^*)^{-1}(D(f)) = D(\varphi(f))$.

$$\begin{array}{ccc} \operatorname{Spec} T & \xrightarrow{\ \psi^*\ } & \operatorname{Spec} S \\ & {\scriptstyle (\psi\circ\varphi)^*}\searrow & \downarrow{\scriptstyle \varphi^*} \\ & & \operatorname{Spec} R \end{array}$$

   Verify the identity explicitly for $R = \mathbb{Z} \hookrightarrow S = \mathbb{Z}[i] \hookrightarrow T = \mathbb{Z}[i, 1/(1+i)]$ by tracing the point $(0) \in \operatorname{Spec} T$.

3. Let $\mathfrak{p} \in \operatorname{Spec} R$ and consider the localization $R \to R_{\mathfrak{p}}$ together with the residue field $\kappa(\mathfrak{p}) = R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}} = \operatorname{Frac}(R/\mathfrak{p})$. Complete the square below relating the two ways of forming the residue field at $\mathfrak{p}$ (localize then quotient, versus quotient then localize), and prove it commutes; conclude that both routes produce the same field $\kappa(\mathfrak{p})$.

$$\begin{array}{ccc} R & \xrightarrow{\text{localize at } \mathfrak{p}} & R_{\mathfrak{p}} \\ {\scriptstyle \text{quotient by } \mathfrak{p}}\downarrow & & \downarrow{\scriptstyle \text{quotient by } \mathfrak{p}R_{\mathfrak{p}}} \\ R/\mathfrak{p} & \xrightarrow[\text{localize at } (0)]{} & \kappa(\mathfrak{p}) \end{array}$$

   Identify the stalk $\mathcal{O}_{\operatorname{Spec} R,\mathfrak{p}}$ of the structure sheaf at $\mathfrak{p}$ with $R_{\mathfrak{p}}$, and verify the diagram for $R = \mathbb{Z}$, $\mathfrak{p} = (5)$, computing $\kappa((5))$ and $\mathcal{O}_{\operatorname{Spec}\mathbb{Z},(5)}$.

4. Let $f = x^3 - x - 1 \in \mathbb{Z}[x]$ and view $V(f) \subseteq \operatorname{Spec}\mathbb{Z}[x]$ as fibered over $\operatorname{Spec}\mathbb{Z}$ via the inclusion $\mathbb{Z} \hookrightarrow \mathbb{Z}[x]$. Complete the diagram below, in which the fiber over (p) is identified with $\operatorname{Spec}\big(\mathbb{F}_p[x]/(\overline{f})\big)$, and prove the induced map is a homeomorphism onto the fiber. Use it to count the closed points of the fiber over (2), (3), and (23) from the factorization type of $\overline{f}$ in $\mathbb{F}_p[x]$.

$$\begin{array}{ccc} \operatorname{Spec}\big(\mathbb{F}_p[x]/(\overline{f})\big) & \hookrightarrow & \operatorname{Spec}\big(\mathbb{Z}[x]/(f)\big) \\ \downarrow & & \downarrow{\scriptstyle \varphi^*} \\ \operatorname{Spec}\mathbb{F}_p & \hookrightarrow & \operatorname{Spec}\mathbb{Z} \end{array}$$

   State the number of distinct irreducible factors of $\overline{f}$ over each of $\mathbb{F}_2, \mathbb{F}_3, \mathbb{F}_{23}$ and confirm it equals the number of closed points in the corresponding fiber.

15.9 Completions, Filtrations, and Graded Rings

Filtrations and the topology they generate

Completion, like localization, is a device for *simplifying a ring near a point.* Localization concentrates near a prime by inverting everything outside it; completion concentrates near an ideal $\mathfrak{a}$ by remembering an element

only through its successive residues modulo $\mathfrak{a}, \mathfrak{a}^2, \mathfrak{a}^3, \dots$. Geometrically this is the passage from a polynomial to its Taylor expansion at a point; arithmetically it is the passage from an integer to its base-p digits, i.e. to its image in all the rings $\mathbb{Z}/p^n\mathbb{Z}$. Atiyah–Macdonald's organizing slogan is that the prime ideal is the common generalization of "a point of geometry" and "a prime of arithmetic," and the $\mathfrak{a}$-adic completion treats both uniformly: the local ring of a nonsingular point of an n-dimensional variety completes to the power series ring $k[[x_1, \dots, x_n]]$, while $\mathbb{Z}$ completed at (p) gives the p-adic integers $\mathbb{Z}_p$.

The technical engine is a *filtration*: a descending chain of subgroups that we declare to be a fundamental system of neighborhoods of 0.

Definition 15.9.1 (topology from a filtration of subgroups)**.** Let G be an abelian group equipped with a descending chain of subgroups

$$G = G_0 \supseteq G_1 \supseteq G_2 \supseteq \cdots \supseteq G_n \supseteq \cdots .$$

Declare the cosets $\{\, g + G_n : g \in G,\ n \geq 0 \,\}$ to be a base of open sets. This makes G a topological abelian group: 0 has the G_n as a fundamental system of neighborhoods, and addition and negation are continuous. Each G_n is simultaneously *open* (it is a neighborhood of each of its points g, since $g + G_n \subseteq G_n$) and *closed* (its complement is the union of the open cosets $h + G_n$, $h \notin G_n$).

Definition 15.9.2 ($\mathfrak{a}$-adic topology)**.** Let R be a ring and $\mathfrak{a} \subseteq R$ an ideal. The $\mathfrak{a}$-*adic filtration* is $G_n = \mathfrak{a}^n$ (with $\mathfrak{a}^0 = R$); the resulting topology is the $\mathfrak{a}$-*adic topology* on R. For an R-module M, the $\mathfrak{a}$-*adic topology* on M comes from the filtration $G_n = \mathfrak{a}^n M$. An element is "small" when it lies in a high power of $\mathfrak{a}$.

The single most important Hausdorffness criterion is purely algebraic. By Lemma 15.9.3 (below) the intersection of all neighborhoods of 0 is a subgroup, and a coset-based topology is Hausdorff exactly when points are separated from 0.

Lemma 15.9.3 (intersection of neighborhoods)**.** *Let $H = \bigcap_n G_n$ be the intersection of all neighborhoods of 0 in a filtered abelian group G. Then*

(i) *H is a subgroup;*

(ii) *H is the closure $\overline{\{\,0\,\}}$ of $\{\,0\,\}$;*

(iii) *G/H is Hausdorff;*

(iv) *G is Hausdorff $\iff$ $H = 0$, i.e. $\iff$ $\bigcap_n G_n = 0$.*

Idea. Continuity of the group operations gives (i). For (ii), $x \in \overline{\{\,0\,\}}$ iff every neighborhood $x + G_n$ of x meets $\{\,0\,\}$, i.e. $-x \in G_n$ for all n, i.e. $x \in H$. Since the cosets of H are exactly the closures of points, they are all closed in G/H, so G/H is Hausdorff, giving (iii); and (iv) is (iii) read at $H = 0$. □

Worked Example 15.9.4 (The p-adic topology on $\mathbb{Z}$ is Hausdorff)**.** For a prime p show that the (p)-adic topology on $\mathbb{Z}$ satisfies $\bigcap_n p^n\mathbb{Z} = 0$, hence is Hausdorff.

Recognition. Hausdorff $\iff$ $\bigcap_n G_n = 0$ with $G_n = p^n\mathbb{Z}$; reduce to: no nonzero integer is divisible by every power of p.

Solution. If $m \in \bigcap_n p^n\mathbb{Z}$ then $p^n \mid m$ for all n. A nonzero integer has finitely many prime factors with finite multiplicities, so $p^n \nmid m$ once $p^n > |m|$. Hence $m = 0$ and $\bigcap_n p^n\mathbb{Z} = 0$, so the topology is Hausdorff by Lemma 15.9.3(iv). Sanity check: the distance $|m|_p = p^{-v_p(m)}$ is a genuine metric precisely because $v_p(m) < \infty$ for $m \neq 0$, matching the vanishing intersection.

Worked Example 15.9.5 (A non-Hausdorff adic topology)**.** Let $R = k[x]_{(x)} \times k$ with $\mathfrak{a} = \mathfrak{m} \times k$ where $\mathfrak{m} = xk[x]_{(x)}$. Exhibit $\bigcap_n \mathfrak{a}^n \neq 0$.

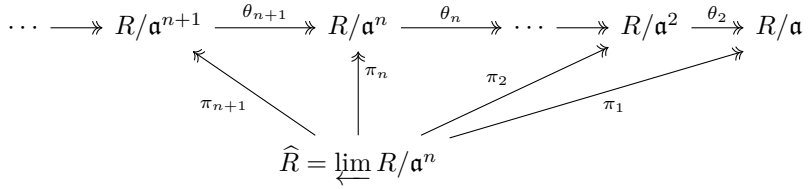
Recognition. Hausdorffness can fail when $\mathfrak{a}$ contains an idempotent-like direction killing no power; the intersection $\bigcap \mathfrak{a}^n$ measures the failure.

Solution. With $\mathfrak{a} = \mathfrak{m} \times k$ we have $\mathfrak{a}^n = \mathfrak{m}^n \times k$ (since $k \cdot k = k$), so $\bigcap_n \mathfrak{a}^n = \left(\bigcap_n \mathfrak{m}^n\right) \times k = 0 \times k \neq 0$. The topology is not Hausdorff: the whole subgroup $0 \times k$ is in the closure of 0. Sanity check: the offending factor k is a field on which $\mathfrak{a}$ acts as the unit ideal, so no power of $\mathfrak{a}$ shrinks it – exactly the obstruction Krull's theorem (below) rules out under Jacobson-radical hypotheses.

Completion as an inverse limit

A Cauchy sequence in the filtration topology is a sequence (x_ν) with $x_\mu - x_\nu \in G_n$ for all μ, ν large (depending on n); two are equivalent if $x_\nu - y_\nu \to 0$. The set $\widehat{G}$ of equivalence classes is again an abelian group, and there is a canonical map $\phi\colon G \to \widehat{G}$ sending x to the class of the constant sequence, with $\ker\phi = \bigcap_n G_n$. So ϕ is injective exactly when G is Hausdorff. A&M's insight is that this analytic picture has a purely algebraic shadow: a Cauchy sequence, projected into each G/G_n, becomes a *coherent sequence*, and chasing coherent sequences avoids any choice of metric.

Definition 15.9.6 (inverse limit and completion)**.** An *inverse system* of abelian groups is a sequence $(A_n)_{n\geq 0}$ with homomorphisms $\theta_{n+1}\colon A_{n+1} \to A_n$. Its *inverse limit* is



$$\varprojlim A_n = \{\, (a_n) \in \textstyle\prod_n A_n :\ \theta_{n+1}(a_{n+1}) = a_n \text{ for all } n \,\},$$

the group of *coherent sequences*. For a filtered group G with the system $G/G_{n+1} \to G/G_n$ (the natural surjections), the *completion* is

$$\widehat{G} \;=\; \varprojlim_n G/G_n.$$

For a ring R with $G_n = \mathfrak{a}^n$ this is the ring $\widehat{R} = \varprojlim R/\mathfrak{a}^n$; for a module, $\widehat{M} = \varprojlim M/\mathfrak{a}^n M$, an $\widehat{R}$-module.

The tower of quotients whose limit is the completion is the central diagram of the whole section:

Each θ_{n+1} is the reduction $R/\mathfrak{a}^{n+1} \twoheadrightarrow R/\mathfrak{a}^n$ (a *surjective* system), and $\widehat{R}$ sits over the tower compatibly with all projections $\pi_n\colon \widehat{R} \to R/\mathfrak{a}^n$. A point of $\widehat{R}$ is precisely a system of "residues to every order" that fit together.

Diagram explanation. Objects: The top row consists of a tower of quotient rings $R/\mathfrak{a}^n$ for $n = 1, 2, \ldots$ (each is a ring, not merely a set; it records the residue of every element modulo $\mathfrak{a}^n$). The bottom vertex is $\widehat{R} = \varprojlim R/\mathfrak{a}^n$, the $\mathfrak{a}$-adic completion of R: it is also a ring (the inverse limit inherits the ring structure coordinatewise from the product $\prod_n R/\mathfrak{a}^n$). These are connected in a directed fan: one row going right, one vertex projecting up.

Arrows: Each horizontal arrow $\theta_{n+1}\colon R/\mathfrak{a}^{n+1} \twoheadrightarrow R/\mathfrak{a}^n$ is the *natural surjective ring homomorphism* (reduction mod $\mathfrak{a}^n$): it sends $a + \mathfrak{a}^{n+1}$ to $a + \mathfrak{a}^n$, which is well-defined since $\mathfrak{a}^{n+1} \subseteq \mathfrak{a}^n$. Each $\pi_n\colon \widehat{R} \to R/\mathfrak{a}^n$ is the *projection onto the n-th stage*: it sends the coherent sequence $(a_m)_{m\geq 1}$ to a_n. These are the canonical maps from the inverse limit to its factors.

What commutes: For every n, the triangle $\widehat{R} \xrightarrow{\pi_{n+1}} R/\mathfrak{a}^{n+1} \xrightarrow{\theta_{n+1}} R/\mathfrak{a}^n$ commutes with the projection π_n:

$$\theta_{n+1} \circ \pi_{n+1} = \pi_n.$$

In other words, reducing a coherent sequence one level and then projecting equals projecting directly. This is not one equation but a whole compatible family, one for each consecutive pair $(n, n+1)$.

Why it commutes: Let $(a_m) \in \widehat{R}$ be a coherent sequence, so $\theta_{m+1}(a_{m+1}) = a_m$ for all m. Following the first path: $\pi_{n+1}(a_m) = a_{n+1}$, then $\theta_{n+1}(a_{n+1}) = a_n$. Following π_n: $(a_m) \mapsto a_n$. Both give a_n. The equality holds by the *definition* of a coherent sequence: the coherence condition $\theta_{n+1}(a_{n+1}) = a_n$ is exactly what living in the inverse limit means. No separate argument is needed; the commutativity is built into the membership criterion of $\varprojlim R/\mathfrak{a}^n$.

Why this matters here: This diagram is the *definition* made visual. The text has just defined $\widehat{R}$ as the subgroup of $\prod R/\mathfrak{a}^n$ consisting of coherent sequences; the diagram encodes the universal property of $\varprojlim$: every

ring fitting over the entire tower compatibly maps uniquely into $\widehat{R}$ compatibly with the projections, which determines $\widehat{R}$ up to unique isomorphism. Every subsequent result in this section – exactness of completion, flatness of $\widehat{R}$, and Noetherianity – is proved by leveraging this tower structure and the surjectivity of the system (θ_{n+1}).

Concrete example: Take $R = \mathbb{Z}$ and $\mathfrak{a} = (p)$. Then $R/\mathfrak{a}^n = \mathbb{Z}/p^n\mathbb{Z}$, each θ_{n+1} reduces a residue mod p^{n+1} to a residue mod p^n (drop the top digit in base p), and $\widehat{R} = \mathbb{Z}_p$ is the ring of p-adic integers. A point of $\mathbb{Z}_p$ is a coherent sequence $(a_1, a_2, a_3, \dots)$ with $a_n \in \mathbb{Z}/p^n\mathbb{Z}$ and $a_{n+1} \equiv a_n \pmod{p^n}$, exactly a formal series $\sum_{k\geq 0} c_k p^k$. The projections π_n send this series to its partial sum mod p^n.

Common pitfall: Students often read $\widehat{R}$ as sitting *below* the tower because the arrows π_n point upward in the diagram, and conclude that $\widehat{R}$ is a quotient of the $R/\mathfrak{a}^n$. It is the opposite: $\widehat{R}$ is a *subring* of $\prod R/\mathfrak{a}^n$, with each π_n a surjection onto $R/\mathfrak{a}^n$ (not an injection). Concretely, $\mathbb{Z}_p \twoheadrightarrow \mathbb{Z}/p^n\mathbb{Z}$ is onto with kernel $p^n\mathbb{Z}_p$ – information is *lost* by projection, never gained.

Takeaway: The point of this diagram is that the completion $\widehat{R}$ is not merely the limit of an algebraic process but the universal ring sitting compatibly over the entire tower of finite-order approximations $R/\mathfrak{a}^n$, so that knowing $\widehat{R}$ is equivalent to knowing all residues of every element to every order simultaneously.

Remark 15.9.1. The inverse-limit description does not depend on a metric and is manifestly functorial: a filtration-compatible homomorphism $f\colon G \to H$ (with $f(G_n) \subseteq H_n$) induces $\widehat{f}\colon \widehat{G} \to \widehat{H}$ on coherent sequences, and $\widehat{g \circ f} = \widehat{g} \circ \widehat{f}$. The only drawback is that this description presupposes a choice of filtration (G_n); the completion itself depends only on the topology, since two filtrations defining the same topology are cofinal in each other and so have the same inverse limit (for instance all stable $\mathfrak{a}$-filtrations, Lemma 15.9.17 below).

Worked Example 15.9.7 (The p-adic integers $\mathbb{Z}_p$)**.** Identify $\widehat{\mathbb{Z}} = \varprojlim \mathbb{Z}/p^n\mathbb{Z}$ and describe its elements.

Recognition. $\widehat{\mathbb{Z}}$ is the inverse limit of the tower $\cdots \to \mathbb{Z}/p^3 \to \mathbb{Z}/p^2 \to \mathbb{Z}/p$; an element is a coherent sequence of residues.

Solution. An element of $\mathbb{Z}_p := \varprojlim \mathbb{Z}/p^n\mathbb{Z}$ is a sequence (a_n) with $a_n \in \mathbb{Z}/p^n\mathbb{Z}$ and $a_{n+1} \equiv a_n \pmod{p^n}$. Writing a_n in base p, coherence means the digits stabilize, so each element is a formal series $\sum_{k\geq 0} c_k p^k$ with $0 \leq c_k < p$ – a "p-adic integer." Addition and multiplication carry as in base-p arithmetic. Sanity check: the constant sequences embed $\mathbb{Z} \hookrightarrow \mathbb{Z}_p$ (injective since $\bigcap p^n\mathbb{Z} = 0$), and $1 + p + p^2 + \cdots$ converges to $(1-p)^{-1}$ because $(1-p)\sum_{k=0}^{N} p^k = 1 - p^{N+1} \to 1$ in the p-adic topology.

Worked Example 15.9.8 (Formal power series $k[[x]]$ as a completion)**.** For $R = k[x]$ and $\mathfrak{a} = (x)$, identify $\widehat{R}$.

Recognition. $\widehat{R} = \varprojlim k[x]/(x^n)$; a coherent sequence is a polynomial specified to all orders, i.e. a power series.

Solution. $k[x]/(x^n)$ is the ring of polynomials of degree $< n$ (truncation), and the maps drop the top term. A coherent sequence assigns to each n a polynomial mod x^n with the lower terms agreeing, hence a formal series $\sum_{k\geq 0} a_k x^k$. Thus $\widehat{k[x]} = k[[x]]$, the ring of formal power series. Sanity check: $\bigcap_n (x)^n = 0$ in $k[x]$ (a nonzero polynomial has finite order of vanishing), so $k[x] \hookrightarrow k[[x]]$ injectively, and $1 - x$ is a unit in $k[[x]]$ with inverse $\sum x^k$, mirroring $(1-p)^{-1}$ above.

Worked Example 15.9.9 (Completion of $k[x_1, \dots, x_n]$ at the origin)**.** Compute $\widehat{R}$ for $R = k[x_1, \dots, x_n]$, $\mathfrak{a} = (x_1, \dots, x_n)$.

Recognition. The geometric picture: completing the polynomial ring at the maximal ideal of the origin should give multivariate Taylor expansions.

Solution. $R/\mathfrak{a}^m$ is spanned by monomials of total degree $< m$, and the system truncates total degree. A coherent sequence is a formal sum of monomials of all degrees, so $\widehat{R} = k[[x_1, \dots, x_n]]$, the formal power series ring in n variables. Sanity check: this matches the slogan that the local ring of a smooth point of an n-dimensional variety completes to $k[[x_1, \dots, x_n]]$; here the "variety" is $\mathbb{A}^n$ and the point is the origin, smooth of dimension n.

Worked Example 15.9.10 ($\widehat{R}$ over the completion functor is functorial and forgets nothing finite)**.** Show $\pi_n\colon \widehat{R} \to R/\mathfrak{a}^n$ is surjective with kernel $\widehat{\mathfrak{a}^n} = \ker(\widehat{R} \to R/\mathfrak{a}^n)$, and $\widehat{R}/\widehat{\mathfrak{a}^n} \cong R/\mathfrak{a}^n$.

Recognition. Surjectivity of an inverse limit onto a finite stage uses that the system $R/\mathfrak{a}^m \to R/\mathfrak{a}^n$ $(m \geq n)$ is surjective; the kernel is the coherent sequences vanishing mod $\mathfrak{a}^n$.

Solution. Given $\bar{a} \in R/\mathfrak{a}^n$, lift it to $a \in R$; its constant coherent sequence projects to $\bar{a}$, so π_n is onto. The kernel consists of coherent sequences (a_m) with $a_n = 0$, which is exactly $\widehat{\mathfrak{a}^n}$. Hence $\widehat{R}/\widehat{\mathfrak{a}^n} \cong R/\mathfrak{a}^n$. Sanity check: with $R = \mathbb{Z}$, $\mathfrak{a} = (p)$ this says $\mathbb{Z}_p/p^n\mathbb{Z}_p \cong \mathbb{Z}/p^n\mathbb{Z}$ – completing does not change any finite-order residue information.

Exactness of completion and flatness

The reason completion is a powerful tool is that, restricted to finitely generated modules over a Noetherian ring, it is *exact*, and the functor $M \mapsto \widehat{M}$ is realized by tensoring with the flat algebra $\widehat{R}$. This is the analogue, for completion, of the fact that localization $S^{-1}(-)$ is exact and flat. The proof rests on a structural property of surjective inverse systems and on the Artin–Rees lemma.

Proposition 15.9.11 (exactness for surjective systems)**.** *If $0 \to (A_n) \to (B_n) \to (C_n) \to 0$ is an exact sequence of inverse systems (compatible exact sequences at each level), then*

$$0 \to \varprojlim A_n \to \varprojlim B_n \to \varprojlim C_n$$

is always exact. If moreover (A_n) is a surjective *system (each $\theta_{n+1}\colon A_{n+1} \to A_n$ is onto), then $\varprojlim A_n \to \varprojlim B_n \to \varprojlim C_n \to 0$ is exact too, so the whole sequence of limits is short exact.*

Idea. Assemble the levelwise maps into $d^A\colon \prod A_n \to \prod A_n$, $d^A(a_n) = a_n - \theta_{n+1}(a_{n+1})$; then $\varprojlim A_n = \ker d^A$ and $\operatorname{coker} d^A = \varprojlim{}^1 A_n$. The snake lemma applied to the commutative ladder gives the six-term sequence $0 \to \varprojlim A \to \varprojlim B \to \varprojlim C \to \varprojlim{}^1 A \to \cdots$. When (A_n) is surjective, d^A is onto, so $\varprojlim{}^1 A_n = 0$ and right-exactness follows. The filtration systems $R/\mathfrak{a}^n$ are surjective, so this case always applies. □

Proposition 15.9.12 ($\mathfrak{a}$-adic completion is exact on f.g. modules over Noetherian R)**.** *Let R be Noetherian and let $0 \to M' \to M \to M'' \to 0$ be exact with all modules finitely generated. Then the sequence of $\mathfrak{a}$-adic completions*

$$0 \to \widehat{M'} \to \widehat{M} \to \widehat{M''} \to 0$$

is exact.

Idea. The filtration $\{\, (\mathfrak{a}^n M) \cap M' \,\}$ on M' is, by Artin–Rees (below), a *stable* $\mathfrak{a}$-filtration of M', hence equivalent to $\{\, \mathfrak{a}^n M' \,\}$ and giving the same completion $\widehat{M'}$. With this identification the systems $(M'/(\mathfrak{a}^n M \cap M'))$, $(M/\mathfrak{a}^n M)$, $(M''/\mathfrak{a}^n M'')$ form a short exact sequence of inverse systems whose left term is surjective, so taking $\varprojlim$ is exact by the previous proposition. □

Proposition 15.9.13 ($\widehat{R}$ is flat)**.** *Let R be Noetherian, $\widehat{R}$ its $\mathfrak{a}$-adic completion. For every finitely generated R-module M the natural map $\widehat{R} \otimes_R M \to \widehat{M}$ is an isomorphism, and consequently $\widehat{R}$ is a* flat *R-module.*

Idea. For $M = R^n$ both sides are $\widehat{R}^{\,n}$ and the map is the identity. A finite presentation $R^p \to R^q \to M \to 0$ gives, after applying the right-exact $\widehat{R} \otimes_R (-)$ and the exact $\widehat{(-)}$ (Proposition 15.9.12), a diagram whose first two vertical maps are isomorphisms; the five lemma makes $\widehat{R} \otimes_R M \to \widehat{M}$ an isomorphism. Flatness then follows because $\widehat{(-)}$ is exact on finitely generated modules and the comparison is natural. □

Worked Example 15.9.14 (Completion of an ideal versus the completed ideal)**.** For R Noetherian and an ideal $\mathfrak{b} \subseteq R$, show $\widehat{\mathfrak{b}} \cong \widehat{R} \otimes_R \mathfrak{b} \cong \widehat{R}\,\mathfrak{b}$, the ideal of $\widehat{R}$ generated by $\mathfrak{b}$.

Recognition. Apply flatness (Proposition 15.9.13) to the finitely generated module $\mathfrak{b}$ and the inclusion $\mathfrak{b} \hookrightarrow R$.

Solution. Tensoring $0 \to \mathfrak{b} \to R$ with the flat $\widehat{R}$ keeps it injective, so $\widehat{R} \otimes_R \mathfrak{b} \hookrightarrow \widehat{R}$ has image the $\widehat{R}$-submodule generated by $\mathfrak{b}$, i.e. $\widehat{R}\mathfrak{b}$. By Proposition 15.9.13, $\widehat{R} \otimes_R \mathfrak{b} \cong \widehat{\mathfrak{b}}$. Hence $\widehat{\mathfrak{b}} = \widehat{R}\mathfrak{b}$. Sanity check: with $R = \mathbb{Z}$, $\mathfrak{b} = (p^k)$, $\mathfrak{a} = (p)$ this reads $\widehat{(p^k)} = p^k\mathbb{Z}_p$, and indeed the completion of $p^k\mathbb{Z}$ is the elements of $\mathbb{Z}_p$ divisible by p^k.

Worked Example 15.9.15 ($\widehat{\mathfrak{a}^n} = \widehat{\mathfrak{a}}^n$ and the topology of $\widehat{R}$)**.** For R Noetherian, show $(\mathfrak{a}^n)\widehat{\ } = \widehat{\mathfrak{a}}^n$ and that $\widehat{R}$ is $\widehat{\mathfrak{a}}$-adically complete with $\bigcap_n \widehat{\mathfrak{a}}^n = 0$.

Recognition. Use flatness/identities $\widehat{\mathfrak{a}^n} = \widehat{R}\mathfrak{a}^n = (\widehat{R}\mathfrak{a})^n = \widehat{\mathfrak{a}}^n$, then $\widehat{R}/\widehat{\mathfrak{a}}^n \cong R/\mathfrak{a}^n$.

Solution. By the previous example $\widehat{\mathfrak{a}^n} = \widehat{R}\mathfrak{a}^n = (\widehat{R}\mathfrak{a})^n = \widehat{\mathfrak{a}}^n$. Since $\widehat{R}/\widehat{\mathfrak{a}}^n = \widehat{R}/\widehat{\mathfrak{a}^n} \cong R/\mathfrak{a}^n$, the completion of $\widehat{R}$ for its $\widehat{\mathfrak{a}}$-topology is $\varprojlim \widehat{R}/\widehat{\mathfrak{a}}^n = \varprojlim R/\mathfrak{a}^n = \widehat{R}$, so $\widehat{R}$ is complete. And $\bigcap_n \widehat{\mathfrak{a}}^n = \ker(\widehat{R} \to \varprojlim R/\mathfrak{a}^n) = 0$, so $\widehat{R}$ is Hausdorff. Sanity check: $\widehat{R}$ is its own completion (idempotence of completion), exactly as $\mathbb{Z}_p$ completed at p is again $\mathbb{Z}_p$.

Stable filtrations and the Artin–Rees lemma

The technical heart making everything above work is the comparison of two filtrations on a submodule. The right notion is *stability*.

Definition 15.9.16 ($\mathfrak{a}$-filtration, stable)**.** An $\mathfrak{a}$-*filtration* of an R-module M is a chain $M = M_0 \supseteq M_1 \supseteq \cdots$ with $\mathfrak{a}M_n \subseteq M_{n+1}$ for all n. It is *stable* if $\mathfrak{a}M_n = M_{n+1}$ for all sufficiently large n. The $\mathfrak{a}$-adic filtration $M_n = \mathfrak{a}^n M$ is stable.

Lemma 15.9.17 (stable filtrations have bounded difference)**.** *Any two stable* $\mathfrak{a}$*-filtrations* $(M_n), (M'_n)$ *of* M *have* bounded difference*: there is* n_0 *with* $M_{n+n_0} \subseteq M'_n$ *and* $M'_{n+n_0} \subseteq M_n$ *for all* $n \geq 0$*. In particular all stable* $\mathfrak{a}$*-filtrations determine the same topology – the* $\mathfrak{a}$*-adic topology – and hence the same completion.*

Idea. It suffices to compare (M_n) with $(\mathfrak{a}^n M)$. From $\mathfrak{a}M_n \subseteq M_{n+1}$ one gets $\mathfrak{a}^n M \subseteq M_n$; stability $\mathfrak{a}M_n = M_{n+1}$ for $n \geq n_0$ gives $M_{n+n_0} = \mathfrak{a}^n M_{n_0} \subseteq \mathfrak{a}^n M$. The two inclusions are the bounded-difference statement. □

The deep input is that intersecting a stable filtration with a submodule stays stable. Over a Noetherian ring this is the Artin–Rees lemma, proved by passing to the graded ring (next subsection).

Theorem 15.9.18 (Artin–Rees lemma)**.** *Let* R *be Noetherian,* $\mathfrak{a} \subseteq R$ *an ideal,* M *a finitely generated* R*-module with a stable* $\mathfrak{a}$*-filtration* (M_n)*, and* $M' \subseteq M$ *a submodule. Then* $(M' \cap M_n)$ *is a stable* $\mathfrak{a}$*-filtration of* M'*. Equivalently, there is an integer* k *with*

$$(\mathfrak{a}^n M) \cap M' = \mathfrak{a}^{n-k}\big((\mathfrak{a}^k M) \cap M'\big) \qquad \text{for all } n \geq k.$$

Idea. Form the *Rees algebra* $R^* = \bigoplus_{n \geq 0} \mathfrak{a}^n = R[\mathfrak{a}t] \subseteq R[t]$; since R is Noetherian and $\mathfrak{a}$ finitely generated, R^* is Noetherian. The stable filtration makes $M^* = \bigoplus_n M_n$ a finitely generated graded R^*-module, and $(M' \cap M_n)$ defines a graded R^*-submodule of M^*. A submodule of a finitely generated module over a Noetherian ring is finitely generated, and for graded modules finite generation is equivalent to the filtration being stable (Lemma 15.9.25). Hence $(M' \cap M_n)$ is stable. □

Theorem 15.9.19 (topology comparison)**.** *With* $R, \mathfrak{a}, M$ *as above and* $M' \subseteq M$ *finitely generated, the filtrations* $(\mathfrak{a}^n M')$ *and* $(\mathfrak{a}^n M \cap M')$ *of* M' *have bounded difference. In particular the* $\mathfrak{a}$*-adic topology of* M' coincides *with the subspace topology induced from the* $\mathfrak{a}$*-adic topology of* M*.*

This is exactly the input identifying $\widehat{M'}$ inside $\widehat{M}$ that made Proposition 15.9.12 work.

Worked Example 15.9.20 (Artin–Rees fails without Noetherian: a non-stable intersection)**.** Illustrate that, over a non-Noetherian ring, $(\mathfrak{a}^n M \cap M')$ need not be $\mathfrak{a}$-stable, by recalling A&M's C^∞ example in spirit.

Recognition. Artin–Rees needs R Noetherian (to make the Rees algebra Noetherian); drop it and the comparison of topologies can break.

Solution. Let R be the ring of C^∞ functions on $\mathbb{R}$ and $\mathfrak{a}$ the ideal of functions vanishing at 0. Take $M = R$ and $M' = (h)$ with $h = e^{-1/x^2}$ (extended by 0). Since $\mathfrak{a} = (x)$ (Hadamard's lemma, see below) and $h = x^n \cdot (h/x^n)$ with h/x^n again smooth, $h \in \mathfrak{a}^n$ for every n, so $\mathfrak{a}^n \cap M' = M'$ for all n (in particular $\bigcap_n \mathfrak{a}^n \neq 0$: the $\mathfrak{a}$-adic topology is not Hausdorff). If this filtration were $\mathfrak{a}$-stable we would get $\mathfrak{a}M' = M'$, i.e. $h = xgh$ for some $g \in R$; then $g(x) = 1/x$ wherever $h(x) \neq 0$, i.e. for all $x \neq 0$, which is unbounded near 0 – impossible. So $(\mathfrak{a}^n \cap M')$ is not stable, and the subspace topology on M' (indiscrete) differs from its $\mathfrak{a}$-adic topology ($h \notin \mathfrak{a}M'$). Non-Hausdorffness alone would not show this: $E = \bigcap_n \mathfrak{a}^n$ satisfies $\mathfrak{a}E = E$, since a flat f equals

$x \cdot (f/x)$ with f/x again flat. Sanity check: $R/\mathfrak{a} \cong \mathbb{R}$ shows $\mathfrak{a}$ is maximal (and by Hadamard's lemma even principal, $\mathfrak{a} = (x)$), yet R is not Noetherian – e.g. the ideal of functions flat at 0 is not finitely generated – so the Noetherian hypothesis of Theorem 15.9.18 fails and the Artin–Rees comparison is unavailable.

Worked Example 15.9.21 (Artin–Rees on $\mathbb{Z}$)**.** For $R = \mathbb{Z}$, $\mathfrak{a} = (p)$, $M = \mathbb{Z}$, $M' = (m)$ with $p \nmid m$, find k in the Artin–Rees identity.

Recognition. Compute $(p^n\mathbb{Z}) \cap m\mathbb{Z}$ and compare with $p^{n-k}\big((p^k\mathbb{Z}) \cap m\mathbb{Z}\big)$.

Solution. Since $\gcd(p^n, m) = 1$, $(p^n\mathbb{Z}) \cap m\mathbb{Z} = p^n m\mathbb{Z} = \operatorname{lcm}(p^n, m)\mathbb{Z}$. Then $p^{n-k}\big((p^k\mathbb{Z}) \cap m\mathbb{Z}\big) = p^{n-k} \cdot p^k m\mathbb{Z} = p^n m\mathbb{Z}$, which agrees for every $n \geq k$ already with $k = 0$. Sanity check: when $\mathfrak{a}$ and M' are "transverse" ($\mathfrak{a}^k M \cap M' = \mathfrak{a}^k M'$ at $k = 0$) the filtration $(M' \cap \mathfrak{a}^n M) = (\mathfrak{a}^n M')$ exactly, the cleanest possible case of bounded difference.

Worked Example 15.9.22 (A nontrivial Artin–Rees constant)**.** In $R = k[x, y]$, $\mathfrak{a} = (x, y)$, $M = R$, $M' = (x)$, compare $(\mathfrak{a}^n) \cap (x)$ with $\mathfrak{a}^{n-1}\big(\mathfrak{a} \cap (x)\big)$.

Recognition. (x) is generated by the degree-1 element x; intersecting with $\mathfrak{a}^n$ should recover $x \cdot \mathfrak{a}^{n-1}$ for $n \geq 1$.

Solution. An element of $(\mathfrak{a}^n) \cap (x)$ is $x \cdot g$ lying in $\mathfrak{a}^n = (x, y)^n$. Since x has degree 1, $xg \in \mathfrak{a}^n \iff g \in \mathfrak{a}^{n-1}$ (as (x, y) is graded and x is a nonzerodivisor of degree 1). Hence $(\mathfrak{a}^n) \cap (x) = x\,\mathfrak{a}^{n-1}$ for $n \geq 1$. In particular $\mathfrak{a} \cap (x) = x\,\mathfrak{a}^0 = xR = (x)$ (taking $n = 1$), since $(x) \subseteq \mathfrak{a}$. With $k = 1$ the Artin–Rees identity reads $(\mathfrak{a}^n) \cap (x) = \mathfrak{a}^{n-1}\big((\mathfrak{a}) \cap (x)\big) = \mathfrak{a}^{n-1}(x) = x\,\mathfrak{a}^{n-1}$, valid for all $n \geq 1$. The constant $k = 0$ does *not* work: $\mathfrak{a}^n\big((\mathfrak{a}^0) \cap (x)\big) = \mathfrak{a}^n(x) = x\,\mathfrak{a}^n \neq x\,\mathfrak{a}^{n-1}$, so $k = 1$ is the smallest admissible Artin–Rees constant here. Sanity check: degrees match – $(\mathfrak{a}^n) \cap (x)$ is spanned by $x \cdot$ (monomials of degree $\geq n - 1$), exactly $x\,\mathfrak{a}^{n-1}$.

Graded rings, $\operatorname{gr}_{\mathfrak{a}}(R)$, and Krull's theorem

Passing from a filtered ring to its *associated graded ring* linearizes the multiplicative structure: it records "leading terms." A&M attach a vivid geometric meaning – for the local ring of a point P on a variety V with $\mathfrak{a} = \mathfrak{m}$ the maximal ideal, $\operatorname{gr}_{\mathfrak{m}}(R)$ is the ring of the *tangent cone*, the lines through P tangent to V.

Definition 15.9.23 (graded ring/module, associated graded)**.** A *graded ring* is $A = \bigoplus_{n \geq 0} A_n$ with $A_m A_n \subseteq A_{m+n}$; then A_0 is a subring and each A_n an A_0-module. A *graded A-module* is $M = \bigoplus_{n \geq 0} M_n$ with $A_m M_n \subseteq M_{m+n}$. For a ring R and ideal $\mathfrak{a}$, the *associated graded ring* is

$$\operatorname{gr}_{\mathfrak{a}}(R) = \bigoplus_{n \geq 0} \mathfrak{a}^n/\mathfrak{a}^{n+1} \qquad (\mathfrak{a}^0 = R),$$

with multiplication $(\bar{x}_m)(\bar{y}_n) = \overline{x_m y_n} \in \mathfrak{a}^{m+n}/\mathfrak{a}^{m+n+1}$. For a filtered module (M_n), $\operatorname{gr}(M) = \bigoplus_n M_n/M_{n+1}$ is a graded $\operatorname{gr}_{\mathfrak{a}}(R)$-module.

Proposition 15.9.24 (Noetherianity of $\operatorname{gr}_{\mathfrak{a}}(R)$ and a graded criterion)**.** (i) *A graded ring A is Noetherian $\iff$ A_0 is Noetherian and A is a finitely generated A_0-algebra.*

(ii) *If R is Noetherian and $\mathfrak{a} \subseteq R$ an ideal, then $\operatorname{gr}_{\mathfrak{a}}(R)$ is Noetherian.*

Idea. For (i): if A is Noetherian then $A_0 = A/A_+$ is Noetherian and $A_+ = \bigoplus_{n>0} A_n$ is finitely generated by homogeneous $x_1, \ldots, x_s$, which then generate A over A_0; conversely Hilbert's basis theorem gives Noetherianity. For (ii): $\operatorname{gr}_{\mathfrak{a}}(R)$ has degree-zero part $R/\mathfrak{a}$ (Noetherian) and is generated over it by the finitely many generators of $\mathfrak{a}$ read in $\mathfrak{a}/\mathfrak{a}^2$, so (i) applies. □

Lemma 15.9.25 (M^* finitely generated $\iff$ filtration stable)**.** *Let R be Noetherian, $\mathfrak{a}$ an ideal, M a finitely generated R-module, (M_n) an $\mathfrak{a}$-filtration. Form $A^* = \bigoplus_n \mathfrak{a}^n = R[\mathfrak{a}t]$ (Noetherian) and the graded A^*-module $M^* = \bigoplus_n M_n$. Then M^* is a finitely generated A^*-module $\iff$ the filtration (M_n) is stable.*

Idea. The truncations $Q_n = \bigoplus_{r \leq n} M_r$ are finitely generated; M^* is finitely generated iff the ascending chain of A^*-submodules generated by the Q_n stabilizes, i.e. iff $M^* = A^* \cdot Q_{n_0}$ for some n_0, i.e. iff $M_{n_0+r} = \mathfrak{a}^r M_{n_0}$ for all r – precisely stability. This lemma supplies the proof of Artin–Rees (Theorem 15.9.18). □

Theorem 15.9.26 (Krull intersection theorem)**.** *Let R be Noetherian, $\mathfrak{a}$ an ideal, M a finitely generated R-module, and $E = \bigcap_{n\geq 1} \mathfrak{a}^n M$. Then $\mathfrak{a}E = E$; equivalently E is annihilated by some element of $1 + \mathfrak{a}$. Consequently:*

(1) *if $\mathfrak{a} \subseteq \mathrm{Jac}(R)$ (the Jacobson radical), then $\bigcap_n \mathfrak{a}^n M = 0$, so the $\mathfrak{a}$-adic topology of M is Hausdorff;*

(2) *(local case) if $(R, \mathfrak{m})$ is Noetherian local, then $\bigcap_n \mathfrak{m}^n = 0$ and $\bigcap_n \mathfrak{m}^n M = 0$;*

(3) *if R is a Noetherian domain and $\mathfrak{a} \neq (1)$, then $\bigcap_n \mathfrak{a}^n = 0$.*

Idea. By Artin–Rees the filtration $(\mathfrak{a}^n M \cap E)$ is stable, but $\mathfrak{a}^n M \cap E = E$ for all n, so stability forces $\mathfrak{a}E = \mathfrak{a}^n M \cap E$ to equal E from some point on, i.e. $\mathfrak{a}E = E$. Now E is a finitely generated module with $\mathfrak{a}E = E$, so by the determinant trick (Cayley–Hamilton form of Nakayama) some $x \equiv 1 \pmod{\mathfrak{a}}$ kills E. If $\mathfrak{a} \subseteq \mathrm{Jac}(R)$ then $x = 1 - a$ with $a \in \mathrm{Jac}(R)$ is a unit, forcing $E = 0$, giving (1) and its special case (2). If R is a domain and $\mathfrak{a} \neq (1)$, then $1 + \mathfrak{a}$ contains no zero-divisors and $x \neq 0$, so again $E = 0$, giving (3). □

Remark 15.9.2. Both Krull's theorem and the exactness of completion are downstream of Artin–Rees, which is why A&M give that lemma the central role. The hypotheses cannot be dropped: over the non-Noetherian C^∞ ring the maximal ideal $\mathfrak{a}$ at 0 has $\bigcap_n \mathfrak{a}^n \neq 0$ (the flat function e^{-1/x^2}), and no element of $1 + \mathfrak{a}$ kills e^{-1/x^2} (such an element u would vanish at every $x \neq 0$, hence at 0 by continuity, while $u(0) = 1$), so Krull's conclusion fails – the obstruction is exactly non-Noetherianity.

Worked Example 15.9.27 (Krull intersection in a Noetherian local domain)**.** Let $(R, \mathfrak{m})$ be a Noetherian local domain. Show $\bigcap_n \mathfrak{m}^n = 0$.

Recognition. $\mathfrak{m} \subseteq \mathrm{Jac}(R) = \mathfrak{m}$ (local), and R is a domain, so Theorem 15.9.26(2)/(3) applies.

Solution. Put $E = \bigcap_n \mathfrak{m}^n$. By Krull $\mathfrak{m}E = E$ with E finitely generated, so Nakayama (with $\mathfrak{m} \subseteq \mathrm{Jac}\, R$) gives $E = 0$. Sanity check: in $R = k[x]_{(x)}$, $\mathfrak{m} = (x)$, indeed $\bigcap_n (x)^n = 0$ – a germ vanishing to all orders is the zero germ; and the completion $\widehat{R} = k[[x]]$ is Hausdorff, consistent with $E = 0$.

Worked Example 15.9.28 (Krull's theorem can fail for non-domains without the radical hypothesis)**.** Show $\bigcap_n \mathfrak{a}^n \neq 0$ is possible when $\mathfrak{a} \not\subseteq \mathrm{Jac}(R)$, using $R = \mathbb{Z}/6\mathbb{Z}$, $\mathfrak{a} = (2)$.

Recognition. Theorem 15.9.26(1) needs $\mathfrak{a} \subseteq \mathrm{Jac}(R)$; in a product of fields $\mathrm{Jac}(R) = 0$, so the conclusion is not guaranteed.

Solution. In $R = \mathbb{Z}/6\mathbb{Z} \cong \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, the ideal $\mathfrak{a} = (2)$ corresponds to $0 \times \mathbb{Z}/3\mathbb{Z}$, which is idempotent: $\mathfrak{a}^2 = \mathfrak{a}$. Hence $\bigcap_n \mathfrak{a}^n = \mathfrak{a} \neq 0$. Here $\mathrm{Jac}(R) = 0$ (a product of fields), so $\mathfrak{a} \not\subseteq \mathrm{Jac}(R)$ and Krull(1) does not apply. The element of $1 + \mathfrak{a}$ annihilating $E = \mathfrak{a}$: take $1 + 2 = 3$, and indeed $3 \cdot \mathfrak{a} = 3 \cdot (0 \times \mathbb{Z}/3\mathbb{Z}) = 0$, so $\mathfrak{a}E = E$ with annihilator $3 \in 1 + \mathfrak{a}$, consistent with the theorem's $\mathfrak{a}E = E$ conclusion. Sanity check: the theorem's true assertion ($\mathfrak{a}E = E$) holds; only the *stronger* $E = 0$ fails, exactly because the radical hypothesis is absent.

Worked Example 15.9.29 (The associated graded of $\mathbb{Z}$ at (p))**.** Compute $\mathrm{gr}_{(p)}(\mathbb{Z})$.

Recognition. $\mathrm{gr}_{\mathfrak{a}}(R) = \bigoplus_n \mathfrak{a}^n/\mathfrak{a}^{n+1}$; here $\mathfrak{a}^n = p^n\mathbb{Z}$.

Solution. Each graded piece $p^n\mathbb{Z}/p^{n+1}\mathbb{Z} \cong \mathbb{Z}/p\mathbb{Z} = \mathbb{F}_p$, generated by the class $\bar{p}^{\,n}$ of p^n. Multiplication sends $\bar{p}^{\,m} \cdot \bar{p}^{\,n} \mapsto \bar{p}^{\,m+n}$, so $\mathrm{gr}_{(p)}(\mathbb{Z}) \cong \mathbb{F}_p[t]$ with $t = \bar{p}$ the class of p in degree 1. Sanity check: $\mathbb{F}_p[t]$ is a Noetherian domain (matching Proposition 15.9.24(ii)); its degree-0 part $\mathbb{F}_p = \mathbb{Z}/p\mathbb{Z} = R/\mathfrak{a}$, as required.

Worked Example 15.9.30 (The associated graded of a regular local ring is a polynomial ring)**.** For $R = k[x_1, \ldots, x_n]_{(x_1,\ldots,x_n)}$, $\mathfrak{m} = (x_1, \ldots, x_n)$, identify $\mathrm{gr}_{\mathfrak{m}}(R)$.

Recognition. $\mathrm{gr}_{\mathfrak{m}}(R) = \bigoplus_d \mathfrak{m}^d/\mathfrak{m}^{d+1}$; the d-th piece is the space of degree-d forms in the x_i.

Solution. $\mathfrak{m}^d/\mathfrak{m}^{d+1}$ has basis the monomials of total degree d in $x_1, \ldots, x_n$, and the product respects degree, so $\mathrm{gr}_{\mathfrak{m}}(R) \cong k[x_1, \ldots, x_n]$ as a graded ring (a polynomial ring, n variables in degree 1). Sanity check: $\dim_k \mathfrak{m}^d/\mathfrak{m}^{d+1} = \binom{d+n-1}{n-1}$, the number of degree-$d$ monomials – the Hilbert function of the tangent cone of the smooth point, which for a regular point is that of affine n-space, confirming the "tangent cone = $\mathbb{A}^n$" picture.

Worked Example 15.9.31 ($\mathrm{gr}_{\mathfrak{a}}(R) \cong \mathrm{gr}_{\widehat{\mathfrak{a}}}(\widehat{R})$)**.** For R Noetherian, show completion does not change the associated graded ring.

Recognition. Use $\widehat{R}/\widehat{\mathfrak{a}}^n \cong R/\mathfrak{a}^n$, hence $\widehat{\mathfrak{a}}^n/\widehat{\mathfrak{a}}^{n+1} \cong \mathfrak{a}^n/\mathfrak{a}^{n+1}$.

Solution. From $\widehat{R}/\widehat{\mathfrak{a}}^n \cong R/\mathfrak{a}^n$ (earlier example) the short exact sequences $0 \to \widehat{\mathfrak{a}}^n/\widehat{\mathfrak{a}}^{n+1} \to \widehat{R}/\widehat{\mathfrak{a}}^{n+1} \to \widehat{R}/\widehat{\mathfrak{a}}^n \to 0$ match those for R, giving $\widehat{\mathfrak{a}}^n/\widehat{\mathfrak{a}}^{n+1} \cong \mathfrak{a}^n/\mathfrak{a}^{n+1}$ in each degree, compatibly with products. Hence $\mathrm{gr}_{\widehat{\mathfrak{a}}}(\widehat{R}) \cong \mathrm{gr}_{\mathfrak{a}}(R)$. Sanity check: with $R = \mathbb{Z}$, $\mathfrak{a} = (p)$: $\mathrm{gr}_{(p)}(\mathbb{Z}) \cong \mathbb{F}_p[t] \cong \mathrm{gr}_{p\mathbb{Z}_p}(\mathbb{Z}_p)$ – the graded ring sees only the finite residues $\mathfrak{a}^n/\mathfrak{a}^{n+1}$, which completion preserves.

Completion preserves Noetherianity; Hensel's lemma

The capstone is that completion stays inside the Noetherian world, proved by lifting Noetherianity from $\mathrm{gr}_{\mathfrak{a}}(R)$ back to $\widehat{R}$ via a filtered-to-graded comparison.

Lemma 15.9.32 (filtered comparison)**.** *Let $\phi\colon A \to B$ be a homomorphism of filtered groups with $\phi(A_n) \subseteq B_n$, inducing $\mathrm{gr}(\phi)\colon \mathrm{gr}(A) \to \mathrm{gr}(B)$ and $\widehat{\phi}\colon \widehat{A} \to \widehat{B}$. If A is complete, B Hausdorff, and $\mathrm{gr}(\phi)$ is surjective (resp. injective), then $\widehat{\phi}$ – equivalently ϕ under completeness – is surjective (resp. injective).*

Proposition 15.9.33 (Noetherian lifting)**.** *Let A be a filtered ring, complete and Hausdorff, with $\bigcap A_n = 0$. If $\mathrm{gr}(A)$ is Noetherian, then A is Noetherian.*

Theorem 15.9.34 ($\widehat{R}$ is Noetherian)**.** *If R is Noetherian and $\mathfrak{a} \subseteq R$ an ideal, then the $\mathfrak{a}$-adic completion $\widehat{R}$ is Noetherian.*

Idea. By Proposition 15.9.24(ii), $\mathrm{gr}_{\mathfrak{a}}(R)$ is Noetherian, and $\mathrm{gr}_{\widehat{\mathfrak{a}}}(\widehat{R}) \cong \mathrm{gr}_{\mathfrak{a}}(R)$ (earlier example) is therefore Noetherian. Now $\widehat{R}$ is complete and Hausdorff for the $\widehat{\mathfrak{a}}$-topology with $\bigcap_n \widehat{\mathfrak{a}}^n = 0$, so Proposition 15.9.33 lifts Noetherianity from the graded ring to $\widehat{R}$ itself. □

Corollary 15.9.35 (formal power series are Noetherian)**.** *If R is Noetherian then $R[[x_1, \dots, x_n]]$ is Noetherian; in particular $k[[x_1, \dots, x_n]]$ (k a field or PID) and $\mathbb{Z}_p$ are Noetherian.*

Idea. $R[x_1, \dots, x_n]$ is Noetherian (Hilbert basis), and $R[[x_1, \dots, x_n]]$ is its $(x_1, \dots, x_n)$-adic completion, so Theorem 15.9.34 applies. □

Remark 15.9.3. A&M also record (Proposition 10.16) that if $(R, \mathfrak{m})$ is Noetherian local then $\widehat{R}$ is again local with maximal ideal $\widehat{\mathfrak{m}}$ and residue field $\widehat{R}/\widehat{\mathfrak{m}} \cong R/\mathfrak{m}$. Completion thus preserves the local-ring structure while improving it: $\widehat{R}$ is complete, so Hensel's lemma is available.

Theorem 15.9.36 (Hensel's lemma, statement)**.** *Let $(R, \mathfrak{m})$ be a complete Noetherian local ring with residue field $k = R/\mathfrak{m}$, and let $f \in R[x]$ be monic. If $\bar{f} \in k[x]$ factors as $\bar{f} = \bar{g}\,\bar{h}$ with $\bar{g}, \bar{h}$ monic and* coprime *(in particular if $\bar{a} \in k$ is a* simple *root of $\bar{f}$, $\bar{f}'(\bar{a}) \neq 0$), then the factorization lifts: there exist monic $g, h \in R[x]$ with $f = gh$, $\bar{g}, \bar{h}$ the given factors (in the simple-root case, a root $a \in R$ with $f(a) = 0$ and $a \equiv \bar{a}$). The lift is unique.*

Worked Example 15.9.37 ($\mathbb{Z}_p$ is a Noetherian complete DVR)**.** Confirm $\mathbb{Z}_p$ is Noetherian and describe its ideals.

Recognition. $\mathbb{Z}_p$ is the (p)-adic completion of the Noetherian $\mathbb{Z}$, so Theorem 15.9.34 applies; locate its ideals via $\widehat{(p^k)}$.

Solution. By Theorem 15.9.34, $\mathbb{Z}_p$ is Noetherian. Its nonzero ideals are $p^k\mathbb{Z}_p = \widehat{(p^k)}$ for $k \geq 0$, since every nonzero $x \in \mathbb{Z}_p$ is $p^v \cdot u$ with u a unit ($v = v_p(x) < \infty$ as $\bigcap p^n\mathbb{Z}_p = 0$). Thus $\mathbb{Z}_p$ is a discrete valuation ring: local, with maximal ideal $p\mathbb{Z}_p$, residue field $\mathbb{F}_p$, and $\mathrm{gr}_{(p)}(\mathbb{Z}_p) \cong \mathbb{F}_p[t]$. Sanity check: the ideals of $\mathbb{Z}_p$ form the single chain $\mathbb{Z}_p \supset p\mathbb{Z}_p \supset p^2\mathbb{Z}_p \supset \cdots \supset 0$; its only primes are $p\mathbb{Z}_p$ and 0, so the longest chain of primes is $0 \subsetneq p\mathbb{Z}_p$, matching $\dim \mathbb{Z}_p = 1$, and every ascending chain of ideals stops, matching the Noetherian conclusion.

Worked Example 15.9.38 ($k[[x]]$ is a complete DVR)**.** Show $k[[x]]$ is Noetherian local with maximal ideal (x), and identify its fraction field.

Recognition. $k[[x]]$ is the (x)-adic completion of $k[x]$; apply Corollary 15.9.35 and the local-completion remark.

Solution. $k[[x]]$ is Noetherian by Corollary 15.9.35. A series is a unit iff its constant term is nonzero, so the non-units form the maximal ideal (x); every nonzero series is $x^v \cdot (\text{unit})$, so the ideals are (x^k) and $k[[x]]$ is a complete DVR. Its fraction field is the formal Laurent series field $k((x)) = k[[x]][x^{-1}]$. Sanity check: $\bigcap_n (x)^n = 0$ (a nonzero series has finite order), so $k[[x]]$ is Hausdorff and equals its own completion, as a complete DVR must.

Worked Example 15.9.39 (Hensel: square roots in $\mathbb{Z}_p$)**.** For p odd and $a \in \mathbb{Z}$ with $p \nmid a$, show a has a square root in $\mathbb{Z}_p$ iff a is a square mod p.

Recognition. Apply Hensel to $f(x) = x^2 - a$: a simple root mod p (where $f' = 2x \not\equiv 0$ since p odd) lifts to $\mathbb{Z}_p$.

Solution. If $a \equiv b^2 \pmod p$ with $p \nmid b$, then $\bar{b}$ is a root of $\bar{f} = x^2 - \bar{a}$ and $\bar{f}'(\bar{b}) = 2\bar{b} \neq 0$ in $\mathbb{F}_p$ (p odd, $p \nmid b$), a simple root. Hensel lifts it to $\alpha \in \mathbb{Z}_p$ with $\alpha^2 = a$. Conversely a square root in $\mathbb{Z}_p$ reduces mod p to a square root in $\mathbb{F}_p$. Sanity check: in $\mathbb{Z}_7$, $2 \equiv 3^2 = 9 \equiv 2 \pmod 7$, so $\sqrt{2} \in \mathbb{Z}_7$ exists; whereas 3 is a nonsquare mod 7 (squares are $1, 2, 4$), so $\sqrt{3} \notin \mathbb{Z}_7$ – exactly the quadratic-residue criterion.

Worked Example 15.9.40 (Hensel: $(p-1)$-th roots of unity in $\mathbb{Z}_p$)**.** Show $\mathbb{Z}_p$ contains $p-1$ distinct $(p-1)$-th roots of unity (the Teichmuller lifts).

Recognition. Apply Hensel to $f(x) = x^{p-1} - 1$; over $\mathbb{F}_p$ it splits into distinct linear factors (all simple roots) by Fermat.

Solution. Over $\mathbb{F}_p$, $x^{p-1} - 1 = \prod_{c \in \mathbb{F}_p^\times} (x - c)$ has $p-1$ distinct simple roots (each nonzero c satisfies $c^{p-1} = 1$ and $\bar{f}'(c) = (p-1)c^{p-2} \neq 0$). Hensel lifts each to a unique $\omega_c \in \mathbb{Z}_p$ with $\omega_c^{p-1} = 1$ and $\omega_c \equiv c \pmod p$. These $p-1$ lifts are distinct (distinct residues), giving a cyclic group $\mu_{p-1} \subset \mathbb{Z}_p^\times$. Sanity check: the ω_c are the Teichmuller representatives, and $\mathbb{Z}_p^\times \cong \mu_{p-1} \times (1 + p\mathbb{Z}_p)$, consistent with $|(\mathbb{Z}/p)^\times| = p - 1$ on residues.

Worked Example 15.9.41 (Completion of a Noetherian ring stays Noetherian: $\mathbb{Z}[x]$ at (p, x))**.** Identify the (p, x)-adic completion of $R = \mathbb{Z}[x]$ and confirm Noetherianity.

Recognition. $R = \mathbb{Z}[x]$ is Noetherian; Theorem 15.9.34 gives $\widehat{R}$ Noetherian, and concretely $\widehat{R}$ is a two-variable formal power series object.

Solution. With $\mathfrak{a} = (p, x)$, $R/\mathfrak{a}^n$ is residues mod p and x to total order n; the completion is $\widehat{R} = \varprojlim \mathbb{Z}[x]/(p, x)^n \cong \mathbb{Z}_p[[x]]$, formal power series over $\mathbb{Z}_p$. By Corollary 15.9.35 (with the Noetherian base $\mathbb{Z}_p$) this is Noetherian. Sanity check: $\widehat{R}$ is local with maximal ideal $(p, x)\widehat{R}$ and residue field $\mathbb{F}_p$, and $\mathrm{gr}_{(p,x)}(\mathbb{Z}[x]) \cong \mathbb{F}_p[s, t]$ (with $s = \bar{p}, t = \bar{x}$), a Noetherian polynomial ring – matching the lifting argument of Theorem 15.9.34.

Worked Example 15.9.42 (Flatness in action: $\widehat{R}$ detects intersections)**.** Use flatness of $\widehat{R}$ over a Noetherian R to show $\widehat{\mathfrak{b} \cap \mathfrak{c}} = \widehat{\mathfrak{b}} \cap \widehat{\mathfrak{c}}$ for ideals $\mathfrak{b}, \mathfrak{c}$.

Recognition. A flat module preserves finite intersections of finitely generated submodules: $\widehat{R} \otimes (\mathfrak{b} \cap \mathfrak{c}) = (\widehat{R} \otimes \mathfrak{b}) \cap (\widehat{R} \otimes \mathfrak{c})$ inside $\widehat{R}$.

Solution. Flatness applied to $0 \to \mathfrak{b} \cap \mathfrak{c} \to \mathfrak{b} \oplus \mathfrak{c} \to \mathfrak{b} + \mathfrak{c} \to 0$ (the Mayer–Vietoris sequence, with the last map $(x, y) \mapsto x - y$) stays exact after $\widehat{R} \otimes_R (-)$, identifying $\widehat{\mathfrak{b} \cap \mathfrak{c}} = \widehat{R}(\mathfrak{b} \cap \mathfrak{c}) = \widehat{R}\mathfrak{b} \cap \widehat{R}\mathfrak{c} = \widehat{\mathfrak{b}} \cap \widehat{\mathfrak{c}}$. Sanity check: with $R = \mathbb{Z}$, $\mathfrak{b} = (4)$, $\mathfrak{c} = (6)$, $\mathfrak{a} = (2)$: $\mathfrak{b} \cap \mathfrak{c} = (12)$, and in $\mathbb{Z}_2$, $4\mathbb{Z}_2 \cap 6\mathbb{Z}_2 = 4\mathbb{Z}_2$ (since $6 = 2 \cdot 3$ with 3 a unit, $6\mathbb{Z}_2 = 2\mathbb{Z}_2$, so $4\mathbb{Z}_2 \cap 2\mathbb{Z}_2 = 4\mathbb{Z}_2$) – and $\widehat{(12)} = 12\mathbb{Z}_2 = 4\mathbb{Z}_2$ likewise (since $12 = 4 \cdot 3$, 3 a unit), matching.

Exercises (Atiyah & Macdonald).

1. Let $\alpha_n \colon \mathbb{Z}/p\mathbb{Z} \to \mathbb{Z}/p^n\mathbb{Z}$ be the injection of abelian groups given by $\alpha_n(1) = p^{n-1}$, and let $\alpha \colon A \to B$ be the direct sum of all the α_n (where A is a countable direct sum of copies of $\mathbb{Z}/p\mathbb{Z}$, and B is the direct sum of the $\mathbb{Z}/p^n\mathbb{Z}$). Show that the p-adic completion of A is just A but that the completion of A for the topology induced from the p-adic topology on B is the direct *product* of the $\mathbb{Z}/p\mathbb{Z}$. Deduce that p-adic completion is *not* a right-exact functor on the category of all $\mathbb{Z}$-modules.

2. In Exercise 1, let $A_n = \alpha^{-1}(p^n B)$, and consider the exact sequence

$$0 \to A_n \to A \to A/A_n \to 0.$$

Show that lim is not exact, and compute $\lim^1 A_n$.

3. Let A be a Noetherian ring, $\mathfrak{a}$ an ideal and M a finitely-generated A-module. Using Krull's Theorem and Exercise 14 of Chapter 3, prove that

$$\bigcap_{n=1}^{\infty} \mathfrak{a}^n M = \bigcap_{\mathfrak{m} \supseteq \mathfrak{a}} \mathrm{Ker}(M \to M_{\mathfrak{m}}),$$

where $\mathfrak{m}$ runs over all maximal ideals containing $\mathfrak{a}$.

Deduce that

$$\widehat{M} = 0 \iff \mathrm{Supp}(M) \cap V(\mathfrak{a}) = \varnothing \quad (\text{in } \mathrm{Spec}(A)).$$

[The reader should think of $\widehat{M}$ as the "Taylor expansion" of M transversal to the subscheme $V(\mathfrak{a})$: the above result then shows that M is determined in a neighborhood of $V(\mathfrak{a})$ by its Taylor expansion.]

4. Let A be a Noetherian ring, $\mathfrak{a}$ an ideal in A, and $\widehat{A}$ the $\mathfrak{a}$-adic completion. For any $x \in A$, let $\widehat{x}$ be the image of x in $\widehat{A}$. Show that

$$x \text{ not a zero-divisor in } A \implies \widehat{x} \text{ not a zero-divisor in } \widehat{A}.$$

Does this imply that

$$A \text{ an integral domain} \implies \widehat{A} \text{ an integral domain?}$$

[Apply the exactness of completion to the sequence $0 \to A \xrightarrow{x} A$.]

5. Let A be a Noetherian ring, let $\mathfrak{a}$, $\mathfrak{b}$ be ideals in A, and let M be an A-module. Let $M^{\mathfrak{a}}$, $M^{\mathfrak{b}}$ denote the $\mathfrak{a}$-adic and $\mathfrak{b}$-adic completions respectively. If M is finitely generated, prove that $(M^{\mathfrak{a}})^{\mathfrak{b}} \cong M^{\mathfrak{a}+\mathfrak{b}}$.

[Take the $\mathfrak{a}$-adic completion of the exact sequence

$$0 \to \mathfrak{b}^n M \to M \to M/\mathfrak{b}^n M \to 0$$

and apply (10.13). Thus use the isomorphism

$$\varprojlim_n \left(\varprojlim_m M/(\mathfrak{a}^m M + \mathfrak{b}^n M) \right) \cong \varprojlim_p M/(\mathfrak{a}^p M + \mathfrak{b}^p M)$$

and the inclusions $(\mathfrak{a}+\mathfrak{b})^{2p} \subseteq \mathfrak{a}^p + \mathfrak{b}^p \subseteq (\mathfrak{a}+\mathfrak{b})^p$.]

6. Let A be a Noetherian ring, $\mathfrak{a}$ an ideal of A, $\widehat{A}$ the $\mathfrak{a}$-adic completion. For any $x \in A$ let $\widehat{x}$ be the image of x in $\widehat{A}$. Prove that $\mathfrak{a}$ is contained in the Jacobson radical of A if and only if every maximal ideal of A is closed for the $\mathfrak{a}$-topology. (A Noetherian topological ring in which the topology is defined by an ideal contained in the Jacobson radical is called a *Zariski ring*. Examples are local rings and ($\mathfrak{a}$-adic) completions.)

7. Let A be a Noetherian ring, $\mathfrak{a}$ an ideal of A, and $\widehat{A}$ the $\mathfrak{a}$-adic completion. Prove that $\widehat{A}$ is faithfully flat over A if and only if A is a Zariski ring (for the $\mathfrak{a}$-topology). [Since $\widehat{A}$ is flat over A, it is enough (Chapter 3, Exercise 16) to show that $M \to \widehat{M}$ is injective for all finitely generated M if and only if A is a Zariski ring; now use (10.19) and Exercise 6.]

8. Let A be the local ring of a point in $\mathbb{C}^n$ (i.e., the ring of all rational functions $f/g \in \mathbb{C}(z_1, \ldots, z_n)$ with $g(0) \neq 0$), let B be the ring of power series in $z_1, \ldots, z_n$ which converge in some neighborhood of the origin, and let C be the ring of formal power series in $z_1, \ldots, z_n$, so that $A \subseteq B \subseteq C$. Show that B is a local ring and that its completion for the maximal ideal topology is C. Assuming that B is Noetherian, prove that B is A-flat. [Use Chapter 3, Exercise 17, and Exercise 7 above.]

9. Let A be a local ring, $\mathfrak{m}$ its maximal ideal. Assume that A is $\mathfrak{m}$-adically complete. For any polynomial $f(x) \in A[x]$, let $\bar{f}(x) \in (A/\mathfrak{m})[x]$ denote its reduction mod $\mathfrak{m}$. Prove *Hensel's lemma*: if $f(x)$ is monic of degree n and if there exist coprime monic polynomials $\bar{g}(x)$, $\bar{h}(x) \in (A/\mathfrak{m})[x]$ of degrees r, $n-r$ with $\bar{f}(x) = \bar{g}(x)\bar{h}(x)$, then we can lift $\bar{g}(x)$, $\bar{h}(x)$ back to monic polynomials $g(x)$, $h(x) \in A[x]$ such that $f(x) = g(x)h(x)$.

   [Assume inductively that we have constructed $g_k(x)$, $h_k(x) \in A[x]$ such that $g_k(x)h_k(x) - f(x) \equiv 0 \pmod{\mathfrak{m}^k A[x]}$. Then use the fact that since $\bar{g}(x)$ and $\bar{h}(x)$ are coprime we can find $\bar{a}_p(x)$, $\bar{b}_p(x)$, of degrees $\le n-r$, r respectively, such that $x^p = \bar{a}_p(x)\bar{g}(x) + \bar{b}_p(x)\bar{h}(x)$, where p is any integer such that $1 \le p \le n$. Finally, use the completeness of A to show that the sequences $g_k(x)$, $h_k(x)$ converge to the required $g(x)$, $h(x)$.]

10. i) With the notation of Exercise 9, deduce from Hensel's lemma that if $\bar{f}(x)$ has a simple root $\alpha \in A/\mathfrak{m}$, then $f(x)$ has a simple root $a \in A$ such that $\alpha = a \bmod \mathfrak{m}$.

    ii) Show that 2 is a square in the ring of 7-adic integers.

    iii) Let $f(x,y) \in k[x,y]$, where k is a field, and assume that $f(0,y)$ has $y = a_0$ as a simple root. Prove that there exists a formal power series $y(x) = \sum_{n=0}^{\infty} a_n x^n$ such that $f(x, y(x)) = 0$. (This gives the "analytic branch" of the curve $f = 0$ through the point $(0, a_0)$.)

11. Show that the converse of (10.26) is false, even if we assume that A is local and that $\widehat{A}$ is a finitely-generated A-module. [Take A to be the ring of germs of C^∞ functions of x at $x = 0$, and use Borel's Theorem (every power series occurs as the Taylor expansion of some C^∞ function).]

12. If A is Noetherian, then $A[[x_1, \ldots, x_n]]$ is a faithfully flat A-algebra. [Express $A \to A[[x_1, \ldots, x_n]]$ as a composition of flat extensions, and use Exercise 5(v) of Chapter 1.]

Practice problems.

1. Let $R = \mathbb{Z}$ and consider the filtration $G_n = 6^n\mathbb{Z}$. Identify $\widehat{R} = \varprojlim \mathbb{Z}/6^n\mathbb{Z}$ as a product of two familiar completions, using $6^n\mathbb{Z} = 2^n\mathbb{Z} \cap 3^n\mathbb{Z}$ and the Chinese Remainder Theorem $\mathbb{Z}/6^n\mathbb{Z} \cong \mathbb{Z}/2^n\mathbb{Z} \times \mathbb{Z}/3^n\mathbb{Z}$. Conclude $\widehat{R} \cong \mathbb{Z}_2 \times \mathbb{Z}_3$, and explain why this completion is *not* a domain even though $\mathbb{Z}$ is.

2. Take $R = k[x,y]$ and $\mathfrak{a} = (x,y)$. Compute the k-dimension of each graded piece $\mathfrak{a}^n/\mathfrak{a}^{n+1}$ of $\mathrm{gr}_{\mathfrak{a}}(R)$, write down the Hilbert function $n \mapsto \dim_k R/\mathfrak{a}^n$, and verify that $\mathrm{gr}_{\mathfrak{a}}(R) \cong k[s,t]$ with s, t in degree 1. Identify $\widehat{R}$ explicitly.

3. Let $\mathfrak{a} = (2) \subseteq \mathbb{Z}$ and let $M = \mathbb{Z}$, $M' = 12\mathbb{Z}$. Compute the intersected filtration $(2^n\mathbb{Z}) \cap 12\mathbb{Z}$ for each n, find the smallest Artin–Rees constant k with $(2^n\mathbb{Z}) \cap 12\mathbb{Z} = 2^{n-k}\big((2^k\mathbb{Z}) \cap 12\mathbb{Z}\big)$ for all $n \ge k$, and confirm $k = 2$ is forced (so $k = 0, 1$ fail).

4. In $\mathbb{Z}_5$, decide whether each of -1, 6, and 10 admits a square root, using Hensel's lemma applied to $x^2 - a$ together with the quadratic-residue criterion mod 5. For the cases that succeed, exhibit the first two 5-adic digits of one square root.

5. Let $(a_n) \in \varprojlim \mathbb{Z}/3^n\mathbb{Z}$ be the coherent sequence with $a_1 = 1$ and $a_{n+1} \equiv a_n \pmod{3^n}$ representing $-1/2 \in \mathbb{Z}_3$ (so $2a_n \equiv -1 \pmod{3^n}$). Compute a_1, a_2, a_3 explicitly and write the first three base-3 digits of $-1/2$ in $\mathbb{Z}_3$.

6. Let $R = k[[x]]$ and let $f = 1 - x + x^2$. Prove f is a unit by exhibiting the first three terms of $f^{-1} = \sum_{k \ge 0} c_k x^k$, and state the general criterion for a power series in $k[[x]]$ to be a unit. Then identify the maximal ideal $\mathfrak{m}$ and the residue field $R/\mathfrak{m}$.

7. Let $\phi\colon \mathbb{Z} \to \mathbb{Z}_p$ be the canonical map into the p-adic completion. Show ϕ is injective with dense image, that ϕ is *not* surjective, and that ϕ induces an isomorphism $\mathbb{Z}/p^n\mathbb{Z} \xrightarrow{\sim} \mathbb{Z}_p/p^n\mathbb{Z}_p$ for every $n \ge 1$.

Additional exercises.

1. Let G be a filtered abelian group with filtration (G_n) and let $H = \bigcap_n G_n$. Prove that the completion map $\phi\colon G \to \widehat{G}$ factors as $G \twoheadrightarrow G/H \hookrightarrow \widehat{G}$, that $\widehat{G} \cong \widehat{G/H}$ for the quotient filtration, and conclude that completion depends only on the Hausdorff quotient. Deduce $\ker \phi = H$.

2. Let R be Noetherian, $\mathfrak{a} \subseteq R$ an ideal, and $\widehat{R}$ the $\mathfrak{a}$-adic completion. Using flatness of $\widehat{R}$ over R (Proposition on $\widehat{R}$ flat), prove that for finitely generated ideals $\mathfrak{b}, \mathfrak{c}$ one has $\widehat{(\mathfrak{b} : \mathfrak{c})} = (\widehat{\mathfrak{b}} : \widehat{\mathfrak{c}})$ in $\widehat{R}$, and that $\widehat{\operatorname{Ann}_R(M)} \subseteq \operatorname{Ann}_{\widehat{R}}(\widehat{M})$ with equality when M is finitely generated.

3. Let $(R, \mathfrak{m})$ be a Noetherian local domain that is *not* a field, with $\dim_{R/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2) = 1$. Prove that $\operatorname{gr}_{\mathfrak{m}}(R) \cong (R/\mathfrak{m})[t]$ as graded rings, deduce that $\bigcap_n \mathfrak{m}^n = 0$ via Krull, and conclude that R is a discrete valuation ring. Show that $\widehat{R} \cong k[[t]]$ for $R = k[x]_{(x)}$, but that in general $\widehat{R} \not\cong (R/\mathfrak{m})[[t]]$: for $R = \mathbb{Z}_{(p)}$, $\widehat{R} = \mathbb{Z}_p$ has characteristic 0 while $\mathbb{F}_p[[t]]$ has characteristic p.

4. Let R be Noetherian and $0 \to M' \to M \to M'' \to 0$ a short exact sequence of finitely generated R-modules. Prove that the associated graded sequence $0 \to \operatorname{gr}(M') \to \operatorname{gr}(M) \to \operatorname{gr}(M'') \to 0$ (for the $\mathfrak{a}$-adic filtrations, with M' given the induced filtration $\mathfrak{a}^n M \cap M'$) is exact, and explain why this needs no Artin–Rees, while Artin–Rees is what shows that the induced filtration on M' and the $\mathfrak{a}$-adic one have bounded difference (hence give the same topology and the same completion $\widehat{M'}$). Show by the example $M = k[x, y]$, $M' = (x, y^2)$, $\mathfrak{a} = (x, y)$ that the two graded modules $\operatorname{gr}(M')$ can nevertheless differ, even up to a shift.

5. Let $f(x) = x^3 - x - 1 \in \mathbb{Z}_3[x]$. Show that $\bar{f} \in \mathbb{F}_3[x]$ has no root in $\mathbb{F}_3$, hence Hensel's lemma gives *no* 3-adic root, but that f *does* acquire a root in the unramified extension of $\mathbb{Z}_3$ with residue field $\mathbb{F}_{27}$. Contrast this with $g(x) = x^2 - 7$ over $\mathbb{Z}_3$, and decide whether g has a root in $\mathbb{Z}_3$.

Commutative-diagram exercises.

1. Complete the inverse-limit tower defining $\mathbb{Z}_p = \varprojlim \mathbb{Z}/p^n\mathbb{Z}$ together with its projections, and prove the universal property of the inverse limit: for every ring T with ring maps $T \to \mathbb{Z}/p^n\mathbb{Z}$ compatible with the θ_n there is a *unique* ring homomorphism $T \to \mathbb{Z}_p$ making every triangle commute. Fill in the skeleton, labelling each θ_n as the reduction $\mathbb{Z}/p^{n+1}\mathbb{Z} \twoheadrightarrow \mathbb{Z}/p^n\mathbb{Z}$:

$$\begin{array}{ccccccc} \cdots & \longrightarrow\!\!\!\!\rightarrow & \mathbb{Z}/p^3\mathbb{Z} & \xrightarrow{\theta_2}\!\!\!\!\rightarrow & \mathbb{Z}/p^2\mathbb{Z} & \xrightarrow{\theta_1}\!\!\!\!\rightarrow & \mathbb{Z}/p\mathbb{Z} \\ & & & \nwarrow^{\pi_3} & \uparrow{\scriptstyle \pi_2} & \nearrow_{\pi_1} & \\ & & & & \mathbb{Z}_p & & \end{array}$$

   Then prove $\ker \pi_n = p^n\mathbb{Z}_p$ and that the induced maps $\mathbb{Z}_p/p^n\mathbb{Z}_p \to \mathbb{Z}/p^n\mathbb{Z}$ are isomorphisms.

2. Let R be Noetherian, $\mathfrak{a}$ an ideal, and $0 \to M' \xrightarrow{f} M \xrightarrow{g} M'' \to 0$ a short exact sequence of finitely generated modules. Draw the diagram of $\mathfrak{a}$-adic completions and prove it is a short exact sequence with the rows below commuting (vertical maps are the completion maps ϕ_M etc.), citing the exactness of completion and the snake lemma:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & M' & \xrightarrow{f} & M & \xrightarrow{g}\!\!\!\!\rightarrow & M'' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \phi_{M'}} & & \downarrow{\scriptstyle \phi_M} & & \downarrow{\scriptstyle \phi_{M''}} & & \\ 0 & \longrightarrow & \widehat{M'} & \xrightarrow[\widehat{f}]{} & \widehat{M} & \xrightarrow[\widehat{g}]{} & \widehat{M''} & \longrightarrow & 0 \end{array}$$

   Prove the right-hand square commutes, identify $\ker \widehat{f}$, and explain why surjectivity of $\widehat{g}$ uses that the system $(M'/(\mathfrak{a}^n M \cap M'))$ is a surjective inverse system.

3. Let R be Noetherian, $\mathfrak{a} \subseteq \mathfrak{b}$ ideals, and write $\widehat{R}^{\mathfrak{a}}, \widehat{R}^{\mathfrak{b}}$ for the two adic completions. The identity of R is filtration-compatible from the $\mathfrak{a}$-adic to the $\mathfrak{b}$-adic filtration, since $\mathfrak{a}^n \subseteq \mathfrak{b}^n$ (the $\mathfrak{a}$-topology refines the $\mathfrak{b}$-topology). Complete the square below, in which the horizontal arrows are completion maps and the

vertical arrows are induced by $R/\mathfrak{a}^n \twoheadrightarrow R/\mathfrak{b}^n$, and prove it commutes:

$$\begin{array}{ccc} R & \xrightarrow{\phi^{\mathfrak{a}}} & \widehat{R}^{\mathfrak{a}} \\ \| & & \downarrow{\scriptstyle \psi} \\ R & \xrightarrow[\phi^{\mathfrak{b}}]{} & \widehat{R}^{\mathfrak{b}} \end{array}$$

Prove that ψ is the unique continuous ring homomorphism with $\psi \circ \phi^{\mathfrak{a}} = \phi^{\mathfrak{b}}$, that $\ker \psi = \bigcap_n \mathfrak{b}^n \widehat{R}^{\mathfrak{a}}$, and that ψ need not be surjective (for $R = k[x,y]$, $\mathfrak{a} = (x)$, $\mathfrak{b} = (x,y)$ it is the inclusion $k[y][[x]] \hookrightarrow k[[x,y]]$); identify ψ concretely for $R = \mathbb{Z}$, $\mathfrak{a} = (p^2)$, $\mathfrak{b} = (p)$.

4. Let R be Noetherian local with maximal ideal $\mathfrak{m}$. Complete the diagram exhibiting $\mathrm{gr}_{\mathfrak{m}}(R) \cong \mathrm{gr}_{\widehat{\mathfrak{m}}}(\widehat{R})$ degree by degree, where the rows are the defining short exact sequences and the vertical isomorphisms come from $\widehat{R}/\widehat{\mathfrak{m}}^{\,n} \cong R/\mathfrak{m}^n$:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathfrak{m}^n/\mathfrak{m}^{n+1} & \hookrightarrow & R/\mathfrak{m}^{n+1} & \twoheadrightarrow & R/\mathfrak{m}^n & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \sim} & & \\ 0 & \longrightarrow & \widehat{\mathfrak{m}}^{\,n}/\widehat{\mathfrak{m}}^{\,n+1} & \hookrightarrow & \widehat{R}/\widehat{\mathfrak{m}}^{\,n+1} & \twoheadrightarrow & \widehat{R}/\widehat{\mathfrak{m}}^{\,n} & \longrightarrow & 0 \end{array}$$

Prove the left vertical map is an isomorphism for every n, that these assemble into a graded ring isomorphism compatible with multiplication, and deduce that $\dim_{R/\mathfrak{m}} \mathfrak{m}^n/\mathfrak{m}^{n+1} = \dim_{R/\mathfrak{m}} \widehat{\mathfrak{m}}^{\,n}/\widehat{\mathfrak{m}}^{\,n+1}$ so that R and $\widehat{R}$ have the same Hilbert function.

15.10 Dimension Theory

Krull dimension and height: chains of primes

The dimension of a ring is, before anything else, a measure of how long a chain of prime ideals can be. Atiyah–Macdonald open this chapter by insisting that dimension "is essentially a local notion": for a variety it counts the number of independent parameters near a point, and the algebraic stand-in for "a point" is a prime ideal. A chain of primes

$$\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_n$$

is a strictly increasing sequence of primes; its *length* is n (the number of strict inclusions, one less than the number of primes). This is the same convention used for the dimension of a variety as the number of strict inclusions in a longest chain of nested irreducible closed subsets.

Definition 15.10.1 (Krull dimension)**.** The *Krull dimension* $\dim A$ of a ring A is the supremum of the lengths n of chains of prime ideals $\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_n$ in A. The *height* of a prime $\mathfrak{p}$, written $\operatorname{ht}\mathfrak{p}$, is the supremum of the lengths of chains $\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_n = \mathfrak{p}$ descending from $\mathfrak{p}$; equivalently $\operatorname{ht}\mathfrak{p} = \dim A_{\mathfrak{p}}$, the dimension of the local ring at $\mathfrak{p}$. Dually the *coheight* (or dimension of $\mathfrak{p}$) is the sup of lengths of chains ascending from $\mathfrak{p}$, equal to $\dim(A/\mathfrak{p})$.

The two halves of a prime split the ambient dimension: chains through $\mathfrak{p}$ are a descending chain (counted by $\operatorname{ht}\mathfrak{p} = \dim A_{\mathfrak{p}}$) glued to an ascending one (counted by $\dim A/\mathfrak{p}$), so $\operatorname{ht}\mathfrak{p} + \dim(A/\mathfrak{p}) \le \dim A$ always, with equality the typical "catenary" situation. Under the inclusion-preserving bijection $\mathfrak{q} \mapsto \mathfrak{q}A_{\mathfrak{p}}$ between primes contained in $\mathfrak{p}$ and primes of the localization $A_{\mathfrak{p}}$, height becomes ordinary dimension — this is localization as "concentrating near the point $\mathfrak{p}$".

Remark 15.10.1. Geometrically, $\operatorname{Spec} A$ carries the Zariski topology in which irreducible closed sets are exactly $V(\mathfrak{p})$ for $\mathfrak{p}$ prime, and $V(\mathfrak{p}) \subseteq V(\mathfrak{q}) \iff \mathfrak{q} \subseteq \mathfrak{p}$. A chain of primes $\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_n$ is therefore a chain of irreducible closed subsets $V(\mathfrak{p}_0) \supsetneq \cdots \supsetneq V(\mathfrak{p}_n)$, so $\dim A$ is the longest such tower. This is the prime ideal serving as "the common generalization of the primes of arithmetic and the points of geometry" (A&M,

Introduction): in $\mathbb{Z}$ the chain $(0) \subsetneq (p)$ has length 1; in $k[x]$ the chain $(0) \subsetneq (x-a)$ also has length 1; both rings are one-dimensional, arithmetic and geometric for the same reason.

Worked Example 15.10.2 (Dimension of a field, a PID, and $\mathbb{Z}$)**.** Compute $\dim k$, $\dim k[x]$, and $\dim \mathbb{Z}$ directly from chains of primes.

Recognition. A field has only the prime (0); in a PID that is not a field, the nonzero primes are maximal, so the longest chain is $(0) \subsetneq (p)$.

Solution. In a field k the only ideals are (0) and k, so the only prime is (0): the longest chain has length 0, $\dim k = 0$. In $\mathbb{Z}$ the primes are (0) and (p) for p prime; since (p) is maximal, no prime lies strictly between (p) and $\mathbb{Z}$, and the longest chain is $(0) \subsetneq (p)$, giving $\dim \mathbb{Z} = 1$. Likewise in $k[x]$ the primes are (0) and the maximal ideals (f) with f irreducible, so the longest chain is $(0) \subsetneq (f)$ and $\dim k[x] = 1$. Sanity check: $\operatorname{ht}(p) = \dim \mathbb{Z}_{(p)} = 1$ and $\dim(\mathbb{Z}/(p)) = \dim \mathbb{F}_p = 0$, so $\operatorname{ht}(p) + \dim(\mathbb{Z}/(p)) = 1 = \dim \mathbb{Z}$, consistent with the height/coheight splitting.

Worked Example 15.10.3 (A chain of length 2 in $k[x,y]$)**.** Exhibit a maximal-length chain of primes in $A = k[x,y]$ and read off a lower bound for $\dim A$.

Recognition. Primes of $k[x,y]$ come in three tiers: (0); height-one primes (f) with f irreducible; and maximal ideals like $(x-a, y-b)$. A chain climbing through all three has length 2.

Solution. Take

$$(0) \;\subsetneq\; (x) \;\subsetneq\; (x,y).$$

Each inclusion is strict and each ideal is prime: (0) since $k[x,y]$ is a domain; (x) since $k[x,y]/(x) \cong k[y]$ is a domain; (x,y) since $k[x,y]/(x,y) \cong k$ is a field. The chain has length 2, so $\dim k[x,y] \geq 2$. Sanity check: geometrically this is the flag (plane) $\supsetneq$ (line $x=0$) $\supsetneq$ (point $(0,0)$), three nested irreducible closed sets, matching length 2; we will see below that $\dim k[x,y] = 2$ exactly.

Worked Example 15.10.4 (Height of a prime versus dimension of the quotient)**.** In $A = k[x,y,z]$, with $\mathfrak{p} = (x,y)$, compute $\operatorname{ht}\mathfrak{p}$ and $\dim(A/\mathfrak{p})$, and check they add to $\dim A$.

Recognition. $\operatorname{ht}(x,y) = \dim A_{\mathfrak{p}}$ counts chains descending from (x,y); $\dim(A/\mathfrak{p}) = \dim k[z]$ counts the room above.

Solution. Descending: $(0) \subsetneq (x) \subsetneq (x,y)$ has length 2, and one checks no longer chain ends at (x,y), so $\operatorname{ht}(x,y) = 2$. Above: $A/(x,y) \cong k[z]$, which is one-dimensional, so $\dim(A/\mathfrak{p}) = 1$. Then $\operatorname{ht}\mathfrak{p} + \dim(A/\mathfrak{p}) = 2 + 1 = 3$. Sanity check: $\dim k[x,y,z] = 3$ (proved below), so the sum equals $\dim A$ and the chain $(0) \subsetneq (x) \subsetneq (x,y) \subsetneq (x,y,z)$ of length 3 realizes both pieces at once.

Hilbert functions and the Hilbert–Samuel polynomial

The conceptual core of A&M's chapter is that dimension can be *computed* by counting, via a polynomial attached to a graded or filtered module. Let $A = \bigoplus_{n \geq 0} A_n$ be a Noetherian graded ring, generated over the Noetherian ring A_0 by finitely many homogeneous elements $x_1, \ldots, x_s$ of degrees $k_1, \ldots, k_s$ (all positive), and let $M = \bigoplus M_n$ be a finitely generated graded A-module. Each homogeneous piece M_n is a finitely generated A_0-module. Fix an additive function λ on finitely generated A_0-modules (for instance $\lambda = \text{length}$, the length, when A_0 is Artin).

Definition 15.10.5 (Poincare series; Hilbert function)**.** The *Poincare series* of M is the generating function

$$P(M,t) = \sum_{n \geq 0} \lambda(M_n)\, t^n \;\in \mathbb{Z}[[t]].$$

Theorem 15.10.6 (Hilbert–Serre)**.** *$P(M,t)$ is a rational function of the form*

$$P(M,t) = \frac{f(t)}{\prod_{i=1}^{s}\left(1 - t^{k_i}\right)}, \qquad f(t) \in \mathbb{Z}[t].$$

Idea. Induct on s, the number of generators. For $s=0$, $A=A_0$ and $M_n=0$ for large n, so P is a polynomial. For the step, multiplication by x_s on M gives an exact sequence of graded modules

$$0 \to K_n \to M_n \xrightarrow{x_s} M_{n+k_s} \to L_{n+k_s} \to 0,$$

where $K=\ker(x_s)$ and $L=\operatorname{coker}(x_s)$ are finitely generated graded modules annihilated by x_s, hence modules over $A_0[x_1,\dots,x_{s-1}]$. Additivity of λ gives $\lambda(K_n)-\lambda(M_n)+\lambda(M_{n+k_s})-\lambda(L_{n+k_s})=0$; multiplying by t^{n+k_s} and summing yields $(1-t^{k_s})P(M,t)=g(t)+P(L,t)-t^{k_s}P(K,t)$, and the induction hypothesis finishes it. $\square$

Corollary 15.10.7 (the case of degree-one generators)**.** *If all $k_i=1$, then for all large n, $\lambda(M_n)$ agrees with a polynomial in n of degree $d-1$, where d is the order of the pole of $P(M,t)$ at $t=1$. We write $d(M)$ for this order; it is a measure of the "size" of M.*

Idea. With $k_i=1$, $P(M,t)=f(t)(1-t)^{-s}$; cancel the factor $(1-t)$ to its true order d, so $P(M,t)=g(t)(1-t)^{-d}$ with $g(1)\neq 0$. Expanding $(1-t)^{-d}=\sum_k \binom{d+k-1}{d-1}t^k$ and reading off the coefficient of t^n shows $\lambda(M_n)$ equals a polynomial in n of degree $d-1$ for $n\geq N$ (use the convention $\binom{n}{-1}=0$ and that the leading coefficient $g(1)/(d-1)!\neq 0$). $\square$

Now pass to the *local* situation, where the grading is replaced by a filtration. Let A be a Noetherian local ring with maximal ideal $\mathfrak{m}$, let $\mathfrak{q}$ be an $\mathfrak{m}$-primary ideal (so $\mathfrak{m}^r\subseteq\mathfrak{q}\subseteq\mathfrak{m}$ for some r), let M be a finitely generated A-module, and let (M_n) be a stable $\mathfrak{q}$-filtration. The associated graded ring $\operatorname{gr}_{\mathfrak{q}}(A)=\bigoplus_n \mathfrak{q}^n/\mathfrak{q}^{n+1}$ is Noetherian and generated over the Artin ring $A/\mathfrak{q}$ by the degree-one piece $\mathfrak{q}/\mathfrak{q}^2$; the associated graded module $\operatorname{gr}(M)=\bigoplus M_n/M_{n+1}$ is finitely generated over it. Each M_n/M_{n+1} has finite length.

Proposition 15.10.8 (Hilbert–Samuel)**.** *With $A,\mathfrak{m},\mathfrak{q},M,(M_n)$ as above:*

(i) *M/M_n has finite length for each n;*

(ii) *for all large n this length is a polynomial $g(n)$ in n of degree $\leq s$, where s is the least number of generators of $\mathfrak{q}$;*

(iii) *the degree and leading coefficient of $g(n)$ depend only on M and $\mathfrak{q}$, not on the chosen stable filtration.*

The polynomial for the $\mathfrak{q}$-adic filtration $(\mathfrak{q}^nM)$ is denoted $\chi_{\mathfrak{q}}^M(n)=\operatorname{length}(M/\mathfrak{q}^nM)$; when $M=A$ we write $\chi_{\mathfrak{q}}(n)=\operatorname{length}(A/\mathfrak{q}^n)$ and call it the characteristic *(Hilbert–Samuel)* polynomial *of $\mathfrak{q}$.*

Idea. Put $G(A)=\operatorname{gr}_{\mathfrak{q}}(A)$ and $G(M)=\bigoplus M_n/M_{n+1}$. Then $G_0(A)=A/\mathfrak{q}$ is Artin, $G(A)$ is Noetherian generated in degree one, and $G_n(M)=M_n/M_{n+1}$ is a finite-length $A/\mathfrak{q}$-module. By the degree-one corollary, $\operatorname{length}(M_n/M_{n+1})=f(n)$ is a polynomial of degree $\leq s-1$ for large n. Since $\operatorname{length}(M/M_n)=\sum_{r=0}^{n-1}\operatorname{length}(M_r/M_{r+1})$ and the successive difference $\operatorname{length}(M/M_{n+1})-\operatorname{length}(M/M_n)=f(n)$, the sum is a polynomial $g(n)$ of degree $\leq s$. Independence of the stable filtration follows because any two stable $\mathfrak{q}$-filtrations have bounded difference (Lemma 15.9.17), forcing the same degree and leading term. $\square$

Proposition 15.10.9 ($\mathfrak{q}$ and $\mathfrak{m}$ give the same degree)**.** *If $\mathfrak{q}$ is $\mathfrak{m}$-primary then* $\deg\chi_{\mathfrak{q}}(n)=\deg\chi_{\mathfrak{m}}(n)$.

Idea. Since $\mathfrak{m}\supseteq\mathfrak{q}\supseteq\mathfrak{m}^r$ for some r, we have $\mathfrak{m}^n\supseteq\mathfrak{q}^n\supseteq\mathfrak{m}^{rn}$, hence $\chi_{\mathfrak{m}}(n)\leq\chi_{\mathfrak{q}}(n)\leq\chi_{\mathfrak{m}}(rn)$ for all large n. Both outer terms are polynomials of the same degree in n (the right one is $\chi_{\mathfrak{m}}$ evaluated at rn), so the middle has that degree too. $\square$

The common degree of all the $\chi_{\mathfrak{q}}(n)$ (over $\mathfrak{m}$-primary $\mathfrak{q}$) is denoted $d(A)$; equivalently $d(A)=d(\operatorname{gr}_{\mathfrak{m}}(A))$ is the pole order at $t=1$ of the Hilbert series of the associated graded ring.

Worked Example 15.10.10 (Hilbert–Samuel polynomial of a regular point on a curve)**.** Let $A=k[x]_{(x)}$, $\mathfrak{m}=(x)$. Compute $\chi_{\mathfrak{m}}(n)=\operatorname{length}(A/\mathfrak{m}^n)$ and read off $d(A)$.

Recognition. $A/\mathfrak{m}^n=k[x]_{(x)}/(x^n)$; a basis over k is $1,x,\dots,x^{n-1}$, so the length is n.

Solution. The quotient $A/(x^n)$ is a k-vector space with basis $\{1,x,\dots,x^{n-1}\}$, so $\operatorname{length}(A/\mathfrak{m}^n)=n=\chi_{\mathfrak{m}}(n)$, a degree-1 polynomial. Hence $d(A)=\deg\chi_{\mathfrak{m}}=1$. Sanity check: A is the local ring of the affine line at the origin, geometrically 1-dimensional, and indeed $d(A)=1$; the leading coefficient 1 counts "one parameter x".

Worked Example 15.10.11 (Hilbert–Samuel polynomial of a smooth surface point)**.** Let $A = k[x,y]_{(x,y)}$, $\mathfrak{m} = (x,y)$. Compute $\chi_{\mathfrak{m}}(n)$ and its degree.

Recognition. $\mathfrak{m}^n/\mathfrak{m}^{n+1}$ has basis the degree-n monomials in x, y, of which there are $n+1$; sum these to get $\text{length}(A/\mathfrak{m}^n)$.

Solution. The monomials of degree exactly r in two variables number $r+1$, so $\text{length}(\mathfrak{m}^r/\mathfrak{m}^{r+1}) = r+1$ and

$$\chi_{\mathfrak{m}}(n) = \text{length}(A/\mathfrak{m}^n) = \sum_{r=0}^{n-1}(r+1) = \frac{n(n+1)}{2} = \binom{n+1}{2},$$

a polynomial of degree 2 with leading coefficient $\frac{1}{2}$. Hence $d(A) = 2$. Sanity check: a smooth point on a surface is 2-dimensional, matching $\deg \chi_{\mathfrak{m}} = 2$; the leading coefficient $\frac{1}{2!}$ has the shape $e/d!$ with multiplicity $e = 1$, the hallmark of a regular point.

Worked Example 15.10.12 (Poincare series of a polynomial ring)**.** For $A = k[x_1, \ldots, x_n]$ graded by total degree (so $A_0 = k$, $\lambda = \dim_k$), compute $P(A,t)$ and the pole order at $t = 1$.

Recognition. A_r has k-dimension equal to the number of degree-r monomials in n variables, $\binom{r+n-1}{n-1}$; sum the generating function.

Solution. The dimension count gives

$$P(A,t) = \sum_{r \geq 0} \binom{r+n-1}{n-1} t^r = \frac{1}{(1-t)^n},$$

the standard expansion of $(1-t)^{-n}$. The pole at $t = 1$ has order n, so $d(A) = n$ and the Hilbert function $\dim_k A_r = \binom{r+n-1}{n-1}$ is a polynomial in r of degree $n-1$. Sanity check: with $n = 2$ this is $\binom{r+1}{1} = r+1$, exactly the count used in the previous example; the pole order n will match $\dim k[x_1, \ldots, x_n] = n$ below.

Worked Example 15.10.13 (A non-reduced (fat point) length count)**.** Let $A = k[x]/(x^3)$, a local Artin ring with $\mathfrak{m} = (x)$. Compute $\chi_{\mathfrak{m}}(n)$ for all n and find $d(A)$.

Recognition. $\mathfrak{m}^3 = 0$, so the filtration stabilizes: $A/\mathfrak{m}^n = A$ for $n \geq 3$ and $\text{length}\, A = 3$.

Solution. For $n = 1, 2, 3, \ldots$ the lengths are $\text{length}(A/\mathfrak{m}) = 1$, $\text{length}(A/\mathfrak{m}^2) = 2$, and $\text{length}(A/\mathfrak{m}^n) = 3$ for all $n \geq 3$. Thus $\chi_{\mathfrak{m}}(n) = 3$ is eventually the constant polynomial, of degree 0, so $d(A) = 0$. Sanity check: A is Artin local, hence 0-dimensional; a degree-0 Hilbert–Samuel polynomial is exactly the signature of $\dim A = 0$, even though A is non-reduced. The constant value $3 = \text{length}\, A$ records the "multiplicity" of the fat point.

The dimension theorem for Noetherian local rings

Everything converges in A&M's central result: three integers attached to a Noetherian local ring — defined respectively by chains of primes, by counting, and by generation — all coincide. Introduce the third integer:

$$\delta(A) = \text{least number of generators of an } \mathfrak{m}\text{-primary ideal of } A.$$

An $\mathfrak{m}$-primary ideal generated by $\delta(A)$ elements is a *system of parameters*; its generators are a system of parameters when $\delta(A) = \dim A$.

Theorem 15.10.14 (Dimension theorem)**.** *For a Noetherian local ring A with maximal ideal $\mathfrak{m}$, the following three integers are equal:*

(i) *the maximal length d_0 of chains of prime ideals in A, i.e.* $\dim A$*;*

(ii) *the degree $d(A)$ of the characteristic polynomial $\chi_{\mathfrak{m}}(n) = \text{length}(A/\mathfrak{m}^n)$;*

(iii) *the least number $\delta(A)$ of generators of an $\mathfrak{m}$-primary ideal of A.*

Idea. The proof is a cycle of three inequalities. $\delta(A) \geq d(A)$: if $x_1, \ldots, x_s$ generate an $\mathfrak{m}$-primary $\mathfrak{q}$, then $A/\mathfrak{q}$ is Artin and $\mathrm{gr}_{\mathfrak{q}}(A)$ is a quotient of $(A/\mathfrak{q})[t_1, \ldots, t_s]$, whose Hilbert series has pole order $\leq s$, so $d(A) = d(\mathrm{gr}_{\mathfrak{q}} A) \leq s$; taking $s = \delta(A)$ gives the bound. $d(A) \geq \dim A$: induct on $d = d(A)$; if $\mathfrak{p}_0 \subsetneq \cdots \subsetneq \mathfrak{p}_r$ is a chain, pass to $A/\mathfrak{p}_0$, choose $x \neq 0$ in $\mathfrak{p}_1/\mathfrak{p}_0$, and compare characteristic polynomials of A' and $A'/(x)$ (using Artin–Rees) to get $d(A'/(x)) \leq d(A') - 1$; the induction yields $r - 1 \leq d - 1$, hence $\dim A \leq d$. $\dim A \geq \delta(A)$: build elements $x_1, \ldots, x_d$ ($d = \dim A$) inductively so that each x_i avoids all minimal primes of $(x_1, \ldots, x_{i-1})$ (prime avoidance); then every prime containing $(x_1, \ldots, x_d)$ has height $\geq d = \dim A$, so it is $\mathfrak{m}$, making $(x_1, \ldots, x_d)$ an $\mathfrak{m}$-primary ideal with d generators, whence $\delta(A) \leq d$. The three inequalities close the loop. □

Corollary 15.10.15 ($\dim A$ is finite; embedding count)**.** *Every Noetherian local ring has finite Krull dimension, and* $\dim A \leq \dim_k(\mathfrak{m}/\mathfrak{m}^2)$ *where* $k = A/\mathfrak{m}$*. Consequently, in any Noetherian ring every prime has finite height, so the prime ideals of a Noetherian ring satisfy the descending chain condition (equivalently, the irreducible closed subsets of its* Spec *satisfy the ascending chain condition).*

Idea. If $x_1, \ldots, x_s \in \mathfrak{m}$ have images spanning $\mathfrak{m}/\mathfrak{m}^2$, then by Nakayama they generate $\mathfrak{m}$ itself, which is $\mathfrak{m}$-primary; so $\delta(A) \leq \dim_k(\mathfrak{m}/\mathfrak{m}^2) < \infty$, and $\dim A = \delta(A)$ is finite. For a general Noetherian ring, $\mathrm{ht}\,\mathfrak{p} = \dim A_{\mathfrak{p}}$ is finite by the local case. □

Remark 15.10.2. The dimension theorem is the precise sense in which the geometric, the analytic, and the algebraic notions of dimension are one. Krull dimension is the geometric count (nested subvarieties); $d(A) = \deg \chi_{\mathfrak{m}}$ is the analytic "growth rate" of the local ring (how fast functions modulo high powers of $\mathfrak{m}$ proliferate); $\delta(A)$ is the algebraic minimum of equations needed to cut out the point. A&M call $x_1, \ldots, x_d$ a *system of parameters* precisely because $d = \dim A$ such functions suffice to pin the point down to finite length.

Worked Example 15.10.16 (The three integers agree for $A = k[x_1, \ldots, x_n]_{\mathfrak{m}}$)**.** Verify $\dim A = d(A) = \delta(A) = n$ for the local ring of affine n-space at the origin $\mathfrak{m} = (x_1, \ldots, x_n)$.

Recognition. Compute each integer separately: the chain length, the degree of $\chi_{\mathfrak{m}}$, and the size of a minimal $\mathfrak{m}$-primary generating set.

Solution. Chains: $(0) \subsetneq (x_1) \subsetneq (x_1, x_2) \subsetneq \cdots \subsetneq (x_1, \ldots, x_n)$ has length n, so $\dim A \geq n$ (and $= n$ below). *Degree*: $\mathrm{gr}_{\mathfrak{m}}(A) \cong k[x_1, \ldots, x_n]$, with Poincare series $(1-t)^{-n}$, pole order n, so $d(A) = n$. *Generators*: $\mathfrak{m} = (x_1, \ldots, x_n)$ is $\mathfrak{m}$-primary with n generators, and $\delta(A) \geq d(A) = n$ by the first inequality in the proof of the dimension theorem, so $\delta(A) = n$. Sanity check: all three equal n, exactly the dimension theorem; and the x_i are a system of parameters because $n = \dim A$.

Worked Example 15.10.17 (Computing dimension from a system of parameters)**.** Let $A = k[x, y]_{(x,y)}$ and $\mathfrak{q} = (x^2, y^3)$. Show $\mathfrak{q}$ is $\mathfrak{m}$-primary, hence $\dim A \leq 2$, and conclude $\dim A = 2$.

Recognition. If $\mathfrak{m}^r \subseteq \mathfrak{q}$ for some r, then $\mathfrak{q}$ is $\mathfrak{m}$-primary; a 2-generated $\mathfrak{m}$-primary ideal shows $\delta(A) \leq 2$, so $\dim A \leq 2$.

Solution. $\sqrt{\mathfrak{q}} = \sqrt{(x^2, y^3)} = (x, y) = \mathfrak{m}$, so $\mathfrak{q}$ is $\mathfrak{m}$-primary; indeed $\mathfrak{m}^5 \subseteq \mathfrak{q}$ since any monomial of degree ≥ 5 in x, y has x-exponent ≥ 2 or y-exponent ≥ 3. Thus $\delta(A) \leq 2$, giving $\dim A = \delta(A) \leq 2$. Combined with the length-2 chain $(0) \subsetneq (x) \subsetneq (x, y)$ giving $\dim A \geq 2$, we get $\dim A = 2$. Sanity check: $\{x^2, y^3\}$ is a system of parameters (two elements, $\dim = 2$) even though it is not a minimal *basis* of $\mathfrak{m}$; parameters need only be $\mathfrak{m}$-primary, not generate $\mathfrak{m}$.

Worked Example 15.10.18 (Dimension is invariant under completion)**.** Let $\hat{A}$ be the $\mathfrak{m}$-adic completion of a Noetherian local ring A. Show $\dim \hat{A} = \dim A$.

Recognition. Completion does not change $A/\mathfrak{m}^n$, hence not the characteristic polynomial; apply the dimension theorem.

Solution. Since $A/\mathfrak{m}^n \cong \hat{A}/\hat{\mathfrak{m}}^n$ for every n, the characteristic polynomials agree: $\chi_{\hat{\mathfrak{m}}}(n) = \chi_{\mathfrak{m}}(n)$. Therefore $d(\hat{A}) = d(A)$, and by the dimension theorem $\dim \hat{A} = d(\hat{A}) = d(A) = \dim A$. Sanity check: $\hat{A} = k[[x_1, \ldots, x_n]]$ is the completion of $k[x_1, \ldots, x_n]_{\mathfrak{m}}$, and both have dimension n; completion is an analytic refinement that preserves the count of parameters.

Worked Example 15.10.19 (A system of parameters need not be a regular sequence's only choice)**.** In $A = k[x, y]_{(x,y)}$, show $\mathfrak{q} = (x + y^2,\ xy)$ is $\mathfrak{m}$-primary and hence a system of parameters.

Recognition. Show $\sqrt{\mathfrak{q}} = \mathfrak{m}$ by proving $x, y \in \sqrt{\mathfrak{q}}$.

Solution. From $x + y^2 \in \mathfrak{q}$ and $xy \in \mathfrak{q}$: multiply $x + y^2$ by y to get $xy + y^3 \in \mathfrak{q}$, and subtract $xy \in \mathfrak{q}$ to get $y^3 \in \mathfrak{q}$, so $y \in \sqrt{\mathfrak{q}}$. Then $x = (x + y^2) - y^2 \in \sqrt{\mathfrak{q}}$ as well. Hence $\sqrt{\mathfrak{q}} \supseteq (x, y) = \mathfrak{m}$, so $\mathfrak{q}$ is $\mathfrak{m}$-primary with 2 generators, a system of parameters. Sanity check: $\delta(A) = \dim A = 2$, and we have produced an $\mathfrak{m}$-primary ideal with exactly 2 generators, neither of which is a coordinate — parameters are flexible.

Krull's principal ideal theorem (Hauptidealsatz)

Krull's theorem is the converse direction made sharp: not only does it take $\dim A$ elements to cut out the maximal ideal, but *one* element can drop the dimension by at most one. It is the engine behind almost every dimension computation.

Theorem 15.10.20 (Krull's principal ideal theorem)**.** *Let A be a Noetherian ring and $x \in A$ neither a zero-divisor nor a unit. Then every prime $\mathfrak{p}$ minimal over the principal ideal (x) has height exactly 1.*

Idea. Localize at $\mathfrak{p}$, reducing to A local with maximal ideal $\mathfrak{p}$ minimal over (x); then $\dim(A/(x)) = 0$, so by the dimension theorem $\dim A \leq 1$. If $\operatorname{ht}\mathfrak{p}$ were 0, $\mathfrak{p}$ would be a minimal prime and x (lying in $\mathfrak{p}$) a zero-divisor, contradiction. Hence $\operatorname{ht}\mathfrak{p} = 1$. The local step uses the inequality $\dim A/(x) \geq \dim A - 1$ from cutting by one element, together with $\dim A \leq \delta(A)$. □

Theorem 15.10.21 (Krull's height theorem; generalized PIT)**.** *Let A be Noetherian and $x_1, \ldots, x_r \in A$. Then every prime $\mathfrak{p}$ minimal over the ideal $(x_1, \ldots, x_r)$ has height $\leq r$. Conversely, a prime of height r is minimal over some ideal generated by r elements. In a Noetherian local ring, $\dim A$ equals the least r such that $\mathfrak{m}$ is minimal over (indeed equals the radical of) an r-generated ideal.*

Idea. The height bound $\operatorname{ht}\mathfrak{p} \leq r$ is the local statement $\dim A_{\mathfrak{p}} \leq r$ when $\mathfrak{p}$ is minimal over an r-generated ideal: cutting by r elements lowers dimension by at most r, and minimality forces $(x_1, \ldots, x_r)A_{\mathfrak{p}}$ to be $\mathfrak{p}A_{\mathfrak{p}}$-primary, so $\delta(A_{\mathfrak{p}}) \leq r$ gives $\dim A_{\mathfrak{p}} \leq r$. The converse is the inductive construction in the dimension theorem: build $x_1, \ldots, x_r$ avoiding lower minimal primes so that $\mathfrak{p}$ is minimal over them. □

Worked Example 15.10.22 (One equation cuts dimension by one: a hypersurface)**.** Let $A = k[x_1, \ldots, x_n]$ and f a nonconstant irreducible polynomial. Compute $\dim A/(f)$ and $\operatorname{ht}(f)$.

Recognition. f is a nonzero non-unit in a domain, so (f) is prime of height 1 by the PIT; cutting one equation drops dimension by one.

Solution. Since A is a UFD and f irreducible, (f) is prime and nonzero; it is not a unit, so by Krull's PIT $\operatorname{ht}(f) = 1$. Then

$$\dim A/(f) = \dim A - \operatorname{ht}(f) = n - 1$$

(in the affine domain A the height and coheight of every prime add up to $\dim A = n$). Sanity check: the plane curve $f = 0$ in $\mathbb{A}^2$ ($n = 2$) has dimension 1, and the surface in $\mathbb{A}^3$ ($n = 3$) has dimension 2 — one equation, one drop, exactly the PIT.

Worked Example 15.10.23 (Height of (x, y) in $k[x, y, z]$ via the height theorem)**.** Show $\operatorname{ht}(x, y) = 2$ in $A = k[x, y, z]$ and that the bound in Krull's height theorem is attained.

Recognition. (x, y) is generated by $r = 2$ elements, so $\operatorname{ht}(x, y) \leq 2$; a length-2 descending chain forces equality.

Solution. By Krull's height theorem any prime minimal over (x, y) has height ≤ 2; and (x, y) is itself prime (quotient $\cong k[z]$ is a domain), hence minimal over itself, so $\operatorname{ht}(x, y) \leq 2$. The chain $(0) \subsetneq (x) \subsetneq (x, y)$ gives $\operatorname{ht}(x, y) \geq 2$, so $\operatorname{ht}(x, y) = 2$. Sanity check: 2 generators, height 2 — the height theorem's bound is sharp, and $\dim A/(x, y) = \dim k[z] = 1 = 3 - 2$.

Worked Example 15.10.24 (A height-one prime needing two generators)**.** In $A = k[x, y, z]/(xy - z^2)$, the prime $\mathfrak{p} = (x, z)$ has height 1 but cannot be generated by one element. Reconcile this with the PIT.

Recognition. The PIT says a prime minimal over a *principal* ideal has height 1; it does *not* say every height-one prime is principal.

Solution. In A one checks $\mathfrak{p} = (x, z)$ is prime (quotient $\cong k[y]$) of height 1, since $\dim A = 2$ and $\dim A/\mathfrak{p} = \dim k[y] = 1$. Yet $\mathfrak{p}$ is not principal: on the quadric cone $xy = z^2$ the line $x = z = 0$ is not a Cartier

divisor at the cone point. The PIT is not violated: $\mathfrak{p}$ is minimal over (x) inside A, since $\sqrt{(x)} = \mathfrak{p}$ — indeed $z^2 = xy \in (x)$ forces $z \in \sqrt{(x)}$, so $(x, z) \subseteq \sqrt{(x)}$, while $V(x) = \{x = z = 0\} = V(\mathfrak{p})$ is irreducible, giving $\sqrt{(x)} = \mathfrak{p}$. Thus $\mathfrak{p}$ *is* minimal over the principal ideal (x), consistent with $\operatorname{ht}\mathfrak{p} = 1$. Sanity check: minimal-over-principal forces height ≤ 1 (PIT), here $= 1$; the failure of principality of $\mathfrak{p}$ itself is a feature of the singular cone, not a contradiction.

Worked Example 15.10.25 (Height bound for an ideal generated by r elements)**.** In $A = k[x_1, \ldots, x_5]$, bound $\operatorname{ht}(x_1^2,\, x_2x_3,\, x_4)$ and identify a minimal prime.

Recognition. Krull's height theorem: any prime minimal over an ideal with r generators has height $\leq r$. Here $r = 3$.

Solution. The ideal $I = (x_1^2, x_2x_3, x_4)$ has 3 generators, so every minimal prime of I has height ≤ 3. Its radical is $\sqrt{I} = (x_1, x_4, x_2) \cap (x_1, x_4, x_3)$; concretely $V(I) = \{x_1 = 0, x_4 = 0,\ (x_2 = 0 \text{ or } x_3 = 0)\}$, a union of two 2-dimensional planes, so the minimal primes are (x_1, x_4, x_2) and (x_1, x_4, x_3), each of height 3. Sanity check: 3 generators, minimal primes of height 3 — the bound is attained; and $\dim A/(x_1, x_4, x_2) = \dim k[x_3, x_5] = 2 = 5 - 3$.

Regular local rings and dimensions of polynomial and affine rings

The dimension theorem singles out a most favorable class: rings where the minimal number of equations cutting out the point equals the number of coordinate directions at the point. These are the algebraic incarnation of *smooth* (non-singular) points.

Theorem 15.10.26 (regular local rings)**.** *Let A be a Noetherian local ring of dimension d with maximal ideal $\mathfrak{m}$ and residue field $k = A/\mathfrak{m}$. The following are equivalent:*

(i) $\operatorname{gr}_{\mathfrak{m}}(A) \cong k[t_1, \ldots, t_d]$ *as graded rings;*

(ii) $\dim_k(\mathfrak{m}/\mathfrak{m}^2) = d$*;*

(iii) $\mathfrak{m}$ *can be generated by d elements.*

A ring satisfying these is called a regular local ring*, and a minimal generating set $x_1, \ldots, x_d$ of $\mathfrak{m}$ is a* regular system of parameters*. The quantity* $\dim_k(\mathfrak{m}/\mathfrak{m}^2)$ *is the* embedding dimension*; regularity says embedding dimension = Krull dimension.*

Idea. (i)⇒(ii) is clear since the degree-one part of $k[t_1, \ldots, t_d]$ has dimension d. (ii)⇒(iii) is Nakayama. (iii)⇒(i): if $x_1, \ldots, x_d$ generate $\mathfrak{m}$, the surjection $k[t_1, \ldots, t_d] \to \operatorname{gr}_{\mathfrak{m}}(A)$, $t_i \mapsto \bar{x}_i$, is an isomorphism because both sides have Hilbert series of pole order $d = \dim A$, forcing the kernel to be zero. The general inequality $\dim_k(\mathfrak{m}/\mathfrak{m}^2) \geq \dim A$ holds always (Corollary above), so regularity is the case of equality. □

Lemma 15.10.27 (regular ⇒ domain)**.** *A regular local ring is an integral domain.*

Idea. If $\operatorname{gr}_{\mathfrak{m}}(A) \cong k[t_1, \ldots, t_d]$ is an integral domain and $\bigcap_n \mathfrak{m}^n = 0$ (Krull intersection), then A is a domain: for $x, y \neq 0$ pick the exact powers $x \in \mathfrak{m}^r \setminus \mathfrak{m}^{r+1}$, $y \in \mathfrak{m}^s \setminus \mathfrak{m}^{s+1}$; their leading forms $\bar{x}, \bar{y}$ are nonzero in $\operatorname{gr}_{\mathfrak{m}}(A)$, so $\overline{xy} = \bar{x}\bar{y} \neq 0$, whence $xy \neq 0$. □

Theorem 15.10.28 (dimension of polynomial rings)**.** *For any field k and $n \geq 0$,*

$$\dim k[x_1, \ldots, x_n] = n.$$

More generally $\dim A[x] = \dim A + 1$ *for A Noetherian.*

Idea. The chain $(0) \subsetneq (x_1) \subsetneq \cdots \subsetneq (x_1, \ldots, x_n)$ gives $\dim \geq n$. For the reverse: the localization at $\mathfrak{m} = (x_1, \ldots, x_n)$ is regular of dimension n (its $\operatorname{gr}_{\mathfrak{m}}$ is $k[t_1, \ldots, t_n]$, pole order n), so $\operatorname{ht}\mathfrak{m} = n$; and the result $\dim A[x] = \dim A + 1$ (proved via the height theorem and the behavior of primes under $A \hookrightarrow A[x]$) gives the bound $\dim k[x_1, \ldots, x_n] = n$ by induction on n. □

Theorem 15.10.29 (affine domains: dimension = transcendence degree)**.** *Let k be a field and A a finitely generated k-algebra that is an integral domain (an* affine domain*), with fraction field $K = \mathrm{Frac}(A)$. Then*

$$\dim A = \mathrm{tr.deg}_k K,$$

the transcendence degree of K over k. Moreover A is catenary, and for every maximal ideal $\mathfrak{m}$, $\dim A_{\mathfrak{m}} = \dim A$, so the local dimension is the same at every point.

Idea. By Noether normalization there is a polynomial subring $B = k[y_1, \dots, y_d] \subseteq A$ with A a finite B-module and $d = \mathrm{tr.deg}_k K$. Since B is integrally closed and A integral over B, the going-up/going-down and lying-over theorems give a length-preserving correspondence of prime chains, so $\dim A = \dim B = d$ (this is A&M's Lemma: for $B \subseteq A$ integral domains with B integrally closed, A integral over B, and $\mathfrak{m}$ maximal in A with $\mathfrak{n} = \mathfrak{m} \cap B$, one has $\dim A_{\mathfrak{m}} = \dim B_{\mathfrak{n}}$). For the geometric statement, the points of an irreducible variety V correspond to maximal ideals of its coordinate ring $A(V)$, and the local dimension $\dim A(V)_{\mathfrak{m}}$ equals $\dim V = \mathrm{tr.deg}_k k(V)$ at every point. □

Remark 15.10.3. This last theorem is the bridge A&M build between the algebra of the chapter and the geometry of varieties. For an irreducible affine variety V over an algebraically closed k, the coordinate ring $A(V) = k[x_1, \dots, x_n]/\mathfrak{p}$ is an affine domain, its function field $k(V)$ is the field of rational functions, and $\dim V$ classically means $\mathrm{tr.deg}_k k(V)$ — the maximum number of algebraically independent rational functions. The theorem says this geometric dimension is exactly the Krull dimension of $A(V)$, and (by the local statement) equals the local dimension $\dim A(V)_{\mathfrak{m}}$ at *every* point. Dimension is local, constant on an irreducible variety, and computable as a transcendence degree: the three viewpoints — chains, parameters, transcendence — are one.

Worked Example 15.10.30 ($\dim k[x_1, \dots, x_n] = n$ as a transcendence degree)**.** Recompute $\dim k[x_1, \dots, x_n]$ via the affine-domain theorem and confirm consistency.

Recognition. The fraction field is $k(x_1, \dots, x_n)$, purely transcendental of transcendence degree n.

Solution. $A = k[x_1, \dots, x_n]$ is an affine domain with $\mathrm{Frac}(A) = k(x_1, \dots, x_n)$, whose transcendence degree over k is n (the x_i are algebraically independent and generate). Hence $\dim A = \mathrm{tr.deg}_k k(x_1, \dots, x_n) = n$. Sanity check: this matches the chain count and the pole-order count of earlier examples; three independent computations of $\dim k[x_1, \dots, x_n]$ all give n.

Worked Example 15.10.31 (Dimension of a coordinate ring of a curve)**.** Let $A = k[x, y]/(y^2 - x^3)$ (the cuspidal cubic). Compute $\dim A$ and its transcendence degree.

Recognition. A is an affine domain ($y^2 - x^3$ is irreducible); its dimension is tr. deg of its fraction field, or $\dim k[x, y] - \mathrm{ht}(y^2 - x^3)$.

Solution. $y^2 - x^3$ is irreducible, so A is a domain. By the PIT $\mathrm{ht}(y^2 - x^3) = 1$, so $\dim A = \dim k[x, y] - 1 = 2 - 1 = 1$. Equivalently, in $\mathrm{Frac}(A)$ the element x is transcendental over k and y is algebraic over $k(x)$ (it satisfies $y^2 = x^3$), so $\mathrm{tr.deg}_k \mathrm{Frac}(A) = 1$. Sanity check: both methods give $\dim A = 1$; the cusp is a (singular) curve, one-dimensional, and the singularity at the origin does not change the dimension.

Worked Example 15.10.32 (A regular local ring: smooth point of a plane curve)**.** Let $A = \big(k[x, y]/(y - x^2)\big)_{\mathfrak{m}}$ localized at $\mathfrak{m} = (x, y)$. Show A is regular of dimension 1.

Recognition. Regular means embedding dimension $\dim_k(\mathfrak{m}/\mathfrak{m}^2)$ equals $\dim A$; for a smooth curve point both should be 1.

Solution. The curve $y = x^2$ has coordinate ring $\cong k[x]$ (eliminate y), so $A \cong k[x]_{(x)}$, a discrete valuation ring of dimension 1. Its maximal ideal is (x), generated by one element, and $\dim_k(\mathfrak{m}/\mathfrak{m}^2) = 1 = \dim A$. Hence A is regular. Sanity check: a smooth point of a curve is regular with a single uniformizer; $\mathrm{gr}_{\mathfrak{m}}(A) \cong k[t]$, embedding dimension 1 = Krull dimension, the defining equality.

Worked Example 15.10.33 (A singular (non-regular) local ring: the node)**.** Let $A = \big(k[x, y]/(xy)\big)_{\mathfrak{m}}$ at $\mathfrak{m} = (x, y)$ (two lines crossing at the origin). Show $\dim A = 1$ but the embedding dimension is 2, so A is not regular.

Recognition. Compute $\dim A$ (a curve, so 1) and $\dim_k(\mathfrak{m}/\mathfrak{m}^2)$ (count x, y modulo $\mathfrak{m}^2$); regularity needs them equal.

Solution. A has dimension 1: $V(xy)$ is a union of two lines, each 1-dimensional, so $\dim A = 1$ (the local ring sees both branches through the origin: its maximal chains of primes are $(x) \subsetneq \mathfrak{m}$ and $(y) \subsetneq \mathfrak{m}$, each of length 1, while (0) is not prime because $xy = 0$). The cotangent space: $\mathfrak{m}/\mathfrak{m}^2$ is spanned by the images of x and y, and the only relation is $xy \in \mathfrak{m}^2$, which is automatic and imposes no linear relation; so $\dim_k(\mathfrak{m}/\mathfrak{m}^2) = 2$. Since $2 \neq 1$, A is not regular. Sanity check: embedding dimension $2 > 1 = \dim A$, the signature of a singular point; the node "needs" a 2-dimensional ambient tangent space to sit in, so it is genuinely singular — matching $\mathrm{gr}_{\mathfrak{m}}(A) = k[x, y]/(xy)$, which is not a polynomial ring.

Worked Example 15.10.34 ($\dim A[x] = \dim A + 1$ for $A = \mathbb{Z}$)**.** Compute $\dim \mathbb{Z}[x]$ and exhibit a maximal-length chain.

Recognition. $\dim \mathbb{Z}[x] = \dim \mathbb{Z} + 1 = 2$; a chain must climb from (0) through a height-one prime to a maximal ideal.

Solution. By the formula $\dim \mathbb{Z}[x] = \dim \mathbb{Z} + 1 = 1 + 1 = 2$. A realizing chain:

$$(0) \subsetneq (p) \subsetneq (p, x),$$

prime since $\mathbb{Z}[x]/(p) \cong \mathbb{F}_p[x]$ is a domain and $\mathbb{Z}[x]/(p, x) \cong \mathbb{F}_p$ is a field. Sanity check: length $2 = \dim \mathbb{Z}[x]$; the maximal ideal (p, x) has height 2, generated by 2 elements — consistent with the height theorem, and with $\mathbb{Z}[x]$ being a 2-dimensional regular ring (its localizations at maximal ideals are regular).

Worked Example 15.10.35 (Lattice of primes through a height-one prime: a Spec picture)**.** Draw the relevant portion of $\mathrm{Spec}\, k[x, y]$ as a lattice of primes, marking heights.

Recognition. Order primes by inclusion; height increases upward. Display (0) at the bottom, height-one primes in the middle, maximal ideals on top.

Solution. The inclusions among (0), the height-one prime (x), and the maximal ideals (x, y) and $(x, y - 1)$:

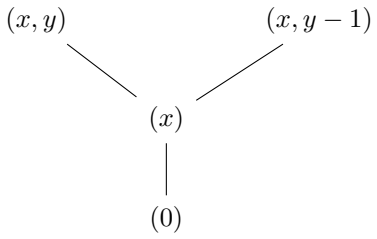


Diagram explanation. Objects: Four prime ideals in $k[x, y]$, arranged by height. (0) is the zero ideal (the generic point, height 0, a prime since $k[x, y]$ is a domain). (x) is a height-one prime (the y-axis $\{x = 0\}$, generated by one irreducible element). (x, y) and $(x, y - 1)$ are distinct maximal ideals of height 2, corresponding to the closed points $(0, 0)$ and $(0, 1)$ on the y-axis; $k[x, y]/(x, y) \cong k$ and $k[x, y]/(x, y - 1) \cong k$ confirm they are maximal.

Arrows: Every arrow is an undirected inclusion edge drawn as a dash, with the convention that lower nodes are contained in higher ones. $(0) \subset (x)$: the zero ideal lies in every nonzero prime. $(x) \subset (x, y)$ and $(x) \subset (x, y - 1)$: the height-one prime (x) is contained in both displayed maximal ideals, since $x \in (x, y)$ and $x \in (x, y - 1)$. There is no edge from (0) directly to (x, y) or $(x, y - 1)$: Hasse convention omits non-covering relations, keeping only the covering inclusions that build up the chain step by step.

What commutes: The diagram does not encode a single commutativity equation but rather displays the containment partial order on primes. The relevant chain equalities are the maximal chains: $(0) \subsetneq (x) \subsetneq (x, y)$ and $(0) \subsetneq (x) \subsetneq (x, y - 1)$, each of length 2. No chain of length 3 exists because (x, y) and $(x, y - 1)$ are maximal, so there is no prime strictly between them and $k[x, y]$ itself (which is not prime).

Why it commutes: Chase a generic prime: $\mathfrak{p} \in \mathrm{Spec}\, k[x, y]$ lies above (x) and below a maximal ideal if and only if $(x) \subsetneq \mathfrak{p} \subsetneq \mathfrak{m}$ for some maximal $\mathfrak{m}$; but in $k[x, y]/(x) \cong k[y]$, the images of such $\mathfrak{p}$ would be primes strictly between (0) and a maximal ideal of $k[y]$, which is a PID – impossible since maximal ideals of $k[y]$ have height 1 and no intermediate primes exist. Hence each displayed edge from (x) up to a maximal ideal is a covering relation. The two displayed chains are not the only ones through (x): every $(x, g(y))$ with g

irreducible in $k[y]$ (for instance $g = y - a$ with $a \in k$) is a maximal ideal containing (x), and the diagram shows just two of them.

Why this matters here: This diagram is placed immediately after the statement that $\dim k[x, y] = 2$ and that $k[x, y]$ is catenary. It makes the abstract assertion *visible*: every maximal chain from the generic point (0) to a closed point (a maximal ideal) passes through exactly one height-one prime and has length exactly 2, so "catenary" and "dim = 2" are not just numerical facts but a structural regularity you can see in the Hasse diagram of $\operatorname{Spec} k[x, y]$.

Concrete example: Take $k = \mathbb{Q}$. $(0) \subsetneq (x) \subsetneq (x, y)$ is a length-2 chain: (0) is the rational plane's generic point, (x) cuts out the y-axis $\{x = 0\}$, and (x, y) cuts out the origin $(0, 0)$. Heights: $\operatorname{ht}(0) = 0$, $\operatorname{ht}(x) = 1$, $\operatorname{ht}(x, y) = 2$. The height-one prime $(y - 1)$ (the horizontal line $y = 1$) would give a second maximal chain $(0) \subsetneq (y - 1) \subsetneq (x, y - 1)$ not shown here, confirming the diagram is only a *portion* of $\operatorname{Spec} \mathbb{Q}[x, y]$.

Common pitfall: Students sometimes read the two top nodes (x, y) and $(x, y - 1)$ as connected to each other by an inclusion. They are not: neither contains the other ($(x, y) \not\subseteq (x, y - 1)$ because $y \notin (x, y - 1)$), so there is no edge between them. Maximal ideals of the same height in a domain are never comparable under inclusion; the diagram's fork shape signals that (x) has two *distinct* maximal overprimes, not that those two overprimes are related.

Takeaway: The point of this diagram is that in $\operatorname{Spec} k[x, y]$, the Hasse diagram of prime containments has exactly three tiers – generic point, curves, closed points – with every maximal chain of length 2, giving a visible proof that $\dim k[x, y] = 2$ and that the ring is catenary.

Heights: $\operatorname{ht}(0) = 0$, $\operatorname{ht}(x) = 1$, $\operatorname{ht}(x, y) = \operatorname{ht}(x, y - 1) = 2 = \dim k[x, y]$. Sanity check: every maximal chain from (0) to a maximal ideal has length 2 (e.g. $(0) \subsetneq (x) \subsetneq (x, y)$), the ring is catenary, and $\dim k[x, y] = 2$ matches the transcendence degree of $k(x, y)$.

Method (Computing the dimension of a finitely generated k-algebra)**.** To find $\dim A$ for $A = k[x_1, \ldots, x_n]/I$: (1) if A is a domain (e.g. I prime), compute $\operatorname{tr.deg}_k \operatorname{Frac}(A)$ by finding a maximal algebraically independent subset of the images $\bar{x}_i$ — that count is $\dim A$. (2) Alternatively, write $\dim A = n - \operatorname{ht} I$ when I is prime, using Krull's PIT/height theorem to find $\operatorname{ht} I$ (often = number of equations cutting out $V(I)$ when they form a system of parameters). (3) If A is not a domain, decompose $V(I)$ into irreducible components $V(\mathfrak{p}_j)$ and take $\dim A = \max_j \dim A/\mathfrak{p}_j$, since dimension is the max over minimal primes. (4) To test *regularity* at a maximal ideal $\mathfrak{m}$, compare the embedding dimension $\dim_k(\mathfrak{m}/\mathfrak{m}^2)$ with $\dim A_{\mathfrak{m}}$; equal means smooth, strictly greater means singular (Jacobian criterion in disguise).

Caution. The dimension theorem's equalities hold for Noetherian *local* rings; for a general ring $\dim A = \sup_{\mathfrak{m}} \dim A_{\mathfrak{m}}$ over maximal ideals, and the local dimensions can differ if $\operatorname{Spec} A$ has components of different dimensions (e.g. $k[x, y, z]/(xy, xz)$, a plane meeting a line). Do not assume "$\dim A$ generators of $\mathfrak{m}$" globally: that count is local. Also, the equality $\operatorname{ht} \mathfrak{p} + \dim A/\mathfrak{p} = \dim A$ requires A catenary (true for affine domains over a field, but not for arbitrary Noetherian rings); without it a prime can have "defect" and the naive subtraction $\dim A - \operatorname{ht} \mathfrak{p}$ may overcount.

Worked Example 15.10.36 (Non-equidimensional Spec: a plane meeting a line)**.** Let $A = k[x, y, z]/(xy, xz)$. Compute $\dim A$ and show $\operatorname{Spec} A$ has components of different dimensions.

Recognition. $\sqrt{(xy, xz)} = (x) \cap (y, z)$, so $V(xy, xz) = \{x = 0\} \cup \{y = z = 0\}$, a plane and a line; take the max of component dimensions.

Solution. The ideal factors as $V(xy, xz) = V(x) \cup V(y, z)$: the plane $x = 0$ (dimension 2, prime (x)) and the line $y = z = 0$ (dimension 1, prime (y, z)). The minimal primes are (x) and (y, z) with $\dim A/(x) = \dim k[y, z] = 2$ and $\dim A/(y, z) = \dim k[x] = 1$. Hence

$$\dim A = \max\{2, 1\} = 2.$$

Sanity check: $\operatorname{Spec} A$ is not equidimensional; the global dimension 2 comes from the plane, while the line contributes a 1-dimensional component — exactly the situation the caution warns about, where naive height/coheight arithmetic at the intersection point can mislead.

Exercises (Atiyah & Macdonald).

1. Let $f \in k[x_1, \ldots, x_n]$ be an irreducible polynomial over an algebraically closed field k. A point P on the variety $f(x) = 0$ is *non-singular* $\iff$ not all the partial derivatives $\partial f/\partial x_i$ vanish at P. Let $A = k[x_1, \ldots, x_n]/(f)$, and let $\mathfrak{m}$ be the maximal ideal of A corresponding to the point P. Prove that P is non-singular $\iff$ $A_{\mathfrak{m}}$ is a regular local ring.

   [By (11.18) we have $\dim A_{\mathfrak{m}} = n - 1$. Now

   $$\mathfrak{m}/\mathfrak{m}^2 \cong (x_1, \ldots, x_n)/\big((x_1, \ldots, x_n)^2 + (f)\big)$$

   (with P taken to be the origin) and has dimension $n - 1$ if and only if $f \notin (x_1, \ldots, x_n)^2$, i.e. if and only if $\partial f/\partial x_i \notin (x_1, \ldots, x_n)$ for some i.]

2. In (11.21) assume that A is complete. Prove that the homomorphism $k[[t_1, \ldots, t_d]] \to A$ given by $t_i \mapsto x_i$ $(1 \leqslant i \leqslant d)$ is injective and that A is a finitely-generated module over $k[[t_1, \ldots, t_d]]$. [Use (10.24).]

3. Extend (11.25) to non-algebraically-closed fields. [If $\bar{k}$ is the algebraic closure of k, then $\bar{k}[x_1, \ldots, x_n]$ is integral over $k[x_1, \ldots, x_n]$.]

4. A counterexample of a Noetherian domain of infinite dimension (Nagata). Let k be a field and let $A = k[x_1, x_2, \ldots, x_n, \ldots]$ be a polynomial ring over k in a countably infinite set of indeterminates. Let $m_1, m_2, \ldots$ be an increasing sequence of positive integers such that $m_{i+1} - m_i > m_i - m_{i-1}$ for all $i > 1$. Let $\mathfrak{p}_i = (x_{m_i+1}, \ldots, x_{m_{i+1}})$ and let S be the complement in A of the union of the ideals $\mathfrak{p}_i$.

   Each $\mathfrak{p}_i$ is a prime ideal and therefore the set S is multiplicatively closed. The ring $S^{-1}A$ is Noetherian (Chapter 7, Exercise 9). Each $S^{-1}\mathfrak{p}_i$ has height equal to $m_{i+1} - m_i$, hence $\dim S^{-1}A = \infty$.

5. Reformulate (11.1) in terms of the Grothendieck group $K(A_0)$ (Chapter 7, Exercise 26).

6. Let A be a ring (not necessarily Noetherian). Prove that

   $$1 + \dim A \leqslant \dim A[x] \leqslant 1 + 2\dim A.$$

   [Let $f\colon A \to A[x]$ be the embedding and consider the fibre of $f^*\colon \operatorname{Spec}(A[x]) \to \operatorname{Spec}(A)$ over a prime ideal $\mathfrak{p}$ of A. This fibre can be identified with the spectrum of $k \otimes_A A[x] \cong k[x]$, where k is the residue field at $\mathfrak{p}$ (Chapter 3, Exercise 21), and $\dim k[x] = 1$. Now use Exercise 7(ii) of Chapter 4.]

7. Let A be a Noetherian ring. Then

   $$\dim A[x_1, \ldots, x_n] = n + \dim A.$$

   [Let $\mathfrak{p}$ be a prime ideal of height m in A. Then there exist $a_1, \ldots, a_m \in \mathfrak{p}$ such that $\mathfrak{p}$ is a minimal prime ideal belonging to the ideal $\mathfrak{a} = (a_1, \ldots, a_m)$. By Exercise 7 of Chapter 4, $\mathfrak{p}[x]$ is a minimal prime ideal of $\mathfrak{a}[x]$ and therefore height $\mathfrak{p}[x] \leqslant m$. On the other hand, a chain of prime ideals $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \cdots \subset \mathfrak{p}_m$ gives rise to a chain $\mathfrak{p}_0[x] \subset \cdots \subset \mathfrak{p}_m[x] = \mathfrak{p}[x]$, hence height $\mathfrak{p}[x] \geqslant m$. Hence height $\mathfrak{p}[x]$ = height $\mathfrak{p}$. Now use the argument of Exercise 6.]

Practice problems.

1. In $A = k[x, y, z]$ exhibit a chain of prime ideals of length 3 that passes through the height-two prime (x, y), and verify each inclusion is strict and each ideal prime by identifying the quotient. Conclude $\dim A \geq 3$ and that $\operatorname{ht}(x, y) = 2$.

2. Let $A = k[x, y, z, w]/(xz - yw)$. Show that $f = xz - yw$ is irreducible, deduce $\operatorname{ht}(f) = 1$ by Krull's principal ideal theorem, and compute $\dim A$. Then find $\operatorname{tr.deg}_k \operatorname{Frac}(A)$ directly and confirm it agrees.

3. For $A = k[x, y]_{(x,y)}$ and the $\mathfrak{m}$-primary ideal $\mathfrak{q} = (x^2, xy, y^2) = \mathfrak{m}^2$, compute $\operatorname{length}(A/\mathfrak{q}^n)$ as a function of n for all $n \geq 1$, identify the degree and leading coefficient of the resulting Hilbert–Samuel polynomial, and check that the degree equals $\dim A$.

4. Let $A = k[x, y, z]/(z^2 - xy)$ localized at $\mathfrak{m} = (x, y, z)$. Compute $\dim A$ and the embedding dimension $\dim_k(\mathfrak{m}/\mathfrak{m}^2)$, and decide whether A is a regular local ring. Justify your answer geometrically.

5. Show that $\mathfrak{q} = (x^3,\, y^2,\, xy)$ is (x,y)-primary in $A = k[x,y]_{(x,y)}$ by exhibiting an explicit r with $\mathfrak{m}^r \subseteq \mathfrak{q}$, and conclude $\dim A \le 3$; then find two of the three generators that already generate an $\mathfrak{m}$-primary ideal and conclude $\dim A \le 2$. Determine whether $\{x^3, y^2, xy\}$ is a system of parameters and explain.

6. In $A = k[x,y,z]$ bound $\operatorname{ht}(xy,\, z)$ using Krull's height theorem, then compute the radical $\sqrt{(xy,z)}$, list the minimal primes over (xy,z), and give the height of each. State $\dim A/(xy,z)$.

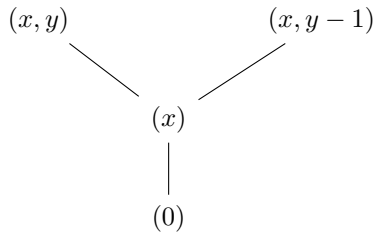
7. Let $A = \mathbb{Z}[x]$. Compute $\dim A$, and for the maximal ideal $\mathfrak{m} = (5, x^2+2)$ verify that $\mathfrak{m}$ has height 2 by exhibiting a maximal-length chain of primes ending at $\mathfrak{m}$ and identifying the residue field $A/\mathfrak{m}$.

8. Let $A = k[[x_1,\dots,x_n]]$ be the formal power series ring over a field k. Using that A is the $\mathfrak{m}$-adic completion of $k[x_1,\dots,x_n]_{(x_1,\dots,x_n)}$, prove $\dim A = n$, exhibit a regular system of parameters, and identify $\operatorname{gr}_{\mathfrak{m}}(A)$.

Additional exercises.

1. Let A be a Noetherian local ring with maximal ideal $\mathfrak{m}$, and let $x \in \mathfrak{m}$ be neither a unit nor a zero-divisor. Prove $\dim A/(x) = \dim A - 1$. (Use Krull's principal ideal theorem for the inequality $\dim A/(x) \ge \dim A - 1$ and the dimension theorem for the reverse, comparing characteristic polynomials.)

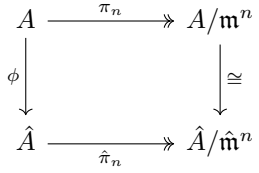
2. Let A be a Noetherian local ring of dimension d. Prove that elements $x_1,\dots,x_d \in \mathfrak{m}$ form a system of parameters if and only if $\mathfrak{m}$ is the unique prime minimal over $(x_1,\dots,x_d)$, i.e. $\sqrt{(x_1,\dots,x_d)} = \mathfrak{m}$. Deduce that any system of parameters generates an $\mathfrak{m}$-primary ideal.



3. Let A be an affine domain over a field k and let $\mathfrak{p}$ be a prime of A. Prove $\operatorname{ht}\mathfrak{p} + \dim(A/\mathfrak{p}) = \dim A$. (Use Noether normalization and that affine domains are catenary, together with $\dim A = \operatorname{tr.deg}_k \operatorname{Frac}(A)$.) Illustrate the formula with $\mathfrak{p} = (x)$ in $k[x,y,z]$.

4. Let A be a Noetherian local ring with residue field $k = A/\mathfrak{m}$. Prove the inequality $\dim A \le \dim_k(\mathfrak{m}/\mathfrak{m}^2)$, with equality if and only if A is regular. Then prove that a regular local ring is an integral domain, using the Krull intersection theorem and that $\operatorname{gr}_{\mathfrak{m}}(A)$ is a polynomial ring.

5. Let A be a Noetherian ring. Prove that for every prime $\mathfrak{p}$, $\operatorname{ht}\mathfrak{p}$ equals the least number of elements $a_1,\dots,a_r \in \mathfrak{p}$ such that $\mathfrak{p}$ is minimal over $(a_1,\dots,a_r)$. Conclude that in a Noetherian ring every prime has finite height even when $\dim A = \infty$.



Commutative-diagram exercises.

1. Let $A = k[x,y]$ and consider the height-one prime (x) together with the two maximal ideals (x,y) and $(x,y-1)$ lying over it. Complete the prime-lattice diagram below, label each upward edge with the difference in heights, and prove that every maximal chain from (0) to a maximal ideal has length 2 (so A is catenary of dimension 2):

   Identify ht of each node and confirm $\operatorname{ht}(x,y) = \operatorname{ht}(x,y-1) = \dim A$.

2. Let $A = k[x,y]_{(x,y)}$ with $\mathfrak{m} = (x,y)$ and let $\hat{A} = k[[x,y]]$ be its $\mathfrak{m}$-adic completion. Prove the square below commutes (horizontal maps are the canonical quotients $A \to A/\mathfrak{m}^n$, vertical maps the completion and the induced map on quotients), and conclude $\chi_{\hat{\mathfrak{m}}}(n) = \chi_{\mathfrak{m}}(n)$ for all n, hence $\dim \hat{A} = \dim A$:

State why the right-hand vertical map is an isomorphism and how this yields equality of Hilbert–Samuel polynomials.

3. Let A be a Noetherian domain and $\mathfrak{p}$ a prime. Complete the localization square below, where $A_{\mathfrak{p}}$ is the localization at $\mathfrak{p}$ and the horizontal maps are the canonical localizations, and prove that the map $\mathfrak{q} \mapsto \mathfrak{q}A_{\mathfrak{p}}$ is an order-isomorphism between primes of A contained in $\mathfrak{p}$ and all primes of $A_{\mathfrak{p}}$; conclude $\operatorname{ht}\mathfrak{p} = \dim A_{\mathfrak{p}}$:

$$\begin{array}{ccc} A & \longrightarrow & A_{\mathfrak{p}} \\ \downarrow & & \downarrow \\ A/\mathfrak{q} & \longrightarrow & A_{\mathfrak{p}}/\mathfrak{q}A_{\mathfrak{p}} \end{array}$$

Identify which primes $\mathfrak{q}$ of A survive under $A \to A_{\mathfrak{p}}$ (i.e. have $\mathfrak{q}A_{\mathfrak{p}} \neq A_{\mathfrak{p}}$), and use this to translate a chain of length $\operatorname{ht}\mathfrak{p}$ descending from $\mathfrak{p}$ into a chain in $A_{\mathfrak{p}}$.

4. Let $B = k[y_1, \dots, y_d] \subseteq A$ be a Noether normalization of an affine domain A over k, so A is a finite B-module and B is a polynomial ring. For a maximal ideal $\mathfrak{m} \subset A$ with $\mathfrak{n} = \mathfrak{m} \cap B$, complete the diagram of inclusions and prove $\dim A_{\mathfrak{m}} = \dim B_{\mathfrak{n}} = d$:

$$\begin{array}{ccc} B & \hookrightarrow & A \\ \downarrow & & \downarrow \\ B_{\mathfrak{n}} & \hookrightarrow & A_{\mathfrak{m}} \end{array}$$

Using going-down for the integral extension $B \subseteq A$ (valid because B is integrally closed and A is a domain), show a chain of primes of length d descending from $\mathfrak{n}$ lifts to a chain of the same length descending from $\mathfrak{m}$, and conclude $\dim A = \operatorname{tr.deg}_k \operatorname{Frac}(A) = d$.

15.11 Graded Problem Bank

Easy

DF 15.1.13 Verify properties (1) through (10) of the maps $\mathcal{Z}$ and $\mathcal{I}$.

DF 15.1.14 Show that the affine algebraic sets in $\mathbb{A}^1$ over any field k are $\varnothing$, k, and finite subsets of k.

DF 15.1.17 If k is a finite field, show that every subset of $\mathbb{A}^n$ is an affine algebraic set.

DF 15.1.18 If $k = \mathbb{F}_q$ is the finite field with q elements, show that $\mathcal{I}(\mathbb{A}^1) = (x^q - x) \subseteq k[x]$.

DF 15.1.15 If $k = \mathbb{F}_2$ and $V = \{(0,0), (1,1)\} \subseteq \mathbb{A}^2$, show that $\mathcal{I}(V)$ is the product ideal $\mathfrak{m}_1\mathfrak{m}_2$ with $\mathfrak{m}_1 = (x, y)$ and $\mathfrak{m}_2 = (x-1, y-1)$.

DF 15.1.21 Identifying a 2×2 matrix over k with a point of $\mathbb{A}^4$, show that $\mathrm{SL}_2(k)$ is an algebraic set in $\mathbb{A}^4$.

DF 15.2.3 Prove that the intersection of two radical ideals is again a radical ideal.

DF 15.2.8 Suppose the prime ideal $\mathfrak{p}$ contains the ideal I. Prove that $\mathfrak{p}$ contains $\operatorname{rad} I$.

DF 15.2.10 Prove that for k a finite field the Zariski topology equals the discrete topology: every subset is closed (and open).

DF 15.2.2d Prove that $\operatorname{rad}(\operatorname{rad} I) = \operatorname{rad} I$.

DF 15.2.2c Prove that $\operatorname{rad}(IJ) = \operatorname{rad}(I \cap J) = \operatorname{rad} I \cap \operatorname{rad} J$.

DF 15.3.4 Use the fact that a U.F.D. is integrally closed to prove that $\mathbb{Z}[i]$ is the ring of integers in $\mathbb{Q}(i)$.

DF 15.3.5 If R is an integral domain with field of fractions F, show that F is a finitely generated R-module if and only if $R = F$.

DF 15.4.1 If M is a finitely generated R-module, prove that $D^{-1}M = 0$ if and only if $dM = 0$ for some $d \in D$.

DF 15.4.13 Prove that if N and N' are R-submodules of M with $N_P = N'_P$ for every prime (or just every maximal) ideal P, then $N = N'$.

DF 15.4.21 If $\varphi : R \to S$ is a ring homomorphism and D' a multiplicatively closed subset of S, prove that $D = \varphi^{-1}(D')$ is multiplicatively closed and that $r/d \mapsto \varphi(r)/\varphi(d)$ is a ring homomorphism $D^{-1}R \to D'^{-1}S$.

DF 15.5.1 If $\mathfrak{N}$ is the nilradical of R, prove that $\operatorname{Spec} R$ and $\operatorname{Spec} R/\mathfrak{N}$ are homeomorphic.

DF 15.5.10 For $X = \operatorname{Spec} R$ and principal open sets, prove $X_f \cap X_g = X_{fg}$, that $X_f = X$ iff f is a unit, and $X_f = \varnothing$ iff f is nilpotent.

DF 15.5.11 Prove that the open set $X_f \cup X_g$ in $\operatorname{Spec} R$ is the complement of $\mathcal{Z}(I)$ where $I = (f, g)$.

DF 15.5.13 Prove that under $\varphi^* : \operatorname{Spec} S \to \operatorname{Spec} R$ the preimage of the principal open set X_f is $Y_{\varphi(f)}$.

Artin 9.5 Prove that the variety of zeros of a set $\{ f_1, \ldots, f_r \}$ of polynomials depends only on the ideal they generate.

Artin 9.3 If $U = \{ f_i(x) = 0 \}$ in $\mathbb{C}^m$ and $V = \{ g_j(y) = 0 \}$ in $\mathbb{C}^n$ are varieties, show that the variety defined by $\{ f_i(x) = 0,\ g_j(y) = 0 \}$ in $\mathbb{C}^{m+n}$ is the product set $U \times V$.

Artin 9.7a Determine the points of intersection in $\mathbb{C}^2$ of $y^2 - x^3 + x^2 = 1$ and $x + y = 1$.

Artin 9.7c Determine the points of intersection in $\mathbb{C}^2$ of $y^2 = x^3$ and $xy = 1$.

Fraleigh 37.1 Find a basis for the ideal in $\mathbb{R}[x, y]$ of all polynomials with constant term 0.

Fraleigh 37.2 Find a basis for the kernel of the evaluation homomorphism $\varphi_{(2,3)} : \mathbb{R}[x, y] \to \mathbb{R}$.

Fraleigh 37.3 Find a basis for the kernel of the evaluation homomorphism $\varphi_{(-4,5)} : \mathbb{R}[x, y] \to \mathbb{R}$.

Fraleigh 37.5 Find a simpler basis for $I = (x + y + z,\ 2x + y + 3z - 4)$ in $\mathbb{R}[x, y, z]$ and describe its variety.

Fraleigh 37.6 Find a simpler basis for $I = (3x + 4y + 7z - 10,\ 2x + 3y - 2z + 1)$ and describe its variety.

Fraleigh 37.7 Find a simpler basis for $I = (x^4 + 5x^3 + 3x^2 - 7x - 2,\ x^3 + 6x^2 + 3x - 10)$ in $\mathbb{R}[x]$ and describe its variety.

Fraleigh 37.8 Find a simpler basis for $I = (x^6 - x^5 - 6x^4 + 3x^3 - 8x^2 - 4x + 3,\ x^3 - 2x^2 - 9)$ in $\mathbb{R}[x]$ and describe its variety.

Fraleigh 37.9 Describe the algebraic variety for the ideal $\{ 0 \}$ in $F[x, y]$.

Fraleigh 37.10 Describe the algebraic variety for the ideal $\{ 1 \}$ in $F[x, y]$.

Fraleigh 37.11 Describe the algebraic variety in F for the ideal $(x^2 + 1)$ when (a) $F = \mathbb{R}$ and (b) $F = \mathbb{C}$.

Fraleigh 37.12 Compare the algebraic varieties for the ideals $I = (x^2 + 4xy + 4y^2)$ and $J = (x + 2y)$.

Fraleigh 37.4 Find a basis for the ideal in $\mathbb{R}[x, y]$ of all polynomials vanishing on the unit circle centered at the origin.

Medium

DF 15.1.1 Prove the converse to Hilbert's Basis Theorem: if $R[x]$ is Noetherian, then R is Noetherian.

DF 15.1.2 Show that the ring of continuous real-valued functions on $[0, 1]$, and the ring of all functions $X \to \mathbb{Z}/2\mathbb{Z}$ for an infinite set X, are not Noetherian by exhibiting explicit infinite increasing chains of ideals.

DF 15.1.4 Prove that if R is Noetherian then so is the power series ring $R[[x]]$.

DF 15.1.6 For an exact sequence $0 \to M' \to M \to M'' \to 0$ of R-modules, prove M is Noetherian iff M' and M'' are.

DF 15.1.7 Prove that submodules, quotient modules, and finite direct sums of Noetherian R-modules are again Noetherian.

DF 15.1.8 If R is Noetherian, prove that M is a Noetherian R-module iff M is finitely generated.

DF 15.1.16 If V is a finite algebraic set in $\mathbb{A}^n$ with m points, prove that $k[V] \cong k^m$ as k-algebras.

DF 15.1.19 For nonconstant $f \in k[x]$, describe $\mathcal{Z}(f) \subseteq \mathbb{A}^1$ via the factorization of f, and deduce $\mathcal{I}(\mathcal{Z}(f)) = (f)$ iff f is a product of distinct linear factors.

DF 15.1.22 Prove that $\mathrm{SL}_n(k)$ is an affine algebraic set in $\mathbb{A}^{n^2}$.

DF 15.1.23 For a line V in $\mathbb{R}^2$, prove $\mathbb{R}[V] \cong \mathbb{R}[x]$ and give the corresponding isomorphism $\mathbb{A}^1 \to V$.

DF 15.1.25 For an affine algebraic set V and $f \in k[V]$, prove that the graph of f is an affine algebraic set isomorphic to V.

DF 15.1.26 For a morphism $\varphi : V \to W$ and an algebraic subset W' of W, prove that $\varphi^{-1}(W')$ is an algebraic subset of V, and if $W' = \mathcal{Z}(I)$ then $V' = \mathcal{Z}(\overline{\varphi}(I))$.

DF 15.1.27 Prove that if V and W are affine algebraic sets then so is $V \times W$, and $k[V \times W] \cong k[V] \otimes_k k[W]$.

DF 15.1.29 If $R = \mathbb{Z}$ and $M = \mathbb{Z}/n\mathbb{Z}$, show that $\mathrm{Ass}_R(M)$ consists of the primes (p) for the prime divisors p of n.

DF 15.1.30 If M is the union of submodules M_i, prove that $\mathrm{Ass}_R(M) = \bigcup \mathrm{Ass}_R(M_i)$.

DF 15.1.31 If $\mathrm{Ann}(m) = P$ (so $Rm \cong R/P$), prove that $\mathrm{Ann}(m') = P$ for $0 \neq m' \in Rm$, and deduce $\mathrm{Ass}_R(R/P) = \{ P \}$.

DF 15.1.24 Prove that $V = \mathcal{Z}(xy - z) \subseteq \mathbb{A}^3$ is isomorphic to $\mathbb{A}^2$, giving explicit isomorphisms; decide whether $\mathcal{Z}(xy - z^2)$ is isomorphic to $\mathbb{A}^2$.

DF 15.2.1 Prove (3) of Corollary 22 directly using the collection of ideals not containing a finite product of prime ideals.

DF 15.2.2 For ideals I, J prove: $I^k \subseteq J$ implies $\operatorname{rad} I \subseteq \operatorname{rad} J$; $I^k \subseteq J \subseteq I$ implies $\operatorname{rad} I = \operatorname{rad} J$; and $\operatorname{rad}(I + J) = \operatorname{rad}(\operatorname{rad} I + \operatorname{rad} J)$.

DF 15.2.4 Prove that $I = \mathfrak{m}_1\mathfrak{m}_2$ with $\mathfrak{m}_1 = (x, y)$, $\mathfrak{m}_2 = (x - 1, y - 1)$ is a radical ideal in $\mathbb{F}_2[x, y]$, and that $(x^3 - y^2)$ is radical in $\mathbb{F}_2[x, y]$.

DF 15.2.5 If $I = (xy, (x - y)z) \subseteq k[x, y, z]$, prove $\operatorname{rad} I = (xy, xz, yz)$, that $\mathcal{Z}(I) = \mathcal{Z}(\operatorname{rad} I)$ is not irreducible, and $\operatorname{rad} I$ is not prime.

DF 15.2.6 Give an example over a non-algebraically-closed k where $I \subseteq \mathcal{I}(\mathcal{Z}(I))$ is proper even though I is radical.

DF 15.2.7 For a ring homomorphism $\varphi : R \to S$ and ideal I, show $\varphi(\operatorname{rad} I) \subseteq \operatorname{rad}(\varphi(I))$, with equality when φ is surjective and $I \supseteq \ker \varphi$.

DF 15.2.9 Prove that the Nullstellensatz map $\mathcal{Z}$ is always surjective and $\mathcal{I}$ always injective; give examples over non-algebraically-closed k where $\mathcal{Z}$ is not injective and $\mathcal{I}$ not surjective.

DF 15.2.11 For a variety $V \subseteq \mathbb{A}^n$ and Zariski-open U_1, U_2, prove $V \cap U_1, V \cap U_2 \neq \varnothing$ implies $V \cap U_1 \cap U_2 \neq \varnothing$; conclude nonempty open subsets are dense.

DF 15.2.12 Use density of nonempty open sets to prove that an affine variety is connected in the Zariski topology.

DF 15.2.14 Prove that if k is infinite, the varieties in $\mathbb{A}^1$ are the whole space and the one-point subsets; describe them when k is finite.

DF 15.2.15 If V is a hypersurface with $\mathcal{I}(V) = (f)$ for nonconstant f, prove V is a variety iff f is irreducible.

DF 15.2.16 For an affine variety V and $f \in k[V]$, prove that the graph of f is an affine variety.

DF 15.2.20 For an algebraic set V and $f \in k[V]$, show $V_f = \{ v \in V \mid f(v) \neq 0 \}$ is Zariski open, may be embedded as a closed set in a larger affine space, and that principal open sets form a base.

DF 15.2.23 Show that if k is infinite then $\{ (a, a^2, a^3) \mid a \in k \} \subseteq \mathbb{A}^3$ is an affine variety, and that for finite k it is always reducible.

DF 15.2.27 Prove that each of $\prod_{i=1}^{\infty} \mathbb{Z}/2\mathbb{Z}$ and $k[x_1, x_2, \ldots]/(x_1x_2, x_3x_4, \ldots)$ has infinitely many minimal primes and that (0) has no primary decomposition.

DF 15.2.28 If $AB \subseteq Q$ for a primary ideal Q and $A \not\subseteq Q$, prove $B \subseteq \operatorname{rad} Q$.

DF 15.2.30 Prove that if Q_1, Q_2 are $\mathfrak{p}$-primary, then $Q_1 \cap Q_2$ is $\mathfrak{p}$-primary; conclude finite intersections of $\mathfrak{p}$-primary ideals are $\mathfrak{p}$-primary.

DF 15.2.31 Prove that if Q_1, Q_2 are $\mathfrak{m}$-primary for a maximal ideal $\mathfrak{m}$, then $Q_1 + Q_2$ and $Q_1 Q_2$ are $\mathfrak{m}$-primary.

DF 15.2.32 For $I = (x^2, xy, xz, yz)$ in $k[x, y, z]$, prove $I = (x, y) \cap (x, z) \cap (x, y, z)^2$, find the isolated and embedded primes, and $\operatorname{rad} I$.

DF 15.2.34 For $I = (xy, x - yz)$ in $k[x, y, z]$, prove that $(x, z) \cap (y^2, x - yz)$ is a minimal primary decomposition.

DF 15.2.35 Prove that a prime $\mathfrak{p}$ contains I iff $\mathfrak{p}$ contains one of the associated primes of a minimal primary decomposition of I.

DF 15.3.1 Use the fact that a U.F.D. is integrally closed to identify $\mathbb{Z}[i]$ as the ring of integers in $\mathbb{Q}(i)$.

DF 15.3.2 For $R = k[x, y]/(x^2 - y^3)$ and $t = x/y$, prove $K = k(t)$ is the fraction field of R and $k[t]$ is the integral closure of R in K.

DF 15.3.8 Prove that if $s_1, \ldots, s_n \in S$ are integral over R, then $R[s_1, \ldots, s_n]$ is a finitely generated R-module.

DF 15.3.10 Prove the generalization of Proposition 28: for R integrally closed with fraction field k, α in an extension is integral over R iff α is algebraic over k with $m_{\alpha,k}(x) \in R[x]$.

DF 15.3.11 For R integrally closed with fraction field k and monic $p(x) \in R[x]$, show that if $p = ab$ with monic $a, b \in k[x]$ then $a, b \in R[x]$.

DF 15.3.20 For $V = \mathcal{Z}(uv + v)$ and $W = \mathcal{Z}(-2y - y^2 + 2z + z^2,\ 2x - yz - z^2)$ in complex space, show that the defining ideals $I = (uv + v)$ and J are radical ideals that are not prime (so V and W are reducible algebraic sets) and that $\varphi((a_1, a_2)) = (a_1^2 + a_2, a_1 + a_2, a_1 - a_2)$ is an isomorphism $V \to W$.

DF 15.4.2 For an ideal I and saturation $c(eI)$ with respect to D, prove $c(eI) = R$ iff $I \cap D \neq \varnothing$; that I is saturated iff $da \in I \Rightarrow a \in I$; and that extension/contraction give inverse bijections; compute the saturation of $(2x, 3y) \subseteq \mathbb{Z}[x, y]$ with respect to $\mathbb{Z} - \{0\}$.

DF 15.4.6 Show that $I = (y^3 - xz, xy^2 - z^2)$ is not prime in $\mathbb{Q}[x, y, z]$ and find a, b with $ab \in I$ but $a, b \notin I$.

DF 15.4.10 Show that $I = (xy - w^3, y^2 - zw)$ is not prime in $\mathbb{Q}[x, y, z, w]$ and find a, b with $ab \in I$, $a, b \notin I$.

DF 15.4.14 Prove that $\varphi : M \to N$ is injective (resp. surjective) iff $\varphi_P : M_P \to N_P$ is injective (resp. surjective) for every prime (or every maximal) P.

DF 15.4.16 Prove that localization commutes with tensor products: $(D^{-1}M) \otimes_{D^{-1}R} (D^{-1}N) \cong D^{-1}(M \otimes_R N)$.

DF 15.4.17 Prove that A is a flat R-module iff A_P is flat over R_P for every prime (or every maximal) P.

DF 15.4.18 Prove that $R_f \cong R[x]/(fx - 1)$ if f is not nilpotent in R.

DF 15.4.19 Prove that if R is an integrally closed domain and D a multiplicatively closed subset, then $D^{-1}R$ is integrally closed.

DF 15.4.20 If S is integral over R and $D \subseteq R$ is multiplicatively closed, prove $D^{-1}S$ is integral over $D^{-1}R$.

DF 15.4.22 For primes $P \subseteq Q$ in R, prove that R_P is isomorphic to the localization of R_Q at PR_Q.

DF 15.4.23 For $\varphi : A \to B$ and a prime P of A, prove that P is the contraction of a prime of B iff $P = (P^e)^c$.

DF 15.4.30 Prove that $M = 0$ iff $\operatorname{Supp}(M) = \varnothing$.

DF 15.4.31 For an exact sequence $0 \to L \to M \to N \to 0$, prove $M_P \neq 0$ iff $L_P \neq 0$ or $N_P \neq 0$, and deduce $\operatorname{Supp}(M) = \operatorname{Supp}(L) \cup \operatorname{Supp}(N)$.

DF 15.4.32 For primes $P \subseteq Q$ and a module M, prove $(M_Q)_P = M_P$.

DF 15.4.33 For primes $P \subseteq Q$ and a module M, prove $P \in \operatorname{Supp}(M)$ implies $Q \in \operatorname{Supp}(M)$.

DF 15.4.37 Prove that $\operatorname{Ass}_R(M) \subseteq \operatorname{Supp}(M)$.

DF 15.5.2 Prove that the map $\operatorname{Spec} R/I \to \operatorname{Spec} R$ induced by $R \to R/I$ is a homeomorphism onto the closed set $\mathcal{Z}(I)$.

DF 15.5.3 Prove that $f, g \in R$ have the same values at all $P \in \operatorname{Spec} R$ iff $f - g$ is nilpotent; deduce an element of an affine k-algebra is determined by its values.

DF 15.5.4 Prove that the primes of $k[x,y]$ are (0), (f) for irreducible f, and $(p(x), g(x,y))$ with p irreducible in $k[x]$ and g irreducible mod $p(x)$; identify $\operatorname{mSpec} k[x,y]$.

DF 15.5.9 Prove that the fiber over (p) of $\operatorname{Spec} \mathbb{Z}[x] \to \operatorname{Spec} \mathbb{Z}$ is homeomorphic to $\operatorname{Spec}(\mathbb{Z}[x] \otimes_{\mathbb{Z}} \mathbb{F}_p)$.

DF 15.5.12 Prove that a Zariski open subset U of $\operatorname{Spec} R$ is quasicompact iff it is a finite union of principal open sets; give a covering with no finite subcovering.

DF 15.5.14 If $R = R_1 \times R_2$, prove that $\operatorname{Spec} R$ is the disjoint union of open-and-closed $X_1 \cong \operatorname{Spec} R_1$ and $X_2 \cong \operatorname{Spec} R_2$.

DF 15.5.15 Prove that $\operatorname{Spec} R$ is disconnected iff R is a product of two nonzero rings iff R has an idempotent $e \neq 0, 1$.

DF 15.5.16 Prove that $\operatorname{Spec} R$ is irreducible iff $X_f \cap X_g \neq \varnothing$ for all nonempty principal opens, hence iff the nilradical is prime.

DF 15.5.21 For a multiplicatively closed D, show $R \to D^{-1}R$ induces a homeomorphism of $\operatorname{Spec}(D^{-1}R)$ onto the primes P with $P \cap D = \varnothing$.

DF 15.5.22 Show that $\operatorname{Spec} k[x,y]/(xy)$ is connected but the union of two proper closed sets each homeomorphic to $\operatorname{Spec} k[x]$, hence not irreducible.

DF 15.5.27 For $R = k[x,y]$ and $M = (x,y)$, prove $\operatorname{Supp}(M) = \operatorname{Spec} R$ and $\operatorname{Ass}_R(M) = \{\, 0 \,\}$.

DF 15.5.30 For $I = (x^2, xy, xz, yz)$ in $k[x,y,z]$, prove $\operatorname{Ass}_R(R/I) = \{\, (x,y), (x,z), (x,y,z) \,\}$.

Artin 9.1 For $I = (y^2 + x^3 - 17)$ in $\mathbb{C}[x,y]$, decide which of $(x-1, y-4)$, $(x+1, y+4)$, $(x^3 - 17, y^2)$ generate maximal ideals in $R = \mathbb{C}[x,y]/I$.

Artin 9.2 For polynomials $f_1, \ldots, f_r$ in $\mathbb{C}[x_1, \ldots, x_n]$ with variety V and ideal I, define a homomorphism from R/I to the ring of continuous complex-valued functions on V.

Artin 9.4 For varieties U, V in $\mathbb{C}^n$, prove $U \cup V$ and $U \cap V$ are varieties; interpret $U \cap V = \varnothing$ and $U \cup V = \mathbb{C}^n$ algebraically.

Artin 9.7b Determine the points of intersection in $\mathbb{C}^2$ of $x^2 + xy + y^2 = 1$ and $x^2 + 2y^2 = 1$.

Artin 9.7d Determine the points of intersection in $\mathbb{C}^2$ of $x + y^2 = 0$ and $y + x^2 + 2xy^2 + y^4 = 0$.

Artin 9.8 Determine which ideals in $\mathbb{C}[x,y]$ contain both $x^2 + y^2 - 5$ and $xy - 2$.

Artin 9.10 For a complex line $L = \{\, ax + by + c = 0 \,\}$ and the curve $C = \{\, f = 0 \,\}$ with f irreducible of degree d, prove $C \cap L$ has at most d points unless $C = L$.

Artin 9.12 Prove in two ways that $f_1 = t^2 + x^2 - 2$, $f_2 = tx - 1$, $f_3 = t^3 + 5tx^2 + 1$ generate the unit ideal in $\mathbb{C}[t,x]$: by having no common zeros, and by writing 1 as a polynomial combination.

Hard

DF 15.1.3 Prove that the field $k(x)$ of rational functions is not a finitely generated k-algebra.

DF 15.1.5 (Fitting's Lemma) For a Noetherian module M and endomorphism φ, prove $\ker(\varphi^n) \cap \operatorname{im}(\varphi^n) = 0$ for large n, and that surjective φ is an isomorphism.

DF 15.1.9 For k a field, prove any subring of $k[x]$ containing k is Noetherian; give a subring that is not a U.F.D.

DF 15.1.10 Prove that the subring $k[x, x^2y, x^3y^2, \ldots] \subseteq k[x,y]$ is not Noetherian, hence not a finitely generated k-algebra.

DF 15.1.11 Prove that a commutative ring in which all prime ideals are finitely generated is Noetherian.

DF 15.1.12 For R Noetherian, S a finitely generated R-algebra, and $T \subseteq S$ with S a finitely generated T-module, prove T is a finitely generated R-algebra.

DF 15.1.20 For irreducible non-associate $f, g \in k[x,y]$, show $\mathcal{Z}((f,g))$ is empty or finite in $\mathbb{A}^2$.

DF 15.1.28 For $V = \mathcal{Z}(xz - y^2, yz - x^3, z^2 - x^2y)$, prove $\varphi(t) = (t^3, t^4, t^5)$ is a surjective morphism $\mathbb{A}^1 \to V$, describe $\overline{\varphi}$, and show φ is not an isomorphism.

DF 15.1.32 If P is maximal among the annihilator ideals $\operatorname{Ann}(m)$ of nonzero $m \in M$, prove P is prime.

DF 15.1.33 For R Noetherian and $M \neq 0$, prove $\operatorname{Ass}_R(M) \neq \varnothing$.

DF 15.1.34 For $L \subseteq M$ with $N \cong M/L$, prove $\operatorname{Ass}_R(L) \subseteq \operatorname{Ass}_R(M) \subseteq \operatorname{Ass}_R(L) \cup \operatorname{Ass}_R(N)$ and that both containments can be proper.

DF 15.1.35 For $S \subseteq \operatorname{Ass}_R(M)$, prove there is a submodule N with $\operatorname{Ass}_R(N) = S$ and $\operatorname{Ass}_R(M/N) = \operatorname{Ass}_R(M) - S$.

DF 15.1.36 Show the Fitting ideal equals the ideal generated by all $n \times n$ minors of relations matrices, and is invariant under elementary row and column operations.

DF 15.1.37 For two generating sets of M, prove the Fitting ideals computed from each agree, so $\mathcal{F}_R(M)$ is independent of generators.

DF 15.1.38 Establish the chain $\operatorname{Ann}(M)^n \subseteq \mathcal{F}_R(M) \subseteq \operatorname{Ann}(M)$ and the multiplicativity, quotient, exact-sequence, and base-change properties of the Fitting ideal, including the $k[x,y,z]$ example.

DF 15.1.39 For a surjection $\varphi : R^n \to M$ with $L = \ker \varphi$, prove the image of $\bigwedge^n(L) \to \bigwedge^n(R^n) \cong R$ is the Fitting ideal $\mathcal{F}_R(M)$.

DF 15.1.40 For $\varphi : R \to S$ and $M' = S \otimes_R M$, prove $\mathcal{F}_S(M')$ is the extension to S of $\mathcal{F}_R(M)$.

DF 15.1.41 For a Grobner basis $\{ g_1, \ldots, g_m \}$ of I, prove the monomials not divisible by any $\operatorname{LT}(g_i)$ form a k-basis of $k[x_1, \ldots, x_n]/I$.

DF 15.1.42 For $I = (x^3y - xy^2 + 1, x^2y^2 - y^3 - 1)$, show $\{ 1, y, y^2, y^3 \}$ is a k-basis for $k[x,y]/I$ and compute the multiplication table.

DF 15.1.43 For $k \subseteq K$ and an ideal I in $k[x_1, \ldots, x_n]$ with extension I' in $K[x_1, \ldots, x_n]$, prove a Grobner basis of I is one of I', the quotient dimensions agree, and $I = k[\underline{x}]$ iff $I' = K[\underline{x}]$.

DF 15.1.44 For $V = \mathcal{Z}(x^3 - x^2z - y^2z)$ and $W = \mathcal{Z}(x^2 + y^2 - z^2)$ in $\mathbb{C}^3$, show $\varphi((a,b,c)) = (a^2c - b^2c, 2abc, -a^3)$ is a morphism $V \to W$.

DF 15.1.45 For $V = \mathcal{Z}(x^3 + y^3 + 7z^3)$, show that $\overline{\varphi}(x) = x(y^3 - 7z^3)$, $\overline{\varphi}(y) = y(7z^3 - x^3)$, $\overline{\varphi}(z) = z(x^3 - y^3)$ define a $\mathbb{C}$-algebra endomorphism of $k[V]$, compute $\varphi((-2,1,1))$, and prove there are infinitely many integer points with $\gcd = 1$.

DF 15.1.46 For $V = \mathcal{Z}(xz + y^2 + z^2,\ xy - xz + yz - 2z^2)$ and $W = \mathcal{Z}(u^3 - uv^2 + v^3)$, show $\varphi((a,b)) = (-2a^2 + ab, ab - b^2, a^2 - ab)$ is a morphism $W \to V$ and find the kernel of the corresponding algebra map.

DF 15.1.47 For $\Phi : \mathbb{Q}[u,v,w] \to \mathbb{Q}[x,y]$ with $\Phi(u) = x^2 + y$, $\Phi(v) = x + y^2$, $\Phi(w) = x - y$, show neither x nor y is in the image, that a given f is, and determine $\ker \Phi$.

DF 15.1.48 Given α a root of irreducible p and $\beta = f(\alpha)/g(\alpha)$, develop the Grobner-basis method for the minimal polynomial of β and apply it to $(3 - \sqrt[3]{2} + \sqrt[3]{4})/(1 + 3\sqrt[3]{2} - 3\sqrt[3]{4})$.

DF 15.2.13 Let V be a nonempty affine algebraic set. Prove that if $k[V]$ is a direct sum of two nonzero ideals, then V is not connected in the Zariski topology, and prove the converse when k is algebraically closed. Give a counterexample to the converse over a field k that is not algebraically closed.

DF 15.2.17 Prove that any permutation of k is Zariski continuous $\mathbb{A}^1 \to \mathbb{A}^1$; deduce for infinite k there are Zariski continuous self-maps of $\mathbb{A}^1$ that are not polynomials.

DF 15.2.18 For $V \subseteq \mathbb{A}^n$ over $\mathbb{C}$, prove morphisms are Euclidean continuous, V is Euclidean closed, and give a Euclidean-closed set that is not Zariski closed.

DF 15.2.19 Give an injective k-algebra homomorphism $\widetilde{\varphi} : k[W] \to k[V]$ whose associated morphism is not surjective.

DF 15.2.21 Prove $\mathrm{GL}_n(k)$ is an open affine algebraic set in $\mathbb{A}^{n^2}$, embeds as a closed set in $\mathbb{A}^{n^2+1}$, and $k^\times$ embeds as the hyperbola $xy = 1$.

DF 15.2.22 Prove that the surjective image of a variety under a morphism of affine algebraic sets is a variety.

DF 15.2.24 For $V = \mathcal{Z}(xz - y^2, yz - x^3, z^2 - x^2y)$ over infinite k, show V is an affine variety.

DF 15.2.25 For an irreducible cubic f of discriminant D and $I = (x + y + z + a, xy + xz + yz - b, xyz + c)$, prove I is prime iff D is not a square, and analyze its primary decomposition when $D = r^2$.

DF 15.2.26 Prove that every affine algebraic set is quasicompact.

DF 15.2.29 For a $\mathfrak{p}$-primary Q and ideal $A \not\subseteq Q$, prove $A' = \{\, r \mid rA \subseteq Q \,\}$ is $\mathfrak{p}$-primary.

DF 15.2.33 For a surjective $\varphi : R \to S$, prove $Q \supseteq \ker \varphi$ is primary iff $\varphi(Q)$ is primary, with associated prime $\varphi(\mathfrak{p})$.

DF 15.2.36 For $\varphi : R \to S$, prove that primary decompositions push forward (surjective case) and pull back, with the stated radicals.

DF 15.2.37 Prove that every associated prime of a radical ideal is isolated.

DF 15.2.38 For fixed a and $I_a = \{\, r \mid ar \in I \,\}$, prove I_a is an ideal, $(I \cap J)_a = I_a \cap J_a$, and for $\mathfrak{p}$-primary Q with $a \notin Q$ that Q_a is $\mathfrak{p}$-primary.

DF 15.2.39 Prove that the associated primes of a minimal primary decomposition are exactly the primes among the $\mathrm{rad}(I_a)$, hence uniquely determined by I.

DF 15.2.40 For the associated primes of (0) in a Noetherian ring, prove their intersection is the nilradical and their union is the set of zero divisors.

DF 15.2.41 Prove that a Noetherian ring is an integral domain, has nonzero nilpotents, or has at least two minimal primes.

DF 15.2.42 Prove that an ideal in a Noetherian ring is radical iff all primary components of a minimal decomposition are prime, and that the decomposition is then unique.

DF 15.2.43 Prove that a Noetherian domain is a U.F.D. iff the isolated primes of every principal ideal (a) are principal.

DF 15.2.44 For the ring of C^∞ functions on $(-1, 1)$ and $F(x) = e^{-1/x^4}$, establish the stated facts: $\mathfrak{m} = (x)$, R is not Noetherian, $\mathfrak{p} = \bigcap \mathfrak{m}^n$ is prime, $A = \mathrm{rad}((F)) \subseteq \mathfrak{p}$ with $A \neq \mathfrak{p}$, and there is a nonzero prime properly inside $\mathfrak{p}$.

DF 15.2.45 For an ideal A in $k[x_1, \ldots, x_n, y_1, \ldots, y_m]$, prove the radical-intersection and zero-set identities used to compute elimination ideals via Hilbert's Nullstellensatz.

DF 15.2.46 Determine the Zariski closure in $\mathbb{C}^3$ of $\{\, (a^2, a^3, a^4) \mid a \in \mathbb{C} \,\}$.

DF 15.2.47 Show $\mathcal{Z}(x^3 - xyz + z^2)$ is the smallest algebraic set in $\mathbb{R}^3$ containing $\{\, (st, s + t, s^2t) \,\}$.

DF 15.2.48 Show $\mathcal{Z}(x^3z^2 - 3xy^2z^2 - y^6 - z^4)$ is the smallest algebraic set in $\mathbb{R}^3$ containing $\{\, (s^2 + t^2, st, s^3) \,\}$.

DF 15.2.49 Find equations defining the Zariski closure of $\{\, (s^4, s^3t, st^3, t^4) \mid s, t \in \mathbb{R} \,\}$.

DF 15.2.50 For the Whitney umbrella $V = \mathcal{Z}(x^2 - y^2z)$, show it is the smallest algebraic set containing $S = \{\, (st, s, t^2) \,\}$ over $\mathbb{R}$, that S is not closed in V, and that $S = V$ over $\mathbb{C}$.

DF 15.2.51 Determine the Zariski closure of the projection of $V = \mathcal{Z}(xz^2 - w^3, xw^2 - y^4, y^4z^2 - w^5) \subseteq \mathbb{C}^4$ to the first three coordinates.

DF 15.2.52 For $V = \mathcal{Z}(xy - 1)$ and its projection S onto the x-axis, compute $\mathcal{I}(V)$ and the elimination ideal over $\mathbb{R}$ (closure is $\mathbb{A}^1$, S not closed) and over $\mathbb{F}_3$ (S closed).

DF 15.2.53 For the ideal quotient $(I : J)$, prove $\mathcal{Z}(I) - \mathcal{Z}(J) \subseteq \mathcal{Z}((I : J))$, equality of closures for radical I over algebraically closed k, and $(\mathcal{I}(V) : \mathcal{I}(W)) = \mathcal{I}(V - W)$.

DF 15.3.3 For relatively prime i, j, find the normalization of $R = k[x,y]/(x^i - y^j)$.

DF 15.3.4' For $P = (y^2 - x^3 - x^2)$ in $k[x,y]$, prove P is prime and find the normalization of $R = k[x,y]/P$.

DF 15.3.6 Exhibit explicit rings $R \subseteq S$ and ideals realizing each of: $I \neq IS \cap R$; a prime P that is no contraction; a maximal M of S with $M \cap R$ not maximal; a prime P with PS not prime; and $J \neq (J \cap R)S$.

DF 15.3.7 For the ring of integers $\mathcal{O}_K$, prove that unique factorization of ideals into prime powers is equivalent to "Q is P-primary iff $Q = P^m$".

DF 15.3.9 For S integral over R and a prime P of R, prove every $s \in PS$ satisfies a monic equation with coefficients in P.

DF 15.3.12 For S a domain integral over integrally closed R and $s \in PS$, prove all non-leading coefficients of the minimal polynomial of s over k lie in P.

DF 15.3.13 For a field K of characteristic 0 and a subring $A \subseteq K$ maximal with respect to $1/2 \notin A$, prove K is algebraic over the fraction field F, A is integrally closed in K, and conclude $K = F$.

DF 15.3.14 Prove that K is the field of fractions of a proper subring iff K is not a subfield of $\overline{\mathbb{F}_p}$.

DF 15.3.15 Using Noether Normalization, prove every affine algebraic set V over algebraically closed k admits a surjective morphism onto $\mathbb{A}^n$ with finite fibers, with $n = \dim V$ when V is a variety.

DF 15.3.16 Prove that an affine algebraic set in $\mathbb{C}^n$ is compact in the Euclidean topology iff it is finite.

DF 15.3.17 For S integral over R, prove R and S have the same Krull dimension via the going-up and lying-over chains.

DF 15.3.18 For $V = \mathcal{Z}(uv + v)$ and $W = \mathcal{Z}(-2y - y^2 + 2z + z^2,\ 2x - yz - z^2)$, prove that the defining ideals I, J are radical ideals that are not prime (so V, W are reducible algebraic sets) and that $\varphi((a_1, a_2)) = (a_1^2 + a_2, a_1 + a_2, a_1 - a_2)$ is an isomorphism.

DF 15.3.19 For $I = (x^3+y^3+z^3, x^2+y^2+z^2, (x+y+z)^3)$, use Grobner bases to show $x, y, z \in \operatorname{rad} I$ when $\operatorname{char} k \neq 2, 3$.

DF 15.3.21 For $I = (x^3 + y^3 + z^3, xy + xz + yz, xyz)$, use Grobner bases to show $x, y, z \in \operatorname{rad} I$.

DF 15.3.22 For $I = (x^4 + y^4 + z^4, x + y + z)$, analyze $\operatorname{rad} I$ across characteristics: smallest power of $xy + xz + yz$ in I, the radical J, and the special cases $\operatorname{char} k = 2, 3$.

DF 15.3.23 For $I = (x^2y + z^3, x + y^3 - z, 2y^4z - yz^2 - z^3)$, use Grobner bases to prove $\operatorname{rad} I = (x, y, z)$ and find the smallest powers x^9, y^7, z^9 in I.

DF 15.3.24 For $V = \mathcal{Z}(x^3 - x^2z - y^2z)$ and $W = \mathcal{Z}(x^2 + y^2 - z^2)$ in $\mathbb{C}^3$, prove $\mathcal{I}(V)$ and $\mathcal{I}(W)$ are the stated principal ideals.

DF 15.3.25 For $V = \mathcal{Z}(x^3 + y^3 + 7z^3) \subseteq \mathbb{C}^3$, prove $\mathcal{I}(V) = (x^3 + y^3 + 7z^3)$.

DF 15.3.26 For $I = (xz+y^2+z^2, xy-xz+yz-2z^2)$ and $K = I+(x^2-3y^2+yz)$, prove K is radical, $\operatorname{rad} I \subseteq K \cap (y,z)$, and $K \cap (y,z) = I$, so I is radical.

DF 15.3.27 Prove the equivalence of the four characterizations of a zero-dimensional ideal in $k[x_1, \ldots, x_n]$ (finite-dimensional quotient; nonzero one-variable elimination ideals; Grobner leading terms; finite zero set in $\overline{k}$).

DF 15.3.28 For a zero-dimensional ideal I, prove $|Z_{\overline{k}}(I)| = \dim_{\overline{k}} \overline{k}[\underline{x}]/\operatorname{rad} I'$ and $|Z(I)| \leq \dim_k k[\underline{x}]/I$.

DF 15.3.29 For a zero-dimensional ideal and squarefree parts r_i, prove $I + (r_1, \ldots, r_n) \subseteq \operatorname{rad} I$ with equality for perfect k; compute several radicals; and give a non-perfect counterexample.

DF 15.4.3 For $\varphi : R[\underline{x}] \to (R/I)[\underline{x}]$ reducing coefficients mod I, prove the stated identities for inverse images of subrings and contractions of ideals.

DF 15.4.4 For $f = y^5 - z^4 \in \mathbb{Q}[z][y]$, prove f has no root in $\mathbb{Q}[z]$, derive the coefficient system of a hypothetical factorization, and conclude f is irreducible in $\mathbb{Q}[y,z]$.

DF 15.4.5 For a U.F.D. R with fraction field F and monic $p \in R[x]$, prove $pR[x]$ is prime iff $pF[x]$ is prime, and that $pR[x]$ is saturated.

DF 15.4.7 Show $P = (y^3 - xz, xy^2 - z^2, x^2 - yz)$ is prime in $\mathbb{Q}[x, y, z]$.

DF 15.4.8 Show $P = (x^2 - yz, w^2 - x^4 z)$ is prime in $\mathbb{Q}[x, y, z, w]$.

DF 15.4.9 Show $P = (xz^2 - w^3, xw^2 - y^4, y^4 z^2 - w^5)$ is prime in $\mathbb{Q}[x, y, z, w]$.

DF 15.4.11 Prove that a P-primary Q satisfies $Q = c(eQ)$ for extension/contraction to R_P, and likewise for P'-primary with $P' \subseteq P$.

DF 15.4.12 For $R = \mathbb{R}[x, y, z]/(xy - z^2)$ and $P = (\overline{x}, \overline{z})$, prove $P^2 R_P \cap R = (\overline{x})$ is strictly larger than P^2.

DF 15.4.15 For $R = \mathbb{Z}[\sqrt{-5}]$ and $I = (2, 1 + \sqrt{-5})$, prove $I_P \cong R_P$ for every prime P but $I \ncong R$ as R-modules.

DF 15.4.24 (Going-down Theorem) For an integrally closed domain $R \subseteq S$ with S a domain integral over R, primes $P_2 \subseteq P_1$ in R, and Q_1 in S over P_1, construct $Q_2 \subseteq Q_1$ over P_2, proving the going-down theorem.

DF 15.4.25 For $V = \mathcal{Z}(xz - yw)$ and $f = x/y \in k(V)$, prove the regular locus of f is exactly $\{\, y \neq 0 \text{ or } z \neq 0 \,\}$ and that no single representative is regular everywhere.

DF 15.4.26 (Differentials of morphisms) Construct the differential $d\varphi : \mathbb{T}_{v,V} \to \mathbb{T}_{w,W}$ of a morphism, prove its explicit Jacobian form, functoriality, and that it is an isomorphism when φ is.

DF 15.4.27 For $\varphi(t) = (t^3, t^4, t^5)$, compute $d\varphi$ explicitly, show it is an isomorphism for $t \neq 0$ and zero at $t = 0$, and conclude $\mathbb{A}^1$ and W are not isomorphic.

DF 15.4.28 For the dual numbers $k[x]/(x^2)$, prove that a k-algebra map $k[V] \to k[x]/(x^2)$ is the same as a k-rational point together with a tangent vector.

DF 15.4.29 (Dimension of a variety) For a prime P and the chain $P_i = P \cap k[x_1, \ldots, x_i]$, prove $\dim V_{i-1} \leq \dim V_i \leq \dim V_{i-1} + 1$, the two extreme cases, and the Grobner-basis count of $\dim V$.

DF 15.4.34 For a cyclic module Rm, characterize $M_P = 0$ and $P \in \operatorname{Supp}(M)$ via annihilators, and extend to finitely generated M with $\operatorname{Supp}(M) = V(\operatorname{Ann}(M))$.

DF 15.4.35 For a prime P with $P \cap D = \varnothing$, prove $P \in \operatorname{Ass}_R(M)$ implies $D^{-1}P \in \operatorname{Ass}_{D^{-1}R}(D^{-1}M)$.

DF 15.4.36 For a finitely generated prime P with $P \cap D = \varnothing$ and $D^{-1}P \in \operatorname{Ass}(D^{-1}M)$, prove $P \in \operatorname{Ass}_R(M)$.

DF 15.4.38 Over a Noetherian R, prove the associated primes with $P \cap D = \varnothing$ correspond bijectively to the associated primes of the localization.

DF 15.4.39 Over a Noetherian R, prove the kernel of $M \to D^{-1}M$ is the unique submodule N with $\operatorname{Ass}_R(N) = S$ and $\operatorname{Ass}_R(M/N) = \operatorname{Ass}_R(M) - S$, where $S = \{\, P \in \operatorname{Ass}_R(M) \mid P \cap D \neq \varnothing \,\}$.

DF 15.4.40 Over a Noetherian R, prove $\operatorname{Ass}_R(M) \subseteq \operatorname{Supp}(M)$ and that the two sets have the same minimal elements.

DF 15.5.5 For a maximal ideal $\mathfrak{m} = (p(x), g(x, y))$ in $k[x, y]$, prove $K = k[x, y]/\mathfrak{m}$ is algebraic over k and $\mathfrak{m} = k[x, y] \cap (x - \alpha, y - \beta)$ in $K[x, y]$.

DF 15.5.6 Describe the elements of $\operatorname{Spec} \mathbb{R}[x]$, $\operatorname{Spec} \mathbb{C}[x]$, and $\operatorname{Spec} \mathbb{Z}_{(2)}[x]$.

DF 15.5.7 For $(f) = (x^5 + x + 1)$ in $\operatorname{Spec} \mathbb{Z}[x]$ over $\operatorname{Spec} \mathbb{Z}$, show there are $2, 3, 4, 5$ closed points in the fibers over $(2), (5), (19), (211)$.

DF 15.5.8 For $(f) = (x^4 + 1)$ in $\operatorname{Spec} \mathbb{Z}[x]$ over $\operatorname{Spec} \mathbb{Z}$, count the closed points in the fiber over each prime via the splitting of $x^4 + 1$.

DF 15.5.17 For $G = \langle a \rangle$ of order 2 and $R = \mathbb{Z}[G]$, analyze $\operatorname{Spec} R$: nilradical (0) not prime, the cover $X^+ \cup X^-$, the two non-closed points, and the picture fibered over $\operatorname{Spec} \mathbb{Z}$.

DF 15.5.18 For the structure sheaf on $\operatorname{Spec} R$ and sections $s = a/f_1^n$, $t = b/f_2^m$, verify the formulas for st and $s + t$ on $X_{f_1 f_2}$, deducing $\mathcal{O}(U)$ is a commutative ring with identity.

DF 15.5.19 For the structure sheaf and $V \subseteq U$, prove restriction of a section is a well-defined ring homomorphism $\mathcal{O}(U) \to \mathcal{O}(V)$.

DF 15.5.20 For $\varphi : R \to S$ and opens $V \subseteq U$, prove the induced map on sections $\varphi^{\#} : \mathcal{O}_X(U) \to \mathcal{O}_Y(U')$ is a ring homomorphism compatible with restriction.

DF 15.5.23 For each of $\mathbb{Z}/4\mathbb{Z}$, $\mathbb{Z}/6\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$, and $(\mathbb{Z}/2\mathbb{Z})^3$, exhibit $\operatorname{Spec} R$, its open sets, the structure-sheaf sections, and the stalks.

DF 15.5.24 Prove: if every ideal of R is principal then every open in $\operatorname{Spec} R$ is principal open; and that $R = \mathbb{Z}[x]/(4, x^2)$ has a nonprincipal ideal yet every open in $\operatorname{Spec} R$ is principal open.

DF 15.5.25 For an R-module M, prove $\operatorname{Supp}(M)$ is the union of the Zariski closed sets $\mathcal{Z}(P)$, $P \in \operatorname{Supp}(M)$, and equals $\mathcal{Z}(\operatorname{Ann}(M))$ when M is finitely generated; show that $\operatorname{Supp}(M)$ need not be Zariski closed (consider the $\mathbb{Z}$-module $\bigoplus_p \mathbb{Z}/p\mathbb{Z}$).

DF 15.5.26 For a finitely generated module over a Noetherian ring, prove the finitely many minimal primes over $\operatorname{Ann}(M)$ are the minimal primes of $\operatorname{Ass}_R(M)$ and that $\operatorname{Supp}(M)$ is their union of closed sets.

DF 15.5.28 Prove that Q in a Noetherian ring is P-primary iff $\operatorname{Ass}_R(R/Q) = \{ P \}$.

DF 15.5.29 For a minimal primary decomposition $I = Q_1 \cap \cdots \cap Q_n$ with $P_i = \operatorname{rad} Q_i$, prove $\operatorname{Ass}_R(R/I) = \{ P_1, \ldots, P_n \}$.

DF 15.5.31 (Spec for quadratic integer rings) For R the ring of integers in $\mathbb{Q}(\sqrt{D})$, determine the primes of R from the primes (p) of $\mathbb{Z}$ via the factorization of $\overline{m_\omega}(x) \bmod p$, classifying ramified, split, and inert primes.

Artin 9.6 Prove that every variety in $\mathbb{C}^2$ is the union of finitely many points and algebraic curves.

Artin 9.9 Prove that an irreducible plane algebraic curve has only finitely many singular points.

Artin 9.11 For zero sets C_1, C_2 of quadratics with no common linear factor, prove the line through two intersection points carries a product of linear polynomials in the pencil, and that C_1, C_2 meet in at most 4 points.

Artin 9.13 For a homomorphism $\varphi : \mathbb{C}[x, y] \to \mathbb{C}[t]$ fixing $\mathbb{C}$ with $x \mapsto x(t)$, $y \mapsto y(t)$ not both constant, prove that $\ker \varphi$ is a principal ideal.

Artin M.6 Prove that the locus $y = \sin x$ in $\mathbb{R}^2$ does not lie on any algebraic curve in $\mathbb{C}^2$.

Artin M.7 For R the ring of continuous functions $[0, 1] \to \mathbb{R}$, prove finitely many functions with no common zero generate the unit ideal, and establish a bijection between maximal ideals of R and points of $[0, 1]$.

Chapter 16

Artinian Rings, Discrete Valuation Rings, and Dedekind Domains

16.1 Artinian Rings

The descending chain condition

Noetherian rings are defined by the ascending chain condition on ideals. Reversing the inequality gives the dual notion, and the surprise of this section is that the dual condition is far more restrictive: where Noetherian rings are abundant ($\mathbb{Z}$, every $k[x_1, \dots, x_n]$, every finitely generated algebra), Artinian rings turn out to be the Noetherian rings of *dimension zero* – exactly the rings whose primes are all maximal. The slogan, due to Atiyah and Macdonald, is

$$\text{Artinian} \;=\; \text{Noetherian} \;+\; \dim 0,$$

and the whole section is built around making this precise and exploiting it.

Definition 16.1.1 (DCC; Artinian module and ring)**.** An R-module M satisfies the *descending chain condition* (DCC) if every chain $M_1 \supseteq M_2 \supseteq M_3 \supseteq \cdots$ of submodules *stabilizes*: there is m with $M_k = M_m$ for all $k \geq m$. Such an M is called *Artinian*. A commutative ring R is *Artinian* if it is Artinian as a module over itself, i.e. every descending chain $\mathfrak{a}_1 \supseteq \mathfrak{a}_2 \supseteq \cdots$ of ideals stabilizes.

Recall the Krull dimension $\dim R$ is the supremum of lengths n of chains $\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_n$ of primes. A field has $\dim 0$; a PID that is not a field (like $\mathbb{Z}$ or $k[x]$) has $\dim 1$. The point of the DCC is that it forces $\dim R = 0$.

Proposition 16.1.2 (minimal-element form of DCC)**.** *M is Artinian if and only if every nonempty collection Σ of submodules of M has a* minimal *element (one containing no other member of Σ). Likewise R is Artinian iff every nonempty set of ideals has a minimal element.*

Idea. If DCC holds and Σ had no minimal element, we could choose $M_1 \supsetneq M_2 \supsetneq \cdots$ indefinitely, contradicting DCC. Conversely, given a descending chain, the minimal element of the set $\{ M_i \}$ is some M_m, and minimality forces $M_k = M_m$ for $k \geq m$. (Exactly the dual of the maximal-element characterization of Noetherian modules.) □

It is immediate from the Lattice Isomorphism Theorem that every quotient $R/\mathfrak{a}$ of an Artinian ring is Artinian, and – as for Noetherian modules – the Artinian property passes through short exact sequences.

Proposition 16.1.3 (exact sequences)**.** *If $0 \to M' \to M \to M'' \to 0$ is exact, then M is Artinian iff both M' and M'' are. Consequently a finite direct sum of Artinian modules is Artinian.*

Idea. A descending chain in M induces descending chains in the sub M' and the quotient M''; if both stabilize, the original stabilizes (the standard two-out-of-three argument by intersecting and projecting). The converse restricts a chain in M' and pulls back a chain in M''. □

Worked Example 16.1.4 ($\mathbb{Z}$ is Noetherian but not Artinian)**.** Exhibit a non-stabilizing descending chain of ideals in $\mathbb{Z}$, and contrast with the ACC.

Recognition. Ideals of $\mathbb{Z}$ are (n), and $(a) \supseteq (b) \iff a \mid b$; the DCC fails exactly because one can keep multiplying.

Solution. The chain $(2) \supsetneq (4) \supsetneq (8) \supsetneq \cdots \supsetneq (2^k) \supsetneq \cdots$ never stabilizes, since $(2^k) \neq (2^{k+1})$. Thus $\mathbb{Z}$ is not Artinian. It *is* Noetherian (every ideal is principal, so ACC holds), and indeed $\dim \mathbb{Z} = 1$ via $(0) \subsetneq (2)$. Sanity check: this matches the slogan – $\mathbb{Z}$ is Noetherian of dimension $1 \neq 0$, so it must fail to be Artinian.

Worked Example 16.1.5 ($k[x]$ is not Artinian)**.** Show $k[x]$ (k a field) is not Artinian.

Recognition. Same mechanism as $\mathbb{Z}$: a domain that is not a field has $\dim \geq 1$, and we can descend through powers of an irreducible.

Solution. $(x) \supsetneq (x^2) \supsetneq (x^3) \supsetneq \cdots$ is a strictly descending chain, so DCC fails. Here $\dim k[x] = 1$ (chain $(0) \subsetneq (x)$), and $k[x]$ is Noetherian (PID). Sanity check: $k[x]$ has the maximal ideal (x) properly containing the prime (0), so not every prime is maximal – dimension is not 0 – consistent with non-Artinian.

Worked Example 16.1.6 (The Prufer-type module $\mathbb{Z}[1/p]/\mathbb{Z}$ is Artinian but not Noetherian)**.** Show that DCC and ACC are genuinely independent for modules.

Recognition. In a module, Artinian and Noetherian are logically independent; the Prufer group $\mathbb{Z}(p^\infty) = \mathbb{Z}[1/p]/\mathbb{Z}$ is the standard separating example.

Solution. Let $M = \mathbb{Z}[1/p]/\mathbb{Z}$. Its proper submodules are the cyclic groups $M_n = \langle 1/p^n + \mathbb{Z} \rangle \cong \mathbb{Z}/p^n\mathbb{Z}$, totally ordered by $M_0 \subsetneq M_1 \subsetneq M_2 \subsetneq \cdots$. An *ascending* chain need not stabilize (take $M_0 \subsetneq M_1 \subsetneq \cdots$), so M is not Noetherian. But any *descending* chain of submodules is a descending subchain of the M_n, which is well-ordered downward (each M_n is finite), so it stabilizes: M is Artinian. Sanity check: the submodule lattice is the chain $\{ M_n \}_{n \geq 0} \cup \{ M \}$, order-isomorphic to $\mathbb{N} \cup \{ \infty \}$ (with M as ∞) – well-ordered, so every descending chain stabilizes, yet containing the infinite strictly ascending chain $M_0 \subsetneq M_1 \subsetneq \cdots$ – exactly the asymmetry between DCC and ACC.

Length and the Jordan–Hölder theorem

The right finiteness measure for modules carrying both chain conditions is *length*. It behaves like dimension for vector spaces and is the bookkeeping device behind every later count.

Definition 16.1.7 (composition series and length)**.** A *composition series* of an R-module M is a chain

$$0 = M_0 \subsetneq M_1 \subsetneq \cdots \subsetneq M_n = M$$

in which each factor M_i/M_{i-1} is *simple* (nonzero, with no proper nonzero submodule). The integer n is the *length* of the series. If a composition series exists, M is said to have *finite length*, written $\operatorname{length}_R(M) < \infty$.

Theorem 16.1.8 (Jordan–Hölder)**.** *If M has a composition series, then* every *composition series of M has the same length $n = \operatorname{length}_R(M)$, and the multiset of simple factors $\{ M_i/M_{i-1} \}$ is determined up to isomorphism and reordering. Moreover M has finite length iff M is both Artinian and Noetherian, and then* length *is additive on short exact sequences.*

Idea. Length-additivity and uniqueness follow from the Schreier refinement theorem: any two composition series have isomorphic refinements, and a composition series admits no proper refinement, so the two series are already equivalent. For the chain-condition statement: a composition series is a maximal finite chain, which forces both DCC and ACC; conversely if both hold, build a series by repeatedly choosing a minimal nonzero submodule of each successive quotient (such a submodule exists by DCC); the resulting strictly ascending chain terminates by ACC. □

Method (Computing length)**.** To find $\operatorname{length}_R(M)$: (i) for a vector space, $\operatorname{length}_k(V) = \dim_k V$ since the simple k-modules are copies of k; (ii) use additivity $\operatorname{length}(M) = \operatorname{length}(M') + \operatorname{length}(M'')$ across $0 \to M' \to M \to M'' \to 0$ to break M along a filtration; (iii) for a local Artinian ring R with maximal ideal $\mathfrak{m}$, filter by the powers $\mathfrak{m}^i$ and read off the dimensions of the successive quotients $\mathfrak{m}^i/\mathfrak{m}^{i+1}$ as $R/\mathfrak{m}$-vector spaces.

Worked Example 16.1.9 (Length of $\mathbb{Z}/p^k\mathbb{Z}$ as a $\mathbb{Z}$-module)**.** Compute $\text{length}_{\mathbb{Z}}(\mathbb{Z}/p^k\mathbb{Z})$ and exhibit a composition series.

Recognition. Simple $\mathbb{Z}$-modules are $\mathbb{Z}/q\mathbb{Z}$ for primes q; build a series with all factors $\cong \mathbb{Z}/p\mathbb{Z}$.

Solution. The chain $0 \subsetneq (p^{k-1}) \subsetneq (p^{k-2}) \subsetneq \cdots \subsetneq (p) \subsetneq \mathbb{Z}/p^k\mathbb{Z}$ has successive quotients $(p^{i-1})/(p^i) \cong \mathbb{Z}/p\mathbb{Z}$, each simple. There are k steps, so $\text{length}_{\mathbb{Z}}(\mathbb{Z}/p^k\mathbb{Z}) = k$. Sanity check: $|\mathbb{Z}/p^k\mathbb{Z}| = p^k$ and each simple factor has p elements, so the length is $\log_p(p^k) = k$, and additivity gives $\text{length}(\mathbb{Z}/p^k\mathbb{Z}) = k \cdot \text{length}(\mathbb{Z}/p\mathbb{Z}) = k$.

Worked Example 16.1.10 (Length of $\mathbb{Z}/n\mathbb{Z}$ via the exponents)**.** For $n = p_1^{a_1} \cdots p_s^{a_s}$ compute $\text{length}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z})$.

Recognition. CRT splits $\mathbb{Z}/n\mathbb{Z}$ into a product of $\mathbb{Z}/p_i^{a_i}\mathbb{Z}$, and length is additive over direct sums.

Solution. By CRT $\mathbb{Z}/n\mathbb{Z} \cong \prod_i \mathbb{Z}/p_i^{a_i}\mathbb{Z}$, so $\text{length}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) = \sum_i \text{length}_{\mathbb{Z}}(\mathbb{Z}/p_i^{a_i}\mathbb{Z}) = \sum_i a_i$. Sanity check: for $n = 12 = 2^2 \cdot 3$, length $= 2 + 1 = 3$, and a series is $0 \subset (6) \subset (3) \subset \mathbb{Z}/12\mathbb{Z}$ with factors of orders $2, 2, 3$ – three simple factors, length 3, matching $a_1 + a_2 = 2 + 1$.

Worked Example 16.1.11 (Length over a field is dimension)**.** Show that for a finite-dimensional k-vector space V, $\text{length}_k(V) = \dim_k V$.

Recognition. The only simple k-module is k itself; a composition series is a complete flag.

Solution. Choose a basis $v_1, \ldots, v_d$ and set $V_i = \text{Span}(v_1, \ldots, v_i)$. Then $0 = V_0 \subsetneq V_1 \subsetneq \cdots \subsetneq V_d = V$ has factors $V_i/V_{i-1} \cong k$, all simple, so $\text{length}_k(V) = d = \dim_k V$. Sanity check: Jordan–Hölder says length is basis-independent, which here recovers the well-definedness of $\dim_k V$; over a field, Artinian = Noetherian = finite-dimensional.

The Jacobson radical and Nakayama

Two ideals control the structure of an Artinian ring: the *nilradical* $\text{nil}(R) = \text{rad}(0)$ (the set of nilpotents, equal to the intersection of all primes) and the *Jacobson radical* $\text{Jac}(R)$, the intersection of all maximal ideals. The Jacobson radical plays, for rings, the role the Frattini subgroup plays for groups.

Proposition 16.1.12 (properties of $\text{Jac}\, R$; Nakayama)**.** *Let* $\mathfrak{r} = \text{Jac}\, R$*. Then:*

(1) *if* $\mathfrak{a}$ *is a proper ideal then* $(\mathfrak{a}, \mathfrak{r})$ *is proper;*

(2) $\text{nil}(R) \subseteq \mathfrak{r}$ *(the nilradical sits inside the Jacobson radical);*

(3) $x \in \mathfrak{r}$ *iff* $1 - rx$ *is a unit for every* $r \in R$*;*

(4) (Nakayama) *if* M *is finitely generated and* $\mathfrak{r}M = M$*, then* $M = 0$*.*

Idea. (1) Any proper ideal lies in some maximal $\mathfrak{m}$, and $\mathfrak{r} \subseteq \mathfrak{m}$, so $(\mathfrak{a}, \mathfrak{r}) \subseteq \mathfrak{m}$. (2) Nilpotents lie in every prime, in particular every maximal ideal. (3) If some $1 - rx$ is a non-unit it lies in a maximal $\mathfrak{m}$; then $rx \notin \mathfrak{m}$ forces $x \notin \mathfrak{m}$, so $x \notin \mathfrak{r}$. Conversely if $x \notin \mathfrak{m}$ then $1 = rx + y$ with $y \in \mathfrak{m}$, so $1 - rx \in \mathfrak{m}$ is a non-unit. (4) Take a minimal generating set $m_1, \ldots, m_n$ of M; writing $m_n = \sum r_i m_i$ with $r_i \in \mathfrak{r}$ gives $(1 - r_n)m_n \in \langle m_1, \ldots, m_{n-1}\rangle$, and $1 - r_n$ is a unit by (3), contradicting minimality unless $M = 0$. □

Worked Example 16.1.13 (Nilradical inside Jacobson radical in $\mathbb{Z}/n\mathbb{Z}$)**.** For $R = \mathbb{Z}/n\mathbb{Z}$ identify $\text{nil}(R)$ and $\text{Jac}(R)$ and verify nil $\subseteq$ Jac.

Recognition. In $\mathbb{Z}/n\mathbb{Z}$ the maximal ideals are (p_i) for the primes $p_i \mid n$; nilpotents are residues of multiples of the squarefree-killing radical.

Solution. Write $n = p_1^{a_1} \cdots p_s^{a_s}$ and $\text{rad}(n) = p_1 \cdots p_s$. The maximal ideals are $(\bar{p}_i)$, so $\text{Jac}(R) = \bigcap_i (\bar{p}_i) = (\overline{p_1 \cdots p_s})$. The nilradical is $\text{nil}(R) = (\overline{p_1 \cdots p_s})$ as well (an element is nilpotent iff every p_i divides it). So here $\text{nil}(R) = \text{Jac}(R)$. Sanity check: $n = 12$ gives rad $= 6$, and $\bar{6}$ is nilpotent ($\bar{6}^2 = \bar{36} = \bar{0}$) and lies in both $(\bar{2})$ and $(\bar{3})$ – the two maximal ideals – so nil = Jac $= (\bar{6})$.

Worked Example 16.1.14 (The hypotheses of Nakayama are necessary)**.** With $R = \mathbb{Z}_{(2)}$ and $M = \mathbb{Q}$, show $\mathfrak{r}M = M$ yet $M \neq 0$, and explain.

Recognition. Nakayama requires M *finitely generated*; drop that and the conclusion fails.

Solution. Here $R = \mathbb{Z}_{(2)}$ is local with $\mathrm{Jac}(R) = \mathfrak{r} = (2)$. Since $\mathbb{Q} = \frac{1}{2}\mathbb{Q} = 2\mathbb{Q}$, we get $\mathfrak{r}M = 2\mathbb{Q} = \mathbb{Q} = M$, but $M = \mathbb{Q} \neq 0$. No contradiction: $\mathbb{Q}$ is *not* finitely generated over $\mathbb{Z}_{(2)}$ (any finite set of fractions has bounded denominators). Sanity check: $\mathbb{Q}/2\mathbb{Q} = 0$, so the finite quotient $M/\mathfrak{r}M$ vanishes, but unlike the finitely generated case this does not force $M = 0$ – precisely the role of the finiteness hypothesis.

Artinian $\iff$ Noetherian of dimension 0

We now reach the heart of the section. We assemble four structural facts – finitely many maximal ideals, nilpotent nilradical, every prime maximal, finite length – and then prove the equivalence with the Noetherian condition.

Proposition 16.1.15 (every prime is maximal)**.** *In an Artinian ring R, every prime ideal is maximal; equivalently* $\dim R = 0$.

Idea. Let $\mathfrak{p}$ be prime, so $B = R/\mathfrak{p}$ is an Artinian integral domain. For $0 \neq x \in B$, the chain $(x) \supseteq (x^2) \supseteq \cdots$ stabilizes: $(x^n) = (x^{n+1})$, so $x^n = x^{n+1}y$ for some y. Cancelling x^n in the domain gives $1 = xy$, so x is a unit. Thus B is a field and $\mathfrak{p}$ is maximal. (This is A&M Proposition 8.1.) □

Proposition 16.1.16 (finitely many maximal ideals)**.** *An Artinian ring R has only finitely many maximal ideals.*

Idea. Let Σ be the set of all finite intersections $\mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_r$ of maximal ideals. By DCC, Σ has a minimal element $\mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n$. For any maximal $\mathfrak{m}$, $\mathfrak{m} \cap \mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n = \mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n$ by minimality, so $\mathfrak{m} \supseteq \mathfrak{m}_1 \cap \cdots \cap \mathfrak{m}_n$; since $\mathfrak{m}$ is prime it contains some $\mathfrak{m}_i$, forcing $\mathfrak{m} = \mathfrak{m}_i$. Hence $\mathfrak{m}_1, \ldots, \mathfrak{m}_n$ are all the maximal ideals. (A&M Proposition 8.3.) □

Proposition 16.1.17 (nilradical is nilpotent)**.** *In an Artinian ring R the nilradical $\mathfrak{N} = \mathrm{nil}(R)$ is a* nilpotent *ideal: $\mathfrak{N}^m = 0$ for some $m \geq 1$. Moreover* $\mathrm{Jac}(R) = \mathrm{nil}(R)$.

Idea. By DCC the chain $\mathfrak{N} \supseteq \mathfrak{N}^2 \supseteq \cdots$ stabilizes at some $\mathfrak{a} = \mathfrak{N}^m = \mathfrak{N}^{m+1} = \cdots$. Suppose $\mathfrak{a} \neq 0$. Among ideals $\mathfrak{b}$ with $\mathfrak{b}\mathfrak{a} \neq 0$ pick a minimal one $\mathfrak{b}_0$; choose $x \in \mathfrak{b}_0$ with $x\mathfrak{a} \neq 0$, so by minimality $\mathfrak{b}_0 = (x)$. Then $(x\mathfrak{a})\mathfrak{a} = x\mathfrak{a}^2 = x\mathfrak{a} \neq 0$, so by minimality $(x) = (x\mathfrak{a})$, i.e. $(x)\mathfrak{a} = (x)$; Nakayama (with $\mathfrak{a} \subseteq \mathrm{Jac}$) gives $(x) = 0$, contradicting $x\mathfrak{a} \neq 0$. Hence $\mathfrak{a} = 0$, i.e. $\mathfrak{N}^m = 0$. For $\mathrm{Jac}(R) = \mathrm{nil}(R)$: the inclusion $\mathrm{nil} \subseteq \mathrm{Jac}$ holds in any ring (nilpotents lie in every maximal ideal); and since $\dim R = 0$ every prime is maximal, so $\mathrm{nil}(R) = \bigcap_{\mathfrak{p}\ \text{prime}} \mathfrak{p} = \bigcap_{\mathfrak{m}\ \text{maximal}} \mathfrak{m} = \mathrm{Jac}(R)$, giving the reverse inclusion. Thus the two radicals coincide. (A&M Proposition 8.4 plus 8.2.) □

Theorem 16.1.18 (Artinian $\iff$ Noetherian + $\dim 0$)**.** *For a commutative ring R the following are equivalent:*

(1) *R is Artinian;*

(2) *R is Noetherian and every prime ideal is maximal, i.e.* $\dim R = 0$*;*

(3) *R has finite length as a module over itself,* $\mathrm{length}_R(R) < \infty$.

When these hold, R is both Artinian and Noetherian, and the three finiteness facts above hold.

Idea. (1) $\Rightarrow$ (2): dimension 0 was shown above. For Noetherian, let $\mathfrak{m}_1, \ldots, \mathfrak{m}_n$ be the maximal ideals; with $\mathfrak{N} = \mathrm{Jac}$ nilpotent, $(\mathfrak{m}_1 \cdots \mathfrak{m}_n)^m \subseteq \mathfrak{N}^m = 0$. Filtering R by the products $\prod \mathfrak{m}_i^{e_i}$ gives successive quotients that are vector spaces over the fields $R/\mathfrak{m}_i$; each is finite-dimensional because R is Artinian (DCC bounds the chain), so R has a composition series – hence finite length, hence Noetherian. (2) $\Rightarrow$ (3): in a Noetherian ring the zero ideal contains a product $\mathfrak{p}_1 \cdots \mathfrak{p}_n$ of (not necessarily distinct) primes; dimension 0 makes each $\mathfrak{p}_i$ maximal, so 0 contains a product of maximal ideals and again the filtration by these products has finite-dimensional vector-space quotients, giving $\mathrm{length}_R(R) < \infty$. (3) $\Rightarrow$ (1): a module of finite length is Artinian (and Noetherian) by Jordan–Hölder. □

Corollary 16.1.19 (R/Jac is a product of fields)**.** *If R is Artinian with maximal ideals $\mathfrak{m}_1, \dots, \mathfrak{m}_n$, then*

$$R/\operatorname{Jac}(R) \;\cong\; k_1 \times \cdots \times k_n, \qquad k_i = R/\mathfrak{m}_i,$$

by the Chinese Remainder Theorem, since the $\mathfrak{m}_i$ are pairwise comaximal with intersection $\operatorname{Jac}(R)$*.*

Worked Example 16.1.20 ($\mathbb{Z}/n\mathbb{Z}$ is Artinian and its dimension is 0)**.** Verify directly that $\mathbb{Z}/n\mathbb{Z}$ is Artinian and that every prime is maximal.

Recognition. A finite ring satisfies DCC trivially; in $\mathbb{Z}/n\mathbb{Z}$ the primes are the (p_i) with $p_i \mid n$, all maximal.

Solution. $\mathbb{Z}/n\mathbb{Z}$ has finitely many ideals (it is finite), so any descending chain stabilizes – Artinian. The primes correspond to primes $p_i \mid n$, and $\mathbb{Z}/n\mathbb{Z}/(p_i) \cong \mathbb{F}_{p_i}$ is a field, so each (p_i) is maximal: $\dim \mathbb{Z}/n\mathbb{Z} = 0$. Sanity check: $\mathbb{Z}/n\mathbb{Z}$ is finite hence Noetherian, of dimension 0 – matching the slogan – and $\operatorname{length}_{\mathbb{Z}}(\mathbb{Z}/n\mathbb{Z}) = \sum a_i < \infty$ as computed earlier.

Worked Example 16.1.21 (An Artinian integral domain is a field)**.** Prove that an Artinian integral domain R is a field.

Recognition. In a domain, dimension 0 means (0) is maximal; the proof of "every prime is maximal" specializes to $\mathfrak{p} = (0)$.

Solution. (0) is a prime ideal of the domain R, and in an Artinian ring every prime is maximal, so (0) is maximal – which says R is a field. Directly: for $0 \neq x$, DCC stabilizes $(x^n) = (x^{n+1})$, so $x^n = x^{n+1}y$ and cancellation gives $xy = 1$. Sanity check: this is why $\mathbb{Z}$ and $k[x]$ (domains, not fields) cannot be Artinian – they are domains of dimension 1, and a 0-dimensional domain would have to be a field.

Worked Example 16.1.22 (A local ring of dimension 0 that is not Artinian)**.** Let $R = k[x_1, x_2, \dots]/(x_1, x_2^2, x_3^2, \dots)$-type construction; concretely take $A = k[x_1, x_2, \dots]$ and $\mathfrak{a} = (x_1, x_2^2, x_3^2, \dots)$, $B = A/\mathfrak{a}$. Show B has a unique prime, so $\dim B = 0$, yet B is not Noetherian, hence not Artinian.

Recognition. Artinian needs Noetherian *and* $\dim 0$; dimension 0 alone is not enough.

Solution. In B each x_i is nilpotent ($x_1 = 0$ and $x_i^2 = 0$ for $i \geq 2$), so the image of $(x_1, x_2, \dots)$ is the nilradical and is the unique prime ideal $\mathfrak{m}$ of B; thus $\dim B = 0$ and B is local. But $\mathfrak{m}$ is not finitely generated (it needs all the x_i), so B is not Noetherian. By the theorem, a non-Noetherian ring cannot be Artinian – concretely the descending chain $(x_2, x_3, \dots) \supsetneq (x_3, x_4, \dots) \supsetneq \cdots$ of ideals fails DCC (the inclusions are strict since $x_j \neq 0$ and $x_j \notin (x_{j+1}, x_{j+2}, \dots)$ in B). Sanity check: this is A&M's example showing "one prime ideal" $\not\Rightarrow$ Artinian; the missing hypothesis is exactly Noetherianness.

Worked Example 16.1.23 (Finite length of an Artinian ring over itself)**.** For $R = k[x]/(x^3)$, exhibit a composition series and compute $\operatorname{length}_R(R)$.

Recognition. R is local with maximal ideal $\mathfrak{m} = (\bar{x})$, $\mathfrak{m}^3 = 0$; filter by powers of $\mathfrak{m}$ and view factors as $k = R/\mathfrak{m}$-vector spaces.

Solution. The filtration $R \supsetneq (\bar{x}) \supsetneq (\bar{x}^2) \supsetneq 0$ has factors $R/(\bar{x}) \cong k$, $(\bar{x})/(\bar{x}^2) \cong k$, $(\bar{x}^2)/0 \cong k$, each 1-dimensional over k, hence simple. So $\operatorname{length}_R(R) = 3$. Sanity check: $\dim_k R = 3$ (basis $1, \bar{x}, \bar{x}^2$), and over the local Artinian ring R the length equals this k-dimension; R is Artinian (finite length) and its unique prime $(\bar{x})$ is maximal, so $\dim R = 0$.

The structure theorem: a product of Artinian local rings

The culminating result decomposes any Artinian ring into local pieces, uniquely. The mechanism is the Chinese Remainder Theorem applied to the (pairwise comaximal) powers of the maximal ideals – equivalently, the lifting of the orthogonal idempotents from $R/\operatorname{Jac} = \prod k_i$ back to R.

Theorem 16.1.24 (structure of Artinian rings)**.** *An Artinian ring R is isomorphic to a finite direct product of Artinian* local *rings,*

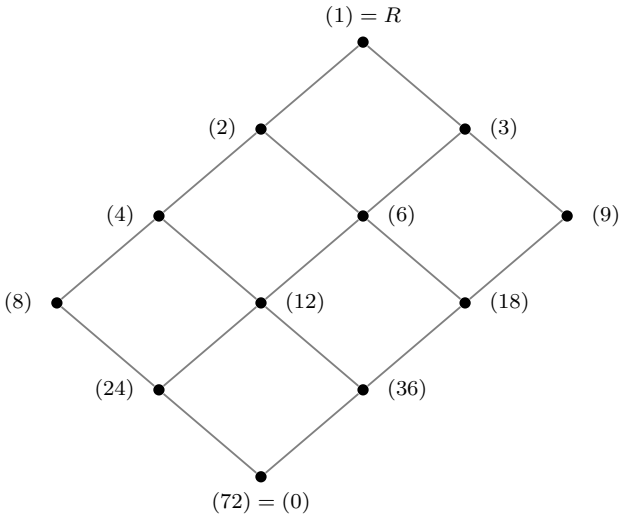
$$R \;\cong\; A_1 \times A_2 \times \cdots \times A_n, \qquad A_i = R/\mathfrak{m}_i^m,$$

where $\mathfrak{m}_1, \dots, \mathfrak{m}_n$ are the maximal ideals and m is large enough that $(\operatorname{Jac} R)^m = 0$*. The factors A_i are unique up to isomorphism (and the decomposition is unique up to the order of factors).*

Idea. With $\mathfrak{m}_1, \dots, \mathfrak{m}_n$ the distinct maximal ideals and $(\operatorname{Jac} R)^m = 0$, the ideals $\mathfrak{m}_i^m$ are pairwise comaximal (distinct maximals are comaximal, hence so are their powers) and $\bigcap_i \mathfrak{m}_i^m = \prod_i \mathfrak{m}_i^m \subseteq (\operatorname{Jac} R)^m = 0$. The Chinese Remainder Theorem then gives $R \cong \prod_i R/\mathfrak{m}_i^m$. Each $A_i = R/\mathfrak{m}_i^m$ is Artinian (quotient of R) with the single maximal ideal $\mathfrak{m}_i/\mathfrak{m}_i^m$, hence local.

Uniqueness: a finite product decomposition corresponds to a complete set of orthogonal idempotents, and in $\prod A_i$ with each A_i local the only idempotents are the coordinate vectors 0/1 (local rings have no nontrivial idempotents). The indecomposable factors – the localizations of R at its primes $\mathfrak{m}_i$ – are therefore determined by R. (A&M Theorem 8.7.) □

Proposition 16.1.25 (Artinian local rings; A&M 8.6, 8.8)**.** *Let A be a Noetherian local ring with maximal ideal $\mathfrak{m}$. Then exactly one holds: either $\mathfrak{m}^k \neq \mathfrak{m}^{k+1}$ for all k, or $\mathfrak{m}^k = 0$ for some k – and in the second case A is Artinian local. If moreover A is Artinian local, then the following are equivalent:* (i) *every ideal of A is principal;* (ii) *$\mathfrak{m}$ is principal;* (iii) $\dim_{A/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2) \leq 1$.



Idea. If $\mathfrak{m}^k = \mathfrak{m}^{k+1}$ then Nakayama (applied to $\mathfrak{m}^k$, finitely generated, with $\mathfrak{m}^k = \mathfrak{m} \cdot \mathfrak{m}^k$) gives $\mathfrak{m}^k = 0$, and then A is Noetherian with nilpotent maximal ideal, hence Artinian. For the equivalence, (iii)⇒(i): if $\dim_{A/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2) = 0$ then $\mathfrak{m} = \mathfrak{m}^2$ so $\mathfrak{m} = 0$ by Nakayama and A is a field; if it is 1, then $\mathfrak{m} = (t)$ is principal by Nakayama, and every nonzero ideal equals $(t^r) = \mathfrak{m}^r$ for the least r with the ideal $\subseteq \mathfrak{m}^r$ but $\not\subseteq \mathfrak{m}^{r+1}$, hence principal. This is the bridge to the next section: an Artinian local ring whose maximal ideal is principal is the 0-dimensional analogue of a DVR. □

Worked Example 16.1.26 ($\mathbb{Z}/n\mathbb{Z}$ as a product of Artinian local rings)**.** Decompose $\mathbb{Z}/360\mathbb{Z}$ according to the structure theorem.

Recognition. CRT on prime-power factors; each $\mathbb{Z}/p^a\mathbb{Z}$ is Artinian local with maximal ideal $(\bar{p})$.

Solution. $360 = 2^3 \cdot 3^2 \cdot 5$, so $\mathbb{Z}/360\mathbb{Z} \cong \mathbb{Z}/8\mathbb{Z} \times \mathbb{Z}/9\mathbb{Z} \times \mathbb{Z}/5\mathbb{Z}$. The factors are Artinian local: $\mathbb{Z}/8\mathbb{Z}$ with maximal ideal $(\bar{2})$ (and $(\bar{2})^3 = 0$), $\mathbb{Z}/9\mathbb{Z}$ with $(\bar{3})$ (and $(\bar{3})^2 = 0$), and $\mathbb{Z}/5\mathbb{Z} = \mathbb{F}_5$ a field. Sanity check: $\operatorname{Jac}(\mathbb{Z}/360\mathbb{Z}) = (\overline{2 \cdot 3 \cdot 5}) = (\overline{30})$ and $\mathbb{Z}/360\mathbb{Z}/(\overline{30}) \cong \mathbb{F}_2 \times \mathbb{F}_3 \times \mathbb{F}_5$, a product of the three residue fields – matching the $R/\operatorname{Jac} = \prod k_i$ corollary.

The ideal lattice of a single Artinian factor is itself a divisor lattice. For $R = \mathbb{Z}/72\mathbb{Z}$ with $72 = 2^3 \cdot 3^2$, write $(d) = d\,\mathbb{Z}/72\mathbb{Z}$ for the ideal generated by the class of d; then $(1) = R$ is the whole ring and $(72) = (0)$, with $(d_1) \supseteq (d_2)$ exactly when $d_1 \mid d_2$. The ideals are indexed by the twelve divisors of 72, and the picture is the product of the chain $(1) \supseteq (2) \supseteq (4) \supseteq (8)$ with the chain $(1) \supseteq (3) \supseteq (9)$ – a 4×3 grid whose two maximal ideals are (2) and (3), the kernels of $R \to \mathbb{F}_2$ and $R \to \mathbb{F}_3$.

Worked Example 16.1.27 ($k[x]/(f)$ as a product of Artinian local rings)**.** With $f = (x-1)^2(x-2)^3 \in k[x]$ ($\operatorname{char} k \neq 2, 3$, k containing $1, 2$), decompose $R = k[x]/(f)$.

Recognition. $k[x]$ is a PID; CRT on the coprime prime-power factors of f gives the local decomposition, mirroring $\mathbb{Z}/n\mathbb{Z}$.

Solution. The factors $(x-1)^2$ and $(x-2)^3$ are coprime in $k[x]$, so

$$R = k[x]/\big((x-1)^2(x-2)^3\big) \;\cong\; k[x]/(x-1)^2 \;\times\; k[x]/(x-2)^3.$$

The first factor is Artinian local with maximal ideal $(\overline{x-1})$, square zero, of length 2; the second is Artinian local with maximal ideal $(\overline{x-2})$, cube zero, of length 3. Sanity check: $\dim_k R = \deg f = 5 = 2+3$, and $\operatorname{length}_R(R) = 2+3 = 5$; the nilradical (Jacobson radical) is generated by the squarefree part $(x-1)(x-2)$, with $R/\operatorname{Jac} \cong k \times k$ – two residue fields, one per root.

Worked Example 16.1.28 (Idempotent lifting recovers the factors)**.** For $R = \mathbb{Z}/12\mathbb{Z}$, find the nontrivial idempotents and match them to the product decomposition.

Recognition. A product decomposition $R \cong A_1 \times A_2$ corresponds to a pair of orthogonal idempotents $e_1 + e_2 = 1$; lift them from $R/\operatorname{Jac} = \prod k_i$.

Solution. $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$. The idempotents of the product are $(1,0)$ and $(0,1)$; pulled back by CRT these are $\bar{9}$ and $\bar{4}$ in $\mathbb{Z}/12\mathbb{Z}$ (since $9 \equiv 1 \bmod 4$, $9 \equiv 0 \bmod 3$ and $4 \equiv 0 \bmod 4$, $4 \equiv 1 \bmod 3$). Indeed $\bar{9}^2 = \overline{81} = \bar{9}$ and $\bar{4}^2 = \overline{16} = \bar{4}$, with $\bar{9} + \bar{4} = \overline{13} = \bar{1}$ and $\bar{9} \cdot \bar{4} = \overline{36} = \bar{0}$. The factor rings are $\bar{9}\,R \cong \mathbb{Z}/4\mathbb{Z}$ and $\bar{4}\,R \cong \mathbb{Z}/3\mathbb{Z}$. Sanity check: $\operatorname{Spec}\mathbb{Z}/12\mathbb{Z}$ is disconnected into the two points $(\bar{2})$ and $(\bar{3})$ exactly because of the nontrivial idempotent $\bar{9}$ $(\neq 0, 1)$ – a ring is a nontrivial product iff it has a nontrivial idempotent.

Worked Example 16.1.29 (Why the local factors must be local (no further splitting))**.** Show that $\mathbb{Z}/8\mathbb{Z}$ is indecomposable as a product, i.e. has no nontrivial idempotents.

Recognition. An Artinian local ring has no idempotents other than $0, 1$, because the maximal ideal is the nilradical.

Solution. Suppose $e^2 = e$ in $\mathbb{Z}/8\mathbb{Z}$. Then $e(e-1) = 0$; since $\mathbb{Z}/8\mathbb{Z}$ is local with maximal ideal $(\bar{2})$ consisting of nilpotents, one of $e, e-1$ is a unit (anything outside $(\bar{2})$ is a unit) and the other is nilpotent. If e is a unit, $e - 1 = 0$ so $e = 1$; if $e - 1$ is a unit, e is nilpotent and idempotent, forcing $e = 0$. So the only idempotents are $0, 1$. Sanity check: $\operatorname{Spec}\mathbb{Z}/8\mathbb{Z}$ is a single point $(\bar{2})$ – connected – consistent with no nontrivial idempotent, and $\mathbb{Z}/8\mathbb{Z}$ is one of the indecomposable local factors in any product it appears in.

Worked Example 16.1.30 (A finite-dimensional algebra is Artinian)**.** Let R be a k-algebra with $\dim_k R < \infty$. Show R is Artinian, and bound its length.

Recognition. Ideals are in particular k-subspaces, so chains of ideals have length bounded by $\dim_k R$.

Solution. Any descending chain of ideals $\mathfrak{a}_1 \supseteq \mathfrak{a}_2 \supseteq \cdots$ is a descending chain of k-subspaces; their dimensions form a non-increasing sequence of non-negative integers bounded by $\dim_k R$, so it stabilizes. Hence R is Artinian, and $\operatorname{length}_R(R) \le \dim_k R$ (each simple factor has k-dimension ≥ 1). Sanity check: for $R = k[x]/(f)$ with f a product of linear factors over k, $\dim_k R = \deg f$ and $\operatorname{length}_R(R) = \deg f$ (length equals k-dimension here since every residue field is k), so the bound is sharp; for a matrix algebra such as $\mathrm{M}_2(k)$, $\dim_k = 4$ but as a left module over itself it is the sum of its two columns, a semisimple module of length $= 2$ (not simple), so the bound can be strict.

Worked Example 16.1.31 (Spec of an Artinian ring is finite and discrete)**.** Show that for an Artinian ring R, $\operatorname{Spec} R$ is a finite discrete topological space, and connect this to the structure theorem.

Recognition. Primes = maximals, finitely many; finitely many points each closed gives the discrete topology.

Solution. Every prime is maximal (dimension 0) and there are only finitely many, say $\mathfrak{m}_1, \ldots, \mathfrak{m}_n$, so $\operatorname{Spec} R = \{\mathfrak{m}_1, \ldots, \mathfrak{m}_n\}$ is finite. Each $\{\mathfrak{m}_i\} = V(\mathfrak{m}_i)$ is closed (maximal ideals are closed points), and a finite T_1 space is discrete. Under the structure theorem $R \cong \prod_i A_i$, the spectrum splits as the disjoint union $\operatorname{Spec} R = \coprod_i \operatorname{Spec} A_i$ with $\operatorname{Spec} A_i = \{\mathfrak{m}_i\}$ a single point. Sanity check: a Noetherian ring has discrete Spec iff it is Artinian; here the n isolated points correspond exactly to the n local factors A_i, the connected components of $\operatorname{Spec} R$.

Worked Example 16.1.32 (Krull dimension contrasts: Artinian vs. DVR vs. Dedekind)**.** Place $\mathbb{Z}/p^k\mathbb{Z}$, $\mathbb{Z}_{(p)}$, and $\mathbb{Z}$ on the dimension scale and say which are Artinian.

Recognition. Artinian = Noetherian + dim 0; a DVR is a Noetherian local domain of dim 1 with principal maximal ideal (equivalently a local PID that is not a field; it is integrally closed); a Dedekind domain is a Noetherian, integrally closed domain of dim 1.

Solution. $\mathbb{Z}/p^k\mathbb{Z}$ is Artinian local: Noetherian (finite) with the single prime $(\bar{p})$ maximal, so dim = 0. The localization $\mathbb{Z}_{(p)}$ is a DVR: Noetherian local with primes $(0) \subsetneq (p)$, so dim = 1 – *not* Artinian. And $\mathbb{Z}$ is a Dedekind domain: Noetherian, integrally closed, of dim 1 – not Artinian. Sanity check: passing $\mathbb{Z} \to \mathbb{Z}/(p^k)$ collapses the chain $(0) \subsetneq (p)$ by killing (0) (it becomes nilpotent), dropping the dimension from 1 to 0 and converting the Dedekind/DVR world into the Artinian world – the precise sense in which Artinian rings are "dimension-zero" fragments of the dimension-one theory developed next.

Caution. Do not conflate the module and ring statements. For *modules*, Artinian and Noetherian are independent (the Prufer module $\mathbb{Z}(p^\infty)$ is Artinian but not Noetherian). For *commutative rings*, by contrast, Artinian *implies* Noetherian – but only because the ring carries its own ideal structure and dimension 0. The implication is a theorem about rings, not a general fact about modules, and it has no converse: $\mathbb{Z}$ is Noetherian but not Artinian.

Let R be a commutative ring with 1 and let $\mathcal{J}$ denote its Jacobson radical.

Exercises (Dummit & Foote).

1. Suppose R is an Artinian ring and I is an ideal in R. Prove that R/I is also Artinian.
2. Show that every finite commutative ring with 1 is Artinian.
3. Prove that an integral domain of Krull dimension 0 is a field.
4. Prove that an Artinian integral domain is a field.
5. Suppose I is a nilpotent ideal in R and $M = IM$ for some R-module M. Prove that $M = 0$.
6. Suppose that $0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$ is an exact sequence of R-modules. Prove that M is an Artinian R-module if and only if M' and M'' are Artinian R-modules.
7. Suppose $R = F$ is a field. Prove that an R-module M is Artinian if and only if it is Noetherian if and only if M is a finite dimensional vector space over F.
8. Let M be a maximal ideal of the ring R and suppose that $M^n = 0$ for some $n \geq 1$. Prove that R is Noetherian if and only if R is Artinian. [Observe that each successive quotient M^i/M^{i+1}, $i = 0, \ldots, n-1$ in the filtration $R \supseteq M \supseteq M^2 \supseteq \cdots \supseteq M^{n-1} \supseteq M^n = 0$ is a module over the field $F = R/M$. Then use the previous two exercises and Exercise 6 of Section 15.1.]
9. Let M be a finitely generated R-module. Prove that if $x_1, \ldots, x_n$ are elements of M whose images in $M/\mathcal{J}M$ generate $M/\mathcal{J}M$, then they generate M. Deduce that if R is Noetherian and the images of $a_1, \ldots, a_n$ in $\mathcal{J}/\mathcal{J}^2$ generate $\mathcal{J}/\mathcal{J}^2$, then $\mathcal{J} = (a_1, \ldots, a_n)$. [Let N be the submodule generated by $x_1, \ldots, x_n$ and apply Nakayama's Lemma to the module $A = M/N$.]
10. Let $R = \mathbb{Z}_{(2)}$ be the localization of $\mathbb{Z}$ at the prime ideal (2). Prove that $\operatorname{Jac} R = (2)$ is the ideal generated by 2. If $M = \mathbb{Q}$, prove that $M/2M$ is a finitely generated R-module but that M is not finitely generated over R. Why doesn't this contradict the previous exercise? [Note the hypotheses in Nakayama's Lemma.]
11. Let V be an affine variety over a field k and let $R = k[V]$ be its coordinate ring. Let $d_1(R)$ denote the transcendence degree of the field of fractions $k(V)$ over k, and let $d_p(R)$ be the Krull dimension of R defined in terms of chains of prime ideals. This exercise shows $d_1(R) = d_p(R)$. By Noether's Normalization Lemma there is a polynomial subring $R_1 = k[y_1, \ldots, y_m]$ of R such that R is integral over R_1.
    (a) Show that $d_1(R_1) = d_1(R) = m$ and that $d_p(R_1) = d_p(R)$. Deduce that we may assume $R = R_1$. [Use the Going-up and Going-down Theorems (cf. Theorem 26, Section 15.3) to prove the second equality.]
    (b) When $R = R_1$ show that $d_p(R) \geq d_1(R)$ by exhibiting an explicit chain of prime ideals of length m.
    (c) When $R = R_1$ show that any nonzero prime ideal of R contains an irreducible element f, and that $R/(f)$ is an integral domain whose field of fractions has transcendence degree $m - 1$ over k. Use induction to show that $d_p(R) \leq d_1(R)$, and deduce that $d_p(R) = d_1(R)$.

12. Let R be a Noetherian local ring with maximal ideal M.

    (a) The quotient M/M^2 is a module (i.e., vector space) over the field R/M. Prove that $d = \dim_{R/M}(M/M^2)$ is finite.

    (b) Prove that M can be generated as an ideal in R by d elements and by no fewer. [Use Exercise 9.]

    (c) Let $R = k[x_1, \ldots, x_n]_{(x_1,\ldots,x_n)}$ be the localization of the polynomial ring $k[x_1, \ldots, x_n]$ over the field k at the maximal ideal $(x_1, \ldots, x_n)$, and let M be the maximal ideal in R. Prove that $\dim_{R/M}(M/M^2) = n = \dim R$. [Cf. the previous exercise.]

13. If R is a Noetherian ring, prove that the Zariski topology on $\operatorname{Spec} R$ is discrete (i.e., every subset is Zariski open and also Zariski closed) if and only if R is Artinian.

14. Suppose I is the ideal $(x_1, x_2^2, x_3^3, \ldots)$ in the polynomial ring $k[x_1, x_2, x_3, \ldots]$ where k is a field and let R be the quotient ring $k[x_1, x_2, x_3, \ldots]/I$. Prove that the image of the ideal $(x_1, x_2, x_3, \ldots)$ in R is the unique prime ideal in R but is not finitely generated. Deduce that R is a local ring of Krull dimension 0 but is not Artinian.

Exercises (Atiyah & Macdonald).

1. Let $\mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_n = 0$ be a minimal primary decomposition of the zero ideal in a Noetherian ring, and let $\mathfrak{q}_i$ be $\mathfrak{p}_i$-primary. Let $\mathfrak{p}_i^{(r)}$ be the rth *symbolic power* of $\mathfrak{p}_i$ (Chapter 4, Exercise 13). Show that for each $i = 1, \ldots, n$ there exists an integer r_i such that $\mathfrak{p}_i^{(r_i)} \subseteq \mathfrak{q}_i$.

   Suppose we allow i to range over those suffixes such that $\mathfrak{p}_i$ is minimal (i.e., $\mathfrak{q}_i$ is an isolated primary component). Then $A_{\mathfrak{p}_i}$ is an Artin local ring, hence if $\mathfrak{m}_i$ is its maximal ideal we have $\mathfrak{m}_i^r = 0$ for all sufficiently large r, hence $\mathfrak{q}_i = \mathfrak{p}_i^{(r)}$ for all large r.

   If $\mathfrak{q}_i$ is an embedded primary component, then $A_{\mathfrak{p}_i}$ is *not* Artinian, hence the powers $\mathfrak{m}_i^r$ are all distinct, and so the $\mathfrak{p}_i^{(r)}$ are all distinct. Hence in the given primary decomposition we can replace $\mathfrak{q}_i$ by any of the infinite set of $\mathfrak{p}_i$-primary ideals $\mathfrak{p}_i^{(r)}$ where $r \geq r_i$, and so there are infinitely many minimal primary decompositions of 0 which differ only in the $\mathfrak{p}_i$-component.

2. Let A be a Noetherian ring. Prove that the following are equivalent:

   i) A is Artinian;

   ii) $\operatorname{Spec}(A)$ is discrete and finite;

   iii) $\operatorname{Spec}(A)$ is discrete.

3. Let k be a field and A a finitely generated k-algebra. Prove that the following are equivalent:

   i) A is Artinian;

   ii) A is a finite k-algebra.

   [To prove that i) $\Rightarrow$ ii), use (8.7) to reduce to the case where A is an Artin local ring. By the Nullstellensatz, the residue field of A is a finite extension of k. Now use the fact that A is of finite length as an A-module. To prove ii) $\Rightarrow$ i), observe that the ideals of A are k-vector subspaces and therefore satisfy d.c.c.]

4. Let $f\colon A \to B$ be a ring homomorphism of finite type. Consider the following statements:

   i) f is finite;

   ii) the fibres of f^* are discrete subspaces of $\operatorname{Spec}(B)$;

   iii) for each prime ideal $\mathfrak{p}$ of A, the ring $B \otimes_A k(\mathfrak{p})$ is a finite $k(\mathfrak{p})$-algebra ($k(\mathfrak{p})$ is the residue field of $A_{\mathfrak{p}}$);

   iv) the fibres of f^* are finite.

   Prove that i) $\Rightarrow$ ii) $\Rightarrow$ iii) $\Rightarrow$ iv). [Use Exercises 2 and 3.]

   If f is integral and the fibres of f^* are finite, is f necessarily finite?

5. In Chapter 5, Exercise 16, show that X is a finite covering of L (i.e., the number of points of X lying over a given point of L is finite and bounded).

6. Let A be a Noetherian ring and $\mathfrak{q}$ a $\mathfrak{p}$-primary ideal in A. Consider chains of primary ideals from $\mathfrak{q}$ to $\mathfrak{p}$. Show that all such chains are of finite bounded length, and that all maximal chains have the same length.

Throughout, R is a commutative ring with 1, ideals are written in fraktur, and length denotes length over the ring acting (over R unless a subscript indicates otherwise). The phrase "Artinian" applied to a ring means Artinian as a module over itself.

Practice problems.

1. For $R = \mathbb{Z}/200\mathbb{Z}$, decompose R as a product of Artinian local rings, list its maximal ideals, identify $\mathrm{Jac}(R)$ and $\mathrm{nil}(R)$, and compute $\mathrm{length}_R(R)$.

2. In $R = k[x]/(x^4)$ (k a field), write out the full descending chain of ideals, exhibit a composition series of R over itself, and give $\mathrm{length}_R(R)$ together with $\dim_{R/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2)$ for the maximal ideal $\mathfrak{m} = (\bar{x})$.

3. Let $R = k[x,y]/(x^2, xy, y^2)$. Show R is Artinian local, find its unique maximal ideal $\mathfrak{m}$, compute $\dim_k R$, $\dim_{R/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2)$, and $\mathrm{length}_R(R)$, and decide whether $\mathfrak{m}$ is principal.

4. Exhibit a strictly descending chain of ideals in $R = k[x_1, x_2, x_3, \dots]/(x_1^2, x_2^2, x_3^2, \dots)$ that never stabilizes, and conclude that R is a local ring of Krull dimension 0 that is not Artinian.

5. Compute $\mathrm{length}_{\mathbb{Z}}(M)$ for the finite abelian group $M = \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/18\mathbb{Z} \oplus \mathbb{Z}/75\mathbb{Z}$, and exhibit a composition series whose simple factors are the groups $\mathbb{Z}/p\mathbb{Z}$ that occur, with multiplicity.

6. Let $R = \mathbb{F}_2[x]/(x^6 - 1)$. Factor $x^6 - 1$ over $\mathbb{F}_2$, decompose R as a product of local rings via the Chinese Remainder Theorem, state which factors are fields and which are Artinian local with nonzero nilradical, and compute $\mathrm{length}_R(R)$.

7. For the local ring $R = \mathbb{Z}_{(3)}/(54)$, identify the maximal ideal $\mathfrak{m}$, show $\mathfrak{m}$ is nilpotent, give the smallest k with $\mathfrak{m}^k = 0$, and compute $\mathrm{length}_R(R)$.

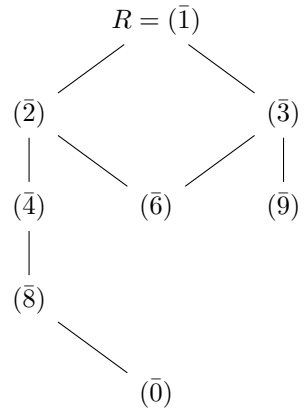
8. In $R = \mathbb{Z}/12\mathbb{Z}$ find all idempotents, write the corresponding complete set of orthogonal idempotents $e_1 + e_2 = 1$, and identify the two local factor rings $e_i R$ together with their residue fields.

Additional exercises.

1. Prove that a commutative ring R is Artinian if and only if R is Noetherian and every prime ideal of R is maximal. Then show by example that "every prime ideal is maximal" alone does not imply Artinian.

2. Let R be Artinian with maximal ideals $\mathfrak{m}_1, \dots, \mathfrak{m}_n$ and let $\mathfrak{N} = \mathrm{nil}(R)$. Prove that $\mathfrak{N} = \mathrm{Jac}(R)$, that $\mathfrak{N}$ is nilpotent, and that $R/\mathfrak{N} \cong \prod_{i=1}^{n} R/\mathfrak{m}_i$ is a finite product of fields.

3. Let A be an Artinian local ring with maximal ideal $\mathfrak{m}$. Prove that the following are equivalent: (i) every ideal of A is principal; (ii) $\mathfrak{m}$ is principal; (iii) $\dim_{A/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2) \le 1$. Conclude that in case (iii) every nonzero ideal of A equals some power $\mathfrak{m}^r$.



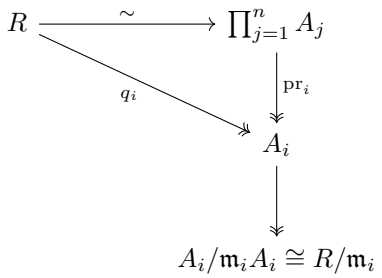
4. Let R be a k-algebra with $\dim_k R < \infty$. Prove that R is Artinian, that $\mathrm{length}_R(R) \le \dim_k R$, and that equality holds when every residue field $R/\mathfrak{m}_i$ equals k. Give an example where the inequality is strict.

5. Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of R-modules in which M has finite length. Prove that M' and M'' have finite length and that $\mathrm{length}_R(M) = \mathrm{length}_R(M') + \mathrm{length}_R(M'')$. Deduce that length is additive over finite direct sums.

Commutative-diagram exercises.

1. Let $R = \mathbb{Z}/72\mathbb{Z}$, with $72 = 2^3 \cdot 3^2$. Complete the ideal-factorization lattice below (each node an ideal $(\bar{d})$ for $d \mid 72$, edges drawn for divisibility/containment), label each edge with the $\mathbb{Z}$-length of the corresponding successive quotient, and confirm that the total length down any maximal chain from R to 0 equals

$\text{length}_{\mathbb{Z}}(R) = 5$:



State which two nodes are the maximal ideals and verify $R/\operatorname{Jac}(R) \cong \mathbb{F}_2 \times \mathbb{F}_3$.

2. Let $R = \mathbb{Z}_{(p)}$ be the localization of $\mathbb{Z}$ at (p), a DVR with maximal ideal $\mathfrak{m} = (p)$, and for each $n \geq 1$ let $R_n = R/(p^n) = \mathbb{Z}/p^n\mathbb{Z}$ be the Artinian local quotient. Complete the commuting square of the quotient maps and verify that the right-hand map ρ is the canonical reduction with kernel $(p^{n-1})R_n$:

$$\begin{array}{ccc} R & \xrightarrow{\ \pi_n\ } & R_n = \mathbb{Z}/p^n\mathbb{Z} \\ {\scriptstyle \pi_{n-1}}\downarrow & & \downarrow{\scriptstyle \rho} \\ R_{n-1} = \mathbb{Z}/p^{n-1}\mathbb{Z} & = & R/(p^{n-1}) \end{array}$$

Show $\operatorname{Ker}(\rho) = (\overline{p^{n-1}})$, that $\operatorname{Ker}(\rho)$ is the unique minimal nonzero ideal of R_n, and that $\text{length}_R(R_n) = n$.

3. Let R be Artinian with maximal ideals $\mathfrak{m}_1, \ldots, \mathfrak{m}_n$, and let m satisfy $(\operatorname{Jac} R)^m = 0$. The structure theorem gives $R \cong \prod_{i=1}^{n} A_i$ with $A_i = R/\mathfrak{m}_i^m$ local. Complete the diagram showing the projection onto a factor followed by reduction to the residue field, and identify each kernel:

Show $\operatorname{Ker}(\text{pr}_i) = \prod_{j \neq i} A_j$, that q_i is the localization map $R \to R_{\mathfrak{m}_i} = A_i$, and that the composite $R \twoheadrightarrow R/\mathfrak{m}_i$ is the ith factor of the corollary $R/\operatorname{Jac}(R) \cong \prod_i R/\mathfrak{m}_i$.

4. Let A be an Artinian local ring with principal maximal ideal $\mathfrak{m} = (t)$, $\mathfrak{m}^k = 0$ and $\mathfrak{m}^{k-1} \neq 0$ – the 0-dimensional analogue of a DVR. Complete the chain of inclusions of its ideals (the full ideal lattice is a single chain) and label each arrow with the length of the successive quotient:

$$0 = (t^k) \hookrightarrow (t^{k-1}) \hookrightarrow \cdots \hookrightarrow (t^2) \hookrightarrow (t) \hookrightarrow (t^0) = A$$

Reading right to left as a descending chain, prove each successive quotient $(t^r)/(t^{r+1})$ is a 1-dimensional $A/\mathfrak{m}$-vector space, that A has exactly $k+1$ ideals, and that $\text{length}_A(A) = k$.

16.2 Discrete Valuation Rings

Discrete valuations and their valuation rings

Artinian rings were the Noetherian rings of dimension 0. We now climb one rung and study the simplest Noetherian domains of dimension 1. The local model for such a ring carries an extra, very concrete piece of data: a way to measure "how divisible" an element is by the maximal ideal. That measurement is a discrete valuation.

Definition 16.2.1 (discrete valuation)**.** A *discrete valuation* on a field K is a function $v : K^\times \to \mathbb{Z}$ (where $K^\times = K \setminus \{0\}$) satisfying

(i) v is surjective;

(ii) $v(xy) = v(x) + v(y)$ for all $x, y \in K^\times$ (so v is a group homomorphism $K^\times \to \mathbb{Z}$);

(iii) $v(x+y) \geq \min\{v(x), v(y)\}$ for all $x, y \in K^\times$ with $x + y \neq 0$.

The set

$$R = \{x \in K : v(x) \geq 0\} \cup \{0\}$$

is a subring of K, the *valuation ring* of v. An integral domain R is a *discrete valuation ring* (DVR) if R is the valuation ring of a discrete valuation v on its fraction field $K = \mathrm{Frac}(R)$.

It is convenient to extend v to all of K by $v(0) = +\infty$; then (ii) and (iii) hold for all elements. The *value group* is the image of v, which by surjectivity is all of $\mathbb{Z}$ – this is what "discrete" refers to (a homomorphism onto $\mathbb{Z}$, not onto a denser subgroup of $\mathbb{R}$).

Remark 16.2.1. Axiom (ii) forces $v(1) = v(1 \cdot 1) = 2v(1)$, so $v(1) = 0$; hence $1 \in R$ and $v(u^{-1}) = -v(u)$ for any unit. Because $R \subseteq K$ is a subring of a field, R is automatically an integral domain with $\mathrm{Frac}(R) = K$. The structural slogan, which the next subsection makes precise, is: a DVR is a *Noetherian local domain of dimension* 1 *that is integrally closed* – the local building block of a Dedekind domain.

Worked Example 16.2.2 (The p-adic valuation on $\mathbb{Q}$)**.** Verify that v_p is a discrete valuation on $\mathbb{Q}$ and identify its valuation ring.

Recognition. Every nonzero rational has a unique form $p^n(a/b)$ with $p \nmid a$, $p \nmid b$; set $v_p = n$.

Solution. Write $x = p^n(a/b) \in \mathbb{Q}^\times$ with a, b prime to p. Surjectivity is clear ($v_p(p^n) = n$). For (ii), if $x = p^m(a/b)$ and $y = p^n(c/d)$ then $xy = p^{m+n}(ac/bd)$ with ac, bd prime to p, so $v_p(xy) = m+n = v_p(x)+v_p(y)$. For (iii), with $m \leq n$, $x + y = p^m\big(a/b + p^{n-m}c/d\big) = p^m \cdot \frac{ad+p^{n-m}bc}{bd}$; the denominator is prime to p, the numerator may or may not be, so $v_p(x+y) \geq m = \min\{v_p(x), v_p(y)\}$. The valuation ring is $\{a/b : p \nmid b\} = \mathbb{Z}_{(p)}$, the localization of $\mathbb{Z}$ at (p). Sanity check: $v_p(p) = 1$ and $v_p(1/p) = -1$, so $p \in \mathbb{Z}_{(p)}$ but $1/p \notin \mathbb{Z}_{(p)}$, exactly the elements with nonnegative valuation.

Worked Example 16.2.3 (The order valuation on a rational function field)**.** For $K = F(x)$ and an irreducible $f \in F[x]$, show v_f is a discrete valuation and find its ring.

Recognition. Each nonzero element of $F(x)$ is uniquely $f^n(a/b)$ with $f \nmid a$, $f \nmid b$.

Solution. The verification is identical to the p-adic case with the prime p replaced by the irreducible f and $\mathbb{Z}$ replaced by the UFD $F[x]$: $v_f(gh) = v_f(g) + v_f(h)$ and the ultrametric inequality both follow from unique factorization. The valuation ring is the localization $F[x]_{(f)}$ of rational functions whose reduced denominator is not divisible by f. When $f = x - a$ has degree 1, v_f measures the *order of vanishing* at $x = a$: $v_f \geq 0$ means defined at a, $v_f < 0$ means a pole. Sanity check: $v_{x-a}\big(\frac{1}{x-a}\big) = -1$ (simple pole), $v_{x-a}\big((x-a)^2\big) = 2$ (double zero), consistent with (ii).

Worked Example 16.2.4 (The valuation on formal Laurent series)**.** Show the order map on $F((x))$ is a discrete valuation with ring $F[[x]]$.

Recognition. A nonzero Laurent series $\sum_{i \geq n} a_i x^i$ with $a_n \neq 0$ has order n.

Solution. Define $v\big(\sum_{i \geq n} a_i x^i\big) = n$ where $a_n \neq 0$ is the lowest nonzero coefficient. Multiplying two series, the lowest terms multiply to give $a_n b_m x^{n+m}$ (nonzero, as F is a domain), so v is additive. For the sum, the

lowest possible surviving term has exponent $\geq \min(n, m)$, giving (iii). The valuation ring $\{\, v \geq 0 \,\} \cup \{\, 0 \,\}$ is the power series ring $F[[x]]$. Sanity check: $v(x) = 1$ and $v(x^{-1}) = -1$, so $x \in F[[x]]$, $x^{-1} \notin F[[x]]$; and $F((x)) = \mathrm{Frac}(F[[x]])$ since inverting x recovers all Laurent series.

Uniformizers and the structure of a DVR

Once a discrete valuation is in hand, every element factors as a unit times a power of a single distinguished element of valuation 1. This is the arithmetic heart of the subject and makes a DVR the most rigidly structured of all one-dimensional rings.

Definition 16.2.5 (uniformizer)**.** If R is a DVR with valuation v, an element $t \in R$ with $v(t) = 1$ is a *uniformizing parameter* (or *uniformizer*, or *local parameter*). Such t exists by surjectivity of v.

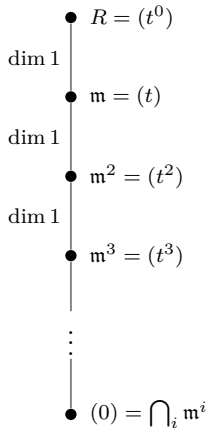
Proposition 16.2.6 (factorization in a DVR)**.** *Let R be a DVR with valuation v and uniformizer t.*

(1) *A nonzero $u \in R$ is a unit iff $v(u) = 0$.*

(2) *Every nonzero $r \in R$ is $r = u\,t^n$ for a unit u and $n = v(r) \geq 0$; every nonzero $x \in K$ is $x = u\,t^n$ for a unit u and $n = v(x) \in \mathbb{Z}$. The factorization is unique.*

(3) *Every nonzero ideal of R is $\mathfrak{m}^n = (t^n)$ for some $n \geq 0$. In particular R is Noetherian, indeed a PID.*

Idea. (1) If $uw = 1$ with $w \in R$ then $v(u) + v(w) = v(1) = 0$ with both ≥ 0, forcing $v(u) = 0$; conversely $v(u) = 0$ gives $v(u^{-1}) = 0$, so $u^{-1} \in R$. (2) If $v(x) = n$ then $v(xt^{-n}) = 0$, so $xt^{-n} = u$ is a unit and $x = ut^n$. (3) For a nonzero ideal I pick $r \in I$ of minimal valuation n; then $r = ut^n$ gives $t^n \in I$, so $(t^n) \subseteq I$, and any $a \in I$ has $v(a) \geq n$, whence $at^{-n} \in R$ and $a \in (t^n)$. So $I = (t^n)$. □



Corollary 16.2.7 (ideal theory and spectrum)**.** *Let R be a DVR with maximal ideal $\mathfrak{m} = (t) = \{\, r : v(r) > 0 \,\}$.*

(1) *R is an integrally closed local ring; its nonzero ideals are exactly $\mathfrak{m}^n$, $n \geq 0$, forming a single descending chain $R \supsetneq \mathfrak{m} \supsetneq \mathfrak{m}^2 \supsetneq \cdots$.*

(2) *$\operatorname{Spec} R = \{\, 0, \mathfrak{m} \,\}$: the only primes are (0) and $\mathfrak{m}$. Hence $\dim R = 1$.*

Idea. A DVR is a PID, hence a UFD, hence integrally closed in its fraction field. Locality and the ideal description come from the previous proposition; the chain $\mathfrak{m}^n$ has trivial intersection $\bigcap_n \mathfrak{m}^n = 0$ since v of a nonzero element is finite. As every nonzero ideal is some $\mathfrak{m}^n$ and a prime containing $\mathfrak{m}^n$ contains $\mathfrak{m}$, the only nonzero prime is $\mathfrak{m}$. □

Thus the entire ideal lattice of a DVR is a single descending chain, with each covering step $\mathfrak{m}^i \supsetneq \mathfrak{m}^{i+1}$ recording one unit of valuation. The successive quotients $\mathfrak{m}^i/\mathfrak{m}^{i+1} \cong R/\mathfrak{m}$ are all 1-dimensional over the residue field $F = R/\mathfrak{m}$ (each is spanned by the class of t^i), so every covering has the same "size": the lattice is the order type of $\mathbb{Z}_{\geq 0} \cup \{\, \infty \,\}$, with $0 = \bigcap_i \mathfrak{m}^i$ at the very bottom.

Method (To produce a DVR by hand.)**.** Exhibit a discrete valuation v on a field K: typically K is a UFD's fraction field and v counts the multiplicity of a chosen prime/irreducible. Then $R = \{\, v \geq 0 \,\} \cup \{\, 0 \,\}$ is a DVR, a uniformizer is any element of valuation 1 (the chosen prime itself), and the maximal ideal is $\{\, v > 0 \,\}$. To go the other way – recognize an abstractly given ring as a DVR – use the internal characterizations of the next subsection, which never mention v.

Worked Example 16.2.8 (Reading off the valuation in $\mathbb{Z}_{(p)}$)**.** In $R = \mathbb{Z}_{(p)}$ with $p = 5$, factor $r = \frac{50}{3}$ as $u\,t^n$ and identify the ideal it generates.

Recognition. $t = p = 5$ is a uniformizer; $v_5(r) = n$ and $u = r/5^n$ is a unit (valuation 0).

Solution. $\frac{50}{3} = 5^2 \cdot \frac{2}{3}$, and $v_5(2/3) = 0$ so $u = 2/3$ is a unit in $\mathbb{Z}_{(5)}$. Thus $r = u\,5^2$ with $n = v_5(r) = 2$, and $(r) = (5^2) = \mathfrak{m}^2$. Sanity check: $2/3$ is a unit because both numerator and denominator are prime to 5, so $(2/3)^{-1} = 3/2 \in \mathbb{Z}_{(5)}$; and $(r) = (50/3) = (25)$ since $2/3$ is a unit, so $(r) = \mathfrak{m}^2$, which lies in $\mathfrak{m}^2$ but not in $\mathfrak{m}^3$ (as $v_5(r) = 2$), exactly as the valuation predicts.

Worked Example 16.2.9 (The residue field of a DVR)**.** Compute the residue field $R/\mathfrak{m}$ for $\mathbb{Z}_{(p)}$, $k[x]_{(x)}$, and $k[[t]]$.

Recognition. $R/\mathfrak{m}$ is the field obtained by "evaluating" an element of valuation 0; killing the uniformizer.

Solution. For $\mathbb{Z}_{(p)}$, $\mathfrak{m} = (p)$ and $R/\mathfrak{m} = \mathbb{Z}_{(p)}/(p) \cong \mathbb{Z}/p\mathbb{Z} = \mathbb{F}_p$. For $k[x]_{(x)}$, $\mathfrak{m} = (x)$ and $R/\mathfrak{m} \cong k$ (set $x = 0$). For $k[[t]]$, $\mathfrak{m} = (t)$ and $R/\mathfrak{m} \cong k$ (take the constant term). Sanity check: in each case the natural surjection $R \to R/\mathfrak{m}$ sends a unit (valuation 0) to a nonzero residue and the uniformizer to 0, and the kernel is exactly $\mathfrak{m} = \{\, v > 0 \,\}$, so the quotient is a field as $\mathfrak{m}$ is maximal.

Worked Example 16.2.10 (The graded quotients $\mathfrak{m}^n/\mathfrak{m}^{n+1}$ are one-dimensional)**.** For a DVR R with residue field $F = R/\mathfrak{m}$, show $\dim_F(\mathfrak{m}^n/\mathfrak{m}^{n+1}) = 1$.

Recognition. $\mathfrak{m}^n = (t^n)$, so $\mathfrak{m}^n/\mathfrak{m}^{n+1}$ is generated over F by the class of t^n.

Solution. Every element of $\mathfrak{m}^n$ is rt^n with $r \in R$; modulo $\mathfrak{m}^{n+1} = (t^{n+1})$ it depends only on r mod $\mathfrak{m}$, giving an F-linear isomorphism $\mathfrak{m}^n/\mathfrak{m}^{n+1} \cong R/\mathfrak{m} = F$, $rt^n \mapsto \bar{r}$. Hence the dimension is 1. Sanity check: the associated graded ring $\operatorname{gr}_{\mathfrak{m}} R = \bigoplus_n \mathfrak{m}^n/\mathfrak{m}^{n+1} \cong F[\bar{t}]$ is a polynomial ring in one variable over F, the algebraic shadow of "t is a single uniformizer." This $\dim = 1$ is precisely the nonsingularity condition for curves at the end of the section.

The internal characterizations

The definition of a DVR is external – it names a valuation on the fraction field. The following theorem replaces it by purely ring-theoretic conditions, fusing D&F's list with the Atiyah–Macdonald viewpoint (their Proposition 9.2). The structural reading to keep in mind: *DVR = regular local ring of dimension* 1 *= the dimension-one analogue of a field*, where unique factorization is restored.

Theorem 16.2.11 (equivalent characterizations of a DVR)**.** *For an integral domain R that is not a field, with fraction field K, the following are equivalent.*

(1) *R is a discrete valuation ring.*

(2) *R is a PID with a unique nonzero prime ideal $\mathfrak{p} \neq 0$.*

(3) *R is a UFD with a unique irreducible element up to associates.*

(4) *R is a Noetherian local domain whose maximal ideal $\mathfrak{m}$ is nonzero and principal.*

(5) *R is a Noetherian, integrally closed local domain of Krull dimension* 1*; equivalently* $\operatorname{Spec} R = \{\, 0, \mathfrak{m} \,\}$ *with $\mathfrak{m} \neq 0$.*

(6) *R is a Noetherian local domain of dimension* 1 *with* $\dim_{R/\mathfrak{m}}(\mathfrak{m}/\mathfrak{m}^2) = 1$.

Idea. (1) ⇒ everything: shown in the previous subsection. (2) ⇒ (3): in a PID (hence UFD) the unique nonzero prime $\mathfrak{p} = (t)$ is generated by the unique irreducible t. (3) ⇒ (1): unique factorization gives each nonzero element as ut^n uniquely, and $v(ut^n) = n$ is a discrete valuation whose ring is R. (4) ⇒ (2): write $\mathfrak{m} = (t)$; Krull's intersection / Nakayama gives $\bigcap \mathfrak{m}^i = 0$, and any proper nonzero ideal I sits in some $\mathfrak{m}^n \setminus \mathfrak{m}^{n+1}$, so $I = (t^n)$ – every ideal is principal with a single prime $\mathfrak{m}$. The subtle implication is (5) ⇒ (4): one must show $\mathfrak{m}$ is principal. Since $\mathfrak{m} = \operatorname{Jac} R \neq \mathfrak{m}^2$ (Nakayama), choose $t \in \mathfrak{m} \setminus \mathfrak{m}^2$. Dimension 1 makes $\mathfrak{m}$ the radical of (t), so $\mathfrak{m}^n \subseteq (t)$ for some n; take n least and $x \in \mathfrak{m}^{n-1} \setminus (t)$, so that $x\mathfrak{m} \subseteq \mathfrak{m}^n \subseteq (t)$, and set $y = x/t \in K$. Then $y \notin R$ but $y\mathfrak{m} \subseteq R$. If $y\mathfrak{m} = R$ then $\mathfrak{m} = (t)$ after all; otherwise $y\mathfrak{m} \subseteq \mathfrak{m}$, so y stabilizes the finitely generated faithful module $\mathfrak{m}$, forcing y integral over R (determinant trick), hence $y \in R$ by integral closure – contradiction. So $\mathfrak{m} = (t)$. Finally (4) ⇔ (6): by Nakayama a Noetherian local $\mathfrak{m}$ is principal iff $\dim_{R/\mathfrak{m}} \mathfrak{m}/\mathfrak{m}^2 = 1$ (the minimal number of generators of $\mathfrak{m}$ equals this dimension). □

Corollary 16.2.12 (localizing at a minimal prime gives a DVR)**.** *If R is a Noetherian, integrally closed integral domain and $\mathfrak{p}$ is a minimal nonzero prime ideal, then the localization $R_\mathfrak{p}$ is a discrete valuation ring.*

Idea. Localization preserves all five hypotheses of characterization (5): $R_\mathfrak{p}$ is Noetherian, integrally closed, a domain, local with unique maximal ideal $\mathfrak{p}R_\mathfrak{p}$, and that ideal is the unique nonzero prime because $\mathfrak{p}$ was minimal – so $\dim R_\mathfrak{p} = 1$. By the theorem $R_\mathfrak{p}$ is a DVR. This is the bridge to the next section: it is exactly how a Dedekind domain breaks up into DVRs, one for each nonzero prime. □

Worked Example 16.2.13 (Why the local model must be one-dimensional)**.** Show that condition (5) genuinely needs $\dim R = 1$: a dimension-0 Noetherian local domain is a field, hence not a DVR.

Recognition. Dimension 0 means every prime is maximal; the unique prime (0) is then maximal.

Solution. If R is a Noetherian local domain of dimension 0, the zero ideal (0) is prime (domain) and is the only prime, hence is maximal, so $\mathfrak{m} = (0)$ and R is a field. A field K is not the valuation ring of any discrete valuation on K (a surjective v takes negative values, so $\{\, v \geq 0 \,\} \cup \{\, 0 \,\} \neq K$), so it is excluded – consistent with the theorem requiring "R is not a field." Sanity check: this is the Artinian boundary case from Section 16.1 (Noetherian + dimension 0), confirming DVRs sit one dimension above fields.

Worked Example 16.2.14 ($\mathbb{Z}_{(p)}$ satisfies characterization (2))**.** Verify directly that $\mathbb{Z}_{(p)}$ is a PID with a unique nonzero prime.

Recognition. Localizing the PID $\mathbb{Z}$ at (p) keeps it a PID and isolates the single prime (p).

Solution. Ideals of $\mathbb{Z}_{(p)}$ correspond to ideals of $\mathbb{Z}$ contained in (p) together with extension; the primes surviving are exactly those $\subseteq (p)$, namely (0) and (p). Every nonzero ideal is $(p^n)\mathbb{Z}_{(p)}$ since any rational a/b ($p \nmid b$) is $p^{v_p} \cdot \text{unit}$. So $\mathbb{Z}_{(p)}$ is a PID with unique nonzero prime (p) – characterization (2). Sanity check: $\dim \mathbb{Z}_{(p)} = 1$ matches the chain $0 \subsetneq (p)$, and the unique irreducible (up to units) is p itself, matching (3).

Worked Example 16.2.15 ($k[[t]]$ via characterization (4))**.** Show the power series ring $k[[t]]$ is a Noetherian local domain with principal maximal ideal, hence a DVR.

Recognition. Units of $k[[t]]$ are the series with nonzero constant term; the non-units form the ideal (t).

Solution. A series $\sum a_i t^i$ is a unit iff $a_0 \neq 0$ (invert by geometric series). Thus the non-units are exactly (t), so $k[[t]]$ is local with maximal ideal $\mathfrak{m} = (t)$, principal and nonzero. It is a Noetherian domain (e.g. it is the t-adic completion of $k[t]$, or directly each ideal is (t^n)). By characterization (4) it is a DVR with uniformizer t. Sanity check: every nonzero series is $t^n \cdot (\text{unit})$ where n is the lowest exponent, giving the valuation $v = n$ and recovering characterization (1).

Worked Example 16.2.16 (A non-example: $k[x,y]_{(x,y)}$ is not a DVR)**.** Explain why the localization of $k[x,y]$ at the maximal ideal (x,y) fails to be a DVR.

Recognition. A DVR is dimension 1 with a principal maximal ideal; here both fail.

Solution. The local ring $R = k[x,y]_{(x,y)}$ has $\dim R = 2$ (chain $0 \subsetneq (x) \subsetneq (x,y)$), violating characterization (5). Equivalently $\mathfrak{m} = (x,y)$ needs two generators: $\dim_{R/\mathfrak{m}} \mathfrak{m}/\mathfrak{m}^2 = 2 \neq 1$, violating (6). So R is a regular local ring but of dimension 2, not a DVR. Sanity check: R is integrally closed and Noetherian, so it satisfies every condition *except* dimension 1 / principal maximal ideal – pinpointing exactly which hypotheses are doing the work.

Worked Example 16.2.17 (A non-example: a non-integrally-closed dimension-1 local ring)**.** Show $R = k[t^2, t^3]_{(t^2,t^3)}$ is a Noetherian local domain of dimension 1 that is *not* a DVR.

Recognition. Characterization (5) requires integral closure; the cusp coordinate ring fails it.

Solution. Let $A = k[t^2, t^3] \subseteq k[t]$, the coordinate ring of the cuspidal cubic $y^2 = x^3$, and $R = A_{\mathfrak{m}}$ at $\mathfrak{m} = (t^2, t^3)$. Then $\dim R = 1$ (it is a curve), R is Noetherian and local. But $u = t^3/t^2 = t \in K = \mathrm{Frac}(R)$ satisfies $u^2 = t^2 \in R$, so u is integral over R yet $u = t \notin R$. Thus R is not integrally closed, so not a DVR. Sanity check: $\dim_{R/\mathfrak{m}} \mathfrak{m}/\mathfrak{m}^2 = 2$ here (generators t^2, t^3 are independent mod $\mathfrak{m}^2$), so (6) also fails – the cusp is a singular point of the curve, the geometric face of "not a DVR."

The p-adic integers and completion

The valuation supplies a metric, and completing with respect to it produces the most important DVRs in number theory and geometry. This is where Atiyah–Macdonald's "apply analysis to algebra" theme enters.

Definition 16.2.18 (v-adic metric)**.** A discrete valuation v on K gives, for any fixed real $\beta > 1$, an absolute value $\|a\|_v = \beta^{-v(a)}$ (with $\|0\|_v = 0$) and metric $d_v(a, b) = \|a - b\|_v$. Axiom (iii) yields the *ultrametric* inequality $d_v(a, b) \leq \max\{\, d_v(a, c), d_v(c, b) \,\}$. The completion K_v is again a field with a discrete valuation extending v, and $\{\, v \geq 0 \,\}$ inside it is a complete DVR.

Worked Example 16.2.19 (The p-adic integers $\mathbb{Z}_p$ as a DVR)**.** Show $\mathbb{Z}_p = \varprojlim \mathbb{Z}/p^n\mathbb{Z}$ is a DVR and identify its uniformizer and residue field.

Recognition. $\mathbb{Z}_p$ is the completion of $\mathbb{Z}_{(p)}$; it is a PID with unique maximal ideal $p\mathbb{Z}_p$.

Solution. Every nonzero $\alpha \in \mathbb{Z}_p$ is uniquely $p^n u$ with $u \in \mathbb{Z}_p^\times$ a unit (constant p-adic digit nonzero), so $v_p(\alpha) = n$ is a discrete valuation and $\mathbb{Z}_p$ is its ring – a DVR by characterization (1). The uniformizer is $t = p$, the maximal ideal is $p\mathbb{Z}_p$, and the residue field is $\mathbb{Z}_p/p\mathbb{Z}_p \cong \mathbb{F}_p$. Its fraction field is $\mathbb{Q}_p$, in which every nonzero element is $p^n u$ with $n \in \mathbb{Z}$. Sanity check: the sequence $1, p, p^2, \ldots$ has $v_p \to +\infty$, so $\|p^k\|_p = p^{-k} \to 0$; it converges to 0 in the p-adic metric, the hallmark that "divisible by a high power of p" means "small."

Worked Example 16.2.20 ($\mathbb{Z}_p$ as the completion of $\mathbb{Z}_{(p)}$, and $\mathbb{Q}_p$ from $\mathbb{Q}$)**.** Explain the sense in which $\mathbb{Z}_p$ and $\mathbb{Q}_p$ are completions, via p-adic Laurent expansions.

Recognition. Completing $\mathbb{Q}$ in the p-adic metric gives $\mathbb{Q}_p$; each element has a digit expansion $\sum_{i \geq n_0} a_i p^i$.

Solution. Cauchy sequences in $(\mathbb{Q}, d_{v_p})$ have limits represented as $\alpha = \sum_{i \geq n_0} a_i p^i$ with digits $a_i \in \{\, 0, \ldots, p-1 \,\}$ and $v_p(\alpha) = n_0$ when $a_{n_0} \neq 0$. The subset with $n_0 \geq 0$ (no negative powers of p) is the completion of $\mathbb{Z}$, namely $\mathbb{Z}_p$; allowing finitely many negative powers gives $\mathbb{Q}_p = \mathrm{Frac}(\mathbb{Z}_p)$. This mirrors the power-series case $F[[x]] \subseteq F((x))$ exactly, with p in place of x. Sanity check: truncating the series at p^n recovers $\mathbb{Z}/p^n\mathbb{Z}$, so $\mathbb{Z}_p = \varprojlim \mathbb{Z}/p^n\mathbb{Z}$ and $\bigcap_n p^n\mathbb{Z}_p = 0$, consistent with v_p of a nonzero element being finite.

Worked Example 16.2.21 (Laurent series as the completion of $k[x]_{(x)}$)**.** Identify $\mathrm{Frac}(k[[x]])$ and relate $k[[x]]$ to the localization $k[x]_{(x)}$.

Recognition. Completing $k(x)$ at the valuation v_x (order at $x = 0$) gives $k((x))$ with ring $k[[x]]$.

Solution. The valuation ring $k[x]_{(x)}$ (rational functions defined at 0) is dense in its v_x-completion $k[[x]]$, and $\mathrm{Frac}(k[[x]]) = k((x))$, the formal Laurent series. Every nonzero Laurent series is $x^n \cdot (\text{unit})$, recovering $v_x = n$. Sanity check: $k[x]_{(x)}$ and $k[[x]]$ have the same residue field k and the same uniformizer x, but only the completion is complete – e.g. the partial sums of $\sum_{i \geq 0} x^{i^2}$ form a Cauchy sequence in $k[x]_{(x)}$ with no limit there, since this series is not a rational function (its coefficients satisfy no linear recurrence), whereas $\sum_{i \geq 0} x^i = 1/(1-x)$ already lies in $k[x]_{(x)}$.

Worked Example 16.2.22 (The ultrametric inequality sharpened)**.** In a DVR's fraction field, prove that $v(x) < v(y) \Rightarrow v(x + y) = \min\{\, v(x), v(y) \,\} = v(x)$.

Recognition. Equality holds in the ultrametric law whenever the two valuations differ; write $x + y = x(1 + y/x)$.

Solution. Suppose $v(x) < v(y)$, so $v(y/x) = v(y) - v(x) > 0$, i.e. $y/x \in \mathfrak{m}$. Then $1 + y/x$ is a unit (it is 1 plus a non-unit in a local ring), so $v(1 + y/x) = 0$, giving $v(x + y) = v(x) + v(1 + y/x) = v(x) = \min\{\, v(x), v(y) \,\}$. Sanity check: in $\mathbb{Z}_{(p)}$, $v_p(p + p^2) = v_p\big(p(1 + p)\big) = 1 + 0 = 1 = \min(1, 2)$; the only way the strict inequality $v(x + y) > \min$ can occur is when $v(x) = v(y)$ and leading terms cancel, e.g. $v_p(p - p) = +\infty$.

Fractional ideals and nonsingularity of curves

Two further faces of a DVR close the section: an ideal-theoretic one (every fractional ideal is invertible – the local seed of the Dedekind story) and a geometric one (DVR = nonsingular point of a curve).

Definition 16.2.23 (fractional ideal)**.** For a domain R with fraction field K, a *fractional ideal* is a nonzero R-submodule $A \subseteq K$ with $dA \subseteq R$ for some nonzero $d \in R$ (equivalently $A = d^{-1}I$ for an ordinary ideal I). Products are defined by $AB = \{ \sum a_i b_i \}$; A is *invertible* if $AB = R$ for some fractional ideal B, necessarily $B = A^{-1} = \{ x \in K : xA \subseteq R \}$.

Proposition 16.2.24 (DVRs via fractional ideals)**.** *Let R be a local domain that is not a field. Then R is a DVR if and only if every nonzero fractional ideal of R is invertible.*

Idea. If R is a DVR with uniformizer t, every nonzero fractional ideal is $t^N R$ for some $N \in \mathbb{Z}$ (clear denominators, then use that ordinary ideals are $\mathfrak{m}^n = (t^n)$), hence principal and invertible. Conversely, if every nonzero fractional ideal is invertible then every ideal is finitely generated (invertible $\Rightarrow$ finitely generated), so R is Noetherian. With $\mathfrak{m}$ the maximal ideal, $\mathfrak{m} \neq \mathfrak{m}^2$ (else $\mathfrak{m} = 0$ by Nakayama and R is a field), so pick $t \in \mathfrak{m} \setminus \mathfrak{m}^2$. Then $t\mathfrak{m}^{-1}$ is a nonzero ideal of R; it cannot lie in $\mathfrak{m}$ (that would force $t \in \mathfrak{m}^2$), so $t\mathfrak{m}^{-1} = R$, i.e. $\mathfrak{m} = (t)$ is principal. By characterization (4), R is a DVR. □

Remark 16.2.2. Invertibility is the same as being projective: a nonzero fractional ideal A of a domain is invertible iff A is a projective R-module. Over a DVR every fractional ideal is even *free* of rank 1 (it is principal), so the class group is trivial – a DVR is a PID. Relaxing "local" while keeping "every fractional ideal invertible" gives, for domains that are not fields, exactly the Dedekind domains of the next section (Theorem 15(3) there; the definition itself is Noetherian, integrally closed, of dimension 1); the class group then measures the failure to be a PID.

Proposition 16.2.25 (nonsingularity = DVR)**.** *Let C be an irreducible affine curve over an algebraically closed field k, and $v \in C$ a point with local ring $\mathcal{O}_{v,C}$ and maximal ideal $\mathfrak{m}_v$. Then C is nonsingular at v (i.e. $\dim_k(\mathfrak{m}_v/\mathfrak{m}_v^2) = 1$) if and only if $\mathcal{O}_{v,C}$ is a discrete valuation ring.*

Idea. $\mathcal{O}_{v,C}$ is a Noetherian local domain of dimension 1 (the curve has $\operatorname{tr.deg}_k k(C) = 1$). Nonsingularity says $\dim_k(\mathfrak{m}_v/\mathfrak{m}_v^2) = 1$, which by characterization (6) is exactly the DVR condition for a one-dimensional Noetherian local ring. The residue field is k (Nullstellensatz, $k = \bar{k}$), so the $R/\mathfrak{m}$-dimension is the k-dimension. □

Corollary 16.2.26 (smoothness = integral closure)**.** *An irreducible affine curve C over $k = \bar{k}$ is smooth (nonsingular at every point) iff its coordinate ring $k[C]$ is integrally closed.*

Idea. C is smooth iff every local ring $\mathcal{O}_{v,C}$ is a DVR iff (characterization (5), using $\dim = 1$) every $\mathcal{O}_{v,C}$ is integrally closed iff $k[C]$ itself is integrally closed (integral closure is a local property). □

Worked Example 16.2.27 (Order of a zero/pole on a smooth curve)**.** At a smooth point v with uniformizer t, define and compute the order of f.

Recognition. Every $f \in \mathcal{O}_{v,C}$ (and every f in the function field) is $u\,t^n$; set $\operatorname{ord}_v(f) = n = v_v(f)$.

Solution. The valuation v_v on $k(C)$ attached to the DVR $\mathcal{O}_{v,C}$ assigns $\operatorname{ord}_v(f) = n$ where $f = u\,t^n$, u a unit. Then $n > 0$ means a zero of order n, $n < 0$ a pole of order $-n$, $n = 0$ a nonzero finite value. For $C = \mathbb{A}^1$ with coordinate x and v the point $x = a$: $t = x - a$, and $f = (x-a)^2/(x-b)$ has $\operatorname{ord}_v f = 2$ at a and $\operatorname{ord} = -1$ at b. Sanity check: $\operatorname{ord}_v(fg) = \operatorname{ord}_v f + \operatorname{ord}_v g$ by additivity of v_v, so orders add under multiplication and the "divisor" $\sum_v \operatorname{ord}_v(f) \cdot v$ is well defined – the entry point to the theory of divisors on curves.

Worked Example 16.2.28 (A singular point fails to be a DVR)**.** For the cusp $C : y^2 = x^3$ at the origin, show $\dim_k(\mathfrak{m}_v/\mathfrak{m}_v^2) = 2$, hence singular.

Recognition. Compute $\mathfrak{m}_v/\mathfrak{m}_v^2$ in $\mathcal{O}_{0,C}$; if it has dimension > 1 the local ring is not a DVR.

Solution. With $k[C] = k[x,y]/(y^2 - x^3)$ and $\mathfrak{m} = (x,y)$ at the origin, in $\mathfrak{m}/\mathfrak{m}^2$ the relation $y^2 = x^3$ lives in $\mathfrak{m}^3 \subseteq \mathfrak{m}^2$ and imposes nothing, so x, y are linearly independent mod $\mathfrak{m}^2$: $\dim_k(\mathfrak{m}/\mathfrak{m}^2) = 2 > 1$. Hence $\mathcal{O}_{0,C}$ is not a DVR and the origin is singular. Sanity check: this is the cusp $R = k[t^2, t^3]_{(t^2,t^3)}$ from earlier, where $t = y/x$ is integral but not in R – non-integral-closure and the dimension-2 cotangent space are two views of the same singularity.

Worked Example 16.2.29 (Localizing a PID at a prime always gives a DVR)**.** Show every localization $R_{\mathfrak{p}}$ of a PID R at a nonzero prime $\mathfrak{p} = (p)$ is a DVR.

Recognition. A PID is integrally closed (it is a UFD) and its nonzero primes are maximal, so the corollary on minimal primes applies.

Solution. R is Noetherian, integrally closed, a domain; $\mathfrak{p} = (p)$ is a minimal nonzero prime (in a PID all nonzero primes are minimal = maximal). By the corollary, $R_{\mathfrak{p}}$ is a DVR, with valuation $v_p(p^n a/b) = n$ for a, b prime to p. This unifies the $\mathbb{Z}_{(p)}$ and $F[x]_{(f)}$ examples. Sanity check: the fraction field of $R_{\mathfrak{p}}$ equals $\mathrm{Frac}(R)$, so each nonzero prime p of R yields one valuation on the common field K – exactly the family of DVRs that reassembles into the Dedekind domain R in Section 16.3.

Worked Example 16.2.30 (From a Dedekind domain to its DVRs (forward link))**.** If R is Noetherian, integrally closed, of dimension 1, describe the family $\{ R_{\mathfrak{p}} \}$ and why each is a DVR.

Recognition. Each nonzero prime $\mathfrak{p}$ is minimal; localizing gives a one-dimensional integrally closed Noetherian local domain.

Solution. For each nonzero prime $\mathfrak{p}$ of R, the localization $R_{\mathfrak{p}}$ satisfies characterization (5): Noetherian, integrally closed, local with unique nonzero prime $\mathfrak{p}R_{\mathfrak{p}}$, dimension 1. So $R_{\mathfrak{p}}$ is a DVR with a valuation $v_{\mathfrak{p}}$ on $K = \mathrm{Frac}(R)$, and the maximal ideals of R are in bijection with these valuations. Sanity check: this is condition (2) of the upcoming Dedekind characterization (R Noetherian with every $R_{\mathfrak{p}}$ a DVR), so a Dedekind domain is precisely a "global" object whose every local piece is a DVR – the local-global principle that restores unique factorization at the level of ideals.

Exercises (Dummit & Foote).

1. Suppose R is a Discrete Valuation Ring with respect to the valuation v on the fraction field K of R. If $x, y \in K$ with $v(x) < v(y)$ prove that $v(x + y) = \min(v(x), v(y))$. [Note that $x + y = x(1 + y/x)$.]

2. Suppose R is a Discrete Valuation Ring with unique maximal ideal M and quotient $F = R/M$. For any $n \geq 0$ show that M^n/M^{n+1} is a vector space over F and that $\dim_F(M^n/M^{n+1}) = 1$.

3. Suppose R is an integral domain that is also a local ring whose unique maximal ideal $M = (t)$ is nonzero and principal, and suppose that $\bigcap_{n\geq 1}(t^n) = 0$. Prove that R is a Discrete Valuation Ring. [Show that every nonzero element in R can be written in the form ut^n for some unit $u \in R$ and some $n \geq 0$.]

4. Suppose R is a Noetherian local ring whose unique maximal ideal $M = (t)$ is principal. Prove that either R is a Discrete Valuation Ring or $t^n = 0$ for some $n \geq 0$. In the latter case show that R is Artinian.

5. Suppose that R is a Noetherian integral domain that is also a local ring of Krull dimension 1. Let M be the unique maximal ideal of R and let $F = R/M$, so that M/M^2 is a vector space over F.

   (a) Prove that if $\dim_F(M/M^2) = 1$ then R is a Discrete Valuation Ring.

   (b) If every nonzero ideal of R is a power of M prove that R is a Discrete Valuation Ring.

6. Let R be an integral domain with fraction field K. Prove that every finitely generated R-submodule of K is a fractional ideal of R. If R is Noetherian, prove that A is a fractional ideal of R if and only if A is a finitely generated R-submodule of K.

7. If R is an integral domain and A is a fractional ideal of R, prove that if A is projective then A is finitely generated. Conclude that every integral domain that is not Noetherian contains an ideal that is not projective.

8. Suppose R is a Noetherian integral domain that is also a local ring with nonzero maximal ideal M. Prove that R is a D.V.R. if and only if the only M-primary ideals in R are the powers of M.

9. Let $C = Z(xz - y^2,\, yz - x^3,\, z^2 - x^2y) \subset \mathbb{A}^3$ over the algebraically closed field k. If $v = (0, 0, 0) \in C$, prove that $\dim_k(\mathfrak{m}_{v,C}/\mathfrak{m}_{v,C}^2) = 3$ so that v is singular on C. Conclude that $k[C]$ is not integrally closed in $k(C)$ and determine its integral closure. [cf. Exercise 27, Section 15.4.]

Throughout, R denotes a discrete valuation ring (DVR) with fraction field $K = \mathrm{Frac}(R)$, discrete valuation v, maximal ideal $\mathfrak{m}$, uniformizer t, and residue field $F = R/\mathfrak{m}$, unless stated otherwise.

Practice problems.

1. In $R = \mathbb{Z}_{(7)}$ with uniformizer $t = 7$, write each of $r_1 = \frac{98}{15}$, $r_2 = \frac{6}{343}$, and $r_3 = \frac{21}{50} \cdot \frac{20}{63}$ in the form $u\,7^n$ with $u \in R^\times$ and $n = v_7(r_i) \in \mathbb{Z}$, and decide which r_i lie in R.

2. Let $K = \mathbb{Q}$ with the 5-adic valuation v_5. Using only $v_5(x) < v_5(y) \Rightarrow v_5(x+y) = \min\{\, v_5(x), v_5(y) \,\}$ and additivity, compute $v_5\big(\frac{1}{25} + \frac{3}{10}\big)$ and $v_5\big(\frac{2}{5} + \frac{8}{5}\big)$, and explain why the second case can exceed the minimum.

3. In the power series DVR $R = \mathbb{F}_2[[t]]$, determine $v(f)$ and the unit part of $f = t^3 + t^5 + t^7$ and of $g = t^2(1+t)^{-1}$, then factor the product fg as $u\,t^n$. Identify the ideal (fg) as a power of $\mathfrak{m} = (t)$.

4. Let R be a DVR and let $a, b \in R$ be nonzero with $v(a) = 3$ and $v(b) = 5$. Compute $v(a^2 b)$, decide whether $a \mid b$ in R, and determine the smallest n with $\mathfrak{m}^n \subseteq (a)$ and the largest m with $b \in \mathfrak{m}^m$.

5. For the localization $R = k[x]_{(x-2)}$ (rational functions defined at $x = 2$), find the order $v_{x-2}(f)$ of $f = \dfrac{(x-2)^4(x+1)}{(x^2-4)}$ at $x = 2$, give a uniformizer, and state the residue field $R/\mathfrak{m}$.

6. Let $\mathfrak{m} = (t)$ be the maximal ideal of a DVR R with residue field F. Exhibit an explicit F-basis of the two-dimensional F-vector space $R/\mathfrak{m}^2$ when R contains a field mapping isomorphically onto F (e.g. $R = F[[t]]$), and explain why $R/\mathfrak{m}^2$ is a local ring that is not a domain.

7. In $\mathbb{Z}_{(3)}$, list all ideals containing (81), arrange them in their (totally ordered) chain, and for each quotient $\mathfrak{m}^i/\mathfrak{m}^{i+1}$ with $0 \le i \le 3$ state its dimension over $F = \mathbb{F}_3$.

8. Let R be a DVR with valuation v and let $x \in K$ satisfy $v(x) = -2$. Show $x \notin R$ but $x \in t^{-2}R$, find the least $N \ge 0$ with $t^N x \in R$, and identify the fractional ideal Rx as $\mathfrak{m}^{N'}$ for the appropriate $N' \in \mathbb{Z}$.

Additional exercises.

1. Let R be a DVR with valuation v and uniformizer t. Prove that an element $a \in R$ is irreducible if and only if a is an associate of t, and deduce that R has, up to associates, exactly one irreducible element. Conclude that R is a UFD with this property and hence satisfies characterization (3) of a DVR.

2. Let R be a DVR with fraction field K. Prove that for any subring S with $R \subseteq S \subseteq K$, either $S = R$ or $S = K$. [Show that if some $x \in S$ has $v(x) < 0$ then $t^{-1} \in S$.] Conclude that R is a maximal proper subring of K.

3. Let v and w be two discrete valuations on the same field K having the same valuation ring R. Prove that $v = w$. [Compare uniformizers and use that every nonzero element is a unit times a power of a uniformizer.]

4. Let R be a Noetherian local domain with principal maximal ideal $\mathfrak{m} = (t) \neq 0$, and suppose R is *not* a field. Prove that $\bigcap_{n \ge 1} \mathfrak{m}^n = 0$ and deduce that every nonzero $x \in R$ has a well-defined largest n with $x \in \mathfrak{m}^n$; use this to construct the valuation directly and prove R is a DVR.

5. Let R be a DVR with fraction field K and let $A \subseteq K$ be a nonzero fractional ideal. Prove that $A = t^N R$ for a unique $N \in \mathbb{Z}$, that $A^{-1} = t^{-N} R$, and hence that the group of nonzero fractional ideals of R under multiplication is infinite cyclic, generated by $\mathfrak{m} = (t)$ and isomorphic to $\mathbb{Z}$ via $A \mapsto N$.

Commutative-diagram exercises.

1. Let R be a DVR with uniformizer t. The nonzero ideals form the single descending chain below, with each quotient one-dimensional over $F = R/\mathfrak{m}$. Complete the diagram, label each downward edge with the

codimension (the F-dimension of the corresponding quotient $\mathfrak{m}^i/\mathfrak{m}^{i+1}$), and prove $\operatorname{length}(R/\mathfrak{m}^n) = n$:

$$\begin{array}{c} R \\ | \\ \mathfrak{m} = (t) \\ | \\ \mathfrak{m}^2 = (t^2) \\ | \\ \vdots \\ | \\ \mathfrak{m}^n = (t^n) \end{array}$$

Verify that the inclusions are strict and that $\bigcap_{n \geq 0} \mathfrak{m}^n = 0$.

2. Let R be a Noetherian integrally closed domain and $\mathfrak{p}$ a minimal nonzero prime. The localization square below realizes the passage from the global domain to the local DVR. Prove the square commutes (horizontal maps are localization at $\mathfrak{p}$, vertical maps the inclusions $\mathfrak{p} \hookrightarrow R$ and $\mathfrak{p}R_{\mathfrak{p}} \hookrightarrow R_{\mathfrak{p}}$), and that $R_{\mathfrak{p}}$ is a DVR with maximal ideal $\mathfrak{p}R_{\mathfrak{p}}$:

$$\begin{array}{ccc} \mathfrak{p} & \longrightarrow & \mathfrak{p}R_{\mathfrak{p}} \\ \downarrow & & \downarrow \\ R & \xrightarrow[\ell_{\mathfrak{p}}]{} & R_{\mathfrak{p}} \end{array}$$

Identify the residue field $R_{\mathfrak{p}}/\mathfrak{p}R_{\mathfrak{p}}$ in terms of $\operatorname{Frac}(R/\mathfrak{p})$, and explain why $\dim R_{\mathfrak{p}} = 1$.

3. Let R be a DVR with fraction field K and let $\mathcal{F}$ denote the group of nonzero fractional ideals. The diagram exhibits the valuation as a group isomorphism. Complete it and prove every map shown is well-defined and that the square commutes (the left vertical map sends $x \mapsto Rx$, the right vertical map is the identity, the top map is v, the bottom map is $A \mapsto N$ where $A = t^N R$):

$$\begin{array}{ccc} K^\times & \xrightarrow{\ v\ } & \mathbb{Z} \\ {\scriptstyle x \mapsto Rx}\downarrow & & \| \\ \mathcal{F} & \xrightarrow[A \mapsto N]{} & \mathbb{Z} \end{array}$$

Identify the kernel of $v : K^\times \to \mathbb{Z}$ as $R^\times$, and conclude that $K^\times/R^\times \cong \mathbb{Z} \cong \mathcal{F}$.

4. Let R be a DVR with maximal ideal $\mathfrak{m} = (t)$ and residue field $F = R/\mathfrak{m}$. The diagram relates the quotient $R/\mathfrak{m}^2$ to its layers via the short exact sequence of R-modules. Complete it and prove the rows are exact, where π is reduction mod $\mathfrak{m}$ and the left map is multiplication by t:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathfrak{m}/\mathfrak{m}^2 & \hookrightarrow & R/\mathfrak{m}^2 & \xrightarrow{\ \pi\ } & R/\mathfrak{m} & \longrightarrow & 0 \\ & & {\scriptstyle \cdot t}\uparrow \cong & & & & \| & & \\ & & F & & & & F & & \end{array}$$

Identify both end terms with F, conclude $\operatorname{length}(R/\mathfrak{m}^2) = 2$, and explain why the sequence does not split as R-modules unless $\mathfrak{m}^2 = 0$.

16.3 Dedekind Domains

Fractional ideals and invertibility

Throughout, R is an integral domain with fraction field $K \neq R$. The arithmetic of ideals in R becomes a group theory once we enlarge the ideals slightly to allow a bounded denominator.

Definition 16.3.1 (fractional ideal)**.** A *fractional ideal* of R is an R-submodule $A \subseteq K$ for which there is a nonzero $d \in R$ with $dA \subseteq R$. Equivalently, $A = d^{-1}I$ for some nonzero $d \in R$ and some (ordinary) ideal $I \subseteq R$. The ordinary ideals of R are exactly the fractional ideals contained in R; to distinguish them we call them *integral ideals*. For $x \in K$ the cyclic module $Rx = \{\, rx : r \in R \,\}$ is the *principal fractional ideal* generated by x.

The equivalence of the two phrasings is the remark that if $dA \subseteq R$ then dA is an integral ideal I and $A = d^{-1}I$. Loosely, a fractional ideal is "an ideal of R up to a fixed denominator d." When R is Noetherian a fractional ideal is the same thing as a finitely generated R-submodule of K.

Definition 16.3.2 (product and inverse)**.** If A, B are fractional ideals their *product* AB is the set of finite sums $\sum a_i b_i$ with $a_i \in A$, $b_i \in B$. If $A = d^{-1}I$ and $B = (d')^{-1}J$ then $AB = (dd')^{-1}IJ$, so AB is again a fractional ideal. We call A *invertible* if $AB = R$ for some fractional ideal B; such a B is unique (if $AB = AC = R$ then $B = B(AC) = (BA)C = C$) and is written A^{-1}.

The candidate inverse is forced on us. For any fractional ideal A set

$$A' = (R : A) = \{\, x \in K : xA \subseteq R \,\}.$$

This is the largest module that multiplies A back into R, so A^{-1}, if it exists, must be A'.

Proposition 16.3.3 (Prop. 9: the calculus of fractional ideals)**.** *Let A be a fractional ideal of R.*

(1) *A nonzero principal fractional ideal $A = xR$ is invertible, with $A^{-1} = x^{-1}R$.*

(2) *If $A \neq 0$ then $A' = (R : A)$ is a fractional ideal, $AA' \subseteq R$ always, and $AA' = R$ iff A is invertible, in which case $A^{-1} = A'$.*

(3) *An invertible fractional ideal is finitely generated.*

(4) *The invertible fractional ideals form an abelian group under multiplication with identity R; the nonzero principal fractional ideals are a subgroup.*

Idea. (1) is immediate. For (2): A' is an R-module; picking a nonzero $a \in A \cap R$ gives $aA' \subseteq R$, so A' is fractional. If $AB = R$ then $B \subseteq A'$, whence $R = AB \subseteq AA' \subseteq R$, forcing $AA' = R$. For (3): from $AA' = R$ write $1 = \sum_{i=1}^{n} a_i a_i'$ with $a_i \in A$, $a_i' \in A'$; then any $a \in A$ is $a = \sum_i (aa_i')a_i$ with $aa_i' \in R$, so $a_1, \dots, a_n$ generate A. (4) is formal, using $(xR)(yR) = (xy)R$. □

Invertibility is closely tied to projectivity: a nonzero fractional ideal A is invertible *iff* A is projective as an R-module. Indeed from $\sum a_i a_i' = 1$ one builds split maps $A \hookrightarrow R^n \twoheadrightarrow A$ exhibiting A as a direct summand of a free module, and conversely a splitting produces dual elements $a_i' \in A'$ with $\sum a_i a_i' = 1$. The bridge from local to global runs through the next fact.

Proposition 16.3.4 (Prop. 11: local invertibility detects a DVR)**.** *Let R be a local domain, not a field. Then R is a DVR iff every nonzero fractional ideal of R is invertible.*

Idea. If R is a DVR with uniformizer t, every nonzero fractional ideal is $t^N R$ for some $N \in \mathbb{Z}$, hence principal, hence invertible. Conversely, invertibility of ideals makes every ideal finitely generated (Prop. 9(3)), so R is Noetherian; if $\mathfrak{m}$ is the maximal ideal then $\mathfrak{m} \neq \mathfrak{m}^2$ (else $\mathfrak{m} = 0$ by Nakayama and R is a field), so pick $t \in \mathfrak{m} \setminus \mathfrak{m}^2$. Then $t\mathfrak{m}^{-1}$ is an integral ideal; it cannot lie in $\mathfrak{m}$ (that would give $t \in \mathfrak{m}^2$), so $t\mathfrak{m}^{-1} = R$, i.e. $(t) = \mathfrak{m}$. A Noetherian local domain with principal maximal ideal is a DVR. □

Worked Example 16.3.5 (The standard fractional ideal $\frac{1}{2}\mathbb{Z}$ of $\mathbb{Z}$)**.** Exhibit $A = \frac{1}{2}\mathbb{Z}$ as a fractional ideal of $\mathbb{Z}$ and compute A' and AA'.

Recognition. A fractional ideal of $\mathbb{Z}$ is $d^{-1}I$ for an integer d and ideal $I = (n)$; the inverse of a principal fractional ideal xR is $x^{-1}R$.

Solution. Take $d = 2$, $I = (1) = \mathbb{Z}$: then $A = 2^{-1}\mathbb{Z} = \frac{1}{2}\mathbb{Z}$ is an R-submodule of $\mathbb{Q}$ with $2A = \mathbb{Z} \subseteq \mathbb{Z}$, so it is fractional. It is principal, $A = (\frac{1}{2})\mathbb{Z}$, so $A' = A^{-1} = 2\mathbb{Z}$ and $AA' = (\frac{1}{2} \cdot 2)\mathbb{Z} = \mathbb{Z} = R$. Sanity check: A is invertible because every nonzero fractional ideal of the PID $\mathbb{Z}$ is principal; here $A^{-1} = 2\mathbb{Z}$ and indeed $\frac{1}{2}\mathbb{Z} \cdot 2\mathbb{Z} = \mathbb{Z}$.

Worked Example 16.3.6 (A non-invertible fractional ideal in a non-normal ring)**.** In $R = k[t^2, t^3] \subseteq k[t]$ (the cusp ring) let $\mathfrak{m} = (t^2, t^3)$. Show $\mathfrak{m}$ is not invertible.

Recognition. For an integral ideal, $\mathfrak{m}$ invertible $\Rightarrow \mathfrak{m}\mathfrak{m}' = R$; one tests whether $\mathfrak{m}' = (R : \mathfrak{m})$ is large enough to recover R.

Solution. Here $K = k(t)$ and $\mathfrak{m}' = (R : \mathfrak{m}) = \{\, x \in K : x\mathfrak{m} \subseteq R \,\}$. The element $t = t^3/t^2$ satisfies $t \cdot t^2 = t^3 \in R$ and $t \cdot t^3 = t^4 = (t^2)^2 \in R$, so $t \in \mathfrak{m}'$; thus $R[t] \subseteq \mathfrak{m}'$ and in fact $\mathfrak{m}' = k[t]$. Then $\mathfrak{m}\mathfrak{m}' = (t^2, t^3)k[t] = (t^2)k[t] = t^2k[t]$, which contains $t^2, t^3, t^4, \ldots$ but *not* 1, so $\mathfrak{m}\mathfrak{m}' \neq R$ and $\mathfrak{m}$ is not invertible. Sanity check: R is not integrally closed (t is integral over R but $t \notin R$), so R is not a Dedekind domain, and Theorem 15 below predicts that some ideal fails to be invertible – exactly what we found.

Worked Example 16.3.7 (The inverse of $(2, 1+\sqrt{-5})$ in $\mathbb{Z}[\sqrt{-5}]$)**.** In $R = \mathbb{Z}[\sqrt{-5}]$ let $\mathfrak{p} = (2, 1+\sqrt{-5})$. Verify $\mathfrak{p}$ is invertible by computing $\mathfrak{p}\mathfrak{p}'$.

Recognition. In a Dedekind domain every nonzero ideal is invertible; one verifies it by producing A' with $AA' = R$. Here $\mathfrak{p}'$ should be $\frac{1}{2}\mathfrak{p}$ (the conjugate scaled).

Solution. Compute $\mathfrak{p}^2 = (2, 1+\sqrt{-5})^2$, generated by 4, $2(1+\sqrt{-5})$, and $(1+\sqrt{-5})^2 = -4 + 2\sqrt{-5}$. Each lies in (2), so $\mathfrak{p}^2 \subseteq (2)$. Conversely $\mathfrak{p}^2$ contains 4 and $-4 + 2\sqrt{-5}$, hence their sum $2\sqrt{-5}$; and it contains $2(1+\sqrt{-5}) = 2 + 2\sqrt{-5}$, so $(2 + 2\sqrt{-5}) - 2\sqrt{-5} = 2 \in \mathfrak{p}^2$, giving $(2) \subseteq \mathfrak{p}^2$. Hence $\mathfrak{p}^2 = (2)$, the statement that the prime 2 is ramified with $N(\mathfrak{p}) = |R/\mathfrak{p}| = 2$. From $\mathfrak{p}^2 = (2)$ we get $\mathfrak{p} \cdot \left(\frac{1}{2}\mathfrak{p}\right) = \frac{1}{2}\mathfrak{p}^2 = \frac{1}{2}(2) = R$, so $\mathfrak{p}$ is invertible with $\mathfrak{p}^{-1} = \frac{1}{2}\mathfrak{p}$. Sanity check: $\mathfrak{p}$ is not principal (no element of R has norm 2, since $a^2 + 5b^2 = 2$ is insoluble), yet it is invertible – the hallmark of a Dedekind domain that is not a PID, and the source of a nontrivial class group.

Dedekind domains: equivalent definitions

We now drop the locality hypothesis from the DVR theory. The result is the central object of classical multiplicative ideal theory.

Definition 16.3.8 (Dedekind domain)**.** A *Dedekind domain* is a Noetherian, integrally closed integral domain of Krull dimension 1. Equivalently: R is a Noetherian, integrally closed domain, not a field, in which every nonzero prime ideal is maximal.

The slogan to carry from Atiyah–Macdonald is the local-to-global one. A DVR is precisely a Noetherian integrally closed local domain of dimension 1; a Dedekind domain is what you get by removing the word "local," and accordingly it is detected one prime at a time by its localizations.

Proposition 16.3.9 (Prop. 14: the two motivating classes)**.** (1) *Every PID that is not a field is a Dedekind domain.*

(2) *The ring of integers $\mathcal{O}_K$ of an algebraic number field K is a Dedekind domain.*

Idea. A PID is Noetherian, is integrally closed (being a UFD), and has every nonzero prime maximal. For $\mathcal{O}_K$ = integral closure of $\mathbb{Z}$ in K: it is integrally closed by construction, Noetherian because it is a finitely generated $\mathbb{Z}$-module (hence a Noetherian $\mathbb{Z}$-module), and dimension 1 because a nonzero prime $\mathfrak{p}$ contracts to a nonzero prime $\mathfrak{p} \cap \mathbb{Z} = (p)$ of $\mathbb{Z}$, which is maximal, forcing $\mathfrak{p}$ maximal by integrality (lying-over / going-up). □

Theorem 16.3.10 (Thm. 15 / A&M Thm. 9.8: equivalent characterizations)**.** *For an integral domain R with fraction field $K \neq R$, the following are equivalent.*

(1) *R is Noetherian, integrally closed, and every nonzero prime is maximal* (i.e. a Dedekind domain).

(2) *R is Noetherian and for each nonzero prime P the localization R_P is a DVR.*

(3) *Every nonzero fractional ideal of R is invertible.*

(4) *Every nonzero fractional ideal of R is a projective R-module.*

(5) *Every nonzero proper ideal I factors as a product of prime ideals $I = P_1 P_2 \cdots P_n$; moreover the multiset $\{ P_1, \ldots, P_n \}$ is uniquely determined, so I is uniquely a product of prime powers.*

Idea. (1)⇒(2): localizing preserves Noetherian, integrally closed, and dimension 1, so R_P is a local Noetherian integrally closed domain of dimension 1, i.e. a DVR. (2)⇒(1): integral closure and "primes are maximal" are local properties, and a domain that is locally a DVR is integrally closed of dimension 1. (1)⇔(3): invertibility $AA' = R$ is a local statement, $(AA')_P = A_P(A_P)'$; each R_P being a DVR makes A_P invertible (Prop. 11), so $AA' = R$ globally. Conversely invertible fractional ideals make R Noetherian and each R_P a local ring with all fractional ideals invertible, hence a DVR (Prop. 11). (3)⇔(4) is the projective = invertible dictionary (the paragraph after Prop. 9). (1)⇒(5): a minimal primary decomposition $I = Q_1 \cap \cdots \cap Q_n$ has pairwise comaximal radicals (primes are maximal), so $\bigcap Q_i = \prod Q_i$, and each P-primary Q_i is a prime power $P_i^{m_i}$ because R_{P_i} is a DVR. (5)⇒(3): one shows invertible primes are maximal and that the factorization forces every nonzero prime to be invertible, whence every ideal – and then every fractional ideal – is invertible. Uniqueness in (5) is the cancellation argument: in $P_1 \cdots P_n = P_1' \cdots P_m'$ a minimal P_1' contains some P_i, which in turn contains some P_j'; minimality of P_1' forces $P_j' = P_i = P_1'$, allowing cancellation of the invertible P_1'. □

Remark 16.3.1. The logic of (5)⇒(3) is purely multiplicative and reverses the historical order. Dedekind *defined* his domains by property (5) – unique factorization of ideals – precisely to repair the failure of unique factorization of *elements* in rings of integers (Section 8.3). It was Noether who recognized the structural characterization (1). The two viewpoints, "ideals factor" and "Noetherian + integrally closed + dimension 1," are the same world seen from arithmetic and from geometry respectively.

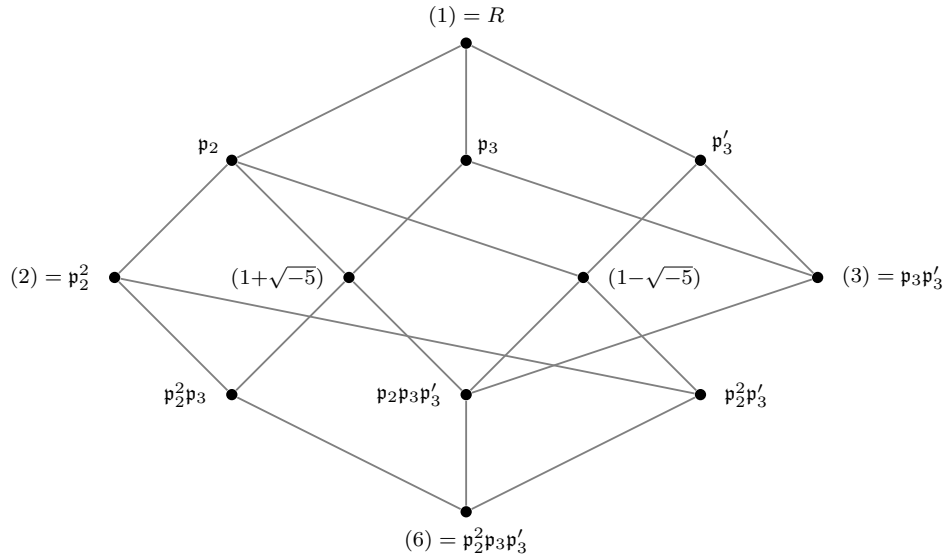
Corollary 16.3.11 (Cor. 16: unique factorization in $\mathcal{O}_K$)**.** *If $\mathcal{O}_K$ is the ring of integers of a number field K then every nonzero ideal I factors uniquely as $I = P_1^{e_1} \cdots P_n^{e_n}$ with distinct primes P_i and $e_i \geq 1$.*

Worked Example 16.3.12 ($\mathbb{Z}$ as a Dedekind domain, all five conditions at once)**.** Check that $\mathbb{Z}$ satisfies each clause of Theorem 15 directly.

Recognition. $\mathbb{Z}$ is a PID, hence Dedekind; the five conditions should each be visible from elementary number theory.

Solution. (1) $\mathbb{Z}$ is Noetherian, integrally closed (UFD), and its nonzero primes (p) are maximal. (2) $\mathbb{Z}_{(p)}$ is the DVR of p-adic valuation. (3) every fractional ideal is $\frac{a}{b}\mathbb{Z}$, invertible with inverse $\frac{b}{a}\mathbb{Z}$. (4) it is principal, hence free of rank 1, hence projective. (5) $(n) = \prod (p_i)^{e_i}$ from $n = \prod p_i^{e_i}$. Sanity check: the prime factorization of the integer n and the prime-ideal factorization of (n) literally coincide because $\mathbb{Z}$ is a PID – the class group is trivial.

Worked Example 16.3.13 (Factoring an ideal in $\mathbb{Z}[\sqrt{-5}]$)**.** Factor the ideal (6) in $\mathcal{O}_K = \mathbb{Z}[\sqrt{-5}]$ into primes.



Recognition. In a Dedekind domain $(6) = (2)(3)$ and each (p) factors according to how p splits; use norms to identify primes.

Solution. Set $\mathfrak{p}_2 = (2, 1 + \sqrt{-5})$, $\mathfrak{p}_3 = (3, 1 + \sqrt{-5})$, $\mathfrak{p}_3' = (3, 1 - \sqrt{-5})$. One checks $(2) = \mathfrak{p}_2^2$ (ramified), $(3) = \mathfrak{p}_3 \mathfrak{p}_3'$ (split). Hence

$$(6) = (2)(3) = \mathfrak{p}_2^2 \, \mathfrak{p}_3 \, \mathfrak{p}_3'.$$

Sanity check: this restores arithmetic to the famous failure $6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$ of unique factorization of *elements*: at the level of ideals, $(2) = \mathfrak{p}_2^2$, $(3) = \mathfrak{p}_3 \mathfrak{p}_3'$, $(1 + \sqrt{-5}) = \mathfrak{p}_2 \mathfrak{p}_3$, $(1 - \sqrt{-5}) = \mathfrak{p}_2 \mathfrak{p}_3'$, and both decompositions of (6) regroup the same four prime factors $\mathfrak{p}_2^2 \mathfrak{p}_3 \mathfrak{p}_3'$.

The divisors of (6) under "to contain is to divide" form the Hasse lattice below, graded by the number of prime factors. The three primes $\mathfrak{p}_2, \mathfrak{p}_3, \mathfrak{p}_3'$ sit directly below R; the four principal ideals $(2) = \mathfrak{p}_2^2$, $(3) = \mathfrak{p}_3\mathfrak{p}_3'$, $(1+\sqrt{-5}) = \mathfrak{p}_2\mathfrak{p}_3$, and $(1-\sqrt{-5}) = \mathfrak{p}_2\mathfrak{p}_3'$ all sit on the level-2 row. Reading (6) as the bottom meet, the two *element*-factorizations regroup into the *same* ideal factorization: $6 = 2 \cdot 3$ pairs the nodes (2) and (3), while $6 = (1+\sqrt{-5})(1-\sqrt{-5})$ pairs $(1+\sqrt{-5})$ and $(1-\sqrt{-5})$; both products equal $\mathfrak{p}_2^2\mathfrak{p}_3\mathfrak{p}_3' = (6)$, so Dedekind factorization restores uniqueness at the ideal level.

Worked Example 16.3.14 (A nonzero prime that is maximal but not principal)**.** Show $\mathfrak{p}_3 = (3, 1+\sqrt{-5})$ in $\mathbb{Z}[\sqrt{-5}]$ is maximal yet not principal.

Recognition. Dimension 1 forces every nonzero prime maximal; non-principality is detected by the norm ($N(\mathfrak{p}_3) = 3$) against the absence of elements of norm 3.

Solution. The quotient $\mathcal{O}_K/\mathfrak{p}_3 \cong \mathbb{F}_3$ is a field, so $\mathfrak{p}_3$ is maximal. If $\mathfrak{p}_3 = (\alpha)$ then $N(\alpha) = |\mathcal{O}_K/\mathfrak{p}_3| = 3$, i.e. $a^2 + 5b^2 = 3$ for integers a, b, which is impossible. Hence $\mathfrak{p}_3$ is not principal. Sanity check: consistent with dimension 1 ($\mathfrak{p}_3$ is maximal) and with a nontrivial class group (a nonprincipal yet invertible prime), exactly as Theorem 15 allows.

Worked Example 16.3.15 (Coordinate ring of a smooth affine curve is Dedekind)**.** Let C be a nonsingular irreducible affine curve over an algebraically closed field k. Show $k[C]$ is a Dedekind domain.

Recognition. Use criterion (2): $k[C]$ is Noetherian of dimension 1, and smoothness says each local ring $\mathcal{O}_{v,C}$ is a DVR.

Solution. $k[C]$ is a finitely generated k-algebra and a domain, hence Noetherian; its dimension equals the transcendence degree of $k(C)$ over k, namely 1. Smoothness at v means $\dim_k(\mathfrak{m}_v/\mathfrak{m}_v^2) = 1$, which for the Noetherian local ring $\mathcal{O}_{v,C}$ of dimension 1 is exactly the DVR condition. So every localization at a closed point is a DVR; by (2), $k[C]$ is Dedekind. Sanity check: equivalently, C is smooth iff $k[C]$ is integrally closed (normal), recovering criterion (1) – "smooth curve = normal one-dimensional ring."

Worked Example 16.3.16 ($k[x,y]/(y^2-x^3)$ is not Dedekind)**.** Show the cuspidal cubic coordinate ring $R = k[x,y]/(y^2-x^3)$ fails to be Dedekind.

Recognition. A Dedekind domain is integrally closed; the cusp is a singular point, so normality fails.

Solution. Writing $t = y/x$ in the fraction field, $t^2 = y^2/x^2 = x^3/x^2 = x$ and $t^3 = tx = y$, so t is integral over R ($t^2 - x = 0$) but $t \notin R$. Thus R is not integrally closed and not Dedekind; its integral closure is $k[t]$, the coordinate ring of the smooth normalization $\mathbb{A}^1$. Sanity check: this matches Worked Example 16.3.6 above, where $\mathfrak{m} = (x, y)$ was a non-invertible ideal – non-invertibility of some ideal is exactly the failure of Theorem 15(3) caused by the singular point.

The group of fractional ideals and the class group

By Theorem 15(3), in a Dedekind domain R *every* nonzero fractional ideal is invertible, so the nonzero fractional ideals form an abelian group.

Corollary 16.3.17 (Cor. 9.9 / Exercise 6: the group of ideals is free)**.** *Let R be a Dedekind domain. The nonzero fractional ideals form an abelian group $I(R)$ under multiplication. Every nonzero fractional ideal is uniquely $\prod_P P^{a_P}$ over the nonzero primes P, with $a_P \in \mathbb{Z}$ and almost all $a_P = 0$. Hence $I(R)$ is the* free abelian group on the set of nonzero prime ideals.

Idea. Unique factorization of integral ideals (Theorem 15(5)) extends to fractional ideals: $A = d^{-1}I$ gives $A = (d)^{-1}I$ in $I(R)$, and the exponents subtract. Freeness is exactly existence-and-uniqueness of the exponent vector $(a_P)_P$. □

The principal fractional ideals $P(R) = \{\, (x) : x \in K^\times \,\}$ form a subgroup, the image of the homomorphism $K^\times \to I(R)$, $x \mapsto (x)$.

Definition 16.3.18 (ideal class group)**.** The *ideal class group* of the Dedekind domain R is the quotient

$$\mathrm{Cl}(R) = I(R)/P(R).$$

Its order $h_R = |\mathrm{Cl}(R)|$ (when finite) is the *class number*. There is an exact sequence

$$1 \longrightarrow R^\times \longrightarrow K^\times \xrightarrow{x \mapsto (x)} I(R) \longrightarrow \mathrm{Cl}(R) \longrightarrow 1,$$

identifying the kernel of $K^\times \to I(R)$ with the unit group $R^\times$.

Theorem 16.3.19 (Cor. 20: Cl measures failure of UFD)**.** *A Dedekind domain R is a PID iff* $\mathrm{Cl}(R)$ *is trivial* ($h_R = 1$) *iff R is a UFD.*

Idea. PID $\Leftrightarrow$ every ideal principal $\Leftrightarrow P(R) = I(R) \Leftrightarrow \mathrm{Cl}(R) = 1$. PID $\Rightarrow$ UFD always. For the converse, in a UFD a prime ideal P contains an irreducible a', and $P = (a')$ because (a') is already a nonzero prime; since every ideal factors into primes, every ideal is principal. □

Remark 16.3.2. For Dedekind domains arising in number theory the class group is a *finite* group: $\mathrm{Cl}(\mathcal{O}_K)$ is finite, its order h_K being a central arithmetic invariant. The unit group is finitely generated by Dirichlet: $\mathcal{O}_K^\times \cong \mu_K \times \mathbb{Z}^{r_1+r_2-1}$, where r_1, r_2 count real and complex-conjugate-pair embeddings. For general Dedekind domains finiteness can fail spectacularly: every abelian group A (finite or infinite) is the class group of some Dedekind domain.

Worked Example 16.3.20 (The class number of $\mathbb{Z}[\sqrt{-5}]$ is 2)**.** Show $\mathrm{Cl}(\mathbb{Z}[\sqrt{-5}]) \cong \mathbb{Z}/2\mathbb{Z}$ using the primes computed above.

Recognition. Each ideal class is represented by an integral ideal of small norm; $\mathfrak{p}_2, \mathfrak{p}_3, \mathfrak{p}_3'$ are non-principal, and one checks the products that become principal.

Solution. The nonprincipal primes $\mathfrak{p}_2, \mathfrak{p}_3, \mathfrak{p}_3'$ all lie in one nontrivial class: $\mathfrak{p}_2\mathfrak{p}_3 = (1+\sqrt{-5})$ and $\mathfrak{p}_2\mathfrak{p}_3' = (1-\sqrt{-5})$ are principal, so $[\mathfrak{p}_3] = [\mathfrak{p}_3'] = [\mathfrak{p}_2]^{-1} = [\mathfrak{p}_2]$ (as $\mathfrak{p}_2^2 = (2)$ is principal, $[\mathfrak{p}_2]$ has order 2). Thus the class group is generated by $[\mathfrak{p}_2]$ with $[\mathfrak{p}_2]^2 = 1$, giving $\mathrm{Cl} \cong \mathbb{Z}/2\mathbb{Z}$. Sanity check: $h = 2 \neq 1$ certifies $\mathbb{Z}[\sqrt{-5}]$ is not a UFD, in exact agreement with $6 = 2 \cdot 3 = (1+\sqrt{-5})(1-\sqrt{-5})$ being two genuinely different element-factorizations.

Worked Example 16.3.21 (Units of $\mathbb{Z}[i]$ and the trivial class group)**.** Identify $\mathbb{Z}[i]^\times$ and explain why $\mathrm{Cl}(\mathbb{Z}[i]) = 1$.

Recognition. $\mathbb{Z}[i]$ is a Euclidean domain, hence a PID, hence a Dedekind domain with trivial class group; units are the elements of norm 1.

Solution. $u \in \mathbb{Z}[i]^\times \Leftrightarrow N(u) = a^2 + b^2 = 1 \Leftrightarrow u \in \{\, 1, -1, i, -i \,\} = \mu_4$. As a PID, $\mathrm{Cl}(\mathbb{Z}[i]) = 1$ and $h = 1$. Sanity check: here $K = \mathbb{Q}(i)$ has $r_1 = 0$, $r_2 = 1$, so the Dirichlet rank is $r_1 + r_2 - 1 = 0$ and $\mathbb{Z}[i]^\times$ is purely torsion – exactly the 4 roots of unity found.

Worked Example 16.3.22 (Units of $\mathbb{Z}[\sqrt{2}]$ are infinite, class number still 1)**.** Describe $\mathbb{Z}[\sqrt{2}]^\times$ and its class group.

Recognition. $\mathbb{Q}(\sqrt{2})$ is real quadratic; $\mathbb{Z}[\sqrt{2}]$ is a PID (Euclidean), so $h = 1$, but the unit group has positive rank.

Solution. $\mathbb{Z}[\sqrt{2}]$ is Euclidean for the norm, so it is a PID and $\mathrm{Cl} = 1$. The fundamental unit is $1 + \sqrt{2}$ (norm $(1)^2 - 2(1)^2 = -1$), and $\mathbb{Z}[\sqrt{2}]^\times = \{\pm(1+\sqrt{2})^n : n \in \mathbb{Z}\} \cong \{\pm 1\} \times \mathbb{Z}$. Sanity check: $K = \mathbb{Q}(\sqrt{2})$ has $r_1 = 2, r_2 = 0$, Dirichlet rank $r_1 + r_2 - 1 = 1$, matching the single fundamental unit $1 + \sqrt{2}$ of infinite order.

Worked Example 16.3.23 (Reading the exact sequence for $\mathbb{Z}$)**.** Interpret $1 \to R^\times \to K^\times \to I(R) \to \mathrm{Cl}(R) \to 1$ for $R = \mathbb{Z}$.

Recognition. The maps are $\mathbb{Z}^\times \hookrightarrow \mathbb{Q}^\times \to I(\mathbb{Z}) \to \mathrm{Cl}(\mathbb{Z})$; identify each term.

Solution. $\mathbb{Z}^\times = \{\pm 1\}$; $\mathbb{Q}^\times \to I(\mathbb{Z})$ sends $x = \pm\prod p^{a_p}$ to the fractional ideal $\prod (p)^{a_p}$, with kernel $\{\pm 1\}$; $I(\mathbb{Z})$ is free abelian on $\{(p)\}$; and $\mathrm{Cl}(\mathbb{Z}) = 1$ since $\mathbb{Z}$ is a PID. Sanity check: the sequence collapses to $1 \to \{\pm 1\} \to \mathbb{Q}^\times \to I(\mathbb{Z}) \to 1$, the statement that a positive rational is uniquely $\prod p^{a_p}$ – the fundamental theorem of arithmetic, recast multiplicatively.

Divisibility, gcd, and the Chinese remainder theorem

Unique factorization of ideals turns ideal theory into a divisibility theory mirroring $\mathbb{Z}$.

Definition 16.3.24 (divides)**.** For ideals A, B of a domain R, say B *divides* A (written $B \mid A$) if $A = BC$ for some ideal C. Then $B \mid A \Rightarrow A \subseteq B$ always; in a Dedekind domain the converse holds: $A \subseteq B$ gives $C = AB^{-1} \subseteq BB^{-1} = R$, an integral ideal with $BC = A$.

This is the celebrated slogan *"to contain is to divide."*

Proposition 16.3.25 (Prop. 17: gcd via factorization)**.** *Let R be Dedekind and $A = \prod P_i^{e_i}$, $B = \prod P_i^{f_i}$ ($e_i, f_i \geq 0$). Then*

(1) *$A \subseteq B \iff B \mid A \iff f_i \leq e_i$ for all i;*

(2) *$A + B = \gcd(A, B) = \prod P_i^{\min(e_i, f_i)}$ and $A \cap B = \mathrm{lcm}(A, B) = \prod P_i^{\max(e_i, f_i)}$. In particular $A + B = R$ (coprime) iff A, B share no prime factor.*

Idea. (1) is "contain = divide" read off exponents. For (2): $A + B$ is the smallest ideal containing both, so every common divisor of A and B (an ideal containing both) contains $A + B$, i.e. divides it; matching exponents gives the min, and dually $A \cap B$ gives the max. □

Proposition 16.3.26 (Prop. 18: Chinese Remainder Theorem)**.** *Let R be Dedekind, $P_1, \ldots, P_n$ distinct nonzero primes, $a_i \geq 0$. Then*

$$R/(P_1^{a_1} \cdots P_n^{a_n}) \;\cong\; R/P_1^{a_1} \times \cdots \times R/P_n^{a_n}.$$

Equivalently, given $r_1, \ldots, r_n \in R$ there is $r \in R$, unique modulo $P_1^{a_1} \cdots P_n^{a_n}$, with $r \equiv r_i \pmod{P_i^{a_i}}$ for each i.

Idea. Distinct primes are maximal (dimension 1), so the $P_i^{a_i}$ are pairwise comaximal; CRT for comaximal ideals applies, and $\bigcap P_i^{a_i} = \prod P_i^{a_i}$. □

Corollary 16.3.27 (Cor. 19: approximation and two-generation)**.** *Let R be Dedekind, I a nonzero ideal.*

(1) *There is an ideal J coprime to I with $IJ = (a)$ principal; J lies in the inverse class $[I]^{-1}$.*

(2) *Every ideal of R/I is principal; equivalently, if $I_1 \supseteq I$ then $I_1 = I + Rb$ for some b.*

(3) *Every ideal is generated by two elements: if $0 \neq a \in I$ then $I = Ra + Rb$ for some $b \in I$.*

Idea. (1) For $I = \prod P_i^{e_i}$ pick $r_i \in P_i^{e_i} \setminus P_i^{e_i+1}$ and use CRT to get a with $v_{P_i}(a) = e_i$ exactly; then $(a) = IJ$ with J coprime to I. (2) reduces via CRT to $R/P^m \cong R_P/P^m R_P$, a quotient of a DVR (a local PID), where ideals are principal. (3) is (2) applied with $I_1 = I$, b lifting a generator. □

Worked Example 16.3.28 (CRT in $\mathbb{Z}$ recovered)**.** Specialize Proposition 18 to $R = \mathbb{Z}$ with $P_i = (p_i)$.

Recognition. $\mathbb{Z}$ is Dedekind; distinct primes (p_i) are comaximal, so CRT for ideals is ordinary CRT for integers.

Solution. With $m = \prod p_i^{a_i}$, $\mathbb{Z}/m\mathbb{Z} \cong \prod_i \mathbb{Z}/p_i^{a_i}\mathbb{Z}$, the classical statement. Solving $x \equiv r_i \pmod{p_i^{a_i}}$ has a unique solution mod m. Sanity check: e.g. $\mathbb{Z}/12\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z}$ from $12 = 2^2 \cdot 3$, and $|\mathbb{Z}/12\mathbb{Z}| = 12 = 4 \cdot 3$ matches.

Worked Example 16.3.29 (gcd of two ideals in $\mathbb{Z}[i]$)**.** Compute $(3+i) + (1+3i)$ and $(3+i) \cap (1+3i)$ in $\mathbb{Z}[i]$ via factorization.

Recognition. In the Dedekind (in fact principal) domain $\mathbb{Z}[i]$, sum = gcd and intersection = lcm, read off prime factorizations.

Solution. Norms: $N(3+i) = 10 = 2 \cdot 5$, $N(1+3i) = 10$. With $\pi_2 = (1+i)$ $(N = 2)$ and the split primes over 5, $\pi_5 = (2+i), \bar{\pi}_5 = (2-i)$, one finds $(3+i) = \pi_2\,(2-i)$ up to units and $(1+3i) = \pi_2\,(2+i)$. So $\gcd = (3+i) + (1+3i) = \pi_2 = (1+i)$ and $\mathrm{lcm} = (3+i) \cap (1+3i) = \pi_2(2+i)(2-i) = (1+i)(5) = (5+5i)$ up to units. Sanity check: norms multiply correctly, $N(\gcd) \cdot N(\mathrm{lcm}) = 2 \cdot 50 = 100 = N(3+i)N(1+3i) = 10 \cdot 10$, the ideal analogue of $\gcd \cdot \mathrm{lcm} = \text{product}$.

Worked Example 16.3.30 (Every ideal of $\mathbb{Z}[\sqrt{-5}]$ needs at most two generators)**.** Illustrate Corollary 19(3) on $\mathfrak{p}_2 = (2, 1+\sqrt{-5})$.

Recognition. Two-generation: pick any nonzero $a \in I$, then $I = Ra + Rb$; here $a = 2$.

Solution. $\mathfrak{p}_2$ is already exhibited with two generators 2 and $1+\sqrt{-5}$, and it is not principal (as in Worked Example 16.3.7: no element of norm 2), so two is the minimum. Sanity check: this is sharp – a non-principal ideal in a Dedekind domain genuinely needs two generators but never more, matching Corollary 19(3).

Worked Example 16.3.31 (Finding a coprime ideal in the inverse class)**.** For $I = \mathfrak{p}_3 = (3, 1+\sqrt{-5})$ in $\mathbb{Z}[\sqrt{-5}]$, find J coprime to I with IJ principal.

Recognition. Corollary 19(1): J should sit in $[I]^{-1}$; here $\mathfrak{p}_3' = (3, 1-\sqrt{-5})$ is coprime to $\mathfrak{p}_3$ and $\mathfrak{p}_3\mathfrak{p}_3' = (3)$.

Solution. Take $J = \mathfrak{p}_3'$. Then $\mathfrak{p}_3 + \mathfrak{p}_3' = R$ (they share no prime factor) and $\mathfrak{p}_3\mathfrak{p}_3' = (3)$ is principal. Sanity check: $[\mathfrak{p}_3'][\mathfrak{p}_3] = [(3)] = 1$ in $\mathrm{Cl}(R)$, so indeed $[J] = [I]^{-1}$, exactly as the corollary promises.

Modules over Dedekind domains

The structure theorem for finitely generated modules over a PID generalizes verbatim once we allow the free part to be twisted by an ideal class.

Proposition 16.3.32 (Prop. 21: ideals as modules and the Steinitz class)**.** *Let R be Dedekind with fraction field K.*

(1) *For fractional ideals I, J: $I \cong J$ as R-modules iff $I = (a)J$ for some $a \in K^\times$, i.e. iff $[I] = [J]$ in $\mathrm{Cl}(R)$.*

(2) *For nonzero fractional ideals, $I_1 \oplus \cdots \oplus I_n \cong J_1 \oplus \cdots \oplus J_m$ iff $n = m$ and $[I_1 \cdots I_n] = [J_1 \cdots J_m]$.*

(3) *In particular $I_1 \oplus \cdots \oplus I_n \cong R^{n-1} \oplus (I_1 \cdots I_n)$, and $R^n \oplus I \cong R^n \oplus J \iff [I] = [J]$.*

Idea. (1) multiplication by a is an isomorphism $J \to (a)J$; conversely an R-isomorphism $\varphi : I \to J$ is multiplication by the constant $c = \varphi(x)/x \in K^\times$ (since $x\varphi(y) = y\varphi(x)$), so $J = cI$, i.e. $I = (c^{-1})J$. The key reduction in (3) is the splitting $I \oplus J \cong R \oplus IJ$: replacing I, J by coprime integral representatives, the sum map $I \oplus J \to I + J = R$ has kernel $I \cap J = IJ$, giving a short exact sequence $0 \to IJ \to I \oplus J \to R \to 0$ that splits because R is free. Iterating gives (3); (2) follows by tracking the product class via a determinant. $\square$

Theorem 16.3.33 (Thm. 22: structure of f.g. modules over a Dedekind domain)**.** *Let M be a finitely generated module over the Dedekind domain R, of rank n, with torsion submodule $\mathrm{Tor}(M)$. Then*

$$M \;\cong\; R^{n-1} \oplus I \;\oplus\; \mathrm{Tor}(M) \quad (\textit{when } n = 0 \textit{ the free-and-Steinitz part is absent and } M \cong \mathrm{Tor}(M)),$$

for some nonzero ideal I, and

$$\mathrm{Tor}(M) \;\cong\; R/P_1^{e_1} \oplus \cdots \oplus R/P_s^{e_s}$$

for prime powers $P_i^{e_i}$. The prime powers $P_i^{e_i}$ are unique (the elementary divisors*), and I is unique up to its class $[I] \in \mathrm{Cl}(R)$ (the* Steinitz class*).*

Idea. A finitely generated torsion-free M embeds in $M \otimes_R K \cong K^n$; projecting to a last coordinate gives $0 \to \ker \to M \to I_1 \to 0$ with I_1 a nonzero ideal, which splits because I_1 is projective (Theorem 15(4)). Induction yields $M \cong I_1 \oplus \cdots \oplus I_n$, and Prop. 21(3) collapses this to $R^{n-1} \oplus (I_1 \cdots I_n)$. For general M the sequence $0 \to \mathrm{Tor}(M) \to M \to M/\mathrm{Tor}(M) \to 0$ splits (the quotient is torsion-free, hence projective). The torsion part is handled prime by prime: $\mathrm{Tor}(M) \cong \bigoplus N/P_i^{e_i}N$, and each piece, being a module over the DVR R_{P_i}, decomposes by the PID structure theorem. □

Corollary 16.3.34 (Cor. 23: projective = torsion-free)**.** *A finitely generated module over a Dedekind domain is projective iff it is torsion-free. Moreover the class number is* 1 *iff every finitely generated projective R-module is free.*

Worked Example 16.3.35 (A PID that is not a field is a Dedekind domain of class number 1)**.** Show Theorem 22 reduces to the PID structure theorem when $\mathrm{Cl}(R) = 1$.

Recognition. If $h_R = 1$ every ideal I is principal, hence $I \cong R$ as a module, so the Steinitz class drops out.

Solution. When $\mathrm{Cl}(R) = 1$, $[I] = [R]$ forces $I \cong R$, so $R^{n-1} \oplus I \cong R^n$ and $M \cong R^n \oplus \bigoplus R/P_i^{e_i}$ – the elementary-divisor form of the PID theorem. Sanity check: for $R = \mathbb{Z}$, $P_i = (p_i)$, this is $M \cong \mathbb{Z}^n \oplus \bigoplus \mathbb{Z}/p_i^{e_i}\mathbb{Z}$, the classification of finitely generated abelian groups.

Worked Example 16.3.36 (A rank-one nonfree projective module)**.** Exhibit a finitely generated projective module over $\mathbb{Z}[\sqrt{-5}]$ that is not free.

Recognition. By Cor. 23, projective = torsion-free; a non-principal ideal is torsion-free (projective) but not $\cong R$ (not free) when its class is nontrivial.

Solution. Take $M = \mathfrak{p}_2 = (2, 1+\sqrt{-5})$. As a fractional ideal it is invertible, hence projective; it has rank 1. It is *not* free: free of rank 1 would mean $\mathfrak{p}_2 \cong R$, i.e. $\mathfrak{p}_2$ principal, which it is not. Sanity check: $[\mathfrak{p}_2] \neq 1$ in $\mathrm{Cl}(\mathbb{Z}[\sqrt{-5}]) \cong \mathbb{Z}/2\mathbb{Z}$, so by the last clause of Cor. 23 not every projective is free, consistent with $h = 2 \neq 1$.

Worked Example 16.3.37 (Steinitz class detects a non-split direct sum)**.** Decide whether $\mathfrak{p}_2 \oplus \mathfrak{p}_2 \cong R \oplus R$ over $R = \mathbb{Z}[\sqrt{-5}]$.

Recognition. Use Prop. 21(2)/(3): $\mathfrak{p}_2 \oplus \mathfrak{p}_2 \cong R \oplus \mathfrak{p}_2^2$, and $\mathfrak{p}_2^2 = (2)$ is principal.

Solution. $\mathfrak{p}_2 \oplus \mathfrak{p}_2 \cong R \oplus (\mathfrak{p}_2 \cdot \mathfrak{p}_2) = R \oplus \mathfrak{p}_2^2 = R \oplus (2) \cong R \oplus R$, since $(2) \cong R$ as a module. So yes, $\mathfrak{p}_2 \oplus \mathfrak{p}_2 \cong R^2$. Sanity check: the Steinitz class is $[\mathfrak{p}_2^2] = [\mathfrak{p}_2]^2 = 1$ in $\mathbb{Z}/2\mathbb{Z}$, so the rank-2 projective is free even though each summand $\mathfrak{p}_2$ is not – the class group is where the obstruction lives, and it vanishes after squaring.

Worked Example 16.3.38 (Torsion module over a Dedekind domain)**.** Classify $M = R/\mathfrak{p}_2^3 \oplus R/\mathfrak{p}_3$ as in Theorem 22 over $R = \mathbb{Z}[\sqrt{-5}]$.

Recognition. This is already in elementary-divisor form: the prime powers are $\mathfrak{p}_2^3$ and $\mathfrak{p}_3^1$, the module is pure torsion (rank 0).

Solution. The rank is 0, so there is no free or Steinitz part; $\mathrm{Tor}(M) = M$ with elementary divisors $\mathfrak{p}_2^3$ and $\mathfrak{p}_3$. Sanity check: the two primes are distinct, so by CRT (Prop. 18) the summands are coprime and combine into the cyclic module $M \cong R/\mathfrak{p}_2^3\mathfrak{p}_3$ (the invariant-factor form); the elementary divisors $\{\mathfrak{p}_2^3, \mathfrak{p}_3\}$ are the unique invariants.

Worked Example 16.3.39 (Quotient R/I is Artinian)**.** Show that for a nonzero ideal I of a Dedekind domain R, the ring R/I is Artinian.

Recognition. R is Noetherian of dimension 1; modding out a nonzero ideal kills the dimension, and Noetherian + dimension 0 = Artinian.

Solution. Write $I = \prod P_i^{e_i}$. By CRT $R/I \cong \prod R/P_i^{e_i}$, and each $R/P_i^{e_i} \cong R_{P_i}/P_i^{e_i}R_{P_i}$ is a quotient of a DVR by a power of its maximal ideal, hence a local Artinian ring (a finite-length module over itself). A finite product of Artinian rings is Artinian. Sanity check: R/I is Noetherian (quotient of Noetherian) with every prime maximal (dimension 0), and Noetherian + dimension 0 is exactly Artinian – the Akizuki–Hopkins criterion, tying back to Section 16.1.

Worked Example 16.3.40 (Localizing a Dedekind domain stays Dedekind)**.** If R is Dedekind and $S \subseteq R$ is multiplicatively closed with $0 \notin S$, show $S^{-1}R$ is Dedekind or a field.

Recognition. Localization preserves Noetherian, integral closure, and can only lower dimension; the primes of $S^{-1}R$ are those of R missing S.

Solution. $S^{-1}R$ is Noetherian (localization of Noetherian), integrally closed (integral closure commutes with localization), and a domain with fraction field K. Its nonzero primes correspond to nonzero primes of R disjoint from S, each still maximal; so $\dim S^{-1}R \leq 1$. If some nonzero prime survives, $S^{-1}R$ is Dedekind; if all nonzero primes meet S, then $S^{-1}R = K$, a field. Sanity check: taking $S = R \setminus P$ recovers the localization R_P, which is a DVR – a local Dedekind domain – exactly criterion (2) of Theorem 15. The induced map on ideals $I(R) \to I(S^{-1}R)$ is the surjection sending the killed primes to 1, so $\mathrm{Cl}(S^{-1}R)$ is a quotient of $\mathrm{Cl}(R)$.

Exercises (Dummit & Foote).

1. If R is an integral domain, show that every fractional ideal of R is invertible if and only if every integral ideal of R is invertible.

2. Suppose R is an integral domain with fraction field K and $A_1, A_2, \ldots, A_n$ are fractional ideals of R whose product is a nonzero principal fractional ideal: $A_1 A_2 \cdots A_n = Rx$ for some $0 \neq x \in K$. For each $i = 1, \ldots, n$ prove that A_i is an invertible fractional ideal with inverse $(x^{-1})A_1 \cdots A_{i-1} A_{i+1} \cdots A_n$.

3. Suppose R is an integral domain with fraction field K and P is a nonzero prime ideal in R. Show that the fractional ideals of R_P in K are the R_P-modules of the form AR_P where A is a fractional ideal of R.

4. Suppose R is an integral domain with fraction field K and A is a fractional ideal of R in K. Let $A' = \{x \in K \mid xA \subseteq R\}$ as in Proposition 9.

   (a) For any prime ideal P in R prove that the localization $(A')_P$ of A' at P is a fractional ideal of R_P in K.

   (b) If A is a finitely generated R-module, prove that $(A')_P = (A_P)'$ where $(A_P)'$ is the fractional R_P ideal $\{x \in K \mid xA_P \subseteq R_P\}$ corresponding to the localization A_P.

5. If Q_1 is a P_1-primary ideal and Q_2 is a P_2-primary ideal where P_1 and P_2 are comaximal ideals in a Noetherian ring R, prove that Q_1 and Q_2 are also comaximal. [Use Proposition 14 in Section 15.2.]

6. Suppose R is a Dedekind Domain with fraction field K.

   (a) Prove that every nonzero fractional ideal of R in K can be written uniquely as the product of distinct prime powers $P_1^{a_1} \cdots P_n^{a_n}$ where the a_i are nonzero integers, possibly negative.

   (b) If $0 \neq x \in K$, let $P^{v_P(x)}$ be the power of the prime P in the factorization of the principal ideal (x) as in (a) (where $v_P(x) = 0$ if P is not one of the primes occurring). Prove v_P is a valuation on K with valuation ring R_P, the localization of R at P.

7. Suppose R is a Noetherian integral domain that is not a field. Prove that R is a Dedekind Domain if and only if for every maximal ideal M of R there are no ideals I of R with $M^2 \subset I \subset M$. [Use Exercise 12 in Section 1 and Theorems 7 and 15.]

8. Suppose R is a Noetherian integral domain with Krull dimension 1. Prove that every nonzero ideal I in R can be written uniquely as a product of primary ideals whose radicals are all distinct. [Cf. the proof of Theorem 15. Use the uniqueness of the primary components belonging to the isolated primes in a minimal primary decomposition (Theorem 21 in Section 15.2).]

9. Suppose R is an integral domain. Prove that R_P is a D.V.R. for every nonzero prime ideal P if and only if R_M is a D.V.R. for every nonzero maximal ideal.

10. Suppose R is a Noetherian integral domain that is not a field. Prove that R is a Dedekind Domain if and only if nonzero primes M are maximal and every M-primary ideal is a power of M.

11. If I and J are nonzero ideals in the Dedekind Domain R show there exists an integral ideal I_1 in R that is relatively prime to both I and J such that $I_1 I$ is a principal ideal in R.

12. If I and J are nonzero fractional ideals for the Dedekind Domain R prove there are elements $\alpha, \beta \in K$ such that αI and βJ are nonzero integral ideals in R that are relatively prime.

13. Suppose I and J are nonzero ideals in the Dedekind Domain R. Prove that there is an ideal $I_1 \cong I$ that is relatively prime to J. [Use Corollary 19 to find an ideal I_2 with $I_2 I = (a)$ and $(I_2, J) = R$. If $I_2 = P_1^{e_1} \cdots P_n^{e_n}$, choose $b \in R$ with $b \in P_i^{e_i} - P_i^{e_i+1}$ and $b \equiv 1 \bmod P$ for every prime P dividing J. Show that $(b) = I_2 I_1$ for some ideal I_1 and consider $(a)I_1$ to prove that $I_1 \cong I$.]

14. Prove that every finitely generated torsion module over a Dedekind Domain R is isomorphic to a direct sum $R/I_1 \oplus R/I_2 \oplus \cdots \oplus R/I_n$ with unique nonzero ideals $I_1, \ldots, I_n$ of R satisfying $I_1 \subseteq I_2 \subseteq \cdots \subseteq I_n$ (called the invariant factors of M). [cf. Section 12.1.]

15. If P is a nonzero prime ideal in the Dedekind Domain R prove that R/P^n is not a projective R-module for any $n \geq 1$. [Consider the exact sequence $0 \to P^n/P^{n+1} \to R/P^{n+1} \to R/P^n \to 0$.] Conclude that if $M \neq 0$ is a finitely generated torsion R-module then M is not projective. [cf. Exercise 3, Section 10.5.]

16. Prove that the class number of the Dedekind Domain R is 1 if and only if every finitely generated projective R-module is free.

17. Suppose R is a Dedekind Domain.

    (a) Show that $I \sim J$ if and only if $I \cong J$ as R-modules defines an equivalence relation on the set of nonzero fractional ideals of R. Let $C(R)$ be the corresponding set of R-module isomorphism classes and let $[I] \in C(R)$ denote the equivalence class containing the fractional ideal I of R.

    (b) Show that the multiplication $[I][J] = [IJ]$ gives a well defined binary operation with respect to which $C(R)$ is an abelian group with identity $1 = [R]$.

    (c) Prove that the abelian group $C(R)$ in (b) is isomorphic to the class group of R.

18. If R is a Dedekind Domain and I is any nonzero ideal, prove that R/I contains only finitely many ideals. In particular, show that R/I is an Artinian ring.

19. Suppose I is a nonzero fractional ideal in the Dedekind Domain R. Explicitly exhibit I as a direct summand of a free R-module to show that I is projective. [Consider $I \oplus I^{-1}$ and use Proposition 21.]

20. Suppose I and J are two nonzero fractional ideals in the Dedekind Domain R and that $I^n = J^n$ for some $n \neq 0$. Prove that $I = J$.

21. Suppose K is an algebraic number field and O_K is the ring of integers in K. If P is a nonzero prime ideal in O_K prove that $P = (p, \pi)$ for some prime $p \in \mathbb{Z}$ and algebraic integer $\pi \in O_K$.

22. Suppose $K = \mathbb{Q}(\sqrt{D})$ is a quadratic extension of $\mathbb{Q}$ where D is a square free integer and O_K is the ring of integers in K.

    (a) Prove that $|O_K/(p)| = p^2$. [Observe that $O_K \cong \mathbb{Z}^2$ as an abelian group.]

    (b) Use Corollary 16 to show that there are 3 possibilities for the prime ideal factorization of (p) in O_K:

        (i) $(p) = P$ is a prime ideal with $|O_K/P| = p^2$,

        (ii) $(p) = P_1 P_2$ with distinct prime ideals P_1, P_2 and $|O_K/P_1| = |O_K/P_2| = p$,

        (iii) $(p) = P^2$ for some prime ideal P with $|O_K/P| = p$.

        (In cases (i), (ii), and (iii) the prime p is said to be inert, split, or ramified in O_K, respectively. The set of ramified primes is finite: the primes p dividing D if $D \equiv 1, 2 \bmod 4$; $p = 2$ and the primes p dividing D if $D \equiv 3 \bmod 4$. Cf. Exercise 31 in Section 15.5.)

    (c) Determine the prime ideal factorizations of the primes $p = 2, 3, 5, 7, 11$ in the ring of integers $O_K = \mathbb{Z}[\sqrt{-5}]$ of $K = \mathbb{Q}(\sqrt{-5})$.

23. Let O be the ring of integers in the algebraic closure $\overline{\mathbb{Q}}$ of $\mathbb{Q}$.

    (a) Show that the infinite sequence of ideals in O, $(2) \subseteq (\sqrt{2}) \subseteq (\sqrt[4]{2}) \subseteq (\sqrt[8]{2}) \subseteq \cdots$, is strictly increasing, and so O is not Noetherian.

(b) Show that O has Krull dimension 1. [Use Theorem 26 in Section 15.3.]

(c) Let K be a number field and let I be any ideal in O_K. Show that there is some finite extension L of K such that I becomes principal when extended to O_L, i.e., the ideal IO_L is principal (where L depends on I)—you may use the theorem that the class group of K is a finite group. [cf. Exercise 20.]

(d) Prove that O is a Bezout Domain (cf. Section 8.1).

24. Suppose F and K are algebraic number fields with $\mathbb{Q} \subseteq F \subseteq K$, with rings of integers O_F and O_K, respectively. Since $O_F \subseteq O_K$, the ring O_K is naturally a module over O_F.

(a) Prove O_K is a torsion free O_F-module of rank $n = [K : F]$. [Compute ranks over $\mathbb{Z}$.] If O_K is free over O_F then O_K is said to have a relative integral basis over O_F.

(b) Prove that if F has class number 1 then O_K has a relative integral basis over O_F. If $K = \mathbb{Q}(\sqrt{-5}, \sqrt{2})$ then the ring of integers O_K is given by $O_K = \mathbb{Z} + \mathbb{Z}\sqrt{-5} + \mathbb{Z}\sqrt{-10} + \mathbb{Z}\omega$ where $\omega = (\sqrt{-10} + \sqrt{2})/2$.

(c) If $F_1 = \mathbb{Q}(\sqrt{2})$ prove that O_K has a relative integral basis over O_{F_1} and find an explicit basis $\{\alpha, \beta\}$: $O_K = O_{F_1} \cdot \alpha + O_{F_1} \cdot \beta$.

(d) If $F_2 = \mathbb{Q}(\sqrt{-5})$, show that $P_3 = (3, 1 - \sqrt{-5}) = (3, 5 + \sqrt{-5})$ is a prime ideal of O_{F_2} that is not principal and that $O_K = O_{F_2} \cdot 1 + (1/3)P_3 \cdot \omega$. [Check that $\sqrt{-10} = (5 + \sqrt{-5})\omega/3$.] Conclude that the Steinitz class of O_K as a module over O_{F_2} is the nontrivial class of P_3 in the class group of O_{F_2} and so there is no relative integral basis of O_K over O_{F_2}.

(e) Determine whether O_K has a relative integral basis over the ring of integers of the remaining quadratic subfield $F_3 = \mathbb{Q}(\sqrt{-10})$ of K.

25. Suppose C is a nonsingular irreducible affine curve over an algebraically closed field k. Prove that the coordinate ring $k[C]$ is a Dedekind Domain.

Exercises (Atiyah & Macdonald).

1. Let A be a Dedekind domain, S a multiplicatively closed subset of A. Show that $S^{-1}A$ is either a Dedekind domain or the field of fractions of A.

   Suppose that $S \neq A - \{0\}$, and let H, H' be the ideal class groups of A and $S^{-1}A$ respectively. Show that extension of ideals induces a surjective homomorphism $H \to H'$.

2. Let A be a Dedekind domain. If $f = a_0 + a_1 x + \cdots + a_n x^n$ is a polynomial with coefficients in A, the *content* of f is the ideal $c(f) = (a_0, a_1, \ldots, a_n)$ in A. Prove *Gauss's lemma* that $c(fg) = c(f)c(g)$. [Localize at a maximal ideal.]

3. A valuation ring (other than a field) is Noetherian if and only if it is a discrete valuation ring.

4. Let A be a local domain which is not a field and in which the maximal ideal $\mathfrak{m}$ is principal and $\bigcap_{n=1}^{\infty} \mathfrak{m}^n = 0$. Prove that A is a discrete valuation ring.

5. Let M be a finitely-generated module over a Dedekind domain. Prove that M is flat $\Leftrightarrow$ M is torsion-free. [Use Chapter 3, Exercise 13 and Chapter 7, Exercise 16.]

6. Let M be a finitely-generated torsion module ($T(M) = M$) over a Dedekind domain A. Prove that M is uniquely representable as a finite direct sum of modules $A/\mathfrak{p}_i^{n_i}$, where $\mathfrak{p}_i$ are non-zero prime ideals of A. [For each $\mathfrak{p} \neq 0$, $M_{\mathfrak{p}}$ is a torsion $A_{\mathfrak{p}}$-module; use the structure theorem for modules over a principal ideal domain.]

7. Let A be a Dedekind domain and $\mathfrak{a} \neq 0$ an ideal in A. Show that every ideal in $A/\mathfrak{a}$ is principal.

   Deduce that every ideal in A can be generated by at most 2 elements.

8. Let $\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{c}$ be three ideals in a Dedekind domain. Prove that

$$\mathfrak{a} \cap (\mathfrak{b} + \mathfrak{c}) = (\mathfrak{a} \cap \mathfrak{b}) + (\mathfrak{a} \cap \mathfrak{c})$$

$$\mathfrak{a} + (\mathfrak{b} \cap \mathfrak{c}) = (\mathfrak{a} + \mathfrak{b}) \cap (\mathfrak{a} + \mathfrak{c}).$$

   [Localize.]

9. (Chinese Remainder Theorem). Let $\mathfrak{a}_1, \dots, \mathfrak{a}_n$ be ideals and let $x_1, \dots, x_n$ be elements in a Dedekind domain A. Then the system of congruences $x \equiv x_i \pmod{\mathfrak{a}_i}$ $(1 \le i \le n)$ has a solution x in $A \Leftrightarrow x_i \equiv x_j \pmod{\mathfrak{a}_i + \mathfrak{a}_j}$ whenever $i \neq j$.

   [This is equivalent to saying that the sequence of A-modules

$$A \xrightarrow{\phi} \bigoplus_{i=1}^{n} A/\mathfrak{a}_i \xrightarrow{\psi} \bigoplus_{i<j} A/(\mathfrak{a}_i + \mathfrak{a}_j)$$

   is exact, where ϕ and ψ are defined as follows: $\phi(x) = (x + \mathfrak{a}_1, \dots, x + \mathfrak{a}_n)$; $\psi(x_1 + \mathfrak{a}_1, \dots, x_n + \mathfrak{a}_n)$ has (i,j)-component $x_i - x_j + \mathfrak{a}_i + \mathfrak{a}_j$. To show that this sequence is exact it is enough to show that it becomes exact when localized at any $\mathfrak{p} \neq 0$; in other words we may assume that A is a discrete valuation ring, and then it is easy.]

Throughout these problems R denotes an integral domain with fraction field $K \neq R$, and "Dedekind domain" has its usual meaning (Noetherian, integrally closed, of Krull dimension 1). For ideal-class computations in $\mathbb{Z}[\sqrt{-5}]$ you may use $\mathrm{Cl}(\mathbb{Z}[\sqrt{-5}]) \cong \mathbb{Z}/2\mathbb{Z}$ and the factorizations $(2) = \mathfrak{p}_2^2$, $(3) = \mathfrak{p}_3\mathfrak{p}_3'$ with $\mathfrak{p}_2 = (2, 1+\sqrt{-5})$, $\mathfrak{p}_3 = (3, 1+\sqrt{-5})$, $\mathfrak{p}_3' = (3, 1-\sqrt{-5})$.

Practice problems.

1. In $R = \mathbb{Z}$ with $K = \mathbb{Q}$, write the fractional ideal $A = \frac{3}{10}\mathbb{Z}$ as $d^{-1}\mathfrak{a}$ for an integer d and an integral ideal $\mathfrak{a}$, then compute $A' = (R : A)$ and verify $AA' = R$ directly.

2. Let $R = \mathbb{Z}[\sqrt{-5}]$ and $\mathfrak{p}_3 = (3, 1+\sqrt{-5})$. Verify that $\mathfrak{p}_3' = (3, 1-\sqrt{-5})$ satisfies $\mathfrak{p}_3\mathfrak{p}_3' = (3)$, and use this to write $\mathfrak{p}_3^{-1}$ as a principal multiple of $\mathfrak{p}_3'$ in $K = \mathbb{Q}(\sqrt{-5})$.

3. Factor the ideal (15) in $\mathcal{O}_K = \mathbb{Z}[\sqrt{-5}]$ into a product of prime powers, and from your factorization read off the exponents $v_{\mathfrak{p}}(15)$ for each prime $\mathfrak{p}$ appearing.

4. In $R = \mathbb{Z}[\sqrt{-5}]$ compute $\mathfrak{a} + \mathfrak{b}$ (the gcd) and $\mathfrak{a} \cap \mathfrak{b}$ (the lcm) for $\mathfrak{a} = \mathfrak{p}_2^2\mathfrak{p}_3$ and $\mathfrak{b} = \mathfrak{p}_2\mathfrak{p}_3^2$, expressing each as a product of prime powers, and decide whether $\mathfrak{a}$ and $\mathfrak{b}$ are comaximal.

5. Let R be the localization $\mathbb{Z}_{(5)}$ of $\mathbb{Z}$ at the prime (5). Show R is a DVR, name a uniformizer t, and write every nonzero fractional ideal of R in the form $t^N R$; then give $v_5(\frac{50}{3})$.

6. Over $R = \mathbb{Z}[\sqrt{-5}]$ classify the torsion module $M = R/\mathfrak{p}_2^2 \oplus R/\mathfrak{p}_2 \oplus R/\mathfrak{p}_3$ by listing its elementary divisors, and state its rank.

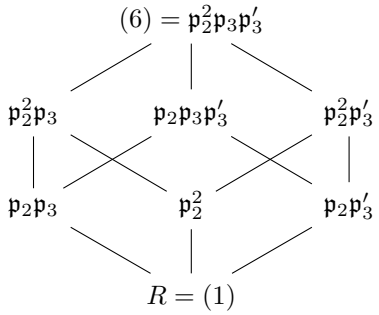
7. Decide whether the rank-2 projective module $\mathfrak{p}_3 \oplus \mathfrak{p}_3$ over $\mathbb{Z}[\sqrt{-5}]$ is free, justifying your answer through the Steinitz class $[\mathfrak{p}_3\mathfrak{p}_3] \in \mathrm{Cl}(\mathbb{Z}[\sqrt{-5}])$.

8. In $\mathbb{Z}[i]$ compute $(7+i)+(3-i)$ and $(7+i)\cap(3-i)$ as principal ideals by factoring each into Gaussian primes (use the norms $N(7+i) = 50$, $N(3-i) = 10$), and check the identity $N(\mathrm{gcd})\,N(\mathrm{lcm}) = N(7+i)\,N(3-i)$.

Additional exercises.

1. Let R be a Dedekind domain and $\mathfrak{a}, \mathfrak{b}$ nonzero integral ideals. Prove that $\mathfrak{a} \subseteq \mathfrak{b}$ if and only if $\mathfrak{b} \mid \mathfrak{a}$ (there is an integral ideal $\mathfrak{c}$ with $\mathfrak{a} = \mathfrak{b}\mathfrak{c}$), and deduce that $\mathfrak{a}$ is maximal among proper ideals if and only if $\mathfrak{a}$ is a nonzero prime.

2. Let R be a Dedekind domain and let $v_{\mathfrak{p}} \colon K^\times \to \mathbb{Z}$ be the exponent of $\mathfrak{p}$ in the factorization of (x). Prove that for all $x, y \in K^\times$ one has $v_{\mathfrak{p}}(xy) = v_{\mathfrak{p}}(x) + v_{\mathfrak{p}}(y)$ and $v_{\mathfrak{p}}(x+y) \ge \min\{\, v_{\mathfrak{p}}(x), v_{\mathfrak{p}}(y) \,\}$ whenever $x + y \neq 0$, and conclude that $\{\, x \in K^\times : v_{\mathfrak{p}}(x) \ge 0 \,\} \cup \{\, 0 \,\}$ is the valuation ring $R_{\mathfrak{p}}$.



3. Let R be a Dedekind domain with only finitely many nonzero prime ideals. Prove that R is a PID. [Use that for each prime $\mathfrak{p}$ one can find x with $v_{\mathfrak{p}}(x) = 1$ and $v_{\mathfrak{q}}(x) = 0$ for the other primes $\mathfrak{q}$, via the Chinese Remainder Theorem.]

4. Let R be a Dedekind domain and $\mathfrak{p}$ a nonzero prime. Prove that the $R_{\mathfrak{p}}$-module $\mathfrak{p}^n R_{\mathfrak{p}}/\mathfrak{p}^{n+1}R_{\mathfrak{p}}$ is one-dimensional over the residue field $R/\mathfrak{p}$ for every $n \ge 0$, and use this to compute $\mathrm{length}(R/\mathfrak{p}^m)$ as a module over R.

5. Let R be a Dedekind domain and I, J nonzero fractional ideals with $[I] = [J]$ in $\mathrm{Cl}(R)$. Prove $I \cong J$ as R-modules, and conversely that an R-module isomorphism $I \to J$ is multiplication by a fixed element of $K^\times$. Deduce that the assignment $[I] \mapsto$ (isomorphism class of I) is injective on $\mathrm{Cl}(R)$.

Commutative-diagram exercises.

1. Let $R = \mathbb{Z}[\sqrt{-5}]$. Complete the divisibility (factorization) lattice below for the ideal $(6) = \mathfrak{p}_2^2\mathfrak{p}_3\mathfrak{p}_3'$, where an edge $\mathfrak{a}$ — $\mathfrak{b}$ drawn upward means $\mathfrak{a} \mid \mathfrak{b}$ (equivalently $\mathfrak{b} \subseteq \mathfrak{a}$). Label each upward edge with the prime being adjoined and verify that "to contain is to divide" makes the diagram a sublattice of the divisor lattice:

   State which of the listed ideals is principal and identify $\gcd(\mathfrak{p}_2^2\mathfrak{p}_3, \mathfrak{p}_2\mathfrak{p}_3\mathfrak{p}_3')$ and $\mathrm{lcm}(\mathfrak{p}_2^2\mathfrak{p}_3, \mathfrak{p}_2\mathfrak{p}_3\mathfrak{p}_3')$ from the lattice.

2. Let R be a Dedekind domain and $\mathfrak{p}$ a nonzero prime. The square below has horizontal maps the localization $R \to R_\mathfrak{p}$ (and its restriction to $\mathfrak{p}$) and vertical maps the inclusions. Prove the square commutes and that the induced map on quotients is an isomorphism $R/\mathfrak{p} \xrightarrow{\sim} R_\mathfrak{p}/\mathfrak{p}R_\mathfrak{p}$, exhibiting $R_\mathfrak{p}$ as a DVR with maximal ideal $\mathfrak{p}R_\mathfrak{p}$:

$$\begin{array}{ccc} \mathfrak{p} & \longrightarrow & \mathfrak{p}R_\mathfrak{p} \\ \downarrow & & \downarrow \\ R & \xrightarrow[\ell]{} & R_\mathfrak{p} \end{array}$$

   Identify a uniformizer of $R_\mathfrak{p}$ as the image of any $t \in \mathfrak{p} \setminus \mathfrak{p}^2$, and explain why the localization map sends the prime power $\mathfrak{p}^n$ to $(\ell(t))^n R_\mathfrak{p}$.

3. Let R be a Dedekind domain. The diagram below is the defining exact sequence of the class group, with $\mathrm{div}\colon x \mapsto (x)$ and π the quotient onto $\mathrm{Cl}(R) = I(R)/P(R)$. Prove exactness at every term and identify $\ker(\mathrm{div})$ and $\mathrm{coker}(\mathrm{div})$:

$$1 \longrightarrow R^\times \hookrightarrow K^\times \xrightarrow{\mathrm{div}} I(R) \xrightarrow{\pi} \mathrm{Cl}(R) \longrightarrow 1$$

   Then, taking $R = \mathbb{Z}[\sqrt{-5}]$, label $I(R)$ as the free abelian group on the nonzero primes and locate the class $[\mathfrak{p}_2]$ of order 2 as the image of π on $\mathfrak{p}_2$.

4. Let R be a Dedekind domain and $S \subseteq R$ multiplicatively closed with $0 \notin S$. Extension of ideals $\mathfrak{a} \mapsto \mathfrak{a}S^{-1}R$ induces the homomorphisms in the square below, where the rows pass to class groups. Prove the square commutes and that the right-hand map $\mathrm{Cl}(R) \to \mathrm{Cl}(S^{-1}R)$ is surjective, with kernel generated by the classes of the primes $\mathfrak{p}$ meeting S:

$$\begin{array}{ccc} I(R) & \xrightarrow{\pi} & \mathrm{Cl}(R) \\ {\scriptstyle \cdot S^{-1}R}\downarrow & & \downarrow{\scriptstyle \overline{\cdot S^{-1}R}} \\ I(S^{-1}R) & \xrightarrow[\pi']{} & \mathrm{Cl}(S^{-1}R) \end{array}$$

   Explain why a prime $\mathfrak{p}$ with $\mathfrak{p} \cap S \neq \varnothing$ maps to the unit ideal of $S^{-1}R$, and conclude that $\mathrm{Cl}(S^{-1}R)$ is a quotient of $\mathrm{Cl}(R)$.

16.4 Algebraic Integers in Quadratic Fields

Algebraic integers in a quadratic field

A complex number α is an *algebraic number* if it is a root of some nonzero polynomial in $\mathbb{Q}[x]$; the monic generator of the kernel of the substitution map $\mathbb{Q}[x] \to \mathbb{C}$, $x \mapsto \alpha$, is its *irreducible polynomial* over $\mathbb{Q}$. We call α an *algebraic integer* when that irreducible polynomial has *integer* coefficients. This is the number-theoretic shadow of the ring theory in this chapter: just as $\mathbb{Z}$ sits inside $\mathbb{Q}$, a distinguished subring of algebraic integers sits inside every number field, and for the quadratic fields it can be written down explicitly. The first surprise is that the answer depends on a congruence mod 4.

Definition 16.4.1 (quadratic field)**.** For a square-free integer $d \neq 1$ (positive or negative, not a square in $\mathbb{Q}$), the *quadratic number field* is

$$\mathbb{Q}[\sqrt{d}] \;=\; \{\, a + b\sqrt{d} \mid a, b \in \mathbb{Q} \,\},$$

real if $d > 0$ and imaginary if $d < 0$. Here $\sqrt{d}$ is the positive real root when $d > 0$ and the positive imaginary root when $d < 0$. Pulling square factors out of the radical lets us always take d square-free, so $d \equiv 1, 2,$ or $3 \pmod 4$ (never 0, since d is square-free).

Write $\delta = \sqrt{d}$, so $\delta^2 = d$. For $\alpha = a + b\delta$ with $b \neq 0$, the *conjugate* is $\overline{\alpha} = a - b\delta$, and $\alpha, \overline{\alpha}$ are the two roots of

$$(x - \alpha)(x - \overline{\alpha}) \;=\; x^2 - 2a\,x + (a^2 - b^2 d),$$

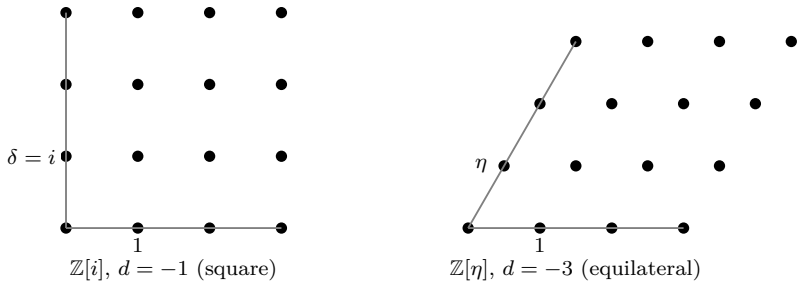
a quadratic with rational coefficients. Since $\alpha \notin \mathbb{Q}$ it is not a root of any linear polynomial, so this quadratic is irreducible: it is *the* irreducible polynomial of α over $\mathbb{Q}$. Reading off when its coefficients are integers gives the next two facts.

Lemma 16.4.2 (rational integers; integrality criterion)**.** *A rational number is an algebraic integer if and only if it is an ordinary integer. Consequently $\alpha = a + b\sqrt{d}$ (with $a, b \in \mathbb{Q}$) is an algebraic integer if and only if $2a \in \mathbb{Z}$ and $a^2 - b^2 d \in \mathbb{Z}$.*

Proof. A rational a has irreducible polynomial $x - a$, which has integer coefficients exactly when $a \in \mathbb{Z}$. For the second statement, when $b \neq 0$ the irreducible polynomial is $x^2 - 2a\,x + (a^2 - b^2 d)$, integral precisely when $2a$ and $a^2 - b^2 d$ lie in $\mathbb{Z}$; the case $b = 0$ is the first statement. □

Theorem 16.4.3 (ring of integers of $\mathbb{Q}[\sqrt{d}]$; Artin 13.1.6)**.** *Let d be square-free and $\delta = \sqrt{d}$. The algebraic integers in $\mathbb{Q}[\sqrt{d}]$ form a ring R, the* ring of integers*, described by:*

$$R = \begin{cases} \mathbb{Z}[\sqrt{d}] = \{\, a + b\sqrt{d} \mid a, b \in \mathbb{Z} \,\}, & d \equiv 2, 3 \pmod 4, \\ \mathbb{Z}[\eta] = \{\, a + b\eta \mid a, b \in \mathbb{Z} \,\}, \quad \eta = \tfrac{1}{2}(1 + \sqrt{d}), & d \equiv 1 \pmod 4. \end{cases}$$



When $d \equiv 1 \pmod 4$ the generator $\eta = \frac{1}{2}(1 + \sqrt{d})$ is a root of the monic integer polynomial $x^2 - x + h$ with $h = (1 - d)/4$.

Proof. Write $\alpha = a + b\delta$ and use the criterion: $2a \in \mathbb{Z}$ and $a^2 - b^2 d \in \mathbb{Z}$. There are two cases for a.

If $a \in \mathbb{Z}$, then $a^2 \in \mathbb{Z}$ forces $b^2 d \in \mathbb{Z}$; since d is square-free it cannot cancel a square in the denominator of b^2, so $b^2 \in \mathbb{Z}$ and hence $b \in \mathbb{Z}$. (This square-free cancellation is the lemma "$r^2 d \in \mathbb{Z} \Rightarrow r \in \mathbb{Z}$".)

If $a = m + \frac{1}{2}$ is a half-integer ($m \in \mathbb{Z}$), then $a^2 = m^2 + m + \frac{1}{4} \in \mathbb{Z} + \frac{1}{4}$, so integrality of $a^2 - b^2 d$ puts $b^2 d \in \mathbb{Z} + \frac{1}{4}$. Then $4b^2 d \in \mathbb{Z}$, so $2b \in \mathbb{Z}$ by the same square-free argument, i.e. b is a half-integer. Writing $b = n + \frac{1}{2}$, one checks $b^2 d \in \mathbb{Z} + \frac{1}{4}$ holds if and only if $d \equiv 1 \pmod 4$. Thus half-integer coordinates occur exactly when $d \equiv 1 \pmod 4$, and then a, b are *both* half-integers; these are precisely the elements $a' + b'\eta$ with $a', b' \in \mathbb{Z}$. That R is closed under multiplication (hence a ring) is the direct computation $\eta^2 = \eta - h$, or $\delta^2 = d$. □

Remark 16.4.1. For $d < 0$ the ring R is a *lattice* in $\mathbb{C}$: rectangular when $d \equiv 2, 3 \pmod 4$ (basis $1, \delta$ with δ purely imaginary) and "isosceles-triangular" when $d \equiv 1 \pmod 4$ (basis $1, \eta$). Two famous cases: $d = -1$ gives the Gauss integers $\mathbb{Z}[i]$ on a *square* lattice, and $d = -3$ gives $\mathbb{Z}[\eta]$ on an *equilateral* triangular lattice. The geometry of R as a lattice is what makes the imaginary case tractable, and it drives the unit count below.

$\mathbb{Z}[i]$, $d = -1$ (square) $\mathbb{Z}[\eta]$, $d = -3$ (equilateral)

The norm and the units

From here we focus on the imaginary case $d < 0$, where R is a lattice; let R denote the ring of integers in $\mathbb{Q}[\delta]$. The single tool that organizes factorization is the norm, a multiplicative map to $\mathbb{Z}^+$ that turns questions about R into questions about ordinary integers.

Definition 16.4.4 (norm)**.** The *norm* of $\alpha = a + b\delta \in R$ is

$$\mathrm{N}(\alpha) \;=\; \alpha\,\overline{\alpha} \;=\; a^2 - b^2 d \;=\; |\alpha|^2.$$

For $d < 0$ this is a non-negative integer, and $\mathrm{N}(\alpha) = 0$ only when $\alpha = 0$; so $\mathrm{N}(\alpha)$ is a positive integer for every $\alpha \neq 0$.

Proposition 16.4.5 (multiplicativity)**.** *The norm is multiplicative:* $\mathrm{N}(\beta\gamma) = \mathrm{N}(\beta)\,\mathrm{N}(\gamma)$ *for all* $\beta, \gamma \in R$.

Proof. Conjugation $\alpha \mapsto \overline{\alpha}$ is a ring homomorphism of R (it is the restriction of complex conjugation, and $\overline{\sqrt{d}} = -\sqrt{d}$ for $d < 0$). Hence $\mathrm{N}(\beta\gamma) = \beta\gamma\,\overline{\beta\gamma} = \beta\gamma\,\overline{\beta}\,\overline{\gamma} = (\beta\overline{\beta})(\gamma\overline{\gamma}) = \mathrm{N}(\beta)\,\mathrm{N}(\gamma)$. □

Multiplicativity is the lever: if $\alpha = \beta\gamma$ then $\mathrm{N}(\alpha) = \mathrm{N}(\beta)\,\mathrm{N}(\gamma)$ is a factorization in $\mathbb{Z}$, so the only possible factors β of α are those whose norm divides $\mathrm{N}(\alpha)$. When $\mathrm{N}(\alpha)$ is small this is a finite, hand-checkable list. The first dividend is a complete description of the units.

Theorem 16.4.6 (units; Artin 13.2.2)**.** *Let R be the ring of integers in an imaginary quadratic field $\mathbb{Q}[\sqrt{d}]$, $d < 0$.*

(1) *$\alpha \in R$ is a unit if and only if $\mathrm{N}(\alpha) = 1$, and then $\alpha^{-1} = \overline{\alpha}$.*

(2) *The units are exactly $\{\pm 1\}$,* unless *$d = -1$ or $d = -3$.*

(3) *If $d = -1$ (the Gauss integers $\mathbb{Z}[i]$), the units are the four powers of i: $\{\pm 1, \pm i\}$.*

(4) *If $d = -3$, the units are the six powers of $\zeta_6 = e^{2\pi i/6} = \frac{1}{2}(1 + \sqrt{-3})$, namely the sixth roots of unity.*

In every case the units of an imaginary quadratic field are exactly the roots of unity it contains.

Proof. (1) If α is a unit with inverse $\alpha^{-1} \in R$, then $\mathrm{N}(\alpha)\,\mathrm{N}(\alpha^{-1}) = \mathrm{N}(1) = 1$ with both factors positive integers, forcing $\mathrm{N}(\alpha) = 1$. Conversely $\mathrm{N}(\alpha) = \alpha\overline{\alpha} = 1$ exhibits $\overline{\alpha} \in R$ as a two-sided inverse, so α is a unit and $\alpha^{-1} = \overline{\alpha}$.

(2)–(4) We solve $\mathrm{N}(\alpha) = 1$ on the lattice. For $d \equiv 2, 3 \pmod 4$ with $\alpha = a + b\delta$ $(a, b \in \mathbb{Z})$, $\mathrm{N}(\alpha) = a^2 - b^2 d = a^2 + b^2|d| = 1$. If $|d| \geq 2$ this forces $b = 0, a = \pm 1$, giving $\{\pm 1\}$; the only escape is $d = -1$, where $a^2 + b^2 = 1$ has the four solutions $\pm 1, \pm i$. For $d \equiv 1 \pmod 4$ with $\alpha = a + b\eta$, the norm is the positive-definite form $\mathrm{N}(a + b\eta) = a^2 + ab + \frac{1-d}{4}\,b^2$; for $|d| \geq 7$ the b^2-coefficient is ≥ 2 and again only $b = 0, a = \pm 1$ solve $= 1$, while $d = -3$ gives $a^2 + ab + b^2 = 1$ with the six solutions that are the powers of ζ_6. Geometrically, the unit circle $|\alpha| = 1$ meets the lattice in just $\{\pm 1\}$ except for the square lattice ($d = -1$, 4 points) and the equilateral lattice ($d = -3$, 6 points). □

Remark 16.4.2. The exceptional unit groups are exactly the lattice symmetries: $\mathbb{Z}[i]$ on the square lattice has the 4 rotational symmetries $\{\pm 1, \pm i\}$, and $\mathbb{Z}[\eta]$ on the equilateral lattice has the 6 symmetries given by the powers of ζ_6. Every other imaginary quadratic ring has only $\{\pm 1\}$.

Theorem 16.4.7 (factorization terminates; Artin 13.2.3)**.** *In the ring of integers R of an imaginary quadratic field, every nonzero non-unit is a product of finitely many irreducibles; factoring cannot continue forever.*

Proof. If $\alpha = \beta\gamma$ is a *proper* factorization (neither factor a unit), then by part (1) of the units theorem $\mathrm{N}(\beta), \mathrm{N}(\gamma) > 1$, so $\mathrm{N}(\alpha) = \mathrm{N}(\beta)\,\mathrm{N}(\gamma)$ is a proper factorization of the positive integer $\mathrm{N}(\alpha)$, and both factors are strictly smaller. Thus each proper factorization *strictly decreases* the norm. A strictly decreasing sequence of positive integers terminates, so after finitely many steps every factor is irreducible. (This is the integrality of the norm doing the work of a well-ordering.) □

Method (Factoring by norm bookkeeping)**.** To factor $\alpha \in R$ or test irreducibility: (i) compute $N = \mathrm{N}(\alpha) = a^2 - b^2 d$; (ii) list the divisors $m \mid N$ with $1 < m < N$ – a proper factor β must have $\mathrm{N}(\beta) = m$; (iii) for each such m, solve $\mathrm{N}(a' + b'\delta) = m$ (a finite search on the lattice); (iv) if no m is hit, α is irreducible; otherwise $\beta = a' + b'\delta$ is a candidate and $\gamma = \alpha/\beta$ completes the split. Norms multiply, so a clash $\mathrm{N}(\beta) \nmid N$ rules β out instantly.

Worked Example 16.4.8 (Units of the Gauss integers)**.** Find all units of $R = \mathbb{Z}[i]$ ($d = -1$) and confirm the count from the lattice.

Recognition. A unit is exactly an element of norm 1; here $\mathrm{N}(a + bi) = a^2 + b^2$, so we solve $a^2 + b^2 = 1$ over $\mathbb{Z}$.

Solution. The integer solutions of $a^2 + b^2 = 1$ are $(\pm 1, 0)$ and $(0, \pm 1)$, i.e. $\{\, 1, -1, i, -i \,\}$. These are the four powers of i: $i^0 = 1$, $i^1 = i$, $i^2 = -1$, $i^3 = -i$, so $\mathbb{Z}[i]^\times = \langle i \rangle$ is cyclic of order 4. *Check.* The four points lie on the unit circle at the 4 lattice points nearest the origin – the rotational symmetries of the square lattice – matching $|R^\times| = 4$ for $d = -1$.

Worked Example 16.4.9 (Units when $d = -3$)**.** Show $R^\times$ has order 6 for $R = \mathbb{Z}[\eta]$, $\eta = \frac{1}{2}(1 + \sqrt{-3})$.

Recognition. Norm 1 on the equilateral lattice; here $\mathrm{N}(a + b\eta) = a^2 + ab + b^2$ (since $h = (1 - d)/4 = 1$), a positive-definite form.

Solution. Solve $a^2 + ab + b^2 = 1$ over $\mathbb{Z}$. Treating it as $a^2 + ab + (b^2 - 1) = 0$, the discriminant in a is $4 - 3b^2 \geq 0$ forces $b \in \{\, -1, 0, 1 \,\}$; checking each gives the six solutions

$$(a, b) \in \{\, (1,0), (-1,0), (0,1), (0,-1), (1,-1), (-1,1) \,\}.$$

As elements these are $\pm 1, \pm\eta, \pm(\eta - 1)$, the six powers of $\zeta_6 = \frac{1}{2}(1 + \sqrt{-3})$. *Check.* ζ_6 is a primitive 6th root of unity, so $R^\times = \langle \zeta_6 \rangle \cong \mathbb{Z}/6\mathbb{Z}$, the 6 rotational symmetries of the equilateral lattice.

Worked Example 16.4.10 (2 is irreducible in $\mathbb{Z}[\sqrt{-5}]$)**.** Let $R = \mathbb{Z}[\sqrt{-5}]$ ($d = -5 \equiv 3 \bmod 4$, units $\{\, \pm 1 \,\}$). Show 2 is irreducible.

Recognition. $\mathrm{N}(2) = 4$; a proper factor would need norm 2 (the only proper divisor of 4 that is > 1 and < 4), so check whether norm 2 is attainable.

Solution. Here $\mathrm{N}(a + b\sqrt{-5}) = a^2 + 5b^2$. Setting $a^2 + 5b^2 = 2$ has no integer solution: $b = 0$ gives $a^2 = 2$ (impossible) and $|b| \geq 1$ gives ≥ 5. So no element has norm 2. If $2 = \beta\gamma$ properly, then $4 = \mathrm{N}(\beta)\,\mathrm{N}(\gamma)$ with both factors > 1, forcing $\mathrm{N}(\beta) = \mathrm{N}(\gamma) = 2$ – impossible. Hence 2 is irreducible. *Check.* The same computation shows 3 is irreducible ($a^2 + 5b^2 = 3$ is unsolvable), and $1 \pm \sqrt{-5}$ each have norm $1 + 5 = 6$; these norms are exactly what powers the non-unique factorization next.

Worked Example 16.4.11 ($6 = 2 \cdot 3 = (1 + \sqrt{-5})(1 - \sqrt{-5})$: two factorizations)**.** Exhibit 6 as a product of irreducibles in $R = \mathbb{Z}[\sqrt{-5}]$ in two genuinely different ways, and explain why R is not a UFD.

Recognition. Compare norms. The two products must use irreducibles (terminating factorization guarantees an irreducible factorization exists); inequivalence is detected because the only units are ± 1, so associates differ only by sign.

Solution. Compute norms: $\mathrm{N}(2) = 4$, $\mathrm{N}(3) = 9$, and $\mathrm{N}(1 \pm \sqrt{-5}) = 1^2 + 5 \cdot 1^2 = 6$. Both products give 6:

$$6 \;=\; 2 \cdot 3 \;=\; (1 + \sqrt{-5})(1 - \sqrt{-5}), \qquad \mathrm{N}(6) = 36 = 4 \cdot 9 = 6 \cdot 6.$$

Each of $2, 3, 1 + \sqrt{-5}, 1 - \sqrt{-5}$ is irreducible: norms $4, 9, 6, 6$ would split only through a factor of norm 2 or 3, and we saw $a^2 + 5b^2 \in \{\, 2, 3 \,\}$ is unsolvable. Now 2 cannot be an associate of $1 \pm \sqrt{-5}$ – the only units

are ± 1, and $\pm(1 \pm \sqrt{-5}) \neq \pm 2$ – so the two factorizations are not rearrangements of one another. *Check.* Multiplicativity is consistent ($36 = 4 \cdot 9 = 6 \cdot 6$), yet 2 divides $6 = (1+\sqrt{-5})(1-\sqrt{-5})$ without dividing either factor (that would need $\frac{1}{2}(1 \pm \sqrt{-5}) \in R$, false for $d \equiv 3 \bmod 4$). So 2 is irreducible but not prime: $R = \mathbb{Z}[\sqrt{-5}]$ is *not* a unique factorization domain.

Caution. Irreducible is not the same as prime here. In $\mathbb{Z}[\sqrt{-5}]$ the element 2 is irreducible (its norm 4 admits no proper factor) yet not prime (it divides the product $(1+\sqrt{-5})(1-\sqrt{-5})$ but neither factor). Factorization into irreducibles always *terminates* – the norm descends – but it need not be *unique*. Uniqueness is the strictly stronger UFD condition, and Artin's theorem (13.2.5) records that for imaginary $\mathbb{Q}[\sqrt{d}]$ it holds for only nine values $d = -1, -2, -3, -7, -11, -19, -43, -67, -163$. The repair, pursued next, is to factor *ideals* rather than elements.

16.5 Ideals as Lattices and Ideal Multiplication

Ideals as lattices in the complex plane

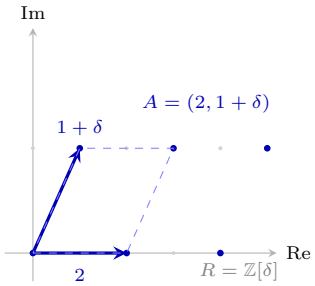
Artin's route to ideal factorization in a quadratic ring is resolutely geometric: a nonzero ideal of $R = \mathbb{Z}[\sqrt{d}]$ is first of all a *lattice* in $\mathbb{C}$, a discrete rank-2 subgroup. The arithmetic that ordinary elements fail to provide – unique factorization – is then recovered at the level of these lattices. Throughout we take $d < 0$ squarefree and R the ring of integers in $F = \mathbb{Q}(\sqrt{d})$; for concreteness the running example is $\delta = \sqrt{-5}$, $\delta^2 = -5$, where $d \equiv 3 \pmod 4$ so $R = \mathbb{Z}[\delta]$ with $\mathbb{Z}$-basis $1, \delta$.

Definition 16.5.1 (ideal as a sublattice)**.** A nonzero subset $A \subseteq R$ is an *ideal* iff it is a subgroup closed under multiplication by every element of R. When $d \equiv 2, 3 \pmod 4$ (as in the running example), $R = \mathbb{Z} \oplus \mathbb{Z}\delta$ is a lattice in $\mathbb{C}$, and any subgroup of R closed under multiplication by δ is already an ideal: closure under $\mathbb{Z}$ is automatic, and $a + b\delta$ then acts because δ does. (When $d \equiv 1 \pmod 4$, $R = \mathbb{Z} \oplus \mathbb{Z}\eta$ and one tests closure under η instead.)

Proposition 16.5.2 (Artin 13.3.1: every nonzero ideal is a full lattice)**.** *Let R be the ring of integers in an imaginary quadratic field, $d \equiv 2, 3 \pmod 4$. Every nonzero ideal A of R is a sublattice of R of full rank 2. Conversely a sublattice $A \subseteq R$ is an ideal if and only if $\delta A \subseteq A$.*

Proof. If $A \neq 0$ pick $\alpha \in A$, $\alpha \neq 0$; then $\{\, \alpha, \alpha\delta \,\}$ is $\mathbb{R}$-independent (as $\delta \notin \mathbb{R}$), so A contains two independent vectors. Being a subgroup of the lattice R, A is discrete, hence itself a lattice (a discrete subgroup containing two independent vectors is a full lattice). For the converse, a sublattice is closed under addition and under multiplication by $\mathbb{Z}$ automatically; if in addition $\delta A \subseteq A$, then A is closed under multiplication by every $a + b\delta \in R$, so A is an ideal. □

The decisive structural input is a lattice basis for the ideal, and Artin shows there are exactly two shapes.



Theorem 16.5.3 (Artin 13.3.3: lattice basis of an ideal in $\mathbb{Z}[\sqrt{-5}]$)**.** *Let $R = \mathbb{Z}[\delta]$, $\delta^2 = -5$, and let A be a nonzero ideal. Let $\alpha \in A$ be nonzero of minimal absolute value. Then exactly one of the following holds:*

(i) *$\{\, \alpha, \alpha\delta \,\}$ is a lattice basis for A, and $A = (\alpha)$ is principal; or*

(ii) *$\{\, \alpha, \frac{1}{2}(\alpha + \alpha\delta) \,\}$ is a lattice basis for A, and A is not principal.*

Sketch, following Artin. Since $\alpha \in A$, the principal ideal $(\alpha) \subseteq A$ has lattice basis $\{\, \alpha, \alpha\delta \,\}$. If $A = (\alpha)$ we are in case (i). Otherwise choose $\beta \in A \setminus (\alpha)$ lying in the fundamental rectangle of (α), i.e. $\beta = r\alpha + s\alpha\delta$ with $0 \leq r, s \leq 1$ (the rectangle, since δ is purely imaginary, has side ratio $1 : \sqrt{5}$). The geometric lemma – disks of radius $r = |\alpha|$ about the four vertices together with disks of radius $\frac{1}{2}r$ about the three half-lattice points $\frac{1}{2}\alpha\delta$, $\frac{1}{2}(\alpha + \alpha\delta)$, $\alpha + \frac{1}{2}\alpha\delta$ cover the rectangle, and the only lattice points interior to such disks are their centers – forces β to be one of the three half-lattice points. If $\beta = \alpha + \frac{1}{2}\alpha\delta$ then $\frac{1}{2}\alpha\delta \in A$, reducing to that case. If $\beta = \frac{1}{2}\alpha\delta \in A$, multiplying by δ gives $\frac{1}{2}\alpha\delta^2 = -\frac{5}{2}\alpha \in A$, and subtracting integer multiples of α shows $\frac{1}{2}\alpha \in A$, contradicting minimality of $|\alpha|$. The only survivor is $\beta = \frac{1}{2}(\alpha + \alpha\delta)$, the rectangle center, giving case (ii); the resulting lattice is the non-principal shape. □

Two principal ideals (α) are related by multiplication: writing $\alpha = re^{i\theta}$, the basis $(\alpha, \alpha\delta)$ is $(1, \delta)$ rotated by θ and scaled by r. So all principal ideals are *similar* figures, and the non-principal ideals form a second similarity class. The number of similarity (= *ideal*) classes is the *class number*; for $\mathbb{Z}[\sqrt{-5}]$ it is 2.

The bold points are the ideal $A = (2, 1+\delta)$ sitting inside the faint full lattice R; A has index 2 in R and is the non-principal shape of Artin's Theorem 13.3.3.

The conjugate ideal and the main lemma

Because $\overline{R} = R$ (complex conjugation fixes $\mathbb{Z}$ and sends $\delta \mapsto -\delta \in R$), conjugation carries ideals to ideals.

Definition 16.5.4 (conjugate ideal)**.** The *conjugate* of an ideal A is $\overline{A} = \{\, \overline{\alpha} : \alpha \in A \,\}$, again an ideal of R. If (α, β) is a lattice basis for A, then $(\overline{\alpha}, \overline{\beta})$ is a lattice basis for $\overline{A}$. The *norm* of A is the lattice index $\mathrm{N}(A) = [R : A]$.

Ideal multiplication is Dedekind's device for extending divisibility to ideals. The product AB is the smallest ideal containing all products $\alpha\beta$ with $\alpha \in A,\ \beta \in B$; concretely:

Proposition 16.5.5 (Artin 13.4.3: products via generators)**.** *Let $A = (\alpha_1, \dots, \alpha_m)$ and $B = (\beta_1, \dots, \beta_n)$ be ideals of a ring R.*

(a) *AB is generated as an ideal by the mn products $\alpha_i\beta_j$.*

(b) *$(\alpha)(\beta) = (\alpha\beta)$: a product of principal ideals is principal.*

(c) *If $A = (\alpha)$ is principal then $AB = \alpha B = \{\, \alpha\beta : \beta \in B \,\}$.*

Proof. Every element of AB is a finite sum $\sum_k a_k b_k$ with $a_k \in A,\ b_k \in B$; expanding $a_k = \sum_i r_{ki}\alpha_i$, $b_k = \sum_j s_{kj}\beta_j$ and collecting coefficients in R writes it as an R-combination of the $\alpha_i\beta_j$, proving (a). Parts (b) and (c) are the case $m = 1$. □

The engine of the whole theory is the following lemma, which says that although a single ideal A need not be principal, the symmetric product $A\overline{A}$ always is, and is generated by an honest positive integer.

Theorem 16.5.6 (Artin 13.4.8, Main Lemma)**.** *Let R be the ring of integers in an imaginary quadratic field. For every nonzero ideal A,*

$$A\,\overline{A} = (n) = nR \qquad \text{for a positive integer } n,$$

and that integer is $n = \mathrm{N}(A) = [R : A]$.

Following Artin. Let (α, β) be a lattice basis for A, so $(\overline{\alpha}, \overline{\beta})$ is one for $\overline{A}$. By Artin's Proposition 13.4.3(a), $A\overline{A}$ is generated by the four products $\alpha\overline{\alpha},\ \alpha\overline{\beta},\ \beta\overline{\alpha},\ \beta\overline{\beta}$. Now $\alpha\overline{\alpha} = |\alpha|^2$ and $\beta\overline{\beta} = |\beta|^2$ and $\beta\overline{\alpha} + \alpha\overline{\beta}$ are each equal to their own complex conjugates, hence rational; being algebraic integers, they are ordinary integers. Let n be their greatest common divisor in $\mathbb{Z}$. As an integer combination of generators of $A\overline{A}$, we get $n \in A\overline{A}$, so $(n) \subseteq A\overline{A}$.

For the reverse inclusion it suffices to show n divides each generator in R. It already divides $\alpha\overline{\alpha}$ and $\beta\overline{\beta}$ in $\mathbb{Z}$. For the cross terms set $\gamma = \alpha\overline{\beta}/n$ and $\overline{\gamma} = \beta\overline{\alpha}/n$. These are the two roots of

$$p(x) = x^2 - \left(\tfrac{\beta\overline{\alpha} + \alpha\overline{\beta}}{n}\right)x + \tfrac{\alpha\overline{\alpha}\,\beta\overline{\beta}}{n^2},$$

whose coefficients are integers because n divides $\beta\overline{\alpha}+\alpha\overline{\beta}$, $\alpha\overline{\alpha}$, and $\beta\overline{\beta}$. Thus $\gamma, \overline{\gamma}$ are algebraic integers, hence lie in R, so n divides $\alpha\overline{\beta}$ and $\beta\overline{\alpha}$ in R. Therefore $A\overline{A} \subseteq (n)$ and $A\overline{A} = (n)$. That $n = [R : A]$ follows because multiplication by A scales lattice covolumes by $\mathrm{N}(A)$ and $A\overline{A} = (n)$ has index n^2, while $[R : A] = [R : \overline{A}]$. □

Corollary 16.5.7 (Artin 13.4.9: cancellation and "to contain is to divide")**.** *For nonzero ideals A, B, C of R:* (a) *$AB = AC \iff B = C$, and $AB \subseteq AC \iff B \subseteq C$;* (b) *$A \supseteq B$ if and only if A* divides *B, i.e. $B = AC$ for some ideal C.*

Proof. (a) If $AB = AC$, multiply by $\overline{A}$: by the Main Lemma $A\overline{A} = (n)$, so $nB = nC$, and dividing by n gives $B = C$. (b) If a principal $(n) \supseteq B$ then n divides every element of B, and $C = n^{-1}B$ is an ideal with $(n)C = B$. In general $A \supseteq B$ gives $(n) = A\overline{A} \supseteq \overline{A}B$, so $\overline{A}B = (n)C = A\overline{A}C$ for some C, and cancellation yields $B = AC$. Conversely $B = AC$ gives $B = AC \subseteq AR = A$. □

Unique factorization of ideals

In R the "prime ideals" that arise are exactly the maximal ideals (a nonzero prime has finite index, so R/P is a finite integral domain, hence a field). Artin's containment-is-divisibility corollary turns the Euclid-style argument into ideal language.

Theorem 16.5.8 (Artin 13.5.5: unique factorization of ideals)**.** *Let R be the ring of integers in an imaginary quadratic field. Every nonzero proper ideal of R is a product of nonzero prime (= maximal) ideals, and the factorization is unique up to the order of the factors.*

Proof. Existence. If B is maximal it is prime. Otherwise some ideal A properly contains B; by Artin's Corollary 13.4.9(b), A divides B, say $B = AC$, and cancellation forces $C \supsetneq B$ too. Since only finitely many ideals contain B (each has $[R : B] < \infty$), recursively factoring A and C terminates with all factors maximal.

Uniqueness. Suppose $P_1 \cdots P_r = Q_1 \cdots Q_s$ with all P_i, Q_j prime. Then $P_1 \supseteq Q_1 \cdots Q_s$, so by primeness $P_1 \supseteq Q_j$ for some j, say $j = 1$; as Q_1 is maximal, $P_1 = Q_1$. Cancel P_1 (Artin's Corollary 13.4.9(a)) and induct. □

Remark 16.5.1. A prime $p \in \mathbb{Z}$ either *remains prime* (if (p) is a prime ideal), or *splits* as $(p) = P\overline{P}$ with $P \neq \overline{P}$, or *ramifies* when $P = \overline{P}$. The Main Lemma's $P\overline{P} = (\mathrm{N}\,P)$ forces $\mathrm{N}\,P$ to be p or p^2, matching this trichotomy.

The $d = -5$ example: ideal factorization restores order

In $R = \mathbb{Z}[\sqrt{-5}]$ element factorization fails to be unique:

$$6 = 2 \cdot 3 = (1 + \delta)(1 - \delta),$$

and $2, 3, 1 \pm \delta$ are all irreducible (norms $4, 9, 6, 6$ with no element of norm 2 or 3). The fix is to refine these into ideals.

Worked Example 16.5.9 (The ideals over 2 and 3, and $A\overline{A} = (2)$)**.** With $A = (2, 1 + \delta)$, $\overline{A} = (2, 1 - \delta)$, $B = (3, 1 + \delta)$, $\overline{B} = (3, 1 - \delta)$, compute $A\overline{A}$.

Recognition. Use Artin's Proposition 13.4.3(a): $A\overline{A}$ is generated by the four products of generators; then squeeze it between (2) and itself.

Solution. The four products of $\{\, 2, 1 + \delta \,\}$ and $\{\, 2, 1 - \delta \,\}$ are

$$A\overline{A} = \big(4,\ 2(1 - \delta),\ 2(1 + \delta),\ (1 + \delta)(1 - \delta)\big) = (4,\ 2 - 2\delta,\ 2 + 2\delta,\ 6).$$

Every generator is divisible by 2, so $A\overline{A} \subseteq (2)$. Conversely $2 = 6 - 4 \in A\overline{A}$, so $(2) \subseteq A\overline{A}$. Hence $A\overline{A} = (2)$.
Check. The Main Lemma predicts $A\overline{A} = (\mathrm{N}\,A)$, and indeed $[R : A] = 2$, so $n = 2$ as found.

Worked Example 16.5.10 (The split prime 3 and the mixed products)**.** Show $B\overline{B} = (3)$, and $AB = (1+\delta)$, $\overline{A}\,\overline{B} = (1-\delta)$.

Recognition. Same generator-product computation; each product ideal turns out principal, generated by a shared divisor of all four generators.

Solution. For $B\overline{B}$ the four products are 9, $3(1-\delta)$, $3(1+\delta)$, 6, all divisible by 3, and $3 = 9 - 6 \in B\overline{B}$, so $B\overline{B} = (3)$. For AB the four products of $\{2, 1+\delta\}$, $\{3, 1+\delta\}$ are 6, $2(1+\delta)$, $3(1+\delta)$, $(1+\delta)^2$, each divisible by $1+\delta$; moreover $1+\delta = 3(1+\delta) - 2(1+\delta) \in AB$, so $AB = (1+\delta)$. Conjugating gives $\overline{A}\,\overline{B} = (1-\delta)$. *Check.* $\mathrm{N}(AB) = |1+\delta|^2 = 6 = [R:A][R:B] = 2 \cdot 3$, consistent with norms being multiplicative.

Worked Example 16.5.11 (The common refinement of $6 = 2 \cdot 3 = (1+\delta)(1-\delta)$)**.** Express the principal ideal (6) as a product of the prime ideals $A, \overline{A}, B, \overline{B}$ and reconcile the two element-factorizations.

Recognition. Multiply the relations from the previous examples; both elementwise factorizations of 6 must collapse to the *same* ideal factorization.

Solution. Using $A\overline{A} = (2)$, $B\overline{B} = (3)$, $AB = (1+\delta)$, $\overline{A}\,\overline{B} = (1-\delta)$,

$$(6) = (2)(3) = (A\overline{A})(B\overline{B}) = (AB)(\overline{A}\,\overline{B}) = (1+\delta)(1-\delta).$$

The single ideal factorization $(6) = A\,\overline{A}\,B\,\overline{B}$ is the common refinement: regrouping $A\overline{A}\cdot B\overline{B}$ recovers $2\cdot 3$, while regrouping $(AB)(\overline{A}\,\overline{B})$ recovers $(1+\delta)(1-\delta)$. *Check.* Every factor is a genuine prime ideal ($\mathrm{N}\,A = \mathrm{N}\,\overline{A} = 2$, $\mathrm{N}\,B = \mathrm{N}\,\overline{B} = 3$, all prime), so this is the unique prime factorization of (6) guaranteed by Artin's Theorem 13.5.5; the apparent non-uniqueness of element factorization was only a regrouping ambiguity among these prime factors. (Only three of them are distinct: $\overline{A} = A$, see the Remark below, so $(6) = A^2 B\overline{B}$.)

Remark 16.5.2. The phenomenon is sharp: $A = \overline{A}$ here (an accidental symmetry of this lattice, since $1-\delta = 2-(1+\delta) \in A$), so 2 ramifies, $(2) = A^2$; whereas $B \neq \overline{B}$, so 3 splits, $(3) = B\overline{B}$. The failure of *element* factorization is precisely the failure of these prime ideals to be principal – which the class number 2 measures. Restoring unique factorization at the level of ideals is exactly the order that the geometry of lattices recovers.

16.6 Splitting, Ramification, and Inert Primes

Splitting, ramifying, and inert primes

Let R be the ring of integers in an imaginary quadratic number field $\mathbb{Q}[\sqrt{d}]$, with $d < 0$ squarefree. When $d \equiv 2$ or $3 \pmod 4$ we have $R = \mathbb{Z}[\sqrt{d}]$, and when $d \equiv 1 \pmod 4$ we have $R = \mathbb{Z}[\eta]$ with $\eta = \frac{1}{2}(1+\sqrt{d})$. A rational prime p generates the ideal $(p) = pR$, but this ideal need not be prime in R. The central question of this section is: *how does the prime p behave in R?* Artin's answer is that the behaviour of (p) is governed entirely by how a single quadratic polynomial factors modulo p – which, in turn, is read off from the Legendre symbol $\left(\frac{d}{p}\right)$.

Theorem 16.6.1 (decomposition of a rational prime, Artin 13.6.1)**.** *Let R be the ring of integers in an imaginary quadratic number field, and let p be a rational prime.*

(a) *For a nonzero prime ideal P of R, write $P\overline{P} = (n)$ with n a positive integer. Then n is either a rational prime or the square of a rational prime.*

(b) *The ideal $(p) = pR$ is either a prime ideal, or the product $P\overline{P}$ of a prime ideal and its conjugate.*

(c) *If $d \equiv 2$ or $3 \pmod 4$, then (p) is prime if and only if d is not a square modulo p, equivalently if and only if $x^2 - d$ is irreducible in $\mathbb{F}_p[x]$.*

(d) *If $d \equiv 1 \pmod 4$, put $h = \frac{1}{4}(1-d) \in \mathbb{Z}$. Then (p) is prime if and only if $x^2 - x + h$ is irreducible in $\mathbb{F}_p[x]$.*

Proof of (c). Suppose $d \equiv 2$ or $3 \pmod 4$, so $R = \mathbb{Z}[\sqrt{d}] \cong \mathbb{Z}[x]/(x^2 - d)$. The prime p remains prime in R exactly when the quotient $\widetilde{R} = R/(p)$ is a field (a nonzero quotient of a Dedekind domain by a maximal

ideal). Reducing mod p commutes with forming $\mathbb{Z}[x]/(x^2-d)$: the two ways of passing from $\mathbb{Z}[x]$ to $\widetilde{R}$ – first kill x^2-d then reduce mod p, or first reduce mod p then kill x^2-d – agree, giving

$$\widetilde{R} \;=\; R/(p) \;\cong\; \mathbb{Z}[x]/(x^2-d,\,p) \;\cong\; \mathbb{F}_p[x]/(x^2-d).$$

This last ring is a field precisely when x^2-d is irreducible in $\mathbb{F}_p[x]$. A monic quadratic over a field is irreducible iff it has no root, and x^2-d has a root in $\mathbb{F}_p$ iff d is a square modulo p. So (p) is prime iff d is not a square mod p; otherwise $x^2-d=(x-a)(x+a)$ splits and $(p)=P\overline{P}$ with $P=(p,\sqrt{d}-a)$. The proof of (d) is identical with x^2-x+h, the minimal polynomial of η, in place of x^2-d. Parts (a) and (b) follow the norm/unique-factorization argument of the Main Lemma and are taken as given here. □

The commuting reductions in the proof are exactly the square (13.6.3) in Artin: the two routes from $\mathbb{Z}[x]$ down to $\widetilde{R}$ must agree.

$$\begin{array}{ccc} \mathbb{Z}[x] & \xrightarrow{\quad x^2-d \quad} & \mathbb{Z}[\sqrt{d}] \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ \mathbb{F}_p[x] & \xrightarrow[\quad x^2-d \quad]{} & \widetilde{R}=\mathbb{F}_p[x]/(x^2-d) \end{array}$$

Diagram explanation. Objects: Four quotient rings arranged in a commutative square. Upper-left: the polynomial ring $\mathbb{Z}[x]$, the ambient free ring before imposing any relation. Upper-right: $\mathbb{Z}[\sqrt{d}]\cong\mathbb{Z}[x]/(x^2-d)$, the ring of integers (when $d\equiv 2,3 \pmod 4$), obtained by killing the relation $x^2=d$. Lower-left: $\mathbb{F}_p[x]=\mathbb{Z}[x]/(p)$, polynomials over the prime field, obtained by reducing coefficients mod p. Lower-right: $\widetilde{R}=\mathbb{F}_p[x]/(x^2-d)\cong R/(p)$, the target quotient that determines whether p stays prime.

Arrows: The top horizontal arrow is the surjection $\mathbb{Z}[x]\twoheadrightarrow\mathbb{Z}[\sqrt{d}]$ with kernel (x^2-d); it sends $x\mapsto\sqrt{d}$. The left vertical arrow is the reduction $\mathbb{Z}[x]\twoheadrightarrow\mathbb{F}_p[x]$ with kernel (p); it reduces each coefficient mod p. The right vertical arrow is the reduction $\mathbb{Z}[\sqrt{d}]\twoheadrightarrow\widetilde{R}=\mathbb{Z}[\sqrt{d}]/(p)$ with kernel $p\mathbb{Z}[\sqrt{d}]$; it is a quotient of rings. The bottom horizontal arrow is the surjection $\mathbb{F}_p[x]\twoheadrightarrow\mathbb{F}_p[x]/(x^2-d)$ killing x^2-d; it is well-defined because $x^2-d\in\mathbb{F}_p[x]$ (the relation descends from $\mathbb{Z}[x]$).

What commutes: The two composites from upper-left to lower-right agree: (top then right) = (left then bottom), i.e. the map $\mathbb{Z}[x]\to\widetilde{R}$ obtained by first killing x^2-d and then reducing mod p equals the map obtained by first reducing mod p and then killing x^2-d. In ring-quotient language: $\mathbb{Z}[x]/(x^2-d,p)\cong(\mathbb{Z}[x]/(x^2-d))/(p)\cong(\mathbb{Z}[x]/(p))/(x^2-d)$, all three rings being canonically the same.

Why it commutes: Chase the generator $x\in\mathbb{Z}[x]$. Along the top-then-right path: $x\mapsto\sqrt{d}$ in $\mathbb{Z}[\sqrt{d}]$, then $\sqrt{d}\mapsto\overline{\sqrt{d}}$ in $R/(p)$. Along the left-then-bottom path: $x\mapsto\bar{x}$ in $\mathbb{F}_p[x]$, then $\bar{x}\mapsto\bar{x}+(x^2-d)$ in $\mathbb{F}_p[x]/(x^2-d)$. Both images represent the same class in the joint quotient $\mathbb{Z}[x]/(x^2-d,p)$. Well-definedness of the right vertical arrow: a different lift $f+(x^2-d)$ of an element of $\mathbb{Z}[\sqrt{d}]$ differs from f by a multiple of x^2-d; that multiple maps to 0 in $\mathbb{F}_p[x]/(x^2-d)$, so the result is independent of the chosen representative.

Why this matters here: This square is the algebraic backbone of the inertness criterion. The theorem needs to compare $R/(p)$ with $\mathbb{F}_p[x]/(x^2-d)$ to decide whether (p) is prime. The square certifies these two rings are the same, so asking "is $R/(p)$ a field?" and "is x^2-d irreducible over $\mathbb{F}_p$?" are literally the same question – which is what the proof exploits.

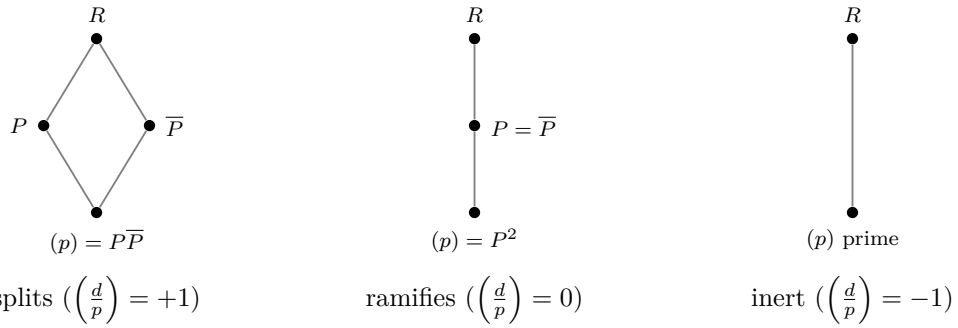
Concrete example: Take $d=-5$, $p=11$. Top-right: $\mathbb{Z}[\sqrt{-5}]$; right-down: $\mathbb{Z}[\sqrt{-5}]/(11)\cong\mathbb{F}_{11}[x]/(x^2+5)$. Left-down: $\mathbb{F}_{11}[x]$; bottom-right: $\mathbb{F}_{11}[x]/(x^2+5)$. Both routes land in $\mathbb{F}_{11}[x]/(x^2+5)\cong\mathbb{F}_{121}$, confirming 11 is inert (x^2+5 is irreducible mod 11).

Common pitfall: Students sometimes read the right vertical arrow $\mathbb{Z}[\sqrt{d}]\to R/(p)$ as an isomorphism, as if nothing changes – but it is a genuine surjection with a nontrivial kernel $p\mathbb{Z}[\sqrt{d}]$. A second common error is thinking the bottom arrow requires checking that x^2-d is irreducible in $\mathbb{F}_p[x]$ for the arrow to *exist*; in fact the surjection $\mathbb{F}_p[x]\twoheadrightarrow\mathbb{F}_p[x]/(x^2-d)$ always exists; irreducibility only determines whether the codomain is a *field*.

Takeaway: The point of this diagram is that reducing mod p and reducing mod $x^2 - d$ are independent operations that commute, so the quotient $R/(p)$ and the polynomial ring $\mathbb{F}_p[x]/(x^2 - d)$ are the same ring, reducing the primeness question for (p) in R to an irreducibility question in the familiar ring $\mathbb{F}_p[x]$.

Definition 16.6.2 (split, ramified, inert)**.** Let p be a rational prime. By part (b) of the theorem, either (p) is prime, or $(p) = P\overline{P}$ for a prime ideal P. We say:

- p *remains prime* (is *inert*) if $(p) = pR$ is itself a prime ideal of R;
- p *splits* if $(p) = P\overline{P}$ with $P \neq \overline{P}$;
- p *ramifies* if $(p) = P\overline{P}$ with $P = \overline{P}$, i.e. $(p) = P^2$.



When p splits or ramifies, $P\overline{P} = (p)$, so the norm of P is $N(P) = p$; when p is inert, the prime ideal (p) itself has norm $N\big((p)\big) = p^2$.

For $d \equiv 2, 3 \pmod 4$ the trichotomy is read off the Legendre symbol $\left(\frac{d}{p}\right)$, defined for odd p by $\left(\frac{d}{p}\right) = +1$ if d is a nonzero square mod p, -1 if d is a nonsquare, and 0 if $p \mid d$. The number of roots of $x^2 - d$ in $\mathbb{F}_p$ is $1 + \left(\frac{d}{p}\right)$, and that root count is exactly what distinguishes the three cases.

Method (To decide the behaviour of an odd prime p in $\mathbb{Z}[\sqrt{d}]$ ($d \equiv 2, 3 \bmod 4$).)**.** Compute the Legendre symbol $\left(\frac{d}{p}\right)$.

- $\left(\frac{d}{p}\right) = +1$: $x^2 - d$ has two roots mod p, so p *splits*, $(p) = P\overline{P}$ with $P = (p, \sqrt{d} - a)$ where $a^2 \equiv d$.
- $\left(\frac{d}{p}\right) = 0$ (i.e. $p \mid d$): $x^2 - d = (x)^2$ has a double root, p *ramifies*, $(p) = (p, \sqrt{d})^2$. The prime $p = 2$ is a separate ramification case.
- $\left(\frac{d}{p}\right) = -1$: $x^2 - d$ is irreducible, so p is *inert* and (p) stays prime.

Remark 16.6.1. The three behaviours are visible in the lattice of ideals between (p) and R. By Artin's Corollary 13.6.2, any proper ideal strictly larger than (p) is prime, hence maximal. So the interval $[(p), R]$ has at most one intermediate floor, and the trichotomy says how many distinct primes sit on it: two when p splits, one (doubled) when p ramifies, none when p is inert.

We now run Artin's running example $d = -5$, $R = \mathbb{Z}[\sqrt{-5}]$. Here $d \equiv 3 \pmod 4$, so the governing polynomial is $x^2 + 5$ and the relevant ideals are $A = (2, 1 + \sqrt{-5})$ and $B = (3, 1 + \sqrt{-5})$ from Artin's (13.4.5).

Worked Example 16.6.3 (The prime 2 ramifies in $\mathbb{Z}[\sqrt{-5}]$)**.** Show that $(2) = A^2$ where $A = (2, 1 + \sqrt{-5})$, so 2 ramifies.

Recognition. Here $p = 2$, the degenerate case (note $2 \nmid d = -5$; the prime 2 ramifies whenever $d \equiv 2, 3 \pmod 4$): $x^2 - d \equiv x^2 + 5 \equiv x^2 - 1 \equiv (x - 1)^2 \pmod 2$ has a repeated root, signalling ramification. Compute $A\overline{A}$ directly.

Solution. Modulo 2, $x^2+5 \equiv x^2+1 \equiv (x+1)^2$, a perfect square, so 2 should ramify. Check it by hand: $\overline{A} = (2, 1-\sqrt{-5})$, and $A\overline{A}$ is generated by the four products of generators,

$$A\overline{A} = \big(4,\ 2(1+\sqrt{-5}),\ 2(1-\sqrt{-5}),\ (1+\sqrt{-5})(1-\sqrt{-5})\big) = (4,\ 2+2\sqrt{-5},\ 2-2\sqrt{-5},\ 6).$$

Each generator is divisible by 2, so $A\overline{A} \subseteq (2)$; conversely $2 = 6-4 \in A\overline{A}$, so $(2) \subseteq A\overline{A}$. Hence $A\overline{A} = (2)$. But $A = \overline{A}$: complex conjugation sends $1+\sqrt{-5} \mapsto 1-\sqrt{-5} = 2-(1+\sqrt{-5}) \in A$, so $\overline{A} \subseteq A$ and by symmetry $A = \overline{A}$. Therefore $(2) = A\overline{A} = A^2$, and 2 ramifies. *Check.* $N(A) = 2$, so $N\big((2)\big) = N(A)^2 = 4 = 2^2$, matching the index $[R:(2)] = 4$.

Worked Example 16.6.4 (The prime 3 splits in $\mathbb{Z}[\sqrt{-5}]$)**.** Show that $(3) = B\overline{B}$ with $B \neq \overline{B}$, so 3 splits but does not ramify.

Recognition. Check the Legendre symbol $\left(\frac{-5}{3}\right)$: a value $+1$ predicts splitting. Then confirm $B\overline{B} = (3)$ and $B \neq \overline{B}$.

Solution. Modulo 3, $-5 \equiv 1 = 1^2$, so $\left(\frac{-5}{3}\right) = +1$ and $x^2+5 \equiv x^2-1 = (x-1)(x+1) \pmod 3$ has two distinct roots: 3 splits. Concretely $B = (3, 1+\sqrt{-5})$ and $\overline{B} = (3, 1-\sqrt{-5})$. The product $B\overline{B}$ is generated by

$$\big(9,\ 3(1-\sqrt{-5}),\ 3(1+\sqrt{-5}),\ 6\big),$$

each divisible by 3, so $B\overline{B} \subseteq (3)$; and $3 = 9-6 \in B\overline{B}$, so $(3) \subseteq B\overline{B}$, giving $B\overline{B} = (3)$. Finally $B \neq \overline{B}$: if they were equal then B would contain both $1+\sqrt{-5}$ and $1-\sqrt{-5}$, hence their difference $2\sqrt{-5}$ and (with $3 \in B$) eventually $1 \in B$, forcing $B = R$ – but $N(B) = 3 \neq 1$. So $B \neq \overline{B}$ and 3 splits without ramifying. *Check.* $\left(\frac{-5}{3}\right) = +1$ correctly predicted two prime factors, and $N(B) = 3$ gives $N\big((3)\big) = 9 = 3^2$.

Worked Example 16.6.5 (The prime 7 splits in $\mathbb{Z}[\sqrt{-5}]$)**.** Decide the behaviour of 7 and exhibit a prime factor P of (7).

Recognition. Reduce $d = -5$ mod 7 and test whether it is a square: $\left(\frac{-5}{7}\right) = +1$ means split, -1 means inert.

Solution. Modulo 7, $-5 \equiv 2$. The squares mod 7 are $\{1,4,2,2,4,1\} = \{1,2,4\}$, and indeed $3^2 = 9 \equiv 2$, so 2 is a square and $\left(\frac{-5}{7}\right) = +1$. Thus $x^2+5 \equiv x^2-2 \equiv (x-3)(x+3) \pmod 7$ (check: $(x-3)(x+3) = x^2-9 \equiv x^2-2$), so 7 splits. A prime factor is

$$P = (7,\ \sqrt{-5}-3), \qquad (7) = P\overline{P}, \quad \overline{P} = (7, \sqrt{-5}+3),$$

following the recipe $P = (p, \sqrt{d}-a)$ with $a = 3$, $a^2 = 9 \equiv -5 \pmod 7$. *Check.* $N(P) = 7$ and $P \neq \overline{P}$ (a root $a = 3 \not\equiv -a = 4 \pmod 7$ since $7 \nmid 2a = 6$), so 7 splits, consistent with $\left(\frac{-5}{7}\right) = +1$.

Worked Example 16.6.6 (The prime 11 is inert in $\mathbb{Z}[\sqrt{-5}]$)**.** Show that (11) is a prime ideal of $\mathbb{Z}[\sqrt{-5}]$.

Recognition. Inertness is the case $\left(\frac{d}{p}\right) = -1$: $x^2 - d$ stays irreducible mod p, so (p) is already maximal.

Solution. Modulo 11, $-5 \equiv 6$. The nonzero squares mod 11 are $\{1,4,9,5,3\}$, and 6 is not among them, so $\left(\frac{-5}{11}\right) = -1$. Hence $x^2+5 \equiv x^2-6$ has no root in $\mathbb{F}_{11}$ and is irreducible there, so by part (c) of the theorem $(11) = 11R$ is prime in $\mathbb{Z}[\sqrt{-5}]$: 11 is inert. *Check.* $R/(11) \cong \mathbb{F}_{11}[x]/(x^2-6) \cong \mathbb{F}_{121}$ is a field, confirming (11) is maximal; the norm of the prime (11) is $11^2 = 121$, the inert signature.

Caution. The polynomial criterion in part (c) is stated for $d \equiv 2, 3 \pmod 4$ and for odd p. When $d \equiv 1 \pmod 4$ you must use $x^2 - x + h$ (part (d)), *not* $x^2 - d$: the ring is $\mathbb{Z}[\eta]$, not $\mathbb{Z}[\sqrt{d}]$, and using the wrong polynomial can mispredict the prime 2. The Legendre symbol $\left(\frac{d}{p}\right)$ also says nothing directly at $p = 2$; that prime is handled by the root-count of the correct polynomial mod 2, where a repeated root signals ramification. (At an odd $p \mid d$ the symbol is 0, and p ramifies for every d.)

Remark 16.6.2. Collecting the $d = -5$ data: 2 ramifies, 3 and 7 split, 11 is inert. For the split and ramified primes $2, 3, 7$ the factorization $(p) = P\overline{P}$ (with $P = \overline{P}$ allowed) recovers (p) on multiplying a prime by its conjugate – the ideal-theoretic shadow of the norm being multiplicative – while the inert 11 generates a prime ideal (11) of norm 121. This is the local mechanism behind the global factorization $(6) = A\overline{A}\,B\overline{B} = (2)(3)$ of Artin's (13.4.7): the rational primes dividing a norm split, ramify, or stay inert one at a time, and their prime ideals reassemble into the unique factorization of any ideal of R.

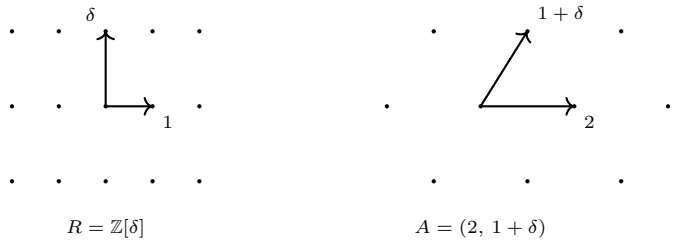
16.7 Computing the Ideal Class Group

Ideal classes and the class group

Let R be the ring of integers in an imaginary quadratic number field $\mathbb{Q}[\sqrt{d}\,]$, d a square-free negative integer. In Artin's development R has unique factorization of *ideals* into primes, but typically fails unique factorization of *elements*; the class group is the precise algebraic gadget measuring that failure. We regard each nonzero ideal of R as a lattice in $\mathbb{C}$, and two such lattices are "the same shape" exactly when they differ by a complex scaling.

Definition 16.7.1 (similar ideals, ideal classes)**.** Two nonzero ideals A, A' of R are *similar* if $A' = \lambda A$ for some $\lambda \in \mathbb{C}^\times$. Similarity is an equivalence relation; its classes are the *ideal classes*. The class of A is written (A). Geometrically $A \sim A'$ iff, as lattices in $\mathbb{C}$, they are orientation-preservingly similar figures (a rotation followed by a scaling), since a lattice looks the same at each point and the similarity may be assumed to carry $0 \mapsto 0$, i.e. to be multiplication by some λ.

Lemma 16.7.2 (the principal class)**.** *The class (R) of the unit ideal consists of exactly the principal ideals.*



Proof. If $(A) = (R)$ then $A = \lambda R$ for some $\lambda \in \mathbb{C}$. Since $1 \in R$ we get $\lambda \in A \subseteq R$, so $A = \lambda R = (\lambda)$ is principal. Conversely $(\lambda) = \lambda R \sim R$. □

Recall the *norm* of an ideal: by the Main Lemma the product $A\overline{A} = (n)$ is principal, generated by a positive integer, and one sets $\mathrm{N}(A) = n$. The norm is multiplicative, $\mathrm{N}(AB) = \mathrm{N}(A)\,\mathrm{N}(B)$, and on a principal ideal it agrees with the element norm, $\mathrm{N}((\alpha)) = \mathrm{N}(\alpha) = \alpha\overline{\alpha}$.

Proposition 16.7.3 (the class group)**.** *The ideal classes form an abelian group C under $(A)(B) = (AB)$, with identity $1 = (R)$. It is the* class group *of R; its order is the* class number *h.*

Proof. If $(A) = (A')$ and $(B) = (B')$, say $A' = \lambda A$, $B' = \mu B$, then $A'B' = \lambda\mu AB$, so $(A'B') = (AB)$ and the law is well defined. Commutativity and associativity descend from ideal multiplication, and (R) is the identity since $AR = A$. For inverses, the Main Lemma gives $A\overline{A} = (n)$ principal, so $(A)(\overline{A}) = (A\overline{A}) = (R) = 1$ and $(A)^{-1} = (\overline{A})$. □

Remark 16.7.1. Thus R is a principal ideal domain iff $h = 1$, and for these rings PID $\Leftrightarrow$ UFD. The class number quantifies how badly element factorization fails: when $h = 2$, for instance, the product of any two non-principal ideals is principal (the non-trivial class has order 2).

The two lattices are *not* similar (one is rectangular, the other is not), which is the geometric reason A is non-principal: $A \not\sim R$ means $(A) \neq 1$.

The finiteness bound and the algorithm

The whole subject is computable because every class is represented by an ideal of bounded norm. Artin states the bound through a constant μ that depends only on d.

Theorem 16.7.4 (Minkowski-type bound and finiteness)**.** *Let R be the ring of integers of $\mathbb{Q}[\sqrt{d}\,]$, $d < 0$, and put*

$$\mu = \begin{cases} \dfrac{2}{\sqrt{3}}\sqrt{|d|}\,, & d \equiv 2, 3 \pmod 4, \\[2mm] \dfrac{1}{\sqrt{3}}\sqrt{|d|}\,, & d \equiv 1 \pmod 4. \end{cases}$$

Then:

(a) *every ideal class contains an ideal A with $\mathrm{N}(A) \le \mu$;*

(b) *C is generated by the classes of prime ideals P whose norm is a prime integer $p \le \mu$;*

(c) *C is finite.*

Sketch. (a) The shortest-vector estimate (Minkowski) gives, in any nonzero ideal A, an element $\alpha \neq 0$ with $\mathrm{N}(\alpha) \le \mathrm{N}(A)\,\mu$; here $\mu = \frac{2}{\sqrt{3}}A(R)$ where $A(R)$ is the covolume of R. Since $\alpha \in A$ we have $A \mid (\alpha)$, say $(\alpha) = AC$, so $\mathrm{N}(A)\,\mathrm{N}(C) = \mathrm{N}(\alpha) \le \mathrm{N}(A)\mu$ and hence $\mathrm{N}(C) \le \mu$. As $(\alpha) = AC$ is principal, $(C) = (A)^{-1} = (\overline{A})$, and $\overline{C}$ then lies in the class (A) with $\mathrm{N}(\overline{C}) = \mathrm{N}(C) \le \mu$. (b) Factor such an A into primes $A = P_1 \cdots P_k$; then $\mathrm{N}(P_i) \le \mathrm{N}(A) \le \mu$. A prime ideal has norm p or p^2; if $\mathrm{N}(P) = p^2$ then $P = (p)$ is principal with trivial class, so only primes of norm $p \le \mu$ matter. (c) Only finitely many products of primes have norm $\le \mu$, and at most two primes lie over each integer, so finitely many ideals (hence classes) occur. □

Method (Computing C from the splitting of small primes.)**.** 1. Compute $\lfloor \mu \rfloor$ and list the primes $p \le \mu$.

2. Determine the splitting of each such p. For $d \equiv 2, 3 \pmod 4$: $p = 2$ and the odd $p \mid d$ *ramify*, $(p) = P\overline{P}$ with $P = \overline{P}$, so $(P)^2 = 1$ (order ≤ 2); an odd $p \nmid d$ *splits* iff $x^2 - d$ has a root in $\mathbb{F}_p$; if p stays prime, (p) has trivial class and is discarded. For each prime that splits or ramifies, include one prime factor's class as a generator.

3. Find relations by computing element norms: a factorization $\mathrm{N}(\alpha) = p^i q^j s^k$, with α divisible by none of the integers p, q, s, yields an ideal relation $(\alpha) = P^i Q^j S^k$ (up to conjugates), hence a relation $(P)^i(Q)^j(S)^k = 1$ in C.

4. Read off the group from generators and relations; a prime P over p is non-principal iff p has no proper factor (norm-p element) in R.

Lemma 16.7.5 (why norms detect relations)**.** *If P, Q, S are primes of norms p, q, s and $(P)^i(Q)^j(S)^k = 1$ in C, then there is $\alpha \in R$ with $\mathrm{N}(\alpha) = p^i q^j s^k$.*

Proof. The relation says $P^iQ^jS^k = (\alpha)$ is principal. Then $(\alpha)(\overline{\alpha}) = (P\overline{P})^i(Q\overline{Q})^j(S\overline{S})^k = (p)^i(q)^j(s)^k = (p^iq^js^k)$, so $\mathrm{N}(\alpha) = \alpha\overline{\alpha} = p^iq^js^k$. □

Worked computations

Worked Example 16.7.6 (The class group for $d = -5$ $(h = 2)$)**.** Compute C for $R = \mathbb{Z}[\delta]$, $\delta = \sqrt{-5}$, and exhibit the non-trivial class.

Recognition. $d = -5 \equiv 3 \pmod 4$, so $\mu = \frac{2}{\sqrt{3}}\sqrt{5} \approx 2.58$, $\lfloor \mu \rfloor = 2$: only the prime $p = 2$ need be examined.

Solution. The prime 2 ramifies: $x^2 - (-5) = x^2 + 5 \equiv x^2 + 1 \equiv (x + 1)^2 \pmod 2$, and $(2) = A\overline{A}$ with $A = (2, 1 + \delta)$, $A = \overline{A}$. By the ramified-prime analysis (A) has order 1 or 2, and order 1 would make $A = (\alpha)$ with $\mathrm{N}(\alpha) = \mathrm{N}(A) = 2$, i.e. $a^2 + 5b^2 = 2$ for integers a, b – impossible. So (A) has order 2. Every class is represented by an ideal of norm ≤ 2; the ideals of norm 1 form the class 1 and the only ideal of norm 2 is A, giving exactly two classes. Hence $C \cong \mathbb{Z}/2\mathbb{Z}$, generated by (A), and R is *not* a UFD.

Check. The failure of unique factorization is visible directly: $6 = 2 \cdot 3 = (1 + \delta)(1 - \delta)$ with all four factors irreducible, while at the ideal level $(6) = (2)(3) = A\overline{A}\,B\overline{B}$ refines both, where $B = (3, 1 + \delta)$, $A\overline{A} = (2)$, $B\overline{B} = (3)$, and $AB = (1 + \delta)$ is principal – confirming $(A)(B) = 1$, i.e. $(B) = (A)^{-1} = (A)$, consistent with a group of order 2.

Worked Example 16.7.7 (The class group for $d = -23$ $(h = 3)$)**.** Compute C for the ring of integers of $\mathbb{Q}[\sqrt{-23}\,]$.

Recognition. $d = -23 \equiv 1 \pmod 4$, so $R = \mathbb{Z}[\eta]$ with $\eta = \frac{1}{2}(1 + \sqrt{-23})$ and $\mu = \frac{1}{\sqrt{3}}\sqrt{23} \approx 2.77$, $\lfloor \mu \rfloor = 2$: examine $p = 2$ only.

Solution. The minimal polynomial of η is $x^2 - x + 6$. Modulo 2, $x^2 - x + 6 \equiv x^2 + x = x(x + 1)$ is reducible with distinct roots, so 2 *splits*: $(2) = P\overline{P}$ with $P \neq \overline{P}$, $\mathrm{N}(P) = 2$. So C is generated by the

single class (P). To find its order, hunt for element norms that are powers of 2. The norm form is $\mathrm{N}(a+b\eta) = (a+b\eta)(a+b\overline{\eta}) = a^2+ab+6b^2$ (since $\eta+\overline{\eta}=1$, $\eta\overline{\eta}=6$). Compute:

$$\mathrm{N}(\eta) = 6, \quad \mathrm{N}(1+\eta) = 1+1+6 = 8 = 2^3.$$

The value $\mathrm{N}(1+\eta) = 8 = 2^3$ gives the ideal relation $(1+\eta) = P^3$ or $\overline{P}^3$ (the conjugate splits the two prime factors of (2), and $(1+\eta)\overline{(1+\eta)} = (P\overline{P})^3 = (2)^3$ with $2 \nmid (1+\eta)$, so $(1+\eta)$ is one of $P^3, \overline{P}^3$). Either way $(P)^3 = 1$, so (P) has order 1 or 3. Order 1 would require a norm-2 element: $a^2+ab+6b^2 = 2$ has no integer solution ($b=0$ gives $a^2=2$; $b=\pm1$ gives $a^2 \pm a + 6 = 2$, i.e. $a^2 \pm a + 4 = 0$, discriminant < 0; and $|b| \geq 2$ gives $a^2+ab+6b^2 = (a+\frac{b}{2})^2 + \frac{23}{4}b^2 \geq 23$). So P is non-principal and (P) has order 3. Hence $C \cong \mathbb{Z}/3\mathbb{Z}$, generated by a prime over 2.

Check. A cyclic group of order 3 has no element of order 2, consistent with 2 *splitting* (not ramifying) – a ramified 2 would force an order-2 class and an even class number, contradicting $h = 3$. The relation $\mathrm{N}(1+\eta) = 2^3$ is exactly the "$(P)^3 = 1$" witness predicted by the norm lemma.

Worked Example 16.7.8 (A larger run: $d = -14$ ($h = 4$))**.** Determine the structure of C for $d = -14$.

Recognition. $d = -14 \equiv 2 \pmod 4$, $\mu = \frac{2}{\sqrt{3}}\sqrt{14} \approx 4.32$, $\lfloor \mu \rfloor = 4$: inspect $p = 2, 3$ (the prime 4 is not prime).

Solution. Here $R = \mathbb{Z}[\delta]$, $\delta = \sqrt{-14}$, $\mathrm{N}(a+b\delta) = a^2+14b^2$. The prime 2 ramifies: $(2) = P\overline{P}$, $P = (2, \delta)$, $P = \overline{P}$, so $(P)^2 = 1$. For 3: $x^2+14 \equiv x^2+2 \pmod 3$ has roots $x = \pm 1$ ($1+2 = 3 \equiv 0$), so 3 splits, $(3) = Q\overline{Q}$, $\mathrm{N}(Q) = 3$, contributing a generator (Q). Now compute norms:

$$\mathrm{N}(\delta) = 14 = 2 \cdot 7, \quad \mathrm{N}(2+\delta) = 4+14 = 18 = 2 \cdot 3^2, \quad \mathrm{N}(1+\delta) = 1+14 = 15 = 3 \cdot 5.$$

From $\mathrm{N}(2+\delta) = 2 \cdot 3^2$ we get $(2+\delta) = P\,Q^2$ (up to conjugating Q), so the relation $(P)(Q)^2 = 1$, i.e. $(P) = (Q)^{-2} = (Q)^2$. Thus every generator is a power of (Q), and $C = \langle (Q) \rangle$ is cyclic. Moreover P is non-principal: a generator would have norm 2, and $a^2+14b^2 = 2$ is impossible. So $(P) = (Q)^2$ has order exactly 2, and (Q) has order 4 (in particular (Q) is non-principal, as also follows from $a^2+14b^2 = 3$ being impossible). Counting ideals of norm ≤ 4 – R, P, the two primes over 3, and the only norm-4 ideal $P^2 = (2)$ – gives at most four classes, so $C = \langle (Q) \rangle \cong \mathbb{Z}/4\mathbb{Z}$.

Check. $(Q)^2 = (P)$ has order 2 and $(Q)^4 = (P)^2 = 1$, so the order of (Q) is exactly 4, matching the tabulated class group C_4 for $d = -14$. The single relation $(P)(Q)^2 = 1$ collapsing two generators to one cyclic generator is the typical end state of the algorithm.

Caution. Do not conflate the two norms. $\mathrm{N}(\alpha) = \alpha\overline{\alpha}$ is an integer attached to an *element*; $\mathrm{N}(A) = n$ where $A\overline{A} = (n)$ is attached to an *ideal*. They agree only on principal ideals, $\mathrm{N}((\alpha)) = \mathrm{N}(\alpha)$. The algorithm works precisely by passing between them: a multiplicative element norm $\mathrm{N}(\alpha) = p^i q^j s^k$, with α divisible by none of p, q, s, certifies a principal ideal $P^i Q^j S^k = (\alpha)$ (up to conjugates), hence a relation in C. Also, an integer prime p with $\mathrm{N}(P) = p^2$ means $(p) = P$ stayed prime – its class is trivial and must be discarded, not used as a generator.

Remark 16.7.2. The same procedure runs for any imaginary quadratic d: a UFD is detected exactly when no prime $p \leq \mu$ contributes a non-trivial class (e.g. $d = -1, -2$ give $\mu < 2$ with no primes to check, and $d = -163$, where $x^2 - x + 41$ stays irreducible mod $2, 3, 5, 7$, both give $h = 1$). The finiteness of C – a theorem here proved by the lattice bound – is the first structural invariant of a number field beyond its degree, and the class group $\cong \mathbb{Z}/h\mathbb{Z}$ in all examples above is the cyclic shadow of how far R sits from being a principal ideal domain.

16.8 Real Quadratic Fields and Pell's Equation

Real quadratic fields: the lattice in the plane

For a square-free positive integer $d > 0$ the field $\mathbb{Q}[\sqrt{d}]$ is a subfield of $\mathbb{R}$, and its ring of integers R is no longer embedded as a lattice in $\mathbb{C}$ the way the imaginary fields were. Artin's device for recovering a planar picture is to use the *two* real embeddings at once. Throughout this subsection $R = \mathbb{Z}[\sqrt{d}]$ (the case $d \equiv 2, 3 \bmod 4$), $\alpha = a + b\sqrt{d}$ with $a, b \in \mathbb{Z}$, and $\overline{\alpha} = a - b\sqrt{d}$ is the conjugate; the norm is $\mathrm{N}(\alpha) = \alpha\overline{\alpha} = a^2 - b^2 d$.

Definition 16.8.1 (the real embedding $R \to \mathbb{R}^2$)**.** Associate to $\alpha = a + b\sqrt{d} \in R$ the point

$$\Phi(\alpha) = (u, v), \qquad u = a + b\sqrt{d} = \alpha, \quad v = a - b\sqrt{d} = \overline{\alpha}.$$

These are the two ways the abstract field $\mathbb{Q}[x]/(x^2 - d)$ embeds in $\mathbb{R}$, one sending the residue of x to $+\sqrt{d}$ and the other to $-\sqrt{d}$. The image $\Phi(R)$ is a lattice in $\mathbb{R}^2$ spanned by $\Phi(1) = (1, 1)$ and $\Phi(\sqrt{d}) = (\sqrt{d}, -\sqrt{d})$.

Remark 16.8.1. Under Φ the product structure becomes coordinatewise: $\Phi(\alpha\beta) = (\alpha\beta, \overline{\alpha}\,\overline{\beta})$, so Φ is a ring homomorphism into $\mathbb{R} \times \mathbb{R}$ with pointwise operations. The norm reads off as the product of coordinates,

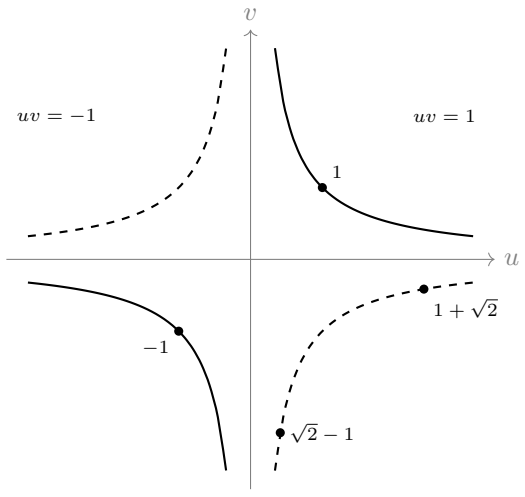
$$\mathrm{N}(\alpha) = \alpha\overline{\alpha} = uv,$$

which is the geometric fact that drives everything below. The norm is multiplicative, $\mathrm{N}(\alpha\beta) = \mathrm{N}(\alpha)\,\mathrm{N}(\beta)$, but unlike the complex case it is *not* $|\alpha|^2$ and need not be positive.

Worked Example 16.8.2 (Reading the norm as a product of coordinates)**.** For $\alpha = 1 + \sqrt{2}$ in $R = \mathbb{Z}[\sqrt{2}]$, compute $\Phi(\alpha)$ and $\mathrm{N}(\alpha)$ and check the two agree.

Recognition. Apply Φ coordinatewise; the norm is $a^2 - b^2 d$ and also the product uv.

Solution. Here $a = b = 1$, $d = 2$, so $u = 1 + \sqrt{2}$ and $v = 1 - \sqrt{2}$, giving $\Phi(\alpha) = (1 + \sqrt{2},\, 1 - \sqrt{2})$. Then $\mathrm{N}(\alpha) = a^2 - b^2 d = 1 - 2 = -1$, and indeed $uv = (1 + \sqrt{2})(1 - \sqrt{2}) = 1 - 2 = -1$. *Check.* The point lies on the hyperbola $uv = -1$, with $u \approx 2.414$, $v \approx -0.414$, so $uv = -1$ to the displayed accuracy.



Units lie on the hyperbolas $uv = \pm 1$

The norm being an ordinary integer immediately pins down the units.

Proposition 16.8.3 (units have norm ± 1)**.** *An element $\alpha \in R$ is a unit if and only if $\mathrm{N}(\alpha) = \pm 1$. Equivalently, $\Phi(\alpha)$ lies on one of the two hyperbolas*

$$uv = 1 \qquad \text{or} \qquad uv = -1.$$

Proof. If α is a unit with inverse $\beta \in R$, then $\mathrm{N}(\alpha)\,\mathrm{N}(\beta) = \mathrm{N}(1) = 1$ in $\mathbb{Z}$, and both factors are integers, so $\mathrm{N}(\alpha) = \pm 1$. Conversely, if $\mathrm{N}(\alpha) = \alpha\overline{\alpha} = \pm 1$, then $\overline{\alpha}$ or $-\overline{\alpha}$ is an inverse of α lying in R (the conjugate of an algebraic integer is again an algebraic integer in R), so $\alpha \in R^\times$. The condition $\mathrm{N}(\alpha) = uv = \pm 1$ is exactly membership of $\Phi(\alpha)$ in the two hyperbolas. □

The two hyperbolas $uv = \pm 1$ for $d = 2$, with the points $\Phi(\alpha)$ of the units $\alpha = \pm 1,\ 1 + \sqrt{2},\ \sqrt{2} - 1$ marked; the units of R are exactly the points of the lattice $\Phi(R)$ lying on these curves.

Theorem 16.8.4 (Dirichlet, rank one; Artin 13.9.9)**.** *Let R be the ring of integers in a real quadratic field. The group of units $R^\times$ is infinite. More precisely,*

$$R^\times \;\cong\; \langle -1\rangle \times \langle \epsilon\rangle \;\cong\; \mathbb{Z}/2\mathbb{Z} \;\times\; \mathbb{Z},$$

where $\epsilon > 1$ is a uniquely determined fundamental unit*.*

Sketch, after Artin. Infinitude is the geometric heart. View R as a lattice in the (u, v)-plane containing no point of the coordinate axes except the origin (since $\sqrt{d}$ is irrational, $u = a + b\sqrt{d} = 0$ or $v = a - b\sqrt{d} = 0$ forces $a = b = 0$). Squeezing the plane by the area-preserving maps $\varphi_s(x, y) = (sx, s^{-1}y)$, one shows every thin elliptical disk D_s about the u-axis still contains a nonzero lattice point, and these points have bounded $|uv| = |\mathrm{N}|$. Hence infinitely many elements of R share a single norm value n; among them infinitely many are congruent modulo n, and if $\beta_1 \equiv \beta_2 \pmod n$ with equal norm then $\beta_2/\beta_1 \in R^\times$. So $R^\times$ is infinite.

For the structure, map $R^\times \to \mathbb{R}$ by $\alpha \mapsto \log|\alpha| = \log|u|$. The kernel is the units with $|\alpha| = 1$ and $|\overline{\alpha}| = 1/|\alpha| = 1$, i.e. roots of unity in a real field, namely $\{\pm 1\}$. The image is a nonzero subgroup of $\mathbb{R}$ that is discrete (lattice points cannot accumulate), hence infinite cyclic, generated by $\log\epsilon$ for the smallest unit $\epsilon > 1$. Thus $R^\times = \langle -1\rangle \times \langle \epsilon\rangle$ with $\langle -1\rangle \cong \mathbb{Z}/2\mathbb{Z}$ and $\langle \epsilon\rangle \cong \mathbb{Z}$. □

Method (To locate the fundamental unit ϵ of $\mathbb{Z}[\sqrt{d}]$.)**.** Seek the smallest $\epsilon = a + b\sqrt{d} > 1$ with $a, b > 0$ and $a^2 - b^2 d = \pm 1$ by scanning $b = 1, 2, 3, \ldots$ and testing whether $b^2 d \pm 1$ is a perfect square a^2. The first hit gives ϵ; every unit is then $\pm\epsilon^n$, $n \in \mathbb{Z}$. The first quadrant units (those with $u > 0$, $v > 0$, which are the powers ϵ^n of norm consistent with $uv = 1$ after squaring) form the infinite cyclic group U_0 of Artin's Exercise 9.5.

Worked Example 16.8.5 (The fundamental unit for $d = 2$)**.** Show $\epsilon = 1 + \sqrt{2}$ is the fundamental unit of $\mathbb{Z}[\sqrt{2}]$ and has infinite order.

Recognition. Scan $b = 1$: need $2 \cdot 1^2 \pm 1 = a^2$, i.e. $a^2 \in \{1, 3\}$; the value 1 works.

Solution. With $b = 1$, $2b^2 - 1 = 1 = 1^2$, so $a = 1$ and $\epsilon = 1 + \sqrt{2}$ has $\mathrm{N}(\epsilon) = 1 - 2 = -1 = \pm 1$, a unit; it is the smallest with $a, b > 0$. Its powers are

$$\epsilon^2 = 3 + 2\sqrt{2}, \quad \epsilon^3 = 7 + 5\sqrt{2}, \quad \epsilon^4 = 17 + 12\sqrt{2}, \ldots$$

with $\mathrm{N}(\epsilon^n) = (-1)^n$. Since $\epsilon > 1$, the values ϵ^n are strictly increasing, so ϵ has infinite order and $R^\times = \{\pm(1 + \sqrt{2})^n\}$. *Check.* $\epsilon^2 = (1 + \sqrt{2})^2 = 1 + 2\sqrt{2} + 2 = 3 + 2\sqrt{2}$ and $\mathrm{N}(\epsilon^2) = 9 - 8 = 1$, consistent with $(-1)^2$; this recovers Artin's Exercise 9.1 that $1 + \sqrt{2}$ has infinite order.

Worked Example 16.8.6 (The fundamental unit for $d = 3$)**.** Find the fundamental unit of $\mathbb{Z}[\sqrt{3}]$ and the generator of the first-quadrant group U_0.

Recognition. Scan $b = 1$: need $3 \cdot 1^2 \pm 1 = a^2$, i.e. $a^2 \in \{2, 4\}$; the value 4 works.

Solution. With $b = 1$, $3b^2 + 1 = 4 = 2^2$, so $a = 2$ and $\epsilon = 2 + \sqrt{3}$ has $\mathrm{N}(\epsilon) = 4 - 3 = 1$. No smaller $a, b > 0$ gives a square ($b = 1, a = 1$ fails since $3 \pm 1 \in \{2, 4\}$ only matched $a = 2$), so $\epsilon = 2 + \sqrt{3}$ is fundamental. Because $\mathrm{N}(\epsilon) = +1$ already, every power has norm 1 and $\Phi(\epsilon^n)$ lies on $uv = 1$ in the first quadrant for $n \geq 0$; thus $U_0 = \langle\epsilon\rangle = \langle 2 + \sqrt{3}\rangle$ is infinite cyclic. *Check.* $\epsilon^{-1} = 2 - \sqrt{3} = \bar{\epsilon}$ since $\epsilon\bar{\epsilon} = \mathrm{N}(\epsilon) = 1$, and $\epsilon^2 = (2 + \sqrt{3})^2 = 7 + 4\sqrt{3}$ with $\mathrm{N} = 49 - 48 = 1$, matching Artin's Exercise 9.5(b) for $d = 3$.

Pell's equation

When the fundamental unit has norm $+1$, the embedding turns unit-finding into solving the classical Pell equation.

Proposition 16.8.7 (units of norm $+1$ and Pell solutions)**.** *Integer solutions (x, y) of*

$$x^2 - d\,y^2 = 1$$

correspond bijectively to elements $x + y\sqrt{d} \in R$ with $\mathrm{N} = +1$, i.e. to lattice points on the hyperbola $uv = 1$. The solutions with $x, y > 0$ are exactly the powers ϵ_1^n $(n \geq 1)$ of the smallest such unit $\epsilon_1 > 1$ of norm $+1$, generated from the fundamental unit by

$$\epsilon_1 = \begin{cases} \epsilon, & \mathrm{N}(\epsilon) = +1, \\ \epsilon^2, & \mathrm{N}(\epsilon) = -1. \end{cases}$$

Proof. The equation $x^2 - dy^2 = 1$ is precisely $\mathrm{N}(x + y\sqrt{d}) = 1$, so its solutions are the norm-$+1$ elements of R, a subgroup of $R^\times$ of index 1 or 2 (the kernel of $\mathrm{N} : R^\times \to \{\pm 1\}$). Inside $R^\times = \langle -1\rangle \times \langle \epsilon\rangle$ this kernel is $\langle -1\rangle \times \langle \epsilon_1\rangle$ with $\epsilon_1 = \epsilon$ if $\mathrm{N}(\epsilon) = +1$ and $\epsilon_1 = \epsilon^2$ if $\mathrm{N}(\epsilon) = -1$ (so that $\mathrm{N}(\epsilon_1) = (\pm 1)^2 = 1$). Discarding the sign, the positive solutions are the positive powers ϵ_1^n, ordered by size since $\epsilon_1 > 1$. □

Worked Example 16.8.8 (Generating Pell solutions for $d = 2$)**.** List the positive solutions of $x^2 - 2y^2 = 1$ from the fundamental unit.

Recognition. Here $\mathrm{N}(1 + \sqrt{2}) = -1$, so the norm-$+1$ generator is $\epsilon_1 = (1 + \sqrt{2})^2 = 3 + 2\sqrt{2}$.

Solution. The smallest solution is $\epsilon_1 = 3 + 2\sqrt{2}$, i.e. $(x, y) = (3, 2)$: indeed $3^2 - 2 \cdot 2^2 = 9 - 8 = 1$. Successive solutions come from ϵ_1^n:

$$\epsilon_1^2 = 17 + 12\sqrt{2} \Rightarrow (17, 12), \qquad \epsilon_1^3 = 99 + 70\sqrt{2} \Rightarrow (99, 70).$$

Equivalently $(x_{n+1}, y_{n+1}) = (3x_n + 4y_n,\ 2x_n + 3y_n)$ from multiplying by $3 + 2\sqrt{2}$. *Check.* $17^2 - 2 \cdot 12^2 = 289 - 288 = 1$ and $99^2 - 2 \cdot 70^2 = 9801 - 9800 = 1$. The odd powers $(1 + \sqrt{2})^{2k+1}$ instead solve $x^2 - 2y^2 = -1$, e.g. $(1, 1)$ and $7^2 - 2 \cdot 5^2 = -1$.

Worked Example 16.8.9 (Generating Pell solutions for $d = 3$)**.** List the positive solutions of $x^2 - 3y^2 = 1$.

Recognition. Here $\mathrm{N}(2 + \sqrt{3}) = +1$, so $\epsilon_1 = \epsilon = 2 + \sqrt{3}$ already generates.

Solution. The fundamental solution is $(x, y) = (2, 1)$: $2^2 - 3 \cdot 1^2 = 4 - 3 = 1$. Powers of $\epsilon = 2 + \sqrt{3}$ give the rest:

$$\epsilon^2 = 7 + 4\sqrt{3} \Rightarrow (7, 4), \qquad \epsilon^3 = 26 + 15\sqrt{3} \Rightarrow (26, 15),$$

with recurrence $(x_{n+1}, y_{n+1}) = (2x_n + 3y_n,\ x_n + 2y_n)$. *Check.* $7^2 - 3 \cdot 4^2 = 49 - 48 = 1$ and $26^2 - 3 \cdot 15^2 = 676 - 675 = 1$. Unlike $d = 2$, there is no solution of $x^2 - 3y^2 = -1$, because the fundamental unit already has norm $+1$ and N takes only the value $+1$ on $R^\times$ here.

Caution. The lattice picture and the norm $a^2 - b^2 d$ are tied to the ring $R = \mathbb{Z}[\sqrt{d}]$, valid when $d \equiv 2, 3 \bmod 4$. When $d \equiv 1 \bmod 4$ the ring of integers is the larger $\mathbb{Z}[\frac{1+\sqrt{d}}{2}]$, the fundamental unit may have a half-integer coordinate (e.g. $\epsilon = \frac{1+\sqrt{5}}{2}$ for $d = 5$), and the Pell correspondence then runs through $x^2 - dy^2 = \pm 4$ rather than ± 1. The structure theorem $R^\times \cong \langle -1\rangle \times \langle \epsilon\rangle$ is unchanged.

16.9 Graded Problem Bank

Easy

DF 16.1.1 If R is Artinian and I an ideal, prove R/I is Artinian.

DF 16.1.2 Show that every finite commutative ring with 1 is Artinian.

DF 16.1.3 Prove that an integral domain of Krull dimension 0 is a field.

DF 16.1.4 Prove that an Artinian integral domain is a field.

DF 16.2.1 If R is a DVR with valuation v on K and $v(x) < v(y)$, prove $v(x + y) = \min(v(x), v(y))$.

DF 16.2.2 If R is a DVR with maximal ideal M and $F = R/M$, show M^n/M^{n+1} is an F-vector space of dimension 1 for every $n \geq 0$.

DF 16.3.9 For an integral domain R, show R_P is a DVR for every nonzero prime P iff R_M is a DVR for every nonzero maximal ideal M.

DF 16.3.21 If K is a number field and I any ideal of O_K, exhibit I explicitly as a direct summand of a free O_K-module (via $I \oplus I^{-1}$) to show I is projective.

A&M 16.3.7 Let A be a Dedekind domain and $\mathfrak{a} \neq 0$ an ideal; show every ideal in $A/\mathfrak{a}$ is principal.

Artin 1.1 Decide whether $\frac{1}{2}(1 + \sqrt{5})$ is an algebraic integer.

Artin 1.4 For integers d, d', determine when the fields $\mathbb{Q}(\sqrt{d})$ and $\mathbb{Q}(\sqrt{d'})$ are distinct.

Artin 3.2 For $\delta = \sqrt{-5}$, decide whether each lattice of integer combinations is an ideal: (a) $(5, 1+\delta)$, (b) $(7, 1+\delta)$, (c) $(4-2\delta,\ 2+2\delta,\ 6+4\delta)$.

Artin 4.1 In $R = \mathbb{Z}[\delta]$, $\delta = \sqrt{-6}$, find a lattice basis for the product ideal AB where $A = (2, \delta)$ and $B = (3, \delta)$.

Artin 5.1 In $R = \mathbb{Z}[\sqrt{-5}]$: (a) decide whether 11 is irreducible and whether (11) is prime; (b) factor the principal ideal (14) into prime ideals.

Artin 7.1 For $R = \mathbb{Z}[\sqrt{-5}]$ and $B = (3, 1+\delta)$, find a generator for the principal ideal B^2.

Artin 7.3 For $d = -26$ decide for each of $n = 75, 250, 375, 5^6$ whether n is the norm of an element $\alpha \in R$, and if so find α.

Artin 9.1 Prove that $1 + \sqrt{2}$ has infinite order in the group of units of $\mathbb{Z}[\sqrt{2}]$.

Artin 10.1 Let M be the integer lattice in $\mathbb{R}^2$ and L the lattice with basis $((2,3)^{\mathsf{T}}, (3,6)^{\mathsf{T}})$; determine the index $[M : L]$.

Medium

DF 16.1.5 If I is a nilpotent ideal in R and $M = IM$ for an R-module M, prove $M = 0$.

DF 16.1.6 For an exact sequence $0 \to M' \to M \to M'' \to 0$, prove M is Artinian iff M' and M'' are.

DF 16.1.7 If $R = F$ is a field, prove an R-module M is Artinian iff Noetherian iff a finite-dimensional F-vector space.

DF 16.1.9 If $x_1, \dots, x_n \in M$ have images generating $M/\operatorname{Jac} R\, M$, prove they generate M (M finitely generated); deduce that if R is Noetherian and images of $a_1, \dots, a_n$ generate $\operatorname{Jac} R/\operatorname{Jac} R^2$ then $\operatorname{Jac} R = (a_1, \dots, a_n)$.

DF 16.1.10 For $R = \mathbb{Z}_{(2)}$, prove $\operatorname{Jac} R = (2)$, and with $M = \mathbb{Q}$ show $M/2M$ is finitely generated over R but M is not; explain why this does not contradict the previous exercise.

DF 16.2.3 If R is a local domain with $M = (t) \neq 0$ principal and $\bigcap_{n\geq 1}(t^n) = 0$, prove R is a DVR.

DF 16.2.4 If R is a Noetherian local ring with $M = (t)$ principal, prove R is a DVR or $t^n = 0$ for some n (in which case R is Artinian).

DF 16.2.6 Prove every finitely generated R-submodule of K is a fractional ideal; if R is Noetherian, prove A is a fractional ideal iff A is a finitely generated R-submodule of K.

DF 16.2.7 If R is a domain and A a fractional ideal, prove A projective implies A finitely generated; conclude every non-Noetherian domain has a non-projective ideal.

DF 16.3.1 Show every fractional ideal of a domain R is invertible iff every integral ideal of R is invertible.

DF 16.3.2 If $A_1 A_2 \cdots A_n = Rx$ $(0 \neq x \in K)$ for fractional ideals A_i, prove each A_i is invertible with inverse $(x^{-1})A_1 \cdots A_{i-1} A_{i+1} \cdots A_n$.

DF 16.3.3 Show the fractional ideals of R_P in K are exactly the R_P-modules AR_P with A a fractional ideal of R.

DF 16.3.5 If Q_1 is P_1-primary and Q_2 is P_2-primary with P_1, P_2 comaximal in a Noetherian ring, prove Q_1, Q_2 are comaximal.

DF 16.3.11 If I, J are nonzero ideals of a Dedekind domain R, show there is an integral ideal I_1 coprime to both I and J with $I_1 I$ principal.

DF 16.3.12 If I, J are nonzero fractional ideals of a Dedekind domain R, prove there exist $\alpha, \beta \in K$ with $\alpha I, \beta J$ coprime integral ideals.

DF 16.3.19 If R is a Dedekind domain and $I \neq 0$ an ideal, prove R/I has only finitely many ideals and is Artinian.

DF 16.3.22 If I, J are nonzero fractional ideals of a Dedekind domain with $I^n = J^n$ for some $n \neq 0$, prove $I = J$.

DF 16.3.23 If K is a number field with ring of integers O_K and P a nonzero prime ideal, prove $P = (p, \pi)$ for some rational prime p and algebraic integer π.

A&M 16.1.1 In a Noetherian ring with minimal primary decomposition $\mathfrak{q}_1 \cap \cdots \cap \mathfrak{q}_n = 0$ ($\mathfrak{q}_i$ being $\mathfrak{p}_i$-primary), show for each i there is r_i with the symbolic power $\mathfrak{p}_i^{(r_i)} \subseteq \mathfrak{q}_i$; deduce that if $\mathfrak{q}_i$ is an embedded component, there are infinitely many minimal primary decompositions of 0 differing only in the $\mathfrak{p}_i$-component.

A&M 16.1.6 For a Noetherian ring A and a $\mathfrak{p}$-primary ideal $\mathfrak{q}$, show every chain of primary ideals from $\mathfrak{q}$ to $\mathfrak{p}$ has finite bounded length and all maximal such chains have equal length.

A&M 16.3.1 Let A be Dedekind and S multiplicatively closed; show $S^{-1}A$ is Dedekind or the fraction field, and (for $S \neq A - \{0\}$) that extension of ideals gives a surjection of class groups $H \to H'$.

A&M 16.3.2 For a Dedekind domain prove Gauss's lemma $c(fg) = c(f)c(g)$ for contents of polynomials.

A&M 16.3.3 Prove a valuation ring (not a field) is Noetherian iff it is a DVR.

A&M 16.3.4 Let A be a local domain (not a field) whose maximal ideal $\mathfrak{m}$ is principal with $\bigcap_n \mathfrak{m}^n = 0$; prove A is a DVR.

A&M 16.3.8 For ideals $\mathfrak{a}, \mathfrak{b}, \mathfrak{c}$ in a Dedekind domain prove $\mathfrak{a} \cap (\mathfrak{b} + \mathfrak{c}) = (\mathfrak{a} \cap \mathfrak{b}) + (\mathfrak{a} \cap \mathfrak{c})$ and $\mathfrak{a} + (\mathfrak{b} \cap \mathfrak{c}) = (\mathfrak{a} + \mathfrak{b}) \cap (\mathfrak{a} + \mathfrak{c})$.

Artin 1.2 Prove that the integers in $\mathbb{Q}[\sqrt{5}]$ form a ring.

Artin 2.1 Prove that 2, 3, and $1 \pm \sqrt{-5}$ are irreducible in $R = \mathbb{Z}[\sqrt{-5}]$ and that the units are ± 1.

Artin 2.2 For which negative integers $d \equiv 2 \pmod 4$ is the ring of integers in $\mathbb{Q}[\sqrt{d}]$ a UFD?

Artin 3.1 For $\alpha \in R = \mathbb{Z}[\sqrt{-5}]$ and $\gamma = \frac{1}{2}(\alpha + \alpha\delta)$, determine when the lattice with basis (α, γ) is an ideal.

Artin 3.3 Prove that an ideal A of the ring of integers R in an imaginary quadratic field has a lattice basis one of whose elements is an ordinary positive integer.

Artin 4.2 In $R = \mathbb{Z}[\delta]$, $\delta = \sqrt{-5}$, for A generated by (a) $3 + 5\delta$, $2 + 2\delta$ and (b) $4 + \delta$, $1 + 2\delta$, decide whether the generators form a lattice basis and identify $A\overline{A}$.

Artin 4.3 For ideals $A = (\alpha, \frac{1}{2}(\alpha + \alpha\delta))$, $B = (\beta, \frac{1}{2}(\beta + \beta\delta))$ in $\mathbb{Z}[\delta]$, $\delta = \sqrt{-5}$, prove AB is principal by exhibiting a generator.

Artin 5.2 Let $\delta = \sqrt{-3}$, $R = \mathbb{Z}[\delta]$ (not the full ring of integers) and $A = (2, 1 + \delta)$: (a) prove A is maximal and identify R/A; (b) prove $A\overline{A}$ is not principal and the Main Lemma fails; (c) prove $A \supseteq (2)$ but $A \nmid (2)$.

Artin 5.3 Decide whether the ring $\mathbb{C}[x, y]/(y^2 - x^3 - x)$ is an integral domain.

Artin 6.1 For $d = -14$ and each prime $p = 2, 3, 5, 7, 11, 13$, decide whether p splits or ramifies in R, and if so find a lattice basis of a prime factor of (p).

Artin 6.2 For $d < 0$ with $d \equiv 1 \pmod 4$, analyze whether 2 remains prime in R in terms of the congruence of d modulo 8.

Artin 6.3 For R the integers in an imaginary quadratic field: (a) if a prime p remains prime, prove $R/(p)$ is a field with p^2 elements; (b) if p splits but does not ramify, prove $R/(p) \cong \mathbb{F}_p \times \mathbb{F}_p$.

Artin 7.4 For $R = \mathbb{Z}[\delta]$, $\delta^2 = -6$: (a) prove $P = (2, \delta)$ and $Q = (3, \delta)$ are prime; (b) factor (6) into primes; (c) determine the class group of R.

Artin 9.2 Determine the solutions of $x^2 - y^2 d = 1$ for d a positive integer.

Artin 9.5 For R the integers in a real quadratic field, let U_0 be the units in the first quadrant of the embedding: (a) prove U_0 is an infinite cyclic subgroup of the units; (b) find a generator when $d = 3$ and $d = 5$; (c) draw the hyperbolas and units for $d = 3$.

Artin 10.2 For lattices $L \subseteq M$ with bases B, C and integer matrix A with $CA = B$, prove $[M : L] = |\det A|$.

Hard

DF 16.1.8 If M is a maximal ideal with $M^n = 0$, prove R is Noetherian iff Artinian, using the filtration $R \supseteq M \supseteq \cdots \supseteq M^n = 0$ with each M^i/M^{i+1} a vector space over $F = R/M$.

DF 16.1.11 Prove the transcendence degree of $k(V)$ over k equals the Krull dimension of the coordinate ring $R = k[V]$, via Noether normalization $R_1 = k[y_1, \dots, y_m] \subseteq R$: (a) reduce to $R = R_1$ using Going-up/Going-down; (b) exhibit a chain showing $d_p(R) \geq d_t(R)$; (c) show $d_p(R) \leq d_t(R)$ by induction.

DF 16.1.12 For a Noetherian local ring R with maximal ideal M: (a) prove $d = \dim_{R/M}(M/M^2)$ is finite; (b) prove M needs exactly d generators; (c) for $R = k[x_1, \dots, x_n]_{(x_1,\dots,x_n)}$ prove $\dim_{R/M}(M/M^2) = n = \dim R$.

DF 16.1.13 If R is Noetherian, prove the Zariski topology on $\operatorname{Spec} R$ is discrete iff R is Artinian.

DF 16.1.14 For $I = (x_1, x_2^2, x_3^3, \dots)$ in $k[x_1, x_2, \dots]$ and R the quotient, prove the image of $(x_1, x_2, \dots)$ is the unique prime of R but is not finitely generated; deduce R is local of Krull dimension 0 but not Artinian.

DF 16.2.5 For a Noetherian local domain R of Krull dimension 1 with $F = R/M$: (a) if $\dim_F(M/M^2) = 1$ prove R is a DVR; (b) if every nonzero ideal is a power of M prove R is a DVR.

DF 16.2.8 For a Noetherian local domain R with nonzero maximal ideal M, prove R is a DVR iff the only M-primary ideals are powers of M.

DF 16.2.9 For $C = Z(xz - y^2,\ yz - x^3,\ z^2 - x^2y) \subseteq \mathbb{A}^3$ over $k = \overline{k}$ and $v = (0,0,0) \in C$, prove $\dim_k(\mathfrak{m}_{v,C}/\mathfrak{m}_{v,C}^2) = 3$ so v is singular; conclude $k[C]$ is not integrally closed and determine its integral closure.

DF 16.3.4 For a fractional ideal A with $A' = \{x \in K \mid xA \subseteq R\}$: (a) prove $(A')_P$ is a fractional ideal of R_P for any prime P; (b) if A is finitely generated, prove $(A')_P = (A_P)'$.

DF 16.3.6 For a Dedekind domain R with fraction field K: (a) prove every nonzero fractional ideal is uniquely $P_1^{a_1} \cdots P_n^{a_n}$ with $a_i \in \mathbb{Z}$; (b) prove $v_P(x)$ is a valuation on K with valuation ring R_P.

DF 16.3.7 For a Noetherian domain R (not a field), prove R is Dedekind iff for every maximal M there is no ideal I with $M^2 \subset I \subset M$.

DF 16.3.8 For a Noetherian domain of Krull dimension 1, prove every nonzero ideal is uniquely a product of primary ideals with distinct radicals.

DF 16.3.10 For a Noetherian domain R (not a field), prove R is Dedekind iff nonzero primes M are maximal and every M-primary ideal is a power of M.

DF 16.3.13 If I, J are nonzero ideals in a Dedekind domain R, prove there is an ideal $I_1 \cong I$ (as R-modules) coprime to J.

DF 16.3.14 Prove every finitely generated torsion module over a Dedekind domain is $R/I_1 \oplus \cdots \oplus R/I_n$ with unique ideals $I_1 \subseteq \cdots \subseteq I_n$ (the invariant factors).

DF 16.3.15 If P is a nonzero prime in a Dedekind domain R, prove R/P^n is not projective for any $n \geq 1$; conclude no nonzero finitely generated torsion module is projective.

DF 16.3.16 Prove the class number of a Dedekind domain R is 1 iff every finitely generated projective R-module is free.

DF 16.3.17 For a Dedekind domain R: (a) show $I \sim J$ iff $I \cong J$ as modules is an equivalence relation on nonzero fractional ideals; (b) show $[I][J] = [IJ]$ makes $C(R)$ an abelian group with identity $[R]$; (c) prove $C(R)$ is isomorphic to the class group of R.

DF 16.3.18 Prove every nonzero ideal I of a Dedekind domain R is uniquely a product of distinct prime powers $P_1^{a_1} \cdots P_n^{a_n}$ (extending to negative exponents for fractional ideals), establishing the valuation v_P.

DF 16.3.20 For $K = \mathbb{Q}(\sqrt{D})$ (D squarefree) with ring of integers O_K: (a) prove $|O_K/(p)| = p^2$; (b) using Corollary 16, show (p) factors as inert P, split P_1P_2, or ramified P^2; (c) determine the factorizations of $p = 2, 3, 5, 7, 11$ in $O_K = \mathbb{Z}[\sqrt{-5}]$.

DF 16.3.24 For O the integers in $\overline{\mathbb{Q}}$: (a) show $(2) \subseteq (\sqrt{2}) \subseteq (\sqrt[4]{2}) \subseteq \cdots$ is strictly increasing so O is not Noetherian; (b) show $\dim O = 1$; (c) show any ideal of O_K becomes principal in some finite extension O_L; (d) prove O is a Bezout domain.

DF 16.3.25 For number fields $\mathbb{Q} \subseteq F \subseteq K$ with rings of integers $O_F \subseteq O_K$: (a) prove O_K is torsion-free of rank $[K : F]$ over O_F; (b) if F has class number 1 prove a relative integral basis exists; (c)–(e) for $K = \mathbb{Q}(\sqrt{-5}, \sqrt{2})$ work out relative integral bases over $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(\sqrt{-5})$ (Steinitz obstruction), and $\mathbb{Q}(\sqrt{-10})$.

DF 16.3.26 Prove the coordinate ring $k[C]$ of a nonsingular irreducible affine curve over $k = \overline{k}$ is a Dedekind domain.

A&M 16.1.2 For a Noetherian ring A, prove the equivalence of: A Artinian; $\mathrm{Spec}(A)$ discrete and finite; $\mathrm{Spec}(A)$ discrete.

A&M 16.1.3 For a field k and a finitely generated k-algebra A, prove A is Artinian iff A is a finite k-algebra.

A&M 16.1.4 For a finite-type homomorphism $f\colon A \to B$, prove f finite $\Rightarrow$ fibres of f^* discrete $\Rightarrow$ $B \otimes_A k(\mathfrak{p})$ finite over $k(\mathfrak{p}) \Rightarrow$ fibres finite; and discuss whether integral plus finite fibres forces finite.

A&M 16.1.5 Show that a certain finite covering $X \to L$ (Chapter 5, Exercise 16) has the number of points over each point finite and bounded.

A&M 16.3.5 For a finitely generated module M over a Dedekind domain, prove M is flat iff M is torsion-free.

A&M 16.3.6 Prove a finitely generated torsion module over a Dedekind domain A is uniquely a finite direct sum of $A/\mathfrak{p}_i^{n_i}$ with nonzero primes $\mathfrak{p}_i$.

A&M 16.3.9 Prove the Chinese Remainder Theorem in a Dedekind domain: the system $x \equiv x_i \pmod{\mathfrak{a}_i}$ is solvable iff $x_i \equiv x_j \pmod{\mathfrak{a}_i + \mathfrak{a}_j}$ for all $i \neq j$ (equivalently a certain module sequence is exact).

Artin 1.3 (a) If α is a root of a monic integer polynomial (not necessarily irreducible), prove α is an algebraic integer; (b) if α is a root of $a_n x^n + \cdots + a_0$, prove $a_n\alpha$ is an algebraic integer; (c) if α is an algebraic integer with irreducible polynomial $x^n + \cdots + a_0$, prove α^{-1} is an algebraic integer iff $a_0 = \pm 1$.

Artin 3.4 For each ring $R = \mathbb{Z}[\sqrt{-3}]$, $\mathbb{Z}[\frac{1}{2}(1+\sqrt{-3})]$, $\mathbb{Z}[\sqrt{-6}]$, $\mathbb{Z}[\frac{1}{2}(1+\sqrt{-7})]$, $\mathbb{Z}[\sqrt{-10}]$, use Prop 13.3.3 to describe the ideals and draw the possible lattice shapes.

Artin 6.4 For $d \equiv 2, 3 \pmod 4$, p remains prime in the integers of $\mathbb{Q}[\sqrt{d}]$ iff $x^2 - d$ is irreducible mod p: (a) prove this also holds when $d \equiv 1 \pmod 4$ and $p \neq 2$; (b) analyze $p = 2$ when $d \equiv 1 \pmod 4$.

Artin 6.5 For $d \equiv 2, 3 \pmod 4$: (a) prove p ramifies iff $p = 2$ or $p \mid d$; (b) for ramified $(p) = P^2$ find an explicit lattice basis of P and decide when P is principal.

Artin 6.6 For $d \equiv 2, 3 \pmod 4$, relate whether a prime p has the form $a^2 - b^2 d$ to the prime ideal factorization of (p) in R.

Artin 6.7 For $d \equiv 2, 3 \pmod 4$ and a prime $p \neq 2$ not remaining prime, with $a^2 \equiv d \pmod p$, prove $(p, a + \delta)$ is a lattice basis of a prime ideal dividing (p).

Artin 7.2 Prove two nonzero ideals A, A' in the integers of an imaginary quadratic field are similar iff there is a nonzero ideal C with AC and $A'C$ both principal.

Artin 8.1 In Example 13.8.6, with $(P) = (S)^3$ and $(Q) = (S)^2$, find elements whose norms are $2 \cdot 5^3$ and $3^2 \cdot 5^2$ as predicted by Lemma 13.8.7.

Artin 8.2 In Example 13.8.8, explain why $N(4 + \delta)$ and $N(14 + \delta)$ do not lead to contradictory conclusions.

Artin 8.3 For $R = \mathbb{Z}[\delta]$, $\delta = \sqrt{-29}$, compute $N(1 + \delta), N(4 + \delta), N(5 + \delta), N(9 + 2\delta), N(11 + 2\delta)$, draw conclusions about ideals, and determine the class group.

Artin 8.4 Prove that the values of d listed in Theorem 13.2.5 give unique factorization.

Artin 8.5 Determine the class group and draw the possible lattice shapes for (a) $d = -10$, (b) $d = -13$, (c) $d = -14$, (d) $d = -21$.

Artin 8.6 Determine the class group for (a) $d = -41$, (b) $d = -57$, (c) $d = -61$, (d) $d = -77$, (e) $d = -89$.

Artin 9.3 (a) Prove $\sigma(\alpha) = |N(\alpha)|$ makes $\mathbb{Z}[\sqrt{2}]$ a Euclidean domain (hence a UFD); (b) sketch the principal ideal $(\sqrt{2})$ of $\mathbb{Z}[\sqrt{2}]$ in the embedding of Figure 13.9.6.

Artin 9.4 For R the integers in a real quadratic field, determine what structures are possible for the group of units of R.

Artin M.1 Describe the subrings S of $\mathbb{C}$ that are lattices in the complex plane.

Artin M.2 For $R = \mathbb{Z}[\sqrt{-5}]$ and a prime p: (a) if p splits, $(p) = P\overline{P}$, prove exactly one of $x^2+5y^2 = p$ or $x^2+5y^2 = 2p$ has an integer point; (b) find a property determining which ellipse has an integer point.

Artin M.3 Describe the prime ideals in (a) the polynomial ring $\mathbb{C}[x, y]$ and (b) the ring $\mathbb{Z}[x]$ of integer polynomials.

Artin M.4 (a) Prove Pick's Theorem that a lattice polygon has area $a + \frac{b}{2} - 1$ (a interior, b boundary lattice points); (b) derive Proposition 13.10.6 from it.
